TATSUYA MORI (Presenter), YUTA IIJIMA, Division of Materials Science, University of Tsukuba, YASUHIRO FUJII, Department of Physical Sciences, Ritsumeikan University, SUGURU KITANI, Laboratory for Materials and Structures, Tokyo Institute of Technology, JAE-HYON KO, Department of Physics, Hallym University, AKITOSHI KOREEDA, Department of Physical Sciences, Ritsumeikan University, HITOSHI KAWAJI, Laboratory for Materials and Structures, Tokyo Institute of Technology, SEIJI KOJIMA, Division of Materials Science, University of Tsukuba — The boson peak (BP) is a universal feature of amorphous materials and it appears in the spectra of $g(\nu)/\nu^2$ ($g(\nu)$: vibrational density of states), in the terahertz region. The BP can be famously detected by inelastic neutron scattering, low-temperature specific heat, and Raman scattering. Recently, we confirmed that terahertz time-domain spectroscopy (THz-TDS) is suitable to detect the BP. The BP in the infrared (IR) spectra appears in the spectrum of $\alpha(\nu)/\nu^2$ ($\alpha(\nu)$: absorption coefficient). In this study, we investigate the BP dynamics of lithium borate glass by THz-TDS and evaluate IR light-vibration coupling coefficient.

3:54PM P58.00008: The relation between ridges and crumples*  
ANDREW CROLL (Presenter), TIMOTHY TWOHIG, THERESA M ELDER, North Dakota State University — Crumpling is the name given to the structure created when a thin sheet has been forced to occupy a volume much smaller than the sheet's largest dimension. Crumples strongly resist compression, making them an interesting lightweight material. How a crumple resists compression is a challenging question to answer, though recently we have proposed an empirical relation which applies to both elastic and plastic sheets. Here we examine different 'building block' structures for clues as to the origin of the empirical force law. Specifically, we focus on the stretching ridge which joins two developable-cones and has long been hypothesized to be responsible for the crumple's strength. We show that elastic and plastic ridges, though geometrically identical when formed, behave very differently under compression. The elastic ridge smoothly collapses annihilating one d-cone in the process, whereas the plastic material allows no motion of the d-cone cores, building stress until buckling. Remarkably, before failure the plastic and elastic ridges can be fit by the same empirical model as can the crumple itself. We discuss the curious relationship.

Evidence of a fragility window that correlates with the reversibility window in (Na2O)x(B2O3)100-x glasses

CHARLES SKIPPER (Presenter), RALPH CHBEIR, KANDASAMY VIGNAROOBAN, PUNIT BOOLCHAND,
University of Cincinnati — Evidence for a reversibility window in titled glasses was reported1 recently and permitted fixing the Topological phases. The reversibility window permitted one to identify glasses at x < 20% to be in the Stressed-rigid phase those at x > 40% to be in the flexible phase and those in between with the Intermediate Phase. We now report on melt fragility index using mDSC. The imaginary part of Cp, examined in the cool down mode, shows a Gaussian-like peak that shifts to higher T as the modulation frequency is increased. By tracking the peak shift in Cp^imag with T, we establish how τ , the enthalpic relaxation time with T and deduce the fragility index (m). Our results show that m(x) also displays a square-well like variation with m< 20 in the 20 < x < 40% range of soda, coinciding with the reversibility window. Remarkably if the glasses are not dry the variation of m(x) changes qualitatively2; m(x) increases quadratically in x underscoring that Na^+ ions now diffuse more rapidly. Glass synthesis conditions can qualitatively alter melt dynamics.

Melt fragility index, configurational entropy, and topological phases in ternary GexAsxSe100-2x Chalcogenides

RALPH CHBEIR (Presenter), University of Cincinnati, MATTHIEU MICOULAUT, Univ Pierre et Marie Curie, MATHIEU BAUCHY, University of California, Los Angeles, PUNIT BOOLCHAND, University of Cincinnati — The melt fragility index, m, of titled chalcogenides display a global minimum with m < 20, in the narrow connectivity range 2.28(3) < <r> < 2.51(3) defining a fragility window. Separately, the non-reversing enthalpy of relaxation (ΔHnr) at Tg in corresponding glasses shows a square-well like global minimum, with the ΔHnr term nearly vanishing in the same 2.28(3) < <r> < 2.51(3) connectivity range, defining the reversibility window, which represents the isostatically rigid Intermediate Phase (IP). The near vanishing ΔHnr for IP glasses is signature for the change in excess configurational entropy (ΔS_ex) between melt and glass to be minuscule, and leads to super-strong melts as expected. The order of magnitude increases in ΔHnr for non-IP glass compositions as one goes away from the IP glass compositions, lead both ΔS_ex and m to steadily increase for non-IP melts as observed in experiments.

Observation of a sharp reversibility window in rejuvenated homogenized equimolar Ge_xAs_xSe_100-2x bulk glasses

BADRIAH ALMUTAIRI (Presenter), RALPH CHBEIR, SOUMENDU CHAKRAVARTY, L.C.R. WIJEWARDHANA, PUNIT BOOLCHAND, University of Cincinnati — We have synthesized 1.5-gram sized batches of the title glasses over a wide composition range 2% ≤ x ≤ 25%, taking special care to alloy the starting materials for an extended period (several weeks) in evacuated quartz tubes, and recording FT Raman spectra along the length of the melt column till the spectra became identical. Using Modulated DSC, we then examined calorimetric properties, Tg(x), ΔCp , and ΔHnr (x), and find Tg(x) to increase monotonically with x, and the enthalpy of relaxation, ΔHnr (x) to display a sharp square-well like reversibility window with an onset near x =9.0(5)% (rigidity transition) and an endpoint x = 16.0(5)% (stress transition) in rejuvenated glasses. In FT- Raman scattering we observe modes of Ge-centered CS and ES tetrahedra and the As-centered Pyramidal and Quasi-Tetrahedral units besides modes of S8 rings and polymeric Sn chains. The mode near 537 cm^(-1) due to S=As(S_{1/2}) QT units is observed in FT-Raman but not in dispersive Raman using 514 nm excitation. Complex Cp measurements using MDSC are being undertaken to establish variation in melt fragility index.

Variation in fragility-index, Enthalpy of relaxation at $T_g$ and Molar volumes in especially homogenized bulk As$_x$S$_{100-x}$ glasses*

SOUMENDU CHAKRAVARTY (Presenter), RALPH CHBEIR, PING CHEN, University of Cincinnati, MATHIEU MICOULAUT, Univ Pierre et Marie Curie, MATHIEU BAUCHY, Univ of California - Los Angeles, PUNIT BOOLCHAND, BADRIAH ALMUTAIRI, University of Cincinnati — We have measured the variation of fragility index ($m$), Non-reversing enthalpy of relaxation ($\Delta H_{nr}$) and molar volumes ($V_m$) with $x$ in especially homogenized As$_x$S$_{100-x}$ batches of 1.5 gram in size. FT Raman profiling was used to ascertain homogeneity of glasses. Our results show that $\Delta H_{nr}$ displays a square-well like minimum in the 22.5(5)% < $x$ < 28.5(5)% range defining the reversibility window. Variation of $m$ displays a minimum of $m$ < 20 in the same range of $x$, defining the fragility window. Inverse of the activation energy ($E_a$) for enthalpy relaxation shows a maximum in the IP. Variation in $V_m(x)$ displays a Gaussian-like local minimum in the reversibility window. The fragility-window coinciding with the reversibility window underscores that super-strong (fragile) melts upon cooling give rise to IP (non-IP) glasses. The maximum in $1/E_a$ shows that the excess configurational entropy ($S_{ex}$) peaks for IP glasses. On the other hand, the large build up in $\Delta H_{nr}$ and small increase in $\Delta C_p$ for non-IP compositions (as $x$ > 28.5(5)% and $x$ < 22.5(5)% as one goes away from the IP, accounts for the increased fragility of stressed-rigid and flexible melts.

*Supported by NSF grant DMR-08-53957

New scenario of sound damping in glasses*

LIJIN WANG (Presenter), Beijing Computational Science Research Center, China, LUDOVIC BERTHIER, Laboratoire Charles Coulomb (L2C), University of Montpellier, CNRS, France, ELIJAH FLENNER, Department of Chemistry, Colorado State University, USA, PENGFEI GUAN, Beijing Computational Science Research Center, China, GRZEGORZ SZAMEL, Department of Chemistry, Colorado State University, USA — An understanding of the difference between the universal low-temperature properties of amorphous solids and crystalline solids requires an explanation of the stronger damping of long-wavelength phonons in amorphous solids. A quartic scaling of the sound attenuation coefficient on the wavevector, which was deduced from experiments and later found support in a number of theoretical and simulation investigations, has recently been questioned in a new large scale simulation. Subsequently, quartic scaling was found in another large scale simulational study. These recent conflicting results reopened the problem of the wavevector dependence of sound attenuation. Here, we study simulated glasses with a wide range of stability and demonstrate the existence of a quartic scaling regime of the sound attenuation coefficient on wavevector in very stable glasses but not in poorly annealed glasses. For transverse sound waves in all glasses examined, we observe a long-wavelength quadratic scaling regime whose upper wavevector cutoff increases with increasing stability. Our results demonstrate an intimate connection between stability and sound damping in glasses and a new, unexpected damping scenario.

Topological phases of (Na$_2$O)$_x$(P$_2$O$_5$)$_{100-x}$ glasses and their molecular structure from Raman scattering.

AVIK MANDAL (Presenter), VAMSHI GOGI, CHANDI MOHANTY, RALPH CHBEIR, AARON WELTON, University of Cincinnati, MATHIEU BAUCHY, University of California Los Angeles, MATHIEU MICOULAUT, University Pierre et Marie Curie, PUNIT BOOLCHAND, University of Cincinnati — The observation of both a reversibility window and a fragility window in the 37.5% < $x$ < 46% range of soda in titled glasses from Calorimetric experiments fixes the 3 topological phases. Raman polarization and glass compositional studies show that the feature near 1166 cm$^{-1}$ in glasses at $x$ = 50% consists of a triad of modes, a majority symmetric mode of Q$^2$ species and two minority “defect modes” due to termination of the Q$^2$ bearing long chains by Q$^1$ like local structures, not only at $x$ > 50% but also at $x$ < 50%. These defects are under-constrained and contribute to an increasing baseline in the non-reversing heat flow term with increasing $x$. The fractions of Q$^3$,Q$^2$ and Q$^1$ local structures with composition deduced from respective Raman active modes in the 20% < $x$ < 60% range nicely track the usual mean-field behavior, independently deduced from NMR but with some minor but noticeable differences.

5:18PM P58.00015: Structure of (Na2O)x (P2O5)100-x glasses from Infrared reflectance measurements*  VAMSHI KIRAN GOGI (Presenter), AVIK MANDAL, CHANDI MOHANTY, University of Cincinnati, MATHIEU BAUCHY, University of California, Los Angeles, MATHIEU MICOULAUT, University Pierre and Marie Curie, PUNIT BOOLCHAND, University of Cincinnati — IR reflectance has served as a useful complementary probe to Raman scattering on glasses. One observes a phonon near 1172.2 cm⁻¹, associated with the long chains of Q² species in Raman scattering of c-NaPO₃. On the other hand, in g-NaPO₃, the corresponding vibrational feature consists of a triad of modes¹; a majority mode (1165.6 cm⁻¹) and two minority ones (1151.4 cm⁻¹ and 1105.3 cm⁻¹). These minority modes are weakly excited in Raman but rather strongly in IR TO-response. The minority modes are ascribed to Q¹-like chain terminating topological defects of the long Q² chains and display a global minimum in concentration in the IP composition range¹; 37.5% < x < 46.0%. Additionally, when we examine the variation in the LO-TO splitting of the Q²_asym (near 1282 cm⁻¹) and Q³_asym (near 1316 cm⁻¹) modes with glass composition 'x', one observes a global minimum in the IP range. A similar result is also observed for (Na₂O)x (GeO₂)100-x glasses², suggesting that the reduction of local Electric fields set up in the IP glassy networks could be a general feature.

Session P59 GSOFT DBIO: Driving, Actuating, and Triggering Activity in Biopolymer Networks BCEC 257B - Jennifer Ross, University of Massachusetts Amherst - Tag(s): Focus

2:30PM P59.00001: Closed Loop Mechanical Actuation of Cardiac Microtissue* JOSH JAVOR (Presenter), SUBRAMANIAN SUNDARAM, ANANT CHOPRA, CHRIS CHÉN, DAVID JOHN BISHOP, Boston University — Mechanical forces play a significant role in the maturation and function of stem cell derived cardiac tissue. We present a micromechanical test bed with closed loop actuation to control tissue strain with sub-micron spatial and 10 ms temporal resolution. A hydrogel is self-assembled between two custom elastomer posts, where one post is functionalized with a rare-earth magnet. Opposing it is a spherical pillar top facilitating hydrogel attachment. An anti-Helmholtz coil imposes gradient magnetic fields on the magnet translating to nanoNewton forces and tissue strain. The cardiomyocytes beat spontaneously, imposing another force on the magnet. The magnet position is detected without contact by imbedding a hall sensor. The detected signal is processed by analog filters and phase-sensitive detection. The loop is closed with an Arduino MEGA, which digitizes the signal, performs an algorithm, and drives the coils with an arbitrary analog signal.

2:42PM P59.00002: Microscale Mechanics of triggered bundling and unbundling of actin networks* BEKELE GURMESSA (Presenter), University of San Diego, LEILA FARHADI, Department of Physics, University of Massachusetts, Amherst, MICHAEL RUST, Molecular Genetics and Cell Biology Institute for Genomics and Systems Biology, University of Chicago, JENNIFER ROSS, Department of Physics, University of Massachusetts, Amherst, MOUMITA DAS, Department of Physics, Rochester Institute of Technology, RAE ROBERTSON-ANDERSON, University of San Diego — Networks of semiflexible actin filaments play key roles in many mechanical processes. The functionality of actin networks arises from the ability for actin filaments to dynamically entangle, crosslink, and bundle with one another. For example, simply increasing divalent salt concentration can trigger varying degrees and types of bundling in entangled actin networks. However, how the mechanical properties vary with varying degrees of salt-induced bundling remains unknown. More importantly, how the mechanical properties vary in time as actin networks transition between bundled and unbundled states has yet to be explored. Here, we couple optical tweezers microrheology with microfluidics to measure the viscoelastic response of entangled actin networks during triggered bundling and unbundling. We measure the frequency-dependent viscoelastic moduli in set time intervals as we cyclically vary the salt concentration via microfluidic perfusion chambers. We also use fluorescence confocal microscopy to image labeled filaments and characterize the corresponding time-varying network mobility and structure. Our measurements shed new light into how bundling and unbundling can dynamically tune the mechanical properties of actin networks.

2:54PM P59.00003: Modeling dividing actomyosin droplets as colloids in liquid crystal*  KINJAL DASBISWAS (Presenter), Physics, University of California Merced, ELI ALSTER, Chemical Engineering, Northwestern University, KIMBERLY WEIRICH, THOMAS A WITTEN, MARGARET GARDEL, SURIYANARAYANAN VAIKUNTHANATHAN, University of Chicago — Biopolymer networks are often organized into oriented bundles both in reconstituted in vitro situations and in the cell. Motivated by dividing fluid droplet-like bundles of actomyosin observed in experiments, we propose a theoretical mechanism for division of a droplet of liquid crystal material induced by a colloidal particle. The preferred alignment of actin filaments at the droplet surface and that at the motor cluster, modeled as a colloidal inclusion wet by the droplet, together result in a deformed droplet having minimal free energy. The dynamics of the model are illustrated by continuum simulations which show droplet deformation and pinching off into two equal daughter droplets. While colloidal inclusions are widely known to induce defects in a surrounding bulk liquid crystal, we predict here that the colloid can in principle deform and divide droplets of liquid crystal. Our description of these liquid crystal droplet dynamics, where the active forces of molecular motors is accounted for effectively through aligning interactions, explores the physical aspects of complex fluid phase separation in biology and suggests that self-assembly of motors may occur through interactions mediated by ordered biopolymers.

3:06PM P59.00004: Light-controlled biomolecular phase transitions in living cells [Invited]  JEFFREY MORRIS (Presenter), City College of New York — In this talk I will discuss recent advances toward understanding and engineering intracellular phase transitions, which play an important role in organizing the contents of living cells. Membrane-less RNA and protein rich condensates are found throughout the cell, and regulate the flow of genetic information. We’ve shown that liquid-liquid phase separation (LLPS) underlies the assembly of these structures. LLPS driven by intrinsically disordered protein regions (IDRs) explains many condensate features, for example the internal subcompartments of the nucleolus, which has important consequences for sequential ribosomal RNA processing. Our lab has developed a suite of new approaches, which use light to enable spatiotemporal control of intracellular phase transitions, allowing us to engineer the assembly and disassembly of these structures within defined subregions of the cytoplasm and nucleus. We are now using these tools to quantitatively map intracellular phase diagrams for the first time, providing unprecedented access to the biophysical principles underlying RNP condensate self-assembly. This approach has also begun to yield rich insights into the link between intracellular liquids, gels, and the onset of pathological protein aggregation.

3:42PM P59.00005: Elucidating the consequences of heterogeneous activity in an actin based liquid crystal  STEVEN REDFORD (Presenter), RUI ZHANG, NITIN KUMAR, University of Chicago, PAUL RUIJGROK, Stanford University, ALI MOZAFFARI, AARON DINNER, VINCENZO VITELLI, University of Chicago, ZEV BRYANT, Stanford University, JUAN DE PABLO, MARGARET GARDEL, University of Chicago — Active matter is generally studied in cases in which activity is spatially uniform. However, many of the biological systems that inspire this line of research, such as forces in a cell, feature activity that is highly spatially inhomogeneous. While generating spatially inhomogeneous stress has historically been difficult, here we present an experimental system in which spatial control of myosin activity in an actin liquid crystal allows for patterning of activity within the sample. Using this system, and comparing with hydrodynamic simulations, we show that patterned activity has the potential to direct the motion of +1/2 defects within a liquid crystal and constrain fluid flow.

3:54PM P59.00006: Driving, Actuating, and Triggering Activity in Biopolymer Networks [Invited]  WEIHONG TAN (Presenter), University of Florida — Active and driven biopolymer networks, such as networks of cytoskeleton proteins, have been intensely investigated over the past decade due to their promise for designing smart materials and understanding cell mechanics. These materials continuously alter their mechanical properties by varying the structural properties and interactions of the comprising biopolymers. Non-equilibrium activity can be driven by external triggers such as light, salt, temperature, or magnetic or electric fields. Activity can also be internally driven via molecular motors. This session will bring together studies on a wide-range of non-equilibrium biopolymer networks to elucidate the functional design principles of driven soft matter, as well as the time-dependent structural and rheological properties of these non-equilibrium networks. Advances in modulating and characterizing driven networks will also be discussed.
Myosin II filament size and activity influences localization in nematic actin droplets

KIMBERLY WEIRICH (Presenter), University of Chicago, KINJAL DASBISWAS, University of California, Merced, THOMAS A WITTEN, SURIYANARAYANAN VAIKUNTANATHAN, MARGARET GARDEL, University of Chicago — Soft, active materials self-organize from macromolecules in cells to form precisely structured assemblies, such as the mitotic spindle, that orchestrate specific biological functions. A central question is how these self-organized assemblies arise from their macromolecular components. We investigate mechanisms of self-organization in structured biopolymer assemblies, using a minimal model system of biopolymer droplets constructed from cross-linked actin filaments. These droplets have nematic structure, which arises from the actin filaments. Myosin II motor proteins, which form filaments that bind to and translocate actin filaments, spatially self-organize in these actin droplets. We find that motors large compared to the characteristic structure of the nematic liquid self-organize to the center of the droplet, evocative of mitotic spindle configurations. In contrast, motors small compared to the liquid are dispersed throughout the droplet. We investigate the influence of motor size and activity on the dynamics and localization within the droplet and capture the spatial localization with a continuum model based on liquid crystal theory. Our results reveal potential physical mechanisms of self-organization in biological assemblies and bio-inspired soft materials design.

The paradoxical material properties of living matter*

GIJSJE KOENDERINK (Presenter), AMOLF — This talk will focus on the mechanics of the polymeric load-bearing structures that support living matter: cells have a fibrous cytoskeleton, whilst tissues are supported by the extracellular matrix. Living matter uses dynamic materials in order to combine mechanical resistance with the ability to adapt and self-heal. Whereas synthetic transient networks readily fracture due to the inherent force sensitivity of dynamic bonds, biological networks are surprisingly strong. How does biological matter achieve the ability to flow without risking mechanical failure? I will discuss our recent findings on the nonlinear time-dependent mechanical properties and rupture of passive and active biopolymer networks reconstituted from purified components, which begin to shed some light on this question.

Nonequilibrium dynamics of semiflexible filaments in an active fluid

JUNANG LI (Presenter), SHREYAS GOKHALE, SAMI KAYA, ALEXANDRE SOLON, JEFFREY GORE, NIKTA FAKHRI, Massachusetts Institute of Technology — Active fluids exhibit a variety of complex dynamical phenomena that are not observed in their passive counterparts, largely due to the breaking of detailed balance at the particle level. This breaking of detailed balance can also be manifested in the dynamics of passive objects immersed in an active fluid. For instance, Nikola et al. have demonstrated numerically that a semiflexible filament exhibits spontaneous buckling and directed motion when immersed in an active bath. Despite considerable progress on the theoretical and numerical front, experimental investigations of the dynamics of passive objects in active media were so far restricted to the simplest cases. Here, we have developed an experimental system to systematically analyze the nonequilibrium dynamics of semiflexible filaments in an active fluid. We perform optical video microscopy on DNA-linked magnetic colloidal chains immersed in a quasi-2D bacterial bath, and quantify the diffusivity and the amplitudes of the bending mode fluctuations of the chains as a function of chain length, stiffness and bacterial density. Using fluorescent bacteria, we compute the active flow fields to uncover the underlying mechanism of the nonequilibrium dynamical phenomena.

Wednesday, March 6, 2019 2:30 PM - 5:30 PM

Session P61 GSOFT DBIO GSNP: Active Matter VI BCEC 258B - Benjamin Loewe, Syracuse University - Tag(s): Focus
2:30PM P61.00001: Spontaneous buckling of contractile poroelastic actomyosin sheets [Invited] YARON IDESES, VITALY ERUKHIMOVITCH, RON BRAND, Chemical Engineering and Ilse Kats Institute for Nanoscale Science and Technology, Ben-Gurion University of the Negev, SAMUEL A SAFRAN, Chemical and Biological Physic, Weizmann Institute of Science, KARSTEN KRUSE, Biochemistry and Theoretical Physics, University of Geneva, ANNE BERNHEIM-GROSWASSER (Presenter), Chemical Engineering and Ilse Kats Institute for Nanoscale Science and Technology, Ben-Gurion University of the Negev — Shape transitions in developing organisms can be driven by active stresses, notably, active contractility generated by myosin motors. The mechanisms generating tissue folding are typically studied in epithelia. There, the interaction between cells is also coupled to an elastic substrate, presenting a major difficulty for studying contraction induced folding. Here we study the contraction and buckling of active, initially homogeneous, thin elastic actomyosin networks isolated from bounding surfaces. The network behaves as a poroelastic material, where a flow of fluid is generated during contraction. Contraction starts at the system boundaries, proceeds into the bulk, and eventually leads to spontaneous buckling of the sheet at the periphery. The buckling instability resulted from system self-organization and from the spontaneous emergence of density gradients driven by the active contractility. The buckling wavelength increases linearly with sheet thickness. Our system offers a well-controlled way to study mechanically induced, spontaneous shape transitions in active matter (Ideeses Nat. Comm. 2018).

3:06PM P61.00002: ABSTRACT WITHDRAWN —

3:18PM P61.00003: Collective dynamics of microtubule-based 3D active fluids from gliding assay EDWARD JARVIS (Presenter), TEAGAN E BATE, MEGAN VARNEY, KUN-TA WU, Worcester Polytechnic Institute — Flows in passive fluids require temperature or pressure gradients. The gradients are not required for active fluids due to their capability of consuming local fuel to generate kinetic energy. The energy generated at a microscopic scale cascades up, resulting in macroscopic flows. However, the relation between microscopic and macroscopic dynamics remains unclear. Here we approach the problem with molecular motor-driven, microtubule (MT)-based 3D active fluids. We measure their flow mean speed at a millimeter scale, as a function of temperature, comparing with MT 2D gliding assay at a micron scale. We found that despite both systems differed in scales and dimensionality, they responded to temperature similarly. Moreover, such similarity was invariant under the change of motor processivity. Our work demonstrates collective dynamics of microtubule-based active fluids depends primarily on motor’s energy transducing rates, rather than motor’s dynamic details. Our finding expands flexibility in designing 3D active fluids using miscellaneous types of motors, as well as paves the path to outlining principles of self-organization of active fluids.

3:30PM P61.00004: Active nematic microtubule systems in confined geometries DIMITRIUS KHALADJ (Presenter), AMANDA TAN, LINDA S. HIRST, Physics, University of California, Merced — With the growing interest in active nematic systems, the introduction of restricted geometries is a novel method to investigate flows and mixing in active networks. In this study, we demonstrate active nematic motion of microtubules driven by kinesin clusters in confined and non-confined micro-environments. We use photolithography to fabricate bio-compatible micro-channels with varying widths to confine the active nematic microtubule network. Remarkably, we observe that nanoscale motion leads to continuous large-scale flow dynamics reminiscent of microscopic mixing. Furthermore, we propose that increasing confinement can have a significant effect on these large-scale transport phenomena. To quantify mixing, we directly couple beads to the microtubule network and apply methods from non-linear fluid dynamics to the spontaneous flows in the active nematic. We use fluorescence microscopy to track bead motion and record their trajectories. From this data, we measure Lyapunov exponents and Mean-Square-Displacement (MSD). We are interested in the relationship between flow dynamics and geometrical confinement.

3:42PM P61.00005: Active phase separation of biphasic polymer gels* NICHOLAS DERR (Presenter), Harvard University, CHRISTOPH WEBER, Max Planck PKS, L MAHADEVAN, CHRISTOPHER RYCROFT, Harvard University — Biological systems allow for the generation of active stresses, which can lead to mechanical and chemical instabilities and the formation of patterns. Many relevant systems - e.g. bone, developing tissue, cellular interiors - can be described as multiple immiscible phases of varying rheology, introducing a rich set of couplings between active stress generation and the corresponding passive mechanical responses. One area of particular interest is the generation of contractile forces within the cytoskeleton by the binding of myosin and kinesin motor proteins onto actin and microtubule networks, respectively. In this talk, we present a phenomenological model for active stresses induced by the fuel-dependent binding dynamics of molecular motors in biphasic, incompressible, transiently cross-linked polymer gels. We show that these stresses are analogous to a spatially and temporally varying dis-affinity between polymer and solvent which drives phase separation. The system’s behavior on long time scales is investigated by time-integration of the complete non-linear system of gel equations, and the results are contrasted with the case of a demixing passive gel described by classical Flory-Huggins theory.

2204 of 3305
AMANDA TAN (Presenter), KEVIN MITCHELL, LINDA S. HIRST, University of California, Merced — We study an active self-mixing fluid composed of biopolymers (microtubules) and molecular motors (kinesin). The kinesin motors are clustered together and crosslink bundles of microtubules. As the motors hydrolyze ATP, they walk along the microtubule bundles, forcing the bundles to extend away from each other. When confined in 2D at an oil-water interface, the network forms an active nematic with defects that are continuously created and annihilated. We consider these defects to be virtual stirring rods and the microtubule/kinesin system to be the fluid. We use fluid dynamic concepts to characterize this new self-mixing fluid by measuring the mixing efficiency, or topological entropy, by coupling beads directly onto the microtubule bundles and tracking their motion as they are mixed. The separation between beads in the material is exponential. We use these trajectories to measure the rate of separation in the material and thereby to calculate the topological entropy. In addition, we change the local stretching rate by varying the ATP concentration to study how changing the energy input on the microscale changes the global mixing efficiency.

NSF-CREST: Center for Cellular and Biomolecular Machines at UC Merced (NSF-HRD-1547848)

KEVIN MITCHELL (Presenter), AMANDA TAN, ERIC ROBERTS, University of California, Merced, SPENCER SMITH, Physics, Mount Holyoke, LINDA S. HIRST, University of California, Merced — Recent years have seen a surge of interest in active materials, in which energy injected at the microscale gives rise to larger-scale coherent motion. One prominent example is an active 2D liquid crystal composed of microtubules in the nematic phase. The activity is generated by molecular motors that consume ATP to generate local shearing between the microtubules. The resulting 2D fluid flow exhibits self-generated mesoscale chaotic dynamics with a characteristic folding and stretching pattern. We analyse this dynamics in the context of chaotic advection, in which the fluid can be viewed as "stirred" by the topological defects in the nematic order parameter. We compute the topological entropy from the braiding of these defects and show that all of the entropy arises from the positive one-half defects; the negative one-half defects, which are also present, contribute nothing to the entropy. We also show that the topological entropy generated by this stirring can be understood as a direct consequence of the micro-scale stretching quantified by the Lyapunov exponent, which is computed from PIV data. Our work is based on experimental fluorescence images of the microtubule structure.

*This work is supported in part by NSF grant DMR-1808926.

SHUO GUO (Presenter), University of Minnesota, XINLIANG XU, complex systems, Beijing Computational Science Research Center, XIANG CHENG, University of Minnesota — For an equilibrium system, thermodynamic pressure is considered as a fundamental state variable of the system, which always equals to mechanical pressure, i.e., force per unit area acting on confining walls. In contrast, for an active system out-of-equilibrium such as bacterial suspensions, mechanical pressure is no longer a state variable, which may depend on the stiffness and shape of confining walls. Here, by combining optical tweezers with biochemical engineering technique, we create quasi-two-dimensional bacterial suspensions and systematically study active pressure exerted by swimming E. coli on confining walls of different geometries. In particular, we measure the pressure of bacterial suspensions on V-shaped walls of different angles. We find that the active pressure is a function of the angle of the walls: a sharper angle leads to a stronger pressure. In addition, the fluctuation of pressure increases with decreasing angle. We construct a simple model based on the wall-induced alignment of bacteria to quantitatively explain our observations. Our study provides benchmark experiments for characterizing the mechanical pressure of bacterial suspensions and sheds new light on the nonequilibrium statistical principle of active fluids.

Bacteria Motility in Porous Media: Not a Random Walk

TAPOMY BHATTACHARJEE (Presenter), Andlinger Center for Energy and the Environment, Princeton University, SUJIT DATTA, Chemical and Biological Engineering, Princeton University — While bacterial motility is well-studied for motion on flat surfaces or in unconfined liquid media, most bacteria are found in heterogeneous porous media, such as biological gels and tissues, soils, sediments, and subsurface formations. Understanding how confinement alters bacterial motility is therefore critical to model the progression of infections, apply beneficial bacteria for drug delivery, and bioremediation. Unconfined bacteria move via runs and tumbles, leading to random walk-like motion; in a porous medium, previous research has assumed random walk-like motion for bacteria, with a reduced diffusivity due to collisions with obstacles. However, this assumption has never been directly tested due to the inability to visualize processes in opaque 3D media. Here, we directly visualize the motion of single E. coli cells inside a model 3D porous medium, having controlled pore structure. By analyzing the individual cell trajectories, we find that the bacteria do not move via a random walk process. We will present how bacterial motility depends sensitively on pore-scale confinement. Our findings overturn standard assumptions made in the field and provide guidance for the development of more accurate macroscopic models of bacterial motion.

Shape-directed rotation of homogeneous micromotors via catalytic self-electrophoresis

ALLAN BROOKS (Presenter), Chemical Engineering, Pennsylvania State University, MYKOLA TASINKEVYCH, Centro de Fisica Teorica e Computacional, Departamento de Fisica, Universidade de Lisboa, SYEDA SABRINA, DARRELL VELEGOL, Chemical Engineering, Pennsylvania State University, AYUSMAN SEN, Chemistry, Pennsylvania State University, KYLIE J. M. BISHOP, Chemical Engineering, Columbia University — The purpose of this work is to demonstrate that platinum microparticles with asymmetric geometries move spontaneously in hydrogen peroxide solutions. We can rationally design these motions by controlling particle shape using nanofabrication techniques. We design particles with n-fold rotational symmetry that rotate about their axis at rates specified by their extent of shape asymmetry. Experiments support a self-electrophoretic propulsion mechanism, where anodic oxidation and cathodic reduction of hydrogen peroxide occur at different rates at different locations across the particle surface. We develop a model to explain how the transport-limited electrochemical decomposition of hydrogen peroxide across an asymmetric particle surface leads to electro-osmotic flows that drive particle motion. Our results suggest that geometric control is an effective method to encode micromotor dynamics at the individual particle level. Insights from our proposed mechanism should be useful to design catalytic micromachines with complex dynamics and functions.

Controlling Morphology of Aerotactic Bacterial Bands

HIRAN WIJESINGHE (Presenter), ERIC MUMPER, ZACHARY OESTREICHER, STEVEN LOWER, BRIAN LOWER, RATNASINGHAM SOORYAKUMAR, Ohio State University — Microorganisms have perfected numerous evolutionary adaptations to improve their odds of survival and proliferation. This study exploits some of these adaptations such as flagellated swimming, aerotaxis and magnetotaxis in magnetic bacteria (MTB) to reshape entire swarms of them. These microorganisms have specialized strategies to navigate oxygen landscapes, of which perhaps the most intriguing is the biomineralization of magnetic nanoparticles that are thought to help them align with the geomagnetic field (magnetotaxis) and swim along natural oxygen gradients. Resulting migration to oxic-anoxic transition zones (OATZ) leads to aerotactic band formation. Many bacteria achieve motility through spinning helical flagellar appendages that produce flow fields that are well described in the far field by analytical models. However near-field dynamics remain elusive. We utilize lattice Boltzmann-based numerical models to simulate near field hydrodynamic interactions, metabolism-dependent oxygen diffusion in the medium, aerotactic response of the cells, as well as field controlled magnetotaxis. Strategies to achieve swarm morphologies beyond simple MTB aerotactic bands will be discussed.

Three-body Interactions Drive the Transition to Polar Order in a Simple Flocking Model

PURBA CHATTERJEE (Presenter), NIGEL DAVID GOLDENFELD, Physics, University of Illinois at Urbana-Champaign — Active systems are characterized by a discontinuous flocking transition from a disordered isotropic state to a polar ordered state with increasing density and decreasing noise. A large class of mesoscopic or macroscopic theories for flocking are coarse grained from microscopic models that feature binary interactions as the chief aligning mechanism. However, at the high densities at which the system flocks, binary interactions are too weak to account for the ordering transition. Here we introduce a solvable one-dimensional model of flocking, and derive a series of approximations for the stochastic hydrodynamics. We show that three-body interactions are not only necessary but also sufficient to capture the full phenomenology of flocking.
5:18PM P61.00013: Active reorientation in an active granular system powered by toy vibrobots* KYLE WELCH (Presenter), BO-KAI ZHANG, Complex Systems Division, Beijing Computational Science Research Center, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota, XINLIANG XU, Complex Systems Division, Beijing Computational Science Research Center — While emergent collective motion in systems of self-propelled objects is remarkable, one proclivity of active agents, particularly animals, is often overlooked when building models: collision avoidance. We present here an active granular experiment of disks propelled by toy vibrobots, which integrates an “active reorientation” behavior in analogy to collision avoidance in animals. The system demonstrates local flocking, wherein particle velocities locally align. Inspired by this experiment, we develop a computational model of self-propelled disks with an active reorientation mechanism. This simple numerical model exhibits rich phase behaviors: a disordered state, a flocking state and a clustering state under different parametric conditions. We find a notable suppression of aggregation in regions of parameter space corresponding to strong collective motion. Clusters develop quickly in this region, but are metastable, and collapse once the flocking state is achieved. Our experiment and model demonstrate the importance of active reorientation on emergent behaviors in systems of self-propelled agents, and illustrate the profound interplay between different emergent phases of active matter.

Session P62 DCOMP GSCCM: Physics of Planetary Interiors: Modeling Planets From Atomic to Global Scale BICEC 258C - Philip Armitage, JILA - Tag(s): Invited, Undergraduate

2:30PM P62.00001: What Juno and Cassini have told us about Giant Planet interiors* [Invited] DAVID STEVENSON (Presenter), Caltech — Juno is in orbit about Jupiter and will likely continue collecting data for several more years. Cassini collected data during close encounters within the Saturn ring plane for several months in 2017. The main source of information is the gravity data and magnetic field data, augmented in the case of Juno by microwave radiometry data that inform us about atmospheric composition, a key boundary condition for the interior. Juno gravity indicates that the innermost part of Jupiter is enriched in heavy elements (everything heavier than H and He), perhaps at the extent of around 10 or 15 Earth masses (~5% of the planet mass) but this enrichment is not in the form of a discrete core but is instead diluted by the overlying H and He. This is consistent with current ideas for planet formation, where very high temperatures lead to evaporation and mixing of incoming solids. The distribution of heavier elements in the region where hydrogen begins to metallize is less clear and may be affected by and entangled with the possible rain-out of helium. Saturn, unlike Jupiter, benefits from ring seismology: the existence of ring structure that must be attributed to density anomalies within the planet. In both Jupiter and Saturn, the region of magnetic field generation extends out beyond the metallic hydrogen region in to primarily molecular hydrogen that is sufficiently hot and compressed that it has significant conduction electrons. Coupling of the magnetic field to the zonal flow extends out further still, to a region where the electrical conductivity is of order 1 S/m. Although there has been much improvement in our understanding of H-He, the uncertainties, both in theory and experiment, remain large enough that they limit our ability to make full use of the spacecraft results. We need experiments at relevant temperatures and pressures, since most current experiments are either too hot or too cold at the pressures of importance.

*Work supported by the Juno mission

3:06PM P62.00002: Setting the stage: dynamics of planet formation and water delivery* [Invited] SEAN RAYMOND (Presenter), Laboratoire d’Astrophysique de Bordeaux, CNRS — In addition to our Solar System, exoplanet systems provide a sample of thousands of outcomes of planet formation. Even though Jupiter is the only Solar System planet likely to be detected with present-day technology, the past decade of observations has shown that the Solar System is quantifiably unusual among exoplanet systems at the ~1% level. Instead, at least half of main sequence stars host close-in “super-Earths”, and ~10% have Jupiters on non-Jupiter-like orbits. In this talk I will explore how the Solar System fits in a larger context by addressing key steps in planetary system formation. I will present models to explain the diversity of observed planetary systems and the mechanisms that create that diversity. I will focus on the processes that create a diversity in planetary compositions and formation times, with a particular emphasis on the origin of water. While there is as yet no consensus on exactly how the Solar System formed it is clear that Jupiter played a central role.

*I thank the Agence Nationale pour la Recherche for support via grant ANR-13-BS05-0003-002 (grant MOJO) and acknowledge NASA Astrobiology Institute’s Virtual Planetary Laboratory Lead Team, funded via the NAI under solicitation NNH12ZDA002C and cooperative agreement No. NNA13AA93A.
3:42PM P62.00003: Imaging the Earth's Interior based on Seismic Full Waveform Inversion* [Invited] JEROEN TROMP
(Presenter), Geosciences, Princeton University — Information about Earth’s interior comes from seismograms recorded at its surface. Seismic imaging based on spectral-element and adjoint-state methods has enabled assimilation of this information for the construction of 3D (an)elastic Earth models. These methods account for the physics of wave excitation and propagation by numerically solving the equations of motion, and require the execution of complex computational procedures that challenge the most advanced high-performance computing systems. Current research is petascale; future research will require exascale capabilities. Our research addresses the long-standing challenge of imaging Earth's interior based on full-waveform inversion. What we mean by 'full-waveform inversion' is combining 3D forward simulations with Fréchet derivatives computed in 3D background models to fit complete three-component seismograms both in phase (traveltime) and amplitude.

The inverse problem consists of reconstructing the characteristics of the medium from -often noisy- observations. A nonlinear functional is minimized, which involves both the misfit to the measurements and a Tikhonov-type regularization term to tackle inherent ill-posedness. Achieving scalability for the inversion process on tens of thousands of multicore processors is a task that offers many research challenges.

We are performing global adjoint tomography using a data set of 1,480 events recorded by tens of thousands of seismographic stations. We observe a significant increase in the resolution of plume and slab features throughout the mantle. The level of detail in our current model enables us to answer some of the questions the geosciences community has been asking about the existence of plumes and hotspots. In this presentation I will present our latest model.

4:18PM P62.00004: Spin crossover in iron in lower mantle minerals* [Invited] RENATA WENTZCOVITCH (Presenter), Columbia University — Pressure and temperature induced spin-state change in iron in lower mantle minerals is an unusual phenomenon with previously unknown consequences. High pressure and high temperature experiments have offered a wealth of new information about this class of materials problems, which includes the insulator to metal transition in Mott systems. I will discuss key experimental data, contrast them with our ab initio results and thermodynamic models, show the implications for fundamental phenomena taking place at the atomic scale and their macroscopic manifestations, and discuss potential geophysical consequences of this phenomenon.

4:54PM P62.00005: Numerical Simulations of Mantle Convection and Plate Tectonics in the Earth and Planets: From Magma Oceans to Present Day [Invited] PAUL J TACKLEY (Presenter), CHARITRA JAIN, ANTOINE B ROZEL, PATRICK SANAN, Department of Earth Sciences, ETH Zurich, DIOGO LOURENCO, Department of Earth and Planetary Sciences, University of California, Davis — The coupled system of convection of the Earth's solid mantle and plate tectonics is the driver of geological change on our planet, including continental drift, volcanoes, earthquakes, crustal production, atmospheric degassing the recycling, and cooling of the core, which drives the geodynamo. Modelling of this process is challenging due to the wide range of length scales (from faults to continents) and time scales (seconds to billions of years) and the complex rheology of rocks, which exhibit visco-elasto-plastic behaviour with strongly temperature-dependent viscosity varying by orders of magnitude over short length scales. Nevertheless, it is now routine to perform global-scale 3-D spherical simulations that span the 4.5 billion year age of our planet and contain complex effects such as partial melting and crustal production and solid-solid phase transitions.

StagYY [1] is one of the leading codes for performing such simulations. It uses a finite-volume discretization on a yin-yang spherical grid. Both built-in geometric multigrid, and the range of solvers available through PETSc, can be used. Here, technical details will be discussed, including recent enhancements made with funding from the Swiss Platform for Advanced Scientific Computing (PASC) project. Recent scientific results on contrasting tectonic regimes and the long-term evolution of Earth, solar system planets and exoplanets will be presented [2-4].

NIKO BEERENWINKEL, Biology, ETH Zurich, ALEX GAVRYUSHKIN, Computer Science, University of Otago, JEAN CARLSON, Physics, UC Santa Barbara, NIKO BEERENWINKEL, Biosystems Science & Engineering, ETH Zurich, VILHELM ANDERSEN WOLTZ (Presenter), CLARE I ABREU, JEFFREY GORE, Massachusetts Institute of Technology — The fly gut serves as an effective combinatorial model to dissect the gut microbiome. Interactions with previous colonizers due both to spatial and metabolic interactions. These interactions also shape host fitness, altering the lifespan and reproduction of flies. We find that colonization ability of new species is strongly influenced by these interactions influence physiology of the fly. To deconstruct this complexity, my lab develops a microbiome model using the fruit fly as the host and its natural set of just five stably colonizing gut bacteria as the microbiome. We reconstruct this system combinatorially, starting with germ-free flies, to ask how bacteria influence each other's ability to colonize the gut and how these interactions influence physiology of the fly. We find that colonization ability of new species is strongly influenced by previous colonizers due both to spatial and metabolic interactions. These interactions also shape host fitness, altering the lifespan and reproduction of flies. We introduce new mathematical tools called epistatic filtrations to calculate microbiome interactions. The fly gut serves as an effective combinatorial model to dissect the gut microbiome.

3:06PM P63.00002: Predictability in the assembly of microbial communities JEFFREY GORE (Presenter), Massachusetts Institute of Technology — Multispecies microbial communities are essential for the health of the planet as well as the human body. A major challenge is to develop a predictive understanding of which species will be able to coexist in a given environment. This task is potentially made even more difficult if there are strong higher-order interactions between species, in which the presence of a third species changes the nature of the interaction between two other species. In a series of laboratory experiments we have demonstrated that pairwise competitive outcomes are typically sufficient to predict the composition of simple communities containing three species. These results argue that higher-order interactions, while undoubtedly present, are typically not so strong as to make prediction impossible.

3:18PM P63.00003: Alternative stable states in microbial communities induced by environmental fluctuations VILHELM ANDERSEN WOLTZ (Presenter), CLARE I ABREU, JEFFREY GORE, Physics, Massachusetts Institute of Technology — Environmental fluctuations are pervasive in ecosystems, from daily and yearly variations in temperature to gut microbes receiving influxes of resources. In experiments with soil microbes, we have observed that a fluctuating environment causes a two-species community to exhibit alternative stable states that depend on the initial abundances of each species. Environmental disturbances were administered via daily dilutions of bacteria competitions. The magnitude of the daily dilution factor determines the fraction of cells discarded and therefore the depth of disturbance to the environment. We found the outcome of a competition with a fluctuating dilution factor to be the same as that with a constant dilution factor equal to the average of the fluctuating dilution factors. This outcome is in line with a prediction of the Lotka-Volterra competition model with an added global mortality rate: an environment with a fluctuating death rate equilibrates to the same fixed point as one with the time-averaged added mortality rate. We also observed fluctuation-induced alternate stable states in a more complex community with three species. These results suggest that, at least in a simple ecosystem, a fluctuating environment and a constant environment are in fact equivalent.

3:30PM P63.00004: Increasing Temperature Favors Slower-Growing Bacterial Species SIMON LAX (Presenter), CLARE I ABREU, JEFFREY GORE, Massachusetts Institute of Technology — Temperature is among the cardinal environmental variables which affect the growth and survival of microorganisms. Although the effects of temperature on the growth rates and metabolic activities of individual species is a central focus of microbiology, the manner in which temperature regulates competition between species is less well understood. Using a simple adaptation of the Lotka-Voltera competition models, we hypothesize that temperature should have generic effects on microbial competition, such that slower-growing species should consistently be favored by increasing temperature. We demonstrate that this prediction holds true in experimental pairwise competitions between a diverse set of species, and discuss how a community-wide death rate and the growth rates of the individual species interact to shape competitive landscapes. Finally, we show that pairwise dynamics are predictive of competitive outcomes in more complex communities, suggesting it should be possible to make general predictions for how communities might react to warming environments.
3:42PM P63.00005: Decomposition of generalized Lotka-Volterra systems and microbiome recovery*  ERIC JONES (Presenter), JEAN CARLSON, University of California, Santa Barbara — In the gut microbiome the successful administration of fecal microbiota transplantation (FMT) will convert a person's diseased microbial composition into a healthy one. We model these "healthy" and "diseased" microbial states as idealized ecological species, and characterize their behavior by homogenizing the properties of their constitutive microbial populations in a process called "steady state reduction" (SSR). This method decomposes a generalized Lotka-Volterra (gLV) system of many microbial species into two-dimensional (2D) subsystems that each span a pair of steady states of the high dimensional model and obey gLV dynamics. We investigate an experimentally derived model of antibiotic-induced *C. difficile* infection (CDI), and study the clinically relevant transition between CDI-vulnerable (diseased) and CDI-resilient (healthy) states with the 2D subspace generated by SSR. Specifically, we investigate the ability of FMT to convert a diseased state into a healthy state, and observe that a delay in FMT administration following antibiotics may undermine its success.

3:54PM P63.00006: What's love got to do with it? Stable marriage in microbial ecosystems limited by two essential nutrients  SERGEI MASLOV (Presenter), VERONIKA DUBINKINA, Bioengineering and Carl R. Woese Institute for Genomic Biology, University of Illinois at Urbana-Champaign, YULIA FRIDMAN, Department of Plasma Technologies, Kurchatov Institute, Moscow, Russia, PARTH PRATIM PANDEY, Carl R. Woese Institute for Genomic Biology and National Center for Supercomputing Applications, University of Illinois at Urbana-Champaign — Microbial communities routinely have several alternative stable states observed for the same environmental parameters. A possibility of sudden and irreversible transitions between these states (regime shifts) complicates external manipulation of these systems. Can we predict which specific perturbations may induce such regime shifts and which would have only a transient effect? To study this topic we introduce and study a model of a microbial ecosystem colonized by a large number of specialist species. Each species can be limited by essential nutrients of two types, e.g. carbon and nitrogen, each represented in the environment by multiple metabolites. We demonstrate that our model has an exponentially large number of potential stable states realized for different nutrient fluxes. Using game theoretical methods adapted from the stable marriage problem, we predict all of these states based only on ranked lists of competitive abilities of species for each of the nutrients. We show that several mutually uninvadable stable states are generally feasible for a given set of environmental conditions, and explore an intricate network of discontinuous transitions between these states upon changes of nutrient fluxes.

4:06PM P63.00007: The Minimum Environmental Perturbation Principle*  ROBERT MARSLAND (Presenter), Physics, Boston University, WENPING CUI, Physics, Boston College, PANKAJ MEHTA, Physics, Boston University — Variational principles have served as powerful conceptual tools throughout all areas of physics, often providing some geometrical intuition for the behavior of an otherwise intractable model. Variational principles have also been found for some of the paradigmatic models of theoretical ecology, but they usually lack a clear physical interpretation, and are therefore of limited use for building intuition. In this talk, I will show that competition among consumers for a common pool of resources leads to steady-state resource concentrations that solve a constrained optimization problem. Specifically, the magnitude of the environmental perturbation induced by resource consumption is minimized, subject to the constraint that the per-capita growth rate of each consumer species in the regional pool is zero or negative. This "Minimum Environmental Perturbation Principle" applies to a wide class of models with arbitrarily large numbers of species and resource types, whether the resources are substitutable or essential. But it is broken by environmental feedbacks, whereby consumers return resources to the environment as metabolic byproducts or decaying biomass.

4:18PM P63.00008: Higher order interaction inhibits bacterial invasion of a producer-predator microbial community*  HARRY MICKALIDE (Presenter), SEPP KUEHN, University of Illinois at Urbana-Champaign — Microbial communities must resist invasion in order to maintain biodiversity, stabilize industrial bioreactors, and preserve human microbiome health. It is widely believed that the more diverse a microbial community is, the more resistant to invasion it will be, and that this increased invasion resistance arises from a niche complementarity effect: more diverse communities consume a greater range of resources and thus eliminate niches for would-be invaders. Here we show that in a community of the algae *Chlamydomonas reinhardtii* (producer) and the ciliate *Tetrahymena thermophila* (predator), invasions by the bacteria *Escherichia coli* fail even when there is a niche of resources available to the bacteria. In contrast, bacteria successfully invade communities of algae or ciliates alone. We attribute the invasion resistance of the algae-ciliate community to a higher-order (3-way) interaction: the algae inhibits the bacteria’s ability to aggregate which leaves the bacteria susceptible to the ciliate’s predation. This method of invasion resistance requires both the algae and the ciliate to be present and thus provides an example of diversity leading to invasion resistance due to a higher-order interaction rather than niche complementarity.

4:30PM P63.00009: Bacterial cohesion predicts spatial distribution in the larval zebrafish intestine*  BRANDON SCHLOMANN (Presenter), TRAVIS WILES, ELENA WALL, KAREN GUILLEMIN, RAGHUVEER PARTHASARATHY, University of Oregon — Are there general biophysical relationships governing the spatial organization of the gut microbiome? Despite growing realization that spatial structure impacts microbial ecological dynamics, it is unclear in any animal gut whether structure is governed by predictive, unifying rules, of if it results from contextual, species-specific behaviors. I'll present work that explores this question through light sheet fluorescence microscopy of live, larval zebrafish that are raised germ-free and then associated with model microbial communities consisting of fluorescently tagged, symbiotic bacteria. Through comparative study of seven different species in isolation, we uncovered an unexpected and striking correlation between bacterial cohesion—the degree to which bacteria auto-aggregate—and position along the length of the intestine. We propose that this relationship emerges from the mechanical response of communities to flows generated by peristaltic contractions, and test this idea with genetic and antibiotic perturbations that modulate bacterial cohesion. The generality of this phenomenon points to bacterial cohesion as an ideal target for precision microbiome engineering.

4:42PM P63.00010: Spatial dynamics of multispecies mutualism  KIRILL KOROLEV (Presenter), RAJITA MENON, Boston University — Ecosystems function via a network of interactions between the species. Many of these interactions require physical proximity and are therefore affected by the spatial distribution of the species. We explore spatial structure that emerges due to facilitation and mutualism in multispecies communities and investigate its effects on ecosystem dynamics. In addition to one-way and two-way metabolite exchanges, interactions in multispecies community include loops of cyclic cross-feeding and higher order interactions such as collective mutualism. Collective mutualism requires that several species simultaneously contribute to a particular task such as digestion of a complex polysaccharide. We show that collective interactions become increasingly unstable to demographic fluctuations as the number of participating species increases. Such higher order interactions can nevertheless be stabilized by a network of reciprocal cross-feeding. We show how our results connect to the theory of nonequilibrium phase transitions and discuss the implications of our findings for the design of synthetic microbial communities.

4:54PM P63.00011: Dynamics of a predator-prey system with multiple predation strategies  RITWIKA VALLOMPARAMBATH PANIKKASSERYSU (Presenter), Physics, University of California, Merced, JUSTIN YEAKEL, Life and Environmental Sciences, University of California, Merced, AJAY GOPINATHAN, Physics, University of California, Merced — Predator foraging behavior includes hunting, scavenging, and stealing. Despite a wealth of literature about predator-prey dynamics, studies with different predator behavioral modalities are rare. We use non-linear dynamics to understand how populations evolve in predator-prey systems with multiple predator behaviors. Predator-prey interactions are summarized by coupled differential equations describing predator and prey population fluxes. The predator population is described by a single variable while the prey population is described by three – alive prey, prey being eaten by predators and is available for stealing, and dead prey available for scavenging. The size of each prey group serves as a proxy for the proportion of the relevant predator behavior. Fixed point analysis yields two trivial and one non-trivial fixed point, and the latter depends on predator death rate, prey growth rate, and relative strengths of different predator-prey interactions. Numerical simulations yield at least three distinct families of solutions depending on interaction strengths between prey types and predator – i.e., the system has multiple bifurcations. Finally, we show that hunting is more prevalent than scavenging or stealing.
5:06PM P63.00012: Investigating the role of pairwise interactions in microbial community assembly* JAMES BRUNNER (Presenter), NICHOLAS CHIA, Mayo Clinic — Using metabolic and ecological modeling, we investigate the question: is microbial co-occurrence in the human gut a result of pairwise interactions, or do higher order interactions play a significant role? We perform model fitting on data from pairwise bacterial growth experiments to produce deterministic and stochastic growth models for pairs and triplets of bacterial species. We measure the accuracy of the predictions given by the triplet models to assess the extent to which pairwise interaction parameters can explain triplet outcomes. We also use metabolic models to assess bacterial growth in pairs and triplets. Pairwise metabolic modeling can be used to determine interaction parameters between species, using for example dynamic flux balance analysis (dFBA). We compare the apparent pairwise interaction parameters derived from pair community models and triplet community models to determine whether or not constraint based metabolic modeling of communities depends strongly on only pairwise interactions, or if higher order interactions must be taken into account.

*We would like to thank the Jack DeWitt and Jackie Curtiss Foundation for their support.

5:18PM P63.00013: Immigration-induced phase transition in a regulated multispecies birth-death process* SONG XU (Presenter), Biomedical Informatics, Stanford University, THOMAS CHOU, Mathematics, UCLA — Power-law-distributed species counts or clone counts arise in many biological settings such as multispecies cell populations, population genetics, and ecology. This empirical observation that the number of species \( c_k \) represented by \( k \) individuals scales as negative powers of \( k \) is also supported by a series of theoretical birth-death-immigration (BDI) models. However, we show how a simple global population-dependent regulation in a neutral BDI model destroys the power law distributions. Simulation of the regulated BDI model shows a high probability of observing a high-population species that dominates the total population. Further analysis reveals that the origin of this breakdown is associated with the failure of a mean-field approximation for the expected species abundance distribution. We find an accurate estimate for the expected distribution \( \langle c_k \rangle \) by mapping the problem to a lower-dimensional Moran process, allowing us to also straightforwardly calculate the covariances \( \langle c_k c_l \rangle \). Finally, we exploit the concepts associated with energy landscapes to explain the failure of the mean-field assumption by identifying a phase transition in the quasi-steady-state species counts triggered by a decreasing immigration rate.

Session P64 DBIO: Systems Biology and Stochasticity in Biological Networks BCEC 259B - Po-Yi Ho, Harvard University

2:30PM P64.00001: The effects of the circadian clock on cell cycle regulation in cyanobacteria PO-YI HO (Presenter), ARIEL AMIR, Harvard University — The circadian clock affects the timing of cell divisions in cyanobacteria such that cells tend not to divide near dawn or dusk. The mechanism underlying the coupling between the clock and division remains unclear. We developed a phenomenological model that captures the single-cell statistics of the timing of cell divisions in the cyanobacteria _Synechococcus elongatus_. The model reproduces experimental results for both the wildtype and a clock-deletion mutant, in constant as well as periodic environments. We further study, within the model, how coupling division to the clock may affect the fitness of the population as a whole.

2:42PM P64.00002: Molecular search for a target with a conformational change: First passage time approach* JAEOH SHIN (Presenter), ANATOLY BORIS KOLOMEISKY, Rice University — The process of a molecule search for its target is ubiquitous in Nature. During the process, the molecule is often moving in complex inhomogeneous environments with random transitions between different dynamic modes. A notable example is transcription factors searching for target sequences on a DNA. Here we study the search dynamics with stochastic transitions between two conformations in a one-dimensional lattice. Using the first passage time approach, we explicitly analyze the mean search time for arbitrary system parameters. We found that there are several dynamic regimes in the search dynamics, which are determined by the relative values of the relevant length scales in the system. Moreover, the search time can be minimized by the combination of two different modes. Intriguingly, a recent analysis of hOGG1 protein shows that the protein moves on a DNA in the optimal parameter range. Additionally, we construct a general dynamic phase diagram.

*The work was supported by the Welch Foundation (C-1559), by the NSF (CHE-1664218), and by the Center for Theoretical Biological Physics sponsored by the NSF (PHY-1427654).
Precise timing can be advantageous in many biological processes, whether to coordinate events in the cell cycle, determine the duration of cell states, or create reliable rhythms. However, it can be hard to achieve because chemical reactions often produce exponentially distributed waiting times for individual events even when the rates are perfectly constant. Here we develop mathematical theories to dissect classes of timing mechanisms in single cells -- derive fundamental limits and optimal strategies, and how simpler and realistic circuits would approach the optimal. For some broad but naturally occurring distributions, the noise is limited by the inverse quartic root of the average number of states, and even that requires intricate mechanisms. We discuss how known synthetic and natural genetic timers appear to employ these mechanisms to create precise rhythms or accurate multigenerational cell fate decisions.

*This work was supported by NSF award 1517372 and by DARPA Agreement HR0011-16-2-0049.

Exponential growth naturally arises in many biochemical, cellular, ecological and economic flux networks. While the majority of mathematical models focus on balanced, steady-state growth, the general existence criteria for a stable long-term growth rate remains unclear. Here, we introduce a theoretical framework by connecting ergodic theory to the long-term behavior of flux networks. We investigate the convergence of exponential growth rate for a broad class of nonlinear flux networks, constructed by scalable flux functions. Scalable networks expand our analytic tools for studying non-steady-state growing systems, including the cell cycle and oscillating ecosystems. We demonstrate how scalable networks facilitates the analysis of objective functions in flux optimization, and use them for characterizing the essential motif of autocatalytic flux networks. Overall, our theory allows systematic construction of nonlinear networks and investigate their growth rate under optimization, regulation and perturbation.

Cellular events such as cell migration, division, and cell differentiation rely on precise timing. Molecular events inside cells are highly stochastic, and yet cells trigger events with high timing precision. We explore the effect of gene regulatory networks on first passage timing precision. We devise a method to find the global regulation function between the regulator and target gene which optimizes the timing precision. This method can be applied to a range of networks involving two genes such as regulation by an external species combined with autoregulatory feedback on the target gene itself. We confirm that feedback alone is not helpful in increasing timing precision. However, if a regulator is present then the combination of feedback and regulation is more beneficial than regulation alone. Specifically, higher timing precision is achieved by positive feedback when the regulator is high and negative feedback when the regulator is low. Our results are relevant to experimental gene regulatory systems where high timing precision is crucial, such as neuroblast migration during Caenorhabditis elegans development.

We acknowledge the Human Frontier Science Program.

The ability to measure shallow gradients in a chemical concentration plays an important role in a number of cellular processes, from chemotaxis to wound healing and development. Berg and Purcell were the first to demonstrate that diffusion sets a fundamental physical limit to the accuracy with which a cell can measure chemical concentrations. There is a growing body of physical literature concerning many aspects surrounding cellular concentration sensing. This includes the effects of receptor cooperativity, cellular shape and memory, and collective effects in multicellular sensing. Notably absent from this list is the role of fluid flow. In this talk, we discuss the problem of a low Reynolds number spherical squirmer directly sensing spatial gradients in concentration. By constructing a renormalization group improved solution of the appropriate advection-diffusion equation, we derive physical limits to the accuracy of spatial gradient sensing by swimming cells. At small Péclet number, advection is a singular perturbation in the problem. As a result, the sensory limits differ qualitatively from the case of pure diffusion which neglects the effects of fluid flow.
on the energetic cost associated with each task and the benefit provided by the trait. We show the optimum initial ratio of these two subpopulations depends on conditions heterogeneity in communication networks and division of tasks between two different phenotypes representing a public good, can freely diffuse into the environment and breakdown a substrate. We verify under what conditions an exoenzyme under quorum sensing regulation can increase the growth rate of individuals. This exoenzyme, representing a public good, can freely diffuse into the environment and breakdown a substrate. We verify under what conditions heterogeneity in communication networks and division of tasks between two different phenotypes are metabolically beneficial for the whole population. We show the optimum initial ratio of these two subpopulations depends on the energetic cost associated with each task and the benefit provided by the trait.

4:30PM P64.00011: Optimal control of aging in complex networks  ERIC SUN (Presenter), THOMAS MICHAELS, L MAHDEVAN, Harvard University — Aging is a shared process of biological and technical systems. As structural and organizational complexity increases, the phenomenon of aging—the progressive increase in the probability of death or decay—arises as an emergent property. A key question is how to maximize longevity of an aging system at minimal cost of maintenance and intervention. Here, we answer this question using optimal control theory and machine learning on a network model of aging. We derive and numerically validate optimal protocols for repair that emerge from a balance between maximizing system healthspan and minimizing the overall cost of repair. These protocols may motivate the design of rational strategies for delaying aging in complex systems.

4:42PM P64.00012: Integrating epigenetics to construct gene regulatory networks  ABHIJEET SONAWANE (Presenter), KIMBERLY RENEE GLASS, Medicine, Harvard Medical School — The biological processes that drive cellular function can be modeled by a complex network of interactions between regulators (transcription factors) and their targets (genes), summarized by gene regulatory networks (GRNs). The cell’s “epigenetic state” governs the potential targeting of genes by influencing chromatin accessibility. However, integrating such information to construct GRNs remains a challenge. Here, we develop an approach SPIDER using epigenetic information (DNase-I Seq data) and message-passing algorithm to estimate networks between transcription factors and genes in multiple cell lines. We validate our predictions against public ChIP-Seq data. SPIDER was more accurate, in predicting GRNs that other methods that integrate epigenetics compared to existing methods and improved detection of cell-line specific interactions in respective GRNs. SPIDER was also able to identify indirect interactions when putative motifs are absent in the regulatory region of genes, but with ChIP-Seq evidence of regulation. The epigenetically-informed GRNs from SPIDER can be used to identify targets of key regulators, or regulators of important genes from an experiment, in the given context of the cell-type.

4:54PM P64.00013: Kinetic PDE models of cell size control: size blow-up and evolution of growth rate*  MINGTAO XIA, Mathematics, Peking University, THOMAS CHOU (Presenter), Mathematics, UCLA — We derive kinetic equations for the distribution of cells in age, size, and added size after birth. These kinetic PDE models incorporate timer, sizer, and adder mechanisms of cell division. After properly constructing cell division rates, we show that an sizer-adder PDE model can lead to diverging cell sizes, particularly if the distribution of daughter cells immediately after birth is broad. The kinetic models are also extended to include growth rate correlation between successive generations. As the population evolves, so does the distribution of cellular growth rates. Representative numerical solutions to our PDEs will be presented.

*NSF DMS-1814364

5:06PM P64.00014: Exploiting a Percolation Transition for the Clustering of Noisy Gene Expression Data*  STEFFEN WERNER (Presenter), TOM S SHIMIZU, AMOLF, GREG STEPHENS, Physics, Vrije Univ (Free Univ) Amsterdam — Gene expression largely determines the fate of individual cells and ultimately influences development and behaviour of entire organisms. Thus, the ability to assess the abundance of mRNA intermediates of gene expression on a genome-wide scale (down to single cell resolution) promises to revolutionize our understanding of biological processes. While the collection of such data is rapidly growing thanks to experimental innovations, researchers face the challenge of identifying meaningful patterns and often need to discriminate subtle signals from a high noise floor. Here, we describe a density-based clustering approach that takes advantage of a percolation transition generically arising in random data to help discriminate meaningful patterns of variation from noise. The method allows clustering parameters to be defined by statistical properties of the data itself, thus obviating arbitrary parameter choices or detailed knowledge of experimental noise sources. By applying this approach to data from single cells to whole organisms, we reveal known as well as unknown modules of co-regulated genes.

5:18PM P64.00015: Dynamical network formation of *C. elegans* KEN NAGAI (Presenter), School of Materials Science, Japan Advanced Institute of Science and Technology, HIROSHI ITO, Faculty of Design, Kyushu University, TAKUMA SUGI, Molecular Neuroscience Research Center, Shiga University of Medical Science — Ordered collective motions are ubiquitous among locally interacting living beings. Experimental systems have been developed for non-living self-propelled particles, bacteria, and mammalian cells on a substrate, but there have been no experimental systems of multicellular organisms, which have much more complex behaviours, with various controllable parameters over a wide range.

Here, we have constructed an experimental system in which *C. elegans* collectively forms dynamical networks. We investigated the dependence of our designed experimental system on the substrate, ambient humidity and density of worms. Taking advantage of *C. elegans* genetics, we also controlled genetically determined motility by mutations. Furthermore, we developed an agent-based model with simple rules that reproduced the dynamical network formation and its dependences on the parameters, suggesting that the key behaviours for the network formation were alignment of worms after collision and smooth turning. This result revealed that the collective motion of the living things with advanced information processing systems can be described by a simple minimal model in a broad area of parameter space.

2:30PM P65.00001: Tissue flow genetics: mapping the forces that shape complex organs* [Invited] SEBASTIAN STREICHAN (Presenter), Physics, University of California Santa Barbara — Developmental biology established principles of how the body plan is laid out, morphogens setup axes, and gene expression patterns determine cell fates - yet how the form of organs emerges from coordinated action of multiple domains of distinct cell types remains elusive. We combine *in toto* live imaging and automated data analysis with physical modeling to investigate the link between kinetics of global tissue transformations and patterns of force generation during *Drosophila* gastrulation. We find our visco-elastic model driven by stress proportional to the spatial distribution and anisotropy of two quantitatively measured myosin pools achieves a 90% accurate description of the measured tissue flow - using only 3 parameters. Our analysis shows (i) forces driving the flow arise from non-uniformity of stress, thus spatial myosin modulation is critical for dynamics. Long-range modulation of the anisotropic part along the Dorso-Ventral (DV) axis suggests a novel role for the DV patterning system in convergent extension. (ii) The relation between flow and myosin forcing is non-local, and a transition towards areal incompressibility during germband extension further enhances non-locality. (iii) Mutant analysis indicates mechanical feedback on myosin recruitment relating it to the local strain rate. We conclude that understanding morphogenetic flows requires a fundamentally global perspective.

3:06PM P65.00002: Quantifying the changes in cell morphology with changes in cell state* ELAHEH ALIZADEH, Cell & Molecular Medicine, Univ. of Arizona, WENLONG XU, Chem & Bio Engr, Colorado State Univ, JORDAN CASTLE, Colorado State Univ, JACQUELINE FOSS, Biomedical Engr, Colorado State Univ, ASHOK PRASAD (Presenter), Chem & Bio Engr, Colorado State Univ — The shape of an adherent cell on a surface depends upon its active cytoskeletal properties and can change with a change in cell state. We have developed a large number of parameters to quantify cell shape and cytoskeletal morphology[1]. Using these to study different cell lines, as well as different experimental conditions, we show, with the help of statistical analysis and neural networks, that cell shape and cytoskeletal texture can discriminate between different states. Projections into lower-dimensional shape space allow us to distinguish between similar and dissimilar changes in shape, and identify similarities in shape changes between breast cancer and osteosarcoma cell lines accompanying the acquisition of invasive characteristics. We also discuss the similarities and differences between shape changes of different cell lines with similar experimental perturbations, as well as the heterogeneity in shape characteristics. Our data indicates that cellular morphology may be a powerful and sensitive window into the physiological state of the cell [2].

3:18PM P65.00003: Loss of vimentin intermediate filaments increases motility and nuclear damage in confining spaces* ALISON KOSER PATTESON (Presenter), Physics Department, Syracuse University, PAUL JANMEY, University of Pennsylvania — Cell migration is important to many biological processes, such as embryogenesis, wound healing, and cancer metastasis. The proper migration of cells is regulated by the mechanical properties of the cytoskeleton. The cytoskeleton is comprised of three main polymers, F-actin, microtubules, and intermediate filaments. When cells transition from stationary to migratory states, they often upregulate the intermediate filament vimentin. The viscoelasticity of vimentin networks in shear deformation has been documented, but its role in motility remains largely mysterious. Here, we used mouse embryo fibroblasts derived from wild-type and vimentin-null mice and examined their migration in microfluidic constrictions. We find that loss of vimentin increases 3D motility, unlike on rigid 2D substrates. Migrating through small constrictions leads to stress-induced nuclear damage in the form of blebs, nuclear envelope rupture, and double-stranded DNA breaks. These nuclear damage markers increase in the absence of a filamentous vimentin network. Our findings indicate that vimentin hinders 3D motility by providing mechanical resistance against large strains and thereby protects the structural integrity of the cell.

3:30PM P65.00004: Probing the mechanical organization of k-fiber microtubule bundles within the mammalian mitotic spindle via targeted laser ablation and speckle microscopy MARCUS A BEGLEY, ELIZABETH MAE DAVIS, MARY WILLIARD ELTING (Presenter), Physics, North Carolina State University — In dividing cells, a self-assembling microtubule-based machine called the mitotic spindle segregates chromosomes, ensuring that each new daughter cell has exactly one copy of its genetic information. Spindle microtubule organization imparts shape and structural robustness. For example, bundles of microtubules called kinetochore-fibers (k-fibers) attach chromosomes to the spindle and exert force to align and ultimately segregate them. Thus, the mechanical integrity of the k-fiber is critical to spindle function, yet its organization is not well-understood. For example, we do not fully understand how molecules that crosslink microtubules along k-fiber lengths contribute to overall k-fiber mechanics, nor whether k-fiber microtubules remain rigidly associated or fluidly slide past each other in response to spindle dynamics. To address these questions, we are probing the mechanics of inter-microtubule associations within the k-fiber by single-molecule speckle microscopy and by severing k-fibers via laser ablation. Our initial results suggest that k-fiber microtubules associate along their lengths and primarily act in the spindle as single rigid objects, but that connections between their microtubules are weak enough to be disrupted by our mechanical perturbations.

3:42PM P65.00005: Stress-stabilized sub-isostatic fiber networks in a rope-like limit* SADJAD ARZASH (Presenter), JORDAN SHIVERS, Department of Chemical & Biomolecular Engineering, Rice University, ALBERT JAMES LICUP, Department of Physics & Astronomy, VU University Amsterdam, ABHINAV SHARMA, Leibniz Institute of Polymer Research Dresden, FRED C. MACKINTOSH, Department of Chemical & Biomolecular Engineering, Rice University — Biological networks are common in both intercellular and extracellular environments. Mechanics of these disordered fibrous networks is strongly dependent on their local coordination number. It is observed that real biopolymer networks have connectivity between three and four. Such networks are sub-isostatic with only central force interactions, but exhibit a mechanical phase transition between floppy and rigid states under shear. Introducing weak bending interactions stabilizes these networks and decreases the critical signatures of this transition. We show that applying external stresses on a sub-isostatic network with only tensile central force interactions, i.e., a rope-like potential also stabilizes these systems. Moreover, we find that the linear shear modulus shows a power law scaling with the external normal stress, with a non-mean-field exponent. We also find a critical strain that shifts to lower values under prestress. Applied normal stress also suppresses criticality in these systems.

3:54PM P65.00006: Mobility of Molecular Motors Regulates Contractile Behaviors of Actin Networks  ATSUSHI MATSUDA, Institute for Frontier Life and Medical Sciences, Kyoto University, JING LI, PETER BRUMM, Interdisciplinary Life Science - PULSe, Purdue University, TAJI ADACHI, YASUHIRO INOUE, Institute for Frontier Life and Medical Sciences, Kyoto University, TAEYOON KIM (Presenter), Interdisciplinary Life Science - PULSe, Purdue University — Cells generate mechanical forces primarily from interactions between F-actin, cross-linking proteins, myosin motors, and other actin-binding proteins in the cytoskeleton. To understand how molecular interactions between the cytoskeletal elements generate forces, a number of in vitro experiments have been performed but are limited in their ability to accurately reproduce the diversity of motor mobility. In myosin motility assays, myosin heads are fixed on a surface and glide F-actin. By contrast, in reconstituted gels, the motion of myosin and F-actin are both unrestricted. Since only these two extreme conditions have been used, the importance of mobility of motors for network behaviors has remained unclear. In this study, to illuminate the impacts of motor mobility on the contractile behaviors of the actin cytoskeleton, we employed an agent-based computational model based on Brownian dynamics. We found that if motors can bind to only one F-actin like myosin I, networks are most contractile at intermediate mobility. On the contrary, if motors can bind to a pair of F-actins, a network can exhibit larger contraction with higher motor mobility. Results from this study imply that mobility of molecular motors may critically regulate contractile behaviors of actin networks in cells.

4:06PM P65.00007: Mechanical and Kinetic Factors Drive Sorting of Actin Crosslinkers*  SIMON FREEDMAN (Presenter), Engineering Sciences and Applied Mathematics, Northwestern University, CRISTIAN SUAREZ, JONATHAN WINKELMAN, DAVID KOVAR, GREGORY A VOTH, AARON DINNER, University of Chicago, GLEN HOCKY, Chemistry, New York University — In cells, actin crosslinkers segregate to different cytoskeletal networks to perform distinct functions, such as forming filopodia to enable cell migration, or polarizing actin bundles to enable cell division. Recent experimental work revealed a passive mechanism that may control this spatial localization: the binding of a short crosslinker to two actin filaments can promote binding of other short crosslinkers and inhibit binding of longer crosslinkers. We hypothesize that this spatial localization is due to the fact that actin is semiflexible and cannot bend over short lengths. We develop a mathematical theory and a Monte Carlo simulation to elucidate the quantitative predictions of this hypothesis. Experiments confirm the predictions but reveal an unanticipated dependence of crosslinker domain size on the kinetics of actin filament polymerization and crosslinker binding affinity. We use simulations of a coarse-grained but molecularly explicit model to characterize the interplay of mechanical and kinetic parameters and understand the observed behavior. Our work demonstrates a physical mechanism by which cells can organize molecular material to drive biological processes, and it can guide the choice and/or design of crosslinkers for protein-based materials.

4:18PM P65.00008: Reconstitution of aster movement and cell division plane positioning mechanisms in Xenopus egg extract*  JAMES PELLETIER (Presenter), Physics, Massachusetts Institute of Technology, CHRISTINE FIELD, Systems Biology, Harvard Medical School, NIKITA FAKHRI, Physics, Massachusetts Institute of Technology, JOHN OAKLEY, Chemical Engineering, University of Wyoming, JAY GATLIN, Molecular Biology, University of Wyoming, TIMOTHY MITCHISON, Systems Biology, Harvard Medical School — During early development, microtubule asters move through the cytoplasm to position microtubule organizing centers (MTOCs) near the centers of subsequent cells. Aster movement is thought to depend on pulling forces by cytoplasmic dynein opposed by hydrodynamic drag; however, it remains unclear what are the cytoplasmic anchors, and how other cytoplasmic networks such as actin facilitate or hinder aster movement. We reconstituted aster growth, interaction, and movement in an actin-intact Xenopus egg extract system under quasi-2D confinement. We imaged microtubules, actin, and candidate cytoplasmic anchors. Asters interacted to generate dynamic Voronoi tessellations with edges corresponding to division planes. MTOCs moved toward the center of each polygon, mimicking their movement in vivo. Dynein inhibition blocked inward transport of cytoplasmic anchors. Actin depolymerization increased the rate of inward transport of anchors, but decreased the rate of aster movement. Actin depolymerized at Voronoi edges due to AukkB activity, resulting in aster movement away from edges. Our experiments inform how dynamic cytoplasmic networks interact to drive aster movement by dynein-dependent and -independent mechanisms.

4:30PM P65.00009: Chromatin Mechanics and the Biological Implication*  YAOJUN ZHANG (Presenter), DANIEL LEE, Princeton University, YIGAL MEIR, Ben Gurion University, CLIFF BRANGWYNNE, NED WINGGREEN, Princeton University — The nucleus of the cell is a dense repository of information. But the DNA of the genome is more than just a string of letters – it forms “chromatin” a protein-nucleic-acid fiber with complex organization. Increasingly, the spatial organization of the genome has come into focus based on a suite of new technologies. The emerging picture spans scales from nucleosomes to loop domains to phase-separated regions. In parallel, the mechanics of chromatin has been probed by passive and active rheology, with its own emerging picture of chromatin as a viscoelastic and heterogeneous material. How are these two pictures related? To address this question, we developed a mechanistic model of chromatin using coarse-grained molecular dynamics simulations. The model captures chromatin's central viscoelastic nature and its observed heterogeneity, and has revealed long-range cross-links as critical to reproduce experimental observations. Our results further elucidate the role of mechanics in fundamental biological processes taking place in the cell nucleus.

4:42PM P65.00010: Bacterial chromosome organization by collective dynamics of SMC condensins*  CHRISTIAAN A. MIERMANS (Presenter), CHASE P. BROEDERSZ, Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians University of Munich — Recent Hi-C experiments of many bacterial species indicate a juxtaposed organization of the two chromosomal arms. These features in Hi-C maps have been attributed to various nucleoid-associated proteins, including the highly conserved SMC condensin. Although the molecular structure of these ATPases has been mapped in detail, it has been unclear how only a small number of condensins orchestrates this remarkable spatial organization. To resolve this puzzle, we developed a computational model for the dynamic organization of DNA by condensins as active slip-links. We first consider a scenario in which the ATPase activity of slip-links regulates their DNA-recruitment near the origin of replication, while the slip-link dynamics is assumed to be purely diffusive. We find that such diffusive slip-links can organize the entire chromosome into a state with aligned arms, but not within physiological constraints. However, slip-links that include motor activity are far more effective at organizing the entire chromosome, dynamically driving an entire chromosome into the juxtaposed state at physiological densities. We expand on these insights by showing the relation between this out-of-equilibrium organization and chromosome segregation.

4:54PM P65.00011: Ionic Conductance of 1.5 nm Diameter Carbon Nanotube Porins*  ALEKSANDR NOY (Presenter), Lawrence Livermore Natl Lab — Controlling ion transport on a molecular scale is important for applications ranging from industrial water treatment, to membrane separations, to bioelectronic interface design. Carbon nanotube porins—pore channels formed by ultra-short carbon nanotubes assembled in a lipid membrane—exploit nanoscale confinement and unique structure of carbon nanotube walls to transport water, protons, and small ions with efficiency that rivals and sometimes exceeds that of biological channels. We report the ion conductance characteristics and ion selectivity of the individual 1.5 nm diameter carbon nanotube porins. The conductance follows the power law scaling that is distinct from the previously reported characteristics of carbon nanotubes. We will also discuss the physical mechanisms that lead to these conductance characteristics. Overall, carbon nanotube porins represent versatile biomimetic membrane pores that are ideal for studying nanoscale transport phenomena and building new separation technologies and bioelectronic interfaces.

*These studies were supported by the U.S. DOE, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under award SCW0972. Work at LLNL was performed under the auspices of the U.S. Department of Energy under Contract DE-AC52-07NA27344.
We propose an extremely simple but efficient self-propelled cruiser, able to travel freely in 2D granular materials made of bidisperse dissipative particles under gravity. The cruiser has a round shape and a square indentation on its edge. To move into a given direction, perpendicular or parallel to gravity, we orient the indentation in line with the desired direction, and the cruiser shifts the granular particles entering its indent-region to its rear-half by a prescribed distance and then ejects them backward to gain thrust for moving forward. Using frictionless molecular dynamics (MD) method, we identify three universal phases of the cruiser during one particle-ejection process: 1) acceleration due to the ejection-thrust, 2) deceleration by the compressed particles ahead and 3) relaxation with the decompressed particles. We also confirm that the cruiser can travel continuously within the granular medium by successive particle-ejection, and the cruising performance increases with the ejection-strength and decreases by the interference from gravity. We believe our study demonstrates a novel approach to engineer self-propelled machines in granular materials.

*Startup funding, Shizuoka University, Japan

We find the general solution to the Fokker-Planck equation using homotopic methods. This result is represented as a series solution in time. The series coefficients are determined as phase-space derive operators. In addition, the general formalism is used to find mean values (variance and mean-square displacements) for the case of active Brownian particles on Euclidian and non-Euclidian spaces and under external fields. The theoretical results are validated using Brownian Dynamics simulations.

[2:30PM P66.00001: Active wetting of epithelial tissues* [Invited] RICARD ALERT (Presenter), Princeton Center for Theoretical Science, Princeton University, CARLOS PEREZ-GONZALEZ, Institute for Bioengineering of Catalonia, CARLES BLANCH-MERCADER, University of Geneva, MANUEL GOMEZ-GONZALEZ, Institute for Bioengineering of Catalonia, TOMASZ KOLODZIEJ, Jagiellonian University in Kraków, ELSA BAZELLIERES, Institute for Bioengineering of Catalonia, JAUME CASADEMUNT, University of Barcelona, XAVIER TREPAT, Institute for Bioengineering of Catalonia — Development, regeneration, and cancer involve drastic transitions in tissue morphology. In analogy with the behavior of inert fluids, some of these transitions have been interpreted as wetting transitions. The validity and scope of this analogy are unclear, however, because the active cellular forces that drive tissue wetting have been neither measured nor theoretically accounted for. We show that the transition between two-dimensional epithelial monolayers and three-dimensional spheroidal cell aggregates can be understood as an active wetting transition whose physics differs fundamentally from that of passive wetting phenomena. By combining an active polar fluid model with measurements of physical forces as a function of tissue size, contractility, cell-cell and cell-substrate adhesion, and substrate stiffness, we show that the wetting transition results from the competition between active traction forces and contractile intercellular stresses. This competition defines a new intrinsic length scale of active polar fluids that gives rise to a critical size for the wetting transition: Tissues larger than the critical size wet the substrate whereas smaller tissues dewet — a striking feature that has no counterpart in classical wetting. Finally, we show that active fluctuations of the tissue shape are dynamically amplified during the dewetting process. Overall, we conclude that tissue spreading constitutes a prominent example of active wetting — a novel physical scenario that may explain morphological transitions during tissue morphogenesis and tumor progression.

A Computational Model of Calcium Signals Around Laser-Induced Epithelial Wounds

AARON STEVENS (Presenter), KAZI TASNEEM, JAMES OCONNOR, SHANE HUTSON, ANDREA PAGE-MCCAW, Vanderbilt University — Epithelial wounds heal in multiple stages that involve wound detection, cell migration, and cell proliferation. One of the earliest signals of wound detection is an increase in cytosolic calcium concentration. Laser-ablation wounds in Drosophila epithelia trigger complex calcium signaling dynamics on multiple spatiotemporal scales. Given multiple hypothesized mechanisms that may drive calcium signals, we have developed a computational model to test the plausibility of these hypotheses and further understand the underlying biology. The model consists of intracellular exchange of calcium between cytosol and endoplasmic reticulum (ER), as well as exchange of calcium and other ions with the extracellular space and neighboring cells. The model thus couples calcium concentrations and membrane potentials among gap-junction-connected epithelial cells. These ion exchanges are initiated in the model by microtears in the plasma membranes of cells near the wound and by the activation of G-protein coupled receptors via a wound-induced diffusible ligand. We will discuss the model in detail, evaluate the plausibility of its hypotheses, and describe its experimentally testable predictions.

Controlling collective cell migration using geometric boundary perturbations

MATTHEW HEINRICH (Presenter), DANIEL COHEN, ANDREJ KOSMRLJ, Princeton University — We work at the intersection of the active matter and tissue engineering communities, where our goal is to learn more about emergent behaviors of cellular collectives in response to perturbations of the microenvironment and to exploit these to develop design rules for controlling tissues. Here, we try to bias MDCK tissue expansion using asymmetric geometric boundary perturbations, a known strategy for biasing transport in several active matter systems. We aim to find the minimal boundary perturbation that can influence behavior in the bulk of a cell collective. Using a high throughput, high-resolution tissue-patterning assay, we can study the effects of these patterns on tissue expansion, wound healing (tissue collisions), and collective cell migration in general without typical microfabrication processes.

Coupling between symmetry and motion in 3D printed microtissue arrays

SARAH ELLISON (Presenter), CHRISTOPHER O’BRYAN, CAMERON MORLEY, THOMAS ANGELINI, University of Florida — Symmetry plays a major role in the emergence of collective phases of inanimate materials. In magnetism, for example, geometric frustration leads to spin-glass phases. If similar principles could be leveraged to control collective phases of biological materials, like living cell assemblies, a new set of design strategies could be developed in tissue engineering applications. Building symmetry into biological systems is often challenging and is sometimes achieved through surface micropatterning; achieving such patterns in 3D is even more challenging. To fabricate 3D multi-cellular systems of designed symmetry and spatial patterning, we 3D print geometric patterns of collagen and 3T3 fibroblast cells. These cell/ECM patterns are printed directly into a 3D growth media made from jammed microgels, providing a well-defined yet reconfigurable environment on all sides of the structures. By comparing the collective motion arising in systems with hexagonal and square symmetries, we probe the potential role of geometric frustration in multicellular structure maturation. Preliminary data and analysis will be presented.

Instabilities on the leading front of collectively migrating tissue

YANJUN YANG (Presenter), HERBERT LEVINE, Rice University — Instabilities are often observed on the leading front of a collectively migrating cellular sheet both in vivo and in vitro. Instead of moving forward uniformly, the leading front often destabilizes into multicellular fingering-like structures. To decipher the mechanical origin of the instabilities, we develop a continuous model based on the Toner-Tu equations for active fluids, in which the collectively moving cells are modeled as a system of self-propelled particles. We perform different perturbations on the front edge and analyze the linear stability. We show the instabilities are due to some kinds of perturbations, for example, leader cells. Finally, we show our simulation of figuring-like protrusions with the guidance of leader cells.

3:54PM P66.00006: Different modes of fluidization in Human Bronchial Epithelial Cells -- the Unjamming Transition vs. the Epithelial-Mesenchymal Transition  
AMIT DAS (Presenter), Northeastern University, JENNIFER A MITCHEL, Harvard T.H. Chan School of Public Health, DAPENG BI, Northeastern University, JIN-AH PARK, Harvard T.H. Chan School of Public Health — Epithelial tissues are non-migratory and behave as a jammed system under homeostatic conditions. Using a jammed layer of human lung epithelial cells we compare a new mode of tissue fluidization, induced by mechanical compression, namely the unjamming transition (UJT) with the epithelial-mesenchymal transition (EMT). Our analyses of experimental data reveal the following: Strong cellular elongation and large fast moving Nematic swirls during the UJT while retaining epithelial nature. All these features are lost during the EMT when the cells become mesenchymal. To further our understanding we developed a dynamic vertex model (DVM) which differs from previous vertex models in that the cell edges can now become curved and can thus reflect the competition of the forces acting on the edge locally. These forces include cortical tension, intracellular-pressure differences, and polarized motility forces. We explore different paths of solid-to-fluid transitions based on different parameters in the model, such as individual cell motility and preferred cell shapes, and compare our predictions with the experimental observations on UJT and EMT. Based on our comparisons, we propose that the UJT could be an alternative route to fluidization of jammed epithelial tissues, independent of the EMT.

4:06PM P66.00007: How the mechanics of extracellular matrices interacts with cells*  
YOUYUAN DENG (Presenter), HERBERT LEVINE, Center for Theoretical Biological Physics, Rice University — In the last twenty years, we have seen all-round progress in modeling the mechanics of the biopolymer network. Its stability is understood based on Maxwell counting arguments. The lattice-based models numerically predict the phase diagrams and other bulk properties that are consistent with experimental observations. Other analytical theories, such as mean-field approximation and scaling laws, also enlighten our understanding.

Part of the reason behind it being so intensively investigated is that, a good example of biopolymer networks, extracellular matrices(ECM), plays a central role in many cellular processes. On the single-cell level, experiments have shown that the ECM interact with biochemical networks in a cell, e.g. inducing the epithelial-mesenchymal transition. On multi-cellular levels, the ECM modulates collective biophysical processes like the durotaxis. Deciphering the force pattern behind many collective cellular behaviors is still under its way. We hereby showcase our recent efforts in modeling the couplings between the mechanics of ECM and biology of cells embedded inside the former.

4:18PM P66.00008: The origin of solidity and fluidity in cellular materials and biological tissues.  
DAPENG BI (Presenter), Northeastern University, LE YAN, Kavli Institute for Theoretical Physics — Models for confluent biological tissues often describe the network formed by cells as a triple-junction network, similar to foams. However, higher order vertices or multicellular rosettes exist prevalently in developmental and in vitro processes and have been recognized as crucial in many important aspects of development, disease and physiology. In this work, we study the influence of rosettes on the mechanics of a confluent tissue. We find that the existence of rosettes in a tissue can greatly influence its rigidity. Using a generalized vertex model and effective medium theory we find a fluid-to-solid transition driven by rosette density and intracellular tensions. This phase transition exhibits several hallmarks of a second-order phase transition such as a growing correlation length and a universal critical scaling in the vicinity a critical point. Further, we elucidate the nature of rigidity transitions in dense tissues using a generalized Maxwell constraint counting to answer a long-standing puzzle of the origin of solidity in cellular materials.
4:30PM P66.00009: The dynamics of laminin-mediated red blood cell adhesion in sickle cell disease*  SHAMREEN IRAM (Presenter), Physics, Case Western Reserve University, UTKU GOREKE, Mechanical and Aerospace Engineering, Case Western Reserve University, GUNDEEP SINGH, Physics, Case Western Reserve University, JANE LITTLE, University Hospitals, UMIT GURKAN, Mechanical and Aerospace Engineering, Case Western Reserve University, MICHAEL HINCZEWSKI, Physics, Case Western Reserve University — Understanding red blood cell (RBC) adhesion to blood vessel walls is crucial to treat sickle cell disease. We have developed a microfluidic RBC adhesion assay [Alapan et al., Translational Research, 173, 74-91, (2016)] and performed experiments on clinical whole blood samples to probe RBC adhesion biomechanics. Microchannels functionalized with laminin (an endothelial protein) were integrated with a programmable syringe pump to mimic physiological flow conditions in microvessels. A novel set of methods for automated identification and tracking of adherent RBCs from video data was developed. We analyzed the dynamical data using a theoretical approach adapted from a prior study on heterogeneity in protein adhesion in Atomic Force Microscopy (AFM) experiments [Hinczewski et al., Proc. Natl. Acad. Sci., 113, E3852 (2016)]. Our analysis yielded a minimal physical model of the RBC detachment process, and comprehensively characterized the adhesion dynamics across patient samples. Model parameters also revealed statistically significant correlations with patient clinical data, opening the possibility of diagnostic applications suited to automated, high-throughput and low cost diagnostic platforms with clinical utility.

4:42PM P66.00010: Shape Fluctuations and Curvature-Driven Mechanics of Heterogeneous Lipid Vesicles*  DAVID ROWER (Presenter), PAUL J ATZBERGER, Mathematics/Mechanical Engineering, UCSB — We investigate heterogeneous vesicles consisting of mixtures of different lipids. We develop single-bead implicit-solvent coarse-grained models based on anisotropic pair potentials to capture vesicle shapes arising from species with different preferred curvatures. We develop theory and methods for mapping our molecular results to continuum mechanics descriptions, useful for analysis of fluctuation spectra to estimate bending elasticities and other mechanical parameters. For mixed lipid species, we find that passive fluctuation spectra are significantly influenced by the formation of small curved segregated domains. We actively probe the vesicle mechanics with compression and narrow-passage transport experiments. When compressed, we find that high-curvature domains arrange circumferentially, leading to a smaller resistance force. When transporting through a narrow passage, we find that mixed vesicles are characterized by much higher variances in passage times. We also find that geometric effects can delay phase-separation in the bulk and promote phase-separation during channel transport, resulting in occasional budding events. Our results may have implications for biological systems, fluidics utilizing vesicles, and other experimental assays.

4:54PM P66.00011: Theory of cytoskeletal rearrangement and force generation*  ADAM LAMSON (Presenter), SHANE FIORENZA, MATTHEW GLASER, M. BETTERTON, University of Colorado, Boulder — Cytoskeletal networks that include microtubules, crosslinkers, and kinesin motors are the basis of the mitotic spindle and cytoplasmic transport. The large separation of time scales between motor and crosslinker activity (sub-second to second) and network function (minutes to hours) is a challenge for theoretical approaches. We developed a minimal model, building on the separation of time scales between relatively fast crosslinker and motor rearrangement and relatively slow filament movement. The model reproduces experimentally measured force, torque, and self-organization in cytoskeletal networks of different length scales. With this model, we study mitotic spindle assembly from a monopolar initial condition and compare the mechanisms of motor- versus crosslinker-mediated spindle assembly. The results show how torque-balance and force-balance properly align microtubule bundles. In another study, we propose that oscillating optically trapped microtubule pairs crosslinked with motors and/or crosslinkers can be used to determine the kinetics and mechanics of crosslinking proteins.

5:06PM P66.00012: Force Generation by Curvature-Generating Molecules* JONAH SCHER-ZAGIER (Presenter), Department of Physics, Washington University, St. Louis, ANDERS CARLSSON, Department of Physics and Center for Engineering Mechanobiology, Washington University, St. Louis — Curvature-generating molecules (CGMs) are central to a variety of biological processes. In particular, proteins such as clathrin help provide bending forces and moments to drive endocytosis. We develop a discrete mechanical model of the shape of a small CGM-membrane complex that incorporates the effects of cell wall elasticity and high turgor pressure. We study the dependence of the force generated by the CGMs on several parameters, including the bending modulus, the complex size, and the turgor pressure. We find evidence of transitions as a function of external turgor pressure and intrinsic curvature. This work also compares the discrete model to previous continuous models of CGM forces, finding that the distribution of the forces depends on the strength of the turgor pressure relative to the bending energy. The forces are localized at the edges for high turgor pressure, and more widely distributed for low turgor pressure. In addition, the energy exhibits a minimum at small numbers of molecules. Further, for realistic values of the bending rigidity and curvature, CGMs alone are insufficient to initiate endocytosis against turgor pressure, in agreement with previous findings.

Session P67 DBIO: Physics of Neural Systems I BCCE 050 - Joshua Shaevitz, Princeton University - Tag(s): Focus

2:30PM P67.00001: What the odor is not: Estimation by elimination* [Invited] VIJAY SINGH (Presenter), Physics, University of Pennsylvania, Philadelphia, PA, USA, MARTIN TCHERNOOKOV, Physics, University of Wisconsin, Whitewater, WI, USA, VIJAY BALASUBRAMANIAN, Physics, University of Pennsylvania, Philadelphia, PA, USA — The olfactory system is thought to encode vast numbers of odors combinatorially in the responses of a much smaller number of broadly sensitive receptors. Here, we propose a method for decoding such a distributed representation. The main idea is that it is much easier to identify what the odor is not, rather than what the odor is. This is because a typical receptor binds to many odorants; so a response below threshold signals the absence of all such odorants. We demonstrate that, for biologically realistic numbers of receptors, response functions, and odor mixture complexity, this remarkably simple method of elimination turns an underdetermined decoding problem into an overdetermined one, allowing accurate determination of the odorants in a mixture and their concentrations. We give a simple neural network realization of our algorithm which resembles the known circuit architecture of the piriform cortex.

3:06PM P67.00002: Quantifying Multi-neuronal Olfactory Responses in C. elegans* ALBERT LIN (Presenter), Department of Physics, Harvard University, VIVEK VENKATACHALAM, Department of Physics, Northeastern University, WESLEY HUNG, MIN WU, MEI ZHEN, Samuel Lunenfeld Research Institute, Mount Sinai Hospital, ARAVINTHAN SAMUEL, Department of Physics, Harvard University — Complex animal behaviors arise in response to an organism’s environment, as perceived through its senses. Unlike other stimuli animals experience, such as light or sound, chemosensory stimuli form a high dimensional space, making the computational problem faced by organisms interpreting olfactory cues especially complex. The processes by which olfactory information is encoded are poorly understood. To better understand ensemble-level olfactory representation, we record from all sensory neurons in the nematode C. elegans simultaneously, while presenting stimuli in a highly controlled manner in a microfluidics environment. Observing the dynamics of these neurons in response to odors and odor mixtures of varying identity and strength has allowed us to build a quantitative and comprehensive picture of the way the olfactory system in C. elegans consolidates and represents high-dimensional sensory information. Our results suggest that olfactory stimuli are represented by distinct constellations of multiple chemosensory neurons, and that response characteristics of individual neurons is odor-dependent.

Seizure Prediction with Machine Learning using Real and Simulated Electrocorticography Data*

LOUIS NEMZER (Presenter), Nova Southeastern University, ROBERT WORTH, Indiana University, GARY D CRAVENS, VICTOR CASTRO, ANDON PLACZEK, KRISTINA BOLT, Nova Southeastern University — Epilepsy is the most common chronic neurological disorder, affecting approximately one percent of people worldwide. Patients with symptoms not well controlled with medication often suffer significantly reduced quality of life due to the unpredictable nature of seizures, which are periods of pathological synchronization of neural activity in the brain. Using a surgically-implanted intracranial electrode grid, electrocorticography (ECoG) provides better spatial and temporal resolution of brain electrical activity, compared with conventional scalp electroencephalography (EEG). We combine this patient data with simulated output from a full Hodgkin-Huxley calculation using in silico neurons connected with a small-world network topology. Supervised Machine Learning, a set of powerful and flexible artificial intelligence techniques that allow computers to classify complex data without the need for explicit programming, along with topological data analysis methods, are employed with a goal of developing an algorithm that can be used for the real-time clinical prediction of seizure risk.

Attractor-state itinerancy in neural circuits with synaptic depression*

BOLUN CHEN (Presenter), PAUL MILLER, Brandeis University — Neural populations with strong excitatory recurrent connections support bistable states in their mean firing rates. Multiple fixed points in a network of such bistable units can be used to model memory retrieval and pattern separation. The stability of fixed points may change on a slower timescale than that of the dynamics due to short-term synaptic depression. This leads to state-transitions that depend on the history of stimuli. We study a minimal model which characterizes multiple fixed points and transitions in response to diverse stimuli. We show that the slow synaptic depression introduces multiple time-scales. The interplay between fast and slow dynamics of synaptic input and depression makes the system's response sensitive to the amplitude and duration of square-pulse stimuli in a history-dependent manner. Weak cross-couplings further deform the basins of attraction for different fixed points into intricate and even fractal-like shapes. Our analysis provides a natural explanation for the system's rich responses to stimuli with different duration and amplitudes while demonstrating the encoding capability of bistable neural populations for dynamical features.

Nonlinear Brain Dynamics via Neural Field Theory*

PETER ROBINSON (Presenter), School of Physics and Center for Integrative Brain Function, Univ of Sydney — Going beyond well-known nonlinear effects at the single-neuron level, nonlinear effects at the systems and whole-brain levels are manifest in epileptic seizures (Hopf bifurcations, limit cycles, saddle cycles), migraines and visual hallucinations (Turing and Hopf-Turing patterns), strong visual stimulation (harmonic and subharmonic generation, phase locking, entrainment), deep brain stimulation therapy of Parkinson's disease (entrainment, harmonic and subharmonic generation, resonance suppression), the natural 10 Hz alpha rhythm (bistability), and normal sleep-wake dynamics (near-criticality, hysteresis, critical slowing).

Recent analyses of the above nonlinear effects are surveyed here, showing that they can be explained by neural field theory, whose predictions reproduce experimental results on large-amplitude normal, abnormal, and driven brain oscillations.

3:54PM P67.00006: Dynamics of excitable tree networks: Application to sensory neurons* ALI KHALEDI NASAB (Presenter), Department of Physics and Astronomy, Ohio University, JUSTUS KROMER, Department of Neurosurgery, Stanford University, LUTZ SCHIMANSKY-GEIER, Department of Physics, Humboldt-Universität zu Berlin, ALEXANDER NEIMAN, Department of Physics and Astronomy, Ohio University — We study the collective dynamics of diffusively coupled excitable elements on small tree networks with regular and random connectivity, which model sensory neurons with branched myelinated distal terminals. Examples of such neurons include touch receptors, muscle spindles, and some electroreceptors. We developed a theory that predicts the collective spiking activity in the physiologically-relevant strong coupling limit. We show that the mechanism of coherent firing is rooted in the synchronization of local activity of individual nodes, even though peripheral nodes may receive random independent inputs. The structural variability in random tree networks translates into collective network dynamics leading to a wide range of firing rates and coefficients of variations, which is most pronounced in the strong coupling regime.

4:06PM P67.00007: Role of geometrical cues in neuronal growth* CRISTIAN STAII (Presenter), Physics and Astronomy, Tufts University — I will present a systematic experimental and theoretical investigation of neuronal growth on micro-patterned surfaces. The experimental results show that neurons cultured on surfaces with periodic geometrical patterns display a significant increase in the total length of axons, as well as axonal alignment along preferred growth directions, which are controlled by the surface geometry. We demonstrate that axonal dynamics is governed by non-linear stochastic differential equations, and use this theoretical model to measure key dynamical parameters: angular distributions, correlation functions, diffusion coefficients and cell-surface coupling forces. Our results show that neuronal alignment on these surfaces is completely determined by the surface geometry, and that the growth dynamics can be quantified by a minimal set of experimentally measurable parameters. I will also discuss how to generalize this approach to include mechanical and biochemical external cues, and introduce a general framework for the quantitative description of neuronal growth and self-organization in complex environments.

4:18PM P67.00008: Long-lasting desynchronization achieved by decoupling stimulation JUSTUS KROMER (Presenter), PETER A. TASS, Stanford University — Abnormally strong synchronization of neuronal activity is a hallmark of several brain disorders. In Parkinson's patients, deep brain stimulation is permanently delivered at high frequencies (> 100 Hz) to suppress symptoms. A qualitatively different, theory-based approach uses dedicated stimulus patterns to cause a desynchronization-induced decoupling of oscillatory neurons. Corresponding long-lasting desynchronizing effects were demonstrated in animal and clinical studies. However, parameters of desynchronizing stimuli, e.g. the stimulation frequency, have to be adapted to the dominant neuronal rhythm. This is an issue since different abnormal brain rhythms may coexist.

We here present a novel approach which causes long-term desynchronization by decoupling stimulation, primarily targeting the slow synaptic weight dynamics - Random Step (RS) stimulation. It ultimately leads to full-blown desynchronization by shifting neural networks from attractors with synchronized to attractors with desynchronized neuronal activity. Compared to desynchronizing stimulation techniques, the acute desynchronizing effect of RS stimulation is weaker, but the robust long-lasting effect does not require fine-tuning to the dominant neuronal rhythms. This may enable novel clinical applications.

4:30PM P67.00009: Cooling Reverses Pathological Bifurcations to Spontaneous Firing Caused by Mild Traumatic Injury* BENJAMIN BARLOW (Presenter), BELA JOOS, University of Ottawa, ANH-KHOI TRINH, McGill University, ANDRE LONGTIN, University of Ottawa — Experimental studies have revealed that mild trauma in the form of e.g. physical pressure or chemical stimuli can alter the properties of the main current (sodium) responsible for the voltage swings or “firings” of neurons. This leads to ongoing firings even when the cell should be quiescent. Such pathological firing interferes with the usual input integration properties of the cell, and in particular has been implicated in the genesis of pathological pain, which persists even after the injury-producing stimulus is removed. From a dynamical point of view, this mild trauma lowers the threshold for firing. This presentation explores the possibility of using temperature to offset this effect by raising the firing threshold back up (see Chaos, 28, 106328 (2018)). Our modeling study predicts that cooling the neuron by just a few degrees – as is possible e.g. for peripheral nerve cells – can counteract the pathological state. The sensitivity of the sodium current to temperature is the key determinant of this effect.

*This work was supported by the Natural Sciences and Engineering Research Council (Canada).
4:42PM P67.00010: Utilizing network analysis and fMRI to infer key language modules and their circuits from healthy human controls*  QIONGGE LI (Presenter), Physics, City College of New York, GINO DEL FERRARO, LUCA PASQUINI, KYUNG K. PECK, Radiology, Memorial Sloan Kettering Cancer Center, HERNÁN A. MAKSE, Physics, City College of New York, ANDREI I. HOLODNY, Radiology, Memorial Sloan Kettering Cancer Center — Traditional task-based functional Magnetic Resonance Imaging (tb-fMRI) statistical analysis has served as a powerful tool to identify brain areas associated with language. However, it does not provide an explanation of how different functional areas interact and integrate with each other to form comprehensive language tasks.

We abstracted task-correlated areas at different anatomical locations as network modules where each voxel within the module is a network node and utilized statistical inference methods to infer the links between each node pair from their correlation matrix. We applied this network analysis to language tb-fMRI scans acquired from 9 healthy right-handed individuals.

Our results show that a robust fully-connected functional language network exists across 8 out of 9 healthy individuals, which entangles the Brocas Area, Wernickes Area, Supplementary Motor Area, and Pre-Motor Area, all in the left hemisphere. Furthermore, we uncovered the functional connectivity of the anatomical sub-divisions (pars-opercularis and pars-triangularis) of the Broca's Area.

4:54PM P67.00011: The effects of inhibitory neuron fraction on the dynamics of an avalanching neural network*  JACOB CARROLL (Presenter), ADA WARREN, UWE CLAUS TAUBER, Virginia Tech — The statistical analysis of the collective neural activity known as avalanches provides insight into the proper behavior of brains across many species. In this talk we present a neural network model based on the work of Lombardi, Herrmann, de Arcangelis et al. that captures the relevant dynamics of neural avalanches, and we show how the active neuron fraction can be used as a control mechanism to introduce exponential cut-offs in the distributions of avalanche strength and duration, transition the power spectral density of the network out of an epileptic regime, and drive the evolution of the network structure over time.

5:06PM P67.00012: Quantitative Characterization of Neuromorphic Neural Circuits  JASON PLATT (Presenter), JUN WANG, HENRY D. I. ABARBANE, GERT CAUWENBERGHS, University of California, San Diego — NeuroDyn is a neuromorphic very large scale integrated circuit (VLSI) capable of modelling four interconnected Hodgkin-Huxley like neurons coupled through twelve chemical synapses. The 384 digitally programmable parameter space specifies ion conductances, reversal potentials and ion channel gating variables. Errors during the manufacturing process can result in a large mismatch between a specified design parameter and the value realized in the hardware. Statistical data assimilation (SDA) is a technique that can estimate parameters in a non-linear dynamical system. By inputting a current designed to probe the full dynamical range of the chip and then measuring the four state variables of the NaKL Neuron (V, m, h, n) we can estimate the mismatch between the programmed and physical parameters. Characterization of the errors in the VLSI chip will help standardize and render useful all manufactured neuromorphic chips such that they can interchangeably be used for applications and research.

5:18PM P67.00013: Neural Correlates of Cognition in Primary Visual versus Downstream Posterior Cortices During Evidence Accumulation*  SUE ANN KOAY (Presenter), DAVID W TANK, CARLOS D BRODY, Princeton University — The ability of animals to accumulate sensory information across time is fundamental to decision-making. Using a mouse behavioral paradigm where navigational decisions are based on accumulating pulses of visual cues, I compared neural activity in primary visual (V1) to secondary visual and retrosplenial cortices. Even in V1, only a small fraction of neurons had sensory-like responses to cues. Instead, all areas were grossly similar in how neural populations contained a large variety of task-related information from sensory to cognitive, including cue timings, accumulated counts, place/time, decision and reward outcome. Across-trial influences were prevalent, possibly relevant to how animal behavior incorporates past contexts. Intriguingly, all these variables also modulated the amplitudes of sensory responses. While previous work often modeled the accumulation process as integration, the observed scaling of sensory responses by accumulated counts instead suggests a recursive process where sensory responses are gradually amplified. I show that such a multiplicative feedback-loop algorithm better explains psychophysical data than integration, particularly in how the performance transitions into following Weber-Fechner's Law only at high counts.

Session Q80 APS: LGBTQ+ Roundtable Discussion  Westin Stone - Tag(s): Diversity, Undergraduate

4:00PM Q80.00001: LGBTQ+ Roundtable Discussion  — This roundtable discussion will focus on ways to improve the professional and educational climate within physics for those who identify as gender and sexual minorities (LGBTQQIAAP+). We will review the findings of the report, LGBT Climate in Physics: Building an Inclusive Community (https://www.aps.org/programs/lgbt/index.cfm), and brainstorm strategies to improve support for physicists across the spectrum of career stages and work environments. All are welcome to attend.

Wednesday, March 6, 2019 5:00 PM - 6:00 PM

Session Q81 APS: National Society of Black Physicists (NSBP) Meetup & Reception  Westin Quincy - Tag(s): Diversity

5:00PM Q81.00001: National Society of Black Physicists (NSBP) Meetup & Reception  — The National Society of Black Physicists (NSBP) Meetup will provide opportunities for NSBP members and those interested in the work of the societies to gather, network, and learn about NSBP initiatives. All are welcome. Students and postdoctoral researchers are especially encouraged to attend.

Wednesday, March 6, 2019 5:30 PM - 6:30 PM

Session Q34 FIAP: FIAP Business Meeting  BCEC 205A

5:30PM Q34.00001: FIAP Business Meeting  — FIAP Business Meeting

Wednesday, March 6, 2019 5:45 PM - 6:45 PM

Session Q18 DCOMP: DCOMP Business Meeting  BCEC 156B

5:45PM Q18.00001: DCOMP Business Meeting  — tbd

Wednesday, March 6, 2019 5:45 PM - 7:15 PM

Session Q21 GMED: GMED Business Meeting  BCEC 157B

5:45PM Q21.00001: GMED Business Meeting  — GMED Business Meeting

Wednesday, March 6, 2019 5:45 PM - 6:45 PM

Session Q51 APS: Scholarly Metrics in Research Assessment  BCEC 253A
5:45PM Q51.00001: Scholarly Metrics in Research Assessment — Scholarly metrics play a significant role in the way scientists and their research are assessed for funding, hiring, and promotion. The APS editors will host a special session in which three panelists with experience in university administration, bibliometrics research, computational social science, and science policy will present their perspectives on scholarly metrics and research assessment.

Topics will include:
Current metrics and tools for assessing the impact of researchers and journals
Best practices and responsible use of metrics
Potential adverse effects of evaluation on research
Latest developments on scholarly metrics and indicators

Panelists:
Johan Bollen, Professor of Informatics and Computing, Indiana University
Vincent Larivière, Associate Professor of Information Science, University of Montréal, Canada.
Rashid Zia, Dean of the College and Associate Professor of Engineering & Physics, Brown University

Moderator:
Manolis Antonoyiannakis, Associate Editor/Bibliostatistics Analyst, American Physical Society

Wednesday, March 6, 2019 5:45 PM - 6:45 PM

Session Q60 GSOFT: GSOFT Business Meeting BCEC 258A

5:45PM Q60.00001: GSOFT Business Meeting — GSOFT Business Meeting

Wednesday, March 6, 2019 6:00 PM - 7:00 PM

Session Q83 APS: National Society of Hispanic Physicists (NSHP) Meetup & Reception Westin Paine - Tag(s): Diversity

6:00PM Q83.00001: National Society of Hispanic Physicists (NSHP) Meetup & Reception — The National Society of Hispanic Physicists (NSHP) Meetup will provide opportunities for NSHP members and those interested in the work of the societies to gather, network, and learn about NSHP initiatives. All are welcome. Students and postdoctoral researchers are especially encouraged to attend.

Wednesday, March 6, 2019 7:00 PM - 8:30 PM

Session Q84 APS: Education & Diversity Reception Westin Sauciety - Tag(s): Diversity, Education

7:00PM Q84.00001: Education & Diversity Reception — Join us for an opportunity to learn about current diversity efforts spearheaded by the APS, the Committee on Minorities (COM), the Committee on the Status of Women in Physics (CSWP), and the LGBT+ physicists group. This is also a great time to network with colleagues. Light refreshments will be served.

Wednesday, March 6, 2019 7:30 PM - 8:30 PM

Session Q53 : Public Lecture: The Physics and Materials Science of Superheroes BCEC 253C - Tag(s): Invited

7:30PM Q53.00001: The Physics and Materials Science of Superheroes [Invited] JAMES KAKALIOS (Presenter), University of Minnesota — While physicists, engineers, and material scientists don't typically consult comic books when selecting research topics; innovations first introduced in superhero adventures as fiction sometimes find their way off the comic book page and into reality.

Wednesday, March 6, 2019 8:00 PM - 10:00 PM
Session Q85 APS: Imaginative Performances: Quantum Voyages and the History of Physics in 13 Songs  Westin Commonwealth A/B - Tag(s): Outreach, Undergraduate

8:00PM Q85.00001: Imaginative Performances: Quantum Voyages and the History of Physics in 13 Songs — Quantum Voyages: Two voyagers, guided by the spirit of wisdom, enter the microscopic realm of atomic landscapes and quantum conundrums to discover a magnificent and baffling world foreign to everyday human experience. The piece weaves together dramatic performance, movement, music, and guest appearances by physicists. The University of Illinois at Urbana-Champaign production team, includes Creative and Scientific Director, Smitha Vishveshwara; Performance Director, Latrelle Bright; Production Manager, Maddie Martin; and Principal Performers Kalan Benbow, Michael Highman, and Gloria Lee.

The History of Physics in 13 Songs: Highlights turning points in the history of Physics. The performance establishes theatrical interpretations by creating lyrics from the writings of some of the most prominent physicists and presents original songs based on these fragments. The University of Michigan team consists of lyricists and musician Alberto Rojo, percussionist Michael Gould, and narrator Malcolm Tulip.

Sponsored by the APS: Forums on History of Physics, Outreach and Engaging the Public, Physics and Society, and Education; Division of Condensed Matter Physics; and Committee on the Status of Women in Physics. Produced by Smitha Vishveshwara, University of Illinois, and Brian Schwartz, CUNY.

Wednesday, March 6, 2019 9:15 PM - 10:45 PM

Session Q86 APS: Rock-n-Roll Physics Sing-Along  Westin Marina Ballroom I-II - Tag(s): Outreach, Undergraduate

9:15PM Q86.00001: Rock-n-Roll Physics Sing-Along — Join us for an evening of fun physics tunes set to familiar rock, blues, and swing music. Light refreshments will be served.

Thursday, March 7, 2019 8:00 AM - 11:00 AM

Session R01 DCMP: Fractional Quantum Hall Effect: Novel States  BCEC 106 - Ravindra Bhatt, Princeton University

8:00AM R01.00001: Incompressible Even Denominator Fractional Quantum Hall States in the Zeroth Landau Level of Monolayer Graphene*  SUJIT NARAYANAN (Presenter), Physics, Simon Fraser University, BITAN ROY, Max Planck Institute for the Physics of Complex Systems, MALCOLM KENNED, Physics, Simon Fraser University — Incompressible fractional quantum Hall states at even denominator fractions (ν = 1/2, 1/4) have recently been observed in experiments in monolayer graphene. We use a Chern-Simons description of multicomponent fractional quantum Hall states in graphene to study these incompressible fractional quantum hall states in the zeroth Landau level and suggest variational wavefunctions that may describe them. We find that the experimentally observed even denominator fractions and standard odd fractions (such as ν = 1/3, 2/5, etc.) can be accommodated within the same flux attachment scheme and argue that they may arise from sublattice or chiral symmetry breaking orders (such as charge-density-wave and antiferromagnetism) of composite Dirac fermions. We also discuss possible experimental probes that can narrow down the candidate broken symmetry phases for the fractional quantum Hall states in the zeroth Landau level of monolayer graphene.

*This work was supported by NSERC

8:12AM R01.00002: Pfaffian paired states at filling factor 5/2  MILICA MILOVANOVIĆ (Presenter), JAKSA VUCICEVIC, Institute of Physics Belgrade, LUKA ANTONIC, Faculty of Physics, Belgrade — Within the Dirac composite fermion theory of fractional quantum Hall effect (FQHE), we investigate which Pfaffian paired state will dominate at a fixed value of a particle-hole (PH) symmetry breaking parameter - the mass of Dirac composite fermions. The Dirac mass mimics the presence of Landau level mixing in experiments. We demonstrate that the presence of mass stabilizes PH Pfaffian topological pairing contrary to our naive expectation that the PH Pfaffian will be relevant for the (zero-mass) PH symmetric case. Using only field theoretical means we show that, due to gauge field effects, there is a strong competition among Pfaffians; depending on the sign of mass, Pfaffian or anti-Pfaffian will dominate for small masses, consistent with numerical experiments at filling factor 5/2, and PH Pfaffian may be present for larger masses. L. Antonic, J. Vucicevic, and M.V. Milovanovic, Paired states at 5/2 : Particle-hole Pfaffian and particle-hole symmetry breaking, Physical Review B 98, 115107 (2018).
A Study of Reentrant Integer Quantum Hall States in High Landau Levels*
DOHYUNG RO (Presenter), NIANPEI DENG, MICHAEL MANFRA, Purdue University, LOREN PFEIFFER, KENNETH WEST, Princeton University, GABOR CSATHY, Purdue University — Reentrant integer quantum Hall states are widely thought to be realizations of the so-called electronic bubble phases, some of the most intricate electron solids forming in the two-dimensional electron gas. According to the predictions of the Hartree-Fock theory, different types of bubble phases may exist, as distinguished by the number of electrons per bubble. So far, in the third and higher Landau levels four reentrant integer quantum Hall states were seen. Here we report the observation of eight reentrant integer quantum Hall states developing in the fourth Landau level. Properties of these reentrant states will be discussed. Our observation highlights the development of correlated phases of increasing complexity in improved samples and support the bubble interpretation of the reentrant integer quantum Hall states.

Geometry of flux attachment in anisotropic fractional quantum Hall states*
RAVINDRA BHATT (Presenter), Electrical Engineering, Princeton University, MATTEO IPPOLITI, FREDERICK D HALDANE, Physics, Princeton University — We study the internal metric of fractional quantum Hall (FQH) states, a degree of freedom which allows them to variationally optimize their energy in the presence of competing geometries. In particular, we focus on incompressible FQH states in the presence of isotropic Coulomb interaction and anisotropic band mass [1]. We use an infinite-cylinder density matrix renormalization group method [2] to numerically simulate these states and access their internal metric through the long-wavelength limit of their static guiding center structure factor. We find the response to band mass anisotropy is approximately the same for all states belonging to the first Jain sequence (ν = 1/3, 2/5, ...). The ν = 1/5 state, on the other hand, exhibits markedly smaller anisotropy. The observed behavior is well captured by a two-body model of flux attachment.

Working principles of the short-period superlattice structure in GaAs quantum wells*
EDWIN CHUNG (Presenter), K. W. BALDWIN, KENNETH WEST, MANSOUR SHAYEGAN, LOREN PFEIFFER, Princeton University — We present the design rules of GaAs quantum wells that utilize the short-period superlattice (SPSL) structure to achieve a two dimensional electron system (2DES). By changing growth conditions such as doping density, barrier composition, and well width within the SPSL, we show that the density of the 2DES can be tuned from 2.0 x 10^11 cm^-2 to 4.5 x 10^11 cm^-2 even with a fixed spacer thickness. This implies we can prepare samples that have quite different 2DES density but rather similar scattering conditions. The magnetotransport is analyzed in detail and the influence of the change in 2DES density is discussed, with an emphasis on the strength of the fraction quantum Hall states.

*Work supported by the NSF (Grants DMR 1709076, ECCS 1508925, and MRSEC DMR 1420541), the DOE Basic Energy Sciences (Grant DE-FG02-00-ER45841), and the Gordon and Betty Moore Foundation (Grant GBMF4420).

A recursion approach to thin cylinder approximants for fractional quantum Hall states
MATHEUS SCHLOSSER (Presenter), SUMANTA BANDYOPADHYAY, ALEXANDER SEIDEL, Washington University, St. Louis — Aside from the beautiful many-body wave functions that have defined the field, recursive and/or second-quantized presentations of fractional quantum Hall states have played an increasingly important role in the past. Examples include the recent discovery of the MPS structure of many quantum Hall states, but also a recursion for the Laughlin state related to the “non-local order parameter” defined by Read, originally defined in a mixed first/second quantized manner. Such recursions have recently been generalized to all composite fermion states, and put into a purely second-quantized, “all guiding-center” form. Here we observe that these recursions commute with the expansion of cylinder fractional quantum hall states in a “thin-cylinder parameter”. This allows one to define not only the full quantum Hall state recursively, but also any “thin cylinder approximant”, to any order. Relations/differences with the MPS are discussed, and we speculate on broader implications for DMRG approaches to quantum Hall states, in particular the efficient evaluation of non-local order parameters.
9:12AM R01.00007: Evidence for an even-denominator fractional quantum Hall state in the ground Landau level of an anisotropic system  
MD. SHAFAYAT HOSSAIN (Presenter), MENG MA, EDWIN CHUNG, LOREN PFEIFFER, KENNETH WEST, K. W. BALDWIN, MANSOUR SHAYEGAN, Princeton University — Even-denominator fractional quantum Hall states (FQHs) are widely believed to host a novel class of matter that obey non-Abelian statistics and could be of potential use in topological quantum computing. Examples of such states include the $\nu = 5/2$ FQHS in GaAs two-dimensional (2D) electron systems. Even-denominator FQHs have also been reported in both 2D electron and 2D hole systems confined to wide GaAs quantum wells, in bilayer GaAs 2D electron systems and, more recently, in 2D electrons in ZnO and in graphene. We report here the observation of an even-denominator FQHS at filling factor $\nu = 1/2$ in a 2D electron system confined to a wide AlAs quantum well where the electrons can occupy multiple conduction-band valleys with an anisotropic effective mass. We observe phase transitions from a compressible Fermi liquid to an incompressible FQHS and then to an insulating phase as we tilt the sample in the magnetic field, thus rendering the electron charge distribution more bilayer-like.

9:24AM R01.00008: Hall viscosity of manifestly modular invariant composite fermion wave functions*  
SONGYANG PU (Presenter), JAINENDRA JAIN, Pennsylvania State University — The Hall viscosity has been proposed to be robust within a topological phase [1]. We perform a numerical calculation of the Hall viscosity of general fractional quantum Hall states by deforming the modular parameter $\tau$ on a torus. For this purpose, we follow the approach in [2] to construct composite fermion wave functions on a torus in terms of Haldane's modified sigma function [3] to achieve a manifestly modular invariant form. (Numerical calculations show that the wave functions in this new form are identical to those in Ref. [2], therefore proving modular invariance for the latter wave functions as well.) We compare our Hall viscosities with the orbital spins for various fractional quantum Hall states in a broad region of the modular parameter $\tau$.

*This work was supported by DOE under Grant no. DE-SC0005042.

9:36AM R01.00009: Kohn-Sham Theory of the Fractional Quantum Hall Effect*  
YAYUN HU (Presenter), JAINENDRA JAIN, Pennsylvania State University — The Kohn-Sham (KS) formulation of the density functional theory (DFT) fails for FQHE because the FQHE state cannot be mapped into a system of non-interacting electrons. We instead map the FQHE system into a system of non-interacting composite fermions, which experience an effective magnetic field that depends on density. We generalize the Hohenberg-Kohn theorem to systems with a density-dependent kinetic energy operator, and formulate the KS equations for the FQHE. We also show the equivalence of our formulation with the generalized Kohn-Sham scheme. Numerical results show that our method produces densities that are good approximations to those obtained from many-body wave functions for states with general occupation configurations. As two applications of our method, we (i) obtain the density profile at the edge of fractional quantum Hall states, finding edge reconstruction as the confinement potential becomes softer; and (ii) show how an external charge produces a screening cloud with a fractionally quantized charge accumulation. We speculate on the implications of our method for general strongly correlated systems.

*This work is supported in part by DOE under Grant no. DE-SC0005042 and by the China Scholarship Council.

9:48AM R01.00010: Fixed phase diffusion Monte Carlo study of finite width effect in FQHE*  
TONGZHOU ZHAO (Presenter), JAINENDRA JAIN, Department of Physics, Penn State University — In FQHE, it is customary to include finite width effects by calculating the transverse wave function at zero magnetic field in LDA, and assuming that it does not change as a high perpendicular magnetic field is applied. We instead determine the transverse density profile directly at a high magnetic field through the fixed phase diffusion Monte Carlo method, where the phase is fixed by the in-plane FQHE state. While the results are in qualitative agreement with those obtained from zero-field LDA, there are interesting quantitative deviations. We will discuss the implications of our study to experiments.

*Supported by DOE under Grant no. DE-SC0005042
10:00AM R01.00011: Composite fermions with quenched disorder at the half-filled Landau level*  PRASHANT KUMAR (Presenter), KEVIN SHENGYI HUANG, Physics, Stanford University, MICHAEL C MULLIGAN, Physics & Astronomy, University of California, Riverside, SRINIVAS RAGHU, Physics, Stanford University — The gapless state at the half-filled Landau level is approximately described in terms of nearly-free composite fermions. Within the mean-field approximation, it has recently been shown that the composite fermions describe a quantum phase transition between an insulator and an integer quantum Hall state when the effects of a quenched disorder are included. Here, we further characterize this random quantum critical point using the non-linear sigma model and network model approaches to disordered fermions.

10:12AM R01.00012: Observation of new plasmons in the fractional quantum Hall effect: interplay of topological and nematic orders(*)*  LINGJIE DU, Department of Applied Physics and Applied Mathematics, Columbia University, URSULA WURSTBAUER (Presenter), Walter Schottky Institut and Physik-Department, Nanosystems Initiative Munich, Technische Universität München, SAEED FALLAHI, GEOFFREY GARDNER, Department of Physics and Astronomy, Purdue University, MICHAEL MANFRA, Department of Physics and Astronomy, School of Materials Engineering and School of Electrical and Computer Engineering, Purdue University, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, ARON PINCZUK, Department of Applied Physics and Applied Mathematics and Department of Physics, Columbia University — Collective modes of exotic quantum fluids reveal underlying physical mechanisms responsible for emerging ground states. We observe unexpected collective modes in the fractional quantum Hall (FQH) regime of the second Landau level (LL): intra-Landau-level plasmons measured by resonant inelastic light scattering. The plasmons herald nematic phases in the second LL and uncover the nature of long-range translational invariance in these phases. The fascinating dependence of plasmon features on filling factor provides new insights on interplays between topological quantum Hall order and nematic electronic liquid crystal phases. At LL filling factor \( v = \frac{7}{3} \), a sharp and strong plasmon peak that links to emerging macroscopic coherence supports the proposed model of a FQH nematic state at this filling factor. A marked intensity minimum in the plasmon spectrum at \( v = \frac{5}{2} \) strongly suggests that the paired state overwhelms competing nematic phases, unveiling the robustness of the superfluid state.

10:24AM R01.00013: Half-filled Landau level in a honeycomb lattice: Chern insulator of composite fermions  SAURABH MAITI (Presenter), TIGRAN SEDRAKYAN, Physics, University of Massachusetts, Amherst — The study of electronic correlations in half-filled Landau level presents a challenge due to the massive degeneracy in the single-particle spectrum. The most successful description of this exotic state has been in terms of field theory of composite fermions: either the Halperin-Lee-Read (HLR) version where the composite fermions are the original electrons bound to some fluxes; or the Dirac composite fermion which exploits the duality of the field strength and density. In this work we demonstrate the construction of a lattice version of the long-wavelength field theories. We show that for a honeycomb lattice, a HLR type construction of composite fermions leads to a Chern insulator which reduces to the Haldane model at half-filling. As a result, the K and K' points are gapped out which can be measured in tunneling experiments.

10:36AM R01.00014: Probing the Melting of Two-dimensional Quantum Wigner Crystal via its Screening Efficiency*  HAO DENG (Presenter), MENG MA, LOREN PFEIFFER, KENNETH WEST, K. W. BALDWIN, MANSOUR SHAYEGAN, Princeton University — One of the most fundamental and yet elusive collective phases of an interacting electron system is the quantum Wigner crystal (WC), an ordered array of electrons dominated by Coulomb repulsion energy. In low-disorder, two-dimensional (2D) electron systems, the quantum WC is known to be favored at very low temperatures (T) and small Landau level filling factors (v). Pinned by the disorder potential, the WC phase exhibits an insulating behavior. An experimental determination of a T vs v phase diagram for the melting of the WC, however, has proved to be challenging. Here we use capacitance measurements to probe the 2D WC thorough its effective screening as a function of T and v. We find that, as expected, the screening efficiency of the pinned WC is very poor at very low T and improves at higher T once the WC melts. Surprisingly, the screening efficiency shows a well-defined maximum at a T which is close to the previously-reported melting temperature of the WC. Our experimental results suggest a new method to map out the T vs v phase diagram of the magnetic-field-induced WC precisely.

*Work supported by NSF (Grants DMR 1709076, ECCS 1508925, MRSEC DMR 1420541), the DOE (Grant DE-FG02-00-ER45841), and the Gordon and Betty Moore Foundation (Grant No. GBMF4420).
Aharonov-Bohm interference of integer and fractional quantum Hall edge modes in small electronic Fabry-Perot interferometers

JAMES NAKAMURA (Presenter), SAEED FALLAHI, SHUANG LIANG, GEOFFREY GARDNER, MICHAEL MANFRA, Purdue University — Electronic Fabry-Perot interferometers may be used to probe quantum Hall edge states; however, Coulomb charging effects complicate the operation of small devices. We implement a novel GaAs/AlGaAs heterostructure design in which Coulomb charging effects are suppressed, enabling operation of small interferometers in the Aharonov-Bohm regime with high quantum coherence. We present measurements of the selective interference of inner and outer edge states in the integer quantum Hall regime. Aharonov-Bohm oscillations are observed at the fractional quantum Hall states $\nu = 2/3$ and $\nu = 1/3$.

8:00AM R02.00001: Towards Topological States in Silver Bismuthates Synthesized under High-Pressure

MOHAMED OUDAH (Presenter), University of British Columbia, MINU KIM, Max Planck Institute for Solid State Research, DOUGLAS ANDREW BONN, University of British Columbia, BERNHARD KEIMER, HIDENORI TAKAGI, Max Planck Institute for Solid State Research — The stoichiometric silver bismuthate Ag$_2$BiO$_3$ typically contains equal amounts of bismuth in the Bi$^{+3}$ and Bi$^{+5}$ states, and this charge ordering renders Ag$_2$BiO$_3$ insulating [1]. Recent theoretical predictions of metal-insulator transition and Weyl semimetal state in Ag$_2$BiO$_3$ have revived the interest in this material [2]. However, such novel properties are only expected in the absence of the charge ordering of bismuth. Here, we examine the possibility of achieving a topologically nontrivial phase and suppressing the charge ordering in Ag$_2$BiO$_3$ via chemical substitution/doping. We present a new high-pressure synthesis route for Ag$_2$BiO$_3$, which we utilize for substituting/doping at the Ag site. Also, we explore the possibility of making Ag-deficient Ag$_{2-x}$BiO$_3$ phases using high pressure synthesis. In the presentation, we will discuss the specific synthesis conditions, Rietveld refinement, and some magnetic and transport properties in detail.

8:12AM R02.00002: Controlled layer growth and topological states in stanene studied by STM

XIAOHU ZHENG (Presenter), JIANFENG ZHANG, RUI-RUI DU, Peking University — It is proposed that stanene (a single layer of Sn) is a two-dimensional topological insulator with a bandgap of more than 0.3 eV [1]. Moreover, its band structure and properties may be modulated with increasing thickness (layers), ranging from topological insulator, topological Dirac semimetal to zero gap semimetal [2-3]. We have grown high quality few layer Sn on B-faced InSb (111) through MBE and measured their structural and electronic properties by 400 mK STM. The topological properties of various trivial/non-trivial phases are also investigated in-situ in magnetic field. Main results and discussions will be presented.

*The work is supported by NBRPC (No. 2014CB920901), National Key R and D Program of China (No. 2017YFA0303301) and NSFC (No.11704010)
8:24AM R02.00003: Revealing Optical Transitions and Carrier Dynamics within the Bulk Band Structure of Chiral Tellurium Nanosheets* GIRIRAJ JNAWALI (Presenter), SAMUEL M LINSER, SEYYEDESADAF POURNIA, IRAJ ABBASIAN SHOJAEI, HOWARD E JACKSON, LEIGH SMITH, Department of Physics, University of Cincinnati, RUOXING WANG, School of Industrial Engineering, Purdue University, GANG QIU, School of Electrical and Computer Engineering, Purdue University, WENZHUO WU, School of Industrial Engineering, Purdue University, PEIDE (PETER) YE, School of Electrical and Computer Engineering, Purdue University — Tellurium is a chiral crystal consisting of helical chains arranged in a hexagonal array along the c-axis. The bulk band structure due to the spin-orbit interaction exhibits Weyl nodes with opposite chirality at the H and H’ points in the Brillouin zone. Here we use polarized mid-infrared pump-probe spectroscopy on nanosheets of tellurium to map the band-edge electronic structure and interrogate carrier relaxation processes over a wide energy range (0.3 to 1.2 eV). We observe a series of transitions between all three valence bands at H-point of the Brillouin zone (H4, H5 and H6 symmetries) with the doubly degenerate conduction band with Weyl points (H6 Symmetry) with dynamic response of polarization anisotropy. The main decay of photoexcited carriers occurs within the first 50 ps, followed by a weak long-lived decay of carriers. The carrier thermalization process varies with polarization state of the probe beam at different bands. Such knowledge of electronic structure and carrier dynamics provides a foundation for understanding the topological and anisotropic nature of the material.

8:36AM R02.00004: Effects of Cu intercalation in Single Crystals of CuxBi2Te2Se* YANAN LI (Presenter), CHRISTIAN PARSONS, NATHANIEL SMITH, PRASENJIT GUPTASARMA, Department of Physics, University of Wisconsin Milwaukee, Wisconsin — Intercalation of Cu in Topological Insulators such as Bi2Se3 and Bi2Te3 is known to yield superconductivity. The fundamental origin of superconductivity in these systems, whose parent compounds have non-trivial topology, remains under intense scrutiny. Bi2Te2Se is believed to be a topological insulator with structure similar to Bi2Se3 and Bi2Te3, but with much higher bulk resistivity. Here, we report structure-property relationships of Cu-intercalation in single crystals of CuxBi2Te2Se (0<x<0.5) using X-ray Diffraction, Raman Spectroscopy and X-ray Photoemission Spectroscopy. For x<0.2, Cu intercalates in Bi2Te2Se as Cu1+. Increasing x results an increase in c-axis length along with a softening of A1g2 and Eg2 Raman modes. We observe a double-mode behavior in both A1g2 and Eg2 modes corresponding to the outer atoms of Bi and Te(1)/Se(1). Thus, Bi-Te(1) and Bi-Se(1) vibrations are decoupled from each other. For higher x, we observe a triple mode behavior in both A1g2 and Eg2 modes. We ascribe this to additional Cu atoms partially substituting at Bi sites and creating additional modes such as Cu-Se(1) and Cu-Te(1).

*AFOSR-MURI

8:48AM R02.00005: Collective magnon excitations observed in a dilute ferromagnetic topological insulator* ROBERT MCQUEENEY (Presenter), Ames Laboratory, DANIEL PAJEROWSKI, Oak Ridge National Laboratory, DEBORAH SCHLAGEL, DAVID VAKNIN, Ames Laboratory — Inelastic neutron scattering measurements are presented on ferromagnetic Mn-doped Bi2Te3 with a concentration of 0.1 Mn per formula unit. Susceptibility and neutron diffraction measurements find a Curie temperature (T_C) of 12 K and ordered moments oriented perpendicular to the quintuple-layer structure. Sharp magnetic diffraction peaks suggest long-ranged and homogeneous ferromagnetism. Despite the dilute nature of the magnetic constituents, collective ferromagnetic magnon excitations are observed below T_C with a bandwidth of ~3 meV, although the dispersive features are broadened by site disorder. The magnons are two-dimensional in character, indicating that the strongest magnetic interactions occur within the quintuple-layer with weaker interlayer interactions. In addition, sharp, low-energy (< 1 meV) localized excitations are observed which are consistent with free Mn pairs or small clusters separated from the main percolated ferromagnetic Mn network.

*Work at the Ames Laboratory was supported by the U. S. Department of Energy (DDOE), BES, Division of Materials Sciences and Engineering, under Contract No. DEAC02-07CH11358. This research used resources at the Spallation Neutron Source, a DOE Office of Science User Facility operated by the Oak Ridge National Laboratory.
Topological Insulator Superlattices via Spinodal Decomposition*  
DEMET USANMAZ (Presenter), PINKU NATH, CORMAC TOHER, JOSE JAVIER PLATA, RICO FRIEDRICH, Center for Materials Genomics, Duke University, MARCO FORNARI, Department of Physics and Science of Advanced Materials Program, Central Michigan University, MARCO BUONGIORNO NARDELLI, Department of Physics and Department of Chemistry, University of North Texas, STEFANO CURTAROLO, Materials Science, Electrical Engineering, Physics and Chemistry, Duke University — Advanced thermodynamic and electronic structure concepts are combined to define a design strategy for topological insulator superlattices – an alternative to the costly and time-consuming experimental artificial growth methods [1]. Stabilizing self-assembled interfaces between iso-structural and iso-valent topological insulators is possible through spinodal decomposition. To investigate the composition range guaranteeing the topologically protected gapless metallic states, various thermodynamically driven boundaries are designed between constituent materials. The dimensions and topological nature of the metallic channels are tracked by following the spatial distribution of the charge density and spin-texture. The results validate the proof of concept for obtaining spontaneously forming two-dimensional topologically protected metallic states embedded in a three-dimensional insulating environment without any vacuum interfaces.

*The authors acknowledge support by DOD-ONR (N00014-13-1-0635, N00014-15-1-2863, N00014-16-1-2326). R. F and S.C. acknowledges the Alexander von Humboldt Foundation for financial support.

Hybrid Quantum Anomalous Hall Effect at Graphene-Oxide Interfaces*  
ZEILA ZANOLLI (Presenter), Catalan Institute of Nanoscience and Nanotechnology (ICN2) — Interfaces are ubiquitous in materials science, and devices in particular. As device dimensions are constantly shrinking, understanding the physical properties emerging at interfaces is crucial to exploit them for applications. Using first principles techniques and Monte Carlo simulations, we investigate the mutual magnetic interaction at the interface between graphene and an antiferromagnetic semiconductor, BaMnO3 [1]. We find that graphene deeply affects the magnetic state of the substrate, down to several layers below the interface, by inducing an overall magnetic softening, and switching the in-plane magnetic ordering from anti- to ferromagnetic. The graphene-BaMnO3 system presents a Rashba gap 300 times larger than in pristine graphene, leading to a new flavor of Quantum Anomalous Hall effect (QAHE), a hybrid QAHE, characterized by the coexistence of metallic and topological insulating states. These findings could be exploited to fabricate novel devices that use graphene to control the magnetic configuration of a substrate [2].

*Ramon y Cajal (RYC-2016-19344), EC H2020-EINFRA-5-2015 MaX CoE (824143), Severo Ochoa (SEV-2013-0295), CERCA (2017SGR1506), MINECO (FIS2015-64886-C5-3-P)
After our first screening step, we use Wannier-interpolation to calculate the topological invariants and to search for band crossings in our candidate materials. We discuss some individual example materials, as well as trends throughout our dataset, that is available at JARVIS-DFT website: http://jarvis.nist.gov.

We demonstrate that in addition to Z2 topological insulators, this screening method successfully identifies many semimetals and topological crystalline insulators. Our approach is applicable to the investigation of disordered or nontrivial band structures.

Recently, transition metal silicides with B20 crystal structure have been found to belong to the class of topologically nontrivial materials. The electronic structure of CoSi contains linear dispersion branches with nodal points located near the Fermi level. Therefore, CoSi is an interesting candidate to study the correlation between electronic structure and thermoelectric properties.

Micro wires of CoFeSi were prepared by FIB from samples grown by Bridgeman method. The morphology and chemical composition was analysed by TEM, EDX and XRD. Furthermore, the micro ribbons were contacted via lithography patterning. Afterwards, the temperature and magnetic field dependent transport properties were characterized. The CoFeSi reveals a monocrystalline B20 crystal structure. We analysed the electrical transport for parallel and perpendicular field. In parallel field, we observe a positive magneto resistance switching to comparable high positive magneto resistance for low temperature. In perpendicular field, we see a positive magneto resistance increasing for low temperature.

**9:36AM R02.00009: Discovery and Categorization of Topological Materials** [Invited] MAIA VERGNIORY (Presenter), Donostia International Physics Center, LUIS EL Coro, Condensed Matter Physics Department, University of the Basque Country, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, NICOLAS REGNAULT, ENS Paris-CNRS, ANDREI B BERNEVIG, ZHIJUN WANG, Princeton University — Topological Quantum Chemistry (TQC) links the chemical and symmetry structure of a given material with its topological properties. This field tabulates the data of the 10398 real-space atomic limits of materials, and solves the compatibility relations of electronic bands in momentum space. A material that is not an atomic limit or whose bands do not satisfy the compatibility relations, is a topological insulator/semimetal. We use TQC to find the topological stoichiometric non-magnetic, “high-quality” materials in the world. We develop several code additions to VASP which can compute all characters of all symmetries at all high-symmetry points in the Brillouin Zone (BZ).

Using TQC, we then develop codes to check which materials in ICSD are topological. Out of 26938 stoichiometric materials in our filtered ICSD database, we find around 7300 topological materials. For the majority of the “high-quality” topological materials, we compute: the topological class (equivalence classes of TQC elementary band representations - equivalent to the topological index), the symmetry(ies) that protects the topological class, the representations at high symmetry points and the direct gap (for insulators), and the topological index. For topological semimetals we then compute whether the system becomes a topological insulator (whose index/class we compute) upon breaking symmetries - useful for experiments. Our exhaustive results show that a large proportion of all materials in nature are topological. We confirm the topology of several new materials by Wilson loop calculations. I will also explain an open-source code and end-user button on the Bilbao Crystallographic Server (http://www.cryst.ehu.es/cgi-bin/cryst/programs/topological.pl) which checks the topology of any material.

**10:12AM R02.00010: High-throughput discovery of topological materials using spin-orbit spillage** KAMAL CHOUHARY (Presenter), KEVIN GARRITY, FRANCESCA TAVAZZA, MML, National institute of standards and technology, MD, USA — We present the results of a high-throughput, first principles search for topological materials based on identifying materials with band inversion induced by spin-orbit coupling. Out of the currently available 30000 materials in our database, we investigate more than 4507 non-magnetic materials having heavy atoms and low bandgaps. We compute the spillage between the spin-orbit and non-spin-orbit wave functions, resulting in more than 1699 high-spillage candidate materials. We demonstrate that in addition to Z2 topological insulators, this screening method successfully identifies many semimetals and topological crystalline insulators. Our approach is applicable to the investigation of disordered or distorted materials, because it is not based on symmetry considerations, and it can be extended to magnetic materials.

After our first screening step, we use Wannier-interpolation to calculate the topological invariants and to search for band crossings in our candidate materials. We discuss some individual example materials, as well as trends throughout our dataset, that is available at JARVIS-DFT website: http://jarvis.nist.gov.
10:24AM R02.00011: Electrides as a New Platform of Topological Materials  MOTOAKI HIRAYAMA (Presenter), Center for Emergent Matter Science, RIKEN, SATORU MATSUISHI, HIDEO HOSONO, Materials Research Center for Element Strategy, Tokyo Institute of Technology, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology — Research on the topological properties of the wave function attracts a great deal of attention [1]. In our presentation, we show that electrides are suitable for achieving various topological insulating and topological semimetal phases [2]. In electrides, some electrons reside in the interstitial regions and act as anions to stabilize the structure. Since interstitial electrons have small work function, band inversion around the Fermi level is likely to occur. We find that Sc$_2$C shows nontrivial insulating phase characterized by the π Zak phase. This π Zak phase appears as a surface polarization charge, and we propose that this surface charge is useful for carrier doping by using the electride. We find various topological electrides such as Y$_2$C, Sr$_2$Bi (nodal-line semimetal), HfBr (quantum spin Hall system), and LaBr (quantum anomalous Hall insulator). We also discuss one-dimensional electride materials as topological electrides with corner charges.

10:36AM R02.00012: Restoring $E$ vs $k$ band structure dispersion in low symmetry disordered systems*  ZHI WANG (Presenter), Renewable and Sustainable Energy Institute, Univ of Colorado - Boulder, QIHANG LIU, Southern University of Science and Technology, ALEX ZUNGER, Renewable and Sustainable Energy Institute, Univ of Colorado - Boulder — Many target properties of materials are not readily available for pure components AX or BX but do exist in alloys of (AX)$_x$(BX)$_{1-x}$. Substitutional alloy disorder generally results in the distribution of local environments as well as symmetry-breaking atomic displacements as seen in EXAFS, leading to the removal of band degeneracies and meaning of sharp wavevectors $k$ hence $E$ vs $k$ band dispersion. These effects are not treatable by single-site disorder theories such as CPA. Supercells do retain atomic resolution of disorder but do not readily produce $E$ vs $k$ dispersion needed to judge topological properties. We combine supercells with band unfolding [1] in alloys, leading to Effective Band Structure which recognizes local symmetry yet informs about the extent to which the long-range translational symmetry is retained. We show how the scale of disorders in alloy systems, such as PbS-PbTe, PbSe-SnSe, CdTe-HgTe, PM phase Mott insulators and ABO$_3$ perovskites affects the topological properties, and how the restored band dispersion helps us to understand experimental observations.

*DOE-BES-MSE grant DE-FG02-13ER46959

10:48AM R02.00013: Flat Energy Bands within Antiphase and Twin Boundaries and at Open Edges in Topological Materials*  LINGHUA ZHU (Presenter), Department of Physics, New Jersey Institute of Technology, EMIL PRODAN, Department of Physics, Yeshiva University, KEUN HYUK AHN, Department of Physics, New Jersey Institute of Technology — We present a model of two-dimensional electronic, photonic, and mechanical metamaterial systems, which has flat one-dimensional zero-mode energy bands and stable localized states of a topological origin confined with twin boundaries, antiphase boundaries, and at open edges. Topological origins of these flat bands are analyzed for an electronic system as a specific example, using a two-dimensional extension of the Su-Schrieffer-Heeger Hamiltonian with alternating shift of the chains. It is demonstrated that the slow group velocities of the localized flat band states are sensitively controlled by the distance between the boundaries and the propagation can be guided through designed paths of these boundaries. We also discuss how to realize this model in metamaterials.

Session R03 DCMP: Topological Phases  BCEC 107B - Haruki Watanabe
Controlling topologically protected states by external fields and doping

ALVARO DIAZ FERNANDEZ (Presenter), FRANCISCO DOMÍNGUEZ-ADAME, ELENA DÍAZ, Materials Physics, Complutense University of Madrid — Topological materials often display topologically protected surface states with Dirac-like dispersions. Controlling their properties is desirable for their foreseen applications and a number of proposals have been put forward to this respect (e.g. [1,2,3,4]). In this contribution, the system I will consider is a topological boundary. I will discuss how applying uniform electric and magnetic fields that preserve the symmetries lead to an anisotropic reduction of the Fermi velocity as the fields are increased. [5,6]. I will also show how a δ-layer of donor atoms at the boundary can lead to a coexistence of a two-dimensional electron gas with the topological surface states. Moreover, the linear optical response is markedly reshaped by the presence of the topological state [7].

*This research has been supported by MINECO (Grant No. MAT2016-75955) and the UCM-Santander Program (Grant No. CT27/16-CT28/16).

Topological phases of the rainbow chain

GERMAN SIERRA (Presenter), Instituto de Física Teórica UAM-CSIC, Madrid, Spain — Inhomogenous quantum many body systems exhibit novel phenomena such as the breaking of the area law of entanglement entropy. A notable example is the so called rainbow model which consists of a XX spin chain where the exchange coupling constants decrease exponentially from the center towards the edges. This system has been analyzed in great detail using the strong disorder renormalization group method and conformal field theory. These methods explain the appearance of long range valence bonds across the spin chain, having the shape of a rainbow. In this talk, we shall explain another feature which is the appearance of topological order in the rainbow chain with an odd number of sites. In the particular case when there is rotational symmetry one obtains the Haldane phase. This result indicates that the short range entanglement characteristic of the SPT phases can be related to the long range entanglement of the critical phases by considering the inhomogenous deformation of the latters.

Topology and localization in the Kondo lattice model

YING SU (Presenter), SHIZENG LIN, Los Alamos National Laboratory — The Kondo lattice model describing the coupling between conduction electrons and localized magnetic moments is relevant for a large family of physical systems. Here we reveal that the one-dimensional Kondo lattice model with a magnetic elliptical spiral is a topological insulator with a Chern number 2Z in the two-dimensional space with one physical dimension and one ancillary dimension spanned by the Goldstone mode of the spiral. The 2Z topological classification can be reduced to Z if certain spin rotation symmetry is broken. Moreover, when the elliptical spiral is incommensurate, the electronic states can be localized for a strong local exchange coupling. The topological protected edge states are responsible for the pumping of electron charge, and give rise to multiferroic response. The coexistence of nontrivial band topology and Anderson localization results in a unique charge pumping. Our work uncovers hitherto undiscovered nontrivial topology and Anderson localization in the Kondo lattice model. Ref: Ying Su and Shi-Zeng Lin, arXiv:1809.06295 (2018).

8:36AM R03.00004: Topology of Quantum Systems Out of Equilibrium* MAX McGINLEY (Presenter), NIGEL R COOPER, Physics, University of Cambridge — We investigate the topological properties of many-body quantum systems undergoing unitary time-evolution. We find that it is possible for the topology of the wavefunction to change out of equilibrium, and accordingly establish the existence of a robust nonequilibrium topological classification which generally differs from equilibrium [1]. The classification naturally inherits phenomenology familiar from equilibrium – it is robust against disorder and interactions, and exhibits a nonequilibrium bulk-boundary correspondence, which we probe using the entanglement spectrum. We explicitly construct a nonequilibrium generalisation of the `ten-fold way', which applies to non-interacting fermionic systems with non-spatial symmetries in all dimensions [2]. The differences between equilibrium and nonequilibrium topology are shown to have directly observable consequences, in both bulk and boundary physics. In particular, we show that non-equilibrium topological effects have important ramifications for various Majorana fermion-based implementations of quantum memories.

8:48AM R03.00005: Self-assembled Bismuth Selenide (Bi$_2$Se$_3$) quantum dots grown by molecular beam epitaxy* MARCEL CLARO, Chemistry, The City College of New York, ABHINANDAN GANGOPADHYAY, Engineering, Arizona State University, DAVID SMITH, Physics, Arizona State University, MARIA TAMARGO (Presenter), Chemistry, The City College of New York — Three-dimensional topological insulators (TIs) are insulators in the bulk with surface states that have spins locked with momentum and are protected by time-reversal symmetry. Control of these states can be useful for novel applications in quantum computing and spintronics. Some properties of these materials can be enhanced by electronic confinement in quantum dots (QDs)$^{1,2}$. Bi$_2$Se$_3$ is particularly interesting since its band gap is relatively large and the experimentally verified Dirac cone is in the Γ-point. Bi$_2$Se$_3$ has been grown successfully by molecular beam epitaxy (MBE) on different substrates, and a lithographically defined QD with quantum confinement was previously demonstrated$^3$. We report the growth of self-assembled Bi$_2$Se$_3$ QDs by MBE using the droplet epitaxy technique. The QDs form after anneal of Bi droplets under a Se flux. They are crystalline and have average dimensions of 12-nm height (12 quintuple layers) and 46-nm width, and a density of 8.5x10$^9$ cm$^{-2}$. The QD formation process developed is simple, reproducible and tunable.

9:00AM R03.00006: Quantization of Fractional Corner Charge in C$_n$-symmetric Topological Crystalline Insulators* WLADIMIR BENALCAZAR (Presenter), Physics, The Pennsylvania State University, TIANHE LI, TAYLOR HUGHES, University of Illinois at Urbana-Champaign — We show that C$_n$ symmetries quantize the corner charge in crystalline topological insulators. We first classify two-dimensional crystalline insulators having time-reversal and C$_n$ symmetries and construct sets of primitive generator models that span these classifications. From these generators, we are able to characterize the existence of corner fractional charge systematically and relate it to the symmetry representations of the occupied energy bands. We find that C$_n$-symmetric crystalline insulators have fractional corner charges in multiples of e/n. Our findings are compiled in a set of topological indices that quantify the amount of charge robustly localized at corners. When an additional chiral symmetry is present, e/2 corner charges are accompanied by zero-energy corner-localized states. Finally, we discuss the role of fractional charges bound to disclinations as bulk probes for these topological insulators.

causes the topological insulating phase to become stable at either a small or zero strain (with respect to the ground state impossible. We show that instead, chemical functionalization using -CX3 groups (X = F, Cl, Br, I) induces giant chemical strains (of 9.5%, 37.4%, 48.9% and 62.8%, respectively) on the germanene lattice, relative to GeCH3. For X = F and Cl, this causes the topological insulating phase to become stable at either a small or zero strain (with respect to the ground state geometry of GeCX3), respectively. When X = Cl, the system undergoes a symmetry-lowering distortion that shifts the valence band maximum and conduction band minimum away from the zone center, while preserving the topological insulator phase. For X = Br, we obtain a trivial insulator, and for X = I, the system is unstable. Our finding that monolayer GeCCl3 is a topological insulator under ambient conditions is of interest for possible applications in future devices.

10:00AM R03.00011: Inequivalent Berry Phases for the Bulk Polarization* HARUKI WATANABE (Presenter), Applied Physics, University of Tokyo, MASAKI OSHIKAWA, Institute for Solid State Physics, University of Tokyo — We discuss the characterization of the polarization for insulators under the periodic boundary condition in terms of the Berry phase, clarifying confusing subtleties. For band insulators, the Berry phase can be formulated in terms of the Bloch function in momentum space. More generally, in the presence of interactions or disorders, one can instead use the many-body ground state as a function of the flux piercing the ring. However, the definition of the Bloch function and the way of describing the flux are not unique. As a result, the value of the Berry phase and its behavior depend on how precisely it is defined. In particular, identifying the Berry phase as a polarization, its change represents a polarization current, which also depends on the definition. We demonstrate this by elucidating mutual relations among different definitions of the Berry phase and showing that they correspond to currents measured differently in real space. Despite the nonuniqueness of the polarization current, the total charge transported during a Thouless pumping process is independent of the definition, reflecting its topological nature.

10:12AM R03.00012: Magic-Angle Physics in Two-Dimensional Topological Insulators YIXING FU (Presenter), JUSTIN WILSON, JED PIXLEY, Rutgers University, New Brunswick — The Bernevig-Hughes-Zhang (BHZ) model is a quintessential model for a two-dimensional Z₂ topological insulator with topological and trivial insulator phases separated from each other by semimetallic critical points. We study the fate of the BHZ model in the presence of a quasiperiodic potential by using the kernel polynomial method to calculate the density of states and conductivity to determine the zero temperature phase diagram. The semimetal undergoes magic-angle transitions driven by the quasiperiodic potential, which generates flat bands at the transition to a metallic phase similar to other two-dimensional systems with Dirac nodes. Additionally, the topological insulating phases undergo quantum phase transitions into a metallic phase due to the quasiperiodic potential closing the insulating band gap. Lastly, we also study how the surface states strongly renormalize due to these unique quasiperiodic driven transitions.

10:24AM R03.00013: Disentangling interacting symmetry protected phases of fermions in two dimensions* TYLER ELLISON (Presenter), LUKASZ FIDKOWSKI, University of Washington — We explicitly construct the ground states of certain 2+1D fermionic symmetry protected topological (SPT) phases using finite depth circuits of local unitaries. We recover the classification of the so called supercohomology SPT phases and demonstrate that the composition of our unitaries captures the corresponding SPT group structure. Our strategy is to first build an auxiliary bosonic model from group supercohomology data and then employ the recently developed lattice-level fermionization duality to obtain the fermionic SPT. This construction both yields fixed point lattice Hamiltonians that can be defined on arbitrary triangulations and disentangles the roles of supercohomology data and spin structure in fermionic SPT phases. Further, the global symmetry of our circuits implies that these SPT phases can be many-body localized.

10:36AM R03.00014: Symmetry and Topology in Non-Hermitian Systems HENGYUN ZHOU (Presenter), JONG YEON LEE, SHANG LIU, Department of Physics, Harvard University, BO ZHEN, Department of Physics and Astronomy, University of Pennsylvania — The ideas of topology have found great success in Hermitian physical systems, but the incorporation of non-Hermitian effects may lead to even richer possibilities. Here, we present two results regarding the roles of symmetry and topology in non-Hermitian physical systems. First, we provide a systematic classification of non-Hermitian symmetry protected topological phases in arbitrary spatial dimension, based on the Bernard-LeClair symmetry classes. We discuss the physical insights provided by such a classification, and how it can serve as an important guide for future searches of non-Hermitian topological systems. We then discuss how symmetries can protect the existence of a surface of exceptional points, which are a natural generalization of Hermitian topological nodal phases.
Topological crystalline insulator states in the Ca$_2$As family

XIAOTING ZHOU (Presenter), National Cheng Kung University, CHUANG-HAN HSU, National University of Singapore, TAY-RONG CHANG, National Cheng Kung University, QIONG MA, PABLO JARILLO-HERRERO, NUH GEDIK, Massachusetts Institute of Technology, ARUN BANSIL, Northeastern University, VITOR PEREIRA, National University of Singapore, SUYANG XU, Massachusetts Institute of Technology, HSIN LIN, Academia Sinica, LIANG FU, Massachusetts Institute of Technology — Topological crystalline insulators (TCIs) are insulating electronic phases of matter with nontrivial topology originating from crystalline symmetries. Recent theoretical advances have proposed new TCI states protected by rotational symmetries and provided powerful guidelines to search for TCIs in real materials. Building upon recent theoretical works, we demonstrate a feasible method to identify new TCI states based on first-principles calculations. We systematically unveil the topological properties of the TCI states in Ca$_2$As. On both top and side surfaces, we observe topological surface states protected independently by rotational and mirror symmetries. We show that a particular lattice distortion can single out the newly proposed topological protection by the rotational symmetry. As a result, the Dirac points of the topological surface states are moved to generic locations in momentum space away from any high-symmetry lines. Such topological surface states have not been seen before. Our work reveals rich and exotic TCI physics across the Ca$_2$As family of materials and demonstrates a complete roadmap for uncovering TCIs topological nature based on first-principles calculations. Such a method can be broadly applied in searching for new TCIs.

Session R04 DCMP: Mechanical, Structural and Thermal Behavior of Metals

BCEC 107C - Avadh Saxena, Los Alamos National Laboratory

8:00AM R04.00001: Physical and Thermal Properties of Iron Meteorites below 300 K* MATTHEW BONIDIE (Presenter), CHRISTOPHER NOYES, Physics Department, Boston College, DANIEL BRITT, Physics Department, University of Central Florida, GUY CONSOLMAGNO, ROBERT MACKE, Specula Vaticana, GEORGE SCHMIEDESHOFF, Department of Physics, Occidental College, CYRIL OPEIL, Physics Department, Boston College — The iron meteorites Canyon Diablo [IAB-MG] and Agoudal [IIAB] are primarily kamacite or taenite based Fe-Ni polycrystalline alloys that solidify from planetary cores over a timespan of t > 10$^6$ years via thermal radiation into the vacuum of space. Depending on their Ni composition and cooling rates, iron meteorites crystallize into a fine octahedrite, coarse octahedrite, or hexahedrite crystal structure.

Using resonant ultrasound spectroscopy, the elastic constants (c$_{11}$, c$_{22}$, c$_{44}$) and Young's modulus were measured as a function of temperature from 10-300 K. These measurements allow a comparison of how Ni percentage, crystallographic structure, and impact history effect the mechanical behavior of these meteorites. Specific heat capacity and thermal expansion measurements permit an analysis of the Grüneisen parameter as a function of the same temperature range.

8:12AM R04.00002: First-principles study for the enhancement of the stability of the precipitates in the Cu alloys EUN-AE CHOI (Presenter), SEUNG ZEON HAN, JEE HYUK AHN, Korea Institute of Materials Science, SATOSHI SEMBOSHI, Institute for Materials Research, Tohoku University — Cu is widely used as an electronic circuit component because of its high conductivity. However, in order to be used as connector materials, high strength as well as the high conductivity is required to maintain the desired shape. The Cu-Ti alloy is one of precipitation hardening alloys with the tensile strength of 800-1200MPa and the conductivity of 10-20%IACS. In general, the precipitation hardening alloys can be strengthened more by additional cold working after aging. However, we confirmed that these precipitates dissolve in Cu matrix during cold working, lowering the conductivity considerably. To obtain high conductivity and high strength simultaneously, it is essential to solve this problem. In this study, we tried to find a way to increase the stability of the precipitates in order to avoid dissolution of them during cold working. Using the density functional theory(DFT) calculations, we analyzed the characteristics of the precipitates in Cu-Ti alloy. To find additional elements to enhance the stability of the precipitates, we investigated the properties of them doped with 3d transition metals. Based on DFT results, we found a proper element stabilizing the precipitate and confirmed that the dissolution was inhibited after cold working in Cu-Ti alloys experimentally.
Metallic Refractory Titanium Nitride: An alternative stable metal with tunable optical properties for high temperature plasmonic applications

MENA N GADALLA (Presenter), ANDREW GREENSPON, MICHELE TAMAGNONE, FEDERICO CAPASSO, EVELYN L HU, John A. Paulson School of Engineering and Applied Sciences, Harvard University — The increasing demands of high temperature plasmonic applications require a refractory plasmonic material that is more stable than commonly used metals such as gold (Au). Although a dielectric, under different deposition conditions titanium nitride (TiN) can be converted into a metal-like material that is stable at high temperatures and with plasmonic performance similar to that of Au. We produce TiN films with tunable optical properties ranging from those characteristic of a dielectric to strong metallic behavior with high negative real part of its frequency dependent dielectric function. Various nanostructures formed from both Au and TiN were characterized and compared, using Fourier Transform Infrared Spectroscopy and Scanning Near Field Optical Microscopy. TiN nano-antennas show tunable and distinct localized surface plasmon resonances that are comparable to those of Au. Moreover, the TiN nano-antennas exhibit a significantly more robust optical response after being annealed at high-temperatures, demonstrating the suitability of TiN to act as a stable metal for high temperature plasmonic applications.

First-Principles Molecular Dynamics Simulation of a Liquid Li-Sn as a Plasma-Facing Component

BEATRIZ GONZALEZ DEL RIO (Presenter), Mechanical and Aerospace Engineering, Princeton University, EMILY K. DE JONG, Chemical and Biological Engineering, Princeton University, EMILY ANN CARTER, School of Engineering and Applied Science, Princeton University — Liquid metals, with inherent disorder, have long been suggested as plasma-facing components (PFC) in fusion reactors due to their imperviousness to mechanical damage, thereby allowing for a self-healing and self-replenishing surface. The most promising candidates for liquid PFCs are lithium (Li) and the lithium-tin alloys (Li30Sn70 and Li20Sn80) due to their low melting points and evaporation rates. Although liquid Li properties have been studied extensively, further research into the behavior of LiSn is needed.

We present results of first-principles molecular dynamics simulations of liquid Li30Sn70 and its interaction with various concentrations of deuterium from the melting point up to 970 K. Static and dynamic properties such as pair distribution functions, diffusion coefficients, and viscosities are evaluated. Moreover, deuterium retention in the liquid Li-Sn alloy is compared to that of pure liquid Li. Overall, we provide insight into the atomic-scale behavior of Li30Sn70, which will be useful for further research into PFCs for fusion reactors.

High Strength Al Alloy Thin Films: A Nanoscale Analysis of Microstructure and Interface Segregation

PRAKASH PARAJULI (Presenter), RUBEN MENDOZA-CRUZ, MIGUEL YACAMAN, ARTURO PONCE, Physics and Astronomy, University of Texas at San Antonio — Aluminum alloy (AA) 7075 is commonly used in industries for manufacturing highly stressed structural materials including various parts of commercial aircraft, aerospace and transportation equipment because of its extremely high strength to density ratio. This yield strength relies primarily on the microstructural properties, particularly the structure (types, frequency, and connectivity), geometry (inclination and dihedral angle), and chemistry (segregation and precipitation) of the grain boundaries. Herein, experimental results on the microstructural features and atomic scale Cu grain boundary segregation of high strength Al alloy 7075 thin films are analyzed in detail using advanced microscopic characterization techniques. Two distinct types (point and parallel array) of Cu grain boundary segregation behavior are demonstrated for the Al alloy GBs for the first time; GBs misoriented by less than 28° displayed point (highly segregated atomic column surrounded by low segregated columns) segregation behavior whereas more than the 28° displayed parallel array (two highly segregated columns opposite to each other across the interface surrounded by low segregated columns) segregation behavior.

Welch Foundation-Grant No. AX-1615
9:00AM R04.00006: Modeling dislocation evolution around precipitates in superalloy  
PARINIT ANGADI, DEBIPROSAD ROY MAHAPATRA (Presenter), Indian Institute of Science —  
In this paper we discuss a new approach to correlate the dynamic mechanical properties of Nickel based superalloys to their precipitate driven mechanism of dislocation evolution. These precipitates are responsible for arresting defects or dislocations and enhancing the life of a structural component. The mechanism of dislocation evolution across grain or phase boundaries give complex patterns whose initial stages can be correlated to strain rate dependent damping parameters. We show here molecular dynamic simulation of dislocation evolution under cyclic loading of Ni3Al precipitates in Ni matrix and make an attempt to relate the growth rate parameters to the size of the precipitate and damping constants. The mechanism of deformation under cyclic normal and shear loading are investigated. This is an ongoing effort to extend our understanding to more complex and realistic situation involving temperature effects and microstructure of the superalloys.

9:12AM R04.00007: Atomistic simulation of dislocation-assisted γ-precipitate nucleation in Mg-Al alloys  
PENG YI (Presenter), MICHAEL FALK, Johns Hopkins University —  
Magnesium has drawn increasing interests as a lightweight material for applications in transportation and aerospace industries. Mechanical processing methods like equal channel angular extrusion (ECAE) have shown potential in controlling the morphology of the precipitate particles for enhanced precipitation hardening performance. Understanding how deformation affects the precipitation process is crucial for processing condition optimization, property prediction, and materials design.  
We study the dislocation-assisted precipitate nucleation of Mg17Al12 precipitates in Mg-Al alloys. We determine the critical nucleus size under different composition and stress conditions. The critical nucleus size is very sensitive to the solute concentration. The local stress introduced by dislocations can significantly change the nucleation barrier and the nucleation path. The local stress not only affects the misfit strain energy, but also significantly alters the relative stability of the phases. As a result, although γ precipitate is denser than the α matrix, counter-intuitively nucleation is favored under tension conditions rather than compression conditions. We incorporate our results into continuum model and compare with recent ECAE experiments.

9:24AM R04.00008: Stabilizing the Simple Hexagonal Structure -- Alloys of Tin*  
MICHAEL MEHL (Presenter), MATEO RONQUILLO, United States Naval Academy, COREY OSES, STEFANO CURTAROLO, CORMAC TOHER, Duke University —  
Approximately thirty elements have ground state or room-temperature structures with only one atom in the unit cell: fcc (Cu, Ir, Pb, etc.), bct (Cr, Ta, W, etc.), bct (In), rhombohedral (Hg), and even simple cubic (Po) lattices. The simple hexagonal (sh) lattice is never seen, even though it has a higher symmetry than rhombohedral and the same number of near neighbors as the bcc lattice. Only element, tin, has even a relatively low-energy sh structure.  
Experimentally, the sh structure is found in mercury-tin alloys. To understand this, we performed a series of Density Functional calculations on HgxSn1-x and CdxSn1-x structures by the virtual crystal approximation (VCA); supercell calculations with ordered placement of the Cd/Hg atom (e.g., one impurity atom per unit cell); and using high-throughput AFLow calculations to sample larger supercells with random impurities.  
Both Cd and Hg stabilize the simple hexagonal structure against α- and β-Sn. The success of the VCA suggests that this is a density of states effect, and we examine the effect of alloying on the density of states using all of our techniques.  
*MJ Mehl is funded by the Kinnear Foundation and Duke University. Duke University research is funded by the US Office of Naval Research grant N00014-17-1-2090.
glass transition and primary crystallization of melt-spun Al₈₆Ni₆Y₄.₅Co₂La₁.₅ metallic glass have been investigated at modified description of the crystal growth kinetics in the whole temperature range is obtained. In the analysis a theoretical model is employed which takes into account equation for the description of the viscosity and the Maxwellian relaxation time. This result is confirmed by measurements of primary crystallization performed also over a wide range of scanning rates. The results reveal that the kinetics of crystallization follows a non-Arrhenius behavior. In the heating rate dependence of the glass transition temperature can be described by a generalization of the Bartenev-Ritland equation utilizing the Vogel-Fulcher-Tammann theory (DFT), molecular dynamics (MD), and high-throughput nanocalorimetry to study the Cu-Zr-X high-temperature shape memory alloy system (X= Ni/Co/Hf). Nanocalorimetry shows the martensite-austenite transformation temperature and stability on thermal cycling as a function of composition. DFT and MD are used to map out the martensitic transformation pathways. We found that the martensite-austenite energy difference and transformation temperature are positively correlated, while the martensite-austenite lattice mismatch and transformation hysteresis are negatively correlated. Our results provide a map of the shape-memory properties of Cu-Zr-X, and can be extrapolated to a larger compositional space to search for novel shape memory alloys.

This work was supported by the Air Force Office of Scientific Research under Grant No. FA9550-16-1-0180. It was performed in part at the Harvard University Center for Nanoscale Systems (CNS), which is supported by the National Science Foundation under NSF ECCS award no. 1541959.

Thermonelectance NICHOLAS VU (Presenter), RONALD WARZOH, ANDREW SMITH, BRIAN DONOVAN, United States Naval Academy, DARIN SHARAR, Army Research Laboratory — Shape Memory Alloys (SMAs) have a wide range of applications due to their unique thermal-mechanical properties caused by the austenitic-martensitic phase transformation. One of the most promising applications is in elastocaloric cooling, which has the potential to become a small, environmentally friendly, and efficient alternative to vapor-compression systems. The SMA with the most promise is Nickel Titanium (NiTi) due to its stability and thermal-mechanical performance. The mechanisms that govern the thermal properties of NiTi are not well characterized and may be affected grain size, strain, and temperature. Using the frequency-domain thermoreflectance (FDTR) method, the thermal properties of NiTi SMAs with different grain sizes will be determined as a function of strain and temperature. FDTR is a pump-probe non-contact optical technique that can accurately determine the thermal properties such as heat capacity, thermal conductivity, and thermal boundary conductance of thin films and bulk materials. It is expected that measuring the thermal properties of NiTi will help to determine its viability as a candidate material for strain-induced elastocaloric cooling.

Computational Investigation of the Mechanical Properties of Alloys MICHAEL WOODCOX (Presenter), JOSHUA YOUNG, MANUEL SMEU, Physics, State University of New York at Binghamton — The nature of alloying is to combine other elements with a metal in order to make a unique material that possesses desired properties that are lacking in the separate constituents. However, with these novel materials there are new and exciting physical implications that need to be studied in order to collectively understand the alloy process; which is also crucial for their use in industrial applications. We have used DFT to calculate the mechanical properties of several bulk materials to gain a quantitative understanding of the nature of ductility. Specifically, using the VASP code, we have been able to calculate the elastic tensor of different materials, which allows for the calculation of elastic properties: including the bulk, shear, and Young's moduli, Poisson's ratio, and the Pugh ratio. We have applied this process to previously unstudied alloy materials with the goal of offering a further insight into the nature of ductility and a means to quantify it. Through Bader charge analysis, and calculation of the density of states, we have also worked to understand the significance of ductility as it relates to bonding. We anticipate that the proposed technique will help guide experimentalists in the development of ductile materials, in the interest of replacing Pb based solders.

Glass transition and primary crystallization of Al₈₆Ni₆Y₄.₅Co₂La₁.₅ metallic glass at heating rates spanning over six orders of magnitude BIN YANG (Presenter), JÜRN W. P. SCHMELZER, Institute of Physics, University of Rostock, BINGGE ZHAO, YULAI GAO, Shanghai University, CHRISTOPH SCHICK, Institute of Physics, University of Rostock — The glass transition and primary crystallization of melt-spun Al₈₆Ni₆Y₄.₅Co₂La₁.₅ metallic glass have been investigated at continuous heating covering more than six orders of magnitude of heating rates (0.083 K/s to 40,000 K/s). Differential fast scanning calorimetry (DFSC) and conventional differential scanning calorimetry (DSC) were employed, by which the glass transition kinetics was analyzed. In particular, it is shown that the heating rate dependence of the glass transition temperature can be described by a generalization of the Bartenev-Ritland equation utilizing the Vogel-Fulcher-Tammann equation for the description of the viscosity and the Maxwellian relaxation time. This result is confirmed by measurements of primary crystallization performed also over a wide range of scanning rates. The results reveal that the kinetics of crystallization follows a non-Arrhenius behavior. In the analysis a theoretical model is employed which takes into account the effect of decoupling of viscosity and diffusion, i.e., the breakdown of the Stokes-Einstein equation. In this way, a modified description of the crystal growth kinetics in the whole temperature range is obtained.
Magnetic Shape Memory Alloys

JOSE MARIA PORRO AZPIAZU (Presenter), ANABEL PEREZ CHECA, BCMaterials, PATRICIA LAZPITA, JORGE FEUCHTWANGER, Departamento de electricidad y electrónica, University of the Basque Country, VOLODYMYR CHERNENKO, Ikerbasque, the Basque Foundation for Science — Magnetic Shape Memory Alloys (MSMAs) are a group of active materials that undergo phase transitions (resulting in large recoverable mechanical deformations) induced by temperature, stress and/or magnetic fields. Their superfast response and high energy density makes them ideal candidates to be implemented in the field of sensors and actuators. The magnetic properties of MSMAs depend on the magnetic coupling between atoms that, in turn, depends on the atomic positions within the lattice. We have performed powder neutron diffraction experiments in order to elucidate the crystal structure of the martensite phases of Ni\textsubscript{51}Mn\textsubscript{28-x}Ga\textsubscript{21}Y\textsubscript{x} MSMAs, where the doping element is Y=Co,Fe and x=0,1,3,5. The analysis of the diffractograms obtained in the experiment shows that the x=0 alloy has a mixture of modulated orthorhombic and tetragonal phases; the Co-rich samples tend to stabilize the tetragonal phase towards a non-modulated one; and the Fe-rich samples tend to stabilize the orthorhombic phase. We have determined the atomic site occupancies in both the martensite and austenite phases of all the alloys studied, and explored their relation with the changes on the magnetic properties of the alloys.

Spherical Nanomechanical Characterization of Novel Nanocrystalline Cu Cold Spray Manufactured Materials

BRYER SOUSA (Presenter), KRISTIN LUISE SUNDBERG, CHRISTOPHER J. MASSAR, Worcester Polytechnic Institute, VICTOR K. CHAMPAGNE, JR., US Army Research Lab, DANIELLE L. COTE, Worcester Polytechnic Institute — The novel mechanical, microstructural, and functional properties associated with nanocrystalline metal materials has brought about interdisciplinary interest and curiosity. Nanostructured metals can be manufactured by way of multiple methods; however, during the course of this research the method studied herein is employs severe plastic deformation processing via cold spray powder deposition. TEM and SEM analysis confirmed the noteworthy grain refinement brought about by cold spray for two copper feed stocks. More specifically, the two types of copper powders were that of conventional gas atomized Cu as well as nanostructured Cu powders produced by way of spray drying and agglomeration. As such, the classical nanoindentation properties of hardness and Elastic modulus are experimentally determined using both static and dynamic nanomechanical testing. Dynamic spherical nanoindentation methodologies are employed to unveil the cold spray consolidated coating's stress-strain response and flow behavior. The mechanical flow curves extracted herein suggest that the protocol refinements proposed by Leitner, Maier-Kiener, and Kiener may have fundamentally advanced spherical nanoindentation testing at large.

*US Army Research Laboratory grant W911NF-15-2-0024
Topological superconductivity revealed by scanning tunneling spectroscopy

DONGLAI FENG (Presenter), QIN LIU, RAN TAO, CHEN CHEN, YAJUN YAN, TONG ZHANG, Fudan University, QIANG-HUA WANG, Physics, Nanjing University, ZHIPING YIN, Beijing Normal University, XIAOLI DONG, Institute of Physics, CAS, YOICHI ANDO, University of Cologne, ZHONGXIAN ZHAO, Institute of Physics, CAS — CuₓBi₂Se₃ hosts both topological surface states and bulk superconductivity. It has been identified recently as a topological superconductor (TSC) with an extraordinary nematic, i.e. C₂-symmetric, superconducting state and odd-parity pairing. Using scanning tunneling microscopy (STM), we directly examine the response of the superconductivity of CuₓBi₂Se₃ to magnetic field. Under out-of-plane fields, we discover elongated magnetic vortices hosting a zero-bias conductance peak (ZBCP) consistent with the Majorana zero mode (MZM) expected in a TSC. Under in-plane fields (B//), the average superconducting gap exhibits two-fold symmetry with field orientation, the long C₂ symmetry axes are pinned to the dihedral mirror planes under B//=0.5 T but slightly rotate under B//=1.0 T. Moreover, a nodeless Δ₄ₓ gap structure is semi-quantitatively determined for the first time. Our data paint a microscopic picture of the nematic superconductivity in CuₓBi₂Se₃ and pose strong constraints on theory. [1]

The MZMs in CuₓBi₂Se₃ are neither clean nor robust, most likely due to contamination from impurity states or other closely-packed Caroli-de Gennes-Matricon (CdGM) states, which hampers further manipulations of Majorana fermions. We show that a ZBCP well separated from the other discrete CdGM states exists ubiquitously in all cores of free vortices in the defect free regions of (Li₀.₈₄Fe₀.₁₆)OHFeSe, which has a superconducting transition temperature of 42 K. Moreover, a Dirac-cone-type surface state is observed by angle-resolved photoemission spectroscopy, and its topological nature is confirmed by band calculations. The observed ZBCP can be naturally attributed to a MZM arising from this chiral topological surface states of a bulk superconductor. (Li₀.₈₄Fe₀.₁₆)OHFeSe thus provides an ideal platform for studying MZMs and topological quantum computing. [2]

Superconductivity in zerovalent copper intercalated Bi₂Se₃ crystals

MIN-NAN OU (Presenter), SHIH-HSUN YU, Institute of Physics, Academia Sinica, MITCH M. C. CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, YANG-YUAN CHEN, Institute of Physics, Academia Sinica — In order to understanding of the role of Cu atoms to the formation of superconducting quasiparticles. A series of CuₓBi₂Se₃ (x= 0~ 0.3) crystals prepared with Bridgman method followed by an electrochemical technique (EC method) at room temperature. The existence of copper confirmed by means of XRD, SEM and TEM EDS mapping as well. Where the obvious increasing on lattice c confirm the intercalating of copper atoms rather than the substitution. The further study on temperature dependent electrical resistance and magnetic susceptibility revealed a superconducting transition at about T_C = 3 ~ 3.5 K. As an illustration, optimized 10 at% of Cu, a clear superconducting transition at T_C = 3.4 K with large shielding fraction (volume susceptibility) of ~ 95% is observed. The characteristic peaks of the zerovalent chemical state of copper confirmed by x-ray photoelectron spectra (XPS) and Auger electron spectra (AES). By the electron energy loss spectroscopy (EELS), near-edge fine structure revealed the absence of Cu¹⁺ and Cu²⁺ characterization peaks, which confirmed the zerovalent of intercalated copper atom. The results of this work suggested that the formation of superconducting quasiparticles do not relate to the charge transfer of copper.
8:48AM R05.00003: Reproducible Growth of Superconducting Sr$_2$RuO$_4$ Films by Molecular-Beam Epitaxy*

NATHANIEL SCHREIBER (Presenter), HARI NAIR, JACOB P RUF, LUDI MIAO, YINGFEI LI, MORGAN GRANDON, DAVID BAEK, BERIT GOODGE, LENA FITTING KOURKOUTIS, KYLE M SHEN, DARRELL G. SCHLOM, Cornell University — The unconventional, likely chiral $p$-wave, superconductivity in Sr$_2$RuO$_4$ has been studied extensively in bulk single crystals since its discovery over 20 years ago. The superconducting state in Sr$_2$RuO$_4$ is extremely sensitive to defects and non-magnetic impurities, and therefore superconductivity has only been observed in very pure crystals with a midpoint $T_c$ of up to ~1.5 K [1]. Thin films of Sr$_2$RuO$_4$ have only recently been realized, and this advancement is important for both the study of the unconventional superconducting properties and for the implementation of Sr$_2$RuO$_4$ in any future practical applications. In this talk, we report a thermodynamic growth window, in which we can reproducibly grow superconducting Sr$_2$RuO$_4$ thin films by molecular-beam epitaxy with transition temperatures of up to 1.8 K on (110) NdGaO$_3$ substrates [2].

9:00AM R05.00004: Effects of deep superconducting gap minima and disorder on thermal transport in Sr$_2$RuO$_4$*

ZHIQIANG WANG (Presenter), McMaster University, JOHN DODARO, Stanford University, CATHERINE KALLIN, McMaster University — Recent thermal conductivity measurements on Sr$_2$RuO$_4$ were interpreted as favoring a pairing gap function with vertical line nodes while conflicting with chiral $p$-wave pairing. Motivated by this work we study the effects of deep superconducting gap minima on impurity induced quasiparticle thermal transport in chiral $p$-wave models of Sr$_2$RuO$_4$. Combining a self-consistent T-matrix analysis and self-consistent Bogoliubov-de-Gennes calculations, we show that the dependence of the residual thermal conductivity on the normal state impurity scattering rate can be quite similar to the $d$-wave pairing state that was shown to fit the thermal conductivity measurements, provided the normal state impurity scattering rate is large compared with the deep gap minima. Consequently, thermal conductivity measurements on Sr$_2$RuO$_4$ can be reconciled with a chiral $p$-wave pairing state with deep gap minima. However, the data impose serious constraints on such models and these constraints are examined in the context of several different chiral $p$-wave models.

9:12AM R05.00005: Superconducting Symmetries of Sr$_2$RuO$_4$ from Spin- and Charge-fluctuations*

OLIVIER GINGRAS (Presenter), RQMP, Université de Montréal, REZA NOURAFKAN, ANDRE-MARIE TREMBLAY, Institut quantique and RQMP, Université de Sherbrooke, MICHEL COTE, RQMP, Université de Montréal — Although the normal state of Sr$_2$RuO$_4$ is well understood, its pairing symmetry is still debated [1]. From its correlated multi-orbital normal state, we construct the spin- and charge-fluctuation pairing interactions. These interactions depend on the proximity to an instability and on the size of the screened Hund’s coupling. We present the leading gap function symmetries obtained by solving the frequency dependent linearized Eliashberg equation [2]. Close to magnetic instabilities, we find spin-singlet $d$-wave pairing. Away, where charge-fluctuations increase, we observe the emergence of two even-parity spin-triplet states: an odd in frequency $s$-wave and two degenerate momentum-independent states that pair electrons on different orbitals and are odd in orbital indices. We will explain by what means spin- and charge-fluctuations mediated pairing favors such symmetries, how to understand them from specific features of the correlated electronic structure and compare their gap value with experiments.

9:24AM R05.00006: STM study of impurity states in topological superconducting candidates Li(Fe,Co)As and PbTaSe$_2$*

SONGTIAN SONIA ZHANG (Presenter), JIAXIN YIN, Department of Physics, Princeton University, GENFU CHEN, Institute of Physics, Chinese Academy of Sciences, GUOQING CHANG, Department of Physics, Princeton University, TAY-RONG CHANG, Department of Physics, National Cheng Kung University, KUN JIANG, Department of Physics, Boston College, CHANGQING JIN, Institute of Physics, Chinese Academy of Sciences, ZIQIANG WANG, Department of Physics, Boston College — Introducing impurities, both magnetic and nonmagnetic, into superconducting systems via surface or bulk chemical substitution can both provide a wealth of information about the underlying system, as well as manipulate some of its crucial properties. Here, we use low temperature scanning tunnelling microscopy to study vortex core and impurity states in topological superconductor candidates Li(Fe,Co)As and PbTaSe$_2$ at 0.4K. We perform a systematic study in the Li(Fe,Co)As system of eight Co concentrations, spanning its entire superconducting phase diagram. Using a superconducting tip, we explore the impurity effects on the topological surface states as well as bulk superconductivity in PbTaSe$_2$. Our results not only provides strong constraints on their superconducting order parameters, but also sheds light on the interplay of magnetism and topological superconductivity.

9:36AM R05.00007: Rotational symmetry breaking in the upper critical field of topological superconductor candidate CaSn$_3$

YASUYUKI NAKAJIMA (Presenter), K A M HASAN SIDDIQUEE, RIFFAT MUNIR, CHARUNI DISSANAYAKE, PRIYANKA VAIDYA, CAMERON NICKLE, ENRIQUE DEL BARCO, University of Central Florida, DERRICK VANGENNEP, JAMES HAMLIN, University of Florida — Electronic nematicity is a quantum analogue to liquid crystals, breaking the rotational symmetry, but preserving the translational symmetry. The electronic nematic states emerge not only in strongly correlated systems, including quantum Hall liquids, high temperature cuprate and iron-based superconductors, and heavy fermion compounds [1], but also in weakly correlated systems, such as the superconducting states in doped-topological insulators known as nematic superconductivity [2]. Closely correlated with the topological nature, the nematic superconductivity in topological materials has attracted great interest. Here, we report systematic studies of the upper critical field of topological superconductor candidate CaSn$_3$, forming a cubic structure with point group Oh. We reveal two-fold symmetry in the anisotropy of upper critical field, breaking the underlying lattice structure. Similar to doped-topological insulator M$_x$Bi$_2$Se$_3$ (M=Sr, Cu and Nb), the rotational symmetry breaking indicates the realization of nematic superconductivity in CaSn$_3$. We will discuss the possible superconducting pairing state stabilized in this system.

9:48AM R05.00008: Band Structure Perfection and Superconductivity in Type-II Dirac Semimetal Ir$_{1-x}$Pt$_x$Te$_2$

FUCONG FEI (Presenter), FENGQI SONG, Nanjing University — Recent levels of interest in topological semimetals have stimulated a fruitful avenue of research in materials science. A new concept of type-II Dirac semimetal (DSM) with tilted Dirac dispersion has been predicted and confirmed by multiple experimental techniques in PdTe$_2$, PtTe$_2$ and PtSe$_2$. However, the Dirac points in these materials are far below the Fermi level and several trivial bands cross the Fermi level. Many exotic properties thus disappear or are concealed by trivial signals. Here we discover a new type-II DSM in Ir$_{1-x}$Pt$_x$Te$_2$ with optimized band structure. Pt dopants protect the 1T-phase crystal structure and tune the Fermi level close to the Dirac point. Type-II Dirac dispersion in Ir$_{1-x}$Pt$_x$Te$_2$ is confirmed by angle-resolved photoemission spectroscopy and first-principle calculations. Superconductivity is also observed and persists when the Fermi level aligns with the Dirac points. Ir$_{1-x}$Pt$_x$Te$_2$ is an ideal platform for further studies on the type-II DSMs, and opens up a new route for the possible topological superconductivity and Majorana physics.
10:00AM R05.00009: Topological superconductivity in full shell proximitized nanowires*  ROMAN LUTCYN (Presenter), GEORG W. WINKLER, BERNARD VAN HECK, TORSTEN KARZIG, Station Q, Microsoft Corp, KARSTEN FLENSBERG, University of Copenhagen, LEONID GLAZMAN, Yale University, CHETAN NAYAK, Station Q, Microsoft Corp — We consider a new model system supporting Majorana zero modes based on semiconductor nanowires with a full superconducting shell. We demonstrate that, in the presence of spin-orbit coupling in the semiconductor induced by a radial electric field, the winding of the superconducting order parameter leads to a topological phase supporting Majorana zero modes. The topological phase persists over a large range of chemical potentials and can be induced by a predictable and weak magnetic field piercing the cylinder. The system can be readily realized in semiconductor nanowires covered by a full superconducting shell, opening a pathway for realizing topological quantum computing proposals.

*This work was performed in part at Aspen Center for Physics, which is supported by National Science Foundation grant PHY-1607611.

10:12AM R05.00010: Topological superconductivity in full-shell nanowires: numerical results and phase diagrams ROMAN LUTCYN, GEORG W. WINKLER, BERNARD VAN HECK (Presenter), TORSTEN KARZIG, Microsoft Station Q, Microsoft Quantum, KARSTEN FLENSBERG, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, LEONID GLAZMAN, Departments of Physics and Applied Physics, Yale University, CHETAN NAYAK, Microsoft Station Q, Microsoft Quantum — We investigate numerically the Majorana topological phase appearing in semiconductor nanowires with a full superconducting shell. We consider both toy models and more realistic models where the electrostatic profile in the semiconducting core is computed self-consistently and the semiconductor and superconductor are treated on equal footing in the strong coupling regime. The topological phase diagram is computed for different core radii. This talk is a continuation of the previous talk on the same topic by R.M. Lutchyn.

10:24AM R05.00011: Josephson junctions with weak links of topological crystalline insulator nanowires*  CHRISTIE J TRIMBLE (Presenter), University of Maryland, College Park, PENGZI LIU, JUDY CHA, Yale University, JAMES R WILLIAMS, University of Maryland, College Park — Incorporating superconductivity in topological states of matter offers potential routes to novel excitations with properties essential to topological quantum computation. Topological crystalline insulators (TCIs) are topological states of matter protected by crystalline symmetry, in contrast to the more commonly used time-reversal invariant topological insulators. In this talk, we report on the fabrication of Josephson junctions using nanowires of SnTe, a TCI, as the weak link material. We show the divergence of our devices from standard Josephson junction behavior using DC techniques, highlighting intriguing novel behavior in the magnetic diffraction pattern, and discuss the origin of this behavior in terms of pi phase difference across the junction.

*NSF Award #1743913

10:36AM R05.00012: Is a quantum dot a good tool to detect the topological properties of a proximitized Rasba nanowire?  DENIS CHEVALLIER (Presenter), OLESIA DMYTRUK, DANIEL LOSS, JELENA KLINOVAJA, University of Basel — Recent experiments in developing Majorana qubits have focused on semiconductor-superconductor Rashba nanowire junctions. A quantum dot is located in the non-superconducting section of the nanowire and is used to probe its topological properties. Various phenomena can be understood with the transport measurement through the quantum dot such as the renormalization of the g-factor [1] as well as the flipping of the bulk band resulting from the topological transition [2,3]. However, the presence of such quantum dot can also mimic the zero-bias peak feature [4], questioning the presence of the topological phase and, as a consequence, temporarily blocking the road towards topological quantum computation.

10:48AM R05.00013: Andreev bound states and Fabry-Perot interference in InAsSb nanowires  FANMING QU (Presenter), JIANGBO HE, JIANGHUA YING, GUANGTONG LIU, JIE FAN, ZHONGQING JI, Institute of Physics, Chinese Academy of Sciences, DONG PAN, JIANHUA ZHAO, Institute of Semiconductors, Chinese Academy of Sciences, LI LU, Institute of Physics, Chinese Academy of Sciences — Andreev bound states (ABSs) are electronic analogues of Fabry-Perot interference. Signatures of Majorana zero modes have been demonstrated as merging of electron and hole ABSs as well as zero bias conductance peaks. We take the bottom-up route to study the ABSs and Fabry-Perot interference in InAsSb nanowires. The superconductor-InAsSb-superconductor device shows induced hard superconducting gap in the quantum dot regime. The g factor is extracted consistently from the evolution of both the excited states and the Kondo effect in magnetic field. Moreover, the device can be driven to the Fabry-Perot interference regime where ABSs are observed.
8:00AM R06.00001: Anomalous critical exponents in itinerant ferromagnets $\text{Ni}_{1-x}\text{Rh}_x$ ($x = 0.3 - 0.375$) close to a quantum phase transition*  
CHIEN-LUNG HUANG (Presenter), BIANCA SPIESS, Physics and Astronomy, Rice University, SEBASTIAN KUNTZ, KAI GRUBE, Institute fuer Festkoerperphysik, Karlsruhe Institute of Technology, ALANNAH HALLAS, KYLE BAYLIFF, Physics and Astronomy, Rice University, TIGLET BESARA, THEO SIEGRIST, National High Magnetic Field Laboratory, YIPENG CAI, JAMES BEARE, GRAEME LUKE, Department of Physics and Astronomy, McMaster University, EMILIA MOROSAN, Physics and Astronomy, Rice University — We studied the critical behavior of itinerant ferromagnets $\text{Ni}_{1-x}\text{Rh}_x$ with $x = 0.3 - 0.375$ based on the Arrott-Noakes scaling analysis. The ferromagnetic ordering temperature is continuously suppressed to zero at a critical concentration $x_c \sim 0.375$. For $x = 0.3$, mean-field like exponents $\beta \sim 0.5, \gamma \sim 1.5$, and $\delta \sim 3$ are observed. With increasing $x$, critical exponents vary smoothly and reach at $\beta \sim 0.6, \gamma \sim 0.7,$ and $\delta \sim 2.3$ for $x = 0.37$. The evolution of exponents with $x$ and the exponent values close to $x_c$ cannot be described by any known universality class for classical models. The possible explanation for the trend of exponents is that, close to $x_c$, strong quantum fluctuations enhance the role of disorder and drive the system to a new strong-coupling regime.

8:12AM R06.00002: Search for a magnetic quantum critical point in LuFe$_2$Ge$_2$ substitution series*  
RAQUEL RIBEIRO (Presenter), Universidade Federal do ABC (Brazil), Iowa State University (USA), SERGEY BUDKO, PAUL CANFIELD, Iowa State University — As part of an extensive study of the RFe$_2$Ge$_2$ series [1] a SDW-like transition was discovered in LuFe$_2$Ge$_2$ near 9 K. Given that LuFe$_2$Ge$_2$ has the same structure as the AFe$_2$As$_2$ (A =Alkali and Alkali-Earth) Fe-based superconductors, the possibility of LuFe$_2$Ge$_2$ manifesting fragile magnetism [2], and even exotic, emergent states that could be revealed as T-SDW is suppressed toward zero, was enticing. To address this, a study of Y, Sc, Co and Ru substitutions into LuFe$_2$Ge$_2$ was made [3]. Although phase diagrams constructed down to 2-3 K failed to reveal emergent effects [3], in this talk we will present magnetization and specific heat data down to 400 mK and 100 mK respectively. Updated phase diagrams will be presented and discussed.

*Work at Ames Laboratory was supported by the U.S. DOE, BES, DMSE. Ames Laboratory is operated for the U.S. Department of Energy by Iowa State University under Contract No. DE-AC02-07CH11358. RAR was funded by the Gordon and Betty Moore Foundation’s EPIQS Initiative through Grant GBMF4411

8:24AM R06.00003: Hall Coefficient of Pure Chromium at Finite Temperatures and High Pressures  
STEPHEN ARMSTRONG (Presenter), Caltech, YISHU WANG, Johns Hopkins University, DANIEL SILEVITCH, Caltech, YEJUN FENG, Okinawa Institute of Science and Technology, THOMAS F ROSENBAUM, Caltech — Elemental chromium is a spin density wave antiferromagnet which may be tuned through a second order quantum phase transition by the application of pressure or by chemical doping with e.g. vanadium. For both routes, the Hall coefficient has proven to be a powerful probe of the quantum critical region. In the low temperature limit, the Hall coefficient varies rapidly through the transition due to Fermi surface reconstruction. However, critical scaling of the Hall coefficient differs between pressure and doping driven transitions, establishing disorder as a relevant parameter in defining the universality class of a quantum phase transition. For doped chromium, the measured finite temperature behavior of the Hall coefficient cannot be described by band theory, and instead has been interpreted as evidence of a pseudogap phase. Here, we examine the pressure-driven Hall coefficient in pure chromium at finite temperature in search of signatures of a pseudogap phase in the absence of disorder.
8:36AM R06.00004: Ferromagnetic quantum phase transition in compressed CePd$_2$P$_2$* TIMOTHY A ELMSLIE (Presenter), DERRICK VANGENNEP, Department of Physics, University of Florida, YOU LAI, DAVID E GRAF, RYAN BAUMBACH, National High Magnetic Field Laboratory, Florida State University, JAMES J. HAMLIN, Department of Physics, University of Florida — The correlated electron material CePd$_2$P$_2$ crystallizes in the ThCr$_2$Si$_2$ structure and orders ferromagnetically at 28 K. Recently, Y. Lai et al. [1] found evidence for a ferromagnetic quantum critical point induced by chemical compression via substitution of Ni for Pd. In this present work, we examine the T-H-p phase diagram of single crystalline CePd$_2$P$_2$ to 25 GPa using a combination of resistivity, magnetic susceptibility, and x-ray diffraction measurements. We find that the ferromagnetism is destroyed near 20 GPa. These results are compared to similar experiments on the ferromagnets CeTiGe$_3$ [2] and LaCrGe$_3$ [3].

*Work supported by NSF CAREER DMR-1453752 and NSF NHMFL UCGP. A portion of this work was performed at the NHMFL supported by NSF DMR-1157490, DMR-1644779, and the state of Florida. R.E.B., Y.L., D.G., supported in part by DOE DE-SC0016568.

8:48AM R06.00005: Observation of Griffiths phase at an anti-ferromagnetic quantum critical point in Ce(Cu$_{1-x}$Co$_x$)$_2$Ge$_2$ RAJESH TRIPATHI (Presenter), Indian Institute of Technology Kanpur, DEBARCHAN DAS, CHRISTOPH GEIBEL, Max-Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany, SUDESH KUMAR DHAR, DCMP and MS, Tata Institute of Fundamental research, Mumbai 400005, India, ZAKIR HOSSAIN, Indian Institute of Technology Kanpur — A comprehensive study has been carried out on polycrystalline samples of Ce(Cu$_{1-x}$Co$_x$)$_2$Ge$_2$ by means of electrical resistivity, magnetic susceptibility, specific heat and thermo electric power measurements. The long-range antiferromagnetic order, at $T_N = 4.1$ K in CeCu$_2$Ge$_2$, is suppressed by non-iso-electronic cobalt (Co) doping at a critical value of the concentration $x_c = 0.6$, accompanied by non-Fermi-liquid behavior. A power-law dependence of heat capacity and susceptibility i.e. $C(T)/T$ and $\chi(T)$ $\sim T^{-1+\lambda}$ down to 0.4 K are observed around $x_c = 0.6$ which is compatible with the quantum Griffiths phase scenario and attributed to an antiferromagnetic quantum critical point. Our results on Ce(Cu$_{1-x}$Co$_x$)$_2$Ge$_2$ manifest a complex magnetic phase diagram, where we have observed a continuous decrease of $T_N$ with large negative slope down to $T_N = 0.83$ K at $x = 0.1$, and then a comparatively small negative slope takes over. We conclude that the rapid decrease of $T_N$ upon Co-doping is mainly due to carrier concentration change and associated change of $T_K$ and $T_{RKKY}$. We have not seen any superconducting phase in the quantum critical regime down to 0.4 K

Pressure-induced quantum critical behavior and magnetic order in YbNi$_3$Ga$_9$ with a chiral crystal structure: AC-calorimetric measurements up to 12 GPa

KAZUNORI UMEO (Presenter), N-BARD, Hiroshima University, TAKUMI OTAKI, YUDAI ARAI, AdSM, Hiroshima University, SHIGEO OHARA, Graduate School of Engineering, Nagoya Institute of Technology, TOSHIRO TAKABATAKE, AdSM, Hiroshima University — YbNi$_3$X$_9$ (X=Al, Ga) crystallize in the trigonal ErNi$_3$Al$_9$-type structure with a chiral space group $R32$. YbNi$_3$Al$_9$ undergoes a magnetic transition at $T_M=3.4$ K. By substituting Cu for Ni, a chiral soliton lattice (CSL) is realized under magnetic fields $B_{\perp c}$. While YbNi$_3$Ga$_9$ resides in an intermediate-valence regime under ambient pressure, application of pressure $P$ is expected to drive this compound into a magnetic ordered state. Indeed, a magnetic order above $P_c=9$ GPa was inferred from the electrical resistivity and AC magnetic susceptibility measurements.

In this work, we have investigated the magnetic order in YbNi$_3$Ga$_9$ using AC-calorimetric measurements under $P$ up to 12 GPa. With applying $P$, the Sommerfeld coefficient dramatically increases and reaches to $1 J/K^2\text{mol}$ at 8.6 GPa=$P_c$. A broad maximum in $C/T$ at 1.6 K for $P=9.3$ GPa>$P_c$ shifts to higher temperatures and becomes a sharp $\lambda$-type peak at 5 K for $P\geq11$ GPa. The sets of data of $C(T, P)$ under $B//c$ and $B_{\perp c}$ at $P\geq11$ GPa revealed that another field-induced ordered phase (FIOP) appears only for $B_{\perp c}$. We discuss the origin of the FIOP in relation to the CSL for Yb(Ni$_{1-x}$Cu$_x$)$_3$Al$_9$ and A-phase for MnSi and EuPtSi.

Tuning a quantum phase boundary with microwaves

MATTHEW LIBERSKY (Presenter), THOMAS F ROSENBAUM, DANIEL SILEVITCH, Caltech — The ferromagnet LiHoF$_4$ is a realization of the dipole-coupled transverse field Ising model with a Curie temperature of 1.53 K and a transverse-field-driven quantum phase transition (QPT) at 5 T. The strong hyperfine coupling of the Ho$^{3+}$ ion leads to an effective spin rescaling to $I+J$ below 400 mK, increasing the transverse field required to drive the QPT. This spin rescaling can be suppressed by exciting the nuclear moments into their highest spin states using a strong RF field in the microwave band as a pump. We employ a high-Q loop-gap resonator tuned to approximately 3 GHz to drive the nuclear spins and simultaneously perform dc magnetometry to probe the bulk magnetization. We tune the location of the phase transition as a function of microwave power, and explore the further possibility of studying quantum quench dynamics in a system with a thermodynamic number of spins.

Electrical transport near an Ising nematic quantum critical point

XIAOYU WANG (Presenter), James Frank Institute, University of Chicago, EREZ BERG, Weizmann Institute of Science — Electrical transport properties near an Ising-nematic quantum critical point are of both theoretical and experimental interest. The difficulty of the problem is in part due to the fact that the electronic scattering mediated by critical fluctuations are momentum-conserving, and that one needs to incorporate additional current relaxation mechanisms into the low-energy theory. In this talk, we discuss two mechanisms relevant in such systems, namely Umklapp scattering and compensated metal. We present a memory matrix calculation of the DC resistivity, which treats the quasiparticle density at each patch on the Fermi surface as a slow variable. We work in the temperature regime where electrons are coherent but the fluctuations are Landau-damped. We show that in the case of Umklapp scattering, resistivity shows a smooth crossover from $T^2$ at low temperatures to sublinear at high temperatures. For a compensated metal where current and momentum are orthogonal, resistivity shows a surprising T-linear behavior. Connections to recent numerical simulations and experiments will be discussed.

*The authors acknowledge funding support from University of Chicago and Weizmann Institute of Science.
The emergence of novel quantum phenomena is often shown in materials close to a zero temperature phase transition. Much of the effort to study these new effects, like Kondo entanglement and its breakdown in heavy-fermion metals, has been focused mainly in fermionic systems. Here, we demonstrate that a phonon (bosonic) system can exhibit a quantum phase transition with dislocations. The quantum critical point (QCP) reached by the phonons arises at a second-order transition between two-ground states corresponding to a conventional phonon state (symmetric phase) and a dynamically-induced dipole field (symmetry-broken phase), at zero temperature. The distinct ground states arise from a competition between the phonon-dislocation anharmonic interaction and the topological nature of the dislocation. Furthermore, through renormalization group analysis, this phonon system provides a very different type of quantum critically which can be used to tailor phonon transport at the single-mode level [arXiv:1809.06495].

10:24AM R06.00013: Quantum Criticality and the Non-linear I-V Curve of Two-channel Kondo-Luttinger System*  
CHAO-YUN LIN, YUNG-YEH CHANG, Department of Electrophysics, National Chiao Tung University, COLIN RYLANDS, NATAN ANDREI, Department of Physics and Astronomy, Rutgers University, CHUNG-HOU CHUNG (Presenter), Department of Electrophysics, National Chiao Tung University — We theoretically study the quantum phase transition and non-linear I-V curve of a Kondo impurity in a Luttinger liquid wire. With decreasing Luttinger parameter K (or increasing electron interactions), it has been known since 1990s that the system undergoes a quantum phase transition from 1-channel (1CK) to 2-channel Kondo (2CK) ground states at K=1/2. However, the quantum critical properties near this transition is not known to date due to the lack of controlled theoretical tools to examine the physics near the strong coupling 2CK fixed point. Via bosonization-refermionization approach, we map the system near 1CK-2CK quantum critical point (QCP) and near the Toulouse limit onto an effective fermionic model in weak coupling regime subject to a bosonic bath. The 1CK-2CK QCP is identified via renormalization group technique. The analytical form of the non-linear differential conductance and various critical exponents near this novel QCP are obtained. Our results are relevant for the recent experiment in a dissipative quantum dot via a double-barrier potential.

10:36AM R06.00014: Unconventional superconductivity driven by Kondo-destruction quantum criticality*  
ANG CAI (Presenter), Department of Physics and Astronomy, Rice University, JED PIXLEY, Department of Physics and Astronomy, Rutgers University, KEVIN INGERSENT, Department of Physics, University of Florida, QIMIAO SI, Department of Physics and Astronomy, Rice University — How quantum criticality affects superconductivity is a central issue in strongly correlated systems. Particularly pressing is for the beyond-Landau type quantum criticality, such as appearing in heavy fermion systems in the form of Kondo destruction [1]. This is exemplified by the heavy fermion superconductor CeRhIn5, which has an antiferromagnetic quantum critical point (QCP) accompanied by a sharp Fermi surface reconstruction, and in which d-wave superconductivity develops with a high Tc [2]. Here we address the pairing instabilities near a Kondo destruction QCP by studying the Anderson lattice model using the Cluster Extended-DMFT approach [3]. For extreme Ising anisotropic case, the pairing susceptibility is significantly enhanced near the QCP. Whereas for SU(2) symmetric case, we find superconducting order around the QCP [4]; Tc is comparably high as compared with the observation in CeRhIn5 under optimal pressure. In both cases, we find the paring tendency to be stronger for the Kondo destruction type QCP than for the spin density wave type.

10:48AM R06.00015: Kondo destruction in multipolar order: Implications for heavy-fermion quantum criticality*  
HSIN-HUA LAI (Presenter), Rice University, EMILIAN NICA, University of British Columbia, WENJUN HU, Rice University, SHOUSHU GONG, Beihang University, SILKE PASCHEN, Vienna University of Technology, QIMIAO SI, Rice University — Motivated by the quantum-critical heavy-fermion systems [1,2] exhibiting multipolar orders, we theoretically study an effective field theory of a Kondo lattice model involving both spin and quadrupole degrees of freedom. The field theory contains a quantum non-linear sigma model of the antiferroquadrupolar (AFQ) phase in spin-1 systems, with Kondo couplings to conduction electrons. In the absence of the Kondo coupling, we demonstrate the stability of the AFQ phase using density matrix renormalization group analysis in the underlying spin model. We proceed to analyze the effect of the Kondo couplings, using a mixed fermion-boson renormalization group procedure [3]. We show that the Kondo couplings are exactly marginal, which implies a Kondo destruction in the multipolar phase. Our results provide theoretical basis for the recently advanced notion of sequential Kondo-destruction [1]. Implications of our results for the global phase diagram of the heavy fermion systems are discussed. [1] V. Martelli et al., arXiv:1709.09376. [2] J. Custers et al, Nat. Mater. 11, 189 (2012). [3] S. Session R07 DCMP: Mott Insulators and the Hubbard Model  
BCEC 109B - Bruce Normand, Paul Scherrrer
Institute - Tag(s): Focus
8:00AM R07.00001: Finite-temperature charge dynamics and the melting of the Mott insulator* 

BRUCE NORMAND (Presenter), Paul Scherrer Institute, Switzerland, XING-JIE HAN, RWTH Aachen University, Aachen, Germany, CHUANG CHEN, JING CHEN, HAI-DONG XIE, RUI-ZHEN HUANG, HAI-JUN LIAO, ZI YANG MENG, TAO XIANG, Chinese Academy of Sciences (CAS), China — The Mott insulator is the quintessential strongly correlated electronic state. A full understanding of the coupled charge and spin dynamics of the Mott-insulating state is thought to be the key to a range of phenomena in ultracold atoms and condensed matter, including high-$T_c$ superconductivity. Here we extend the slave-fermion (holon-doublon) description of the two-dimensional Mott insulator to finite temperatures. We benchmark its predictions against state-of-the-art quantum Monte Carlo simulations, finding quantitative agreement. Qualitatively, the short-ranged spin fluctuations at any finite temperatures are sufficient to induce holon-doublon bound states, and renormalize the charge sector to form the Hubbard bands. The Mott gap is understood as the charge (holon-doublon) gap renormalized downwards by these spin fluctuations. With increasing temperature, the Mott gap closes while the charge gap remains finite, causing a pseudogap regime to appear naturally during the process of melting the Mott insulator.

8:12AM R07.00002: Local Density distribution of disordered Bose-Hubbard Model

K HETTIARACHCHILAGE (Presenter), Physics, The Collage of New Jersey, C MOORE, V. G ROUSSEAU ROUSSEAU, KA-MING TAM, MARK JARRELL, J MORENO, Physics, Louisiana State University — We study the local density of the Bose-Hubbard model in the presence of on-site disorder in the canonical ensemble. At incommensurate filling, our findings support the scenario of percolating superfluid clusters enhancing Anderson localization. Scaling analysis of the superfluid density at the incommensurate filling of $\rho=1.1$ and on-site interaction $U=80t$ predicts a superfluid-Bose glass transition at disorder strength of $\Delta_c\sim30t$. At this filling, the local density distribution becomes more skew with increasing disorder strength. In the Bose glass phase, the mode of the local density distribution approaches an integer value as expected from typical medium theory for the Anderson localization. On the other hand, the behavior at commensurate filling is rather different. Close to the tip of the Mott lobe $\rho=1$, $U=22t$ we find a Mott insulator-Bose glass transition at disorder strength of $\Delta_c\sim16t$. An analysis of the local density distribution shows Gaussian like behavior for a wide range of disorders above and below the transition.

8:24AM R07.00003: Resonant Driving induced Ferromagnetism in the Fermi Hubbard Model

NING SUN (Presenter), PENGFEI ZHANG, HUI ZHAI, Tsinghua University — In this letter we consider quantum phases and the phase diagram of a Fermi Hubbard model under periodic driving that has been realized in recent cold atom experiments, in particular, when the driving frequency is resonant with the interaction energy. Due to the resonant driving, the effective Hamiltonian contains a correlated hopping term where the density occupation strongly modifies the hopping strength. Focusing on half filling, in addition to the charge and spin density wave phases, large regions of ferromagnetic phase and phase separation are discovered in the weakly interacting regime. The mechanism of this ferromagnetism is attributed to the correlated hopping because the hopping strength within a ferromagnetic domain is normalized to a larger value than the hopping strength across the domain. Thus, the kinetic energy favors a large ferromagnetic domain and consequently drives the system into a ferromagnetic phase. We note that this is a different mechanism in contrast to the well-known Stoner mechanism for ferromagnetism where the ferromagnetism is driven by interaction energy.

8:36AM R07.00004: WITHDRAWN ABSTRACT

8:48AM R07.00005: The spectral function of Mott-insulating Hubbard ladders: From fractional excitations to coherent quasi-particles

CHUN YANG, ADRIAN FEIGUIN (Presenter), Physics, Northeastern University — We study the spectral function of two-leg Mott insulating Hubbard ladders using the time-dependent density matrix renormalization group method (tDMRG). The spectrum displays features of both spin-charge separation and coherent bound states. As the inter-leg hopping is increased, both spin and hole branches merge into a single coherent quasi-particle band and the spectrum undergoes a crossover from a regime with two incommensurate minima, to one with a single minimum. At the same time, the system shifts from a Mott insulator to a band insulator. Interestingly, while the bonding sector of the spectrum realizes quasi-particles, the anti-bonding one displays a broad low energy scattering continuum, which can be associated to the lack of quasi-particles. We identify the processes leading to quasiparticle formation by studying the time evolution of charge and spin degrees of freedom in real space after a hole is created. At short times, incoherent holons and spinons are emitted but charge and spin quickly form polarons that propagate coherently.
9:00AM R07.00006: The Hall conductivity in correlated electron systems  GEORG ROHRINGER (Presenter), ANTON MARKOV, ALEXEY RUBTSOV, Correlated Quantum Systems, Russian Quantum Center — The Hall conductivity describes the response current perpendicular to the direction of an applied electric field which occurs in many-electron systems exposed to a transverse magnetic field. It has been found that in lattice systems this quantity is typically quantized[1] and corresponds to a topological invariant[2], i.e., the so-called first Chern number. Such an exact correspondence holds for non-interacting systems at zero temperature and the effect of correlations on the quantized Hall conductivity is still unclear. We have calculated the Hall conductivity in the Hubbard model in a magnetic field by means of dynamical mean field theory (DMFT). Within this approach all purely local correlation effects are included by means of a local self-energy. We find that upon increasing the interaction strength between the particles the size of the quantized plateaus of the Hall conductivity is reduced and eventually vanishes. This reduction of the Hall conductivity can be explained by a correlation driven shift of spectral weight to the –otherwise gaped– Fermi level which destroys the exact correspondence to the topological invariant and, hence, the integer quantum Hall effect.

9:12AM R07.00007: Scaling theory for Mott-Hubbard transitions  ANIRBAN MUKHERJEE (Presenter), SIDDHARTHA LAL, Department of Physical Sciences, Indian Institute of Science Education and Research, Kolkata — We present a zero temperature nonperturbative analytical renormalization group (RG) investigation of the electronic Hubbard model in two dimensions on a square lattice. The source of quantum fluctuations in the occupation number of an electronic state is driven by elements of the Hubbard Hamiltonian that are off-diagonal in the Fock representation. Our RG resolves these quantum fluctuations via an iterative scheme involving the unitarily decoupling of an electronic state at every RG step. Stable fixed points of the RG identify effective Hamiltonians associated with various phases as a function of the fluctuation energy scale and doping. We find that the half-filled Mott transition involves passage from a gapless non-Fermi liquid to a gapped Mott liquid through a pseudogapped phase upon lowering the fluctuation scale. Upon doping, we show the collapse of the Mott liquid at a quantum critical point possessing d-wave structure in k-space: a nodal non-Fermi liquid with large superconducting fluctuations, and pre-formed Cooper pairs lying within spin-pseudogapped parts of k-space located away from the nodes. By allowing for symmetry breaking, we find an emergent d-wave superconducting phase surrounding the quantum critical point. This work is available at arXiv:1802.06528.

9:24AM R07.00008: Rectification in Mott-insulator p-n junctions  ZEKUN ZHUANG (Presenter), Brown University, JAIME MERINO, Universidad Autónoma de Madrid, JOHN MARSTON, Brown University — AC currents are typically rectified by semiconducting p-n junctions. Here, we theoretically explore the possibility of realizing a rectifier based on a doped Mott-insulator p-n junction. First, we obtain the time dependence of a dissipationless Mott p-n junction along one-dimensional chains modeled by a Hubbard model and an extended Hubbard model. We numerically integrate the many-body Schrodinger equation in time and show that rectification only occurs when both Coulomb repulsion and inversion symmetry breaking are simultaneously present. We then show how rectification is also captured when the Hubbard interaction is treated within a time-dependent Hartree-Fock (TDHF) approximation. Finally, we analyze the effect of dissipation in the Mott p-n junction by combining the time-dependent Hartree-Fock (TDHF) approximation with the Lindblad equation. This permits investigation of the transport properties of realistic three-dimensional junctions that can be compared to experimental observations.
9:36AM R07.00009: Prediction of Mott insulation and atomic displacements in 3d ABO₃ oxide perovskites without Hubbard U* JULIEN VARIGNON (Presenter), MANUEL BIBES, Unité Mixte de Physique CNRS Thales, ALEX ZUNGER, University of Colorado, Boulder, Colorado — The existence of insulating band gaps in both spin-ordered and disordered phases of 3d ABO₃ perovskite oxides has been traditionally ascribed within the Mott picture to the formation of a two-electron state on a 3d site and an empty 3d site; the separation between these upper-Hubbard and lower-Hubbard states is the interelectronic repulsion U. The observed structural distortions such as bond disproportionation or Jahn-Teller motions appear as secondary effects. The non-spin polarized DFT approach gives zero gap, a result that was used in the literature as a basis to argue that DFT fails. We apply to all ABO₃ 3d perovskites DFT with (i) fully relaxed large supercells (ii) using XC functionals that have small delocalization errors (DFT+U and SCAN without U) and (iii) occupying single partners in degenerate levels. We find DFT even without U capture gapping trends and structural distortions in ABO₃ materials ranging from titanates to nickelates in both AFM and PM phases. Our results thus suggest that dynamical correlations are not playing a universal role in gapping of 3d ABO₃ insulators, and demonstrate that DFT is a viable platform fully able to model their ground states.

9:48AM R07.00010: Mott transitions in a class of solvable models WAYNE ZHENG (Presenter), YUAN-MING LU, Department of Physics, Ohio State University — We construct a class of lattice models, where an electronic superconductor can be driven into a fractionalized Mott insulator by increasing the onsite Coulomb repulsion. We obtain the exact ground states of these models and study their quantum critical phenomena using quantum Monte Carlo simulations.

10:00AM R07.00011: Nature of Mott Insulator in 2D Hubbard Model by Eliashberg Theory* JOSE RODRIGUEZ (Presenter), GEOFANI A MONTOYA, Physics and Astronomy, California State University Los Angeles — We introduce an Eliashberg theory in the particle-hole channel for the Hubbard model over the square lattice that exploits the perfect nesting shown by the Fermi surface at half filling[1]. It results in Eliashberg equations for the wavefunction renormalization 1/Z and for the gap ΔSDW in quasi-particle excitations at half filling. They are solved within the approximation that the corners of the diamond Fermi surface control the physics at half filling. We find that the wavefunction renormalization 1/Z vanishes as (t/U)² at strong on-site repulsion U compared to the hopping matrix element t. By comparison with mean field theory, the SDW gap is accordingly reduced down in size by the wavefunction renormalization to ΔSDW ~ t²/U. In other words, the SDW gap is of order the antiferromagnetic exchange coupling constant J. These results will be checked against direct numerical solutions of the former Eliashberg equations.

*Research supported in part by the AFOSR and the NSF.

10:12AM R07.00012: Local entropies across the Mott transition in an exactly solvable model* LUKE YEO (Presenter), PHILIP PHILLIPS, Physics, University of Illinois at Urbana-Champaign — Spatial entanglement is a natural probe of delocalisation across metal-insulator transitions, but little is known of its behaviour in two or three dimensions near interaction-driven Mott transitions. We address this problem for the exactly solvable Hatsugai-Kohmoto model, whose Mott transition occurs at zero temperature between classically mixed states. We find that both its single-site entropy and its classical entropy density exhibit kinks at the Mott transition, only in one and two dimensions. Although the variation in entropy density across the transition dominates in the thermodynamic limit, the single-site entropy increases even as the degree of classical mixing is decreased. This suggests that the Hatsugai-Kohmoto model maintains quantum-coherent delocalisation even in the presence of classical mixing.

10:24AM R07.00013: Hidden spin current in doped Mott antiferromagnets

WAYNE ZHENG, Department of Physics, Ohio State University, ZHENG ZHU, Department of Physics, Massachusetts Institute of Technology, DONNA SHENG, Department of Physics and Astronomy, California State University, Northridge, ZHENG-YU WENG (Presenter), Institute for Advanced Study, Tsinghua University — We investigate the nature of doped Mott insulators using exact diagonalization and density matrix renormalization group methods. Persistent spin currents are revealed in the ground state, which are concomitant with a nonzero total momentum or angular momentum associated with the doped hole. The latter determines a nontrivial ground state degeneracy. By further making superpositions of the degenerate ground states with zero or unidirectional spin currents, we show that different patterns of spatial charge and spin modulations will emerge. Such anomaly persists for the odd numbers of holes, but the spin current, ground state degeneracy, and charge/spin modulations completely disappear for even numbers of holes, with the two-hole ground state exhibiting a d-wave symmetry. An understanding of the spin current due to a many-body Berry-like phase and its influence on the momentum distribution of the doped holes will be discussed.

10:36AM R07.00014: Doping a 2d Mott insulator – Study of a quantum dimer model

SEBASTIAN HUBER (Presenter), Arnold Sommerfeld Center, Ludwig-Maximilians University, 80333 Munich, Germany, FABIAN GRUSDT, Department of Physics and Institute for Advanced Study, Technical University of Munich, 85748 Garching, MATTHIAS PUNK, Arnold Sommerfeld Center, Ludwig-Maximilians University, 80333 Munich, Germany — Experiments with quantum gas microscopes have started to explore the antiferromagnetic phase of the Fermi-Hubbard model and effects of doping with holes away from half filling1. We show in this talk that the system averaged local two-spin density matrix enables to distinguish magnetically ordered and interesting topologically ordered spin-liquid phases, which might occur in the Hubbard model close to half filling. Fractionalized Fermi liquids (FL*) are a promising candidate for this parameter regime. The generalized quantum dimer model introduced in Ref. [2] is an effective lattice realization of such an FL* with a Hilbert space spanned by configurations of fermionic and bosonic short-range bound states. We construct a rather unconventional dynamical cluster approximation (DCA) by making explicit use of the dimer Hilbert space and show first results of spectral data for a minimal cluster of two lattice sites.

Session R08 DCMP: Non-uniform states in Superconductors

BCEC 150 - Anton Vorontsov, Montana State University, Bozeman

8:00AM R08.00001: Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) State in a Strongly Correlated d-wave Superconductor

ANUSHREE DATTA (Presenter), Indian Institute of Science Education and Research Kolkata, Mohanpur, India-741246, KUN YANG, National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32306, USA, AMIT GHOSAL, Indian Institute of Science Education and Research Kolkata, Mohanpur, India-741246 — The FFLO state is an unconventional superconducting (SC) state found under the influence of the Zeeman field. This is identified by finite center-of-mass momenta in the Cooper pairs which causes the pairing amplitude to modulate in real space. On the other hand, strong repulsion smears out spatial variations in the order parameters. We investigate the effects of strong correlation on the FFLO state in a d-wave superconductor within an integrated framework of Hartree-Fock-Bogoliubov theory and Gutzwiller approximation. Zeeman field causes a superconductor to undergo from BCS to FFLO and finally to a normal state with itinerant magnetism. We find that strong interaction enhances the phase space for the FFLO phase by shifting its boundaries significantly. With strong interaction, the density of states features a significantly sharper mid-gap peak in the FFLO phase creating strongly localized Andreev bound states. We discuss the fate of the FFLO phase in a competing ordered ground state (GS) by considering a GS with d-wave SC and antiferromagnetic (AFM) orders. Upon exposing such a GS to Zeeman field, we find that the FFLO modulation survives along with the AFM order with contrasting spatial features in the presence of strong correlation.
Surface pair-density-wave state and generalisation of Fulde-Ferrell-Larkin-Ovchinnikov state to chiral and nematic superconductors

MATS BARKMAN (Presenter), Theoretical Physics, Royal Institute of Technology, ALEXANDER ZYUZIN, Aalto University, EGOR BABAEV, Theoretical Physics, Royal Institute of Technology — The paramagnetic interaction between the applied magnetic field and the spin of the electrons in a superconductor may lead to the formation of Cooper pairs with non-zero momentum. This results in inhomogeneous superconducting states, breaking translational symmetry, which characterizes the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state. We find that the transition from the FFLO to normal state is not direct. As temperature or applied magnetic field is increased, superconductivity vanishes first in the bulk while the pair-density-waves (PDW) exist on the boundaries. The surface PDW state can exist for significantly larger field and temperature than the FFLO state. I will also discuss generalisation of FFLO states to systems with unconventional pairing. One of the found states is a nematic superconductor where the nematicity vector breaks rotational and translational symmetries due to spontaneous spatial modulation. Another state is a chiral superconductor with spontaneously broken time reversal and translational symmetries, resulting in spatially alternating chirality.

Broken translational symmetry at edges of unconventional superconductors

PATRIC HOLMVALL (Presenter), Chalmers University of Technology, Sweden, ANTON VORONTSOV, Montana State University, Bozeman, MIKAEL FOGELSTROM, TOMAS LOFWANDER, Chalmers University of Technology, Sweden — Flat bands of zero-energy states at edges of $d$-wave superconductors have a topological origin. However, a mechanism that can shift the band to finite energies would lower the free energy, break the initial topological protection, and thereby enable a phase transition. We present results [1] for a second-order phase transition at $T\approx0.2T_c$, where $T_c$ is the superconducting transition temperature, where time-reversal and continuous translational symmetry along the surface are spontaneously broken. The order parameter, the superfluid momentum $p_s$, forms a non-trivial planar vector field with sources and sinks, that satisfies a generalized Poincaré-Hopf theorem, relating the sum of Poincaré indices to the Euler characteristics of the system. We discuss the robustness of this phase against an external magnetic field, mesoscopic surface roughness, and system size. We also present signatures for experimental verification by calorimetry and magnetometry.

*We thank the Swedish Research Council for financial support.

Phase crystallization near surfaces of unconventional superconductors

ANTON VORONTSOV (Presenter), Physics, Montana State University, PATRIC HOLMVALL, TOMAS LOFWANDER, MIKAEL FOGELSTROM, Microtechnology and Nanoscience - MC2, Chalmers University of Technology — We demonstrate that a pairbreaking surface leads to an instability in the phase of the superconducting order parameter. Initially uniform U(1) phase acquires spatial variation, and thus breaks the time-reversal symmetry, below a transition temperature $T^*$ that is only a few times smaller than the bulk $T_c$. The phase modulation appears through a second-order phase transition from the trivial superconducting phase. The most favorable phase distortion occurs at a finite wave vector, thus spontaneously breaking continuous translational symmetry along the surface, and generating periodic superflow and current patterns localized near the surface, which have been previously seen in numerical simulations. We analytically derive the non-local Ginzburg-Landau coefficient that is responsible for this transition, and clarify conditions under which this instability occurs, the reason for the periodic modulation, and the geometry of emerging superflow and current patterns.

*We thank the Swedish Research Council for financial support.
8:48AM R08.00005: Fine structure in the thermal conductivity of unconventional superconductor CeCoIn$_5$ in rotating magnetic field*  
ROMAN MOVSHOVICH, SHIZENG LIN, Los Alamos National Laboratory, DUK YOUNG KIM (Presenter), Institute for Basic Science, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory — Thermal-conductivity measurements are a powerful method of studying superconductivity. Cooper pairs of the condensate do not carry heat, and only unpaired electrons participate in a heat transport. We have measured the thermal conductivity of unconventional superconductor CeCoIn$_5$ in a rotating magnetic field. At a sufficiently low temperature below 100 mK, multiple features, including sharp resonances, are observed in the thermal conductivity as a function of the direction of the magnetic field. This fine structure of thermal conductivity may come from the interaction between the magnetic field and normal electrons in this multiband superconductor. Our measurements represent a new way of studying the superconducting state of a material.

* Work at Los Alamos was supported by the Los Alamos Laboratory Directed Research and Development program.

9:00AM R08.00006: Time-reversal symmetry breaking in superconductors through loop pair-current order*  
SUDEEP GHOSH (Presenter), JORGE QUINTANILLA, School of Physical Sciences, University of Kent, Canterbury, UK, JAMES ANNETT, H. H. Wills Physics Laboratory, University of Bristol, Bristol, UK — We propose a superconducting instability where microscopic loop pair-currents form spontaneously within a unit cell at the critical temperature, $T_c$. Such currents break time-reversal symmetry (TRS) without needing an unconventional pairing mechanism. Using Ginzburg-Landau theory we show how they emerge in a toy model and estimate an upper bound for the resulting magnetisation, which is consistent with recent muon-spin relaxation experiments. We discuss the crystal symmetry requirements and show that they are met by the Re6X (X=Zr, Hf, Ti) family of TRS-breaking, but otherwise seemingly conventional, superconductors.

*We acknowledge support from EPSRC (EP/P007392/1, EP/P00749X/1).

9:12AM R08.00007: Study of inhomogenous superconducting gap in titanium nitride (TiN) films measured by low-temperature STM*  
WAN-TING LIAO (Presenter), Physics, Univ of Maryland-College Park, KEVIN DANIEL OSBORN, ROBERT E BUTERA, Laboratory for Physical Sciences, CHRISTOPHER J LOBB, FREDERICK C WELLSTOOD, Physics, Univ of Maryland-College Park, MICHAEL DREYER, Laboratory for Physical Sciences — Titanium nitride films with low loss and high kinetic inductance show great promise for use in superconducting qubits and resonators. Here we report STM measurements performed at 500 mK on 25 nm and 50 nm thick films of TiN that have been prepared with oxygen. After gentle Ar-ion sputter cleaning of the surface, we observe a topographically rough surface with tip-sample current-voltage (I-V) characteristics that show a superconducting gap. We use both the Dynes model and the Blonder-Tinkham-Klapwijk (BTK) model to fit the I-V data. The Dynes model fits depend upon the superconducting gap and a quasiparticle lifetime (broadening) parameters, while the BTK model depends upon the gap, the temperature and the barrier transparency. Surprisingly, the two models yield strikingly different results and we present evidence that in these samples the BTK model yields the correct physical interpretation.

Spatially modulated superconductivity in CeIrIn$_5$ microstructures

GEORGE FERGUSON (Presenter), Laboratory of Atomic and Solid State Physics, Cornell University, MAJA BACHMANN, Max Planck Institute for Chemical Physics of Solids, FLORIAN THEUSS, Laboratory of Atomic and Solid State Physics, Cornell University, TOBIAS MENG, Institute for Theoretical Physics, Technical University Dresden, CARSTEN PUTZKE, TONI HELM, KENT SHIRER, YOU-SHENG LI, KIMBERLY MODIC, MICHAEL NICKLAS, MARKUS KOENIG, Max Planck Institute for Chemical Physics of Solids, DAVID LOW, SAYAK GHOSH, Laboratory of Atomic and Solid State Physics, Cornell University, ANDREW MACKENZIE, FRANK ARNOLD, ELENA HASSINGER, Max Planck Institute for Chemical Physics of Solids, ROSS MCDONALD, LAUREL WINTER, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory, BRAD RAMSHAW, Laboratory of Atomic and Solid State Physics, Cornell University, PHILIP MOLL, Swiss Federal Institute of Technology in Lausanne, KATJA NOWACK, Laboratory of Atomic and Solid State Physics, Cornell University — We present scanning SQUID microscopy of CeIrIn$_5$ Focused Ion Beam (FIB) defined microstructures. By imaging the diamagnetic response of the microstructure, we identify micrometer scale modulation in the superconducting transition temperature. We find that the rich spatial structure of the superconducting and metallic regions in the device is determined by a strain field generated by the thermal contraction mismatch between CeIrIn$_5$ and the sapphire substrate. By imaging microstructures with different FIB defined features, we demonstrate that the strain field and the geometry of the superconducting regions can be controlled with the FIB. Given that strain can serve as a clean tuning parameter for strongly correlated matter, our experimental approach illustrates a general approach to modulating the electronic properties of these materials on micrometer length scales.

Work at Cornell University was supported primarily by the Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under Award DE-SC0015947 (scanning SQUID imaging, implementation of mK microscope). We also acknowledge funding from the Cornell Center of Materials Research with funding from the NSF MRSEC program under Award DMR-1719875 (SQUID and microscope design).

Topological Behavior of Pair Density Waves on a Kondo-Heisenberg Ladder

RYAN LEVY (Presenter), JULIAN MAY-MANN, BRYAN CLARK, EDUARDO HECTOR FRADKIN, University of Illinois at Urbana-Champaign — The pair density wave (PDW) phase, characterized by an oscillating superconductor order parameter, was proposed as part of the rich phase diagram of certain high temperature superconductors such as LBCO. One model exhibiting this phase in 1D is the Kondo-Heisenberg model (KHM). Past work has predicted that the PDW phase is topological, hosting protected edge modes. Using the density matrix renormalization group (DMRG), we explicitly illustrate the topological properties of the PDW phase of the KHM on finite systems. In particular, we show the emergence of half spin edge states within the PDW phase.

This research is part of the Blue Waters sustained petascale computing project, which is supported by the NSF (award no. OCI-0725070 & ACI-1238993) and the State of Illinois.

Suppression of superfluid stiffness near Lifshitz-point instability to finite momentum superconductivity

JONATAN WARDH (Presenter), University of Gothenburg, BRIAN ANDERSEN, Niels Bohr Institute, MATS GRANATH, University of Gothenburg — We derive the effective Ginzburg-Landau theory for finite momentum (FFLO/PDW) superconductivity without spin population imbalance from a model with local attraction and a repulsive pair-hopping. We find that the GL free energy must include up to sixth order derivatives of the order parameter, providing a unified description of the interdependency of zero and finite momentum superconductivity. For weak pair-hopping, there is a line of Lifshitz points with a continuous change from zero to finite momentum which for larger pair-hopping is replaced by a bicritical region where pair momentum changes discontinuously. Proximity to a Lifshitz point provides a mechanism for reduced superfluid stiffness and we discuss implications of the model for the cuprate superconductors.

Orbitally limited pair-density wave phase of multilayer superconductors* DAVID MÖCKLI (Presenter), The Hebrew University of Jerusalem, YOUICHI YANASE, Kyoto University, MANFRED W SIGRIST, ETH Zürich — We investigate the magnetic field dependence of an ideal superconducting vortex lattice in the parity-mixed pair-density wave phase of multilayer superconductors. In multilayer systems, due to local inversion symmetry breaking, a Rashba spin-orbit coupling is induced at the outer layers. This combined with a perpendicular paramagnetic limiting magnetic field stabilizes a layer dependent pair-density wave phase in the superconducting singlet channel. The high-field pair-density wave phase is separated from the low-field BCS phase by a first-order phase transition. The motivating guiding question in this paper is: what is the minimal necessary Maki value for the appearance of the pair-density wave phase of a superconducting trilayer system? To address this problem we generalize the circular cell method for the regular flux-line lattice of a type-II superconductor to include paramagnetic depairing effects. Then, we apply the model to the trilayer system, where each of the layers are characterized by Ginzburg-Landau parameter, and a Maki value. We find that when the spin-orbit Rashba interaction compares to the superconducting condensation energy, the orbitally limited pair-density wave phase stabilizes for Maki values above 10.

Mass hierarchy in collective modes of pair-density-wave superconductors SHAOKAI JIAN (Presenter), Tsinghua University, MICHAEL M SCHERER, Institute for Theoretical Physics, University of Cologne, HONG YAO, Tsinghua University — We study collective modes near the quantum critical point of a pair-density-wave (PDW) superconductor in 2+1 dimensions. The fate of gaps of various collective modes is investigated by functional renormalization. For incommensurate PDW superconductors, we show that the gapless Leggett mode, protected by the emergent U(1) symmetry, can induce an exponentially small Higgs mass compared to the superconducting gap. Further, for commensurate PDW superconductors, we find an emergent mass hierarchy in the collective modes, i.e., the masses of Leggett boson, Higgs boson, and the superconducting gap can differ by several magnitudes in the infrared. This may shed light to a mechanism underlying the hierarchy problem in the Standard Model of particle physics.

Study of over-doped thin film LSCO with scanning squid microscopy* RUBY SHI (Presenter), CAROLINA ADAMO, JOHN ROBERT KIRTLEY, Stanford University, J. STEVEN DODGE, Physics, Simon Fraser University, KATHRYN ANN MOLER, Stanford University — The high-temperature superconductor cuprates, with their complex phase diagram, offer an intriguing playground for testing new theories. It has recently been proposed that homogeneous, intermediate-strength disorder is responsible for several previously unexplained features of the superfluid density in the overdoped cuprates [1]. To test the validity of this picture, we have characterized the spatial homogeneity of zero-frequency superfluid density using scanning-SQUID microscopy. We performed simultaneous magnetometry and susceptometry scans of various-doped LSCO epitaxially grown on LSAO by MBE. We observed higher than expected critical temperature (45K for x=0.23) and spatial inhomogeneity of superfluid density (variation by a factor of 10 across 3mm). Therefore, local variation of superfluid density in these LSCO thin film samples has to be taken into account for future experiments.

Inhomogeneous superconductivity in PdTe2* GOUTAM SHEET (Presenter), ANSHU SIROHI, SHEKHAR DAS, AMIT VASHIST, Indian Institute of Science Education and Research, Mohali, PRIYO ADHIKARY, Indian Institute of Science, Bangalore, SIRSHENDU GAYEN, RAJESWARI ROY CHOWDHURY, YOGESH SINGH, Indian Institute of Science Education and Research, Mohali, TANMOY DAS, Indian Institute of Science, Bangalore — PdTe2 is a type II Dirac semimetal which also shows superconductivity below 1.7 K. We have performed scanning tunneling microscopy and spectroscopy on single crystals of PdTe2 and have shown that despite such unique co-existence of Dirac physics and superconductivity, the superconducting phase of PdTe2 is conventional in nature. As revealed by our magnetic field dependent STM experiments, the single crystals of PdTe2 display a type I-like behavior at certain points and type-II like behavior at certain other points. We will discuss the details of this inhomogeneous superconducting phase and comment on its relationship with the intrinsic electronic inhomogeneity that was also detected in the normal state of PdTe2.

Local versus Global Superconductivity in Atomic Layer Indium on Si(111)*

MENGKE LIU (Presenter), HYOUNGDO NAM, JUNGDAE KIM, CHIH-KANG SHIH, University of Texas at Austin — Superconductivity at the two-dimensional limit has attracted intense interest, and monolayer Indium on Si(111) provides a perfect platform for investigating this fascinating phenomenon. To better understand the role of defects in superconductivity, we studied superconducting monolayer Indium films by tailoring the step density of the substrate. We probed the superconductivity microscopically using scanning tunneling microscopy and spectroscopy. The macroscopic superconducting properties of the same sample were also probed using in-situ double coil mutual inductance measurements to determine the superfluid density and the transition temperature (Tc). By establishing local and global Tc correspondence, we uncover the intriguing nature of 2D superconductivity in indium atomic layer superconductors.

Session R09 DCMP: Superconductivity: Proximity Effect and Josephson Junctions II BCEC 151A

8:00AM R09.00001: Ground-state Phase Oscillations in Josephson Junctions Containing Iron* ALEXANDER MADDEN (Presenter), BEN BYRD, REZA LOLOEE, NORMAN OWEN BIRGE, Physics and Astronomy, Michigan State University — Ferromagnetic Josephson junctions with a controllable ground-state phase difference are now well-established as a potential system for cryogenic memory applications. Many recent demonstrations of this phase control have used nickel as a fixed layer, with the phase controlled by the relative orientation of a magnetically soft layer. While nickel is a hard ferromagnet that allows high transmission of supercurrent, its multidomain structure and stray field have been obstacles to implementation in devices. Iron is another hard ferromagnet that has been investigated in S/F/S Josephson junctions and shown to undergo 0 – π phase oscillations with thickness [1]. We present a further investigation of iron Josephson junctions and their potential for use as memory devices. SQUID magnetometer measurements show that iron grown on a copper buffer layer gives a narrower magnetic transition and thinner magnetic dead layer than if grown directly on niobium. We also present junction transport measurements showing the critical current and 0 – π phase oscillations for a range of iron thickness grown on a 2nm copper buffer.

*This research is based upon work supported by the ODNI, IARPA, via ARO contract number W911NF-14-C-0115.

8:12AM R09.00002: Appearance of above the gap resonances in dirty Josephson junctions with epitaxial contact* SHAHRZAD ZARE (Presenter), WILLIAM ANDREW MAYER, FOSTER H SABATINO, Physics, New York University, CODY YOUMANS, Physics, City College of City University of New York, KAUSHINI WICKRAMASINGHE, JOSEPH YUAN, MATTHIEU DARTAILH, Physics, New York University, AARON SOMOROFF, POUYAN GAEMI MOHAMMADI, Physics, City College of City University of New York, JAVAD SHABANI, Physics, New York University — In Josephson junctions, when the separation of the superconducting contacts is made long enough, the system can be approximated with two superconducting-normal metal junctions connected with a normal link. In devices fabricated on InAs-Al materials, we observe oscillations of conductance with driving bias above the superconducting gap. The frequency of conductance oscillations as a function of the bias is determined by the geometric properties of the junction. We interpret these geometric oscillations (GO) in interference of quasi-particles with energies above the superconductivity gap. This can be compared with a simple quantum mechanical problem involving a particle in the box where the states with energy above the box wall solely gain a phase shift as they pass over the box potential. In the case of GO the variation of the superconducting gap size affect the phase of the quasi-particles as they pass through. We compare our data with our theoretical model and find agreement in dependence of the data to bias, magnetic field and temperature.

8:24AM R09.00003: Pair tunneling in La_{2-x}Sr_xCuO_4 junctions above T_c

PANPAN ZHOU (Presenter), LIYANG CHEN, Physics and Astronomy, Rice University, YUE LIU, Physics, Beijing University, ANTHONY TRAVIS BOLLINGER, XI HE, Condensed Matter Physics & Materials Science, Brookhaven National Lab, ILYA SOCHNIKOV, Physics, University of Connecticut, IVAN BOZOVIC, Condensed Matter Physics & Materials Science, Brookhaven National Lab, DOUGLAS NATELSON, Physics and Astronomy, Rice University — High temperature superconductivity remains challenging more than thirty years after its initial discovery. One of the most captivating ongoing debates is about the mechanism and the normal state above the critical temperature. Various experiments imply paired charge carriers persisting above the transition temperature T_c, but without direct signatures of pairing. Shot noise, the intrinsic current fluctuations that result from the discreteness of current-carrying excitations, probes the magnitude of the charge of carriers. We report measurements on the shot noise of the tunneling current in c-axis epitaxial structure of La_{2-x}Sr_xCuO_4/La_2CuO_4/La_{2-x}Sr_xCuO_4 for several doping levels. At temperatures far above T_c, the shot noise agrees quantitatively with independent tunneling of carriers with charge magnitude $e$.

Approaching but still above T_c, the noise exceeds the expectations of single charge tunneling, indicating pairing of carriers. Well below T_c the noise is greatly enhanced within the bias region of the superconducting gap, consistent with multiple Andreev reflection processes.

8:36AM R09.00004: Infrared and THz Optical Nanoscopy of High-Tc Superconductor Devices

ADRIAN GOZAR (Presenter), QIANBO LU, Applied Physics, Yale University, ANTHONY TRAVIS BOLLINGER, IVAN BOZOVIC, Condensed Matter and Materials Science, Brookhaven National Laboratory — We use cryogenic atomic force microscopy (AFM) combined with scanning near-field optical microscopy (SNOM) to study thin films and nano-constriction devices in La_{2-x}Sr_xCuO_4 high-Tc cuprate superconductors. Using light in the mid-infrared region we demonstrate that our customized AFM-SNOM setup can provide three dimensional dielectric characterization of devices fabricated by tightly focused Helium ion beams. Light demodulation up to the 4th harmonic of the AFM tapping frequency allows us to observe in the dielectric response irradiation induced amorphization effects which extend on length scales that are orders of magnitude larger than the size of the focused ion beam. We ascribe this widespread damage to a Helium depth distribution substantially modified by internal device interfaces. Low-temperature data in the THz range enables detection of superconducting fluctuations in a 13 nm thick La_{2-x}Sr_xCuO_4 film with a superconducting critical temperature T_c ~ 31.5 K. Our results show that AFM-SNOM is a powerful technique for probing and characterizing superconducting interfaces and devices with nanometer scale resolution.

8:48AM R09.00005: Non-vanishing Fraunhofer Pattern in WTe_2 Josephson Junction

YONG-BIN CHOI (Presenter), Department of Physics, Pohang University of Science and Technology, CHUI-ZHEN CHEN, Department of Physics, Hong Kong University of Science and Technology, JINHO PARK, Department of Physics, Pohang University of Science and Technology, GAURAV RANA, Max Plank Institute for Microstructure Physics, HU-JONG LEE, Department of Physics, Pohang University of Science and Technology, MAZHAR ALI, Max Plank Institute for Microstructure Physics, KAM TUEN LAW, Department of Physics, Pohang University of Science and Technology, KIN CHUNG FONG, Quantum Information Processing Group, Raytheon BBN Technologies, GIL-HO LEE, Department of Physics, Pohang University of Science and Technology — WTe_2 is predicted to host Weyl nodes at the contact of electron and hole pockets in a momentum space (Type-II Weyl semimetal) and exhibit novel transport properties. We fabricated proximity Josephson junctions based on mechanically exfoliated WTe_2 layers of thickness around 10-20 nm and studied their Josephson effects under magnetic field. Josephson critical current modulation as a function of perpendicular magnetic field, I_c(\mathbf{B}), (so-called Fraunhofer pattern) exhibited non-vanishing lobes up to ~300 Gauss when Josephson current direction is parallel to a-axis of WTe_2 crystal. This indicates that Josephson current through a-axis of WTe_2 layer has enhanced contribution from the edges of the flake. However, flowing Josephson current parallel to b-axis of WTe_2 resulted in ordinary Fraunhofer pattern. We will discuss about observed anisotropic quantum transport of WTe_2 Josephson junction in regard to its topological nature.
Interestingly, we observe an enhancement in the nonmonotonic dependence of the supercurrent on external pressure in the quantum critical superconductor CeRhIn5. This is a consequence of the interplay between the induced superconducting gap and the spin-orbit coupling in those structures. The high transparency of our contacts can arise from Landau-Zener transitions in our InAs structures.

9:36AM R09.00009: Shapiro steps in InAs-based Josephson junctions with epitaxial Al contacts* MATTHIEU DARTAILLH (Presenter), JOSEPH YUAN, WILLIAM ANDREW MAYER, KAUSHINI WICKRAMASINGHE, DILLON LIU, ADITI MITRA, JAVAD SHABANI, Physics, New York University — Semiconductor-based Josephson junction provide a platform to study the proximity effect and can serve as a platform for the realization of in topological superconductivity. Recently our group has demonstrated the possibility to have a highly transparent contact between the superconductor and the semiconductor by combining InAs high mobility surface 2D-dimensional electron gases with epitaxially grown aluminum. The interplay between the induced superconducting gap and the spin-orbit coupling in those structure is still an on-going field of research. While DC measurements can allow to access the current-phase relation of those structure, some details could be masked by relaxation processes. We utilize microwave radiation on Josephson junctions to unmask the periodicity of the current phase relation. We study Shapiro steps that appear in the IV characteristic of a junction under microwave irradiation. We observe a missing first Shapiro step below 6 GHz that may point to a 4π component in the current-phase relation of those junctions. Similar signatures have been observed in HgTe (in the topological regime) but given the high transparency of our contacts they may arise from Landau-Zener transitions in our InAs structures.

9:48AM R09.00010: Ultrasensitive Calorimetry in an Al/InAs Josephson Junction  RAJ KATTI (Presenter), OLLI SAIRA, MATTHEW MATHENY, MICHAEL ROUKES, Caltech — Calorimetry allows for the detection of single-shot energy pulses over a wide bandwidth. Pushing the limits of energy resolution to the yoctojoule (1e-24 J) regime would allow detection of individual thermal phonons and monitoring of dynamics in open quantum systems. We present work toward development of a Josephson junction-based calorimeter fabricated from an Al/InAs superconductor-semiconductor heterostructure, a material system being developed for scalable topological quantum computation. Ongoing work seeks to demonstrate a device proof-of-principle while simultaneously characterizing fundamental thermal properties of this material system.

10:00AM R09.00011: Unconventional Josephson effect in 2D Josephson junctions based on In0.75Ga0.25As quantum wells  KAVEH DELFANAZARI (Presenter), PENGCHENG MA, University of Cambridge, IAN FARRER, University of Sheffield, DAVID A RITCHIE, HANNAH JOYCE, MICHAEL JOSEPH KELLY, CHARLES G SMITH, University of Cambridge — Here, we report on the discovery of an unconventional Josephson effect in hybrid In0.75Ga0.25As two-dimensional electron gas-Nb junctions that are designed and fabricated for scalable hybrid quantum circuit integration [1-3]. By sweeping the in-plane magnetic field, we observe a completely new type of oscillation mechanism in the differential conductance, that has not been identified before. We find that the differential conductance as a function of source-drain voltage shows two symmetric in-gap resonances, which are strongly temperature and magnetic field dependent. The resonances amplitudes enhance with increasing in-plane magnetic fields up to a critical field where they gradually suppress and disappear. The observed supercurrent also gradually increases with applied magnetic field up to the same critical field. We believe that these striking observed behaviours in our devices-that cannot be explained by the conventional Josephson effect phenomenon-may be related to the context of topological superconductivity in hybrid 2D systems.

10:12AM R09.00012: Effect of Material Quality on Superconducting Proximity Effect in Al-InAs Heterostructures*  KAUSHINI WICKRAMASINGHE (Presenter), Physics, University of Maryland, College Park, WILLIAM ANDREW MAYER, JOSEPH YUAN, Physics, New York University, TRI NGUYEN, Physics, City University of New York, MATHIEU DARTAILH, Physics, New York University, KASRA SARDASHTI, Department of Science and Math, Fashion Institute of Technology, VLADIMIR MANUCHARYAN, Physics, University of Maryland, College Park, JAVAD SHABANI, Physics, New York University — Renewed theoretical and experimental interest in InAs heterostructure with two-dimensional electron systems (2DESs) confined to the surface is partly due to their potential applications in topological and superconducting quantum computation. Here we study Josephson junctions with epitaxial Al-InAs contacts and find large super currents and substantial product of ICRN in our high mobility wafers. We also compare the product of excess current and normal resistance, IexeRN of high mobility samples and low mobility samples. The excess current is negligible in the devices made of lower mobility Al-InAs samples whereas it is substantial and independent of gate voltages and junction length in high mobility sample. For the devices made with high mobility samples, we found that ICRN/Δ~2.2. Further we discuss how the above parameters are linked to the material quality of the samples.

*We acknowledge the support of US Army Office of Research and DARPA.

10:24AM R09.00013: Probing pair-breaking mechanisms in proximity-induced hybrid superconducting interfaces*  KARTHIK RAMAN (Presenter), Hyderabad, Tata Institute of Fundamental Research — Understanding depairing effects in a hybrid-superconducting interface utilizing high spin-orbit materials is an important study in proximity-induced superconductivity. Experimentally, proximity-induced superconductivity is found to suppress at much lower magnetic fields compared to the superconducting layer without a good understanding of its cause. Here, we provide a phenomenological tool to characterize different pair-breaking mechanisms, the ones that break or preserve time reversal symmetry, and show how they affect the differential tunneling conductance response. Importantly, we probe the properties of the SC layer at the hybrid interface and observe conductance peak pinning at zero bias in a larger field range with eventual signs of weak peak splitting. Further, the effect of varying the spin-orbit scattering and the Lande g-factor in tuning the conductance peaks show interesting trends. 

*We would like to thank SERB, DST and DAE, India for supporting our reseach funding.
10:36AM R09.00014: Wavefunction of Andreev bound states with topological Weyl singularity in multi-terminal Josephson junction*  
TOMOHIRO YOKOYAMA (Presenter), Graduate school of Engineering Science, Osaka University, SHIRO KAWABATA, Nanoelectronics Research Institute, National Institute of Advanced Industrial Science & Technology — We theoretically investigate a four-terminal Josephson junction. 
N superconductors can define N-1 independent superconducting phase differences. The spectrum of Andreev bound states (ABSs) in the junction is $2\pi$ periodic in all the phase differences $\{\varphi\}$ and can be regarded as the ``band structure'' in the $\{\varphi\}$-space. In a previous studies, we have exhibited that the band structure can have topologically protected singular points (Weyl points) at zero energy in the spectrum. \footnote{T. Yokoyama and Yu. V. Nazarov, Phys. Rev. B (bf 92), 155437 (2015).} In this study, we investigate the wavefunction of ABSs with and without the Weyl point.

For two-terminal junction, the ABS wavefunction is delocalized to connect the two terminals and does not show any structure except an oscillation associated to the coherence length in the normal region. For multi-terminal case, the wavefunction can be localized between only several terminals. This localization is relevant to the presence and absence of Josephson current between the terminals. At the Weyl points, the spectrum has singularity. We discuss the influence of this singularity on the current and the ABS wavefunction.

10:48AM R09.00015: Reduced Parameter Spread in Arrays of Planar MgB2 Josephson Junctions Made by Focused Helium Ion Beam*  
LEILA KASAEI (Presenter), Temple University, MENGJUN LI, Rutgers University, THOMAS MELBOURNE, Temple University, LEONARD C FELDMAN, TORGNY GUSTAFSSON, Rutgers University, KE CHEN, XIAOXING XI, Temple University — Series arrays of up to 100 planar Josephson junctions on MgB2 film with less than 3 % spread in critical current at 10 K were successfully developed and characterized. This technique uses a 30 keV focused helium ion beam with nominal beam diameter less than 0.5 nm and range of dose from 0.9 to $3 \times 10^{16}$ (Ions/cm²)[1] to locally damage the 25 nm-thick MgB2 thin films grown by hybrid physical-chemical deposition (HPCVD) on SiC substrates to form the junction barriers. A typical single junction has an $I_c R_n$ of 70 μV at 20 K and RSJ-like current-voltage characteristics. Under microwave radiation, flat Shapiro steps up to 150 μA width appear at voltages $V_n = Nn(\Phi_0 f$, where $N$ is the number of junction in the array, $n$ is an integer representing Shapiro step index, and $f$ is the applied microwave frequency. The greatly reduced spread in critical current is a significant improvement over the previous studies. This technique may lead to applications including Josephson voltage standards and arbitrary function generators that can work at around 20 K.

2269 of 3305
8:00AM R10.00001: ARPES of iron-based superconductors: how nematic order sets the stage for magnetic and superconducting ground states in NaFeAs and FeSe [invited] TIMUR KIM (Presenter), Diamond Light Source, MATTWATSON, School of Physics and Astronomy, University of St. Andrews, LUKE RHODES, Department of Physics, Royal Holloway University of London —

Angle-resolved photoemission spectroscopy (ARPES) gives a unique insight into the evolution of the electronic structure of iron-based superconductors. By varying the temperature and doping of the sample, one can investigate all regions of their phase diagrams, including the high-temperature normal state, the magnetic ground state, the so-called nematic state where four-fold symmetry is broken without magnetic order, and the superconducting state. For example, ARPES measurements of FeSe give an exclusive opportunity to investigate the electronic structure in nematic phase without magnetic order. In our measurements, we found substantial shifts of both the electron and hole bands associated with the onset of the nematic order, however the interpretation of these data has caused some controversy due to the formation of twin orthorhombic domains in samples. Our high-resolution ARPES results obtained on FeSe crystals detwinned by application of mechanical strain, reveal remarkable anisotropies hidden in the measurements of twinned samples. We observe that in the nematic phase the Fermi surface consists of one elliptical hole-like pocket and only one orthogonally oriented electron-like pocket. Moreover, we find the same effect in detwinned NaFeAs samples where the spectral weight from only one elliptical electron pocket is detected in the nematic phase.

Finally, we use synchrotron-based high-resolution ARPES to map the 3D momentum dependence of the superconducting gap in FeSe. We find that on both the hole and electron Fermi surfaces, the gap is highly anisotropic, with its magnitude following the distribution of \( d_{yz} \) orbital weight on each pocket. We show that this anisotropic gap structure can be naturally reproduced from theoretical calculations only when the one-electron pocket state, observed in the nematic phase, is taken into account. These results support the spin fluctuation mediated mechanism of superconductivity in FeSe.

8:36AM R10.00002: Characterizing the nematic phase in Ba122 iron arsenides with a SQCRAMscope FAN YANG (Presenter), STEPHEN TAYLOR, JOHANNA PALMSTROM, STEPHEN D EDKINS, IAN R FISHER, BENJAMIN LEV, Stanford University — Microscopic imaging of local magnetic fields provides a window into the organizing principles of complex and technologically relevant condensed matter materials. However, a wide variety of strongly correlated and topologically nontrivial materials exhibit poorly understood phenomena outside the detection capability of state-of-the-art high-sensitivity, high-resolution scanning probe magnetometers. We have recently introduced the Scanning Quantum Cryogenic Atom Microscope (SQCRAMscope), a quantum-noise-limited scanning probe magnetometer that can operate from room-to-cryogenic temperatures. By employing a magnetically levitated atomic Bose-Einstein condensate (BEC) that can be scanned near the surface of a cryogenically cooled material, the microscope achieves unprecedented DC-field sensitivity at micron-scale resolution. Combining this unique probe with optical polarimetry, we present recent work on characterizing the nematic phase transition in unstrained Ba122 iron-based superconductors. Domain structure is visualized through spatial mapping of the current density, from which resistivity anisotropy is extracted as a proxy for the nematic order parameter. The temperature dependence of nematicity is studied and compared to optical polarimetry results from the same sample.

8:48AM R10.00003: Observation of orbital ordering and origin of nematic order in FeSe* GUOQING WU (Presenter), RONGXING CAO, XIANGHUA ZENG, Y. F. XU, Yangzhou University, QIULIANG WANG, Chinese Academy of Science, BING WU, Fayetteville state University — Nematic order has being found to widely exist in the cuprates and in the Fe-based superconductors in most recent years. It is directly linked to the superconductivity because nematic instability is a characteristic feature of the normal state upon which at lower temperatures the superconductivity emerges. FeSe has been regarded as a model system for the study of the Fe-based superconductors. But it is highly controversial as to whether the nematic order is driven by spin order, AFM spin fluctuations, and/or orbital order. Here we report the experimental result of field-dependent \(^{77}\text{Se-NMR}\). Our results shows for the first time that the difference of the static internal field in the \( ab \)-plane in the orthorhombic phase at the Se-nucleus is predominantly from the Fe-ion 3d electron orbitals (essentially all orbital), not from the electron spins, and gain AFM spin fluctuations are gradually developed below \( T \sim 40 \text{ K} \) in the orthorhombic phase, which is far below the nematic order/structure phase transition temperature \( T_{\text{nem}} = T_{\text{s}} = 89 \text{ K} \), while AFM spin order is absent at all temperatures and at all fields. Therefore, for the first time we provide direct evidence that orbital ordering is unequivocally the origin of the nematic order in FeSe.

9:00AM R10.00004: Single Crystal Diffuse Scattering Investigation of Nematic Fluctuations in (Ba,Na)Fe$_2$As$_2$* 
RAYMOND OSBORN (Presenter), MATTHEW KROGSTAD, STEPHAN ROSENKRANZ, Materials Science Division, Argonne National Laboratory, OMAR CHMAISSEM, PUSPA R UPRETI, RYAN STADEL, Department of Physics, Northern Illinois University, KEITH TADDEI, Neutron Scattering Division, Oak Ridge National Laboratory — The phase competition between nematic order and superconductivity has been intensively investigated in iron-based superconductors. Recent neutron pair-distribution-function (PDF) measurements on polycrystalline samples provide evidence of dynamic orthorhombic distortions, even within the C$_4$ tetragonal magnetic phase of hole-doped compounds [1]. We present synchrotron x-ray measurements of diffuse scattering from single crystals of (Ba,Na)Fe$_2$As$_2$, which show that these nematic fluctuations are predominantly two-dimensional. The measurements cover a sufficiently large volume of reciprocal space that they can be transformed into real space, generating 3D PDFs, from which both in-plane and out-of-plane correlation lengths are determined as a function of temperature and dopant concentration. These results will be compared to other measurements of the nematic susceptibility.

*This work was supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division.

9:12AM R10.00005: Quantum critical nematic fluctuations and spin excitation anisotropy in the iron pnictides* 
ELIHU ABRAHAMS (Presenter), University of California, Los Angeles, CHIA-CHUAN LIU, QIMIAO SI, Rice University — Quantum criticality in the iron pnictides involves the nematic and antiferromagnetic channels in a concurrent way [1,2]. To elucidate the nematic correlations, we study the spin excitation anisotropy defined by the difference between the dynamical spin susceptibilities at (π,0) and (0,π) [3]. We consider an effective Ginzburg-Landau theory involving spin and Ising-nematic degrees of freedom [1,2] in the presence of a small external C4-symmetry-breaking potential. Our analysis is carried out in a large N limit [2]. We establish a relation among the spin excitation anisotropy, the dynamical spin susceptibility and the nematic susceptibility, and then show how it can be used to extract the information of the nature of the quantum critical point. The relation we establish provides a means to understand the singular energy dependences observed for the spin excitation anisotropy in the avoided quantum critical regime of the optimally Ni-doped BaFe$_2$As$_2$ under a uniaxial strain. We also propose a mechanism accounting for these singular energy dependences.

9:24AM R10.00006: Origin of diverse nematic orders in Fe-based superconductors: 45 degree rotated nematicity in AFe$_2$As$_2$ (A=Cs, Rb) 
HIROSHI KONTANI (Presenter), SEIICHIRO ONARI, Nagoya University — The origin of nematicity and their order parameters in strongly correlated superconductors have been attracting increasing attention. Both the orbital order without magnetization in FeSe and d-wave bond order in cuprate superconductors are satisfactorily explained based on the spin-fluctuation-driven mechanism [1-3]. Recently, new type nematic order has been discovered in heavily hole-doped (n$_d$ = 5.5) compound AFe$_2$As$_2$ (A = Cs, Rb). The discovered nematicity has B$_{2g}$ symmetry, rotated by 45 degrees from the B$_{1g}$ nematicity in usual Fe-based superconductors. To reveal the origin of B$_{2g}$ nematicity, we analyze the spontaneous symmetry-breaking in the self-energy [2] based on the multiorbital Hubbard model. We predict that the ”nematic bond order”, given by the symmetry-breaking in the d$_{xy}$ orbital correlated hopping, is responsible for the B$_{2g}$ nematic order in AFe$_2$As$_2$. It is concluded that not only conventional B$_{1g}$ orbital order (n$_{x^2-y^2}$ ≠ n$_{xy}$), but also B$_{2g}$ bond order with respect to d$_{xy}$ orbital in AFe$_2$As$_2$ are caused by the same mechanism, that is, the charge-spin mode-coupling due to the Aslamazov-Larkin vertex correction. [1] S. Onari et al., PRL 116, 227001 (2016). [2] Y. Yamakawa et al., PRX 6, 021032 (2016). [3] M. Tsuchiizu et al., PRB 97, 165131 (2018).
9:36AM R10.00007: Orbital-selective superconductivity in the nematic phase of FeSe*  HAOYU HU (Presenter), Department of Physics and Astronomy, Rice University, RONG YU, Department of Physics, Renmin University of China, EMILIAN NICA, Department of Physics, Arizona State University, JIAN-XIN ZHU, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, QIMIAO SI, Department of Physics and Astronomy, Rice University — The considerations of the orbital-selective Mott physics in the normal state [1,2] motivated the theoretical proposal for orbital-selective pairing [3]. The experimental evidence for the latter has come from both the iron pnictides [4] and iron selenides [5]. We study the superconductivity in the presence of nematic order in a multi-orbital model with frustrated spin-exchange interactions [6]. We found that the electron correlation effects amplified by the nematic order [7] give rise to an enhanced orbital-selective pairing. The latter produces a large gap anisotropy on the Fermi surface which naturally explains the experimental observations.

*DOE BES Award # DE-SC0018197

9:48AM R10.00008: Basic principles of disorder-induced electronic nematicity  PANAGIOTIS KOTETES (Presenter), Niels Bohr Institute & ITP-CAS, DANIEL STEFFENSEN, Niels Bohr Institute, INDRANIL PAUL, Universite Paris Diderot-Paris 7 & CNRS, BRIAN M. ANDERSEN, Niels Bohr Institute — Resolving the phenomenon of nematicity, i.e., the breaking of fourfold-rotational (C4) symmetry, remains an outstanding problem in the field of iron-based superconductors. A wide range of techniques have provided experimental evidence for electronic nematic behavior, while more recently, the nucleation of local nematicity around impurities has been also detected. While some of these results may be attributable to residual sample strain, the possible induction of local nematicity due to disorder appears as a prominent and, at the moment, a poorly-explored phenomenon. To shed light on this physics, we perform a detailed theoretical study of the role of disorder in systems exhibiting an electronic nematic instability, with an emphasis on temperatures above the critical temperature at which the spontaneous C4-symmetry breaking sets in. We employ both a phenomenological Ginzburg-Landau theory, as well as a microscopic model, and identify the spatial profile generated by a disorder configuration which either respects or explicitly breaks the fourfold rotational symmetry. In the former case, we find that while such a potential cannot induce net nematicity, it still modifies the Stoner criterion for the nematic instability, thus, generally enhancing the nematic critical temperature.

10:00AM R10.00009: Emergent XY-nematic fluctuations in heavily-hole doped iron-based superconductors  KOUSUKE ISHIDA (Presenter), MASAYA TSUJII, SUGURU HOSOI, YUTA MIZUKAMI, Univ of Tokyo-Kashiwanoha, SHIGEYUKI ISHIDA, AKIRA IYO, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, KAI GRUBE, THOMAS WOLF, HILBERT LOEHNEYSEN, Karlsruhe Institute of Technology, RAFAEL M FERNANDES, University of Minnesota, TAKASADA SHIBAUCHI, Univ of Tokyo-Kashiwanoha — Electronic nematicity, rotational symmetry broken state originating from electronic mechanism, has been identified in several strong correlated systems. However, in contrast to its liquid crystal counterparts, the director of electronic nematic domains cannot point in an arbitrary direction (XY- nematic), but is confined to specific directions via non-negligible coupling to the lattice (Ising-nematic). Here we report the elastoresistance measurements in Ba1-xRbxFexAs2 and CsFexAs2, which can evaluate the nematic fluctuations from the change in the resistance induced by uniaxial strain. In RbFexAs2 and CsFexAs2, we found that B1g nematic fluctuations is more significant than B2g nematic fluctuations, providing the evidence for the nematicity along Fe-As direction in these compounds, 45 degree rotated from the unusual nematicity along Fe-Fe direction in the underdoped region. Furthermore, for the intermediate doping between these two distinct Ising-nematic phase, B1g and B2g nematic fluctuations exhibit identical Curie-Weiss behaviors, revealing that nearly XY-nematic fluctuation regime. This observation opens up a new route to realizing the novel electronic liquid crystal state in iron-based superconductors.
Nematic fluctuations close to quantum criticality: a new method for comparing simulations and experiments*

DANIEL JOST (Presenter), Walther Meissner Institute for Low Temperature Research, SAMUEL LEDERER, Cornell University, THOMAS U BOEHM, Walther Meissner Institute for Low Temperature Research, YONI SCHATTNER, Stanford Institute for Material and Energy Science, EREZ BERG, Chicago University, STEVEN KIVELSON, Stanford University, RUDOLF HACKL, Walther Meissner Institute for Low Temperature Research — The comparison of numerical simulations and spectroscopic results is notoriously difficult because of the analytic continuation in the complex energy plane. In addition to the analytic continuation, lifetime and mass enhancement factors must be extracted from the experimental spectra using, e.g., Kramers-Kronig transformation with the well-known problems resulting from the extrapolations to low and high energies. One way out of this dilemma is a transformation of the experimental results from real to imaginary frequencies which provides us with an imaginary-time-ordered correlation function $\Lambda(\tau)$. For determining $\Lambda(\tau)$, the cutoff is much faster. From this transformation, one can extract the quantity $\beta \Lambda(\beta/2)$ with $\beta=1/k_B T$. We show in this contribution how this quantity can be derived from the electronic Raman spectra of the iron pnictide Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ and varies with doping and temperature. We compare the results with those obtained via the Kramers-Kronig formalism at zero frequency. Additionally, we highlight the perspectives of this method with view on quantum criticality and the comparison of experiment and theory.

The anomalous high magnetic field electronic state of the nematic iron-based superconductor FeSe$_{1-x}$S$_x$*

MATT BRISTOW (Presenter), PASCAL REISS, Physics, University of Oxford, Clarendon Laboratory, Parks Road, Oxford, OX1 3PU, U.K, AMIR HAGHIGHIRAD, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany, ALIX MCCOLLAM, High Field Magnet Laboratory (HFML-EMFL), Radboud University, 6525 ED Nijmegen, The Netherlands, WILLIAM KNAFO, Laboratoire National des Champs Magnétiques Intenses (LCMM), CNRS-UIF-UPS-INSA, Toulouse, France, AMALIA COLDEA, Physics, University of Oxford, Clarendon Laboratory, Parks Road, Oxford, OX1 3PU, U.K — Superconductivity is closely linked to the electronic states from which it emerges. Here we investigate the normal electronic state of the nematic superconductor FeSe$_{1-x}$S$_x$ using magneto-transport and Hall Effect studies in magnetic fields up to 35 T (Nijmegen) and 70 T (Toulouse) over a large temperature range. Inside the nematic phase we find anomalous magneto-resistivity behaviour in very high magnetic fields, well above the upper critical field. The behaviour changes outside the nematic phase, where we show that at low temperatures Fermi-liquid behaviour is recovered. We account for the multiband structure and trace the carrier densities and motilities across the nematic phase transition. We also investigate the regime of superconducting fluctuations, which is expected to varying significantly in this isoelectronic series. We will discuss our results in relation to both Fermi liquid and non-Fermi liquid behaviour, and superconducting fluctuations.

*This work was support by the Engineering and Physical Sciences Research Council (EPSRC, UK) (EP/I004475/1, EP/I017836/1, EP/M020517/1, EP/N01085X/1). Part of this research was also supported by the Oxford Centre for Applied Superconductivity (CFAS) and the John Fell Fund of the Oxford University.

Charge order and structural evolution in nematic superconductor Ba(0.33)Sr(0.67)Ni$_2$As$_2$

JOHN COLLINI (Presenter), CHRISTOPHER ECKBERG, Center for Nanophysics and Advanced Materials, University of Maryland College Park, SANGJUN LEE, STELLA SUN, PETER ABBAMONTE, University of Illinois Urbana-Champaign, JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, University of Maryland College Park — Recent discoveries of charge order in the cuprates and electron nematic order in the iron-based superconductors has pointed towards the possibilities of both orderings being tied to mechanisms of high Tc superconductivity. The (Ba,Sr)Ni$_2$As$_2$ superconducting system has very recently been shown to exhibit both types of ordering without the presence of any magnetic order. Through single crystal x-ray diffraction reports, the Ba parent compound shows the emergence of an incommensurate charge density wave (CDW) before transitioning from a tetragonal structure to a triclinic structure with the emergence of a new commensurate triclinic CDW. We report single crystal x-ray observations how the charge order and structure of the system has evolved up through a Sr concentration of $x=.67$, just before the complete extinction of the triclinic phase and maximal superconducting Tc.

Session R11 DCMP: 2D Materials and Heterostructures BCEC 152 - Oscar Avalos Ovando, Ohio University
8:00AM R11.00001: A first-principles study of the ferroelectricity of two-dimensional IV-VI group compounds
FEN XIONG (Presenter), Department of Mechanical Engineering, The University of Hong Kong, XILIN ZHANG, College of Physics and Materials Science, Henan Normal University, ZHEN LIN, YUE CHEN, Department of Mechanical Engineering, The University of Hong Kong — Two-dimensional (2D) ferroelectric materials with atomic thickness have attracted much research interest due to their potential industrial applications. The recent successful synthesis of 2D SnTe, which exhibits a spontaneous polarization along the in-plane directions, motivates further studies of the related 2D IV-VI group compounds. In this work, we focus on the theoretical calculations of the stability and ferroelectricity of 2D IV-VI compounds based on density functional theory (DFT) and the Berry phase method. Firstly, the energies of the competing 2D crystal structures of the IV-VI compounds have been computed from DFT; it is found that different structures are adopted by the 2D IV-VI compounds. To facilitate the engineering of the crystal structure, the alloying effects on the phase stability and the corresponding electronic origins have been further studied. Secondly, the spontaneous polarization is calculated using the Berry phase approach, and it is found that some of the 2D IV-VI compounds have more robust ferroelectricity than others. Moreover, the manipulation of spontaneous polarization via external strain has also been discussed.

8:12AM R11.00002: Van der Waals induced rippling and anisotropy in the natural superlattice Franckeite
PABLO SAN-JOSE, RICCARDO FRIENDA, ICMM-CSIC, Consejo Superior de Investigaciones Científicas, IOANNA URBAN (Presenter), MICHAL BARANOWSKI, Laboratoire National des Champs Magnétiques Intenses, NIKOS PAPADOPOULOS, HERRE S.J. VAN DER ZANT, TU Delft, GABRIEL SÁNCHEZ-SANTOLINO, MAR GARCÍA-HERNÁNDEZ, ICMM-CSIC, Consejo Superior de Investigaciones Científicas, PAULINA PLOCHOCKA, Laboratoire National des Champs Magnétiques Intenses, ANDRES CASTELLANOS-GOMÉZ, ICMM-CSIC, Consejo Superior de Investigaciones Científicas — Franckeite, a naturally occurring van-der-Waals hetereostructure, is composed of alternating pseudohexagonal and pseudotetragonal two-dimensional layers. While both types of layers are in principle mechanically and electrically isotropic in the plane, Franckeite, like its cousin Cylindrite, exhibits a characteristic rippling pattern, the origin of which has remained unclear. Here we show, using continuum elasticity theory, that rippling is ultimately the result of a mechanical instability produced by a one-dimensional moiré superlattice forming in Franckeite's interlayer alignment. We also show that the ripples give rise to marked anisotropies in the electrical and optical sectors, as measured by differential reflectance, polarised Raman spectroscopy and electrical transport measurements. This picture connects the properties of bulk Franckeite to the basic mechanisms governing low-angle moiré multilayers, such as twisted graphene bilayers.

FIS2015-65706-P, FJCI-2015-25427).

8:24AM R11.00003: Layer Dependent MCD on Van der Waal-like 2D ferromagnetism
YU-CHE CHIU (Presenter), ZHENGUANG LU, National High Magnetic Field Laboratory, DANIEL A RHODES, Columbia University, YUXUAN JIANG, DMITRY SMIRNOV, National High Magnetic Field Laboratory, JAMES HONE, Columbia University, LUIS BALICAS, National High Magnetic Field Laboratory — The layered ferromagnetic semiconductor CrSiTe3 is a promising candidate for spintronic applications. According to DFT calculations, its bulk bandgap is predicted to be ~0.4 eV; meanwhile, a Curie temperature of ~33 K was reported, thus providing evidence for bulk ferromagnetism. More importantly, due to the van der Waal-like interlayer coupling, CrSiTe3 is exfoliable and possible to achieve monolayers through mechanical exfoliation making it appealing for 2D spintronics. However, the fundamental properties of CrSiTe3 have not been thoroughly studied, particularly in the few layers limit. A number of of theoretical reports, suggest that the monolayer could have a larger bandgap but the presence of magnetism is still debatable (FM or AFM order). Nonetheless, among these predictions, the common agreement is that the decisive factor causing FM- or AFM-exchange coupling is the distance between Cr-Te-Cr bonds, which indicates that the spin configuration is closely related to the lattice. Therefore, in order to study the presence of magnetism and to understand the role spin-phonon interaction, we performed layer-dependent magnetization measurements via the magnetic circular dichroism (MCD) and Raman spectroscopy at different Ts.

8:36AM R11.00004: Strain induced half-semiconductor to half-metallic transition in 2D magnet CrI3: A DFT approach
TISTA MUKHERJEE, Presidency University, SUMAN CHOWDHURY (Presenter), Bangabasi College, DEBNARAYAN JANA, University of Calcutta, LOK LEW YAN VOON, University of West Georgia —
In this work, compressive and tensile strain (uniaxial as well as biaxial) upto 12% have been applied to study the variation of the electronic and magnetic properties of CrI3 employing density functional theory in (LDA+U) exchange correlation scheme. The stability limits of the structures under the influence of strains have been carried out via the deformation potential and stress-strain relation. Using appropriate strains, the pristine half-semiconducting nature can be tuned to observe half-metallicity. Further, the indirect band gap in the half-semiconducting phase can be increased by the application of tensile strain. The magnetic moment computed from the density of states is enhanced significantly under the influence of compressive strain. However, it has been observed that after the application of strain in some specific crystal directions, the magnetic moment of monolayer CrI3 remains almost unchanged. Thus, with the help of strain, the tuned half-metallicity along with underlying characteristic ferromagnetism of this material can unfold a new avenue for potential usage in spintronic devices.

8:48AM R11.00005: Emission of Geometrically Modulated Monolayer Semiconductors*
I-TUNG CHEN (Presenter), CHUN AN CHEN, TUNG-HAN YANG, KUAN-CHANG CHIU, YING-YU LAI, YI-HSIEN LEE, National Tsing Hua University —
Emission, including light and electrons, of the monolayer 2D lattices offers significant scientific interests in materials sciences and potential optoelectronics applications. However, monolayers of transition metal dichalcogenides (TMDs) exhibit reduced efficiency on optical emission and electron field emission. Here, emission of the geometrically modulated monolayer semiconductors suspended with 1D nanoarrays is demonstrated. Synthesized TMD monolayers offer an ideal platform to explore the fundamental process of the emission of the TMD. Geometrical modulation and charge transfer of the semiconducting monolayers can be significantly tuned with the structural suspension with nanoarrays.

*We acknowledge support from AOARD grant (co-funded with ONRG) FA2386-16-1-4009, Ministry of Science and Technology (MOST-105-2112-M-007-032-MY3, MOST-106-2119-M-007-027), and Academia Sinica Research Program on Innovative Materials and Analysis Technology Exploration (AS-iMATE-107-11), Taiwan.

9:00AM R11.00006: Barrier tunneling for the dice lattice under linearly-polarized light
DIPENDRA DAHAL (Presenter), CUNY Graduate Center, GODFREY GUMBS, Physics and Astronomy, Hunter college, CUNY, ANDRII IUROV, DANHONG HUANG, Physics, University of New Mexico —
We have investigated electron tunneling across a square barrier under external off-resonance dressing fields in α-T3 lattices with variable interatomic coupling parameter α which yields the dice lattice limit (or T3 material) when α = 1. Our results show strong dependence on both the parameter α and the polarization of the imposed irradiation. In the absence of the irradiation, the low-energy pseudospin-1 Dirac-Weyl Hamiltonian which gives an energy spectrum consisting of a pair of Dirac cones and a dispersionless (at) band in the K and K' valleys is employed for these calculations. For the case of linearly-polarized dressing field, an asymmetric, or non-head on Klein tunneling has been discovered. We explore the dependence of Klein tunneling through rectangular electrostatic barriers as the irradiation intensity varies continuously. However, complete transmission is no longer observed for α ≠ 1 under all types of incident light polarization.
In this talk, we will highlight that nonreciprocity and mechanical motion are deeply intertwined. We will discuss some unusual features of the electrodynamics of moving media [1] and highlight that a translational motion can be mimicked with a drift-current [2]. In particular, we will show that a graphene sheet biased with a direct electric current is a very promising solution to break the Lorentz reciprocity and have a broadband regime of unidirectional propagation of surface plasmons protected against backscattering from obstacles and imperfections [3].

**9:24AM R11.00008: Twisted-bilayer graphene devices fabricated with polymer-free graphene** RUJ LYU (Presenter), Physics and Astronomy, University of California, Riverside, DONGYING WANG, EMILIO A CODECIDO, Physics, the Ohio State University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, CHUN NING LAU, MARC BOCKRATH, Physics, the Ohio State University — The Mott-like insulator state and superconductivity realized by stacking two graphene sheets that are twisted near 1.1°, the "magic angle [1,2," has stimulated a new wave of interest in this newfound material in the two-dimensional material family. We will present our recent work in fabricating twisted bilayer graphene heterostructures. Instead of using graphene exfoliated by tape, we obtain the graphene sheets by scratching thin graphite flake deposited on wafer with a razor blade. Combining with the pick-up technique[3], the graphene is free from any tape or polymer residue. Atomic force microscope images and transport measurements results indicate a high quality in the devices we made. Low temperature magnetocconductance measurements are also performed and the latest results will be discussed. [1] Y. Cao et al, Nature 556, 80-84(2018), [2] Y. Cao et al, Nature 556, 43-50 (2018). [3] L. Wang et al., Science 342, 614-617 (2013).

**9:36AM R11.00009: Electronic and Magnetic Properties of Patterned Hydrogenated Graphene: A First-principles Study** BI-RU WU (Presenter), Department of Natural Science, Center for General Education, Chang Gung University — Graphene is recognized as a promising 2D material with abundant physical properties, and flexibility in designing, but the zero band gap limited its applications. Graphane, a fully hydrogenated graphene, opens a remarkable energy gap. Furthermore, the hydrogenation also provide magnetic configuration of partial hydrogenated graphene due to the unpaired or localized electrons of unhydrogenated carbon atoms. In hydrogenated graphene, the carbon atoms of missing hydrogen atom prefer aggregate and form a cluster or zigzag chains. The former establishes a graphene quantum dot (GQD) embedded in graphene; the later is as a bare carbon chain or chains in graphene. We found the bare carbon chains and embedded GQDs can interact with each other. Such an inter-chain interaction and inter-dot affect the band structure of patterned hydrogenated graphene, and the inter-dot interaction will further change the magnetic properties of the embedded GQDs. It is interesting that the interaction changes the spin orientation of the atoms in the adjacent triangular GQDs and alters the energy dispersions.

*This work was supported by the Ministry of Science and Technology of the Republic of China under grant numbers MOST 105-2112-M-182-002-MY3.

**9:48AM R11.00010: Transport measurement of twisted bilayer-bilayer graphene** THAO DINH (Presenter), ZHIREN ZHENG, QIONG MA, SUYANG XU, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, PABLO JARILLO-HERRERO, NUH GEDIK, Massachusetts Institute of Technology — The recent discovery of correlated insulator behavior and superconductivity in magic-angle graphene has attached tremendous interest in twisted van der Waals systems. So far, people have been focusing on the moiré superlattice and the flat band formed due to the interlayer coupling. In fact, twisting can be used to engineer the symmetry of a 2D system, which may lead to interesting phenomena that are not allowed in their natural form. In this work, we explore such broken symmetry effect in a twisted bilayer-bilayer graphene structure. The two bilayers are rotated with respect to each other by 180°. Based on the symmetry analysis, the twisted four-layer system is strongly inversion-broken and has an out-of-plane polar axis. We fabricated high quality dual-gated devices and we will report on the transport and optical behavior of this novel system.
10:00AM R11.00011: Inter-Landau-level Andreev Reflection at the Dirac Point in a Graphene Quantum Hall State Coupled to a NbSe2 Superconductor* MANAS SAHU (Presenter), department of physics, indian institute of science, bangalore 560012, India, XIN LIU, School of Physics, Huazhong University of Science and Technology, Wuhan 430074, China, ARUP KUMAR PAUL, department of physics, indian institute of science, bangalore 560012, India, SOURIN DAS, Indian Institute of Science Education and Research, Kolkata, Mohanpur 741246, India, PRATAP RAYCHAUDHURI, Tata Institute of Fundamental Research, Homi Bhabha Road, Colaba, Mumbai 400 005, India, JAINENDRA JAIN, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, ANINDYA DAS, department of physics, indian institute of science, bangalore 560012, India — Superconductivity and the quantum Hall effect are distinct states of matter occurring in apparently incompatible physical conditions. Recent theoretical developments suggest that the coupling of the quantum Hall effect with a superconductor can provide fertile ground for realizing exotic topological excitations such as non-Abelian Majorana fermions or Fibonacci particles. As a step toward that goal, we report observation of Andreev reflection at the junction of a quantum Hall edge state in a single layer graphene and a quasi-twodimensional niobium diselenide (NbSe2) superconductor. Our principal finding is the observation of an anomalous finite-temperature conductance peak located precisely at the Dirac point, providing a definitive evidence for inter-Landau-level Andreev reflection in a quantum Hall system. Our observations are well supported by detailed numerical simulations, which offer additional insight into the role of the edge states in Andreev physics. This study paves the way for investigating analogous Andreev reflection in a fractional quantum Hall system coupled to a superconductor to realize exotic quasiparticles.

* A. D. thanks Department of Science and Technology (DST), Government of India, under Grants No. DSTO1470 and DSTO1597.

10:12AM R11.00012: Band structure tuning of doped Graphene/hBN heterostructure HONGYUN ZHANG (Presenter), ERYIN WANG, Tsinghua University, SHUOPEI WANG, XIAOBO LU, Chinese Academy of Science, JONATHAN DENLINGER, ALEXEI V FEDOTOV, Lawrence Berkeley National Labotatory, TAKASHI TANIGUCHI, National Institute for Material Science, GUANGYU ZHANG, Chinese Academy of Science, SHUYUN ZHOU, Tsinghua University — Tuning Dirac electrons by a periodic potential is an important scientific question and graphene/h-BN is a model van der Waals heterostructure for investigating this. Here we report our recent ARPES progress on the electronic band structure of doped graphene/BN, which shows intriguing band structure engineering of both the valence and conduction bands.

10:24AM R11.00013: Nonequilibrium noise measurements using hBN tunnel barriers XUANHAN ZHAO (Presenter), PANPAN ZHOU, LOAH STEVENS, DOUGLAS NATELSON, Rice University — Xuanhan Zhao1, Loah A. Stevens1, Panpan Zhou1, K. Watanabe2, T. Taniguchi2, Douglas Natelson1,3,4

1Department of Physics and Astronomy, Rice University, Houston, TX 77005
2National Institute for Materials Science, Tsukuba, Japan 305-0047
3Department of Electrical and Computer Engineering, Rice University, Houston, TX 77005
4Department of Materials Science and NanoEngineering, Rice University, Houston, TX 77005

Nonequilibrium (or “shot”) noise, which comprises the inherent fluctuations in the electrical current of system driven out of equilibrium, is predicted to be an outstanding experimental probe for underlying physics in many systems. Hexagonal boron nitride is a 2D material with atomically smooth surface available down to thicknesses of single atomic layers and possessing a large bandgap, which makes it an ideal choice for fabrication of tunnel junction. Here we report nonequilibrium charge current noise measurements in a variety of tunnel junctions prepared using different ways of transferring hBN as monolayer tunnel barriers. We will further discuss the prospect of making single-layer hBN a general tool for tunneling spectroscopy of materials.
10:36AM R11.00014: Imaging non-circular cyclotron orbits in a graphene/hBN superlattice  ARTHUR BARNARD
(Presenter), AARON SHARPE, Stanford University, USA, JOHN WALLBANK, University of Manchester, UK, KENJI WATANABE,
TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, VLADIMIR FALKO, University of Manchester, UK, DAVID
GOLDHABER-GORDON, Stanford University, USA — When graphene is rotationally aligned with an underlying hexagonal
boron nitride (hBN) substrate, a superlattice naturally forms. This drastically alters graphene's electronic band structure,
leading to minibands whose structure enables us to electrostatically tune the Fermi-surface size and shape. A striking
consequence of altering the Fermi-surface shape is that electrons are no longer expected to follow circular cyclotron
motion in the presence of a magnetic field. Transverse electron focusing (TEF) measurements have shown signatures of
these non-circular orbits in a graphene/hBN superlattice, however, a direct probe has been lacking.
Here, we image the shape of cyclotron orbits in an hBN/graphene superlattice by performing TEF measurements in a
cryogenic scanning gate microscope (SGM). We study a hall-bar device with collimating contacts and use a home-built
multi-terminal lock-in technique to efficiently determine where electrons are electrostatically deflected by the SGM tip.
With this system, we resolve both circular and triangular orbits, in good agreement with expectations from band structure
calculations.

10:48AM R11.00015: THz spectroscopy of graphene coupled to LaAlO3/SrTiO3 nanoscale junctions*  ERIN SUTTON
(Presenter), LU CHEN, JIANAN LI, QING GUO, University of Pittsburgh, HYUNGWOO LEE, JUNGWOO LEE, CHANG-BEOM EOM,
University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh —

We investigate the gate-dependent optical response of graphene using the broadband nonlinear generation and detection
capabilities of nanoscale junctions created at the LaAlO3/SrTiO3 interface [1]. Using the large non-resonant third-order
nonlinear susceptibility in SrTiO3, strong difference frequency mixing occurs when the junction is biased, leading to
induced polarization that can also be detected at the junction [2]. Here we discuss results of gate-dependent experiments
which interrogate the relationship between the THz signal and the gate location with respect to the Dirac point in devices
where graphene is coupled to the LaAlO3/SrTiO3 interface. Preliminary results suggest we may be detecting a surface
plasmon resonance or phonon mode. We will also discuss results indicating a gate-dependent enhancement of the
graphene absorption.

Session R12 DCMP GMAG: 2D Materials: Magnetism and Optoelectronics BCEC 153A - Erik Henriksen,
Washington Univ - Tag(s): Focus

8:00AM R12.00001: Relative stability and magnetic ground state of all stacking patterns in bilayer chromium
trihalides from first principles*  MARCO GIBERTINI (Presenter), Department of Quantum Matter Physics, University of Geneva
— Chromium trihalides, CrX3 (X = Cl, Br, I), are layered magnetic materials that have recently attracted considerable
attention owing to their easy exfoliability. Their monolayers are ferromagnetic, with spins lying in-plane for CrCl3 and out-
of-plane for CrBr3 and CrI3. This difference is reflected also in distinct interlayer interactions when layers are stacked into
their bulk: antiferromagnetic for CrCl3, while ferromagnetic for the others. Still, even multilayers of CrI3 behave as
antiferromagnets, whereas CrBr3 remains ferromagnetic. Here, we address this controversy by studying bilayers of these
materials using density functional theory. We enumerate all possible stacking patterns with the smallest unit cell and
investigate their relative stability. We show that, depending on the stacking order, the magnetic ground state can be
different. In particular, we recover that the bulk stacking is indeed the most stable and it is correctly ferromagnetic for CrI3
and CrBr3, although there exist other low-lying metastable configurations that are antiferromagnetic. Based on our
findings, we speculate on how the apparent controversy could be resolved.

*Support from the Swiss National Science Foundation through the Ambizione program and the NCCR MARVEL is greatly
acknowledged.
8:12AM R12.00002: C1 vacancy in pentagraphene*  AADITYA MANJANATH (Presenter), CHAO-PING HSU, Institute of Chemistry, Academia Sinica, YOSHIYUKI KAWAZOE, Tohoku University, New Industry Creation Hatchery Center — Pentagraphene (PG), a two-dimensional allotrope of carbon with only five-membered rings, was recently predicted to exhibit exciting electronic and thermal properties with possible implications in nanoelectronics. However, its potential properties arising from defects have not been explored yet. Here, we explore the C1 vacancy in PG using first-principles density functional calculations. This defect introduces four midgap levels indicating the possibility of studying the charge states. The charged defect is amphoteric with deep donor and deep acceptor levels. Introducing the vacancy in the sheet renders it inherently ferromagnetic (FM) with a magnetic moment of 4 $\mu_B$. Upon further investigating spin polarization in PG, three possible unique magnetic configurations are found to exist: FM, anti-ferromagnetic (AFM)–dominant, and quenched-AFM. The energy differences between the FM and the AFM states are on an average ~2 meV/atom, indicating that reversible spin manipulation through thermal energy is possible.

*JSPS Kakenhi Grant no. 17H03384, HPCI project hp170190, Academia Sinica Investigator award AS-IA-106-M01 and MOST of Taiwan with project 105-2113-M- 001-009-MY4, and Academia Sinica Distinguished Postdoctoral Fellowship

8:24AM R12.00003: Magnon-assisted tunnelling in van der Waals heterostructures based on CrBr3  DAVIT GHAZARYAN (Presenter), Department of Physics, National Research University Higher School of Economics, MARK GREENAWAY, Department of Physics, Loughborough University, ZIHAO WANG, IVAN JESUS VERA MARUN, JUN YIN, Physics and Astronomy, The University of Manchester, SERGE MOROZOV, Institute of Microelectronics Technology and High Purity Materials, ALEXANDER LICHTENSTEIN, Institute of Theoretical Physics, University Hamburg, MIKHAIL KATSNELSON, Institute for Molecules and Materials, Radboud University, ARTEM MISHCHENKO, LAURENCE EAVES, ANDRE GEIM, KOSTYA NOVOSELOV, ABHISHEK MISRA, Physics and Astronomy, The University of Manchester — Recently, the family of two-dimensional materials has been expanded to include ferromagnets. It was shown that CrI3 exhibits ferromagnetism down to thicknesses of a single monolayer [Huang, B. et al. Nature 546, 270 (2017)]. CrI3 is part of a group of materials known as the chromium trihalides, CrX3 (where X=Cl, Br or I). I will report on a few layers of exfoliated CrBr3 (2-6 layers) that are also ferromagnetic by fabricating and characterising functional tunnelling devices where the CrBr3 layer is sandwiched in between two graphene electrodes. I will also report a new type of tunnelling mechanism in van der Waals heterostructures by demonstrating that electrons in our device tunnel between the graphene layers via the emission (and, at high temperature, absorption) of magnons in the CrBr3 barrier.

8:36AM R12.00004: Spin texture of a quasi-two-dimensional ferromagnetic kagome metal*  XIAO-MING MA, Physics, Southern University of Science and Technology, XIAO-BO WANG, Physics, Hong Kong University of Science and Technology, YU-JIE HAO, YUE FENG, JIE-MING YANG, TIAN-XIONG HAN, HUI-WEN SHEN, YI-MING XU, RONG-RONG SONG, Physics, Southern University of Science and Technology, HONG DING, Institute of Physics, Chinese Academy of Sciences, CHANG LIU (Presenter), Physics, Southern University of Science and Technology — The discovery of low dimensional, long range magnetic order and the study on accurate control of such order have led to the revolution of magnetic storage devices that reformed our daily lives. Two dimensional systems with underlying kagome symmetry is found to be one of the most convenient platforms for the creation and manipulation of various magnetic structures. For example, planar ferromagnetism and non-collinear antiferromagnetism are present in kagome metals Fe3Sn2 and Mn3Sn, respectively, both of which are also recently found to be topologically nontrivial. In this talk, we report our study on the spin texture of Fe3Sn2, using both spin-resolved ARPES and DFT calculations. Our results show that the topological Dirac bands at the K points of Fe3Sn2 originates from inner layers of the crystal, and are highly spin-polarized along a single spatial direction, realizing in-plane ferromagnetism. This study reveals the low-lying spin texture of a two dimensional topological metal, serving as guidance for spintronic applications on systems alike.

Layered transition metal dichalcogenides are currently intensively investigated due to their opto-electronic, superconducting and topological properties as well as their potential usage as mono-layer building blocks. However, despite their layered nature they often exhibit three dimensional (3D) properties in the bulk. Surprisingly, in semiconducting 2H-MoTe2 long-range magnetic order of unknown origin has recently been observed at low temperature [1]. Here we present the full 3D band structure of 2H-MoTe2, determined with soft X-ray ARPES. We find a pronounced $k_z$ dispersion in most bands, consistent with ab-inito calculations, proving the three dimensional character of this material. Furthermore, we present results of beta detected $^6$Li NMR measurements and show that the spin-lattice relaxation of the implanted Li ions is inconsistent with long range magnetic order, but supports the presence of magnetic fluctuations. We also find signatures of Li diffusion below room temperature, indicating a potential application in Li battery materials.

9:12AM R12.00007: Interacting Rydberg Exciton-Polaritons in Two-Dimensional Transition Metal Dichalcogenides
JIE GU (Presenter), Department of Physics, City College of New York, 160 Convent Ave., New York, NY 10031, USA, LUTZ WALDECKER, Department of Applied Physics, Stanford University, Stanford, California, 94305 USA, DANIEL A RHODES, Department of Mechanical Engineering, Columbia University, New York, NY 10027 USA, ALEXANDRA BOEHMKE, RIAN KOUTS, Department of Physics, City College of New York, 160 Convent Ave., New York, NY 10031, USA, ARCHANA RAJA, Department of Applied Physics, Stanford University, Stanford, California, 94305 USA, JAMES HONE, Department of Mechanical Engineering, Columbia University, New York, NY 10027 USA, TONY F HEINZ, Department of Applied Physics, Stanford University, Stanford, California, 94305 USA, VINOD M MENON, Department of Physics, City College of New York, 160 Convent Ave., New York, NY 10031, USA — Strong optical nonlinearities play a central role in realizing quantum photonic technologies. In solid state systems, the exciton-polariton which result from the hybridization of material excitations and cavity photons are an attractive candidate to realize such nonlinearities. The interaction arising from the material component, excitons, forms the basis of the polaritonic nonlinearity. Several solid state systems have demonstrated nonlinear interaction of polaritons using the \( n = 1 \) excitonic state. However, the nonlinear interaction can be significantly enhanced if excited Rydberg excitonic states can be used instead of the ground state excitons. Recently such excited Rydberg excitonic states have been observed in monolayer transition metal dichalcogenides. Here we demonstrate the formation of Rydberg exciton-polaritons in monolayer WSe\(_2\) embedded in a microcavity. Owing to the larger wavefunctions of the Rydberg excitons, these polaritons show greater nonlinear response evidenced through the blue shift of the lower polariton branch under optical excitation. The demonstration of Rydberg exciton-polaritons in two-dimensional semiconductors and their enhanced nonlinear response may facilitate the realization of quantum photonic logic gates and processors.

9:24AM R12.00008: Room temperature dynamical control and electroluminescence from microcavity polaritons in monolayer transitional metal dichalcogenides* 
BISWANATH CHAKRABORTY (Presenter), JIE GU, PHYSICS, City College of New York, City University of New York, New York 10031, USA, ZHENG SUN, Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania 15260, USA, MANDEEP KHATONIAR, REZLIND BUSHATI, ALEXANDRA BOEHMKE, RIAN KOUTS, VINOD M MENON, PHYSICS, City College of New York, City University of New York, New York 10031, USA — We demonstrate modulation of exciton-photon interaction in strong coupling regime showing polariton branches at room temperature in monolayer WS\(_2\) field effect transistor embedded inside a microcavity. Transitions from strong to weak coupling happens when WS\(_2\) becomes electron doped under gating due to reduction in oscillator strength of the excitons arising from decreased Coulomb interaction. For polariton electroluminescence from a monolayer WS\(_2\) at room temperature we incorporate a tunnel field effect transistor with graphene-hBN-WS\(_2\)-hBN-graphene van der Waal heterostructure inside the microcavity. Injected electrons and holes tunnel through hBN barrier and recombine in the WS\(_2\) resulting in luminescence and shows clear polariton branches. Our findings with these new class of materials pave a novel way to realize low energy optoelectronic switches and possibly room temperature based polariton lasers through electrically controlled polariton luminescence.

9:36AM R12.00009: Collective electronic properties of an \( \alpha \)-\( T_3 \) lattice at finite temperatures* 
ANDRII IUROV (Presenter), University of New Mexico, GODFREY GUMBS, Hunter college, DANHONG HUANG, Air Force Research Labs., LIUBOV ZHEMCHUZHNA, Hunter college — Many-body electronic properties, including plasmons, their damping, static screening and transport coefficients have been calculated based on the finite-temperature polarization function for the \( \alpha \)-\( T_3 \) model. We have thoroughly investigated the role of the coupling strength parameter \( \alpha \) for the extra atom at the center of the honeycomb lattice, which in our case could be continuously varied from 0 (graphene) to 1 (the dice lattice). Specifically, we obtained and analyzed the dice lattice limit. We have derived several crucial semi-analytical approximations for the static and long wavelength limits, related to the finite-temperature behavior of the plasmon excitations in \( \alpha \)-\( T_3 \) materials.

CHENHAO JIN, EMMA REGAN (Presenter), DANQING WANG, IQBAL B UTAMA, JEFFREY CAIN, University of California, Berkeley, YING QIN, YUXIA SHEN, Arizona State University, ZHIREN ZHENG, University of California, Berkeley, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, SEFAATTIN TONGAY, Arizona State University, ALEX K ZETTL, FENG WANG, University of California, Berkeley — Moiré superlattices dramatically modify the properties of electrons and excitons in van der Waals heterostructures by introducing a new length and energy scale. The effect can be especially strong for interlayer excitons, where electrons and holes reside in different layers and are sensitive to the local atomic configuration. For example, it was recently predicted that moiré superlattices can host localized interlayer exciton states with distinct optical selection rules due to an emergent moiré angular momentum. In this talk, I will discuss our effort to observe distinct interlayer exciton states and to probe the possible effects of the moiré angular momentum on the interlayer exciton states.

ROBERT YOUNTS (Presenter), Research and Applied Sciences, Space and Naval Warfare Systems Center Atlantic — Recently, monolayer transition metal dichalcogenides (TMDs) have shown the ability to undergo a phase transition between an insulating gas of strongly bound excitons to a conducting electron-hole plasma (EHP). Typically, to reach this phase transition, ultrashort optical pulses are used to create a non-equilibrium high carrier density. However, this EHP state can also be reached via continuous wave (CW) excitation. In most semiconductors, the high carrier density needed for the EHP phase transition cannot be reached using CW light since nonlinear recombination processes limit the equilibrium carrier density. However, the mechanical properties of monolayer TMDs can be used to manipulate the electronic structure to change the carrier dynamics, allowing for high carrier densities to be reached through CW excitation. Specifically, by applying strain, the energy offset between direct K-K and indirect Γ-K transitions can be used to shift the carrier population between valleys. By interchanging different transition metals or chalcogens, we can change the indirect-direct energy offset creating an EHP predominately in the indirect transition or direct transition. This has a profound impact on the optical properties of the EHP, providing an avenue to engineer novel opto-electronic devices.

CHARLES SAYERS (Presenter), Centre Nanoscience and Nanotechnology (CNAN), Department of Physics, University of Bath, HAMOON HEDAYAT, DAVIDE BUGINI, CLAUDIA DALLERA, Dipartimento di Fisica, Politecnico di Milano, DANIEL WOLVERSON, Centre Nanoscience and Nanotechnology (CNAN), Department of Physics, University of Bath, TIM BATTEN, Renishaw plc, SARA KARBASSI, SVEN FRIEDEMANN, HH Wills Physics Laboratory, University of Bristol, University of Bristol, GIULIO CERULLO, Dipartimento di Fisica, Politecnico di Milano, JASPER VAN WEZEL, Institute for Theoretical Physics, Institute of Physics, University of Amsterdam, STEPHEN CLARK, Centre Nanoscience and Nanotechnology (CNAN), Department of Physics, University of Bath, ETTORE CARPENE, IFN-CNR, Dipartimento di Fisica, Politecnico di Milano, ENRICO DA COMO, Centre Nanoscience and Nanotechnology (CNAN), Department of Physics, University of Bath — Using time- and angle-resolved photoemission spectroscopy (TR-ARPES), we have studied the femtosecond dynamics of the charge density wave (CDW) in 1T-TiSe₂. This material exhibits a commensurate CDW with a (2 x 2 x 2) lattice distortion below 200 K for which the mechanism is still debated today. One of the recurring problems is disentangling the contributions from the electronic and lattice-driven order. Here, we have observed the photo-induced suppression of the CDW in real-time by tracking the valence band maximum at the Γ-point following an intense laser pulse. The timescales of gap closing and band-replica unfolding (< 200 fs), and the relatively low fluence required for these processes are suggestive of an excitonic mechanism. During recovery, coherent oscillations of the CDW gap are observed relating to the Ã₁₈ (3.4 THz) mode. A detailed pump fluence dependence reveals several regimes, including impeded recovery at high fluence. This bottleneck coincides with a change in the dominant frequency seen in the oscillations. Using complementary time-resolved reflectivity, we have established the threshold fluence of this phenomenon to be F > 60 μJ cm⁻². Our work is supported by a rate equation model which highlights the crucial role of excitons and phonons in this complex system.
10:24AM R12.00013: Electromagnetic Field dependent Coulomb renormalisation in Dirac Materials*  
DI MAURO VILLARI LEONE (Presenter), IAN GALBRAITH, FABIO BIANCALANA, Heriot-Watt University — 
Condensed matter physics is witnessing a rapid expansion of materials with Dirac fermion quasiparticle excitations. In recent works it has been shown that a full understanding of the optical properties of such materials requires one to go beyond the standard approach of the semiconductor Bloch equations (SBEs). In his influential paper Ishikawa derived an extended version of the SBEs for graphene using the formalism of instantaneous eigenstates. More recently his approach was generalised further for the case of a gapped material. These generalised Dirac-Bloch (DBEs) equations reproduce novel and previously unexplained nonlinear optical properties of graphene and gapped graphene, however they do not include Coulomb interactions that are in general very strong in two dimensional semiconductors. Starting from the quantisation of the instantaneous Dirac field we include Coulomb interactions and provide a fully renormalised version of the DBEs. By solving these equations we account for the linear optical properties of 2D Dirac semiconductor. We discuss how the absorption spectrum evolves as the energy gap is reduced to zero. We then study the strong Coulomb coupling regime in which the excitons form a relativistic Bose-Einstein condensate.

10:36AM R12.00014: Excited excitonic states in second harmonic spectra of 2D materials with \textit{ab-initio} many-body methods*  
KORY BEACH (Presenter), MICHAEL C LUCKING, HUMBERTO TERRONES, Rensselaer Polytechnic Institute, MARK BRONGERSMA, OZGUR BURAK ASIAN, Stanford University — First principles calculations of the second harmonic generation (SHG) of various semiconducting 2D materials including transition metal dichalcogenides (TMDs) are performed using a time-dependent Bethe-Salpeter Equation (TDBSE) nonequilibrium Green's function approach. It is shown that by increasing simulation time, spectral resolution can be improved, resolving features in the SHG spectrum that can be attributed to excited states of excitons. By comparing the differences in excited exciton energies to the differences observed experimentally, a calibration metric for the degree of over- or under-binding of the excitons can be formulated. Moreover, the degree to which substrate screening in these materials modifies not only the binding energy and the fundamental gap, but also the relative energies of excited states, is explored. The relative intensities of the excited exciton peaks in the SHG are also examined for the additional layer of information they can provide beyond corresponding peaks in the first-order spectra. This focus on a more precise understanding of excitonic resonances in the second harmonic spectrum lays the groundwork for a more systematic use of this TDBSE method for studying nonlinear optical properties in 2D materials.

Session R13 DMP: 2D Materials (General): Transport and Optical Phenomena -- Emerging Materials BCEC 153B - Judy Cha, Stanford University

8:00AM R13.00001: Optical conductivity of black phosphorus*  
SEONGJIN AHN (Presenter), Center for Correlated Electron Systems, Institute for Basic Science (IBS), JIHO JANG, HONGKI MIN, Department of Physics and Astronomy, Seoul National University — Black phosphorus (BP) is a two-dimensional layered material composed of phosphorus atoms. Recently, it was demonstrated that external perturbations such as electric field close the band gap or even induce a band inversion in few-layer BP, resulting in the insulator phase with a finite energy gap or the Dirac semimetal phase characterized by two separate Dirac nodes. At the transition between the two phases, a semi-Dirac state appears in which energy disperses linearly along one direction and quadratically along the other direction. In this work, we study the optical conductivity of few-layer BP using a lattice model and the corresponding continuum model, incorporating the effects of an external electric field and finite temperature. We find that the low-frequency optical conductivity scales as a different power-law depending on the phase, which can be used as an experimental signature. We also demonstrate the change of the material parameters as an external field increases and its consequence on the power law behavior of the optical conductivity.

8:12AM R13.00002: Bright Mid-Infrared Photoluminescence in Thin-Film Black Phosphorus*  CHEN CHEN (Presenter), FENG CHEN, XIAOLONG CHEN, BINGCHEN DENG, Electrical Engineering, Yale University, New Haven, CT, USA, BRENDAN ENG, Electrical and Computer Engineering, University of Illinois Urbana–Champaign, Champaign, IL, USA, DAEHWAN JUNG, Institute for Energy Efficiency, University of California Santa Barbara, Santa Barbara, CA, USA, QIUSHI GUO, SHAOFAN YUAN, Electrical Engineering, Yale University, New Haven, CT, USA, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, 1-1 Namiki, Tsukuba, Japan, MINJOO LAWRENCE LEE, Electrical and Computer Engineering, University of Illinois Urbana–Champaign, Champaign, IL, USA, FENGNIAN XIA, Electrical Engineering, Yale University, New Haven, CT, USA — In this work, we report bright mid-infrared photoluminescence (PL) emission from thin-film black phosphorus (BP). The intensity of the PL emission from a 46-nm thick BP is only seven times weaker than that of an indium arsenide (InAs) multiple quantum well (MQW) structure grown by molecular beam epitaxy, in which the total thickness of the quantum wells is of similar thickness to BP. The PL emission is further tunable by the temperature and layer number of thin-film BP. In the 46-nm thick BP, the PL spectra indicates a bandgap of 0.334±0.003 eV at 300 K, which decreases to 0.308±0.003 eV at 80K. The anomalous redshift of the BP bandgap with decreasing temperature agrees with previous theoretical and experimental results, while the overall energy shift is about 60% of the previously reported value obtained from photocurrent spectroscopy. We also measure the layer number dependence of PL spectra of the thin-film BP (6-to 46-nm), and we show that the emission peaks from around 3.3 to 4 mm at 80 K. Our results reveal the promising future of thin-film BP in mid-infrared light emitting and lasering applications.

8:24AM R13.00003: Barkhausen effects in the first order structural phase transition in type-II Weyl semimetal MoTe2*  CHUANWU CAO, XIN LIU, XIAO REN, Peking University, KENAN ZHANG, Physics, Tsinghua University, DONG SUN, Peking University, SHUYUN ZHOU, Physics, Tsinghua University, YANG WU, Tsinghua University, YUAN LI, JIANHAO CHEN (Presenter), Peking University — We report the first observation of the non-magnetic Barkhausen effect in van der Waals layered crystals, specifically, between the $T_d$ and $1T'$ phases in type-II Weyl semimetal MoTe2. Thinning down the MoTe2 crystal from bulk material to about 25nm results in a drastic strengthening of the hysteresis in the phase transition, with the difference in critical temperature increasing from ~40K to more than 300K. The Barkhausen effect appears for thin samples and the temperature range of the Barkhausen zone grows approximately linearly with reducing sample thickness, pointing to a surface origin of the phase pinning defects. The distribution of the Barkhausen jumps shows a power law behavior, with its critical exponent $\alpha = 1.27$, in good agreement with existing scaling theory. Temperature-dependent Raman spectroscopy on MoTe2 crystals of various thicknesses shows results consistent with our transport measurements. Reference: C. Cao et al., 2D Materials 5, 044003 (2018)

8:36AM R13.00004: Ferroelectric switching of a two-dimensional metal  WENJIN ZHAO (Presenter), ZAIYAO FEI, TAUNO PALOMAKI, BOSONG SUN, MOIRA K MILLER, University of Washington, ZHIYING ZHAO, JIAQIANG YAN, Oak Ridge National Laboratory, XIAODONG XU, DAVID HENRY COBDEN, University of Washington — In its 3D form the semimetal WTe2 has a polar space group, whereas an isolated monolayer of WTe2 is centrosymmetric. We find that when exfoliated down to two- or three-layer thickness, WTe2 exhibits a spontaneous out-of-plane electric polarization, while the monolayer does not. The polarization persists to room temperature and can be switched by a perpendicular electric field using graphite gate electrodes located above and below the sheet. We directly detect and quantify the polarization using graphene as an electric-field sensor. The polarization state can also be distinguished via the in-plane conductivity. The ferroelectricity persists even when the material is metallic in the plane; this is possible because the few-layer WTe2 is so thin that the applied electric field penetrates it.
8:48AM R13.00005: Nonlinear imaging of grain boundaries in monolayer semiconducting transition metal dichalcogenides*  
BRUNO R CARVALHO, Departamento de Física, Universidade Federal de Rio Grande do Norte, YUANXI WANG, MAURICIO TERRONES, Physics, The Pennsylvania State University, LEANDRO M. MALARD (Presenter), Universidade Federal de Minas Gerais — Locating and imaging defects in two-dimensional (2D) materials is a key challenge to probe the material quality for different target applications. Recently, second harmonic generation (SHG) has been used to characterise different 2D materials and defective regions like grain boundaries [1]. However it has been shown that these grain boundaries were revealed by interference between the two neighbouring domains, leading to a dark region (no SHG emission) between them [1]. Here we implemented a nonlinear dark-field SHG microscopy setup to accurately probe grain boundaries and edges from semiconducting transition metal dichalcogenide monolayers. The dark-field SHG efficiently separates the spatial components of the emitted light and accurately locates grain boundaries and edges as bright patterns. The far field SHG pattern is calculated considering the interference between two second harmonic dipoles, which is in agreement with our experimental finding. Therefore the dark field second harmonic imaging opens new opportunities to characterize defects in 2D materials [2].

9:00AM R13.00006: Tightly Coulomb-bound four- and five-particle intervalley states in monolayer tungsten diselenide  
SHAO-YU CHEN (Presenter), THOMAS A GOLDSTEIN, Department of Physics, University of Massachusetts Amherst, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, JUN YAN, Department of Physics, University of Massachusetts Amherst — Tightly-bound excitonic complexes in atomically-thin semiconducting transition metal dichalcogenides (TMDCs) provide an appealing platform for studying many-body correlations. Here, we present the observation of the Coulomb-bound four-particle biexciton and five-particle exciton-trion in monolayer tungsten diselenide by the photoluminescence (PL) measurements. The ultrahigh quality sample enables us to resolve and assign several intrinsic emission features in the energy window right below the bright neutral exciton emission. Interestingly, we discover that the biexciton consists of a spin-zero bright exciton in one valley and a spin-one “dark” exciton in the other, which is confirmed by the magneto-PL measurements. The binding energy of these multi-particle states are further estimated as 18–23 meV and 13–20 meV for the biexciton and the exciton-trion, respectively, by charge doping and thermal activation measurements. The tightly bound nature of the multi-particle states in atomically-thin TMDCs offers opportunities for understanding many-body physics and for realizing interesting applications such as Bose-Einstein condensation, and quantum communication and teleportation.

9:12AM R13.00007: WITHDRAWN ABSTRACT —

9:24AM R13.00008: Layer number dependent barrier height of MoS2 on ultra-flat conducting surfaces*  
HAO LEE, Physics and Astronomy, San Francisco State University, SANCHIT DESHMUKH, Electrical Engineering, Stanford University, JING WEN, Chemical, Biological and Materials Engineering, University of Oklahoma, VIVIANE COSTA, Physics and Astronomy, San Francisco State University, ERIC POP, Electrical Engineering, Stanford University, BIN WANG, Chemical, Biological and Materials Engineering, University of Oklahoma, AKM NEWAZ (Presenter), Physics and Astronomy, San Francisco State University — Transition metal dichalcogenides (TMDs) are layered semiconducting van der Waal crystals and promising materials for wide range of electronic and optoelectronic devices. Realizing practical device application requires an understanding of nanoscale local electronic and optoelectronic properties on layered TMDs on a conducting metal surface. In this work, we have used conducting atomic force microscopy (CAFM) of layered MoS2 (1-5 layers) immobilized on two different ultra-flat conducting surfaces (RMS surface roughness <0.2 nm) Au and indium tin oxide (ITO) forming metal (conductive-tip)-semiconductor-metal devices. First, we have found that the edges of the different layers are insulating. Second, the current increases as the layer number increases. By applying Fowler-Nordheim tunneling theory, we have determined the barrier heights for different layers and observed that the barrier height decreases as the number of layers increases. Our study provides a fundamental understanding of the local electronic behavior of TMD depending on layer numbers and may pave an avenue toward developing nanoscale electronic devices with tailored properties of different layers.

*NSF ECCS-1708907
Second-harmonic generation in strained transition metal dichalcogenide monolayers

LUKAS MENNEL (Presenter), MATTHIAS PAUR, THOMAS MUELLER, Photronics Institute, Vienna University of Technology — Second-harmonic generation (SHG) is a powerful measurement technique to analyze the symmetry properties of crystals. Mechanical strain can reduce the symmetry of a crystal and even weak strain can have an immense impact on the SHG intensity along different polarization directions. The impact of strain on the SHG can be modeled with a second-order nonlinear photoelastic tensor. We determined the photoelastic tensors for four different transition metal dichalcogenide (TMD) monolayers: MoS$_2$, MoSe$_2$, WS$_2$ and WSe$_2$. We find that the photoelastic tensors depend highly on the excitation intensity along different polarization directions. The impact of strain on the SHG can be modelled with a second-order mechanical strain can reduce the symmetry of a crystal and even weak strain can have an immense impact on the SHG harmonic generation (SHG) is a powerful measurement technique to analyze the symmetry properties of crystals.

We acknowledge financial support by the European Union (grant agreement No. 785219 Graphene Flagship), the Austrian Science Fund FWF (START Y 539-N16), and the doctoral college program “TU-D Unravelling advanced 2D materials” funded by TU Vienna.

Computing nonlinear response to arbitrary order in the presence of electronic interactions via time-domain integration of polarizability

EMILIA RIDOLFI (Presenter), PAOLO EMILIO TREVISANUTTO, VITOR PEREIRA, Centre for Advanced 2D Materials, National University of Singapore, 6 Science Drive 2, Singapore 117546 — We describe a theoretical approach to study the nonlinear optical response of electronic systems based on a real-time solution of the electronic dynamics in the presence of time-dependent electromagnetic fields. Using accurately parameterized tight-binding models and electronic interactions, this allows expedite and accurate calculations of the nonlinear response to arbitrary order for realistic systems. We demonstrate its capabilities by computing the excitonic spectrum and high-harmonic generation (SHG, THG, FHG) in MoS$_2$ and BN monolayers. The linear optical conductivity is seen to reproduce exactly the Kubo-formula perturbative results based on the Bethe-Salpeter equation and, moreover, reproduces very well the experimental traces. Such benchmark against experiments in linear order allows us to confidently predict the frequency dependence of the higher-harmonic susceptibilities which, within our scheme, are obtained with no additional effort, in contrast to an order-by-order perturbative approach.

Growth of self-assembled graphene nanoribbons on SiC substrates

HANBYUL JIN (Presenter), MATTIAS KRUSKOPF, ALBERT RIGOSI, DINESH PATEL, SHAMITH PAYAGALA, ALIREZA PANNA, DEAN G. JARRETT, DAVID B NEWELL, RANDOLPH E ELMQUIST, National Institute of Standards and Technology — Graphene nanoribbons (GNRs) hold promise for future nanoelectronics due to their unique band structure. Quantum confinement effects are observed in GNRs, and their bandgap energies increase with inverse proportionality to the GNR width. However, existing lithographic patterning methods cause disordered edges to form during the etching process creating dangling bonds that degrade the electrical properties of the GNR. To overcome these problems, structured silicon carbide (SiC) has been used as a template for selective growth of GNRs, which show outstanding ballistic transport with an electronic mean free path up to 15 μm [1, 2]. In this study, we have demonstrated the growth of narrow GNRs (~40 nm width) with improved structural properties using a surface pre-treatment. This method restrains SiC terrace edge step-flow during the annealing process, helping to form GNRs with the shape of the patterned SiC. The longitudinal and Hall magnetoresistance of GNRs are measured at low temperature using a six-terminal Hall bar geometry and the structural characteristics are demonstrated with atomic force microscopy (AFM), conductive AFM, and field emission scanning electron microscopy.

Two-dimensional electrons electrostatically confined on the surface of graphite

JUN YIN (Presenter), SERGEY SLIZOVSKIIY, SHENG HU, YANG CAO, School of physics and astronomy, the University of Manchester, INNA LOBANOVA, BENJAMIN PIOT, Laboratoire National des Champs Magnétiques Intenses, France, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, KOSTYA NOVOSELOV, ANDRE GEIM, VLADIMIR FALKO, ARTEM Mishchenko, School of physics and astronomy, the University of Manchester — In the bulk of a crystal, charge carriers are described by the Bloch states. At the crystal surface, the lattice periodicity is disrupted transforming itinerant Bloch waves to evanescent states. While easily accessible in semiconductors due to the presence of band gap, surface states are prohibited in gapless metals due to the presence of massive Fermi sea. Here, using capacitance spectroscopy, we show that two-dimensional (2D) charge carriers can be confined on the surface of graphite and electronically decoupled from the bulk simply by electrostatic gating. In the presence of a magnetic field, perpendicular to graphite basal plane, the Landau bands of bulk graphite render to evanescent Landau levels, which, in high magnetic fields, show electron-electron interactions including fractional quantum Hall states and negative electronic compressibility. Our work provides an experimentally convenient and highly tunable system for exploring bulk-surface correspondence.
10:24AM R13.00013: Interlayer interaction and Davydov splitting in MoS₂ polytypes studied by Raman spectroscopy

WOONGKI NA (Presenter), KANGWON KIM, JAE-UNG LEE, HYEONSIK M CHEONG, Physics, Sogang University —

The dependence of the interlayer interaction on the stacking order of MoS₂ is investigated by Raman spectroscopy using three excitation energies of 2.81, 2.41, and 1.96 eV. The low-frequency Raman spectra show distinct correlation with the stacking type [1]. The A-like intra-layer vibration mode at 405 cm⁻¹ exhibit Davydov splitting due to interlayer interactions when the 1.96-eV excitation is used. The positions and the relative intensities of the Davydov-split peaks depend on the stacking type as well. By using the linear-chain model, the interlayer force constants are extracted and compared for 3-layer samples with different stacking types: the 3R-types have a larger force constant than the 2H-type. For the 2H-type, Davydov splitting is analyzed as a function of the number of layers. The force constants for the second-nearest-neighbor interaction are obtained and compared with other transition metal dichalcogenides [2, 3, 4].

10:36AM R13.00014: Current Transport and Phase Transition in MoTe₂

ZIJING ZHAO (Presenter), YUEMING YAN, WENJUAN ZHU, Department of Electrical and Computer Engineering, University of Illinois at Urbana-Champaign — MoTe₂ is an interesting two-dimensional (2D) material, which has small energy barrier between semiconducting 2H phase and metallic 1T′ phase, and has ambipolar transport with high carrier mobility, which makes it promising for phase-change memories and logic devices. In this work, we systematically studied the current transport and phase transition in MoTe₂. The spectral photocurrent measurement reveals that the bandgap of MoTe₂ is ~1eV. The bandgap of MoTe₂ was also extracted using temperature dependence of conductance. The mobility of MoTe₂ was characterized using Hall-bar devices. At low temperatures, the carrier mobility is limited by Columbic scattering, while at high temperatures, it is limited by phonon scattering. Vertical metal/MoTe₂/metal junctions were also fabricated. As the current or voltage applied to the junction increases, MoTe₂ exhibits two transitions: high-to-low resistance transition at medium current levels, and low-to-high resistance transition at high current levels. These two transitions in resistivity in MoTe₂ may correspond to the 2H-to-1T phase transition and 1T-to-amorphous state transition respectively.

10:48AM R13.00015: Impacts of h-BN Stacking Sequence and Layer Thickness on the Band Structure and Radiative Recombination

KELSEY MENGLE (Presenter), EMMANOUIL KIOUPAKIS, University of Michigan — We investigated the variation of the electronic and optical properties of h-BN as a function of stacking sequence and number of layers using first-principles calculations. Our study includes bulk and bilayer structures for the five possible stacking sequences, as well as monolayer and randomly stacked bulk structures (t-BN). Variations of the band structure were studied both at the density functional theory (DFT) and GW levels, with particular focus on the band extrema. The majority of the investigated structures were found to have indirect band gaps, with a few exceptions such as the AB₁ stacking sequence and t-BN. We further calculated the phonon-assisted optical matrix elements (S) for all structures to understand how the number of layers and stacking type influence light emission. Most of the ordered bulk and bilayer structures are capable of efficient light emission with values of S² ranging from ~10-1000× that of bulk Si, indicating that efficient phonon-assisted light emission is possible even though the gap is indirect.

Session R14 DMP: 2D Materials (Metals, Superconductors, and Correlated Materials) -- Twisted Graphene I BCEC 153C - Philip Kim, Harvard University - Tag(s): Focus
8:00AM R14.00001: A scanning tunneling study of twisted bilayer graphene at the first magic angle* YONGLONG XIE (Presenter), BERTHOLD JAECK, CHENG-LI CHIU, Physics department, Princeton University, KYOUNGHWAN KIM, YIMENG WANG, Electrical and Computer Engineering department, The University of Texas at Austin, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, EMANUEL TUTUC, Electrical and Computer Engineering department, The University of Texas at Austin, ALI YAZDANI, Physics department, Princeton University — Recently, bilayer graphene with small twist angle has been shown to be a valuable platform for correlated electron phenomena. Band structure calculations show that at certain twist angle values, labelled magic angles, the lowest band has a flat energy-momentum dispersion. Transport experiments find evidence for a correlated insulating phase when this flat band is exactly half filled. Furthermore, a small doping level away from half filling gives rise to a superconducting instability. In this talk, we will discuss how a scanning tunneling microscope can help to elucidate the electronic properties of twisted bilayer graphene close to the first magic angle.

*This work is supported by the DOE, Moore Foundation, NSF, and DOD-ARO.

8:12AM R14.00002: Atomistic study of electron-phonon coupling in magic-angle twisted bilayer graphene* YOUNG WOO CHOI (Presenter), HYOUNG JOON CHOI, Department of Physics, Yonsei University, Seoul 03722, Korea — We report strong electron-phonon coupling in magic-angle twisted bilayer graphene (MA-TBG) obtained from atomistic description of the system including more than 10,000 atoms in the moiré supercell. Electronic structure, phonon spectrum, and electron-phonon coupling strength λ are obtained before and after atomic-position relaxation both in- and out-of-plane. Obtained λ is very large for MA-TBG, with λ > 1 near the half-filling energies of the flat bands, while it is small (λ~0.1) for monolayer and unrotated bilayer graphene. Significant electron-hole asymmetry occurs in the electronic structure after atomic-structure relaxation, so λ is much stronger with hole doping than electron doping. Electron-phonon coupling is nearly isotropic and very weakly dependent on electron momentum, suggesting single-gap s-wave superconductivity. Relevant phonon energies are much larger than electron energy scale, going far beyond adiabatic limit. Our results provide fundamental understanding of electron-phonon interaction in MA-TBG, highlighting that it can contribute to rich physics of the system.

8:24AM R14.00003: Band Degeneracy and Normal State Properties of Twisted Bilayer Graphene at the Magic Angle CHENG LI (Presenter), TIN-LUN HO, Ohio State University — Recently, superconductivity is discovered in twisted bilayer graphene at a small twist angle. Associated this superconducting state is a whole host of unusual normal state properties: (i) that the band degeneracy between charge neutrality and the insulating phase is 4, instead of the expected 8-fold degeneracy by counting all the relevant quantum numbers (valley indices, two layers and two spins), (ii) the appearance of an insulating phase at a finite chemical potential below charge neutrality, (iii) that the insulating phase is destroyed by an in-plane magnetic field, (iv) a further reduction of the band degeneracy from 4 to 2 on at chemical potential away from the insulating phase, (v) a large asymmetry of the size of Fermi surfaces on different sides of the insulating phase as reveal by quantum oscillation measurements.

In this talk, we show how (i) can come about through coupling of Dirac cones of the opposite valley index in different layers. This reduction of degeneracy immediately provides a natural explanation for all other phenomena (ii) to (v); and that the insulating phase is associated with a spin density wave. Our picture also has implications on light scattering and Raman absorption experiments.
degrees twist mismatch between the layers hosts a low energy flat band in which the Coulomb interaction is large relative to the bandwidth, promoting correlated insulating states at half band filling, and superconducting (SC) phases with dome-like structure neighboring correlated insulating states. Here we show measurements of a dual-graphite-gated twisted bilayer graphene device, which minimizes charge inhomogeneity. We observe new correlated phases, including for the first time a SC pocket near half-filling of the electron-doped band and resistive states at quarter-filling of both bands that emerge in a magnetic field. Changing the layer polarization with vertical electric field reveals an unexpected competition between SC and correlated insulator phases, which we interpret to result from differences in disorder of each graphene layer and underscores the spatial inhomogeneity like twist angle as a significant source of disorder in these devices [1].

9:00AM R14.00006: Wigner Crystallization in Twisted Bi-layer Graphene BIKASH PADHI (Presenter), PHILIP PHILLIPS, CHANDAN SETTY, University of Illinois at Urbana-Champaign — Study of strongly correlated phases took an interesting turn recently by the surprising discovery of high-Tc superconductivity in twisted sheets of graphene. The electronic properties of each graphene-layer can be described by non-interacting electrons. However, in a twisted bi-layer graphene (TBLG), close to the 'magic angles', the kinetic energy of the electrons is heavily quenched. This causes interactions to dominate, paving way for strong correlation. In this talk, I discuss arXiv: 1804.01101 and 1810.00884. We first compute quasiparticle interaction energy and kinetic energy to obtain their ratio, \( r_s \), which quantifies the extent of strong correlation. This ratio crossing unity already signals departure from a perturbative regime (or Fermi liquid behavior). For \( r_s \) larger than 37, the system minimizes the strong Coulomb repulsion by forming electronic crystals, called Wigner crystals. We show that TBLG near magic angles exhibits \( r_s \) much larger than this critical value, facilitating a hierarchy of metal-insulator transitions. Pressure enhances such crystallization. In light of Wigner crystallization we discuss various aspects of the recent experiments and show remarkable agreement with this scenario.

9:12AM R14.00007: Emergent Flat band lattices in spatially periodic magnetic fields* MUHAMMAD TAHIR (Presenter), HUA CHEN, Department of Physics, Colorado state University, Colorado State Univ — Motivated by the recent discovery of Mott insulating phase and unconventional superconductivity due to the flat bands in twisted bilayer graphene, we propose more generic ways of getting two-dimensional (2D) emergent flat band lattices using either 2D Dirac materials or ordinary electron gas subject to moderate periodic magnetic fields with zero spatial average. We provide simple formulas for the "magic ratios" between the field strength and its wavenumber for getting flat bands, and give an intuitive explanation for their origin by constructing coarse-grained lattice models. Our work provides new, flexible platforms for exploring interaction-driven phases in 2D systems with arbitrary superlattice symmetries.

Tuning the electronic structure and electron correlation in 2D twisted massive Dirac system: the case of twisted bilayer hBN

LEDE XIAN (Presenter), Max Planck Institute for the Structure and Dynamics of Matter, DANTE KENNES, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, NICOLAS TANCOCGNE-DEJEAN, MASSIMO ALTARELLI, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter — Recent experiments have suggested that twisted bilayer graphene (TBG) near magic angles can be an ideal platform for the study of strong correlation effects and unconventional superconductivity. Interestingly, our density functional theory (DFT) calculations show that flat bands also develop at both the top of the valence bands and bottom of the conduction bands in bilayer hBN with a twist. But different from the case of TBG systems, the band width of these flat bands decreases monotonically with twist angles and there is no appearance of any magic angles. We further use functional renormalization group (FRG) method to show that the flat band at the top of the valence bands can host exotic strong-correlated physics, such as the appearance of Mott insulator phase and unconventional superconductivity. Our study suggests that the gapless and massless characters of graphene is not essential in the observed strong-correlated phenomena and many more other 2D materials can also be explored in the form of twisted bilayer system for the study of unconventional superconductivity.

This project has received funding from the European Union’s Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No. 709382 (MODHET).

Tunable spin-polarized Mott insulator in twisted bilayer-bilayer graphene

XIAOMENG LIU (Presenter), ZEYU HAO, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, PHILIP KIM, Harvard University — Twisted bilayer graphene, forming a flatband at the magic angle, has become a new platform to study correlated electron states. Superconductivity and Mott insulator phase have been demonstrated in this system. However, the flatband only occurs at a specific twist angle, which is both hard to achieve and lacks tunablity to enable other emergent phenomena.

Here we report experiments on twisted bilayer-bilayer graphene, where two Bernal-stacked bilayer graphene are placed together with a small twist angle. Due to the tunable band structure of bilayer graphene with displacement fields, we can achieve flatband structure in a large range of twist angles. At each twist angle, we observed Mott insulator phase at 1/2 filling in a specific range of displacement fields. Under a parallel magnetic field, additional insulating states emerge at 1/4 and 3/4 filling while the 1/2 filled insulating state become more robust. This suggest the 1/2 insulator is a spin-polarized state.

The nature of correlations in the insulating states of twisted bilayer graphene

MARÍA JOSÉ CALDERÓN (Presenter), JOSÉ MARÍA PIZARRO, ELENA BASCONES, Instituto de Ciencia de Materiales de Madrid, CSIC — The recently observed superconductivity in twisted bilayer graphene emerges from insulating states believed to arise from electronic correlations. While there have been many proposals to explain the insulating behavior, the commensurability at which these states appear suggests they are Mott insulators. We focus on the insulating states with ±2 electrons or holes with respect to the charge neutrality point. We show that the theoretical expectations for the Mott insulating states are not compatible with the experimental dependences on temperature and magnetic field if, as frequently assumed, only onsite (local) correlations are included. We argue that the inclusion of intersite correlations in the treatment of the Hubbard model can bring the predictions for the magnetic and temperature dependencies of the Mott transition to an agreement with experiments. The importance of these non-local correlations indicates that the observed insulating gap is not the one between the Hubbard bands and that antiferromagnetic-like correlations play a key role in the Mott metal insulator transition. arXiv:1805.07303.

On the nature of the correlated insulator states in twisted bilayer graphene

MING XIE (Presenter), ALLAN MACDONALD, Department of Physics, University of Texas at Austin — We use self-consistent Hartree-Fock calculations performed in the full π-band Hilbert space to assess the nature of the recently discovered correlated insulator states in magic-angle twisted bilayer graphene (MATBG). We show that at integer number of electrons per moiré period, the mean-field ground states break the combined two-fold rotation and time reversal symmetry $C_2T$ that protects the moiré-band Dirac points, inducing gaps and establishing valley projected bands that have non-zero Chern numbers. Broken spin/valley flavor symmetries then enable gapped states to form not only at neutrality but also at moiré band filling $n = \pm p/4$, where $p$ is the number of electrons per moiré period. We predict that the MATBG ground states at $n = \pm 1/4$ and $n = \pm 3/4$ have an anomalous Hall effect, and discuss the implications of our findings for theories of magic-angle superconductivity.
GREGORY HOLDMAN (Presenter), WYATT BEHN, ZACH KREBS, KEENAN SMITH, BENNY TOCK, VICTOR W BRAR, University of Wisconsin - Madison — Bilayer graphene (BLG) is known to have a dynamic electronic structure including a continuously tunable bandgap, and correlated electron behavior under a variety of conditions. To better understand these phenomena, it is important to develop local probes that can directly determine how these effects manifest in the presence of defects and impurities. In many semiconducting or metallic systems, scanning tunneling spectroscopy (STS) can serve as such a local probe. However, STS necessarily applies a local electric field to the system it measures. For BLG, this field can alter the local band structure by breaking the symmetry of the two layers and simultaneously doping the surface. This dynamic band structure modification makes STS measurements of BLG difficult to interpret and prevents straightforward extraction of the material parameters. In this talk, we show how these effects can be modeled and understood by computing the expected voltage-dependent tunneling spectrum of a BLG sheet between two gate electrodes. We compare this model to STS data taken from BLG/SiO₂ and BLG/h-BN systems under UHV conditions at a temperature of 4 K and show how to extract the BLG bandgap from STS measurements performed at different back-gate voltages.

10:24AM R14.00013: Graphene quasicrystal
PILKYUNG MOON (Presenter), Department of Physics, New York University Shanghai, MIKITO KOSHINO, Department of Physics, Osaka University, YOUNG-WOO SON, School of Computational Sciences, Korea Institute for Advanced Study — Quasicrystals have been used to study quantum states between the limits of periodic order and disorder. Recently, we reported that quasicrystals can be realized by stacking atomic layers at a specific configuration [1]. And, as a specific example of such designer quasicrystals, we reported a graphene quasicrystal composed of two graphene layers stacked at a rotation angle of 30°.
In this talk, I will discuss the theory of Dirac electrons in a graphene quasicrystal and show the characteristic features of this structure [2]. I will first report a rigorous effective model of the electronic structures of graphene quasicrystal. Then, I will show the emergence of the critical states, which are neither perfectly localized nor fully extended, and reveal the origin of these states as well as the minimum wave functions for describing the electronic structures. In addition, I will show that the wave functions show 12-fold rotational symmetry and report the band dispersion of graphene quasicrystal.

10:36AM R14.00014: Flat bands due to twisted bilayer graphene: A coordinate transformation approach
DAVID SCHMELTZER (Presenter), City College of the City University of New York, AVADH SAXENA, Los Alamos National Laboratory — We consider two-layer graphene with one layer twisted by a small angle θ. This can be investigated using a coordinate transformation given by an angle θ with respect to the untwisted layer. For the untwisted layer two sublattices are a(\textbf{R}) and b(\textbf{R} + δ) and in the twisted layer we have A(\textbf{R}') and B(\textbf{R}' + δ). We consider hopping between the two layers −ta,A and −ta,B. As a result, we obtain four eigenvalues. Two eigenvalues have low energy with vanishing dispersion as a function of the angle. The solution is based on the replacement of the twisted coordinate in the momentum space by a spinor transformation B'σ(k'(\textbf{k})) = exp(iσ3θ/2) Bσ(\textbf{k}). In the presence of interaction the coordinates are affected by the transformation and thus contain the phase exp(iσ3θ/2).

8:00AM R15.00001: Recent STM Studies of Gate-tunable 2D Material Devices
JIONG LU (Presenter), ZHIZHAN QIU, HANYAN FANG, Department of Chemistry, National University of Singapore — 2D materials with reduced dimensionality exhibit unprecedented tunability in both their electronic and optical, chemical properties due to the high susceptibility to the doping and the change of many-electron effects. Here we demonstrate a tunable band gap modulation in back-gated 2D material devices. Using low-temperature scanning tunnelling microscopy (LT-STM), we probed the quasiparticle electronic bandgap of recently emerged 2D materials such as black phosphorus (BP) and 2D TMDCs as a function of electrostatic gating. The demonstration of an electrical field tunable bandgap in 2D material devices paves the way to designing electro-optic modulators and photodetector devices that can be operated in a wider electromagnetic spectral range.

**8:12AM R15.00002: Real-space Observation of Charge Separation in Mixed Dimensional InSe-C\textsubscript{70} van der Waals Heterojunctions**

SHAOWEI LI (Presenter), CHENGMEI ZHONG, ALEX HENNING, MARK HERSAM, Northwestern University —

Two-dimensional InSe is a direct bandgap semiconductor promising for high performance photodetectors and solar cells. Mixed dimensional p-n heterojunction between InSe and organic molecules integrates desirable properties of both. Electronic structure of surface states is critical for optimal band offsets at the heterojunction. Although there is no consensus on the type of intrinsic doping, few-layered InSe field-effect transistors showed exclusively n-type behavior. Here, we report that the atomically clean surface of mechanically exfoliated InSe is unintentionally p-doped. STS taken over the native surface selenium vacancies resolves occupied defect states near the valance band edge. These defect states lead to an upward band bending near the InSe surface, rendering InSe surface p-type. In prototype InSe/C\textsubscript{70} heterojunction, PL spectroscopy and STS both indicate formation of a type-II heterojunction. Electrons can transfer between InSe and C\textsubscript{70} evidence from mutual PL quenching of both InSe and C\textsubscript{70}. STS in vacuum and KPFM in the ambient consistently reveal the electron transfer from InSe to C\textsubscript{70} resulting in a photovoltage of \(\sim 0.25\) eV. This study reveals the unusual electron donor behavior of InSe in an organic-inorganic heterostructure.

**8:24AM R15.00003: Atomically thin dichalcogenide heterostructures and interfaces measured via cathodoluminescence in scanning transmission electron microscope**

AKSHAY SINGH (Presenter), HAEYEON LEE, SILVIJA GRADECAK, Massachusetts Institute of Technology — Atomically thin transition metal dichalcogenides (TMDs) and associated heterostructures have distinct opt-electronic properties including enhanced luminescence and high on-off current ratios. However, optoelectronic properties measured using conventional methods are limited to micro-milimeter scale and with no direct structural correlation, despite the fact that relevant property fluctuations can be caused by significantly smaller structural features. We use cathodoluminescence (CL) in a scanning transmission electron microscope (STEM) as a nanoscale probe that offers direct structure-optical correlation with high spatial resolution. We present the first, to our knowledge, STEM-CL measurements of monolayer tungsten disulfide (WS\textsubscript{2}) encapsulated between hexagonal boron nitride (HBN). We measure spatially inhomogeneous luminescence resulting from variations in the interface quality between layers, and provide a direct way to probe optical properties of TMD heterostructures on the nanoscale. We also discuss role of the electron beam and the ways to minimize it to measure intrinsic properties of TMDs. STEM-CL offers to be a powerful method to directly measure structure-optical correspondence, with applications in measuring lateral or vertical TMD heterostructures and alloys.

**8:36AM R15.00004: Carrier density tuning in single layers of WS\textsubscript{2} via photochlorination**

GEORGE KIOSEOGLOU (Presenter), IOANNA DEMERIDOU, IOANNIS PARADISANOS, Institute of Electronic Structure and Laser - FORTH, and University of Crete, Greece, PANOS PATSALAS, Department of Physics, Aristotle University of Thessaloniki, Greece, EMMANUEL STRATAKIS, Institute of Electronic Structure and Laser - FORTH, and University of Crete, Greece — Monolayers of Transition Metal Dichalcogenides (TMDs) of the form MX\textsubscript{2} (M=Mo or W and X=S or Se) are promising semiconducting materials for future 2D nanoelectronics due to their unique properties. Carrier modulation and doping reversibility are very important issues in the study of the electronic properties of TMDs and at the heart of many applications. We demonstrate electron density control in chlorine-doped WS\textsubscript{2} monolayers by pulsed laser irradiation in a precursor gas atmosphere [1]. The increase of the photochlorination time gives rise to a systematic red-shift in the PL energy of the neutral exciton indicating a reduction in the electron density. This electron withdrawing process enabled also the determination of the trion binding energy of the intrinsic crystal, found to be 20 meV, in accordance to theoretical predictions. At the same time, it is found that the effect can be reversed upon cw laser rastering of the monolayer in air. SAM and XPS reveal that chlorine physisorption is responsible for the e-density modulation induced by the pulsed laser photochemical reaction process and confirmed by DFT calculations. [1] I. Demeridou et al, 2D Mater. 6 (2019), 015003

Surface Oxidation Induced P-doping in Transition Metal Dichalcogenides

MINJU KIM (Presenter), JUNKYEONG JEONG, DONGGUEN SHIN, JEEHONG PARK, JAEHYUN YANG, SANGWAN CHO, Department of Physics, Yonsei University, HYUNBOK LEE, Department of Physics, Kangwon National University, YEONJIN YI, Department of Physics, Yonsei University — Transition metal dichalcogenides (TMDCs) has received tremendous attention due to their fascinating electrical properties, such as a high carrier mobility, high on/off ratio and tunable bandgap. However, TDMC-based electronic devices do not show their pristine properties due to the contact resistance between the metal electrode and TMDCs. Surface oxidation has been known to induce a p-doping and it improves the contact resistance. With optimum oxidation, highly improved contact was evidently observed in field-effect transistors, while it is rather worsen with non-optimum conditions. To elucidate the origin of improvement, the changes in the electronic structure of TMDCs upon the surface oxidation should be understood. In this regard, the electronic structure of TMDCs was studied with ultraviolet and x-ray photoemission and inverse photoemission spectroscopy (UPS/XPS/IPES). TMDCs were treated with UV-ozone and the changes in oxidation states of TMDCs were investigated with XPS. Then, the changes of work function and band edges were directly observed with UPS and IPES. The surface oxidation can control the position of band edges efficiently.

Modulation doping in hexagonal BN atomic-layer semiconductor

SUSUMU SAITO (Presenter), YUUTO MATSUURA, YOSHITAKA FUJIMOTO, Tokyo Institute of Technology — We study the stable stacking sequences and the electronic properties of hexagonal BN (h-BN) trilayers within the framework of the density functional theory. Because of its lower-symmetry geometry of the h-BN sheet than that of graphene, there appear several different stable stacking sequences in the h-BN trilayers. Interestingly, most of stable stacking sequences of trilayers are found to be different from that of the bulk phase. It is also found that spatial distributions of both the valence-band top states and the conduction-band bottom states are rather confined to a certain specific layer in stable h-BN trilayers. By utilizing this fact, we design the C-doped h-BN trilayers where carriers conduct not in the doped layer but mostly in the undoped perfect layer. These systems are therefore considered to be the ultimate modulation-doped semiconductor heterostructure where both the doped region and the conducting region are only one atomic-layer thick. We also discuss several four-layer and five-layer h-BN systems which can host further clear spatial modulation doping.

Doping dependent magnetic properties in monolayer PdSe2

YOSEP CHO (Presenter), HYOUNG JOON CHOI, Physics, Yonsei University — In recent years, ferromagnetism in two-dimensional materials which is induced by charge doping drawn great interest. Density functional theory (DFT) calculations with changing the total number of electrons predict that increase of hole doping leads to ferromagnetism in monolayer (ML) PdSe\textsuperscript{2}. In this work, we investigate doping dependent magnetism in ML PdSe\textsubscript{2} using supercells with differently substituted impurities. Moreover, we performed virtual crystal approximations (VCA) for uniform and non-uniform doping to see doping method dependence for the magnetism. To understand the magnetism in this material, we discuss local-moment interactions and Stoner-type mechanism.

**9:24AM R15.00008: All-optical quality assessment of 2D TMDs using polarization-resolved SHG**  
EMMANUEL STRATAKIS (Presenter), Institute of Electronic Structure and Laser - FORTH, and University of Crete, Greece, SOTIRIS PSILODIMITRAKOPoulos, LEONIDAS MOUCHLIADIS, IOANNIS PARADISANOS, ANDREAS LEMONIS, Institute of Electronic Structure and Laser - FORTH, Greece, GEORGE KIOSEOGLOU, Institute of Electronic Structure and Laser - FORTH, and University of Crete, Greece — While large-area crystal growth techniques, such as chemical vapor deposition (CVD), are successfully used to produce 2D transition-metal dichalcogenides, the presence of grain boundaries, vacancies and arbitrarily oriented grains, substantially affect their crystal quality. We demonstrate a fast, high-resolution non-linear optical method for the quality control of WS2 monolayers. Polarization resolved second harmonic generation (PSHG) imaging reveals with high-precision the orientation of the main crystallographic axis (armchair). By performing a pixel-by-pixel mapping of the armchair orientations on a CVD-grown sample area, we can distinguish between different domains, locate their boundaries and reveal their detailed structure. We fit experimental PSHG images of sub-micron resolution into a generalized theoretical model and we acquire the armchair orientation for every pixel. This allows us to measure the mean orientational average of armchair angle distributions from specific regions of interest and consequently to define the standard deviation of these distributions as a crystal quality factor. [1] S. Psilodimitrakopoulos, et al., Light Science & Applications 7, 18005 (2018).

**9:36AM R15.00009: Chemically Tunable 2D Layered Materials: Acoustic Phonons, Charge Density Waves, & Phase Transitions** [Invited] KRISTIE KOSKI (Presenter), University of California, Davis — I will present an innovative strategy to intercalate atomic species including heavy metals, semiconductors, and semimetals (Ag, Au, Bi, Cr, Cu, Ge, Mn, Mo, Ni, Os, Pb, Pd, Pt, Rh, Ru, Sb, W) into 2D layered materials. With intercalation of zero-valent elements, fundamentally new physical behaviors arise such as chemically-controllable commensurate and incommensurate charge density waves, altered acoustic phonons as measured with Brillouin scattering, and chemically-tunable pressure-dependent phase transitions. This strategy can be further used to achieve 2D metal-semiconductor heterostructures or 2D semiconductor heterostructures with unique physical properties. Chemically tunable physical properties of intercalated Bi2Se3, Si2Te3, GeS and MoO3 are demonstrated.

**10:12AM R15.00010: Understanding bound excitons in 2D monolayer semiconductors with nano-optical imaging and spectroscopy**  
NICHOLAS BORYS (Presenter), Physics, Montana State University, THOMAS DARLINGTON, Physics, University of California, Berkeley, JIM SCHUCK, Mechanical Engineering, Columbia University, ANDREY KRAYEV, Horiba Scientific — Bound excitons in 2D semiconductors are of interest as potential qubits as well as single-photon emitters for quantum computing and information applications. But our limited understanding of these states inhibits overcoming several challenges that they pose for integration into practical technological applications. One such issue is the suppression of bound excitons at temperatures above ~150 K. Employing a suite of time-resolved and nano-optical spectroscopy studies, we find that the thermally-activated process suppresses their formation and develop a nano-optical architectural motif to reverse this suppression and activate the states at room-temperature. Furthermore, using nano-optical imaging and spectroscopy, distinct bound exciton states are optically imaged within strain-induced potentials at resolutions down to 20 nm. This nanoscale resolution allows us to measure the extent to which these states are localized as well as identify how nanoscale strain controls their excited-state properties. From these studies, we can begin to envision how to use nano-optical antennas to integrate patterns of bound exciton states in two-dimensional monolayer semiconductors for model optoelectronic and room-temperature quantum devices.

**10:24AM R15.00011: Laser annealing for Large Excitonic Reflectivity from MoSe2 grown by Chemical Vapor Deposition**  
CHRISTOPHER ROGERS (Presenter), DODD J GRAY, NATE BOGDANOWICZ, HIDEO MABUCHI, Stanford University — We present data of a laser annealing procedure which drastically improves the quality of suspended monolayers of chemical vapor deposition grown MoSe2. Annealing with a green laser locally heats the suspended flake, which both removes contaminants and reduces strain gradients. At 4 K, we observe linewidths as narrow as 3.5 meV (1.6 nm) full width at half maximum for both photoluminescence and reflection. Large peak reflectances up to 47% are also observed. These values are comparable to those of the highest quality hexagonal boron nitride encapsulated samples. We demonstrate that this laser annealing process can yield spatially homogeneous samples where the length scale of the homogeneity is limited primarily by the size of the suspended area. Annealed regions are very stable, exhibiting negligible deterioration over 24 h at cryogenic temperatures. The annealing method is also very repeatable.

Spontaneous Curvature of Janus Transition Metal Dichalcogenide Nanoribbons: Effects on Optoelectronic, Magnetic and Mechanical Properties  JARON KROPP (Presenter), FATIH ERSAN, CAN ATACA, University of Maryland, Baltimore County — Janus transition metal dichalcogenides (TMDs) are two-dimensional materials of the form MXY (M = Mo, W; X, Y = S, Se, Te). These materials are similar to traditional TMDs with structure MX₂, but with one chalcogen layer replaced by another chalcogen type. In this work, we study freestanding armchair and zigzag nanoribbons of the Janus materials Mo/WSSe, Mo/WSTe, and Mo/WSeTe using density functional theory. The lattice mismatch between the X and Y sides of the material causes curvature of the unsupported ribbons. We investigate the magnetic and electronic properties of these structures as a function of ribbon width and curvature angle. Zigzag nanoribbons are found to be metallic while armchair nanoribbons are semiconducting with a band gap that depends on the ribbon width. Additionally, all zigzag nanoribbons possess a magnetic moment while armchair ribbons may not. We also study the effects of edge passivation on both armchair and zigzag nanoribbons. Hydrogen passivation was found to increase the band gap, enhance the stability of nanoribbon edge and induce a magnetic moment in the armchair ribbons. This work sheds light on how the spontaneous curvature of the nanoribbons affect/enhance the optoelectronic, magnetic and mechanical properties.

Session R16 DMP: Transport in Nanostructures -- Electron-phonon Coupling and Phonon Transport in Nanostructures and Heterostructures BICEC 155 - Charles Harris, Sandia National Laboratories - Tag(s):
Focus

8:00AM R16.00001: Spatially-Resolved Non-Equilibrium Phonon Transport Across Nanoscale Interfaces* GEORGIOS VARNAVIDES (Presenter), Department of Materials Science, Massachusetts Institute of Technology, ADAM JERMYN, Kavli Institute for Theoretical Physics, University of California at Santa Barbara, POLINA ANIKEEVA, Department of Materials Science, Massachusetts Institute of Technology, PRINEHA NARANG, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Understanding phonon-mediated heat transfer at the nanoscale, to explain heat-dissipation in nanoelectronics, local temperature effects, and new phenomena probed my ultrafast coherent dynamics, presents a theoretical challenge. Further, nanoscale interfaces pose an exciting experimental frontier, with diverse applications from interface-engineering for thermoelectrics to catalytic interfaces and nanotheranostic agents. Despite the ubiquity of these applications, an accurate microscopic description of thermal interface resistance (TIR) remains elusive. To address this, we introduce a new theoretical and computational framework for semi-classical transport with position-, momentum-space, and scattering event resolution. We demonstrate the recursive formalism for phonon transport in a spherical nanoparticle, and highlight new insights made possible using this multi-dimensional resolution. We extend the formalism to handle interfaces explicitly to quantitatively capture TIR for the technologically relevant Si-Ge heterostructure. Finally, we will present preliminary results in coherent and driven phonon effects, now accesible via ultrafast spectroscopies.

8:12AM R16.00002: Unconventional Impact of Interfacial Thermal Coupling in Film-On-Substrate Systems KARTIK KOTHARI (Presenter), ABHINAV MALHOTRA, MARTIN MALDOVAN, Georgia Institute of Technology — An accurate determination of thermal transport in thin film-on-substrate (FOS) architectures is crucial to optimum performance of nanostructured optoelectronic devices. A rigorous treatment of the nanoscale interfacial coupling between materials accounting for dispersion mismatch, interfacial roughness and shadowing effects is imperative in studying the impact of substrates on thin-film heat conduction. In a unique finding, we discover an increase in thermal conductivity with a reduction in thin-film thickness attributed to phonon injection from the substrate layer. We examine the in-plane and cross-plane configurations of thermal conduction in Ge and Al₀.₁Ga₀.₉As thin-films mounted over Si and GaAs substrates respectively. We provide an extensive analysis of phononic coupling and contrast the results with bulk and isolated thin film values. We present a detailed microscopic and spectral analysis by investigating the spatial thermal flux distribution, modal thermal conductivity, and mean free path and frequency spectra in the FOS architecture. We demonstrate how interlayer phonon coupling opens new avenues for thermal conductivity manipulation in nanostructures and achieves desired thermal properties for rational thermal material design in microelectronics and optoelectronics.
8:24AM R16.00003: Modeling phonon transport in nanowires with rough surfaces  SID ABHINAV (Presenter), KHANDKER A MUTTALIB, University of Florida — We study phonon transmission in thin silicon nanowires where surface-roughness dominates over bulk disorder. Our previous study was based on an exact mapping of surface disorder, modeled as a random distribution of localized phonons\(^1\). Here we extend the idea to study its effects on transport of propagating acoustic phonons. We characterize the localized phonons by surface roughness parameters and study the effects using NEGF techniques. Non-linear heat current is evaluated for various couplings between the propagating phonons from the leads and the localized phonon in the central device. Numerical evaluation gives frequency dependence of heat current at various finite temperatures, where the difference in temperature between the two leads can be large under non-equilibrium conditions. We show that our simple model captures the qualitative features obtained in experiments, and suggests combination of surface parameters that can lead to a substantial reduction in thermal conductivity, as required for applications in thermoelectricity.

8:36AM R16.00004: Phonon-dominated thermal transport in an ultrathin Au-Ni bilayer  ALEXEI MAZNEV (Presenter), Department of Chemistry, Massachusetts Institute of Technology, JAN-ETIENNE PUDELL, MARC HERZOG, Institut für Physik & Astronomie, Universität Potsdam, MATTHIAS KRONSEDER, Physics Department, Technical University Munich, CHRISTIAN BACK, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, GREGORY MALINOWSKI, Institut Jean Lamour, Université Lorraine, ALEXANDER VON REPPERT, MATIAS BARGHEER, Institut für Physik & Astronomie, Universität Potsdam — Thermal conductivity in metals is normally predominantly electronic. However, at small distances, the phonon contribution to thermal transport becomes increasingly important, especially in metals with weak electron-phonon coupling such as Au. In this report, we show that thermal transport in an Au-Ni bilayer becomes predominantly phononic when the Au thickness is ~6 nm or less. We analyze recent ultrafast x-ray diffraction measurements of heat transport in an ultrathin metal bilayer consisting of 5.6 nm Au and 12 nm Ni \(^1\) together with earlier measurements on a thicker bilayer \(^2\) and show that in the experiment \(^1\) more than 50% of the heat flow from the Ni lattice to Au lattice was carried by phonons, despite a high thermal boundary resistance for phonon heat transport due to a large mismatch of the phonon spectra. The measurements reported in Ref. \(^1\) offer a way to study heat transport by phonons in multilayer structures on the single digit nanometer scale and could be used for direct testing of non-equilibrium molecular dynamics simulations.

8:48AM R16.00005: Beyond diffusive scattering: Phonon coupling to reduce thermal conductivity  ABHINAV MALHOTRA (Presenter), KARTIK KOTHARI, MARTIN MALDOVAN, Georgia Institute of Technology — Diffusive scattering has remained the only mechanism to reduce thermal conduction at the nanoscale. In this talk, we show that phonon coupling in layered nanomaterials (bi-layers and tri-layers) can be engineered to reduce the thermal conductivity of a silicon thin-film below its free-standing value. We present a methodology to quantitatively evaluate the impact of phonon coupling on each layer in layered nanostructures. We evaluate the dependence of resultant thermal conductivity modulations on structural parameters and find that they are critically dependent on layer spacings and interface properties. The results of this work open new avenues within the rational thermal design by elucidating a new method that can be used to reduce thermal conductivities beyond the traditional diffusive scattering based approaches. The prospects of being able to modulate the thermal conductivity can radically change how we control heat flow in electronic, optoelectronic, and thermoelectric materials.

9:00AM R16.00006: Electronic Thermal Transport in h-BN/Graphene/h-BN heterostructures* [Invited]  MIR MOHAMMAD SADEGHI, LI SHI (Presenter), University of Texas at Austin — Using a sensitive differential electro-thermal measurement technique, we observe that the Lorenz number for the electronic thermal conductivity of h-BN/graphene/h-BN heterostructures is considerably lower than the Sommerfeld value in the single-band regime at room temperature and below. In the bi-polar regime near the Dirac point, a Lorenz peak well above the Sommerfeld value is observed at room temperature, and decreases with decreasing temperature. The deviation from the Wiedemann-Franz law and its temperature dependence provide insight into the unique transport behavior of Dirac Fermions in this system.

An Onsager reciprocity relation for ballistic phonon heat transport in anisotropic thin films of arbitrary orientation

GEOFF WEHMEYER (Presenter), Mechanical Engineering, Rice University, ANDREA D PICKEL, CHRIS DAMES, Mechanical Engineering, University of California, Berkeley — A classic Onsager reciprocity relation for Fourier heat conduction states that the thermal conductivity tensor in bulk anisotropic solids is symmetric. However, since Fourier's law fails in thin dielectric films due to ballistic phonon transport effects, it is natural to ask whether an analogous Onsager relation can be identified for thin films. To answer this question, we solve the Boltzmann transport equation (BTE) under the relaxation time approximation for in-plane and cross-plane heat transport in thin films with anisotropic phonon dispersion relations and scattering rates. These BTE solutions show that the effective thermal conductivity tensor of thin films is symmetric from the diffusive through the boundary scattering regime. We validate the BTE solution against previous atomistic simulations of arbitrarily aligned graphite thin films, and use published first-principles calculations to model anisotropic heat flow in black phosphorus thin films. This derivation shows how Onsager reciprocity for anisotropic heat conduction extends to the boundary scattering regime, and reduces the number of independent measurements required to characterize heat transport in anisotropic thin films.

Surface Acoustic Wave Generation and Detection on LaAlO$_3$/SrTiO$_3$

DENGYU YANG (Presenter), YUN-YI PAI, YUHE TANG, YANG HU, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNGWOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — We aim to generate and detect surface acoustic waves (SAW) in LaAlO$_3$/SrTiO$_3$ heterostructures. Using a well-developed conductive-AFM lithography technique [1], we “sketch” interdigitated transducers (IDT) on LaAlO$_3$/SrTiO$_3$ “canvases”, which convert electronic signals into SAW and vice-versa. Two sets of IDTs are written on the structure to function as generator and detector. SAW can be used to generate dynamic potentials based on piezoelectric properties of LaAlO$_3$/SrTiO$_3$, and have the potential to drive electrons through nanostructures, a property that could be useful for quantum information applications.

Electron Phonon Coupling in Metallic Superlattices

ANDRIUS BERNOTAS (Presenter), BRIAN DONOVAN, RONALD WARZOHA, Physics, United States Naval Academy, PATRICK HOPKINS, University of Virginia — Superlattices offer potential improvement in microelectronic transistor design as diffusion barriers between the silicon active layer and copper interconnects. While these materials provide a novel path forward in terms of electronic and atomic transport, more work must be done to understand potential thermal bottlenecks that could arise from their use in transistors. A major source of thermal buildup in microelectronic devices is the interaction between electrons and the surrounding atomic species in the form of electron-phonon coupling. In this project we explore the coupling between electrons and phonons as heat carriers in conductive multilayer superlattices of copper with tantalum, tungsten, and tantalum nitride. We use time domain thermoreflectance measurements and the two temperature thermal model to better understand the relationship between the electron phonon coupling in these materials and the physical parameters of the system. A greater understanding of this relationship will allow for greater control of the thermal properties of transistors, hopefully leading to increased thermal efficiency in microelectronics.
10:12AM R16.00010: Tuning the thermal boundary conductance at metal-dielectric interfaces by varying interlayer thicknesses  SHANY MARY OOMMEN (Presenter), Department of Physics and Astronomy, York University, Toronto, ON, Canada, SIMONE PISANA, Department of Electrical Engineering and Computer Science, York University, Toronto, ON, Canada — Interfaces play a significant role in the heat transport across boundaries at sub-micron length scales. Interfacial adhesion and phonon matching are important factors in determining the thermal boundary conductance, and the addition of an interlayer can be used to tune the heat dissipation. In this study, we analyze the modification of the thermal boundary conductance at metal-dielectric interfaces by insertion of metal interlayers with varying thicknesses from 2.5 Å to 100 Å. We show that the insertion of a tantalum interlayer at Al/Si and Al/sapphire interfaces hinders the phonon transmission across the interfaces and it plateaus at ~20 Å. We found that the addition of a nickel interlayer significantly increased the thermal interfacial conductance at both the Al/Si and the Al/sapphire interfaces. The nickel interlayer, having an intermediate Debye temperature as compared to the Aluminum layer and the substrates, increases the phonon transmission across the boundary. Thermal property measurements were performed through time domain thermoreflectance, and are in good agreement with a formulation of the diffuse mismatch model based on real phonon dispersions, accounting for anharmonic phonon scattering and phonon confinement within the interlayer.

10:24AM R16.00011: Lone-pair Electrons do not Necessarily Lead to Low Lattice Thermal Conductivity: an Exception of Two-dimensional Penta-CN$_2$  HUIMIN WANG (Presenter), Nanjing University — It has long been documented in literature that, the lone-pair electrons (LPE) are generally thought to lead to low lattice thermal conductivity ($\kappa_L$) of bulk materials by inducing strong phonon anharmonicity. Herein, we show an exceptional case of two-dimensional (2D) penta-CN$_2$ that possesses LPE but exhibits more than doubled $\kappa_L$ (660.71 W m$^{-1}$ K$^{-1}$) than the LPE free counterpart of penta-graphene (252.95 W m$^{-1}$ K$^{-1}$), which is unexpected and contradictory to the traditional theory of LPE leading to low $\kappa_L$. Based on the comparative study of four 2D systems possessing LPE and their respective LPE free counterparts (planar C$_3$N vs. graphene and penta-CN$_2$ vs. penta-graphene), the underlying mechanism is found lying in the bonds homogenization in penta-CN$_2$ due to the wide spatial extension of the non-symmetrically distributed LPE, which compensates the lattice anharmonicity due to LPE and is responsible for the opposite tendency of LPE affected $\kappa_L$ in the four 2D systems.

10:36AM R16.00012: Tuning thermal transport in nanostructures and nanostructured materials*  KONSTANTINOS TERMENTZIDIS (Presenter), CETHIL, INSA of LYON, CNRS — Due to the rapid evolution of nanomaterials elaboration the last decade a serie of nanostructures and nanostructured material like phononic-like crystals or nanowire networks are easily fabricated today. New physical phenomena are observed in such structures as ballistic phonon transport, phonon focusing, phonon tunneling and coherence effects. In general, nanostructured materials have a much lower thermal conductivity compared to bulk materials, due to phonon confinement and boundary scattering. Such phenomena will be presented with the present work. The thermal conductivity of a serie of structural, diameter, core/shell modulated and growth direction of silicon, silicon carbide and bismuth telluride nanowires and phononic like crystals and nanowire networks are easily fabricated today. New physical phenomena are observed in such structures as ballistic phonon transport, phonon focusing, phonon tunneling and coherence effects. In general, nanostructured materials have a much lower thermal conductivity compared to bulk materials, due to phonon confinement and boundary scattering. Such phenomena will be presented with the present work. The thermal conductivity of a serie of structural, diameter, core/shell modulated and growth direction of silicon, silicon carbide and bismuth telluride nanowires and phononic like crystals and parameters like neck distance, hole diameter, amorphisation of pores and filling of a second type of material will also be presented using atomistic and mesoscopic simulations. The purpose is to appraise the impact of surface roughness, amorphous parts integration, diameter modulation as well growth direction on the thermal conductivity reduction. The addition of both amorphous regions and nanoconstrictions hinder the thermal conductivity even under the amorphous limit, while preserving a large crystalline volume fraction.

10:48AM R16.00013: Calculating lattice thermal conductivity: A comparative study on carbon nanotubes.  DANIEL BRUNS (Presenter), JOERG G ROTTLER, A. SRIKANTHA PHANI, ALIREZA NOJEH, University of British Columbia — Carbon nanotubes (CNTs) are commonly utilized in nanoscale devices. High structural order, rigid sp$^2$-bonds and a low atomic mass result in an exceptionally high lattice thermal conductivity (TC), which motivates their use in applications demanding efficient heat removal. However, pinpointing exact TC values of individual defect-free CNTs remains a challenge both experimentally and computationally. The thermal transport properties of ideal CNTs are dominated by phonon-phonon scattering, and a theoretical prediction of TC has to include anharmonic terms in the interatomic potential energy which give rise to phonon-phonon interaction. Here we compare two computational frameworks that take into account lattice anharmonicity to predict TC: classical molecular dynamics (MD) vs. anharmonic lattice calculation (ALC). Taking the same empirical interaction potential as input to both MD and ALC, we contrast phonon-phonon scattering rates and TC results as a function of temperature. This comparison also allows us to critically evaluate several assumptions in the different methods, namely the description of anharmonicity by a truncated Taylor expansion of the interaction potential in ALC, the use of classical phonon statistics in MD, and the importance of Umklapp processes for the TC.
New directions for random search* [Invited]  
CHRIS PICKARD (Presenter), University of Cambridge —

Genuinely new knowledge and scientific insight can be obtained about dense matter by combining random numbers with reliable and efficient first principles methods. Diverse ensembles of initial structures can be generated, and structurally optimized. The resulting low energy structures are candidates for stable, and metastable, phases and/or defects that might be experimentally realized. This, of course, depends on a sufficiently broad and thorough sampling of configuration space.

Algorithms which attempt to learn from (computational) experience are necessarily sequential, and correlated. A purely random strategy, as employed by Ab Initio Random Structure Searching (AIRSS),[1,2] is entirely parallel, and a natural fit to the high throughput computation (HTC) paradigm. The absence of correlation between the independent random samples ensures that it is possible to estimate when a sufficiently dense sampling has been achieved (or at least, has not been achieved). Challenging cases can be tackled by designing the initial random structures so that they focus the search in regions of configuration space that are anticipated to yield success.

The design of these random “sensible” structures will be explored, along with some new directions which promise to accelerate random search, and recent applications to materials under extreme compression.

Theoretical Prediction of Superhard Materials with the XtalOpt Evolutionary Algorithm  
XIAOYU WANG (Presenter), PATRICK AVERY, Department of Chemistry, University at Buffalo, State University of New York, DAVIDE PROSERPIO, Università degli Studi di Milano, CORMAC TOHER, STEFANO CURTAROLO, Duke University, EVA ZUREK, Department of Chemistry, University at Buffalo, State University of New York —

The XtalOpt evolutionary algorithm for crystal structure prediction has been extended to enable the prediction of superhard stable materials. The hardness is calculated via a linear relationship with the shear modulus (originally discovered by Teter) as reported by Chen. The shear modulus is obtained via AFLOW-ML (Automatic FLOW for Materials Discovery - Machine Learning). A new fitness function has been implemented wherein the user can denote the percent contribution that hardness and enthalpy have on the fitness function. We have used XtalOpt to search for hard and stable carbon allotropes and found 44 hitherto unpredicted phases whose Vickers Harnesses were calculated to be greater than 45 GPa. The structural motifs in these phases were analyzed. We also discuss the thermodynamic and kinetic stability of the predicted structures, and potential ways in which they can be synthesized under pressure.
8:48AM R17.00003: Meta GGA (SCAN) + van der Waals functionals (rvv10) calculation for K-edge X-ray Raman Spectrum of the epsilon and zeta phase of solid oxygen* 

LE ANH (Presenter), Computational Applications Unit, RIKEN, Japan, MASAHIRO WADA, Graduate school of Material Science, University of Hyogo, Japan, ZHI LI, Xinjiang Technical Institute of Physics and Chemistry, Chinese Academy of Sciences, China, HIROSHI FUKUI, Graduate school of Material Science, University of Hyogo, Japan, TOSHIAKI IITAKA, Computational Applications Unit, RIKEN, Japan — Previous theoretical studies could not predict precisely the epsilon-zeta transitional pressure which was measured at 96 GPa by experiments (Weck et al., PRL 2009, 102, 255503). The GW calculation showed the transitional pressure at 50 GPa (Kim et al., RPRB 2008, 77, 092104) while the B3LYP hybrid functional could estimate the co-existence range of epsilon-zeta from 75 GPa to 145 GPa (Ochoa-Calle et al., PRB 2015 92, 085148). The combination of meta GGA(SCAN) and van der Waals functional (rvv10) was demonstrated to enhance the direct epsilon-zeta transition at 70 GPa while the lattice parameters were very closed to the experimental data (in manuscript). On the other hand, the Inelastic X-ray Scattering (IXS) was successfully used to study epsilon phase of solid oxygen (Meng et al., PNAS 2008, 105, 33). In this talk, we will discuss the evolution of calculated IXS K-edge spectra from epsilon phase to zeta phase using SCAN+rvv10. The calculated spectra will be compared to the experimental data.

*This research was supported by MEXT as “Exploratory Challenge on Post-K computer” (Frontiers of Basic Science: Challenging the Limits) and the RIKEN iTHEMS Project and used the computational resources of the Hokusai supercomputer system provided by RIKEN Information Systems and Cybersecurity.

9:00AM R17.00004: Dynamic non-equilibrium chemical bonding pathways under thermomechanical compression

ANGUANG HU (Presenter), Defence Research and Development Canada — The most urgent need in the explosion science of chemical reactions is about time-resolved non-equilibrium processes on when and how mechanical work and thermal heat are deposited into molecules to initiate reactions. Using quantum solid-state chemistry calculations, multi-resolution and multi-scale dynamic non-equilibrium simulations were recently developed for chemical reactions under compression. The non-equilibrium reaction processes are characterized by the lowest resolution in reactant and resultant conformations, the intermediate resolution in energy, enthalpy, mechanical stress, and chemical shear flows, and the highest resolution in reactive modes selected by compression. The dynamic motion of these flows is governed by a number of equations with respect to time, including the conservation of momentum and energy together with effects of mechanical endothermic bond compression, thermal heat transfer, and exothermic energy release of bond breaking related to irreversible Arrhenius kinetics with volume change and energy barriers. It provides details of dynamic non-equilibrium chemical bonding pathways from quantum to continuum scales. Simulations agreed well with experimental observations such as shock compressed graphite transformed into hexagonal diamond.

9:12AM R17.00005: phq: a Fortran code to compute phonon quasiparticle properties and dispersions

ZHEN ZHANG (Presenter), Department of Applied Physics and Applied Mathematics, Columbia University, DONG-BO ZHANG, Beijing Computational Science Research Center, TAO SUN, Key Laboratory of Computational Geodynamics, Chinese Academy of Sciences, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics, Department of Earth and Environmental Sciences, Lamont-Doherty Earth Observatory, Columbia University — Intrinsic thermal shifts of phonon frequencies due to lattice anharmonicity may be significant in solids at high temperatures. As such, the calculation of phonon dispersions incorporating anharmonic effects is critical for predictive studies of vibrational, thermodynamic, and lattice transport properties. Here we introduce the phq code to compute anharmonic phonon dispersions of crystals that combines molecular dynamics (MD) and lattice dynamics calculations. The method invokes the concept of phonon quasiparticles to extract thermal shifts and phonon lifetimes from velocity autocorrelation functions projected into normal modes sampled by MD simulations. With the renormalized frequencies, it is possible to construct an effective harmonic force constant matrix that allows us to calculate the anharmonic phonon dispersion over the whole Brillouin Zone. Due to the nature of phonon quasiparticles, this approach is applicable not only to simply crystals, but also to complex crystal structures with many atoms per primitive cell with extra effort. We demonstrate successful applications of this code to weakly and strongly anharmonic systems. In addition to temperature-dependent anharmonic phonon dispersions, the vibrational entropy and free energy at constant volume can also be obtained.
9:24AM R17.00006: Evolutionary optimized PAW (EPAW) data-sets across the periodic table*  
KANCHAN SARKAR (Presenter), Department of Earth and Environmental Sciences, Lamont-Doherty Earth Observatory (LDEO), and Applied Physics and Applied Mathematics (APAM), Columbia University in the City of New York, RENATA WENTZCOVITCH, Department of Earth and Environmental Sciences, Lamont-Doherty Earth Observatory (LDEO), and Applied Physics and Applied Mathematics (APAM), Columbia University in the City of New York — We have recently designed and implemented a method named “Evolutionary Generator of projector augmented wave datasets” (EPAW-1.0) [1,2] to produce optimized projector augmented-wave (EPAW) data-sets. The generated EPAW data-sets are transferable and can be employed in Quantum ESPRESSO and ABINIT distributions for the accurate prediction of materials properties at the scalar relativistic level. The accuracy level is very close to the highly precise calculations by the all-electron full potential linearized Augmented-plane-wave (AE-FLAPW) approach as implemented in the WIEN2k code. The EPAW performance level in solid-state studies is nearly uniform over an enlarged pressure region and outperforms other standard PAW dataset libraries, ultra-soft, and norm-conserving pseudopotentials mentioned in the reported effort by Lejaeghere et al. [3]. Employing EPAW-1.0, we generate both LDA and GGA EPAW libraries especially for low-pressure calculations for elements across the periodic table.

9:36AM R17.00007: qha: A Python package for quasi-harmonic free energy calculation for multi-configuration system  
QI ZHANG (Presenter), Department of Applied Physics and Applied Mathematics, Columbia University in the City of New York, TIAN QIN, Department of Earth Sciences, University of Minnesota, KOICHIRO UMEMOTO, Earth-Life Science Institute, Tokyo Institute of Technology, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics, Columbia University in the City of New York — The quasi-harmonic approximation (QHA) offers an effective way of calculating the thermodynamic properties of many crystalline solids at high pressures and temperatures. In some cases, e.g., solid solutions or partially disordered systems such as H2O ice-VII, the system has numerous symmetrically distinct configurations. Here we present a Python package, qha, which can calculate the equation of state and various thermodynamic properties of both single- and multi-configuration crystalline systems in the framework of the QHA. This code has a wide range of applications, including, but not limited to, order-disorder phase transitions [1], solid solutions [2], complex defect stability [3], etc. Apart from its versatility, qha has been tested to be both accurate and computationally efficient. It can also be used as an all-in-one executable or taken apart into stand-alone functions, increasing its usability.

9:48AM R17.00008: Intrinsic Lattice anharmonicity and thermal conductivity of PbTe at High Temperature: Breakdown of the Phonon Minimal Mean Free Path Theory  
XINGJU ZHAO (Presenter), DONG-BO ZHANG, YONG LU, Beijing Computational Science Research Center, TAO SUN, Key Laboratory of Computational Geodynamics, University of Chinese Academy of Sciences, Beijing 100049, China — We investigated the vibrational property of lead telluride (PbTe) with a focus on lattice anharmonicity at relatively high temperatures using the phonon quasiparticle approach. The calculated anharmonic phonon dispersions are strongly temperature dependent and some phonon modes adopt giant frequency shifts. As a result, we witness the avoided crossing between transverse optical modes and longitudinal acoustic modes at elevated temperature, in good agreement with experimentation. These results reveal strong anharmonic effects in PbTe. The obtained phonon lifetimes allow studies of transport properties. For considered temperatures, the phonon mean free paths can be shorter than lattice constants at relatively high temperature, especially for optical modes. This finding goes against the widely employed minimal phonon mean free path concept. As such, the calculated lattice thermal conductivity of PbTe, which is indeed relatively small, does not have the prescribed minima at high temperature, showcasing the breakdown of the minimal mean free path theory. Our study provides a basis for delineating vibrational and transport properties of PbTe and other thermoelectric materials within the framework of the phonon gas model.
Predictions of materials properties at extreme conditions of pressures and temperatures are exceedingly important because it is challenging to obtain them experimentally. At the atomistic level, the accuracy of these predictions relies essentially on a satisfactory characterization of lattice anharmonicity which is generally pronounced at high temperatures. This has stimulated the development of several ab initio approaches to address anharmonic effects on lattice vibrations.

In this talk we present an overview of an ab initio method to address lattice anharmonicity based on the concept of phonon quasiparticles and illustrate its applications to some complex systems, e.g., (i) the vibrational and thermodynamic stabilization of cubic CaSiO3-pv at high temperatures, (iii) the hcp-bcc pre-melting transition in beryllium, and (iii) the irregular thermal shifts of IR frequencies and the breakdown of the well-known minimal phonon mean free path theory in MgSiO3-perovskite. We also introduce a computational package for high pressure and high temperature computational studies that interfaces with popular ab initio packages.

8:00AM R18.00001: Heterodimensional Plasmonic Stubs Enabling THz Electronics† MICHAEL SHUR (Presenter), ECSE and Physics, Rensselaer Polytechnic Institute, JOHN MIKALOPAS, GREGORY AIZIN, Physics, The City University of New York — Emerging TeraFET technology has yielded sensitive tunable detectors of terahertz (THz) radiation. Using plasmonic crystals incorporating TeraFETs to achieve the instability of the plasma waves enabling electronic THz sources could revolutionize the THz electronics. But this approach faces challenges related to matching the boundary conditions between dissimilar plasmonic regions. We report on using “plasmonic stubs” – the narrow regions of an increased width to match the conditions at the interfaces between different devices regions. The physics of the problem (explored using the hydrodynamic model) is similar to that of the water flow in a river of a variable width. The mathematics of the problem is based on the transmission line model. Our analysis shows how to achieve tunable plasmonic instability (supporting THz emission) using plasmonic stubs.

8:12AM R18.00002: Measurement and Analysis of Uncertainty in Mechanical Quality Factor and Implications for LIGO Thermal-Noise Estimation* IAN MACMILLAN (Presenter), GREGORY M HARRY, Physics, American University — With the continued push for more-sensitive gravitational wave interferometers, reducing coating Brownian thermal noise becomes increasingly essential. We report on the uncertainty in quality factor experiments, which are key measurements for predicting the thermal noise of the optics in gravitational wave detectors. Through repeated measurements, we investigate the distribution associated with quality factor measurements. We estimate these uncertainties in mechanical loss measurements and discuss their possible causes. Finally, we comment on the implications of our results for the Laser Interferometer Gravitational-Wave Observatory, LIGO.

*This research was made possible by the National Science Foundation grant 1453252, 1707920, and a grant from the NASA DC Space Grant Consortium.
8:24AM R18.00003: Diffusion of Multi-Speed Gear-Shifting Brownian Swimmers.∗ DON KRASKY (Presenter), DAISUKE TAKAGI, Mathematics, University of Hawaii at Manoa — We introduce a model for dispersion of independent swimmers jumping randomly between multiple translational velocities in arbitrary dimensions. Stochastic differential equations are introduced and used to produce simulations for comparison with theory. The associated Fokker-Planck equations are derived from the Langevin dynamics, giving an analytical prediction for the effective diffusion constant. This prediction is shown to be in good agreement with simulations, and is in a relatively simple form yielding a quick tool for experimentalists to obtain an accurate estimate of diffusion coefficient. A full analysis of the model is presented for the case with two velocities, and some extreme cases are discussed in the general model. We show adaptability of the model by fitting to three previous models of swimmers having two or three preferred velocities. These comparisons explore how stochastic vs. deterministic velocity changes and restricting certain velocity jumps result in different rates of dispersion.

8:36AM R18.00004: Unification of Gas Breakdown and Electron Emission* AMANDA LOVELESS (Presenter), ADAM M DARR, SAMUEL DYNAKO, ALLEN GARNER, Purdue University — The miniaturization of technologies requires a deeper understanding of gas breakdown and electron emission at micro- and nanoscales. Previous work [A. M. Loveless and A. L. Garner, Phys. Plasmas, 24, 113522 (2017).] analytically unified Paschen's law (PL) for Townsend avalanche with field emission (FE) to show continuous reduction in breakdown voltage with decreasing gap size. Another study [G. Meng, et al., Phys. Plasmas, 25, 082116 (2018).] demonstrated this behavior experimentally and derived an analytic solution with a linear relationship between breakdown voltage and gap size in the field emission-Townsend regime. Further reductions in gap size result in the transitions to space-charge limited emission (SCLE). This paper assesses the transitions between FE and the Mott-Gurney (MG) law for collisional SCLE, MG to the Child-Langmuir (CL) law for vacuum SCLE, and CL to quantum scales with Schrödinger’s equation. These derivations yield a triple point, where FE, MG, and CL predict a common breakdown voltage at a specific gap size and pressure. The implications of these transitions will be discussed.

8:48AM R18.00005: Nonlinear Evolution of Tearing Modes with Resistivity and Hyper-Resistivity* DING LI (Presenter), Chinese Academy of Sciences — The nonlinear resistive tearing modes with hyper-resistivity has been analytically investigated. In contrast to the flux average method used by previous works, in the present work the quasilinear method has been extended to obtain the time evolution equation for nonlinear tearing modes. This equation can describe the general evolution of nonlinear tearing modes with both plasma resistivity and hyper-resistivity effects, especially the transition between these two situations. It is difficult to obtain its analytical solution directly. One special solution has been obtained. It is found that the magnetic flux grows with time to the one third power. Some discussions about two limiting cases for resistivity or hyper-resistivity dominant will be presented.

9:00AM R18.00006: A Coarse-Graining Procedure for Differential Equation Models PRANAV KANTROO (Presenter), BENJAMIN MACHTA, Yale Univ — The Renormalization Group framework gives a prescription to determine which macroscopic variables are relevant in a system and sufficient to describe large scale dynamics. Can we develop an analogous methodology to extract important parameters of dynamical systems in general? The Fisher Information Matrix (FIM) formalism measures the response sensitivity of a system to perturbations in its control parameters and has emerged as one way of extracting a hierarchy of relevant variables, even when renormalization isn’t straightforward. The relevant parameter directions are given by eigenvectors of FIM: the hierarchy of relevance is induced by the magnitude of their eigenvalues. This procedure has been done previously for discrete diffusion coarse-grained in time and for the lattice Ising model coarse-grained spatially (Machta et al 2013). Relevant parameters had Fisher information eigenvalues that remained large after microscopic data was discarded. We now extend this analysis to systems of stochastic differential equations utilizing a temporal coarse-graining scheme inspired from Compatible Monte Carlo: specific points in the system are held fixed while the rest of the system is free. Coarse-graining then corresponds to increasing the temporal separation between these fixed points.
Wiener-Khinchin theorem for Fourier-Laplace transformation; new derivation, and application to molecular simulations

AKIRA KOYAMA (Presenter), Department of General Education, National Institute of Technology, Toyota College, DAVID A NICHOLSON, MARAT ANDREEV, Department of Chemical Engineering, Massachusetts Institute of Technology, KOJI FUKAO, Department of Physical Sciences, Ritsumeikan University, TAKASHI YAMAMOTO, Graduate School of Science and Engineering, Yamaguchi University, GREGORY C RUTLEDGE, Department of Chemical Engineering, Massachusetts Institute of Technology — The Wiener-Khinchin theorem for Fourier-Laplace transformation (WKT-FLT) provides a general purpose method to calculate numerically the one-sided Fourier transformation of an arbitrary autocorrelation function (ACF) from molecular simulations. However, the existing derivation of the WKT-FLT equation includes some ambiguities. Moreover, the equation obtained always yields 2 artifacts in the data computed. In this work, we present a new derivation that eliminates these ambiguities and artifacts.

We define an ACF as a natural extension of the known ACF, and write its Fourier-Laplace transformation as the Fourier transformation of the product of the Heaviside unit step function and the ACF. As the result, we successfully obtain an equation for the WKT-FLT. Then, we discretized the WKT-FLT equation to compute the frequency-domain correlation function (FDCF) from numerical simulations. It is found that a correction term is needed in order to avoid over-counting and to satisfy the sum rule. With the correction term, an artifact previously observed in the real part of the FDCF disappears. On the other hand, another artifact still remains in the imaginary part of the FDCF. We will discuss the cause of this artifact.

Radiofrequency Bremsstrahlung of Electrons and Nanoparticles of Heterogeneous Plasma with a Condensed Dispersed Phase

VLADIMIR MARENKOV (Presenter), Odessa Mechnikov National University, Ukraine, SERGIY MOKHOV, University of Central Florida — The mechanism of braking radiation generation in the bulk of heterogeneous plasma formations has been studied in the framework of the statistical “cell” approach to the description of the ionization in heterogeneous plasma (HP). In our description of the effective interaction between microfields and charges in plasma, the stochastic motion of charged particles in HP is considered as an evolution of anharmonic oscillations executed by separate charges in an instant field of electric forces in the electroneutral cell. Effective values of frequency and the specific integral power of the braking radiation from HP in the radiofrequency spectral range are calculated by averaging over the ensemble of cells. The amplitude-frequency function and relative contributions of separate oscillation modes of plasma charges to the emitted radiation intensity are determined in the random phase approximation. A comparative analysis of the modeling data and the experimental data obtained for plasma with aluminum oxide nanoparticles was carried out in the space of key HP parameters. A good agreement between numerical results and experimental data was obtained at both qualitative and quantitative levels. Possible applications for telediagnostics of heterogeneous plasma formations were discussed.

Supernova, fluid instabilities, and interfacial mixing

SNEZHANA ABARZHI, Univ of Western Australia, AKLANT BHOWMICK, Carnegie Mellon University, ANNIE NAVEH (Presenter), Univ of Western Australia, ARUN PANDIAN, Carnegie Mellon University, ROBERT F STELLINGWERF, Stellingwerf Consulting, DAVID ARNETT, University of Arizona — Supernovae and their remnants are a central problem in astrophysics due to their role in the stellar evolution and nuclear synthesis. A supernova’s explosion is driven by a blast wave causing the development of Rayleigh–Taylor and Richtmyer–Meshkov instabilities and leading to intensive interfacial mixing of materials of a progenitor star. Rayleigh–Taylor and Richtmyer–Meshkov mixing breaks spherical symmetry of a star and provides conditions for synthesis of heavy mass elements in addition to light mass elements synthesized in the star before its explosion. By focusing on hydrodynamic aspects of the problem, we identify the properties of Rayleigh–Taylor and Richtmyer–Meshkov dynamics with variable acceleration, discover subdiffusive character of the blast wave-induced interfacial mixing, and reveal the new mechanism of energy accumulation and transport at small scales in supernovae.

9:48AM R18.00010: Validation of classical mixing rule coupled with van der Waals type equation of state for sound speed of non-ideal gas mixture*  
RYUJI TAKAHASHI (Presenter), NOBUYUKI TSUBOI, Department of Mechanical and Control Engineering, Kyushu Institute of Technology, TAKASHI TOKUMASU, Institute of Fluid Science, Tohoku University, SATOSHI WATANABE, SHIN-ICHI TSUDA, Department of Mechanical Engineering, Kyushu University — In the CFD analyses for the combustion chamber of liquid rocket engine, classical mixing rule (CMR) has been often applied to van der Waals (vdW) type equation of state (EOS) such as Soave-Redlich-Kwong (SRK) EOS for prediction of the thermodynamic properties of non-ideal gas mixture. However, the CMR has hardly been validated because of the lack of experimental data. In the present study, for validation of the CMR coupled with SRK EOS for sound speed, which is important to compute the flow field in the combustion chamber, we applied molecular dynamics (MD) method to a Lennard-Jones fluid with modified Lorentz-Berthelot rules that simulates oxygen-hydrogen gas mixture. For the computation of sound speed, NVEPG ensemble proposed by Meier and Kabelac (Meier, K. and Kabelac, S., J. Chem. Phys., 2006.) was employed. As a result, the sound speed from the CMR coupled with SRK EOS agreed with that from MD simulation: it was suggested that the CMR can be applied to sound speed of oxygen-hydrogen mixture system in supercritical condition corresponding to the inlet region of combustion chamber.

*This study has been supported by the Collaborative Research Project of the Institute of Fluid Science, Tohoku University.

10:00AM R18.00011: Nucleation of Quantized Vortices within a Quantum-Mechanical Compton Generator*  
MARTIN KANDES (Presenter), San Diego Supercomputer Center, University of California, San Diego, RICARDO CARRETERO, Department of Mathematics & Statistics, San Diego State University — In 1913, Arthur Compton invented a simple way to measure the rotation rate of the Earth with a tabletop-sized experiment. The experiment consisted of a large diameter circular ring of thin glass tubing filled with water and oil droplets. After placing the ring in a plane perpendicular to the surface of the Earth and allowing the fluid mixture to come to rest, he then abruptly rotated the ring, flipping it 180 degrees about an axis passing through its own plane. The result was that the fluid acquired a measurable drift velocity due to the Coriolis effect of the Earth. Compton measured this induced drift velocity by observing the motion of the oil droplets in the water with a microscope. This device, which is now named after him, is known as a Compton generator. The fundamental research objective of this project is to explore the dynamics of a quantum-mechanical analogue to the classical Compton generator experiment through the use of numerical simulations. Here, we present the first definitive results on the nucleation of quantized vortices within a quantum Compton generator and discuss future directions of the project.

10:12AM R18.00012: Using Monte Carlo and self-consistency to solve Newton's 2nd Law  
JAVIER HASBUN (Presenter), University of West Georgia — In working with Newton's 2nd law, given a force, one seeks to solve for the position, x(t), and the velocity, v(t), as a function of time, t. Obtaining an analytic solution is, of course, of great value, when the problem is solvable. However, a numerical solution is a common route to difficult problems and methods to effect them exist. Two different numerical approaches of interest here are a Monte Carlo (MC) approach [1] and a self-consistent (SC) method. The idea, in the MC case, is to make a random guess for the acceleration, a(t), and to use the trapezoid method to get the velocity versus time, v(t). The time dependent position, x(t), follows by standard numerical integration of v(t). Depending on the situation, sometimes this method is not very efficient. In the SC method, one starts by making an initial numerical guess for a(x(t)) to obtain a v(t), which is used to obtain an x(t), which results in a new a(x(t)), etc. The process is repeated until there is no change in x(t). Here both methods are applied to simple systems and compared to the known analytic solutions for comparison and assessment purposes.

10:24AM R18.00013: Dispersion dynamics applications*  
ANTONY BOURDILLON (Presenter), retired — One starting point is the Klein Gordon equation and the stable wave packet [1]. Simpler is relativity: insert Planck's law and the de Broglie hypothesis. In simple units, angular frequency = \(\omega = (k^2 + m_0^2)^{1/2}\), with \(m_0\) the rest mass. Now differentiate with respect to wave vector \(k\). Three related velocities are the phase velocity, the group velocity and the speed of light. Dispersion dynamics requires consistently, negative mass in the antiparticle, with negative kinetic energy, negative momentum and negative angular velocity. These properties have widespread application in: the Hall effect; superconductivity; the switching principle; galactic rotational velocities; event horizons, uncertainty, intrinsic spin, etc.

*none
In Cosmology, both de Sitter space and Anti-de Sitter (AdS) space are both named after the astrophysicist de Sitter. In Einstein's General Theory of Relativity (GR), space and time are on an equal footing, and we have a unified geometry of space-time, instead of a separate space and a separate time. This yields three cases of constantly curved space-time: de Sitter space with positive curvature; Minkowski space with zero curvature; and anti-de Sitter space with negative curvature. Very conveniently, the Anti-de Sitter space can be extended to any number of dimensions, with n representing the number of dimensions. A combination of classical General Relativity (GR) and Quantum Field Theory (QFT) provides an interesting thermodynamic description of black holes. We use an algorithm proposed by Nemati et al. (2013). In this formalism, we start with a hypercube with each of its vertices labeled with black hole binaries. The back holes are associated with probability functions, and the black holes move based on the probabilities. Our research has applications both Quantum Gravity (QG) and in Black Hole Physics (BHP).

Session R19 DMP DCOMP: Computational Materials Design and Discovery -- Catalysis and Electronic Structure

8:00AM R19.00001: Computational design of (electro-)catalysts [Invited] ANDREW PETERSON (Presenter), School of Engineering, Brown University — Catalysts are crucial in energy conversion technologies, and electrocatalysts directly allow the interconversion of electrical and chemical energy carriers. Here, I will discuss atomistic approaches to describe and design catalyst materials from a computational framework. We have recently developed techniques to control the workfunction (and thus, the potential) of simulations in a "Solvated Jellium" approach. We will show how this allows for the inclusion of reaction barriers and the direct deduction of electrocatalytic mechanisms. We will use this to explain the unique reactivity of Pt that has not been accessible from a traditional "volcano plot" approach, and shed insights for the design of earth-abundant materials with high activities.

8:36AM R19.00002: Two-Dimensional Phases of Robust CO2 Reduction Photocatalysts* STEVEN TORRISI (Presenter), Physics, Harvard University, ARUNIMA SINGH, Physics, Arizona State University, JOSEPH MONTOYA, KRISTIN PERSSON, Energy Technologies Area, Lawrence Berkeley National Laboratory — Two-dimensional materials are increasingly popular for applications in catalysis due to useful properties like high surface area, differing surface reactivity from bulk counterparts, and their ability to be formed into nanostructures. This motivates our first-principles based study of the structure and electronic properties of 2D phases of several binary semiconductor materials which have been identified as promising CO2 reduction photocatalysts in the bulk [1]. Using van der Waals corrected functionals as well as HSE06, we identify suitable stable structures with reasonable band gaps for visible light absorption. Finally, we qualitatively evaluate the compounds’ catalytic efficiency by computing the adsorption energy of reaction intermediates on each respective surface.

Computational work was supported by the Materials Project (Grant No. EDCBEE) Predictive Modeling Center through the U.S. (DOE), Office of Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract No. DE-AC02-05-CH11231: Materials Project program KC23MP.
8:48AM R19.00003: Computational Dissection of Two-Dimensional Rectangular Titanium Mononitride TiN: Auxetics and Promises for Photocatalysis* LIUJIANG ZHOU (Presenter), SERGEI TRETIAK, Los Alamos National Laboratory — Recently, two-dimensional (2D) materials with a negative Poisson's ratios (auxetics) have triggered an enormous interest for their potential applications in the next-generation readable/writeable memory and optoelectronic technologies. Here, by using a broad range of first-principles calculations, we report a systematic study of 2D rectangular materials of titanium mononitride (TiN), exhibiting high energetic and thermal stability due to in-plane d–p orbital hybridization and synergetic out-of-plane electronic delocalization. The rectangular TiN monolayer also possesses enhanced auxeticity and ferroelasticity with an alternating order of Possion's Ratios, stemming from the competitive interactions of intra- and inter-Ti—N chains. Such TiN nanosystem is a n-type metallic conductor with specific tunable pseudogaps. Halogenation of TiN monolayer downshifts the Fermi level, achieving the optical energy gap up to 1.85 eV for TiNCl(Br) sheet. Overall, observed electronic features suggest that the two materials are potential photocatalysts for water splitting application.

9:00AM R19.00004: Exploring PtXnY(2-n) (X, Y= S, Se and Te ; 0≤n≤2) monolayers: Is Janus PtXY the most favorable one? FATIH ERSAN (Presenter), CAN ATACA, University of Maryland, Baltimore County — In this study, we investigated Janus and alloy structures of PtXnY(2-n) (X,Y=S,Se,Te; 0≤n≤2) materials on the basis of first-principles plane-wave simulations. Using cluster expansion theory for studying alloys of PtXnY(2-n) monolayers at various concentrations, for half coverage (n=1), our results indicated that Janus type structures are not energetically the most favorable for PtXY monolayers, however they are dynamically and thermally stable. In order to distinguish Janus PtXY structures, we reported the Raman active modes and compared them with bare PtX2 monolayers. Calculated electronic band gap values using hybrid functionals are on-par with available experimental data. It is also reported that spin-orbit coupling significantly modified the electronic band structure of PtXY monolayers. Due to the electronegativity differences of different chalcogen atoms on each surfaces of Janus PtXY structures, the arising dipole moment significantly modified the band alignments on both surfaces. We found that hydrogen evolution and oxygen reduction happen on different surfaces and applied strain enhanced the catalytic activity. Our results indicated that due to their intrinsic dipole moments and band gaps, Janus PtXY monolayers are the perfect candidates for water splitting reactions.

9:12AM R19.00005: Computational design of bimetallic core-shell nanoparticles for hot-carrier photocatalysis* LUIGI RANNO, STEFANO DAL FORNO (Presenter), JOHANNES LISCHNER, Imperial College London — Modelling nanoplasmonic devices with tailored properties for photocatalytic, optoelectronic and photovoltaic applications is an important and interesting research field that can lead to groundbreaking technological discoveries. However, developing a quantitative description of nanoplasmonic systems is challenging as quantum-mechanical theories of electrons in large nanoparticles must be combined with nanophotonic approaches.

In this talk, we present an approach which combines a material-specific effective mass theory for the electrons in core-shell nanoparticles with a quasi-static description of the plasmon potential. We studied 100 different combinations of bimetallic core-shell nanoparticles and found that systems with alkali-metal cores and transition-metal shells exhibit the highest figure of merit for water splitting. We discovered that the electronic structure of such systems features a two-dimensional electron gas in the shell which accounts for their high photocatalytic efficiency.

*Authors aknowledge EPSRC under Grant No. EP/N005244/1 and the Thomas Young Center under Grant No.TYC-101. This work used the ARCHER UK National Supercomputing Service, which is funded by EPSRC (EP/L000202).

9:24AM R19.00006: Electronic and optical properties of 3d-4d double perovskite Sr2VNbO6: a first-principles DFT+DMFT study* ARPITA PAUL (Presenter), TURAN BIROL, University of Minnesota — Double perovskite oxides (A2BB'O6) have drawn enormous interest due to their large variety of emergent properties. We use first-principles DFT+DMFT method to study the electronic and optical properties of Sr2VNbO6, which has both 3d (V) and 4d (Nb) electrons with varying degree of on-site interaction strengths. With both parent compounds SrVO3 and SrNbO3 shown to be promising transparent conductors on the opposite ends of the visible spectrum, we explore the optical properties of the ordered double perovskite Sr2VNbO6. We show that the electronegativity difference and the resulting possibility of charge transfer between the two transition metal cations affect the electronic structure and optical properties such as plasma frequency.

*The authors were supported by NSF DMREF program under the award NSF DMREF project DMREF-1629260.
9:36AM R19.00007: Combined DFT & STM Study of Fe/Ir(111) Surface States*  STEPHEN GANT (Presenter), JACOB REPICKY, ROLAND KAWAKAMI, JAY A GUPTA, Ohio State University — Chiral spin structures like those present in Fe/Ir(111) are playing an increasingly important role as processor and device size continue to shrink to length scales where quantum effects are relevant. Here, we present density functional theory (DFT) calculations of the Fe/Ir(111) and Ir(111) surfaces and compare them with experimental scanning tunneling microscopy (STM) images and spectroscopy. We performed our calculations using a fully relativistic projector augmented-wave (PAW) approach in conjunction with spin-orbit coupling (SOC) to produce band structures, surface local density of states (LDOS), and simulated STM topography. Experimental STM studies were performed at low temperature in an ultrahigh vacuum environment. Ir(111) was prepared via Ar sputtering, while a monolayer of Fe was deposited in bare Ir(111) via molecular beam epitaxy (MBE). We find good agreement between our DFT calculations and STM data. Of particular interest is the correspondence in Ir(111)'s surface state at the Γ point. Additionally, we present an analysis of how this state is affected by a pseudomorphic monolayer of Fe.

*Funding by NSF MRSEC DMR-1420451 and by DARPA-18AP00008

9:48AM R19.00008: First-Principles Study of Magnetism in Bilayer Manganese Phthalocyanine*  HAECHAN PARK (Presenter), HAI-PING CHENG, JAMES NATHAN FRY, SHUANGLONG LIU, YUN-PENG WANG, University of Florida — Magnetism in two dimensional materials has recently become a hot research topic due to its potential applications in spintronics and physical properties that arise from low dimensionality. Previously, monolayer manganese phthalocyanine (MnPc) has been synthesized experimentally, and theoretical studies have revealed that its magnetic properties can be tuned by substituting cations, applying biaxial strain, and imposing a gate voltage. In this first-principles study we examine the properties of bilayer MnPc using density functional theory (DFT). According to our simulations, Mn-to-Mn on-top stacking is found to be energetically less favorable, and we determine the stable position of the top layer relative to the bottom layer. When bilayer MnPc is in its ground state, both MnPc layers are in the Neel anti-ferromagnetic (NAF) state, although the ground state of monolayer MnPc is Collinear Antiferromagnetic (CAF), indicating that the interlayer magnetic coupling is very important. We will discuss further the nature of intra- and inter-layer magnetic couplings.

10:00AM R19.00009: Contrasting Ferromagnetism in FeS2 Pyrites Induced by Cobalt Doping and by Electrostatic Gating  EZRA DAY-ROBERTS (Presenter), RAFAEL M FERNANDES, TURAN BIROL, University of Minnesota — Pyrites are a family of transition metal disulfides that host a wide variety of electronic ground states. In particular, the ferromagnetic transition in Co-doped FeS2 has been studied as a source of variable, experimentally accessible electron spin polarizations. Advances in ionic liquid gating have provided an alternative way to change the electron concentration via electrostatic gating instead of chemical doping, thus avoiding the introduction of impurity scattering centers. We use Density Functional Theory combined with a tight-binding model to compare electrostatic gating and chemical doping with cobalt. Using maximally localized Wannier functions to construct a tight-binding model, we calculate the magnetic susceptibility across the entire range of compounds Fe1-xCoxS2. We find that electrostatic gating requires a higher electron concentration than the equivalent in Co-doping to induce ferromagnetism via a Stoner-like mechanism. We attribute this behavior to the formation of a narrow cobalt band near the bottom of the conduction band under doping. This band is not formed for electrostatic gating and wide, low DOS sulfur states are filled instead.
Ab initio Informed Tight Binding Theory of Axis-dependent Conduction Polarity in Goniopolar Materials

YAXIAN WANG (Presenter), JOSEPH P C HEREMANS, JOSHUA E. GOLDBERGER, WOLFGANG WINDL, Ohio State University — We have recently shown that NaSn$_2$As$_2$ exhibits opposite conduction polarities along in-plane and cross-plane directions, defined as “goniopolarity”. On the lowest level of theory, we can show that this novel phenomenon originates from a special topology of the Fermi surface, which is essentially determined by the nature of the bonding states in this layered crystal. In this paper, we present an improved fundamental understanding of goniopolarity based on a novel formulation of goniopolarity within the tight-binding model. The tight-binding matrix elements are calculated from GW calculations based on Density Functional Theory (DFT) via maximally localized Wannier functions. Considering a minimum-basis set with sp$^3$ orbitals for both Sn and As, the 64 hopping integrals are evaluated. Within our model, we provide a new tight-binding based formulation for both Seebeck and Hall coefficients for NaSn$_2$As$_2$ and can show that critical ratios of hopping and on-site matrix elements exist that pose limits for goniopolarity to appear in materials. Based on that, additional candidate materials for goniopolarity can be proposed, and the design space for goniopolar materials in general will be defined.

Effects of Si Doping on the Electronic Structure and Conductivity of Pure and Off-Stoichiometric Ge$_2$Sb$_2$Te$_5$ Cystrals: First-Principles Investigation

RAJARSHI SINHA-ROY, ANTONIN LOUISET, MAGALI BENOIT, LIONEL CALMELS (Presenter), CEMES, Université de Toulouse, CNRS, 29 rue Jeanne Marvig, 31055 Toulouse, France — We calculate the electronic structure and electrical conductivity of pure and Si-doped off-stoichiometric Ge$_2$Sb$_2$Te$_5$ cubic crystals, using the relativistic Korringa-Kohn-Rostoker method based on the multiple-scattering theory. These crystals are described by a rock-salt unit cell, in which the chemical disorder is taken into account through the coherent potential approximation. The accuracy of the results is verified by comparing, for several compositions, the density of electronic states calculated with this method and with a method that uses Kohn-Sham wave functions in big supercells. The calculated Bloch spectral function shows the dispersion of the electron states and its modification with the atomic disorder. We show the chemical-composition dependence of the electrical conductivity, and discuss it in terms of the concentration of carriers and of the modification of their scattering by atomic disorder. These results can be used to model Ge-Sb-Te phase-change-material samples, the microstructure of which consists of grains with different compositions, each grain being described by a different value of the conductivity.

Electrical Conductivity of Graphene-Polymer Composite Foam

ZILU WANG (Presenter), The University of Akron, ADAMSON H DOUGLAS, Institute of Material Science, University of Connecticut, ANDREY DOBRYNIN, The University of Akron — Graphene-polymer composites have potential applications in energy storage, oil absorption, and sensing. Here, we focus on dependence of the electrical conductivity of the composite graphene-polymer foams as a function of their composition and deformation. Using a combination of the coarse-grained simulations and analytical calculations we developed a bottom-up approach which allows us to express the macroscopic sample conductivity in terms of conductivity of the graphene layers coating the foam's shells. In particular, we propose a close packing shell model to describe the conductivity of the graphene shells with multiple contact points. This shell conductivity model is used to calculate the change in foam conductivity upon deformation which could be induced either by solvent absorption or by external foam compression/elongation. The model predictions are compared with the experimental data on conductivity of composite poly(butyl acrylate)/graphene foams.

*NSF DMR 1535412

Density matrix renormalization group study of Hubbard ladders

YILIN ZHAO (Presenter), Chemistry, McMaster University, LING WANG, Corresponding author, CSRC, GAYANATH FERNANDO, University of Connecticut — Motivated by exact diagonalization work on small Hubbard clusters$^1$, we focus on Hubbard ladder systems using the DMRG method. The exact diagonalization work has yielded an extremely rich variety of results related to the physics of the minimal orbital Hubbard clusters and the present study will attempt to elucidate related size and other effects.

8:00AM R20.00001: Ionic Transport in Materials with Substitutional Disorder [Invited]  ALEXANDER URBAN (Presenter), Department of Chemical Engineering, Columbia University — Substitutional disorder can have a profound impact on the ionic transport properties of crystalline solids, such as the solid electrolytes of solid oxide fuel cells or cation-disordered cathode materials for lithium ion batteries (LIBs). However, the direct experimental investigation of disorder on the atomic scale is challenging, and (conventional) first-principles computational techniques cannot be directly applied to disordered materials.

Here I will show how relatively simple computational models can provide useful insight into the interplay of substitutional disorder and ionic conduction in cation-disordered LIB cathode materials. Over the last years, computational modeling has contributed to the understanding of this new class of materials and has guided the discovery of several new high-energy density cathode materials.

8:36AM R20.00002: Tunable band-gap engineering of ZnSnN$_2$ via cation disorder from first-principles calculations*  ZIHAO DENG (Presenter), LOGAN WILLIAMS, CHRISTINA JONES, EMMANOUIL KIOUPAKIS, University of Michigan — Heterovalent ternary alloys offer a rich space to search for the next-generation optoelectronic materials. Unlike their III-V counterpart, cation disorder can greatly alter the electronic properties of II-IV-V$_2$ compounds by breaking the octet-rule locally. Thus, intentional introduction of cation disorder can provide a new route to tune the electronic band gap of heterovalent ternary compound besides conventional alloying. To demonstrate this possibility, we performed first-principles calculations based on hybrid density functional theory to study the cation disorder effect in ZnSnN$_2$, which is a promising solar material in the II-IV-V$_2$ family. We found a direct relationship between the band gap of ZnSnN$_2$ and the long-range order parameter S, which characterizes the Zn/Sn disorder. Such band gap variations arise from the presence of octet-rule breaking motifs in the lattice (Zn$_3$Sn, ZnSn$_3$, Zn$_4$, Sn$_4$). Our findings reveal the correlations between cation disorder and the band gap of ZnSnN$_2$, and suggest the possibility of alloy-free band gap tuning in heterovalent ternary compounds.

8:48AM R20.00003: Pristine electronic properties in multinary semiconductor alloys at magic compositions  JIE PAN (Presenter), National Renewable Energy Laboratory, JACOB CORDELL, Colorado School of Mines, ANDRIY ZAKUTAYEV, ADELE TAMBOLI, STEPHAN LANY, National Renewable Energy Laboratory — The materials electronic structure is usually very sensitive to topological distribution of atoms in the materials. Generally, the electronic integrity is easily destroyed by defects and disorder causing charge localization. The design of multinary materials has attracted a great interest for its wide tunability in properties. This functional versatility is rooted in many-fold degrees of freedom in composition and atomic distribution. At some “magic” compositions, the disordered material system can exhibit perfect short range ordered (SRO) ionic distributions that conserve the local octet rule despite the absence of long range order. In this contribution, we study the dual sublattice mixed semiconductor alloy (ZnSnN$_2$)$_{1-x}$(ZnO)$_{2x}$ in which perfect SRO are observed when $x=0.0$ and 0.25.

Disordered structures were generated from Monte Carlo simulations and the energies were calculated from first principles. At the magic composition, these SRO conserving systems have a much reduced mixing enthalpy and increased band gap. More importantly, these SRO structures do not have charge localization effects near band edges, as seen in the inverse participation ratio, thereby maintaining a pristine electronic structure.
9:00AM R20.00004: Lattice Constant and Band Gap Tuning in BInGaN Alloys for Next-Generation LEDs* KEVIN GREENMAN (Presenter), LOGAN WILLIAMS, EMMANOUIL KIOUPAKIS, University of Michigan — InGaN light-emitting diodes (LEDs) have enabled significant energy and cost savings, and further savings can be realized by operating at the same efficiency at higher power. However, the efficiency of currently available InGaN LEDs is lowered by the loss of carriers to Auger recombination when operating at high power. The Auger loss can be reduced by increasing the active-region volume, but the lattice mismatch between thick InGaN active layers and underlying GaN layers cause performance-degrading dislocations. Previous work has shown that this problem can be addressed by co-alloying InGaN with BN. Doing so can produce alloys that maintain an approximate lattice match to GaN while allowing for a band gap that is adjustable throughout the visible range. In this work, we expand on previous hybrid density functional theory calculations to explore the thermodynamic, structural, and electronic properties of a larger area of the BxInyGa1-x-yN composition space and examine the wurtzite, zinc blende, and planar hexagonal phases. A more thorough understanding of these properties will help to direct efforts to fabricate thick active regions for more cost-effective BInGaN LEDs.

9:12AM R20.00005: High precision detection of the change in intermediate range order of amorphous thin films due to annealing  KIRAN PRASAI (Presenter), E. L. Ginztion Laboratory, Stanford University, JUN JIANG, ALEC MISHKIN, Department of Physics and Quantum Theory Project, University of Florida, SARAH HOBACK, Department of Physics, American University, DAVID A DRABOLD, Department of Physics and Astronomy, Ohio University, ERIC KEITH GUSTAFSON, LIGO Lab, California Institute of Technology, MARIANA FAZIO, Department of Electrical and Computer Engineering, Colorado State University, GREGORY M HARRY, Department of Physics, American University, APURVA MEHTA, SLAC National Accelerator Laboratory, CARMEN SUSANA MENONI, Department of Electrical and Computer Engineering, Colorado State University, CARL LÉVESQUE, Department of Physics, Université de Montréal, IAN MACLAAREN, School of Physics & Astronomy, University of Glasgow, STEVEN D PENN, Department of Physics, Hobart and William Smith Colleges, FRANÇOIS SCHIETTEKATTE, ROSALIE SHINK, Department of Physics, Université de Montréal, BADRI SHYAM, University of Dayton Research Institute, GABRIELE VAJENTE, LIGO Lab, California Institute of Technology, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida, MARTIN FEJER, RICCARDO BASSIRI, E. L. Ginztion Laboratory, Stanford University — Future gravitational wave detectors, such as Advanced LIGO +, will be limited in sensitivity by thermal noise associated with mechanical loss in the detectors’ amorphous mirror coatings. In order to reduce mechanical loss, we aim to understand the atomic level structures responsible for it and take a directed design approach to suggest improved coatings. Through studies on thin films of amorphous zirconia-doped-tantala (ZrO2-Ta2O5), a potential coating for LIGO mirrors, we present high precision detection of the change in the intermediate range order (IRO) as a function of post-deposition annealing, using grazing incidence x-ray scattering measurements carried out at the Stanford Synchrotron Radiation Lightsource. For the first time, our atomic modeling based on x-ray scattering data is able to capture the changes in IRO. We show that the primary structural units (PSUs), which are disordered oxygen octahedra centered around the metal atoms, remain largely unchanged after annealing. We explain the observed structural changes in terms of the IRO, specifically, the change in metal-oxygen-metal bond angles at the bridging oxygen sites, and the way neighboring PSUs share bridging oxygens. Finally, we discuss correlations between the observed changes in the IRO and mechanical loss.

9:24AM R20.00006: Temperature-dependent properties of thermoelectric clathrates*  MARIA TROPPENZ (Presenter), SANTIAGO RIGAMONTI, CLAUDIA DRAXL, Humboldt University of Berlin — Intermetallic clathrate compounds, among them the type-I clathrate Ba8AlxSi46-x, are promising candidates for high-efficiency thermoelectric applications. They exhibit a strong dependence of the electronic properties on the atomic arrangement of the substitutional Al atoms in the crystal framework [1]. At the charge-balanced composition (x=16), the ground-state configuration is semiconducting, however, configurations higher in energy are metallic. Understanding the temperature-dependent properties is essential, as semiconducting behavior is a prerequisite for thermoelectric applications. By employing the cluster expansion technique combined with Monte-Carlo samplings and the Wang-Landau method [2] we find a semiconductor-to-metal transition at around 600 K which is driven by a partial order-disorder transition. Signatures of this phase transition are observed in the temperature-dependent band structure, specific heat, and partial occupations.

Beyond the constant relaxation time*

ILARIA SILOI (Presenter), ANOOJA JAYARAJ, Physics, University of North Texas, Denton, TX, USA, ANDREW R SUPKA, Department of Physics and Science of Advanced Materials Program, Central Michigan University, Mt. Pleasant, MI, USA, STEFANO CURTAROLO, Materials Science, Electrical Engineering, Physics and Chemistry, Duke University, Durham, NC, USA, MARCO BUONGIORNO NARDELLI, Physics, University of North Texas, Denton, TX, USA, MARCO FORNARI, Department of Physics and Science of Advanced Materials Program, Central Michigan University, Mt. Pleasant, MI, USA —

Over the years, first principles calculations have become a complementary tool for the experimental research aiming to discover high-performance thermoelectrics. This has greatly improved the understanding of the transport properties and has advanced optimization strategies based on “band engineering” [1,2]. In most cases, the constant relaxation time approximation has been used without much analysis. We investigated the limits of the approximations for the relaxation time in the electronic transport coefficients properties of well know TE materials by considering different models that include energy and temperature dependence. Transport coefficients have been computed using the recently developed PAOFLOW package (http://aflowlib.org/src/paoflow/).

Potential Candidate for Thin-Film Photovoltaics: Alloyed Semiconductor Cu2BaGe1-xSnxSe4

TONG ZHU (Presenter), GARRETT C. WESSLER, JON-PAUL SUN, ALEXIS HARRELL, WILLIAM P. HUHN, VOLKER BLUM, DAVID MITZI, Mechanical Engineering & Materials Science, Duke University — Cu2BaGeSe4 (CBGSe) was previously identified as a potential thin-film photovoltaic (PV) candidate based on computationally scanning the I2-II-IV-VI4 (I = Cu, Ag; II = Ba, Sr; IV = Ge, Sn; VI = S, Se) materials family and successful experimental synthesis. This material avoids difficulties of competing PV materials like toxicity (Cd) or scarcity (In, Te) of constituent elements in Cu(In,Ga)(S,Se)2 and CdTe. Moreover, the similar ionic sizes and coordination preferences compared to the recently identified PV material Cu2BaSn(S,Se)4 may provide a potential avenue to overcome the unavoidable antisite disordering that limits the competing material Cu2ZnSn(S,Se)4. In this work, hybrid density functional theory (HSE06) including spin-orbit coupling is used to explore the electronic properties of three cation alloying approaches (Ag for Cu, Sr for Ba, and Sn for Ge ) for unalloyed CBGSe, which has a relatively large band gap (1.91 eV). The largest band gap decrease can be achieved by Sn/Ge alloying. The minimum band gap occurs at 1.57 eV for x≈0.70 in alloyed Cu2BaGe1-xSnxSe4. The minimum occurs just prior to a structural transition from the P31 to the Ama2 space group just above x=0.7; the P31 phase is associated with a significantly lower band gap.

First-principles study of photochromic material YHxOy

YI-YANG SUN (Presenter), State Key Laboratory of High Performance Ceramics and Superfine Microstructure, Shanghai Institute of Ceramics, CAS — Photochromic materials refer to the materials that change color under light illumination, particularly visible light. Organic materials dominate the photochromic materials due to their highly tunable properties. However, inorganic photochromic materials are attractive for their stability and possibly high resistance to fatigue. YHxOy is a new photochromic material found a couple of years ago. However, its chemical composition, atomic structure, electronic properties have not been completely studied so far. The mechanism of the photo-induced color change is still elusive too. In this work, using first-principles calculations based on the density functional theory, we aim to provide a comprehensive understanding on this new material. Possible strategies on how to tune the properties, such as its band gap, through oxygen concentration will be discussed.

8:36AM R21.00002: Simultaneous structure exploration and machine-learned potential fitting* NOAM BERNSTEIN (Presenter), United States Naval Research Laboratory, GÁBOR CSÁNYI, VOLKER L DERINGER, Cambridge University — Defining interatomic potentials using ideas from machine learning that treat the problem as a high-dimensional fit of the reference (usually density functional theory) potential energy surface is an exciting new approach for developing accurate potentials. However, because of their variational freedom such potentials require large fitting datasets, with large amounts of manual selection and tuning of configurations by the researcher. We present an iterative method, where a preliminary potential is used to carry out a number of random-structure searches, and selected configurations from the searches are used to fit the next iteration’s potential. We test the method on a number of elements with different bonding types, including an insulator, a semiconductor, and a metal. We show how the process converges in a few iterations, and how the resulting potentials reproduce the reference DFT values on a number of bulk and defect properties.

8:48AM R21.00003: Adaptive multiple time scales mapping in heterogeneous molecular simulation, a hierarchical domain decomposition approach HORACIO ANDRES VARGAS GUZMAN (Presenter), Theory, Max Planck Institute for Polymer Research, HIDEKI KOBAYASHI, Theory Research Interest Group, University of Cambridge — Heterogeneous molecular systems are mostly inspired by natural phenomena, such as, phase segregation, evaporation, among others. Those systems can be modeled by means of advanced molecular simulations methods, as it is done in multiscale concurrent and non-equilibrium simulations. Interestingly, the heterogeneity of the mentioned systems has a huge potential to map and span time and length scales beyond fully atomistic simulations, because a subdomain of the simulation box can be tackled with slowly diffusive regime, while other remains in a faster diffusive regime. From this description, a decisive question arises on how to map those heterogeneous time scales without losing the theoretical speedup planned from the method development perspective. Here, we introduce the heterogeneous time-spatial domain decomposition approach which is a combination of an heterogeneity sensitive spatial domain decomposition with a time evolution average of particles’ diffusion domainwise estimated. Within this approach, the spatial domain decomposition is theoretically modeled and results in scaling-laws for the force calculation time, while timewise the subdomains with different diffusivity are adapted by means of the number of neighboring shells to a unique frequency of neighbors list updates.

8:48AM R21.00004: Identifying 1H/2T Phases and Defects in MoS2 Using Boltzmann Machines JEREMY LIU (Presenter), RAJIV KALIA, University of Southern California, KE-THIA YAO, Information Sciences Institute — We use Boltzmann machines (BMs), an energy-based learning model, to identify semiconducting (2H) and metallic (1T) phases and defects in molecular dynamics (MD) simulations of strained MoS2 monolayer. We compare various BM models, i.e. Restricted BMs (RBM) versus Limited BMs (LBM) with intra-layer couplings, and measure their performances. Our use of BMs gives insight into the structure of the underlying MD data and is amenable to implementation using sampling via an adiabatic quantum annealer. We show our LBMs have superior performance over RBMs, examine connectivity within our BM variants, explore hardware qubit mapping schemes, and discuss what performance differences may imply about locality within the data without prior knowledge.

HAIXIN WEI (Presenter), Materials Science and Engineering, University of California, Irvine, JUNMEI WANG, Pharmaceutical Sciences, University of Pittsburgh, PIOTR CIEPLAK, SBP Medical Discovery Institute, YONG DUAN, University of California, Davis, RAY LUO, University of California, Irvine — Electrostatic interactions are of fundamental importance to the structures and functions of biomolecules. Their accurate modeling is crucial in the design and development of physical models in computational studies of biomolecules. It is known that widely used point-charge models cannot capture the subtle short-range interactions and molecular anisotropicity. Recently emerged point multipole models, in the meantime, face the so-called “polarization catastrophe” difficulty that requires artificial truncation and omission of important short-range interactions. Considering these limitations, we are developing a new polarizable Gaussian multipole (pGM) framework, which is capable of describing the short-range interactions more accurately without greatly increasing computational cost. Our data shows that the new model greatly improves the modeling of molecular anisotropicity. We are also developing a new set of algorithms for more efficient modeling electrostatics interactions within the pGM scheme. With all its advantages, we believe that the pGM model will positively impact the field of the biomolecular simulations.

REBECCA LINDSEY (Presenter), LAURENCE FRIED, NIR GOLDMAN, SORIN BASTEA, Lawrence Livermore Natl Lab — Understanding chemistry at extreme conditions is crucial in fields including geochemistry, astrobiology, and alternative energy. First principles (quantum-mechanical) methods can provide valuable microscopic insights into such systems while circumventing the risks of physical experiments, however the time and length scales associated with chemistry at high temperature and pressure (i.e. ns and μm, respectively) largely preclude extension of such models to molecular dynamics. In this work, we discuss development of ChIMES, a generalized n-body force field comprised of linear combinations of Chebyshev polynomials. ChIMES models are machine-learned to selected configurations from short Density Functional Theory (DFT) molecular dynamics simulations and are refined through active learning. ChIMES models are found to retain much of the accuracy of DFT at a fraction of the cost and exhibit linear size scalability.

9:36AM R21.00007: Quantum-simulation-informed machine learning of dynamic properties of two-dimensional and layered materials*

LINDSAY BASSMAN (Presenter), ARAVIND KRISHNAMOORTHY, PANKAJ RAJAK, University of Southern California, FUYUKI SHIMOJO, Kumamoto University, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, University of Southern California — Two-dimensional and layered transitional metal dichalcogenides are emerging as promising materials for the electronic and optoelectronic devices of tomorrow due to the large space of design variables (such as configuration of dopant atoms, sequence of stacking along the van der Waals direction etc.) that can be used to tune dynamic properties of the material. The primary challenge for rational design of these materials is navigating this complex design space to identify optimal structures and compositions that possess desired properties. In this work, we show that machine-learning methods applied to atomistic data from quantum mechanical simulations are highly suitable for predicting optimal structures with respect to dynamic properties like thermal, charge and spin transport, electron-phonon coupling and non-equilibrium phonon distributions, and propensity for structural and phase transformations.

10:00AM R21.00009: Metallization of the Si(001) surface: An atomistic study using a neural network potential*
SONALI JOSHI (Presenter), DUY LE, TALAT S. RAHMAN, University of Central Florida — Despite being one of the widely studied surfaces because of its technologically importance, the nature of the metallization of Si(001) at high temperatures is still an open question. The semiconductor-metal transition of the surface occurring at 900 K is often linked to the transformation from asymmetric to symmetric structure of the Si dimers at the surface [1]. In this work, we apply a neural network derived interatomic potential to perform molecular dynamics simulations of Si(001) for a large temperature range. This potential was developed with input from ab initio molecular dynamics simulations of Si(001) and validated to be as accurate as density functional theory. Our simulations show that the asymmetric, buckled structure of the dimer still exists at higher temperatures, but the increased dimer flipping rate makes them spend more time in the symmetric configuration making the surface metallic. Our results also suggested that such phenomenon is appreciable even at temperatures lower than 900 K, in agreement with angle-resolved photoemission spectroscopy data [2].

*This work is support in part by DOE grant DE-FG02-07ER46354.

10:12AM R21.00010: Datasets of Unusual Size: Benchmark Databases of Non-Covalent Interaction Energies of CCSD(T)/CBS Accuracy
ELIZABETH DECOLVENAERE (Presenter), ROBERT T MCGIBBON, ANDREW GARVIN TAUBE, ALEXANDER G DONCHEV, JOHN L KLEPEIS, DAVID E. SHAW, D. E. Shaw Research — We present a new benchmark collection, DES360K, containing interaction energies for 366,117 dimer geometries computed using coupled-cluster with single, double, and perturbative triple excitations [CCSD(T)] extrapolated to the complete basis set (CBS) limit, considered the “gold standard” of quantum chemistry. Our collection spans 392 unique small molecules in 3,697 combinations, and explores both energetically minimized dimers and dimers extracted from molecular dynamics simulations. We extend our dataset using SNS-MP2-Ext, a neural network-based method for predicting CCSD(T) interaction energies from MP2 inputs trained on the DES360K dataset. SNS-MP2-Ext revises our original SNS-MP2 approach to be extensive by construction, resulting in significantly reduced prediction errors and narrower confidence intervals than the original SNS-MP2. More importantly, SNS-MP2-Ext eliminates the large variations in predictive performance shown in SNS-MP2 for different chemical classes and energy scales. We have used both SNS-MP2 and SNS-MP2-Ext to expand our dataset to contain another 5 million unique data points with minimal computational expense while maintaining CCSD(T) levels of accuracy. The resulting collection, DESSM, is the largest-ever available collection of gold standard data.
10:24AM R21.00011: Accelerating atomistic modelling with active learning* JONATHAN VANDERMAUSE (Presenter), STEVEN TORRISI, SIMON BATZNER, Harvard University, ALEXIE M KOLPAK, Massachusetts Institute of Technology, BORIS KOZINSKY, Harvard University — Machine learning provides a path toward fast, accurate, and large-scale materials simulation, promising to combine the accuracy of ab initio methods with the computational efficiency of analytical potentials. However, training current state-of-the-art models, which include Neural Network Potentials and Gaussian Approximation Potentials, often requires hundreds of CPU hours and databases containing tens of thousands of chemical environments. Moreover, these potentials are trustworthy only for chemical configurations that fall within the training set and have so far been restricted to single- or few-component systems. In this talk, we present a multi-component on-the-fly learning scheme that refines the machine learned force-field when a new chemical configuration is encountered, opening the door to ML-driven molecular dynamics that can capture complex many-body dynamics spanning previously unprecedented length- and time-scales.

*S.B.T. acknowledges support from the DOE Computational Science Graduate Fellowship. S.B. acknowledges support from the Skoltech-MIT Center for Electrochemical Energy Storage.

10:36AM R21.00012: Designing High-strength Carbon-nanotube Polymer Composites Using Reinforcement Learning Algorithms Integrated with Molecular Dynamics Simulations* AOWABIN RAHMAN (Presenter), Department of Mechanical Engineering, University of Utah, MATTHEW RADUE, GREGORY ODEGARD, Department of Mechanical Engineering-Engineering Mechanics, Michigan Technological University, MICHAEL CZABAJ, Department of Mechanical Engineering, University of Utah, PRATHAMESH DESHSPANDE, Department of Mechanical Engineering-Engineering Mechanics, Michigan Technological University, ASHLEY SPEAR, Department of Mechanical Engineering, University of Utah — Carbon-nanotube (CNT)-based composites have great potential in modern aerospace applications requiring high-strength, lightweight structural materials. However, one factor that limits the potential of CNT composites is the inefficiency in load transfer between CNTs using a polymeric resin, arising due to low CNT/polymer interfacial strength. This talk presents a modeling framework that uses a reinforcement learning (RL) algorithm along with molecular dynamics (MD) simulations to make design modifications at the CNT/polymer interface for improving the interfacial strength of CNT/polymer composites. The proposed framework uses a modular approach consisting of: (i) reinforcement learning model to recommend design modifications, i.e. inserting reactive groups and dopants, to the CNT/polymer model; (ii) method for rapidly implementing the recommendations by modifying the MD model structure; and (iii) methodology to reduce computational time for performing MD simulations of CNT pullout after making these modifications. The proposed framework would enable fundamental exploration of design space to develop high-strength CNT-based composites and could potentially be extended or adapted for a more general integration of data-driven techniques with MD for design applications.

*NASA NNX17AJ32G

10:48AM R21.00013: "Azide and Alkyne CHARMM Parameterization with the Force Field took kit (ffTK) and Unnatural Amino Acid (uAA) Protein Simulation" ADDISON SMITH (Presenter), THOMAS KNOTTS IV, Brigham Young University — Drug-like small molecules that contain azido and alkynyl groups are structurally unique because they contain linear angles useful in therapeutics and bioconjugation reactions. The bioconjugation "click" reactions has been useful in drug design and uAA research; however, these technologies rely heavily on molecular modeling.

CGenFF and CHARMM are common force fields for drug-like molecules; however, this force field lacks parameters for linearangle molecular moieties and current literature does not contain any solution. We propose a method that (1) develops CHARMM parameters for four small molecules that contain terminal azido and alkynyl groups using ffTK, (2) addresses linearity issues, and (3) validates ffTK results via in silico MD simulation. We then combine these parameters with CGenFF to generate parameters for uAA MD simulation.

In this presentation we prove that the physics of the linear terminal dihedral angles are well-represented by multiple parameter sets as long as they maintain the linear structures. We then show the reliability of our parameter set by running MD simulations to prove our modeled structures match those found in literature and quantum theory. Finally, protein MD compares simulation with crystallographic data using a protein that contains an azide uAA.

Thursday, March 7, 2019 8:00 AM - 11:00 AM

Session R22 DCOMP DCOMP: Electrons, Phonons, Electron-Phonon Scattering and Phononics V BCEC 157C - Mu Wang, American Physical Society - Tag(s): Focus
In this talk, I will discuss our recent theoretical effort towards ultrafast control of dielectric response through the excitation of infrared active phonons. I will highlight cases where the induced unidirectional Raman response is comparable to the dielectric response dictated by the symmetry and amplitude of the excited phonons. This provides a strategy for selective, ultrafast control of dielectric properties through infrared phonon excitation.

Recent developments in the generation and control of intense ultrashort infrared radiation have provided a new approach to nonlinear optics through the coherent excitation of infrared active phonons to large amplitudes. Due to the large oscillating displacement of excited infrared phonons, Raman active phonons can be unidirectionally displaced through special nonlinear coupling terms. In contrast to the typical considerations of nonlinear optics where crystalline symmetry and light intensity dictate the dielectric response of the material, in this “nonlinear phononics” process alteration of the dielectric response is dictated by the symmetry and amplitude of the excited phonons. This provides a strategy for selective, ultrafast control of dielectric properties through infrared phonon excitation.

In this talk, I will discuss our recent theoretical effort towards ultrafast control of dielectric response through the excitation of infrared active phonons. I will highlight cases where the induced unidirectional Raman response is comparable to the excited infrared phonon amplitude.

*DMR-1719875

8:36AM R22.00004: From electron-phonon transport properties to computational discovery of new materials for energy conversion. [Invited] BORIS KOZINSKY (Presenter), Harvard University, GEORGY SAMSONIDZE, Bosch Research — We introduce a novel simplified approach for computing electronic transport properties of complex semiconductors and low-dimensional quantum materials, without empirically fitted parameters. Using this method allowed us to discover new thermoelectric alloy compositions with leading performance and stability. The computational approach achieves good accuracy and transferability while greatly reducing complexity and computation cost compared to the existing methods. The first-principles calculations of the electron-phonon coupling demonstrate that the energy dependence of the electron relaxation time varies significantly with chemical composition and carrier concentration, suggesting that it is necessary to go beyond the commonly used approximations to screen and optimize materials' composition, carrier concentration, and microstructure. The new method is verified using high accuracy computations and validated with experimental data before applying it to screen and discover promising compositions in the space of half-Heusler alloys. We discuss the universality of the Wiedemann-Franz law and deviations from it in semiconductors, computing the Lorenz number from first principles.
9:12AM R22.00005: Influence of Oxygen Phonon Coupling on Fluctuating Stripes in the Three-band Hubbard Model
TIANYI LIU (Presenter), EDWIN HUANG, Stanford University, BRIAN MORITZ, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory — The normal state of high-\( T_c \) cuprate superconductors is characterized by competition between multiple ordered states such as antiferromagnetism, charge-density-waves, and stripes. We use determinant quantum Monte Carlo (DQMC) simulations of the three-band Hubbard model with oxygen phonon coupling to investigate how electron-phonon coupling influences high-temperature fluctuating stripes, in relation to doping level, phonon properties and electron-phonon coupling strength. Quantities such as the spin-spin and density-density correlation functions are extracted from the simulations to illustrate the influence of electron-phonon coupling on stripes.

9:24AM R22.00006: Pressure enhanced superconductivity in MoTe\(_2\)^*
HARI PAUDYAL (Presenter), Department of Physics, Applied Physics, and Astronomy, Binghamton University-SUNY, SAMUEL PONCE, Department of Materials, University of Oxford, ELENA R MARGINE, Department of Physics, Applied Physics, and Astronomy, Binghamton University-SUNY — Molybdenum ditelluride (MoTe\(_2\)) has attracted significant research interest due to the discovery of exotic topological states and pressure-driven superconductivity. First-principles calculations combined with the anisotropic Migdal-Eliashberg formalism have been carried out to investigate the role of electron-phonon interaction and the superconducting pairing mechanism in the two structurally similar phases, T\(_d\) and 1T\(_'\), under pressure. We find that both phases are superconducting, with the centrosymmetric 1T\(_'\) phase displaying a slightly larger electron-phonon coupling strength compared to the non-centrosymmetric T\(_d\) phase due to the softening of the low-energy phonon modes and a small increase in the density of states at the Fermi level.

*H. P. and E. R. M. acknowledge the NSF support (Award No. OAC-1740263) and the computational resources provided by XSEDE (TG-DMR180047).

9:36AM R22.00007: A comparison of molecular dynamics and Boltzmann transport equation approaches for lattice thermal conductivity^*
MARCELLO PULIGHEDDU (Presenter), University of Chicago, YI XIA, Argonne National Lab, Northwestern University, MARIA CHAN, Argonne National Lab, GIULIA GALLI, University of Chicago, Argonne National Lab — The predictive modeling of lattice thermal conductivity \( \kappa_L \) is of importance for both fundamental understanding and materials design. Molecular dynamics (MD) and Boltzmann Transport Equation (BTE) are the two most common approaches used to predict \( \kappa_L \). In this work, we perform a comprehensive comparison between MD and BTE approaches, on two model systems (MgO and PbTe), using interatomic potentials. Comparisons between MD and lifetimes from three- and four-phonon scattering, and between different treatment of statistics, are made. The sources of agreement and differences between MD and BTE are discussed.

^*This work was supported by the Midwest Integrated Center for Computational Materials (MICCoM) as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division (5J-30161-0010A).

9:48AM R22.00008: Four-phonon scattering-dominated linewidth of optical phonons^*
XIAOLONG YANG, Mechanical Engineering, Purdue University, TIANLI FENG, Oak Ridge National Laboratory, XIULIN RUAN (Presenter), Mechanical Engineering, Purdue University — Optical phonon linewidth is crucial to infrared optical properties of polar materials and thermal conductivity of certain materials that have a large number of optical phonon branches. The current understanding is, however, still limited to the lowest order phonon scattering, and the predicted linewidths often have large discrepancy with experiment. In this work we show the significance of four-phonon scattering in determining infrared optical properties for a range of important materials, including cubic boron arsenide (BAs), cubic silicon carbide (3C-SiC), and \( \alpha \)-quartz. Strikingly, We find that four-phonon scattering generally dominates optical phonon linewidths at elevated temperatures over three-phonon scattering. In large band gap-materials, e.g., BAs and AlSb, four-phonon scattering rates are found to be orders of magnitude higher than three-phonon scattering rates even at room temperature. The predicted infrared optical properties of \( \alpha \)-quartz after including four-phonon scattering show good agreements with experimental measurements.

^*We acknowledge the partial support from the National Science Foundation (Award No. 1150948) and Defense Advanced Research Projects Agency (Award No. HR0011-15-2-0037).
10:00AM R22.00009: First-principles calculation of ballistic photocurrents

We apply this methodology to BaTiO$_3$, a typical ferroelectric which displays the BPVE. These results clarify density functional perturbation theory, to find the carrier distribution functions and the magnitudes of ballistic scattering processes. We calculate the amplitudes of these processes using electron-phonon interactions derived from the unbalanced momentum space distribution of carriers, which results from the interference of multiple carrier-phonon scattering processes. These ballistic currents arise from an asymmetry in the phonon-induced ballistic current contribution. These ballistic currents arise from asymmetric phonon scattering, and shift currents, which are displacements of electrons upon photoexcitation, have been proposed as mechanisms responsible for the BPVE under linearly polarized light. However, only the shift current contribution has been routinely studied with first-principles calculations. In this work, we present first-principles calculations of the phonon-induced ballistic current contribution. These ballistic currents arise from an unbalanced momentum space distribution of carriers, which results from the interference of multiple carrier-phonon scattering processes. We calculate the amplitudes of these processes using electron-phonon interactions derived from density functional perturbation theory, to find the carrier distribution functions and the magnitudes of ballistic photocurrents. We apply this methodology to BaTiO$_3$, a typical ferroelectric which displays the BPVE. These results clarify the origin of the BPVE, and the relative importance of shift and ballistic currents.

10:12AM R22.00010: First-principles study of structural phase transition and thermal transport in halide perovskite CsPbBr$_3$

We applied the recently developed self-consistent phonon (SCP) scheme [1] to investigate the three different phases of all-inorganic perovskite CsPbBr$_3$, and calculated the thermal conductivity $\kappa_0$ and vibrational free energy from first principles. The SCP theory incorporates the anharmonic effect non-perturbatively and enables us to obtain well-defined phonons of the high-temperature phases. Also, we predicted the structural phase-transition temperatures $T_c$ of CsPbBr$_3$ by comparing the anharmonic free-energy of the three phases. We will demonstrate the validity of our approach by comparing the predicted $\kappa_0$ and $T_c$ values with available experimental data and discuss the origin of the low $\kappa_0$.

10:24AM R22.00011: Lattice thermal conductivity calculations of $\alpha$-quartz and $\alpha$-cristobalite

Although $\alpha$-quartz and $\alpha$-cristobalite have similar phonon densities of states, phonon frequency dependencies of phonon group velocities and lifetimes are dissimilar, which results in largely different anisotropies of the lattice thermal conductivities. For $\alpha$-quartz and $\alpha$-cristobalite, distributions of the phonon lifetimes effective to determine the lattice thermal conductivities are well described by energy and momentum conservations of three phonon scatterings weighted by phonon occupation numbers and one parameter that represents the phonon-phonon interaction strengths.

Phonon anharmonicity is essential for explaining phenomena such as thermal conductivity, thermal expansion, and the change in phonon frequencies with strain. In particular, strain dependence of phonon frequencies can be expressed through Grüneisen parameters, which are often used as a heuristic to quantify anharmonicity in general for a given system. However, the exact nature by which a system departs from anharmonicity is important - third, fourth, and higher order terms in the atomic potential play different roles in different situations. Are the same higher order force constants that contribute to Grüneisen parameters the ones involved in, for example, thermal transport processes, or are the ones that cause the quasiharmonic approximation to fail at high temperature? Using both analytic methods and density functional theory to inform and understand the underlying features of anharmonicity for a variety of systems, we find that while Grüneisen parameters provide valuable insight for how phonon modes couple to strain, one must take care in relating this quantity to other anharmonic effects. We further explore the relationship between phonons and strain, and other couplings between periodic eigenfunctions and aperiodic perturbations.

Thermal Transport in a Substrate with Periodic Nanoscale Heat Sources

XINPENG ZHAO (Presenter), RONGGUI YANG, Mechanical Engineering, University of Colorado, Boulder — Understanding thermal transport from nanoscale heat sources to a substrate is crucial for the thermal management of high power electronics. When the size of a heat source is in comparison with or smaller than the phonon mean free path, the thermal transport in the substrate would deviate from the diffusive heat transfer described by the Fourier's law of heat conduction. Recent experimental results have shown that the thermal transport in a substrate with periodic nanoscale heat sources could be ballistic or diffusive-like by tailoring the size of the heat source and the distance between neighboring heaters. In this work, heat transport in a substrate with periodic nanoscale heating sources is simulated by solving the frequency-dependent phonon Boltzmann transport equation (BTE) using the Monte Carlo simulations. The effects of geometric sizes such as heat source size and spacing of heat sources on the heat dissipation efficiency are evaluated quantitatively. The results from the simulations could be used to understand the quasi-ballistic phonon transport mechanism in a substrate with periodic heating and to guide the design of the nanostructures for efficient thermal transport.

Session R23 GIMS: Acoustics, Noise and Damping BCEC 158

8:00AM R23.00001: Particulate dampers for absorption of structural vibrations at audible frequencies. Hasson M. Tavossi, Ph.D., Savannah State University, Department of Engineering Technology, 3219 College St., Savannah, GA 31404.* HASSON TAVOSSI (Presenter), Savannah State University — Absorption of mechanical vibrations by particulate material versus frequency are investigated, with the goal of reduction of transmission of vibrations into building structures. Attenuation of vibration by particulates depend mainly on their mechanical properties, shape, size-distribution, and degree of compression. Structural vibrations can be damped by surrounding them with particulate materials. Experimental results show that, particulate dampers behave as band-pass filters for vibrations that pass through them. The frequencies outside their passband range are strongly absorbed. Some particulate materials have a frequency band-gap, where frequencies in the bandgap range are strongly attenuated by scattering, absorption, or localization of vibrational energy. Samples of uniform size are coupled to mechanical vibrations at different frequency and amplitude. Their vibration absorption versus frequency are determined. Effects of layer thickness, particulate size, orientation, at different frequencies, in the audible range, are measured. The goal is to determine optimal vibration dampers to mitigate the transmission of external mechanical vibrations into the buildings.

8:12AM R23.00002: Cancelling Ambient Noise in Spectroscopic Images on a Scanning Tunneling Microscope* ALBERT CHIEN (Presenter), BRYCE PRIMAVERA, HARRIS PIRIE, JENNY HOFFMAN, Harvard University — Scanning tunneling microscopy (STM), a technique to measure the electronic structure of condensed matter systems with atomic resolution, requires an extremely stable environment to operate. Modern ultra-quiet STMs typically employ a combination of pneumatic suspensions and massive inertial blocks to reduce ambient vibrations to the sub-nanometer scale. Yet the tip-sample junction still experiences picometer vibrations that limit the signal-to-noise ratio in the tunneling current. Here we demonstrate a measurement scheme and software algorithm that reduces the effects of residual sub-picometer vibrations by order 50% in both topographic and spectroscopic images. We first calibrate a transfer function between a sensitive geophone on the STM head, and the STM tip-sample distance itself. We then use the simultaneously measured geophone output and tunneling current to cancel the effects of vibrations in the STM data in a 300Hz bandwidth.

8:24AM R23.00003: Design and Characterization of a Cylindrical Inertia Block for an Ultra-Low-Vibration Laboratory WENJIE GONG (Presenter), YU LIU, Harvard University, JOSEPH D. GIBBONS, Wilson HGA Architects, JENNIFER HOFFMAN, Harvard University — Typical low-vibration facilities employ a rectangular concrete inertia block supported on pneumatic isolators that damp vertical oscillation. However, it has been shown that when the inertia block sides are parallel to the surrounding room walls, acoustic standing waves can exert pressure on the parallel faces of the slab that causes measurable motion. To address this problem, we have designed a new low-vibration laboratory room housing a cylindrical inertia block, with no parallel faces. Here we simulate and measure the acoustic modes of the room and place limits on their coupling to the cylindrical inertia block. We further measure the transfer function from the building foundation to the inertia block. Finally, we drive the flexural resonance modes of the cylindrical inertia block and compare their frequencies to more traditional block shapes.
8:36AM R23.00004: Imaging Sound Waves in Phononic Metamaterials

WILLIAM FU (Presenter), NATHAN DRUCKER, HARRIS PIRIE, JENNIFER WANG, WOLFGANG RUECKNER, JENNIFER HOFFMAN, Harvard University — Phononic and photonic metamaterials have recently been proposed as analogs for topologically insulating structures, with a variety of potential applications. Most of these systems have been analyzed by simulation only (e.g. in COMSOL Multiphysics), but it has remained challenging to construct them experimentally and to measure their dynamics. Here we demonstrate two approaches to experimentally characterize real systems of topological phononic metamaterials using schlieren optics and a scanning microphone. In the schlieren setup, a mirror with long focal length is used to detect small changes in the refractive index of air using strobed light, which allows dynamic imaging of sound pressure [1]. Furthermore, we have developed a computer numerical control (CNC) scanning microphone with 6 degrees of freedom for dynamic imaging. Our sound wave imaging enables characterization of a topological phononic waveguide and other devices [2].

8:48AM R23.00005: Observation of GHz Modes in Quartz Circular Surface Acoustic Wave Resonator

JOEL THERRIEN (Presenter), SAISRIDEVESH KADAMBARI, ECE, University of Massachusetts Lowell — A novel form of Surface Acoustic Wave (SAW) resonators functions by exciting SAW modes in a circular acoustic cavity formed on a ST-cut quartz substrate. The resonant and harmonic frequencies of these devices is dependent on the diameter of the cavity. Based on the acoustic properties of ST quartz, devices with dimension in the range of 100's of μm are expected to have resonant frequencies in the range of 10's to 100's of MHz. These modes are indeed observed, however additional modes with frequencies in the GHz range (between 1-8 GHz) have also been observed. These modes do not appear to be part of the harmonic series associated with the MHz range modes. Moreover, specific aspects of these modes are inconsistent with the known acoustic properties of ST-cut quartz. Progress on understanding these modes will be presented.

9:00AM R23.00006: Regenerative Acoustofluidic NanoFilters for Biomolecular Purification and Quantification

WEIWEI CUI (Presenter), State Key Laboratory of Precision Measuring Technology & Instruments, Tianjin University, SHARI YOSINSKI, Biomedicine Engineering, Yale University, XUEXIN DUAN, State Key Laboratory of Precision Measuring Technology & Instruments, Tianjin University, MARK A REED, Yale University — Precise manipulation of target molecules is critical for microfluidic applications, such as molecular purification, target enrichment, and biosensing. Here, we report a microfluidic-based regenerable nanoscale filtration technique for purification and detection of target molecules from complex samples. By assembling specific functionalized nanoparticles (SFNPs) in an acoustofluidic vortex chip, an array of nanofilters is constructed. The acoustofluidic vortex is produced by a gigahertz bulk acoustic wave resonator, which allows for simple regeneration. Additionally, the acoustofluidic vortex increases SFNP-target interactions, overcoming diffusion limits. We demonstrate this nanofiltration method for rapid and effective purification of targets in both buffer and serum samples. We studied the molecular capturing dynamics using the biotin-SAv complex as a model, where we demonstrate a rapid (within 60 seconds) and accurate (with a detection limit of 170ng/mL) molecular quantification biosensor. The approach has the advantages of non-clogging high-throughput capability, as well as excellent flexibility, enabling wide biomedical applications.

9:12AM R23.00007: Non-invasive, non-destructive characterization of subsurface weld defects via directed ultrasound

JOHN GREENHALL (Presenter), ALAN LYMAN GRAHAM, CRISTIAN PANTEA, DIPEN N SINHA, Los Alamos National Laboratory — Directed ultrasound is employed to identify defects in subsurface welded joints and to characterize the defects as either inclusions or voids. We scan over the welded joint with a single ultrasound transducer, which transmits an ultrasound burst, and then we measure the burst after it reflects from the subsurface weld defects. In contrast with existing ultrasound characterization techniques we do not require a mechanical connection between the ultrasound transducer and the welded specimen, which facilitates implementation in the field. We utilize a correlation envelope to identify and locate defects in the presence of noise, and we distinguish between voids and inclusions based on phase change in the measured burst after reflection from a weld defect. We demonstrate the directed ultrasound technique for identifying subsurface defects in a tungsten alloy with a square joint. In contrast with X-ray imaging techniques, which cannot penetrate tungsten alloys, we identify, locate, and characterize known defects at depths of >10 mm. This directed ultrasound technique enables non-invasive, non-destructive inspection of a wide range of materials, and finds application in numerous applications including welding, printed circuit board fabrication, and sintered 3D printing.
9:24AM R23.00008: Ultrasonic Collimated Beams in Elastic Solids*  
VAMSHI KRISHNA CHILLARA (Presenter), CRISTIAN PANTEA, Los Alamos National Laboratory — Ultrasonic collimated beams are directed beams that propagate in materials with very little angular spread. Generation of such beams in solids enable high resolution imaging of heterogeneous and attenuating materials like concrete and noninvasive materials characterization of anisotropic materials like composites. We present a simple approach to generating ultrasonic collimated beams that relies on a novel approach to generating Bessel beams using radial modes of piezoelectric disc transducers. We first discuss the resonance and vibration characteristics of radial modes of piezoelectric discs using numerical and experimental studies. Then, analytical and numerical results on ultrasonic Bessel beam generation in elastic solids will be presented. Finally, a technique for the reduction of side lobes in Bessel beams will be discussed and numerical results on ultrasonic collimated beam generation in elastic solids will be presented.

*This research was funded by DOE office of Energy Efficiency and Renewable Energy (EERE).

9:36AM R23.00009: Multiscale porosity measurements of Shale rocks using multiple gas adsorption and mercury intrusion porosimetry  
NICOLAS CHANUT (Presenter), THIBAUT DIVOUX, RÉNAL BACKOV, CEE, Massachusetts Institute of Technology, JEFF KENVIN, Micromeritics, ROLAND JM PELLENQ, CEE, Massachusetts Institute of Technology — Unconventional oil and gas production from shale has revolutionized the world energy landscape. Shale is a fine-grained sedimentary rock, composed of solid organic matter (OM) scattered in a mineral framework. The decomposition of this OM at high temperature leads to the generation of hydrocarbons during a process known as maturation. The resulting organic matter develops a nanoscale porosity that governs the ability of a shale petroleum reservoir to store and then to yield oil and gas. The mineral matrix also contributes to the overall porosity leading to a pore size distribution spanning from a few Å to the µm range. In this work, we have combined gas adsorption of multiple gases (CO2, H2, N2, and Ar) and mercury intrusion porosimetry to study the pore system of 5 samples from the Vaca Muerta formation that differ in maturities. Indeed, while gas adsorption allows probing the micro and mesoporosity (< 50nm), mercury intrusion allows for the characterization of the macroporosity (10nm to 500µm). Rather than using a fragmented approach of simple overlays from individual techniques, a unified approach that utilizes a kernel constructed from model isotherms and model intrusion curves is used to calculate the complete pore size distribution and the total pore volume of the material.

Thursday, March 7, 2019 8:00 AM - 11:00 AM

Session R24 DAMOP DQI: Hybrid/Macroscopic Quantum Systems, Optomechanics, and Interfacing AMO with Solid State/Nano Systems III  
BCEC 159 - Nathan Schine, University of Chicago

8:00AM R24.00001: Controlling thermal fluctuation of phonon modes with nonreciprocal dynamics in an optomechanical system*  
HAITAN XU (Presenter), LUYAO JIANG, Physics, Yale University, AASHISH CLERK, Institute for Molecular Engineering, University of Chicago, JACK HARRIS, Physics, Yale University — Nonreciprocal dynamics in optomechanical systems is of rising interest in the past several years. While earlier works mainly focused on photonic modes, here we study nonreciprocal dynamics for phonon modes. We have realized nonreciprocal coupling between phonon modes, which leads to nonreciprocal phonon transfer. We achieved phonon isolation which can be tuned continuously over a wide range from -30dB to 30dB. We show the nonreciprocal phonon transfer as a new way to control the thermal fluctuation of phonon modes by controlling laser phases.

8:12AM R24.00002: Diamond optomechanical crystals with embedded nitrogen-vacancy centers* JEFF CADY (Presenter), OHAD MICHEL, KENNETH LEE, ANIA CLAIRE JAYICH, University of California, Santa Barbara — Hybrid mechanical systems, in which qubits are coupled to mechanical degrees of freedom, have recently emerged as a promising alternative and supplement to traditional photonic systems. Recent experiments\(^1\) have demonstrated such a hybrid system with diamond mechanical resonators and embedded nitrogen-vacancy (NV) centers, which interact with one another via crystal strain. While previously realized devices have enabled, for example, extension of coherence using mechanically-dressed spin states and frequency and polarization tuning of the NV center excited state transition, NV-phonon coupling rates have not approached the high quantum cooperativity regime necessary for such applications as phonon-mediated spin-spin interactions and NV-assisted mechanical cooling. As a preliminary step toward the high cooperativity regime in NV center-based hybrid mechanical devices, we design and fabricate single-crystal diamond optomechanical crystals (OMCs), which host GHz-scale mechanical modes and telecom-band optical modes and contain embedded NV centers. Importantly, the spin coherence of these NV centers has been preserved through the fabrication process, with \(T_2^-\) exceeding 1 μs and \(T_2\) exceeding 70 μs.

8:24AM R24.00003: Persistent and Reversible Frequency Tuning in Graphene/Hexagonal Boron-Nitride Nanomechanical Resonators DAVID MILLER (Presenter), ANDREW BLAIKIE, BENJAMIN J ALEMAN, University of Oregon — Persistent and reversible methods for tuning the resonance frequency of a nanomechanical resonator are essential for fields ranging from quantum information to ultra-sensitive force and mass sensing. However, reliable methods to achieve this tuning have been difficult to realize.

Here, we demonstrate that the resonance frequency of nanomechanical resonators can be persistently and reversibly tuned using photoelectric doping[1]. We demonstrate this effect in drumheads made from heterostructures of hexagonal boron-nitride (h-BN) and graphene. However, this technique could potentially be extended to electromechanical resonators made from any material that can be photoelectrically doped. We observe tuning that is robust over weeks, can occur at rates as fast as \(-1\) GHz/s, and has a tuning range of greater than 250%. This could enable future applications which need large numbers of individually tunable nanomechanical elements, such as chip-scale optomechanical circuits.

8:36AM R24.00004: Cooling and amplifying motion of a diamond nanobeam via translation of a focused laser beam* HARISHANKAR JAYAKUMAR (Presenter), BEHZAD KHANALILOO, DAVID LAKE, PAUL BARCLAY, Department of Physics and Astronomy, University of Calgary — Controlling the dynamics of mechanical resonators is central to many quantum science and metrology applications. Optomechanical control of diamond resonators is attractive owing to diamond’s excellent physical properties and its ability to host electronic spins that can be coherently coupled to mechanical motion. Using a confocal microscope, we demonstrate tunable amplification and damping of a diamond nanomechanical resonator’s motion. Observation of both normal mode cooling from room temperature to 80K, and amplification into self-oscillations with 60 μW of optical power is observed via waveguide optomechanical readout. This system is promising for quantum spin-optomechanics, as it is predicted to enable optical control of stress-spin coupling with rates of \(-1\) MHz (100 THz) to ground (excited) states of diamond nitrogen vacancy centers.

8:48AM R24.00005: Measuring the Casimir torque* JEREMY MUNDAY (Presenter), University of Maryland, College Park — It is well-known that the confinement of quantum electromagnetic fluctuations between two macroscopic objects can result in a force, known as the Casimir force. However, in addition to this force, a torque has been predicted between optically anisotropic materials. In this presentation I will discuss counter-intuitive ways to increase the torque (e.g. placing the objects in a dielectric medium rather than vacuum) and our recent experiments that confirm its existence.

*This work was supported by the National Science Foundation under Grant No. PHY-1506047 and PHY-1806768.
Optomechanics for NEMS based Mass Spectrometry  
EWA REJ (Presenter), JARVIS LI, WARREN FON, MATTHEW MATHENY, MICHAEL ROUKES, Caltech — NANOeLectromechanical systems (NEMS) provide an ideal platform for single molecule sensing applications due to their minute size and high quality factors. One application is the measurement of the mass of individual adsorbed molecules, such as single proteins. The mass resolution is governed by the uncertainty in the measured resonance frequency, with contributions from the mechanics (e.g. thermomechanical noise), readout circuitry noise, and the intrinsic instability of the resonator. As a result, a detailed understanding of phase noise is necessary for improved sensor performance. Here we detail a new scheme for NEMS mass sensing based on superconducting microwave cavity optomechanics. The optomechanical transduction scheme is expected to improve the phase noise and resulting mass resolution of NEMS sensors.

Search for light scalar dark matter using optomechanical systems  
SWATI SINGH (Presenter), University of Delaware — Although the existence of dark matter (DM) has been indisputably proven by a range of cosmological and astronomical measurements, there is no viable candidate for dark matter in the Standard Model. In this talk, we will explore optomechanical resonators as detectors of scalar dark matter in the $10^{-12} - 10^{-6}$ eV regime. Light DM particles have large occupation numbers and can be phenomenologically described as a classical field. Irrespective of the model used to produce them, such a classical field can have consequences that can be measured by precision measurement setups, such as varying $\alpha$ or $m_e$ at the frequency associated with DM mass. This effect is enhanced in a solid, and variations in the size of an elastic medium lead to a new force just like the tidal force due to a passing gravitational wave. Moreover, the resonant enhancement over a localized frequency provided by these devices enhances sensitivity to such fields. We will discuss the scalar field parameter space than can be explored by current and future optomechanical devices. Finally, we will comment on how these searches can complement the existing precision measurement based searches based on atomic clocks, spin precession or equivalence principle tests.

Enhanced Optomechanics with Nanostructured Material*  
LI-FAN YANG, ANURUP DATTA, YUCHUN HSUEH, XIANFAN XU, KEVIN WEBB (Presenter), Purdue University — The maximum pressure on a planar surface is understood to be twice the incident wave power density normalized by the background velocity. We demonstrate for the first time that this pressure can be exceeded by a substantial factor by structuring a surface. Experimental results for direct optomechanical deflection of a nanostructured gold film on a silicon nitride membrane illuminated by a laser beam are shown to significantly exceed those for the planar surface. This enhanced pressure can be understood as being associated with an asymmetric optical cavity array realized in the membrane film, and a simple one-dimensional model explains the basic picture. Force control depends on the material properties and the geometrical parameters of the structured material. The interplay between material, structure at the nanometer-scale, and optical force should have substantial consequences in applications that include all-optical communication, remote actuation, propulsion, and biophysics.

Cryogenic Optical and Spin Characterization of Tin-Vacancy Centers in Diamond*  
MATTHEW TRUSHEIM (Presenter), Electrical Engineering and Computer Science, Massachusetts Institute of Technology, BENJAMIN PINGAULT, Cavendish Laboratory, University of Cambridge, NOEL WAN, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, MUSTAFA GUNDOGAN, Cavendish Laboratory, University of Cambridge, LORENZO DE SANTIS, KEVIN CHEN, MICHAEL WALSH, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, JOSHUA ROSE, Cavendish Laboratory, University of Cambridge, JONAS BECKER, Clarendon Laboratory, University of Oxford, ERIC BERSIN, Electrical Engineering and Computer Science, Massachusetts Institute of Technology, GIRISH MALLADI, HASSARAM BAKHRU, College of Nanoscale Science and Engineering, SUNY Poly, IAN A WALMSLEY, Clarendon Laboratory, University of Oxford, METE ATATURE, Cavendish Laboratory, University of Cambridge, DIRK R. ENGLUND, Electrical Engineering and Computer Science, Massachusetts Institute of Technology — Color centers in diamond are promising quantum systems that can combine long-lived spin degrees of freedom with coherent optical transitions. Recently, emitters based on Group IV-vacancy complexes, including the silicon- and germanium-vacancy, have garnered interest as their inversion symmetry protects the optical line from environmental noise. Here, we will discuss cryogenic resonant spectroscopy of tin-vacancy (SnV) center in diamond. Specifically, we will describe its electronic structure, optical signatures of spin, and coherent optical and spin properties. We find that the SnV is a candidate quantum memory that can operate at liquid helium temperatures, potentially enabling scalable quantum networks.

*M.T. acknowledges support by an appointment to the Intelligence Community Postdoctoral Research Fellowship Program at MIT, administered by Oak Ridge Institute for Science and Education through an interagency agreement between the U.S. Department of Energy and the Office of the Director of National Intelligence.
9:48AM R24.00010: Utilizing the nonlinear dynamical response of an optically damped mechanical oscillator*
KJETIL BORKJE (Presenter), University of South-Eastern Norway — We consider a standard cavity optomechanics setup where a mechanical oscillator is coherently driven at its resonance frequency. The cavity mode is driven below its resonance, providing optical damping of the mechanical oscillations. We study the nonlinear coherent response of the mechanical oscillator in this setup. For large mechanical amplitudes, we find that the system can display dynamical multistability if the optomechanical cooperativity exceeds a critical value. We investigate the effect of thermal and quantum noise and estimate the noise-induced switching rate between the stable states of the system. Finally, we discuss how this system can be used as bifurcation amplifiers for the detection of small mechanical or optical signals.

*The author acknowledges funding from the QuantERA ERA-NET Cofund in Quantum Technologies (project QuaSeRT) implemented within the European Union's Horizon 2020 Programme.

10:00AM R24.00011: Ground-state cooling of a mechanical resonator enabled by critical coupling and dark entangled states*
CRISTIAN CORTES (Presenter), MATTHEW OTTEN, STEPHEN K GRAY, Nanoscience and Technology Division, Argonne National Laboratory — Over the past ten years, there has been tremendous interest in achieving ground-state cooling in mechanical resonators in order to enhance the performance characteristics of mechanical-based sensors, quantum memories, and quantum transducers. While there have been successful demonstrations of ground-state cooling using optomechanical systems, an outstanding challenge remains in reaching the ground state using solid-state defects. In this work, we present a novel approach for resonant phonon cooling using the concept of critical coupling, subradiance, and many-body entanglement within an ensemble of two-level systems. We reveal that carefully engineering the strain profile of the mechanical resonator allows phonon cooling to proceed through the dark entangled states of an interacting ensemble, thereby enabling ground-state cooling in spite of the small spin-strain coupling strengths encountered in real systems. Our work provides a new avenue for phonon cooling and should be accessible for experimental demonstrations.

*This work was performed at the Center for Nanoscale Materials, a U.S. Department of Energy Office of Science User Facility, and supported by the U.S. Department of Energy, Office of Science, under Contract No. DE-AC02-06CH11357.

FREDERIC PEYSKENS (Presenter), Massachusetts Institute of Technology, DRIES VAN THOURHOUT, Ghent University, DIRK R. ENGLUND, Massachusetts Institute of Technology — Localized quantum emitters in certain 2D materials show great promise to realize single photon sources on top of photonic integrated circuits, as these materials allow easy and scalable integration with such circuits. Most research so far was however devoted to the study of free-space quantum emitters. We will present our work on the integration of 2D materials on top of a mature silicon nitride photonic platform and moreover elaborate on our analytical framework to describe the interaction of a 2D-material-based cavity-emitter system with a dielectric photonic waveguide. Rather than minimizing the cavity modal volume, our analysis predicts an optimum modal volume to maximize the single photon generation efficiency into the guided mode of the waveguide, thereby balancing waveguide coupling and spontaneous emission rate enhancement. Numerical simulations on realistic systems allow us to extract optimal parameters for the design of integrated quantum photonic circuitry.

*F.P. acknowledges support from a BAEF, Fulbright, and FWO postdoctoral fellowship. D.E. and F.P. acknowledge partial support from the CDQI and the NSF EFRI-ACQUIRE program.

10:24AM R24.00013: Cavity optomagnonics with magnetic textures: coupling a magnetic vortex to light
JASMIN GRAF (Presenter), HANNES PFEIFER, FLORIAN MARQUARDT, SILVIA VIOLA-KUSMINSKIY, Max Planck Institute for the Science of Light — Efforts so far in cavity optomagnonics, where light couples coherently to magnons in a solid state cavity system, have focused on systems with a homogeneous magnetic background. We propose a cavity-optomagnonic system with a non homogeneous magnetic ground state, namely a vortex in a magnetic microdisk. We study the coupling between optical whispering gallery modes to gyrotrropic and flexural magnon modes localized at the vortex. We show that the optomagnonic coupling has a rich spatial structure and that it can be tuned by an externally applied magnetic field. Our results predict cooperativities at maximum photon density of the order of $C \sim 0.01$ by proper engineering of these structures.
10:36AM R24.00014: Nonlinear dynamics in disordered optomechanical arrays  THALES FIGUEIREDO ROQUE (Presenter), FLORIAN MARQUARDT, VITTORIO PEANO, Max Planck Institute for the Science of Light, OLEG YEV TUSHENKO, Ludwig-Maximilians-University — Optomechanical arrays (OMA) have already offered a playground for the theoretical investigation of a broad range of phenomena including synchronization, many-body dynamics, quantum control and topological effects. The implementation of these investigations requires a degree of control on the dispersion of the parameters of the individual optomechanical cells. However, the most promising platforms for OMA are based on nanoscale on-chip technologies such as microdisks and optomechanical crystals. This represents a challenge because fabrication imperfections are difficult to control on the nanoscale. Conversely, disorder can be viewed as a resource which gives rise to interesting physical phenomena. In this talk, we focus on the nonlinear dynamics of disordered OMA. This regime displays a number of nontrivial and yet not explored phenomena involving the interplay of Anderson localization, dissipation and strong nonlinearities.

10:48AM R24.00015: Modeling the Adsorption-Desorption Phase Noise in Optomechanical Oscillators  CIJY MATHAI (Presenter), SIDDHARTH TALLUR, Indian Institute of Technology Bombay — Optomechanical oscillators (OMOs) exhibit self-sustained mechanical oscillations, driven by optical pumping through radiation pressure or optical gradient force. Due to the lack of externally applied feedback, prior theoretical models and experiments have reported that such oscillators are free of 1/f^3 (pink noise) and higher order slopes in the phase noise spectrum [Opt. Exp. 2011;19:24522-29]. However, most OMO results reported at sub-atmospheric temperatures and pressures exhibit significant 1/f^4 phase noise (brown noise), that is not explained by conventional models. In this work, we study the impact of adsorption and desorption (of gas molecules on the resonator surface) on phase noise in OMOs, based on noise analysis in mechanical oscillators [IEEE TUFFC. 1989;36(4):452-8]. Experimental data recorded for a chip-scale silicon OMO (obtained in a liquid nitrogen cooled vacuum ambience) fits well with the theoretical prediction. An additional insight drawn from the model is that unlike phase noise originating from thermal noise sources, the brown phase noise is independent of the mechanical mode shape, as validated through observation of similar magnitude of 1/f^4 noise in oscillations of a radial breathing mode at 70MHz and wineglass mode at 58MHz in the same device.

Thursday, March 7, 2019 8:00 AM - 11:00 AM

Session R25 DAMOP DCMP: Disorder and Localization in AMO Systems III: Many-body Localization  BCEC 160A - Fernando Sols, Complutense University

8:00AM R25.00001: Long-range resonances and the meltdown of many-body localization*  BENJAMIN VILLALONGA (Presenter), BRYAN CLARK, University of Illinois at Urbana-Champaign — Closed, quantum systems with interactions can transition to a many-body localized (MBL) phase in the presence of disorder. In this work, we attempt to numerically identify the presence of resonances in the ergodic-MBL transition. We find evidence for the proliferation of resonances around the transition, where the resonance structure becomes scale invariant. In addition, we consider how the resonances induce the buildup of entanglement and spectral statistics observed in the system through collisions between energy levels. We explore this both in the real-space basis as well as an adiabatic 1-bit basis.

*This research is part of the Blue Waters sustained-petascale computing project, which is supported by the National Science Foundation (awards OCI-0725070 and ACI-1238993) and the state of Illinois. Blue Waters is a joint effort of the University of Illinois at Urbana-Champaign and its National Center for Supercomputing Applications.
8:12AM R25.00002: Critical Dynamics at the Many-Body-Localized Phase Transition*  MATTHEW RISPOLI (Presenter), ALEXANDER LUKIN, ROBERT SCHITTKO, SOOSHIN KIM, JOYCE KWAN, MING E TAI, JULIAN LEONARD, MARKUS GREINER, Harvard University — When an isolated quantum system is prepared far from equilibrium, transport of its constituent particles allows it to relax by energy exchange throughout the remaining system. However, the addition of strong disorder in these interacting systems breaks down transport at a critical disorder strength as a consequence of many-body localization (MBL). Here, we study many-body localization in a 1-D system of interacting bosons with quasi-periodic disorder. Through the site-resolved, correlated density fluctuations, we extract a dynamic transport length and observe exceptionally slow transport near this critical disorder strength. We additionally verify the critical nature of the system’s dynamics by tuning the total system size. Finally, we identify a microscopic mechanism of the interaction-driven delocalization via a sparse-resonant structure. This sparse structure persists into higher-order correlation functions and additionally identifies the many-body critical nature. These results and observed mechanism lay a foundation for characterizing dynamic many-body phases and studying other proposed microscopic mechanisms in interacting, disordered systems.

8:24AM R25.00003: Avoiding Ergodicity: Localization in Clean Interacting Systems YUVAL BAUM (Presenter), EVERT VAN NIEUWENBURG, GIL REFAEL, Caltech — Since the phenomenon of many-body-localization (MBL) was re-postulated more than a decade ago, it has attracted a great deal of attention. A key ingredient for achieving the MBL phase is disorder (randomness). The roots of this phase lie within the phenomenon of Anderson localization, where non-interacting particles form a localized non-ergodic phase. It is the question regarding the fate of Anderson localization in the presence of interactions that plants the seed for the discovery of the MBL phase.

We wish to go beyond the conventional paradigm and ask whether randomness is indeed an essential ingredient in achieving generic non-ergodic interacting phases.

We proposed the idea that the essential ingredient for MBL is localization, which does not necessarily mean disorder. We analyze the spectral and the dynamical properties of one-dimensional interacting fermions and spins in the presence of both disorder and linear potential. We show that by considering these two different localizing mechanisms, i.e., disorder and linear fields, one may construct a two-dimensional phase diagram which hosts a connected non-ergodic (MBL) phase.

8:36AM R25.00004: Dephasing Beyond the Markovian Limit; Implications for Many-Body Localization SETH DAVIS (Presenter), MATTHEW FOSTER, Rice University — Despite progress in understanding many-body localization (MBL) in one-dimension, many questions remain with respect to the nature of the transition and the stability of the MBL phase. We envision approaching the MBL transition from the high-temperature ergodic phase. We search for signatures of the transition as a failure of dephasing, which prevents the infrared divergence of quantum conductance corrections in the ergodic phase in 1D and 2D.

For an isolated fermion system with short-ranged interactions, dephasing is due to diffusive (strongly non-Markovian) thermal density fluctuations. A previous study identified a nontrivial RG fixed point in \(4 - \epsilon\) dimensions, at which the dephasing time diverges (Liao and Foster, PRL 2018). By contrast, long-range Coulomb interactions provide an approximately Markovian bath. A perfectly Markovian bath dephases at any nonzero temperature (Altshuler, Aronov, Khmelnitsky 1982).

We perturb about the exactly solvable Markovian limit, which we re-interpret as an exact, infinite-order diagrammatic summation. Using explicit calculations and scaling arguments, we will describe results beyond the Markovian limit in 1D and 2D.

8:48AM R25.00005: Many Body Localization Transition in Systems with Correlated Disorder* RAJDEEP SENSARMA (Presenter), ABHISEK SAMANTA, AHANA CHAKRABORTY, Tata Institute of Fundamental Research — We study the transition from many body localized to ergodic transitions in disordered spin chains where the disorder at different sites are correlated. In the uncorrelated limit, the system has a well studied transition between many body localized to ergodic phase as a function of increasing disorder strength. On the other hand, in the extremely correlated limit, we essentially obtain a translation invariant system. We use two different models of correlated disorder and map out the phase diagram in the correlation-disorder plane.

Activating many-body localization in solids by driving

ZALA LENARCIC (Presenter), EHUD ALTMAN, University of California, Berkeley, ACHIM ROSCH, University of Cologne —

Coupling to phonons prevents many-body localization (MBL) from occurring in disordered solids even when the disorder is strong. This is because phonons mediate non-local interaction which weakly breaks local conservation laws characteristic for the MBL phase. Nevertheless, I will show that decay of local conservation laws can be compensated when the system is driven out of equilibrium. We propose to detect the fingerprints of an underlying MBL phase by measuring the variation of local temperatures in the resulting steady state.

The concrete example I will consider is a one-dimensional disordered spin-chain which is weakly coupled to a phonon bath and weakly irradiated by white light. The irradiation has weak effects in the ergodic phase. However, if the system is in the MBL phase irradiation induces strong temperature variations. Temperature variation can be used similar to an order parameter to detect MBL phases, the phase transition, an MBL correlation length and even the critical exponents. Finite coupling strengths broaden the transition into a crossover, potentially containing information on the Griffiths effects. I will address this using tensor network and variational ansatz approaches.

Flow Equations for Many-Body Localisation: Dynamics and Dimensionality*

STEVEN THOMSON (Presenter), MARCO SCHIRO, Institut de Physique Théorique — Once thought to destroy localisation completely, we now know that adding interactions into disordered quantum matter can lead to the formation of a many-body localised phase. This phase is characterised by an extensive number of local conserved quantities and a failure to thermalise. Consequently it cannot be described by conventional equilibrium quantum statistical mechanics: new theoretical tools are required. Here, we present a semi-analytic flow equation approach that is capable of simulating large system sizes and of computing the real-time dynamics of observables and correlation functions. We employ a continuous unitary transform to diagonalise the Hamiltonian of a gas of interacting spinless fermions, show how local integrals of motion naturally emerge from this method, and go on calculate time evolution and localisation properties in the strongly-disordered regime in both one and two spatial dimensions. We further comment on ongoing work extending the method to incorporate additional features, including spin, as well as three-dimensional systems.

Localization in Fractonic Random Circuits

SHRIYA RAMACHANDRAN PAI, MICHAEL PRETKO (Presenter), RAHUL NANDKISHORE, University of Colorado, Boulder — In this talk, I will describe a new mechanism for many-body localization, making use of ideas drawn from the field of fractons. Specifically, I will present results on the spreading of initially local operators under random unitary evolution in spin chains subject to fracton conservation laws, such as conservation of dipole moment. We find that fractons remain permanently localized at their initial positions, providing a crisp example of a non-ergodic dynamical phase of random unitary evolution. These results can be interpreted as a consequence of the properties of low-dimensional random walks. This mechanism for localization remains robust in one and two dimensions, but breaks down in three-dimensional fracton systems. We argue that these results extend to Floquet and Hamiltonian time evolution, even in the absence of disorder, thereby providing a mechanism for many-body localization in a translationally invariant system.

Statistics of entanglement spectrum across MBL to ergodic transition.

ABHISEK SAMANTA (Presenter), KEDAR DAMLE, RAJDEEP SENSARMA, Tata Institute of Fundamental Research — We show how the statistics of entanglement spectra change across the transition between a many body localized phase and an ergodic phase of an interacting disordered system. Using a disordered spin chain as a model, we numerically construct various measures and try to find an "order parameter" for the transition. The transition point obtained from this construction matches with those obtained from other indicators like the distribution of many-body energy gaps.
Localization in an interacting system with two degrees of freedom per site: Is charge disorder alone sufficient to localize the Hubbard model or is spin disorder also necessary?* RACHEL WORTIS (Presenter), BRANDON LEIPNER-JOHNS, Physics & Astronomy, Trent University — Many-body localization, the inability of some isolated quantum systems with both interactions and disorder to achieve thermal equilibrium, has been studied primarily in systems with one degree of freedom per site. The addition of a second degree of freedom creates a new avenue for exploration and connects to the Hubbard model, a launch point for the study of a wide range of systems of current interest including transition metal oxides and cold atoms in optical lattices. With both charge and spin degrees of freedom at each site, is disorder in just one of these channels sufficient to cause the full system to be localized? Alternatively, does the degree of freedom without disorder delocalize the one which sees disorder? To what extent is the level of localization in one channel related to the disorder in the other channel? We consider the Hubbard model with both charge and spin disorder. We employ several measures of localization designed to treat spin and charge on equal footing. We find measures based on the local integrals of motion are consistent with those based on the dynamics. For sufficient disorder in one degree of freedom, only a small amount of disorder in the other degree of freedom localizes both degrees of freedom.

Many-body localization in a multifractal fermionic chain* NICOLAS MACÉ (Presenter), NICOLAS LAFloRENCIE, FABIEN ALET, Laboratoire de Physique Théorique, Université de Toulouse — We study the many-body localization (MBL) properties of a chain of interacting fermions subject to a deterministic quasiperiodic on-site potential following the Fibonacci sequence. With this choice, the single-particle eigenstates are delocalized and multifractal, no matter how strong the potential is. Contrary to naive expectations, adding interactions in this system does not enhance delocalization, and a MBL transition is observed. Due to the highly correlated nature of the potential, the MBL phase presents features which differ from those encountered for the more documented random-box potential. We observe for example extra peaks in the fermion density distribution which we can relate to the occurrence of specific local patterns in the quasiperiodic potential. Furthermore, in the ergodic phase, non-trivial properties of the single-particle density matrix are observed, compatible with a persistence of the free fermions multifractality. Our analysis is based on exact numerical studies of eigenstates and dynamical properties after a quench.

Many body localization in the presence of a central qudit* NATHAN NG, Physics, UC Berkeley, MICHAEL KOLODRUBETZ (Presenter), University of Texas at Dallas — We consider a many-body localized system coupled globally to a central d-level system. Under an appropriate scaling of d and system size, we find evidence that the localized phase survives. We argue for two possible thermalizing phases, depending on whether the qudit becomes fully ergodic. This system provides one of the first examples of many-body localization in the presence of long-range (non-confining) interactions. We discuss possible anomalous behavior in the system, such as an inverted mobility edge - localized at high temperature, but ergodic at low temperature.

*We acknowledge support from the U.S. Department of Energy Basic Energy Sciences (BES) TIMES initiative and UTD Research Enhancement Funds.

Stability of quasiperiodic chains to quantum avalanches* ANUSHYA CHANDRAN (Presenter), PHILIP CROWLEY, Boston University — In one dimension, it is conjectured that full many-body localization is unstable if the localization length exceeds a threshold value. The instability is due to the presence of rare ergodic Griffiths regions; each such region thermalizes its environment and grows, resulting in a (slow) avalanching process of thermalization. We show that weakly interacting chains with quasiperiodic potentials violate this conjecture because the sparse local structure of the l-bits prevents thermalization near an ergodic region. Our work identifies the first qualitative difference between random and quasi-periodic localization and suggests new experimental tests of avalanche instabilities.

10:36AM R25.00014: Hilbert space properties of the many-body localization problem: from full ergodicity to multifractality* NICOLAS MACÉ, FABIEN ALET, NICOLAS LAFLORENCIE (Presenter), CNRS, Université Paul Sabatier, Laboratoire de Physique Théorique, Toulouse — In contrast with Anderson localization where a genuine localization is observed in real space, the many-body localization (MBL) problem is much less understood in the Hilbert space, support of the eigenstates. In this work, using exact diagonalization techniques up to L=24 spin-1/2 particles (i.e. Hilbert space of size N=2.7 millions) we address the ergodicity properties in the underlying N-dimensional complex networks spanned by various computational bases. We report fully ergodic eigenstates in the delocalized phase (irrespective of the computational basis), while the MBL regime features a generically (basis-dependent) multifractal behavior, delocalized but non-ergodic. The MBL transition is signaled by a non-universal jump of the multifractal dimensions.

*This work benefited from the support of the project THERMOLOC ANR-16-CE30-0023-02 of the French National Research Agency (ANR) and by the French Programme Investissements d'Avenir under the program ANR-11-IDEX- 0002-02, reference ANR-10-LABX-0037-NEXT. 10:48AM R25.00015: Entanglement, dynamics and breakdown of many-body localization in current driven system* SUMILAN BANERJEE (Presenter), ANIMESH PANDA, Center for Condensed Matter Theory, Department of Physics, Indian Institute of Science — What is the fate of a many-body localized system under a voltage bias between two ends? Can the system undergo a transition to a current carrying non-equilibrium steady state and how the entanglement properties of the quantum states change across the transition? Motivated by these questions, we model a current driven interacting disorder system through a non-Hermitian Hamiltonian and study the entanglement properties of its eigenstates. We also discuss the dynamics, entanglement growth and long-time fate of a generic initial state under an appropriate time-evolution of the system governed by the non-Hermitian Hamiltonian. Our study reveals rich entanglement structures of current driven states and multiple dynamical transitions as a function of disorder and the strength of the non-Hermitian term, that is related to the external bias.

Session R27 DQI: Quantum Error Correction Theory and Experiment II BCEC 160C - Christopher Chamberland, IBM Thomas J Watson Research center - Tag(s): Focus

8:00AM R27.00001: The boundaries and topological defects of the color code* [Invited] MARKUS KESSELRING (Presenter), FU Berlin — We give a thorough exploration of the color code phase to find all of its boundaries and domain walls. This gives us a new playground to discover new quantum error correcting codes and ways of performing gates. Our exploration uncovered improved methods for performing quantum computations by code deformation, a new four-qubit error-detecting code, as well as families of new quantum error-correcting codes we call stellated color codes, which encode logical qubits at the same distance as the next best color code, but using approximately half the number of physical qubits.

8:36AM R27.00002: Connecting discrete and continuous variable quantum codes LINSHU LI (Presenter), Yale Univ, VICTOR ALBERT, Caltech, KYUNGJOO NOH, LIANG JIANG, Yale Univ — We consider the connection between discrete variable (DV) codes based on qubit/qudit systems and continuous variable (CV) codes based on bosonic systems. Specifically, we study generalization of quantum parity codes (QPCs) that allows multiple excitations in each mode and fills in the gap between DV quantum parity codes and single-mode binomial codes. The connection offers an alternative perspective to understand these two types of quantum codes, and can hopefully shed light upon generic connections between the two regimes.
8:48AM R27.00003: Braiding via symmetry transformation: universal transversal gate set for topological codes
GUANYU ZHU (Presenter), MAISSAM BARKESHLI, University of Maryland, College Park — Recent studies of the relationship between symmetry and topology have stimulated a series of new discoveries. A recently developed theory of "quantum origami" revealed the deep relation between mapping glass group, topological symmetry and transversal gates in fault-tolerant quantum computation (arXiv:1711.05752). Motivated by this finding, here we show that elements in the spherical braid group with n punctures (anyons) can be completely generated with two isometries related to different rotational symmetries of the punctured surface. By folding the surface to 2n layers connected with gapped boundaries, we acquire a "folded fan" model for quantum computers in reminiscence of the "pancake" model consisting of multiple disconnected layers. The two isometries in the unfolded manifold can be mapped into onsite symmetry in the folded fan, corresponding to fault-tolerant transversal logical gates which can be used to perform quantum computation. For the non-abelian Fibonacci-Turaev-Viro code, these transversal gates form a universal set, along with a constant-depth circuit switching the symmetry. In contrast to the code switching approach to circumvent the Eastin-Knill no-go theorem, we achieve the circumvention using a symmetry switching approach with constant time overhead.

9:00AM R27.00004: Depth reduction for quantum Clifford circuits through Pauli measurements* YI-CONG ZHENG (Presenter), Quantum Lab, Tencent, CHING-YI LAI, Institute of Communications Engineering, National Chiao Tung University, TODD BRUN, Electrical Engineering, University of Southern California, LEONG-CHUAN KWEK, Centre for Quantum Technologies, National University of Singapore — Clifford circuits play an important role in quantum computation. Gottesman and Chuang proposed a gate teleportation protocol so that a quantum circuit can be implemented by the teleportation circuit with specific ancillary qubits. In particular, an n-qubit Clifford circuit U can be implemented by preparing an ancillary stabilizer state $I \otimes U |\Psi\rangle^\otimes n$ for teleportation and doing a Pauli correction conditioned on the measurement. In this paper, we provide an alternative procedure to implement a Clifford circuit through Pauli measurements, by preparing O(1) ancillas that are Calderbank-Shor-Steane (CSS) stabilizer states. That is to say, O(1) CSS states are sufficient to implement any Clifford circuit. As an application to fault-tolerant quantum computation, any Clifford circuit can be implemented by O(1) steps of Steane syndrome extraction if clean CSS stabilizer states are available.

9:12AM R27.00005: A Systematic Construction of Clifford Perfect Tensors MENGZHEN ZHANG (Presenter), LIANG JIANG, Yale Univ — Perfect tensors are essential building blocks for holographic quantum states, which provide an intriguing platform of combining quantum information theory and physics of spacetime. Network of perfect tensors generated from stabilizer codes can be efficiently analyzed. To our knowledge, the full classification of such perfect tensors is still unknown. In this work, we demonstrate a systematic approach of constructing a large class of perfect tensors, with some existing construction schemes as special cases. Moreover, we investigate their operator generalization to continuous variable systems and identify the differences between the construction schemes in discrete variable and continuous variable systems.

9:24AM R27.00006: Calderbank-Steane-Shor Holographic Quantum Error Correcting Codes* THOMAS STACE (Presenter), Univ of Queensland — We expand the class of holographic quantum error correcting codes by developing the notion of block perfect tensors, a wider class that includes previously defined perfect tensors. The relaxation of this constraint opens up a range of other holographic codes. We demonstrate this by introducing the self-dual CSS heptagon holographic code, based on the 7-qubit Steane code. Finally we show promising thresholds for the erasure channel by applying a straightforward, optimal erasure decoder to the heptagon code and benchmark it against existing holographic codes.

* Australian Research Council, US Air Force

9:36AM R27.00007: Good quantum subsystem codes in 2-dimensions THEODORE YODER (Presenter), Research, IBM Tj Watson — Given any two classical codes with parameters $[n_1, k_1, d_1]$ and $[n_2, k_2, d_2]$, we show how to construct a quantum subsystem code in 2-dimensions with parameters $[[N, K, D]]$ with $N = n_1 n_2$, $K = k_1$, and $D = \min(d_1, d_2)$. These quantum codes are in the class of generalized Bacon-Shor codes introduced by Bravyi. Then, using constructions of good families of classical expander codes, we give constructive families of good quantum subsystem codes in 2-dimensions, that is, families saturating Bravyi's bound $KD = O(N)$. While such codes were known to exist via counting arguments, this is the first explicit construction of them. Additionally, we provide a linear-time decoder for these subsystem codes.
9:48AM R27.00008: Dynamically protected qubit based on high-impedance superconducting circuits*  
PHILIPPE CAMPAGNE-IBARCQ (Presenter), Applied Physics, Yale University, MAZAYAR MIRRAHIMI, Quantic Team, INRIA Paris, MICHEL H. DEVORET, Applied Physics, Yale University — Quantum information encoded in a physical system is submitted to decoherence induced by interaction with uncontrolled degrees of freedom in the environment of the system. However, these interactions are local in the sense that they only induce continuous evolutions of the system in its phase space. One can thus protect quantum information by storing it “non-locally”, i.e. in the correlations between distant phase space regions. Here, we propose to combine a high impedance superconducting resonator with a Josephson junction whose energy is stroboscopically modulated. This system simulates the dynamics of a LC oscillator combined with a Josephson junction and a Quantum Phase Slip element. In presence of these two non-locally acting noiseless elements, the ground states are degenerate non-local grid states of the resonator and are expected to provide a fully protected logical qubit.

*Work supported by ARO, AFOSR and YINQE

10:00AM R27.00009: Natural quantum error-correction in many-body dynamics implies stability of volume-law entangled states against projective measurements  
SOONWON CHOI (Presenter), YIMU BAO, Physics, University of California Berkeley, XIAOLIANG QI, Physics, Stanford University, EHUD ALTMAN, Physics, University of California Berkeley — In a generic isolated quantum many-body system, entanglement entropy of any subsystem grows linearly in time until saturated to a value proportional to its volume. Random projective measurements, however, can severely affect such dynamics by disentangling the measured parts from the rest of the system. In this work, we investigate this interplay between entangling dynamics and projective measurements from the perspective of quantum information theory. We show that volume-law entangled states can remain stable even when a substantial fraction of the system is measured in every time unit. Our key observation, based on the quantum decoupling theorem, is that a sufficiently scrambling unitary can hide quantum correlations in a non-local form such that local measurements cannot decrease entanglement. Such dynamics is generic and can be explicitly demonstrated in a toy model involving random local unitary gates acting on a chain of qubit clusters followed by probabilistic measurements. Our work suggests that the stability of the volume-law entangling phase originates from the effective quantum error correcting feature of scrambling dynamics, which protects quantum entanglement from the noisy environment.

10:12AM R27.00010: Quantum simulation of fermions: geometric locality and error mitigation  
ZHANG JIANG (Presenter), JARROD MCCLEAN, RYAN BABBUSH, HARTMUT NEVEN, Google — We consider mappings from fermionic systems to spin systems that preserve geometric locality in more than one spatial dimension. Such mappings are useful for simulating lattice fermion models (e.g., the Hubbard model) on a quantum computer. Locality-preserving mappings avoid the overhead associated with non-local parity terms in conventional mappings, such as the Jordan-Wigner transformation. As a result, they often provide solutions with lower circuit depth. Moreover, locality-preserving mappings are likely to be more resistant to qubit noises by avoiding encoding the fermionic correlation functions in non-local Pauli operators. Here, we discuss how to detect/correct single-qubit errors with two known locality-preserving maps. We then go beyond that by constructing new mappings with better error detecting/correcting performance than the existing ones. Our methods do no introduce extra physical qubits beyond those required by the original mappings. Being able to detect/correct errors in initial state preparations is crucial to the success of near-term quantum algorithms such as the variational quantum eigensolver. Our results also provide systematic methods to constructing quantum error-detecting/correcting codes with Majorana fermion operators.

10:24AM R27.00011: Approximate stabilizer rank and improved weak simulation of Clifford-dominated circuits for qudits*  
YIFEI HUANG (Presenter), PETER J LOVE, Tufts University — Bravyi and Gosset recently gave classical simulation algorithms for quantum circuits dominated by Clifford operations. These algorithms scale exponentially with the number of T-gate in the circuit, but polynomially in the number of qubits and Clifford operations. Here we extend their algorithm to qudits of odd prime dimensions. We generalize their approximate stabilizer rank method for weak simulation to qudits and obtain the scaling of the approximate stabilizer rank with the number of single-qudit magic states. We also relate the canonical form of qudit stabilizer states to Gauss sum evaluations. We give an O(n^3) algorithm to calculating the inner product of two n-qudit stabilizer states.

*This work is supported by the National Science Foundation award number PHY 1720395 and from Google Inc.
10:36AM R27.00012: Direct Measurement of a Very Small Logical Qubit's Observables* NICHOLAS MATERISE (Presenter), ELIOT KAPIT, Colorado Sch of Mines — We extend recent longitudinal readout schemes to the very small logical qubit (VSLQ) architecture. The two photon X-operators in the VSLQ are read out by borrowing principles from the longitudinal approach, although the operator itself is transverse. Our results follow those of previous studies of coupling between a single cavity mode and superconducting qubit, where high measurement fidelities are realized for shorter measurement pulses compared to dispersive readout. In the interest of minimizing microwave circuit resources per VSLQ unit cell, we have investigated the use of the higher modes of the same resonator for error correction. We demonstrate use of the fundamental resonator mode for fast readout of an inductively coupled VSLQ with improved fidelities compared to the dispersive case. By measuring along the X-axis, we benefit from the added protection of the passive error correction during readout, reducing potential state preparation and measurement error.

*We acknowledge funding support from the National Physical Sciences Consortium graduate fellowship and ARO grant W911NF-18-1-0125.

10:48AM R27.00013: Graph convolutional network for topological stabilizer codes YASUNARI SUZUKI (Presenter), NTT Secure Platform Laboratories, AMARSAANAA DAVAASUREN, University of Tokyo, KEISUKE FUJII, Kyoto University, MASATO KOASHI, YASUNOBU NAKAMURA, University of Tokyo — As quantum computers are close to realization, a fast, versatile, and high-performance decoder for quantum error correction is demanded. In recent years, several machine-learning-based decoders have been proposed, and are expected to enable fast decoding with near-optimal performance for an arbitrary topological code. Since local Pauli errors only flip local syndromes in topological codes, a convolutional neural network is used for explicitly extracting local features in topological codes. However, the filter shapes for the convolution only match to the qubit allocation of [2d^2-2d+1, 1, d]-surface code. It has been not known how we can naturally extract local features of other topological codes.

In this talk, we propose a novel construction of a machine-learning-based decoder with a model known as graph convolutional network. This decoder enables us to utilize local features of an arbitrary topological stabilizer code. With numerical results, we show that our model achieves similar performance to minimum distance decoder, which is known to be inefficient but near-optimal, for several topological codes and noise models using practical size of training datasets.

Session R28 DQI: Distributed Quantum Computation, Networking and Information Security II BCEC 161 - Victoria Lipinska, Delft University of Technology - Tag(s): Focus

8:00AM R28.00001: Entanglement cost of quantum state preparation and channel simulation* XIN WANG (Presenter), University of Maryland, College Park, MARK M WILDE, Louisiana State University — We study various aspects of the entanglement cost of quantum state preparation and quantum channel simulation. First, we establish that the exact entanglement cost of any bipartite quantum state under PPT-preserving operations is given by a single-letter formula, here called the κ-entanglement of a quantum state. This formula is calculable by a semidefinite program, thus allowing for an efficiently computable solution for general quantum states. Notably, this is the first time that an entanglement measure for general bipartite states has been proven not only to possess a direct operational meaning but also to be efficiently computable, thus solving a question that has remained open since the inception of entanglement theory over two decades ago. Second, we study the exact entanglement cost of quantum channel simulation in the parallel setting. In particular, the largest κ-entanglement that can be established via a quantum channel remarkably gives a single-letter formula for the exact parallel PPT-entanglement cost of simulating this channel, and it is also efficiently computable by a semidefinite program.

8:12AM R28.00002: Communicating via Ignorance* KAUMUDIKASH GOSWAMI (Presenter), JACQUILINE ROMERO, ANDREW WHITE, Univ of Queensland — Communication through a sequence of two identical, noisy, depolarising channels is impossible in conventional information theory. Surprisingly, it has been shown in the paper [1] communication becomes possible if the depolarising channels are within a quantum switch, where the order of the channels is in a quantum superposition [2,3]. We experimentally demonstrate this counterintuitive result in a quantum switch that uses polarisation to coherently control the order of two depolarising channels acting on the transverse spatial mode of a photon. We send $(3.41\pm0.15)\times10^{-2}$ bits of information through two fully depolarising channels that are in an indefinite causal order. [4]

8:24AM R28.00003: Quantum Link Prediction in Complex Networks YASSER OMAR (Presenter), Instituto Superior Tecnico, JOÃO MOUTINHO, ANDRÉ MELO, BRUNO COUTINHO, Physics of Information and Quantum Technologies Group, Instituto de Telecomunicações, ISTVAN KOVACS, ALBERT BARABASI, Northeastern University — Predicting the existence of a link in a complex network is a non-trivial task, namely for large social and biological networks, with important applications. Experiments to map the full structure of biological networks (e.g. protein-protein interactions) are very challenging, costly and time consuming, and large amounts of data is still missing. Link prediction methods are not only a key computational tool to aid these efforts in understanding complex biological systems, but also very useful for other studies of time-varying complex networks, as for example social networks.

In this work we present a novel method for link prediction in complex networks based on continuous-time quantum walks. The control of a relative phase allows our method to be used in different types of networks (physical, biological, social, etc.). By exploiting quantum coherence we are able to outperform the state of the art classical methods, indicating that our method is also able to capture complex local patterns (such as local communities around paths of length 3) without the need to impose a specific pattern structure. Our results indicate there is a strong potential for combining quantum algorithms with complex network research to produce tools with direct and immediate experimental relevance.

8:36AM R28.00004: Indefinite Causal Order* JACQUILINE ROMERO, KAUMUDIKASH GOSWAMI, CHRISTINA GIARMATZI, MICHAEL KEWMING, FABIO COSTA (Presenter), School of Mathematics and Physics, University of Queensland, CYRIL BRANCIARD, Institut Neel, CNRS, ANDREW WHITE, School of Mathematics and Physics, University of Queensland — Quantum mechanics allows events to happen with no definite causal order: this can be verified by measuring a causal witness, in the same way that an entanglement witness verifies entanglement. Here we realise a photonic quantum switch, where two operations, A and B, act in a quantum superposition of their two possible orders. The operations are on the transverse spatial mode of the photons, while polarisation coherently controls their order. Our implementation ensures that the operations cannot be distinguished by spatial or temporal position. It also allows qudit encoding in the target. We confirm our quantum switch has no definite causal order by constructing a causal witness and measuring its value to be 18 standard deviations beyond the definite-order bound.

8:48AM R28.00005: Counterfactual Quantum Superdense Coding*  
FAKHRAR ZAMAN (Presenter), YOUNGMIN JEONG, HYUNDONG SHIN, Kyung Hee University — Quantum superdense coding (QSC) is one of the most striking effects in quantum communication. It enables one to transmit a two-bit classical message by sending only one qubit using initially shared entanglement. In this article, we present a counterfactual QSC scheme that enables remote parties to accomplish this task without prior entanglement but no physical particle is found in the transmission channel. We consider two remote parties, namely Alice (sender) and Bob (receiver), have untangled particles—an electron and a photon. First, we generate entanglement between the electron and photon without transmitting any physical particle over the channel. Alice performs one of the four unitary operations $\mu \in \{I, \sigma_x, \sigma_y, \sigma_z\}$ on her entangled particle. Instead of transmitting her entangled particle to Bob, Alice and Bob perform counterfactual Bell-state analysis based on the chained quantum Zeno effect to distinguish between the four Bell-states under local operations and enable Bob to decode the two-bit classical message.

9:00AM R28.00006: Drone-based Quantum Key Distribution*  
ANDREW CONRAD (Presenter), DALTON CHAFFEE, JOSEPH CHAPMAN, CHRIS CHOPP, KYLE HERDON, ALEXANDER HILL, University of Illinois at Urbana-Champaign, DANIEL SANCHEZ-ROSALES, JOSEPH SZABO, DANIEL J GAUTHIER, Dept. of Physics, OSU, PAUL G KWAT, University of Illinois at Urbana-Champaign — Recent advances in quantum memories point to the future viability of quantum networking, including quantum cryptography. To be truly multi-purpose, future quantum communication networks should consist of a variety of platforms, e.g., airplanes, drones, and ships, though the motion of these platforms precludes the use of fiber-based approaches to quantum cryptography; free-space quantum key distribution (QKD) systems have historically been rather bulky. Small moving platforms, such as multirotor drones, are ideal for reconfigurable networks in both urban and rural environments but are only capable of supporting lightweight payloads (< 10 kg). Here we discuss our current progress in developing a reconfigurable network of two or more small multi-rotor drones implementing a modified BB84 quantum key distribution protocol over a free-space optical channel. This requires the development of fast and lightweight sources of polarized photons with no side channel leakage, miniaturization of time-tagging electronics and single-photon detectors, and the development of a robust signal acquisition and pointing and tracking system.

9:12AM R28.00007: Quantum Internet Applications  
[Invited] ELHAM KASHEFI (Presenter), edinburgh — The long-term ambition of the community is to build a Quantum Internet that enables any distributed quantum communication applications (beyond QKD) between any points on Earth. In this talk I will present a set of useful applications that could be executed on the quantum nodes with various hardware capabilities presenting a blueprint for a quantum client-server platform. I will also present the Quantum Protocols Wikipedia, a QIA lead community effort in developing and curating a comprehensive software library for a list of relevant quantum network protocols achieving various functionalities.

EMIL KHABIBOULLINE (Presenter), Harvard University, JOHANNES BORREGAARD, University of Copenhagen, KRISTIAAN DE GREVE, MIKHAIL LUKIN, Harvard University — Quantum networks provide a platform for astronomical interferometers capable of imaging faint stellar objects. We present a protocol with efficient use of quantum resources and modest quantum memories. In our approach, the quantum state of incoming photons along with an arrival time index is stored in a binary qubit code at each receiver. Nonlocal retrieval of the quantum state via entanglement-assisted parity checks at the expected photon arrival rate allows for direct extraction of phase difference, effectively circumventing transmission losses between nodes. Compared to prior proposals, our scheme, based on efficient quantum data compression, offers an exponential decrease in required entanglement bandwidth. We show that it can be operated as a broadband interferometer and generalized to multiple nodes. We also analyze how imaging based on the quantum Fourier transform provides improved signal-to-noise ratio compared to classical processing. Finally, we discuss physical realizations including photon detection-based quantum state transfer. Experimental implementation is then feasible with near-term technology, enabling optical imaging of astronomical objects akin to well-established radio interferometers and pushing resolution beyond what is practically achievable classically.
necessary to realize experimentally desirable levels of non-classical correlations. We present the requirements to quantify the nonclassical correlations that are realized. Analyzing these measures reveals that the key rate of RFI-MDI-QKD can be improved for a large misalignment of the reference frame.

Please see the Reference [H.-W. Liu et al., Optica 5, 902 (2018)] for more information about the results of our paper.

10:12AM R28.00010: Entangled-pulse generation inside coherent Ising machines using entanglement swapping* RYOTATTSU YANAGIMOTO (Presenter), PETER McMATHON, TATSUHIRO ONODERA, EDWIN NG, HIDEO MABUCHI, Stanford University — Coherent Ising machines (CIMs) have been proposed and demonstrated as heuristic solvers of hard combinatorial optimization problems. In current measurement-feedback-based CIMs (P.L. McMahon 2016), interactions between pulses (spins) are mediated via a classical feedback mechanism, and consequently no entanglement among pulses is generated. In this research, we investigate the use of entanglement swapping to introduce inter-pulse entanglement into such CIM-like architectures, using an external source of independently squeezed pulses. We develop models to describe the resulting intracavity dynamics as a function of system parameters, which can be numerically simulated to characterize the quantum noise and correlations in the pulse train. We also introduce and employ several measures of inseparability to quantify the nonclassical correlations that are realized. Analyzing these measures reveals trade-offs between system parameters and produces metrics useful for optimizing them. We present the requirements necessary to realize experimentally desirable levels of non-classical correlations.

10:24AM R28.00011: Maximal LELM Distinguishability of Qubit and Qutrit Bell States using Projective and Non-Projective Measurements NATHANIEL LESLIE (Presenter), Physics, UC Berkeley, JULIEN DEVIN, Physics, Stanford University, THERESA WLYNN, Physics, Harvey Mudd College — Numerous quantum information protocols make use of maximally entangled two-particle states, or Bell states, in which information is stored in the correlations between the two particles rather than their individual properties. Retrieving information stored in this way means distinguishing between different Bell states, yet the well known no-go theorem establishes that projective linear evolution and local measurement (LELM) detection schemes can only reliably distinguish three of the four qubit Bell states. We present newly-established maximum distinguishability bounds for the qutrit Bell states of bosons via projective LELM measurements; only three of the nine Bell states can be distinguished. Next, we extend to the case of non-projective measurements. We present newly-established maximum distinguishability bounds for the qutrit Bell states of bosons via projective LELM measurements; only three of the nine Bell states can be distinguished. We extend to the case of non-projective measurements. We present a strengthened no-go theorem, which shows that general LELM measurements cannot reliably distinguish all four qubit Bell states. We also establish that at most five qutrit Bell states can be distinguished with generalized LELM measurements.

10:36AM R28.00012: Generating accessible entanglement in bosons via pair-correlated tunneling TYLER VOLKOFF, Konkuk University, CHRIS HERDMAN (Presenter), Middlebury College — We consider an extended Bose-Hubbard model that includes pair-correlated tunneling. We demonstrate that a minimal four-mode implementation of this model exhibits a pair-correlated regime in addition to Mott insulator and superfluid regimes. We propose a low complexity variational subspace for the ground state of the system in the pair-correlated regime, which we find to be numerically exact in pure pair-tunneling limit. Additionally, we propose a parameter-free high fidelity model wave function that qualitatively captures the features of the ground state in the pair-correlated regime. Due to particle number conservation, the operationally accessible entanglement vanishes deep inside the Mott insulator and superfluid regimes, however in the pure pair-correlated tunneling limit we find that the accessible entanglement entropy grows logarithmically with the number of particles. Additionally, we demonstrate that upon application of a unitary beamsplitter operation, the pair-correlated ground state is transformed into a state with completely accessible entanglement that is not limited by superselection rules.
8:00AM R29.00001: Quantum control of spins in silicon carbide with photons and phonons* [Invited] DAVID AWSCHALOM (Presenter), University of Chicago — There is a growing interest in exploiting the quantum properties of electronic and nuclear spins for the manipulation and storage of quantum information. Here we focus on recent developments in controlling and connecting individual spins in silicon carbide (SiC) using photons and phonons. We find that defect-based electronic states in SiC [1] can be isolated and optically probed at the single spin level with surprisingly long spin coherence times and high-fidelity control within non-isotopically purified, commercial-grade wafers operating at near-telecom wavelengths. Moreover, a detailed study of the defect spin-photon interface yields efficient quantum control in various polytypes along with near-unity electronic and nuclear polarization, highlighting the potential of SiC for photon-mediated entanglement. In addition, we use Gaussian surface acoustic wave resonators to exploit both the piezoelectric and isotropic phonon dispersion properties of SiC to demonstrate Autler-Townes splittings, mechanically driven Rabi oscillations, and explore spin-strain coupling contributions from all mechanical degrees of freedom, including shear [2]. The spatial confinement of phonons is mapped using a synchrotron-based x-ray diffraction real-space microscopy technique with 25 nm spatial resolution [3]. This work expands the versatility of optically and mechanically driven spins in a material with well-developed device and fabrication capabilities and shows promise towards integrating quantum states with hybrid quantum systems for both control and communication.

8:36AM R29.00002: Quantum network nodes with silicon-vacancy center and coupled nuclear spins in diamond nanocavities DENIS SUKACHEV (Presenter), MIHIR K BHASKAR, CHRISTIAN T NGUYEN, RUFFIN EVANS, BARTHOLOMEUS MACHIELSE, HONGKUN PARK, MARKO LONCAR, MIKHAIL LUKIN, Harvard University — We realize quantum-network nodes based on silicon-vacancy color centers in diamond nanocavities coupled to nearby nuclear spins. A high cooperativity SiV-cavity interface and efficient tapered-fiber collection allows for single-shot readout of the SiV electronic spin. With dynamical decoupling sequences, we measure a coherence time of 400μs. We observe coupling to nearby 13C spins and demonstrate coherent control of the SiV-13C register. By using these nuclear spins, we realize a quantum memory exceeding 1ms. Together with our previous work, these results pave the way for quantum computation based on 2D cluster states with more than 10 photons, and quantum communication based on quantum repeaters.

8:48AM R29.00003: Resonant optical spin initialization and readout of single silicon vacancies in silicon carbide* ONEY SOYKAL (Presenter), United States Naval Research Laboratory, HUNTER BANKS, NRC Postdoc at Naval Research Laboratory, SAMUEL CARTER, THOMAS REINECKE, United States Naval Research Laboratory — The silicon mono-vacancy defect in 4H-SiC is a promising candidate for solid-state quantum information processing. Recent high-resolution resonant optical spectroscopy on single defects have shown favorable low temperature optical properties, i.e., two narrow and nearly lifetime-limited optical transitions with no discernable zero-field splitting fluctuations or spectral diffusion. We present a theoretical fine structure model that describes the energy level structure and reveals all intersystem crossing and spin polarization time constants of the V2 defect, shedding light on its optical and spin characteristics. In particular, we show that the silicon mono-vacancy is described well by a four-level optical structure assisted by additional non-radiative transitions leading to rich dynamical spin pumping behavior. Our calculated rates result in an overall fluorescence lifetime of 5.8 ns in good agreement with measurements. Based on this model, we show that initialization fidelities exceeding 99% are theoretically attainable at low resonant laser powers. Further, we describe the differences in optical properties between the cubic and the hexagonal defect sites due to dynamic and pseudo Jahn-Teller effects.

Fault-Tolerant Quantum Metrology with High-Density Spin Ensembles: Theory

JOONHEE CHOI (Presenter), HENGYUN ZHOU, Harvard University, SOONWON CHOI, UC Berkeley, RENATE LANDIG, HELENA KNOWLES, Harvard University, JUNICHI ISOYA, University of Tsukuba, FEDOR JELEZKO, Ulm University, SHINOBU ONODA, Takasaki Advanced Radiation Research Institute, HITOSHI SUMIYA, Sumitomo Electric Industries Ltd., MIKHAIL LUKIN, Harvard University — One of the most promising routes towards high-sensitivity quantum metrology is to utilize high density spin ensembles. Here, spins are typically periodically manipulated in order to both extend coherence and detect an external signal at a particular frequency. However, spin-spin interactions and on-site disorder may severely limit the coherence time and the achievable sensitivities under such dynamical protocols. In addition, control imperfections pose a significant challenge to the effectiveness of decoupling and sensing sequences. Here, we present a novel formalism for the fault-tolerant design of sensing sequences that simultaneously decouples interactions and suppresses the effects of disorder and imperfect controls, while maximizing sensitivity to an external signal. In addition to the broad applicability to different decoupling and sensing scenarios, this formalism could also serve as a powerful tool for the engineering of Hamiltonians to study many-body physics.

Fault-Tolerant Quantum Metrology with High-Density Spin Ensembles: Experimental Results

HELENA KNOWLES (Presenter), HENGYUN ZHOU, JOONHEE CHOI, Harvard University, SOONWON CHOI, UC Berkeley, RENATE LANDIG, Harvard University, JUNICHI ISOYA, University of Tsukuba, FEDOR JELEZKO, Ulm University, SHINOBU ONODA, Takasaki Advanced Radiation Research Institute, HITOSHI SUMIYA, Sumitomo Electric Industries Ltd., MIKHAIL LUKIN, Harvard University — High density solid-state spin ensembles have shown great promise as high-sensitivity magnetometers on the nanoscale. However, further increases in sensitivity require techniques to overcome the limits to coherence times imposed by spin-spin interactions. Here, using a dense ensemble of Nitrogen-Vacancy centers in diamond, we experimentally demonstrate fault-tolerant decoupling of spin-spin interactions, achieving a ten-fold enhancement of spin coherence times. This was made possible by introducing novel dynamical decoupling sequences that simultaneously suppress disorder, interactions, and imperfections in controls. We utilize the prolonged coherence time to perform quantum metrology, demonstrating an increase in sensitivity compared to conventional sensing protocols such as the XY-8 sequence. These results thus demonstrate a significant enhancement beyond the interaction limit, crucial for high-sensitivity magnetometers in high-density interacting spin ensembles.

Multi-qubit registers with solid-state defect centers

ERIC BERSIN (Presenter), MATTHEW TRUSHEIM, KEVIN CHEN, MICHAEL WALSH, SARA MOURADIAN, TIM SCHRÖDER, DIRK R. ENGLUND, Massachusetts Institute of Technology — Medium-scale ensembles of qubits offer a platform for near-term quantum technologies, as well as studies of many-body physics. Atom-like emitters in solids have emerged as promising candidates for this application, with long coherence times, coherent optical transitions, the ability to couple to long-lived nuclear spins for extended storage, and a path towards scalability. A prerequisite for generating such clusters is subdiffraction localization, necessary to achieve strong spin-spin coupling for efficient state transfer and gates operations.

In this work, we present progress made towards producing such ensembles. We demonstrate subdiffraction registers of multiple nitrogen vacancy centers in diamond that maintain individual control and readout of each constituent spin. We further discuss recent work towards scalable creation of such clusters and techniques for producing systems of coupled spins.

The negatively charged nitrogen-vacancy (NV⁻) center in diamond is emerging as a powerful quantum magnetometer. As an atomic size sensor, an NV⁻ center incorporated into a scanning probe microscope has the potential of imaging molecular structure. To achieve the requisite sensitivity and spatial resolution, it is crucial that NV⁻ centers are located within nanometers from the surface; however, the diamond surface is known to reduce the spin coherence and charge stability of NV⁻ centers, compromising the capacity of single-spin sensitivity. Here, we address charge state instability of single shallow NV⁻ centers both under illumination and in the dark [1]. We identify tunneling to a local electron trap as the mechanism for charge ionization in the dark and develop techniques to control and readout the trap charge state. We demonstrate experimental protocols to mitigate the detrimental effects, and we present progress towards imaging single molecules.

High sensitivity quantum limited electron spin resonance spectroscopy**

Following recent advances in circuit quantum electrodynamics, we have employed high quality factor superconducting resonators to reduce the mode volume around the spins and operate ESR in so-called Purcell regime [1,2] where a larger $g$ not only leads to a larger signal but also provides a high repetition rate. In particular with a nanometric inductor, we show $g/2\pi$ of 3 kHz, which together with Josephson parametric amplifier pushes the spin sensitivity to be 10 spins for unit signal to noise ratio per second of averaging.

Enhanced spin-squeezing using a parametrically-driven cavity

Entangled spin-squeezed states allow the possibility of sensing beyond the standard quantum limit, and have been pursued using a variety of different physical mechanisms. In this talk, we will describe and analyze a new, highly-efficient method for generating spin squeezing that exploits a cavity subject to a two-photon (parametric) drive. Unlike standard methods that use a detuned cavity to induce spin-spin interactions (the “one-axis twist” Hamiltonian), our approach employs a resonant interaction and counterdiabatic driving, leading to a more rapid protocol. Our technique can also achieve true Heisenberg-limited scaling, unlike the standard one-axis twisting approach. We will discuss the main properties of the protocol, and explore its performance in realistic parameter settings. The outlined scheme could be implemented in systems where spin ensembles are coupled to superconducting microwave cavities (e.g. [1]), as well as in systems where spins are strain-coupled to the motion of a nanomechanical resonator (e.g. [2,3]). In both cases, the required resource of a parametric drive is experimentally accessible.

10:12AM R29.00010: All-optical cryogenic thermometry based on NV centers in nanodiamonds* MASAYA FUKAMI (Presenter), CHRISTOPHER G YALE, PAOLO ANDRICH, XIAOYING LIU, Institute for Molecular Engineering, University of Chicago, JOSEPH HEREMANS, Materials Science Division, Argonne National Laboratory, PAUL F NEALEY, DAVID AWSCHALOM, Institute for Molecular Engineering, University of Chicago — Nitrogen vacancy (NV) centers in nanodiamonds (NDs) have been shown to provide an excellent nanometer-scale high-sensitivity thermometry platform. Here we demonstrate a cryogenic-compatible, all-optical thermometry technique based on the emission spectrum of an ensemble of NV centers in NDs that operates from room-temperature to liquid nitrogen temperatures. The sensitivity is found to be slightly improved at cryogenic temperatures, in contrast to the conventional thermometry technique based on the temperature-dependent zero-field splitting of NV centers. We use this all-optical thermometer at T=170 K to measure the surface temperature of a ferromagnetic insulator, yttrium iron garnet (YIG), over tens of microns with the use of an array of NDs on a flexible polydimethylsiloxane (PDMS) sheet, where the YIG is thermally driven by a resistive heater. We directly observe a thermal gradient over micrometers in YIG, indicating that the technique is independent of magnetic noise and microwave resonances.

10:24AM R29.00011: Optically coherent NV centers in um-thick etched diamond membranes for quantum applications MAXIMILIAN RUF (Presenter), MARK IJSPEERT, SUZANNE VAN DAM, MATTHEW WEAVER, Delft University of Technology, NICK DE JONG, *Netherlands Organisation for Applied Scientific Research (TNO, HANS VAN DEN BERG, JASPER FLIPSE, MARTIN ESCHEN, *Netherlands Organisation for Applied Scientific Research (TNO), SANTI SAGER LA GANGA, GUUS EVERS, RONALD HANSON, Delft University of Technology — Future quantum networks depend on efficient entanglement generation between nodes. Recently, we have generated entanglement between nitrogen-vacancy (NV) center nodes with a success rate of up to 40 Hz. This rate is now limited by the zero-phonon-line emission probability as well as the photon collection efficiency. Embedding a diamond slab containing individually resolvable NV centers between two highly reflective mirrors can address both challenges, benefiting from large Purcell enhancement due to a low optical mode volume.

Until now, cavity-enhanced entanglement generation between NV centers has not been achieved, predominantly due to poor optical properties of NV centers close to the diamond surface. Via a combination of electron irradiation and an optimized etch sequence, we have fabricated a 3.5 um thick membrane that combines low surface roughness (< 0.4 nm) and narrow optical NV transitions (<100 MHz). We incorporate such devices in an open, tunable micro-cavity setup, with the potential for a two orders-of-magnitude increase in remote entangling rates.

10:36AM R29.00012: CMOS-Integrated Diamond Nitrogen-Vacancy Quantum Sensor* CHRISTOPHER FOY (Presenter), MOHAMED IBRAHIM, DONGGYU KIM, MATTHEW TRUSHEIM, DIRK R. ENGLUND, RUONAN HAN, EECS, MIT — We report the first on-chip quantum sensor which combines CMOS integrated circuit technologies with nitrogen-vacancy (NV) centers in diamond. We will discuss how this system performs two critical functions for quantum magnetometry with NV centers: strong generation and efficient delivery of microwave for quantum-state control, and optical filtering/detection of spin-dependent fluorescence for quantum-state readout. We demonstrate on-chip optically detectable magnetic resonance (ODMR) for the first time. I will then discuss, some of our more recent efforts toward increasing the capabilities of this system to coherently control the NV's spin state.

*This research is supported in part by the Army Research Office Multidisciplinary University Research Initiative (ARO MURI) biological transduction program, Kwanjeong Educational Foundation, Singaporean-MIT Research Alliance (SMART), MIT Center of Integrated Circuits and Systems, and Master Dynamic Limited. It is also supported by the Intelligence Community Postdoctoral Research Fellowship Program at MIT, administered by Oak Ridge Institute for Science and Education through an interagency agreement between the U.S. Department of Energy and the Office of the Director of National Intelligence.

10:48AM R29.00013: Scanning Nitrogen-Vacancy Center Magnetic Imaging SUSANNE BAUMANN (Presenter), ALEC JENKINS, SIMON A MEYNELL, ANIA CLAIRE JAYICH, University of California, Santa Barbara — The NV center is a quantum probe that is sensitive to a variety of fields (magnetic, electric, thermal, strain), can achieve nanoscale spatial resolution, is non-invasive, and can operate over a wide range of temperatures; hence it is an ideal tool for studying novel phases of matter that often emerge only below a critical temperature. Here we use a cryogenic scanning NV magnetometer to probe materials that exhibit nanoscale magnetic phenomena often inaccessible to other experimental tools over a variety of temperatures.

Thursday, March 7, 2019 8:00 AM - 10:48 AM
8:00AM R30.00001: Mechanically Guided Assembly of Bio-Inspired 3D Mesoscale Frameworks [Invited] JOHN ROGERS (Presenter), Materials Science and Engineering, Northwestern University —
Complex, three dimensional (3D) assemblies of micro/nanomaterials form naturally in biological systems, where they provide sophisticated function in even the most basic forms of life. In spite of their potential utility in man-made devices, design options for analogous abiotic 3D mesostructures are severely constrained by the comparatively primitive capabilities that are available with established techniques for materials growth, assembly and 3D printing. This talk summarizes progress in strategies that rely on geometric transformation of preformed 2D functional micro/nanostructures into 3D architectures by controlled processes of actively induced compressive buckling. The emphasis will be on the foundational physics principles, computational approaches that enable inverse design, and examples of applications in areas ranging from thermoelectrics to microelectromechanical systems to biologically inspired open mesoscale networks as active cellular interfaces.

8:36AM R30.00002: Spatial control of frost formation on hydrophobic surfaces with millimetric serrated features YUEHAN YAO (Presenter), EMMA FELDMAN, KYOO-CHUL (KEN) PARK, Northwestern University — Numerous studies have focused on a low surface energy coating and a micro/nanoscale surface texture to design functional surfaces that delay frost formation and reduce ice adhesion. However, the scientific challenges for long-term icephobic surfaces have not been fully addressed because of degradation such as mechanical wearing. Inspired by the suppressed frost formation on concave regions of natural leaves, here we report findings on the frosting process on hydrophobic surfaces with various serrated structures. Dropwise condensation, the first stage of frosting, is enhanced on the peaks and suppressed in the valleys when the wavy surface is exposed to humid air, causing frosting to initiate from the peak. The condensed droplets in the valley are then evaporated, resulting in a non-frost band. The effects of surface topography on the frost pattern are systematically studied by varying the serrated geometry defined as the vertex angle, and numerically modeling the spatial distribution of diffusion flux of water vapor on the wavy surface. Under different ambient humidity levels, the magnitudes of diffusion flux at the non-frost boundaries of the surfaces are nearly identical, implying that the critical value of diffusion flux is the key to understand the non-frost pattern.

8:48AM R30.00003: Understanding Nanostructured Topography on Flower Petals: Hierarchical Wrinkles in Soft Multilayers* CHAO CHEN (Presenter), ALFRED CROSBY, Polymer Science and Engineering Department, University of Massachusetts Amherst — Hierarchical wrinkles on flower petals enable unique iridescence to attract pollinators. Although similar patterns have been observed on graded elastomers, mimesis of the natural patterns and relative dimensions with a controllable and tunable manner is challenging. Inspired by the multiple-layered structure of petal skins, here we present a physical model and a corresponding numerical model based on three-layered thin films. The layer-by-layer integration provides accuracy in controlling thickness and mechanical properties of thin films, thus enabling quantitative relations between physical and numerical models. We quantify the sequential development of a hierarchical structure, consisting of small wrinkles coupled with larger sinusoidal deformations. We found their wavelength follows the bilayer wrinkling theory; whereas the amplitudes of small wrinkles have a systematic spatial distribution largely controlled by larger wrinkles. We also discovered a collapse from the dual-wrinkling mode to a single-wrinkling mode, which depends upon thickness and mechanical properties of top layers. A phase map of the two wrinkling modes is constructed to guide the design of hierarchical wrinkles.

*This material is based upon work supported by Human Frontier Science Program (No. RGP0019/2017)

9:00AM R30.00004: Mechanics of Elephant Trunk Wrinkles ANDREW SCHULZ (Presenter), DAVID L HU, Georgia Institute of Technology — Elephant skin is obviously wrinkled, but no quantitative measurements have been made of why the trunk has such wrinkly skin. Through videos of trunk movement at Zoo Atlanta and dissections of a trunk from the Smithsonian Institute we report the geometry of the wrinkles and rationalize their function. Elephants can elongate their trunk by over 40%, but have little or no compression capability. Skin at the trunk's root forms square-waved wrinkles and is twice as thick as the skin at the tip which forms sinusoidal wrinkles. We rationalize that elephants use these wrinkling properties to perform incredible bending, elongation, and strength with their trunk. The energy of wrinkling will be compared to wrinkling phenomenon in the biological world. This work will relate to biologically inspired soft robotic manipulators.
Bioinspired materials with self-regulating mechanical properties upon loading/damages

SANTIAGO ORREGO, ZHEZHI CHEN, DECHING HOU, Mechanical Engineering, Johns Hopkins University, URSZULA KREKORA, Chemical and Biomolecular Engineering, Johns Hopkins University, SUNG KANG (Presenter), Mechanical Engineering, Johns Hopkins University — Nature produces outstanding materials for structural applications such as bones and coral reefs that can adapt to their surrounding environment and repair damages. This leads to the formation of mechanically efficient structures for optimal biomechanical and energy-efficient performance and long-term durability. However, it has been a challenge for synthetic materials to change and adapt their structures and properties to address the changes of loading conditions or damages. To address the challenge, we report a bioinspired material system that triggers mineral synthesis from ionic solutions on organic scaffolds upon mechanical loadings and/or damages so that it can self-adapt to mechanical loadings and regenerate upon damages. The mechanism also allows the formation of functionally graded materials using a simple one step process. We envision that our findings can open new strategies for making synthetic materials with self-regulating mechanical properties.

*We would like to thank the financial support from the Johns Hopkins University Whiting School Start-Up Fund and the Air Force Office of Scientific Research Young Investigator Program Award (Award number: FA9550-18-1-0073, Program manager: Dr. Byung-Lip (Les) Lee).

Fog collection on wire arrays

YOUHUA JIANG (Presenter), CHRISTIAN MACHADO, SHAAN SAVARIRAYAN, KYOO-CHUL (KEN) PARK, Northwestern University — The upright, wire-like leaves of Stipagrostis sabulicola, a grass species in the Namib Desert, shows excellent fog collection performance. Inspired by such wire geometry, we aim to understand the mechanism of fog collection on individual vertical wires and multiple-wire arrays. We visualized how fog droplets are collected on a wire and measured the resulting fog-collection rate while varying wire diameter, surface wettability, and wind speed. Results show that fog-collection rates on a single wire are determined by deposition efficiency, an aerodynamics-related parameter. Surface wettability has a negligible effect on the fog collection rate at low wind speeds (e.g., 0.5 m/s). By contrast, there appears to be a strong effect of wettability at high wind speeds (e.g., 3 m/s), where surfaces with the lowest droplet adhesion performs worst. Such phenomenon is explained by the competition between the air drag force and the droplet retention force on a surface, both of which are determined by surface wettability and wire diameter. Building on the knowledge gained from individual wires, we optimize the design of multiple-wire arrays, which shows a four-fold enhancement in fog-collection rate compared to a single wire of the same surface area.

Siderophore Inspired Molecules to Mediate Collagen Thin Film Adhesion

ROBERTO ANDRESEN EGUILUZ (Presenter), GEORGE DEGEN, ERIC VALOIS, GARRETT LINDSEY, KAI KRISTIANSEN, University of California, Santa Barbara — Adhesion in biological environments (aqueous ionic solutions) is challenged by the high dielectric constant of water which reduces van der Waals interactions, ions in solution which screen electrostatic interactions, and the hydration layers both on hydrophilic substrates and surface-bound ions which discourage adhesive contact between glues and the substrate. In this study, we investigated adhesion between symmetric thin films of collagen type-1 (Col-1), a major component of the extracellular matrix (ECM), mediated by synthetic analogs of siderophores (small molecule bacterial iron chelators).

Our SFA measurements indicate that Col-1 films remain strongly bound to the underlying mica substrate, even after repeated loading-unloading cycles. For only Col-1 films, we observed very weak adhesion forces, $F_{ad} < 5$ mN/m. Adsorption of TLC-adhesive molecules to the Col-1 films significantly increased the force of adhesion, $F_{ad}$, to $> 50$ mN/m. This adhesion remained constant over several hours.

These findings suggest that siderophore inspired molecules might be an improved alternative to existing bio-adhesives, as they have been proven to strongly bridge mineral surfaces (mimicking prosthesis metal surfaces) and now interacting with the main ECM component of mammal tissues, Col-1.

systems, however, colloidal glasses can be fabricated in the lab, and we can tune their reflectance spectra. While the

location of the primary structural resonance in their spectra can be predicted using a single-scattering theory, other

features of the spectra, such as the increase in reflection at short wavelengths, cannot be explained by single scattering

alone. To understand the effect of multiple scattering on the color, we do co- and cross-polarized measurements of the

reflection spectra, and we interpret these measurements using Monte Carlo simulations of photons scattering inside the

disordered structure.

Surface segregation of binary particles in photonic colloidal assemblies

Surface segregation also influences the structural colors of these supraballs. In addition, melanin is a multifunctional biological pigment and the control of its segregation at supraball surface leads to novel ways to modulate unique surface properties of colloidal assemblies.

The prediction and design of bio-inspired structural colors using colloidal glasses

Many species of birds display structural colors that arise from the constructive interference of light that is scattered from the internal structure of the feathers. In blue Cotinga birds, the colors are independent of the angle between light source and observer owing to the glassy arrangement of air spheres in keratin in the feather barb (E. R. Dufresne et al, Soft Matter, 2009, 5, 1792-1795). Such colors can be mimicked in colloidal glasses, but while the locations of the peaks in reflectance spectra are accurately predicted by single-scattering models, weak multiple scattering also contributes to the reflected intensity. We develop a model that quantitatively predicts the reflectance spectra of colloidal glasses. To model the multiple scattering, we use a Monte Carlo approach to simulate photon trajectories. We find good agreement between experimental reflectance spectra and the model. We also develop an optimization algorithm to find the parameters required to make specific colors and explore the range of hues that can be achieved with colloidal glasses.

*MRSEC, NSF GRFP, NSERC

The physical origin of the reflectance features of structurally-colored colloidal glasses

We use colloidal glasses as a model system to study the physics in structurally-colored systems in nature, such as the blue feather barbs of the plum-throated Cotinga. Both are composed of spheres in an arrangement with short-range order and long-range disorder, and in both cases the color results from interference rather than absorption. Unlike biological systems, however, colloidal glasses can be fabricated in the lab, and we can tune their reflectance spectra. While the location of the primary structural resonance in their spectra can be predicted using a single-scattering theory, other features of the spectra, such as the increase in reflection at short wavelengths, cannot be explained by single scattering alone. To understand the effect of multiple scattering on the color, we do co- and cross-polarized measurements of the reflection spectra, and we interpret these measurements using Monte Carlo simulations of photons scattering inside the disordered structure.

Learning from butterflies: Folding lipid membranes to build photonic-crystal materials

In some butterfly wing scales, a cellular membrane is folded into a periodic nanostructure which generates color and iridescence by constructive interference of visible light. Inspired by this biological achievement, where protein binding is thought to mediate the energetics and dynamics of membrane folding, we aim to build photonic-crystal materials from self-assembly of small particles on artificial membranes. We start by characterizing the interactions between colloidal particles and a supported phospholipid membrane. We graft single-stranded DNA onto them, so that hybridization of complementary strands generates a specific, attractive force between the particles and the membrane. Using a total internal reflection microscope, we measure interactions with femtonewton resolution and kilohertz dynamics. We find that ligand-receptor affinity dramatically affects the energetics and dynamics of particle-membrane interactions: over a temperature range of a few degrees Celsius, adhesion strength varies by about 10 kT, while bound lifetimes and particle mobility change by orders of magnitude. These results may lead to better understanding of self-assembly of particles on fluid membranes, and ultimately enable self-assembling, membrane-based materials with remarkable optical properties.

*MRSEC, NSF GRFP, NSERC
To achieve this goal, we need to understand and re-design the rules used by nature to encode specificity in protein interactions. Sophisticated techniques for designing proteins de novo have been developed recently in David Baker’s lab. These proteins interact via designed hydrogen-bonding networks and can be used as building blocks to fabricate functional materials. The drawback is the enormous space of interactions that can be designed. In order to explore this space and identify the interactions which lead to specific mechanical properties, we need to understand the link between the protein building blocks and the target structures to assemble. In this talk I will present a theoretical/computational model to predict the yield of some simple protein-made structures as a function of few controlling parameters, such as the binding energies and the concentration of the building blocks.
8:48AM R31.00003: Diffusion Monte Carlo study of hydrogen adsorption on silicon carbide nanotube  GENKI IMAM PRAYOGO (Presenter), KENTA HONGO, Japan Advanced Institute of Science and Technology, HYEONDEOK SHIN, Computational Science Division, Argonne National Laboratory, RYO MAEZONO, Japan Advanced Institute of Science and Technology, ANOUAR BENALI, Computational Science Division, Argonne National Laboratory — Hydrogen is one of the candidates for environmentally friendly energy carriers. Although it has a high energy density per unit weight, its volumetric energy density is rather low, making its compact storage difficult. This is rather important when storage volume is paramount, such as in automobile and aviation industries. Physisorption of hydrogen molecules on materials with high surface area to volume ratio like nanotubes is one of the strategies to increase this volumetric efficiency. Along with carbon nanotube (CNT) and boron nitride nanotube (BNNT), silicon carbide nanotube (SiCNT) is one of the candidate materials for this use. Although it has yet to be experimentally synthesized in single-walled form, larger silicon carbide nanotubes have shown promising gains compared to carbon nanotubes in terms of storage capacity and lack of sorption hysteresis. Theoretical studies point to a stronger binding energy and the existence of point charges naturally occurring on alternating Si-C surface. We present our initial Diffusion Monte Carlo (DMC) results of the adsorption of molecular hydrogen on single walled SiCNT surface. DMC is a stochastic method solving the many-body Schrödinger equation and has demonstrated accuracies below the Kcal/mol for a wide range of materials.

9:00AM R31.00004: Band gaps and excitons in quantum Monte Carlo  MICHAEL BENNETT (Presenter), Department of Physics, North Carolina State University, MATEJ DITTE, Department of Physics, University of Ostrava, CODY MELTON, Department of Physics, North Carolina State University, MATUS DUBECKY, Department of Physics, University of Ostrava, LUBOS MITAS, Department of Physics, North Carolina State University — Using the fixed-node approximation, quantum Monte Carlo (QMC) allows for calculations of both ground and excited energy levels with explicit electron correlations. For example, in periodic systems, one can estimate band gaps by promoting an electron from the valence to conduction band or alternatively from the ionization potential and electron affinity. Since fixed-node QMC’s accuracy depends on the quality of trial functions this tacitly assumes that the relevant states are close to single reference states and well represented by single orbital promotions in the Slater determinant. However, this becomes more challenging for excitations that appear in the gap and are not representative of typical conduction states such as significantly localized excitonic states, impurity or defect levels that are not captured by ordinary band theories. Here the construction of the corresponding trial functions requires more elaborate schemes that might involve multi-reference forms, geometry relaxation and/or additional considerations depending on experiment that one compares with such as optical, conductivity or photoemission measurements. We study a few such cases, eg, benzene molecule and crystal and other systems to capture and illustrate these effects using QMC calculations.

9:12AM R31.00005: Ab Initio Finite Temperature Auxiliary Field Quantum Monte Carlo for Solids*  BRENDA RUBENSTEIN (Presenter), YUAN LIU, Department of Chemistry, Brown University, HANG ZHANG, Department of Chemistry, University of Science and Technology of China — Predicting the finite temperature properties of molecules, and especially, solids is critical for understanding many physical phenomena. Nevertheless, developing accurate, yet efficient methodologies for finite temperature applications remains an outstanding challenge. In this work, we present an Auxiliary Field Quantum Monte Carlo method with an $O(N^2)$ scaling for studying the finite temperature electronic structure of any system that can described by an $ab$ $initio$ Hamiltonian. The algorithm marries the $ab$ $initio$ phaseless auxiliary field quantum Monte Carlo algorithm known to produce high accuracy ground state energies of molecules and solids with its finite temperature variant, long used by condensed matter physicists for studying model Hamiltonian phase diagrams, to yield a phaseless, $ab$ $initio$ finite temperature method. We demonstrate the accuracy of this approach for benchmark solids, including hydrogen chains and networks, and compare to it more popular mean field treatments of real materials. Our method serves as a new, robust tool for studying low, but finite temperature phase transitions in models and solids, ultracold chemistry, and warm dense matter.

Multi-determinant Diffusion Monte Carlo in solids at the thermodynamic limit

KEVIN GASPERICH, Department of Chemistry, University of Pittsburgh, THOMAS APPLENCOURT, YE LUO, Argonne National Laboratory, QIMING SUN, California Institute of Technology, KENNETH D JORDAN, Department of Chemistry, University of Pittsburgh, LUKE SHULENBURGER, Sandia National Laboratories, ANTHONY SCEMAMA, MICHEL CAFFAREL, Universite Paul Sabatier Toulouse, ANOUAR BENALI (Presenter), Argonne National Laboratory — In the past decade, fixed-node diffusion Monte Carlo using a single determinant Slater-Jastrow trial wavefunction as proven to systematically reproduce (within 5-10Kcal/mol) the energies of a wide range of molecules and solids. While it has been demonstrated for molecular systems that the path to chemical accuracy (<1Kcal/mol) can be realized by improving the nodal surface using for example multideterminant trial wavefunctions generated with MCSCF or Selected CI. Reaching the same level of accuracy for solids in the thermodynamic limit has proven harder due to the exponential scaling of these wavefunction generation methods. In this talk, we will discuss the effect of using a multi-determinant Slater-Jastrow trial wavefunction with complex k-points and twist averaging in combination to reach chemical accuracy in the thermodynamic limit for solid carbon.

Progress towards finite temperature density matrix quantum Monte Carlo calculations on solids

HAYLEY PETRAS, JAMES SHEPHERD (Presenter), Chemistry, University of Iowa — There has been a recent surge in interest in finite temperature calculations on molecules driven by methods such as FCI, CC, MP2, and AFQMC. By means of a follow-up to recent work on the uniform electron gas, we here present density matrix quantum Monte Carlo (DMQMC) calculations on molecular Hamiltonians. We compare and contrast molecular diatomics with the electron gas to make comment on the scope for performing periodic calculations with DMQMC. We also describe how DMQMC can contribute to the study of finite temperature ab initio Hamiltonians with other methods.

* We thank the University of Iowa for funding.

Difficulty to capture non-additive enhancement of stacking energy by conventional ab initio methods

KEN QIN (Presenter), TOMOHIRO ICHIBHA, KENTA HONGO, RYO MAEZONO, Japan Advanced Institute of Science and Technology — We evaluated the non-additive contributions in the inter-molecular interactions in B-DNA stacking by using diffusion Monte Carlo (DMC) methods. It is found that only DMC can capture the sign inversion in the contribution (i.e., the non-additivity enhances or reduces the interaction depending on the base pairs of DNA), which is never predicted by any other ab initio methods. Even by CCSD(T), the inversion is found to be difficult to be captured because of the practical handling of CBS (complete basis set correction) at the feasible level with MP2. The predicted non-additivity turns out to be several times larger (~8 kcal/mol) than those by other methods. The importance of the hydrogen bondings between the bases horizontally on the inversion is also clarified.

A simpler twist averaging for the uniform electron gas designed for finite basis set calculations such as coupled cluster and full configuration interaction quantum Monte Carlo

TINA MIHM (Presenter), University of Iowa, ALEXANDRA MCISAAC, Chemistry, MIT, JAMES SHEPHERD, University of Iowa — As a long term aim, we would like to improve the efficiency of wavefunction calculations for solids. An important step is the elimination of finite size error, and it is common for continuum quantum Monte Carlo to use twist averaging. Here, we describe and analyze a simple twist averaging scheme as applied to coupled cluster and full configuration interaction quantum Monte Carlo calculations of the uniform electron gas.

* We thank University of Iowa for their funding.
A diffusion Monte Carlo study of point defect diffusion in rutile TiO$_2$ bulk

TOM ICHIBHA (Presenter), Information Science, Japan Advanced Institute of Science and Technology, ANOUAR BENALI, Argonne Leadership Computing Facility, Argonne National Laboratory, KENTA HONGO, Research Center for Advanced Computing Infrastructure, Japan Advanced Institute of Science and Technology, RYO MAEZONO, Information Science, Japan Advanced Institute of Science and Technology — TiO$_2$ is one of the most popular photocatalysts. The diffusion of point defects (Ti interstitial/O vacancy) is responsible for charge transport. We investigated the diffusion mechanism of the point defects in rutile TiO$_2$ bulk using diffusion Monte Carlo (DMC). There are two issues related to the point defect diffusion: (a) The diffusion of positively charged defects from the bulk inside to the (101) surface promotes the surface oxidation reaction. Then, which type of defect transfers positive charges faster? (b) There are two known diffusion paths for Ti interstitial defects, one parallel to the c-axis and the other perpendicular. In which direction are the defects easier to diffuse? Our DMC calculations established that (a) Ti interstitial defects transfer a larger amount of positive charges to the surface and (b) the primary diffusion direction of Ti interstitial defects changes from `perpendicular to c-axis' to `parallel', along with the change of defect charge, 0 to +4. Both conclusions qualitatively support the previous GGA-DFT work. Yet, the barrier energy prediction is quantitatively much different by ~2eV at the maximum. We will discuss this huge difference and justify the barrier energies predicted by DMC, based on Bader charge analysis and electronic density prediction.

Thursday, March 7, 2019 8:00 AM - 11:00 AM

Session R32 DCP: Solvation and Nanofluidics

8:00AM R32.00001: The Intrinsic Density of a Nanoconfined Liquid* SAMUEL COHEN (Presenter), University of Maryland, College Park; Université Grenoble Alpes and CNRS, JOHN S BENDER, University of Maryland, College Park, BENOIT COASNE, Université Grenoble Alpes and CNRS, JOHN T FOURKAS, University of Maryland, College Park — Liquids confined to nanoscale geometries are ubiquitous in nature and important in many areas of science and technology. However, connecting the microscopic structure and dynamics of a confined liquid to its macroscopic behavior is a fundamental, unsolved problem in liquid-state physics. One key macroscopic property, the density, is highly fluid-dependent, and there is currently no rigorous way of assessing a confined liquid’s accessible volume. Here we present our work using the spectrum of intermolecular vibrational modes to probe the intrinsic density of a confined liquid. In particular, molecular simulations to probe the density will be discussed.

*This material is based upon research supported by the Chateaubriand Fellowship of the Office for Science & Technology of the Embassy of France in the United States and by the National Science Foundation, grant CHE-1362215.

8:12AM R32.00002: Uniaxial-deformation behavior of Ice Ih, as described by the TIP4P/Ice and mW water models

MAURICE DE KONING (Presenter), PEDRO ANTONIO SANTOS-FLÓREZ, Universidade Estadual de Campinas, CARLOS JAVIER RUESTES, CONICET and Facultad de Ciencias Exactas y Naturales, Universidad Nacional de Cuyo — Using molecular dynamics simulations we assess the uniaxial deformation response of ice Ih, as described by two popular water models, namely the all-atom TIP4P/Ice potential and the coarse-grained mW model. In particular, we investigate the response to both tensile and compressive uniaxial deformations along the [0001] and [0-110] crystallographic directions for a series of different temperatures. We classify the respective failure mechanisms and assess their sensitivity to strain rate and cell size. While the TIP4P/Ice model fails by either brittle cleavage under tension at low temperatures or large-scale amorphization/melting, the mW potential behaves in a much more ductile manner, displaying numerous cases in which stress relief involves the nucleation and subsequent activity of lattice dislocations. Indeed, the fact that mW behaves in such a malleable manner even at strain rates that are substantially higher than those applied in typical experiments indicates that the mW description of ice Ih is excessively ductile. One possible contribution to this enhanced malleability is the absence of explicit protons in the mW model, disregarding the fundamental asymmetry of the hydrogen bond that plays an important role in the nucleation and motion of lattice dislocations in ice Ih.
8:24AM R32.00003: Theory of freezing point depression and materials damage by nano-fluidic salt trapping∗
EDMOND ZHOU (Presenter), MOHAMMAD MIRZADEH, ROLAND JM PELLENQ, MARTIN BAZANT, Massachusetts Institute of Technology — The electrolyte solution inside the pore space of many functional materials are subjected to freeze-thaw cycles in a cold season, often undermining the material structure and eventually leading to failure. For more durable designs, it is crucial to understand the interplay between pore surface charge, salt ions and pore connectivity during freezing. We present a continuum theory to distinguish nano-fluidic confined freezing from open systems, and calculate freezing point depression, supercooling and pressure in both limits. As an example application, we provide a possible explanation for the mechanism of freeze-thaw damage in cement paste. Our findings could also provide some insights for cryopreservation and survival of species in winter.

∗This work is supported by CSHub at MIT.

8:36AM R32.00004: Nuclear quantum effects on the liquid–liquid phase transition of a water-like monatomic liquid
NICOLAS GIOVAMBATTISTA (Presenter), Physics, City University of New York (CUNY) - Brooklyn College, GUSTAVO E LOPEZ, BINH NGUYEN, Chemistry, City University of New York (CUNY) - Lehman College — Polyamorphic substances have the ability to exist in more than one liquid and/or glass states. Examples include water, silicon, and hydrogen. In many of these substances, nuclear quantum effects may become important in the proximity of the liquid–liquid and glass–glass transformation. Here, we study the nuclear quantum effects on a monatomic liquid that exhibits water-like anomalous properties and a liquid–liquid phase transition (LLPT) ending at a liquid–liquid critical point (LLCP). By performing path integral Monte Carlo simulations with different values of the Planck's constant \( \hbar \), we are able to explore how the location of the LLCP/LLPT in the P–T plane shifts as the system evolves from classical, \( \hbar = 0 \), to quantum, \( \hbar > 0 \). We find that, as the quantum nature of the liquid (as quantified by \( \hbar \)) increases, and the atoms in the liquid become more delocalized, the LLCP pressure increases, the LLCP temperature decreases, and the LLCP volume remains constant. In addition, the crystallization temperature decreases with increasing \( \hbar \). For large values of \( \hbar \), the LLCP is not accessible due to rapid crystallization. The structure of the liquids studied at different values of \( \hbar \) are also investigated.

8:48AM R32.00005: Strain-Induced Raman Shifts Due to Ice Adhesion∗
SUBASH KATTEL (Presenter), JOSEPH MURPHY, MARINA MACHADO DE OLIVEIRA, SAMUEL PASCO, JOHN ACKERMAN, VLADIMIR ALVARADO, WILLIAM RICE, University of Wyoming — Ice formed on a material creates a strain that is indicative of the adhesive strength between the ice and substrate. Previous determinations of ice adhesion strength, a critical parameter for understanding icing physics, have proven to be both challenging and highly dependent on experiment-specific conditions (surface roughness, icing conditions, water purity, etc.). In this work, we use Raman spectroscopy to contactlessly and non-destructively measure ice-induced strain on silicon and single-layer graphene. To isolate the ice-material interface, we measured the vibrational modes of graphene from 20°C to -30°C with and without ice. Along with the well-known temperature-dependent Raman shift of graphene, a clear, ~3 cm\(^{-1}\) change in the G-mode (~1590 cm\(^{-1}\)) frequency developed upon ice formation. We found this change in the Raman shift tracked closely to the temperature-dependent density of ice, suggesting that we are optically measuring ice-created strain in graphene. When correlated with mechanical adhesion measurements, our non-destructive optical technique provides a way to measure ice adhesive strength, which can be extended to various materials.

∗We acknowledge support from NASA through Grant No. WY-80NSS17M0049 and through the University of Wyoming School of Energy Resources.

9:00AM R32.00006: Size and Aggregation of Ice-binding Proteins Control Their Ice Nucleation Efficiency∗
YUQING QIU (Presenter), ARPA HUDAIT, VALERIA MOLINERO, Chemistry, University of Utah — Ice-binding proteins are the common name shared by antifreeze proteins (AFPs) and ice nucleating proteins (INPs). It has been proposed that the size of ice-binding surface determines the function of these proteins, as INPs or AFPs. Aggregation of proteins can create large ice-binding surfaces, stabilize larger ice nucleus and enhance ice nucleation. However, the quantitative dependence of ice nucleation ability on the size and aggregation of the ice-binding surfaces has not yet been elucidated. We use molecular dynamic simulations to show that the ice nucleating ability of a ice-binding protein increases with their length and saturates at an ice freezing temperature lower that that induced by INP aggregates, because the short dimension of small ice-binding surface limits the formation of ice nucleus. We further demonstrate that INPs dimer with specific separation distance enhances the ice nucleating ability of INPs. We conclude that the size and aggregation of ice-binding proteins control their efficiencies.

Wetting state transition of water droplet on graphene surface with nanoscale pillars*  

HONGRU REN (Presenter), CHUN LI, Northwestern Polytechnical University — The regulation of solid surface wettability can be effectively achieved by controlling surface microstructure and external electric fields. Here, the wetting properties of graphene textured with nanoscale square, circular and cone pillars are systematically investigated by using molecular dynamics simulation. It is shown that the transition of water droplet located on periodic pillars from Wenzel state to Cassie state is highly sensitive to the height of pillars and the hydrophilic-to-hydrophobic switch is achievable by decreasing the inter-pillar spacing. In addition, the behaviors of water droplets situated on graphene under external electric fields are also discussed. The configuration of water droplet performs a hemispherical-conical-ordered cylindrical shape variation with the increase of external electric fields. Notably, the orientations of water dipoles experience remarkable change from disorder to order in the process of increasing electric fields due to the polarization of water molecules induced by static electric fields. These findings could shed some light on future applications of graphene-based devices with controllable wettability.

*National NSF of China (11572251,11872309)

Surface Adsorption and Encapsulated Storage of H2 Molecules in a Cagelike (MgO)12 Cluster*  

YAN ZHANG (Presenter), Beijing Computational Science Research Center, HONGSHAN CHEN, Northwest Normal University — The cluster with a cagelike structure could enable the storage of H2 molecules via surface adsorption and encapsulated storage. Surface adsorption involves the interaction between H2 and host clusters. Encapsulated storage involves the storage of H2 in the interior space of the cagelike structure. The latter is essential for practical applications of cagelike clusters because the interior space is retained when they are assembled into solid-state materials, although many surface adsorption sites are occupied. Here, we report an investigation on surface adsorption and encapsulated storage of H2 molecules in the cagelike (MgO)12 cluster based on a dispersion-corrected density functional theory calculation. The results revealed that the cagelike (MgO)12 cluster surface can adsorb 24 H2 molecules with an average adsorption energy of 0.116 eV/H2, which brings about a gravimetric density of 9.1 wt%. Inside the cagelike (MgO)12 cluster, a maximum capacity of six H2 molecules could be stored according to symmetric configurations. The encapsulated H2 molecules are trapped by energy barriers no more than 2.55 eV, although the storage is an endothermic process.

*This work is financially supported by the National Natural Science Foundation of China (Grant Nos. 11504298 and 11664034).

Kosmotrope and Chaotrope Salts Influence on Water Structural Relaxation and hydrogen Bond Dynamics Investigated by Coherent Quasielastic Neutron Scattering  

ANTONIO FARAONE (Presenter), NIST Center for Neutron Research, National Institute of Standards and Technology, ERKAN SENSES, Department of Chemical and Biological Engineering, Koc University, EUGENE MAMONTOV, Neutron Scattering Division, Neutron Sciences Directorate, Oak Ridge National Laboratory — Salts can either increase or decrease the viscosity when dissolved in water. This phenomenon has been traditionally interpreted within the classification of the solutes as kosmotropes (structure makers) and chaotropes (structure breakers), with reference to their hypothesized property of enhancing or weakening the hydrogen bond network. However, at the molecular level the distinction is less clear as both kosmotropes and chaotropes affect the structure of the surrounding water molecules. Using coherent quasielastic neutron scattering, we have investigated the dynamics of NaCl/D2O and KCl/D2O, NaCl being a kosmotrope and KCl being a chaotrope, respectively. By probing the dynamics of these systems at the structure factor peak, we measured how different salts affect the structural relaxation of water. At the same time, by collecting data at the second peak in the deuterium intermolecular partial structure factor, the hydrogen bond dynamics was probed. Whereas the hydrogen bonding dynamics is largely unchanged by the presence of the salts, NaCl and KCl affect the structural relaxation differently: the former slows down the dynamics whereas the latter mostly leaves the relaxation unchanged.
Agregation Induced Emission (AIE) colloids with enhanced fluorescence activity. Concerning fluorophore encapsulation, it is also possible to control the core-confined crystallization of these to generate capsules loaded inside or on its outskirt with different interesting actives (dyes, meal nanoparticles, biotin...). In this presentation, we show how combining the phase diagrams of simple solutes (oils or solid fluorophores) with hydrophilic polymers (polysaccharides, PVA, pluronics) allows picking a domain where both species co-precipitate into a final capsular object (namely the solute surrounded by the polymer). By crosslinking the shell and functionalize it, one obtains capsules loaded inside or on its outskirt with different interesting actives (dyes, meal nanoparticles, biotin...). Concerning fluorophore encapsulation, it is also possible to control the core-confined crystallization of these to generate Aggregation Induced Emission (AIE) colloids with enhanced fluorescence activity.

**10:00AM R32.00011: Blue Shift of a Molecular Crystal Phonon at the Solid to Liquid Phase Transition**  
ALEX DAVIE (Presenter), Department of Physics, University at Buffalo, Buffalo, New York, United States, FARAH VANDREVALA, Department of Electrical Engineering, University at Buffalo, Buffalo, New York, United States, YANTING DENG, DEEPU GEORGE, Department of Physics, University at Buffalo, Buffalo, New York, United States, ERIC SYLVESTER, Department of Chemistry, University at Buffalo, Buffalo, New York, United States, TIMOTHY KORTER, Department of Chemistry, Syracuse University, Syracuse, New York, United States, ERIK EINARSSON, Department of Electrical Engineering, Department of Materials Design and Innovation, University at Buffalo, Buffalo, New York, United States, JASON BENEDICT, Department of Chemistry, University at Buffalo, Buffalo, New York, United States, ANDREA MARKELZ, Department of Physics, University at Buffalo, Buffalo, New York, United States — We investigate the dielectric response from the optically active phonons of single-crystal fructose using terahertz (THz) spectroscopic techniques. All samples were indexed by x-ray diffraction with space group of P2₁2₁2₁, lattice constants a = 8.09 Å, b = 9.21 Å, c = 10.03 Å and α = β = γ = 90°. Anisotropic THz absorbance unambiguously assigns the measured resonances to specific lattice vibrations calculated by density functional theory. Using [101] face polished crystals, the lowest frequency resonance polarized along the b axis at 1.70 THz is found to continuously red shift with heating to 1.59 THz at the melting temperature 103°C. As the sample is maintained at 103°C the resonance continues to red shift, broaden and decrease in amplitude with melting. Using [010] face polished crystals, the lowest frequency resonance polarized along the c axis at 1.31 THz is found to red shift with heating to 1.25 THz at 103°C, but then blue shifts to 1.26 THz as the temperature is held at 103°C. The peak then remains at this frequency, broadens and decreases in amplitude as the sample enters the liquid phase. The result is inconsistent with expected softening of intermolecular forces during the phase transition.

**10:12AM R32.00012: Caged Contact Pair Formation in Cooled Triiodide-Ethanol Solutions**  
FRANK YI GAO (Presenter), YU-HSIANG CHENG, KEITH ADAM NELSON, Massachusetts Institute of Technology — We have conducted spectrally-resolved optical pump-probe experiments following the photodissociation of triiodide (I₃⁻) in cooled ethanol solutions from 300 K to 80 K. After being excited by a UV pump pulse at 400 nm, I₃⁻ dissociates into I₂⁻ and I fragments, the former of which is monitored by its broad absorption in the 660-870 nm range. Primary geminate recombination occurs within 4 ps over the temperature range studied and occurs in an increasing fraction of photofragments as the solution is cooled. Following an initial period of vibrational relaxation, the observed spectra continuously red-shifts with decreasing temperature before saturating near 800 nm below 160 K. The red-shifted band appears on a timescale similar to geminate recombination. These results are consistent with the increased formation of a caged contact pair species at low temperatures.

**10:24AM R32.00013: Capillary condensation in the atomic-scale slits**  
QIAN YANG (Presenter), ANDRE GEIM, Physics and Astronomy, University of Manchester — Capillary condensation determines fundamentally the adhesion, nucleation, adsorption and friction processes in all granular and porous materials, micromechanical devices and nanotechnology, even in living systems. Its theoretical basis—the Kelvin equation, whose cogency has long been questioned on the nanoscale, is under continuously debate. Consensus has been reached on the validity of the Kelvin equation down to 4 nm, but pores and cracks in nature do not stop their extending to the molecular dimensions. Up to now, little information, at least experimentally, is available at the molecular scale. Here we report water condensation in ultimately thin capillaries, which is capable of accommodate only one layer of water molecules. Pronounced deviations are observed under strong confinement less than 2 nm. Theoretical interpretation of changes in the solid-liquid surface energy resulting from rearranging the water structure near a particular surface complements the Kelvin equation in the ultimate limit of the atomic-scale confinement.
10:36AM R32.00014: Thermodynamics-based electrochemistry transport models: theory and applications  MAXIM ZYSKIN (Presenter), University of Oxford — I will describe Newman-Monroe thermodynamics-based electrochemical transport models and new results on numerical modeling and molecular dynamics based parameter estimation in such models. This work has applications to modeling multiphysics processes in solid electrolytes and is a part of a program of research on electric batteries.

10:48AM R32.00015: Curvature Dependence of Surface Tension and Test of Kelvin Equation at Molecular Scale* SEONGSOO KIM, DOHYUN KIM (Presenter), Seoul National University, JONGWOO KIM, Korea Research Institute of Chemical Technology, SANGMIN AN, WONHO JHE, Seoul National University — Capillary condensation is the vapor-to-liquid phase transition occurring in confined geometries. Such heterogeneous nucleation has been well described by the Kelvin equation, but its applicability at nanoscale is still unresolved. We show it is valid down to 0.5 nm scale when the curvature dependent surface tension is considered. Our results that unify the validity of the Kelvin equation and the curvature effect of surface tension may provide a better understanding of nucleation phenomena.

Session R33 FIAP: Semiconductors and Applications I

8:00AM R33.00001: Local Magnetic Imaging of Epitaxial Magnetic Insulator on Semiconductor Nanowire* ZHENG CUI (Presenter), SEAN J HART, Stanford University, LIU YU, SAULIUS VAITIEKENAS, CHARLES M MARCUS, PETER KROGSTRUP, Niels Bohr Institute, University of Copenhagen, KATHRYN ANN MOLER, Stanford University — The observation of properties related to Majorana bound states in indium arsenide (InAs) nanowire-epitaxial aluminum hybrid structure has been encouraging, but the need for a large external magnetic field makes their control and application very challenging. To locally introduce a magnetic exchange field, a single-crystalline ferromagnetic insulator europium sulfide (EuS) has been grown directly onto the InAs nanowire. Using a scanning Superconducting QUantum Interference Device (SQUID) microscope, we study the local magnetization and susceptibility of the hybrid magnetic structure on a sub-micron scale. Imaging local magnetic properties as a function of temperature and external field on multiple devices allow us to characterize homogeneity, anisotropy and domain formation, which will be crucial to further develop these topological superconducting devices.

8:12AM R33.00002: Magnetic Field Dependent Transport Measurements on High Quality InAs Nanowires MARKUS RITTER (Presenter), IBM Research - Zurich, 8803 Rüschlikon, Switzerland, ZIJIN LEI, Solid State Physics Laboratory, ETH Zürich, 8093 Zürich, Switzerland, BENJAMIN MADON, M A MUEED, AAKASH PUSHP, IBM Research - Almaden, San Jose, California 95120, United States, HEINZ SCHMID, IBM Research - Zurich, 8803 Rüschlikon, Switzerland, THOMAS IHN, KLAUS ENSSLIN, Solid State Physics Laboratory, ETH Zürich, 8093 Zürich, Switzerland, HEIKE RIEL, FABRIZIO NICHELE, IBM Research - Zurich, 8803 Rüschlikon, Switzerland — Semiconductor nanowires with strong spin-orbit interaction are attracting considerable interest as potential platform for spintronic and topological quantum computing applications. However, future progress will require scalability and integration concepts that go well beyond the single nanowire level. We present the low temperature characterization of InAs nanowires grown via the template assisted selective epitaxy (TASE) technique [1]. The TASE approach allows for the deterministic growth of semiconducting nanowires, networks and branched geometries on a two-dimensional silicon platform. Furthermore, structures grow encapsulated in a silicon oxide shell which preserves them from undesirable doping and surface oxidation. The high quality of TASE grown InAs nanowires was recently demonstrated by the observation of ballistic electron transport over length scales approaching one micrometer [2, 3]. In this work we additionally show quantized conductance measurements in a magnetic field and transport spectroscopy of Coulomb island devices for characterization of Landé g-factor and spin-orbit coupling strength.

8:24AM R33.00003: Strain-induced Gunn Effect in Silicon Nanowires

DARYOUSH SHIRI, Department of Microtechnology & Nanosciences, Chalmers University of Technology, Gothenburg, Sweden, AMIT VERMA, REZA NEKOYEV (Presenter), Department of Electrical Engineering & Computer Sciences, Texas A&M University-Kingsville, Kingsville, TX, USA, ANDREAS ISACSSON, Department of Physics, Chalmers University of Technology, Gothenburg, Sweden, SELVA SELVAKUMAR, Department of Electrical & Computer Engineering, University of Waterloo, Waterloo, ON, Canada, ANANT ANANTRAM, Department of Electrical Engineering, University of Washington, Seattle, WA, USA — Gunn (or Gunn-Hilsum) Effect and its associated negative differential resistivity (NDR) does not exist in bulk silicon. This effect which is due to transfer of electrons between two different energy subbands, is very pronounced in direct bandgap semiconductors like GaAs which makes them favorable for microwave Gunn-diode based oscillators.

In stark contrast to GaAs, bulk silicon has a very high energy spacing (~1 eV) which renders the initiation of transfer-induced NDR unobservable. However using Density Functional Theory (DFT), Tight Binding and Ensemble Monte Carlo (EMC) methods we show for the first time that: (1) Gunn Effect can be induced in silicon nanowires (SiNW) under 3% tensile strain and an electric field of 5000 V/cm,

(2) the onset of NDR in I-V characteristic is reversibly adjustable by strain, and (3) strain modulates the resistivity by a factor 2.3 for SiNWs of normal I-V characteristics i.e. those without NDR. Results of this study promise applications of SiNW-based Gunn diodes in microwave oscillators. The observed NDC is different in principle from Esaki-Diode and Resonant Tunneling Diodes (RTD) in which NDR originates from tunneling effect not electron transfer between subbands of different effective mass.

8:36AM R33.00004: The effect of ultrasmall grain sizes on the thermal conductivity of nanocrystalline silicon thin films

XIAO LIU (Presenter), United States Naval Research Laboratory, BATTOTOKH JUGDERSUREN, KeyW Corporation, BRIAN T KEARNEY, NRC Research Associate, JAMES CLIFFORD CULBERTSON, CHRISTOPH N CHERVIN, RHONDA MICHELE STROUD, United States Naval Research Laboratory — We report on the thermal conductivity of nanocrystalline silicon thin films with average grain sizes varying from 3 nm to 10 nm. The films were prepared by plasma-enhanced chemical-vapor deposition. The crystallinity and grain sizes of the films are controlled by hydrogen dilution during growth. Thermal conductivity was measured from 80 K to room temperature. The thermal conductivity of the film with 10 nm grain size roughly follows the minimum thermal conductivity predicted for amorphous silicon. As the grain size decreases to 3 nm, its thermal conductivity is reduced to one third of the minimum thermal conductivity. We extend the model of grain boundary scattering of phonons with Debye and Born-von Karman dispersion relations to explain our results. Although our results can still be explained by strong grain boundary scattering, we find the phonon mean-free-path would have to decrease at a faster rate than the reduction of grain size to explain the strong dependence of thermal conductivity on grain size.

8:48AM R33.00005: First-principles calculation of the dynamic heat current in semiconductors under the application of a thermal gradient

ÉAMONN MURRAY (Presenter), Department of Physics and Department of Materials, Imperial College London, IVANA SAVIC, Tyndall National Institute, Cork, Ireland, STEPHEN B FAHY, Department of Physics, University College Cork, Cork, Ireland — We present calculations of the time evolution of the thermal transport through a material following the application of a thermal gradient. This involves the calculation of the anharmonic force constants from first principles, which are used to find the scattering between phonon modes of different energies and wavelengths. We can then use this to find the dynamical heat current from the Boltzmann transport equation, going beyond the single mode relaxation time approximation and allowing us to see how the heat current evolves in time once the thermal gradient is applied or changes. We present results of this analysis as applied to several semiconductor systems.

9:00AM R33.00006: Ginzburg-Landau-Langevin theory and SSH model for Peierls transition in In/Si(111)

YASEMIN ERGUN (Presenter), Institut für Theoretische Physik, Leibniz Universität Hannover — Motivated by the thermal and photo-induced first-order Peierls transitions observed in atomic wires on semiconducting surfaces [1], we use the Ginzburg-Landau (GL) theory for charge-density-wave systems to investigate the dynamics of collective excitations in Peierls insulators. This formalism allows us to study the vibrations and the non-equilibrium dynamics of the amplitude modes (lattice distortion and density modulation) which are involved in a Peierls transition. We include no phase mode but amplitude modes for the commensurate Peierls system. The Langevin formalism is used to simulate finite temperature and thermalisation. The GL parameters are determined from the 1D Su-Schrieffer-Heeger (SSH) model in the grand canonical ensemble [2]. Next goals are the extension to coupled chains and the inclusion of non-adiabatic effects between electrons and phonons. Ultimately, we want to simulate the nonequilibrium dynamics of the SSH model for wires on substrates.

First-principles calculations of second order nonlinear optical coefficients in the static limit and Pockels coefficients in III-N and II-IV-N₂ compounds

SAI LYU (Presenter), WALTER R L LAMBRECHT, Case Western Reserve University — The second order nonlinear optical coefficients in the static limit are evaluated using density functional perturbation theory from the electronic response to a static electric field for the group III nitrides and several II-IV-N₂ ternary nitrides. They are compared with literature results using the sum over states approach including local field effects. The effects of the scissor correction are evaluated. Good agreement is obtained for GaN, AlN and w-BN. For InN, the small or even negative gap in in the LDA at Γ causes an extreme sensitivity to the k-point summation and pseudopotentials. Similar problems occur for other very small gap II-IV-N₂ semiconductors. The nonlinear optics coefficients are showing a general trend of increasing values with smaller gaps but no clear scaling relation with the direct gaps is obtained. The Pockels coefficient, which include in addition to the electronic response, also the phonon and piezoelectric response and are also evaluated. They show that the phonon and electronic contributions to the response in these materials are comparable in magnitude.

Crystal free energy of SiC polytypes and stacking faults formation energy from DFT-based lattice-dynamics approach.

EMILIO SCALISE (Presenter), ANNA MARZEGALLI, FRANCESCO MONTALENTI, LEONIDA MIGLIO, Materials Science, University of Milano Bicocca — Despite a rising impact of SiC technology in the power electronics industry, some fundamental aspects of this material lack physical understanding. Particularly polytypism and growth of SiC polytypes have been discussed as a paradox from about thirty years because of an evident discrepancy between theory and experiments, not yet elucidated. SiC has more than 200 polytypes and few of them (i.e. 3C, 6H, 4H) are commercially available and used for power devices. Besides the scientific interest, investigating SiC polytypism and understanding its driving force is crucial to correctly predict the energetics of extended defects in SiC, which are one of the main concerns of this wide band gap semiconductor. We perform first-principle calculations, including long range interactions and based on a lattice dynamics approach, we predict the temperature dependent thermodynamic stability of different SiC polytypes which may explain their growth at different temperature. Finally, we estimate the formation energy of stacking faults in SiC and the effect of Van Der Waals corrections are proved to be key for reproducing experimental observations.

High-mobility InAs two dimensional electron systems on GaSb substrates

ANTHONY HATKE (Presenter), Station Q Purdue and Department of Physics and Astronomy, Purdue University, CANDICE THOMAS, AYMERIC TUAZ, RAY KALLAHER, Birck Nanotechnology Center, Purdue University, TIALUNG WU, Station Q Purdue and Department of Physics and Astronomy, Purdue University, TIAN WANG, ROSA DIAZ, GEOFFREY C. GARDNER, MIKE CAPANO, Birck Nanotechnology Center, Purdue University, MICHAEL MANFRA, Station Q Purdue and Department of Physics and Astronomy, Purdue University — The two dimensional electron gas in InAs quantum wells grown on nearly lattice-matched GaSb substrates is an attractive stage for mesoscopic device physics. However, use of this system has remained difficult due to outstanding challenges. Here we report on heterostructure design optimization and device fabrication that satisfies three main criteria for mesoscopic device operation: electrical isolation from the semiconducting substrate, ability to fully deplete the charge carriers and control residual sidewall conduction with lithographic gates, and high mobility to ensure ballistic transport over mesoscopic length scales [1]. In addition, we discuss our current progress in realization of mesoscopic devices including quantum point contacts and quantum dots.

9:48AM R33.00010: High thermal conductivity in cubic boron arsenide crystals  SHENG LI (Presenter), Department of physics, University of Texas at Dallas, QIYE ZHENG, Department of Materials Science and Engineering and Materials Research Laboratory, University of Illinois at Urbana-Champaign, YINCHUAN LV, Department of Physics, University of Illinois at Urbana-Champaign, XIAOYUAN LIU, Department of physics, University of Texas at Dallas, XIQU WANG, Department of Chemistry, University of Houston, PINSHANE HUANG, DAVID G CAHILL, Department of Materials Science and Engineering and Materials Research Laboratory, University of Illinois at Urbana-Champaign, BING LV, Department of physics, University of Texas at Dallas — We report our experimental efforts on the high thermal conductivity above 1000 W/m/K in the zinc blende cubic BAs crystals. First principle calculations have predicted the thermal conductivity of BAs, is second only to that of diamond at room temperature, which may constitute a useful thermal management material for high-power density electronic devices. Herein, we reported our experimental efforts to grow single domain, defect-free, and large size BAs crystals, evidenced by both single crystal diffraction and scanning transmission electron microscopy (STEM) studies, through test and optimization various single-crystal growth methods. Furthermore, the time-domain thermoreflectance (TDTR) measurement of the BAs crystal gives a high thermal conductivity ~1000 W/m K which is consistent with the predicated value based on four phonon calculations, representing BAs as a new class of ultrahigh thermal conductivity materials.

10:00AM R33.00011: Interplay between molecular packing and charge transfer states in 6,13-bis(trisopropylsilylthynyl)-pentacene (TIPS-pentacene) organic semiconductor thin films*  YANG LI (Presenter), JING WAN, University of Vermont, DETLEF-M SMILGIES, Cornell University, JOHN M. HUGHES, RANDALL HEADRICK, University of Vermont — The optical properties of organic semiconductors are influenced by interference between neutral molecular excitations and charge transfer excitations. We present a comprehensive study of this effect for TIPS-pentacene in the temperature range from 25°C to 140°C via the influence of molecular packing on the optical and electronic properties, utilizing in-situ x-ray diffraction, polarized optical spectroscopy and density functional theory. In TIPS-pentacene, anisotropic thermal expansion causes neighboring molecules to “slide” relative to each other. Since charge transfer effects depend sensitively on the nodal structure of the highest occupied and lowest unoccupied molecular orbitals, optical excitations are modulated as the relative displacement is varied. We find that the transition energies of the lowest energy optical excitations are dramatically blue shifted as the temperature is increased, and that changes in the charge transfer integrals can be correlated with an enhancement of field-effect transistor mobility. These results suggest a new approach to improve carrier mobility in strained thin films by decreasing the sensitivity of the charge transfer integrals to dynamic disorder.

10:12AM R33.00012: Overcoming bismuth saturation in GaAsBi by manipulating film strain  MARGARET STEVENS (Presenter), KEVIN GROSSKLAUS, JOHN MCELEARNEY, THOMAS VANDERVELDE, Tufts University — Epitaxially grown III-V-Bismides offer new band gap and lattice constant combinations for near- and mid-IR device applications on GaAs and InP substrates. High bismuth content GaAsBi is typically grown compressively strained on GaAs, though droplet-free thick films have been difficult to realize in that system. Surface Ga-Bi droplets inhibit bismuth incorporation and cause vertical phase separation, yielding films unusable for optoelectronic applications. To produce bismide films that are suitable for IR optoelectronics, we explored the growth of increasingly Bi-rich GaAsBi compounds under a variety of strain conditions ranging from highly compressively strained on GaAs to tensile strained on InGaAs buffer layers. High resolution x-ray diffraction and Rutherford backscatter spectrometry showed higher Bi content can be achieved without droplet formation by reducing film compressive strain. Atomic force microscopy and phase contrast microscopy showed reduced surface droplet density, indicating bismuth is being incorporated in the film rather than surface segregating. Overall, we show that reducing the compressive strain in GaAsBi films is a successful method for reducing droplet formation and enabling increased Bi incorporation.
ALBERT CHANG (Presenter), Duke University, PHILLIP M. WU, IOP, Academia Sinica, Taiwan (ROC) and GUS Technology, Taiwan/San Mateo CA, USA, HAO ZHANG, Tsinghua University, Beijing, China — We present evidence that quantum point contacts (QPCs) fabricated on a high mobility (~$10^6 \text{ cm}^2/\text{Vs}$) GaAs/AlGaAs heterstructure crystal with doping close to the 2D interface exhibit quantum transport conductance which is strongly dependent on the QPC geometry. In particularly, asymmetrically shaped, T-junction QPCs nearly always exhibit strong conductance resonances as well as anomalies in the conductance plateaus, whereas symmetrically shaped QPCs, designed with smooth entrance and exit regions joining to wide 2D regions, are largely devoid of such resonances. The dramatic difference in the conductance traces between the two types of geometries suggest that disorder does NOT play a dominant role in the transport characteristics. Furthermore, this implies that unusual features, including resonances, suppression of quantum plateaus[1,2], and novel differential conductance oscillations [3] previously reported in asymmetric QPCs could arise instead from intrinsic mechanisms, e.g. geometry and/or interaction effects.

*Funding: NSFDMR-0701948 and IOP, Academia Sinica, Taipei.

RASTHEL PRENTKI (Presenter), Physics, McGill University, FEI LIU, Institute of Microelectronics, Peking University, JIAN WANG, Physics, The University of Hong Kong, HONG GUO, Physics, McGill University — Power dissipations are to blame for part of the recent deceleration in the exponential growth rate of the transistor count on integrated circuits predicted by Moore's law. A relevant metric at the device level is the subthreshold swing (S) - the increment in gate voltage required for a tenfold increase in drain current - which is commensurate with energy losses during switching. For the ubiquitous Si Metal-Oxide-Semiconductor Field-Effect Transistor (MOSFET), thermodynamics and electrostatics impose that $S \geq 60 \text{ mV/dec}$ at room temperature. Phenomena beyond MOSFET physics thus need to be exploited to design a low S device; we show how ballistic transport can be used towards this end. In the resulting device, known as the cold source FET, thermionic emission is suppressed in the OFF-state by means of density-of-states engineering, thereby enabling low S while maintaining a high ON-state current. Deviations from the approximation of ballistic transport need to be considered for real-world implementations; we show how rethermalization due to inelastic scattering affects S.

*Supported by Fonds de recherche du Québec - Nature et technologies (FRQNT) and the Area of Excellence grant under project number AoE/P-04/08-1 from the Research Grant Council of Hong Kong.

HUIXIA FU (Presenter), Weizmann Institute of Science — Recently an air-stable layered semiconductor Bi$_2$O$_2$Se was discovered to exhibit an ultrahigh mobility in transistors fabricated with its thin layers. In this work, we explored the mechanism that induces the high mobility and distinguishes Bi$_2$O$_2$Se from other semiconductors. We found that the electron donor states lie above the lowest conduction band. Thus, electrons get spontaneously ionized from donor sites (e.g., Se vacancies) without involving the thermal activation, different from the donor ionization in conventional semiconductors. Consequently, the resistance decreases as reducing the temperature as observed in our measurement, which is similar to a metal but contrasts to a usual semiconductor. Furthermore, the electron conduction channels locate spatially away from ionized donor defects (Se vacancies) in different van der Waals layers. Such a spatial separation can strongly suppress the scattering caused by donor sites and subsequently increase the electron mobility, especially at the low temperature. We call this high-mobility mechanism self-modulation doping, i.e. the modulation doping spontaneously happening in a single-phase material without requiring a heterojunction. Our work paves a way to design novel high-mobility semiconductors with layered materials.

Session R34 FIAP FED: Live Long and Prosper as Physicist, Innovator, and Entrepreneur
BCEC 205A - Chuhee Kwon, Cal State Univ- Long Beach - Tag(s): Careers, Education, Industry, Invited, Undergraduate
Physicists as Master Innovators: Why Innovation and Entrepreneurship should be highlighted in physics education* [Invited] DOUGLAS ARION (Presenter), Carthage College — Physicists are positioned to be some of the most effective innovators - solving real-world problems by applying their broad knowledge and understanding of how the world works, and contributing to all sorts of organizations through an entrepreneurial mindset. How can we make that happen more often, and how can we leverage this to attract a larger and more diverse body of students into the field? Innovation and entrepreneurship education components - whether implemented in curriculum directly, co-curricular programs, or experiential learning opportunities - can be utilized to achieve these goals. Let's consider why we should take this on as an important part of physics education - as important as the canon of content we've always delivered.

*This work supported in part by NSF Grant number 1624822.

Live Long and Prosper as Physicist, Innovator, and Entrepreneur* [Invited] CRYSTAL BAILEY (Presenter), American Physical Society — Physics graduates are among the most employable in the world, with 96% of graduates finding successful employment, mostly in private sector settings. While employers value the technical skills and ability to engage in continued learning that are hallmarks of physics graduates, physics majors also have the potential to become impactful, positive agents of change in the world as effective innovators and entrepreneurs. In this talk, I will explore the skills, knowledge and mindset that are essential to entrepreneurship, and describe national efforts that are taking place to make innovation and entrepreneurship education a regular part of physics students' experience.

*Support for this work is provided by the National Science Foundation's IUSE program under Award No. 1624882 ("The PIPELINE Network").

Understanding the Value of Intellectual Property in Entrepreneurship: Finding Your Path Down the Yellow Brick Road [Invited] CYNTHIA PILLOTE (Presenter), Snell & Wilmer — You're done the hard work and you've got a brilliant idea for an invention. Now what? We'll discuss considerations for faculty and students when developing intellectual property (IP), including university policies and procedures, grant provisions, and getting the most value for your IP.

Making the Shift from Research to Revenue: Skills that Physicists Need to be Successful in Business [Invited] SAM WURZEL (Presenter), None — Physicists bring with them many useful skills for starting businesses: the ability to develop innovative ideas, a comfort with technology and mathematics, and the grit required to solve hard problems. However there are key skills that physicists often lack: sales, marketing, accounting, law, and interpersonal skills key to business. Luckily these skills are learnable. In my talk I will discuss my long path to learning them when I left physics to start Octopart and how this process can be accelerated for physicists starting businesses today.

Academia to Entrepreneurship- A Multi-pronged Journey [Invited] THIRUMALAI VENKATESAN (Presenter), National University of Singapore — There has been a sea change over the last few decades in the way academic institutions view entrepreneurial activities of the faculty and the role of the Institution in fostering an ecosystem conducive to such activities. This has become a global phenomenon and many of the leading Institutions in Europe and Asia are also beginning to replicate the model of the Boston or Silicon Valley academic Institutions. This clearly presents a wonderful opportunity for those who want to strike out on their own as opposed to waiting for someone else to offer them a job. This is the transition from a job seeker to a job creator. This is a multi-pronged journey with differing levels of risks and rewards. In my talk I will discuss a variety of models that are available to the academic entrepreneur, their pluses and minuses and also some of the critical knowledge one needs to understand about the world of entrepreneurship in general. I will use examples from several of my colleagues' startups and my own experience in running a company for over three decades maintaining an academic life.

Thursday, March 7, 2019 8:00 AM - 11:00 AM

Session R35 DQI: Read-out and Measurement of Superconducting Qubits BCEC 205B - Zlatko Minev, Yale Univ - Tag(s): Focus
Reducing measurement errors is critical for performing any quantum algorithm, especially those requiring feedback. In certain situations, e.g. in quantum experiments that only require averaged measurements, errors can be corrected using post-processing techniques. These experiments include any that only require operator expectation value measurements, such as tomography or variational quantum eigensolvers. Here we will present one such method, which involves calibrating these errors via measurements of prepared computational states which are used to feed a neural network. In this way we reduce the experimental overhead from exponential to polynomial scaling. We will present experimental demonstrations of this technique on IBM Q devices.

*This work was supported by the Army Research Office under contract W911NF-14-1-0124

Fault-tolerant quantum computing requires repetitive high-fidelity quantum parity measurements. In quantum processors based on circuit QED, the fidelity of indirect quantum parity measurements using an ancillary qubit is compromised by errors induced in the coherent interaction step and in the ancilla measurement. Here, we improve upon the state of the art by combining two techniques to reduce ancilla measurement time and measurement-induced cross-dephasing of data qubits: dedicated Purcell filtering for each qubit and active photon depletion. We find the parity measurement speed limit by minimizing the parity measurement error rate as a function of the cycle time. We individually quantify the error contributions of one- and two-qubit gates, residual interactions, cross-talk, parasitic measurement-induced dephasing, and quantum demolition.

*This research is funded by IARPA (U.S. Army Research Office Grant W911NF-16-1-0071). Additional funding is provided by Intel Corporation (N.M.).

High-fidelity readout of the state of a qubit is an indispensable part of a quantum computer. Progress in implementation of controllable large-scale quantum computers calls for implementation of a scalable high fidelity multi-qubit readout scheme. In a typical transmon superconducting qubit, measurement is implemented by applying a microwave drive to a readout resonator dispersively coupled to the qubit. Recent experiments demonstrated that despite detuning between the drive and qubit frequencies, measurement renormalizes the spectrum of the combined qubit-resonator system and induces cross-talk between nearby qubits resulting in reduced fidelity. A starting point is to develop an optimized readout scheme for a two-qubit system. With both numerical and approximate analytical analysis, we were able to identify the source of spurious transitions and explore qubit parameters optimal for scalable multi-qubit readout scheme.

*USRA Feynman Quantum Academy Program and NASA Academic Mission Service contract number NNA16BD14C.
High-fidelity, quantum non-demolition qubit measurement is a vital prerequisite for robust, large-scale quantum machines. In superconducting quantum circuits, the typical information carriers for qubit readout are coherent states of light, which must be amplified before they can be efficiently recorded in room-temperature electronics. Typically, these amplifiers consist of one, or two, microwave modes linked by a parametrically driven coupling. Such amplifiers regularly approach the quantum limit for amplification, allowing us to closely track qubits’ states. However, conventional parametric amplifiers lack almost every other desirable property, including high saturation power, large bandwidth, and directional operation. I’ll discuss our recent efforts to address these shortcomings by suppressing unwanted terms in the device’s Hamiltonian and combining multiple, simultaneous parametric drives between a pair of microwave modes. In a single device by varying the parametric drives, we can produce desired behaviors including transmission-only phase-sensitive amplification, input match, and gain-independent bandwidth. We have used observation of quantum jumps and weak measurements of superconducting qubits to benchmark the device’s performance. I will discuss the prospects for adding the final desired property, directionality, via further parametric couplings to a third microwave mode. Another route to higher measurement fidelity is to replace coherent states with squeezed light as the information carrier. I will present data from a recent experiment which uses an interferometric scheme for qubit readout with two-mode squeezed light, achieving a voltage signal-to-noise ratio improvement of ~25 % versus coherent state readout. I will also discuss the prospects for using two-mode squeezed light to remotely entangle distant qubits.

*This work is partially supported by the ARO, NSF, and the Kaufman Foundation.

In this work, we present a filter design allowing multiplexed qubit readout with Purcell protection. The design is composed of four quarter-wave stubs, providing a bandstop filter whose bandwidth is up to 1~GHz at the qubit frequency. Using a three-port scattering matrix formalism, we show that the qubit emission into the readout line is suppressed by more than 75~dB, while the readout line transmission is reduced by less than 3~dB. We then show that in situ tunability of the filter can be obtained by terminating the stubs with RF-Squids. Our results pave the way to large-scale qubit readout with high fidelity and flexibility.

We experimentally test this measurement protocol using a superconducting qubit coupled to a resonator mode. Compared to the conventional dispersive readout, we observe that our protocol yields higher fidelity for a given integration time. Finally, we use an additional resonator drive to leave the resonator state in vacuum if qubit is in the excited state before the measurement protocol. This suggests that the proposed technique may become useful in unconditionally resetting the resonator to a vacuum state after the measurement pulse.

9:36AM R35.00007: Fast Measurement of a Tunable Superconducting Flux Qubit via a Driven Nonlinear Resonator with Applications in Quantum Annealing* DANIEL TENNANT (Presenter), DENIS MELANSON, ANTONIO MARTINEZ, Institute for Quantum Computing, Department of Physics and Astronomy, and Waterloo Institute for Nanotechnology, University of Waterloo, MUHAMMET ALI YURTALAN, Institute for Quantum Computing, Department of Electrical and Computer Engineering, and Waterloo Institute for Nanotechnology, University of Waterloo, YONGCHAO TANG, Institute for Quantum Computing, Department of Physics and Astronomy, and Waterloo Institute for Nanotechnology, University of Waterloo, DAVID K KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, JONILYN L YODER, STEVEN WEBER, Lincoln Laboratory, Massachusetts Institute of Technology, ADRIAN LUPASCU, Institute for Quantum Computing, Department of Physics and Astronomy, and Waterloo Institute for Nanotechnology, University of Waterloo — Development of readout schemes of flux qubits in the persistent current basis is important for quantum annealing applications. High fidelity detection, controlled backaction on the qubit, as well as rapid acquisition, are all relevant for flexible quantum annealing. In order to accommodate these requirements, we develop a readout based on the use of metastable oscillation states in a nonlinear oscillator detection circuit specifically tailored for capacitively shunted flux qubits. In this work, we discuss the design as well as preliminary results for a device specifically designed for tunable capacitively shunted flux qubits specifically designed for use in quantum annealers.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) and the Army Research Office (ARO) under Contract No. W911NF-17-C-0050. 9:48AM R35.00008: Realizing a Catch-Disperse-Release read-out of a qubit* PERONNIN THEAU (Presenter), Univ Lyon, ENS de Lyon, Univ Claude Bernard Lyon 1, CNRS, Laboratoire de Physique, F-69342 Lyon, Franc, DANIJELA MARKOVIC, Laboratoire Pierre Aigrain, Ecole Normale Supérieure, PSL Research University, CNRS, Université Pierre et Marie Curie, Sorbonne Universités, Université Paris Diderot, Sorbonne Pa, QUENTIN FICHEUX, Univ Lyon, ENS de Lyon, Univ Claude Bernard Lyon 1, CNRS, Laboratoire de Physique, F-69342 Lyon, Franc, ZAKI LEGHTAS, Centre Automatique et Systèmes, Mines-ParisTech, PSL Research University, 75006 Paris, France, BENJAMIN HUARD, Univ Lyon, ENS de Lyon, Univ Claude Bernard Lyon 1, CNRS, Laboratoire de Physique, F-69342 Lyon, Franc — Fast read-out is an essential piece of measurement based error correction codes. The usual technique of driving a dispersively coupled resonator presents some limitations such as finite reset time. To overcome these limits Sete and al. [1] proposed a catch, disperse and release scheme that we recently realized.

It uses a resonator with a tunable coupling to the transmission line. That resonator is coupled to the qubit in the dispersive coupling limit. First, we do brief unconditional coherent displacement of the resonator. Then the phase of the stored coherent state grows linearly in time at a rate depending on the state of the qubit. Finally, we release the resonator's state into the transmission line and measure the phase of the outgoing signal.

Our experiment implements that scheme by using a Josephson Parametric Converter as a tunable coupler between a low and a high Q factor resonator [2] to measure a transmon qubit in CPW geometry.

We demonstrate a state-of-the-art read-out with a fidelity of 97.5% in a total of 240 ns. The fidelity is limited by the qubit lifetime. We demonstrate the quantum non-demolition, reset, and Purcell protection granted by this scheme.

10:00AM R35.00009: ABSTRACT WITHDRAWN
10:12AM R35.00010: Tracking non-Markovian quantum dynamics of a superconducting qubit with a recurrent neural network filter*

NOAH STEVENSON (Presenter), BRADLEY MITCHELL, Univ of California - Berkeley, SHIVA BARZILI, RAZIEH MOHSENINIA, JUSTIN G. DRESEL, Chapman Univ, IRFAN SIDDIQI, Univ of California - Berkeley — Determining the time-dependent Hamiltonian for control pulses of superconducting quantum circuits is critical for their use in reliable quantum information processing; however, interactions between coupled qubits and nearby resonators can cause transient dynamics to become non-Markovian. We use quantum state tracking with continuous weak measurement to experimentally investigate non-Markovianity in a transmon superconducting qubit coupled to a readout resonator. By weakly measuring the state of the transmon qubit undergoing tunable Rabi oscillations comparable to the cavity linewidth, we isolate dynamics that are difficult to describe with single-qubit trajectory theory. We address this difficulty by training a recurrent neural network to reconstruct the quantum trajectories, motivated by such a network's demonstrated ability to learn long-time correlations in sequential data. Here we detail the experimental protocol and present preliminary data.

*This work was supported by the Army Research Office.

10:24AM R35.00011: Quantum non-demolition detection of single itinerant microwave photons*

JOHN MARK KREIKEBAUM (Presenter), Univ of California – Berkeley, KEVIN P O'BRIEN, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, BAPTISTE ROYER, Université de Sherbrooke, ARNE GRIMSMO, The University of Sydney, ALEXANDRE BLAIS, Université de Sherbrooke, IRFAN SIDDIQI, Univ of California – Berkeley — The detection of microwave photons is an important capability for superconducting quantum information processing and microwave quantum optics but remains challenging due to the small energy of photons at this frequency. Our circuit quantum electrodynamics (cQED) based detector [1] exploits the superradiant ‘bright’ and subradiant ‘dark’ states that are formed when transmons are coupled an appropriate distance from each other on a waveguide [2]. Detuning each transmon inhomogeneously from the operating frequency leads to coupling of the bright and dark states which allows for absorbed photons to be trapped for longer than the inverse of the absorption bandwidth. We utilize this long interaction time to achieve high-fidelity measurements of the photon number in the ensemble. Using a single photon source, we benchmark the performance of this protocol.

10:36AM R35.00012: Pulsed reset protocol for fixed-frequency superconducting qubits

DANIEL EGGER (Presenter), MAX WERNINGHAUS, MARC GANZHORN, GIAN SALIS, ANDREAS FUHRER, PETER MUELLER, STEFAN FILIPP, IBM Research - Zurich — Improving coherence times of quantum bits is a fundamental challenge in the field of quantum computing. With long-lived qubits it becomes, however, inefficient to wait until the qubits have relaxed to their ground state after completion of an experiment. Moreover, for error-correction schemes it is important to rapidly re-initialize syndrome qubits. We present a simple pulsed qubit reset protocol based on a two-pulse sequence. A first pulse transfers the excited state population to a higher excited qubit state and a second pulse into a lossy environment provided by a low-Q transmission line resonator, which is also used for qubit readout. We show that the remaining excited state population can be suppressed to 1.7 ± 0.1% and that this figure may be reduced by further improving the pulse calibration. We also show that the reset protocol can be used for cooling by removing the thermal qubit population.

10:48AM R35.00013: Diagnostic Single-Qubit Gate Monitoring with Continuous Measurements*

JOHN STEINMETZ (Presenter), ANDREW N JORDAN, University of Rochester — The physical implementation of a quantum gate generally deviates from the desired qubit operation. In order to improve the gate fidelity, we use continuous weak measurements to track the quantum map as it develops in time, so as to identify the origin of any deviations from the desired evolution. This gives insight into how to modify the qubit design as well as the controls applied. We test this diagnostic method on single qubit gates with both correlated and uncorrelated noise.

*US Army Research Office
IT-TaS$_2$ has been studied for a long time as a charge density wave system. The new unit cell consists of 13 site "star of David" clusters forming a triangular lattice. It was proposed 40 years ago that these cluster give rise to a Mott insulator state with $S=1/2$ per cluster. However, the expected local moments have never been observed and no magnetic ordering has been found. We proposed [1] that this material may be an example of the quantum spin liquid that has somehow gone unnoticed for 45 years. Recent experiments have provided strong evidence that this is indeed the case, and that the low energy excitations are characterized by a spinon Fermi surface. We propose that the mechanism has to do with the proximity to the Mott transition, which can be modelled by a spin model with NN exchange $J$ and a 4 site ring exchange term $K$. We performed DMRG calculations on this model [2], extending earlier work to 6 and 8 wide cylinders and found that a modest $K/J$ ratio is sufficient to stabilize a spin liquid ground state with Fermi surface. A strong signature is that the peaks in the spin-spin correlator lie on a circle with radius $2k_F$. We have also performed doping studies on the spin liquid and found that the leading pair correlation is oscillatory in space, ie, a pair density wave. [3] It will be very interesting to dope this and related systems very gently (less than 1% carrier per Ta) by gating to minimize localization of the doped carriers.

Evidence for a quantum spin liquid in single-layer 1T-TaSe$_2$

Quantum spin liquids are a novel state of matter predicted to arise in quantum antiferromagnets where magnetic frustration or quantum fluctuations are strong enough to prevent magnetically ordered states even down to the lowest temperatures. Quantum spin liquids are believed to exist in strongly correlated Mott insulators, and are thus related to unconventional superconductivity. Much work on quantum spin liquids has focused on triangular and kagome lattices where frustration is strong. An example is the bulk Mott insulator 1T-TaS$_2$ which has attracted attention as a quantum spin liquid candidate due to localized $d$-orbitals in the Ta atoms that form a triangular lattice in this material. This scenario, however, is complicated by interlayer coupling and possible different stacking orders in the bulk, thus motivating investigation into related single-layer materials.

I will discuss recent studies that we have performed on single-layer 1T-TaSe$_2$ that provide evidence for 2D spin liquid behavior. We have characterized the electronic structure of single-layer 1T-TaSe$_2$ (grown via molecular beam epitaxy) by means of scanning tunneling microscopy/spectroscopy (STM/STS), angle-resolved photoemission spectroscopy (ARPES), and first-principles calculations. We observe Mott insulating behavior in single-layer 1T-TaSe$_2$, including novel orbital texture not seen in bulk samples. Vertical heterostructures formed by a single 1T-TaSe$_2$ layer placed on top of metallic 1H-TaSe$_2$ exhibit Kondo behavior, providing direct evidence for a triangular array of local magnetic moments in single-layer 1T-TaSe$_2$. Evidence for a spin-liquid-based spinon Fermi surface is observed in both STM and ARPES measurements of single-layer 1T-TaSe$_2$. These results will be discussed in the context of recent theoretical predictions.
Half-integer thermal quantum Hall effect in a Kitaev spin liquid: A signature of Majorana edge modes and non-Abelian excitations

Yuichi Kasahara (Presenter), Department of Physics, Kyoto University — Kitaev quantum spin liquid (QSL) displays the fractionalization of quantum spins into Majorana fermions. In magnetic fields, the emergence of Majorana edge current is predicted to manifest itself in the form of thermal quantum Hall effect. Here we report on thermal Hall conductivity $\kappa_{xy}$ measurements in $\alpha$-RuCl$_3$, a candidate material for Kitaev QSL on two-dimensional (2D) honeycomb lattice. In magnetic field perpendicular to the 2D honeycomb planes, positive $\kappa_{xy}$ develops in a spin-liquid state below the temperature characterized by the Kitaev interaction $J_K/k_B \sim 80$ K, demonstrating the presence of highly unusual itinerant excitations. Although the zero-temperature property is masked by the magnetic ordering at $T_N = 7$ K, the sign, magnitude, and $T$-dependence of $\kappa_{xy}$ at $T_N < T < J_K/k_B$ follows the predicted trend of the itinerant Majorana fermion excitations. The application of a tilted magnetic field suppresses the AFM order, leading to a field-induced QSL ground state. In this QSL state, the 2D thermal Hall conductance per honeycomb plane $\kappa_{xy}^{2D}/T$ shows a plateau behavior as a function of applied magnetic field and has a quantization value of $\pi^2 k_B^2/6h$, which is exactly half of $\kappa_{xy}^{2D}/T$ in the integer quantum Hall state and fractional quantum Hall state that hosts Abelian anyons. This half-integer thermal Hall conductance provides direct evidence of a non-Abelian phase and topologically protected chiral edge modes of charge neutral Majorana fermions (particles that are their own antiparticles), which have half degrees of freedom of conventional fermions. Above a critical field, the quantization disappears and $\kappa_{xy}^{2D}/T$ goes to zero rapidly, indicating a topological phase transition.

Numerical Studies of Quantum Spin Liquids in Kitaev and Heisenberg Models

Donna Sheng (Presenter), California State University, Northridge — Rapid advancement in large-scale numerical simulations for strongly correlated systems has led to great progress in identifying and characterizing emerging new states of matter in realistic many-body systems in past a few years. I will report some of exciting advances including the identification of magnetic fields driven quantum spin liquids in the honeycomb Kitaev model and spin liquids in frustrated kagome and triangular lattice Heisenberg models. Based on the state of the art density matrix renormalization group simulations, we show that the non-Abelian chiral spin liquid emerges for the Kitaev model with antiferromagnetic Kitaev interactions, and remains robust up to a critical magnetic field that is an order of magnitude larger than the corresponding critical field for a ferromagnetic Kitaev model signaling the importance of frustration in such systems. Interestingly, an intermediate gapless spin liquid phase emerges with the increase of the magnetic field, which may be relevant to the experimental system RuCl$_3$ under magnetic fields. For spin Heisenberg lattice models, besides previous discovered robust chiral spin liquid and time-reversal invariant spin liquid, we also establish a new chiral gapless spin liquid on triangular lattice $|1\text{-}j_2\text{-}j_3|$ model. Furthermore, we explore the nature of different quantum spin liquids for kagome systems in the presence of DM interactions based on the dynamic structure factor simulation, which demonstrates consistency with observations in inelastic neutron scattering measurements of herbertsmithite.

8:00AM R37.00001: Refined spin Hamiltonian for Yb2Ti2O7 and its two competing low field states* [invited] ALLEN SCHEIE (Presenter), JONAS KINDERVATER, Johns Hopkins University, GABRIELE SALA, GEORG EHLERS, Oak Ridge National Lab, SEYED KOOHPAYEH, COLLIN BROHOLM, Johns Hopkins University — We present a neutron scattering study of pyrochlore Yb2Ti2O7 in a [111] magnetic field using high-quality stoichiometric single crystals. High magnetic fields (1.5 T) reveal sharp spin wave modes, which we use to further refine the magnetic Hamiltonian, offering corrections to previous Hamiltonian refinements. Low magnetic fields reveal diffuse features which suggest an unconventional ground state, and we discuss mechanisms explaining how such a spectrum can be caused by proximity to a ferromagnetic-antiferromagnetic phase boundary. We present a model which accounts for the observed spectrum, and resolves several long-standing questions concerning the ground state of Yb2Ti2O7 [1].

8:36AM R37.00002: Semiclassical simulation of quantum spin ice: seeing beyond the light* CLAUDIO CASTELNOVO (Presenter), ATTILA SZABÓ, University of Cambridge — We devise a semiclassical numerical method to investigate quantum spin ice, based on classical Monte Carlo and dynamical simulations of the effective ring exchange Hamiltonian in the large-$S$ limit. At low temperatures, this approach is asymptotically equivalent to a path integral field theory, and indeed we find excellent agreement with known results from the latter regarding the dispersion of the photonic modes of the system. We further argue that our method samples the finite-temperature path integral formulation of the quantum spin ice problem accurately, and thus allows us to go beyond the results attainable using the field theoretic description, and study also the isolated as well as collective behaviour of vison excitations.

*This work was supported in part by Engineering and Physical Sciences Research Council (EPSRC) Grants No. EP/P034616/1 and No. EP/M007065/1

8:48AM R37.00003: Vison and photon electrodynamics in quantum spin ice* ATTILA SZABÓ (Presenter), CLAUDIO CASTELNOVO, University of Cambridge — We investigate quantum spin ice on the pyrochlore lattice using semiclassical Monte Carlo and dynamical simulations of the effective ring exchange Hamiltonian. The model exhibits normal modes equivalent to photons as well as gapped vortices of the emergent magnetic field analogous to visons. Contrary to the behaviour of spinons in classical spin ice, we find that visons form a weak electrolyte; that is, their strong interaction makes the energy cost of a bound pair lower than that of an isolated vison. This leads to a qualitatively different temperature dependence of the pinch points in the corresponding emergent magnetic field. Finally, we observe that the thermal bath of photons dresses the visons and drastically reduces their energy. This suggests that visons may hybridise with the photon spectrum in quantum spin ice, which has potential implications on detecting them experimentally.

*This work was supported in part by Engineering and Physical Sciences Research Council (EPSRC) Grants No. EP/P034616/1 and No. EP/M007065/1.

9:00AM R37.00004: Probing the magnetic excitations in the quantum magnet Yb2Ti2O7 XINSHU ZHANG (Presenter), Johns Hopkins University, STEFFEN SÄUBERT, Technische Universität München, SEYED KOOHPAYEH, PETER ARMITAGE, Johns Hopkins University — The pyrochlore magnet Yb2Ti2O7 has shown exotic magnetic properties and has been considered to be a quantum spin ice although there is still considerable uncertainty about its Hamiltonian parameters. We study the evolution of its magnetic excitations as function of magnetic field and temperature using time-domain terahertz spectroscopy. We perform a thorough sum rule analysis of the low energy excitations by combining time domain terahertz spectroscopy and magnetization measurements. The distribution of spectral intensity indicates strong quantum fluctuations and short range spin correlations in Yb2Ti2O7 at low magnetic field. It also shows the very different manifestation of thermal fluctuations vs. quantum fluctuations in this compound.
9:12AM R37.00005: Capacitive Torque Magnetometry: Study of field-induced magnetic transitions and transient states in the Spin-Ice Material Ho$_2$Ti$_2$O$_7$* KEVIN BARRY (Presenter), Physics, Florida State University; NHMFL, Tallahassee, FL, United States, NAWEEN ANAND, NHMFL, Tallahassee, FL, United States, JENNIFER NEU, Physics, Florida State University; NHMFL, Tallahassee, FL, United States, HAIDONG ZHOU, Physics, University of Tennessee, Knoxville, TN, United States, DAVID E GRAF, NHMFL, Tallahassee, FL, United States, THEO SIEGRIST, CHRISTIANNE BEEKMAN, Physics, Florida State University; NHMFL, Tallahassee, FL, United States — We used capacitive torque magnetometry to compile phase diagrams that show the field-induced magnetic transitions between specific spin textures of the spin ice state. High quality single crystals have been measured at 500 mK in applied fields up to 11 T applied along various crystallographic directions. Utilizing reported results from neutron scattering as our starting point we have developed a phenomenological model that fully characterizes the anisotropic magnetic phase diagram of the system. This model clearly shows the evolution of the spin textures between the previously identified $Q = 0$, $Q = X$, and 3-in/1-out states, and it shows the existence of transient states between them. These transient states are characterized by spin flip excitations taking the spin ice away from the well-defined spin textures. Activation energies associated with these excitations have been extracted. This study demonstrates the applicability of torque magnetometry in probing specific spin textures hosted by the spin ice state.

9:24AM R37.00006: Investigations of scaling and dynamics in the kagome ice phase of Ho$_2$Ti$_2$O$_7$* ALEXANDRA TURRINI (Presenter), Paul Scherrer Institute, SEAN GIBLIN, EDWARD RIORDAN, School of Physics and Astronomy, Cardiff University, PETER C. W. HOLDSWORTH, Laboratoire de Physique, Ecole Normale Superieure de Lyon, PATRIK HENELIUS, Kondenserade Materiens Teori, Royal Institute of Technology Stockholm, TOM FENNELL, Paul Scherrer Institute — Applying a medium strength field along the [111] direction of the geometrically frustrated spin ices Ho$_2$Ti$_2$O$_7$ and Dy$_2$Ti$_2$O$_7$ results in a magnetization plateau called kagome ice. Competition between the ice rules and applied field separates the pyrochlore structure into alternating kagome and triangular planes, creating a quasi-two dimensional analog of spin ice with distinct spin correlations [1]. The concentration of spin flip excitations (recontextualized as magnetic monopole quasiparticles [2]) experiences various crossovers with increased field and temperature visible as critical inflections in the magnetization, specific heat [3] and susceptibility [4]. As the energy of spin flip excitations in the kagome plane changes with field, the mobility of monopole quasiparticles is constrained further from their spin ice counterparts. Using diffuse neutron scattering and high frequency susceptibility measurements on a Ho$_2$Ti$_2$O$_7$ single crystal, alongside Monte Carlo simulations, we have observed and characterized signals of scaling and crossovers attributed to changing monopole density above the critical point.

9:36AM R37.00007: Fitting crystal field excitations using point-charge model -- application to rare earth pyrochlore, Kagome, and triangular magnets* ZHILING DUN (Presenter), XIAOJIAN BAI, Georgia Institute of Technology, JOSEPH PADDISON, University of Cambridge, MATTHEW BRANDON STONE, Oak Ridge National Lab, HAIDONG ZHOU, University of Tennessee, MARTIN MOURIGAL, Georgia Institute of Technology — Determining the single ion crystal field (CF) Hamiltonian is usually an indispensable step to understand the collective low-temperature magnetism in rare earth magnets. This sometimes becomes challenging in low-symmetry systems due to the limited experimental observables compared to a large number of fitted CF parameters. Here I describe a general method to fit neutron CF excitation spectrum using point charge models. By benchmarking with the existing inelastic neutron scattering measurements of pyrochlore oxides (R$_2$X$_2$O$_7$), we achieve a simple and universal point-charge model. This model is then modified and applied to the newly discovered tripod Kagome magnets (R$_2$Mg$_2$Sb$_3$O$_{14}$), through which the principal axes and local g-tensor in the pseudo-spin basis can be determined and diagonalized. Finally, we apply the point-charge calculation to the triangular lattice magnet YbMgGaO$_4$ and relates its mysterious extra CF levels to the local structure disorder.

*The work at Georgia Tech was sponsored by the Department of Energy under grant DE-SC-0018660. The work at U. Tennessee was supported by NSF-DMR-1350002.
Correlated Quantum Tunnelling of Monopoles in Spin Ice*

Bruno Tomaseullo (Presenter), Theory Group, Institut Laue-Langevin, Claudio Castelnovo, Cavendish Laboratory, University of Cambridge, Roderich Moessner, MPIPKS, Max Planck Institute, Jorge Quintanilla, SPS, University of Kent — The spin ice materials Ho$_2$Ti$_2$O$_7$ and Dy$_2$Ti$_2$O$_7$ are by now perhaps the best-studied classical frustrated magnets. A crucial step towards the understanding of their low temperature behaviour – both regarding their unusual dynamical properties and the possibility of observing their quantum coherent time evolution – is a quantitative understanding of the spin-flip processes which underpin the hopping of magnetic monopoles. We attack this problem in the framework of a quantum treatment of a single ion subject to the crystal, exchange and dipolar fields from neighbouring ions. By studying the fundamental quantum mechanical mechanisms, we discover a bimodal distribution of hopping rates which depends on the local spin configuration, in broad agreement with rates extracted from experiment. Applying the same analysis to Pr$_2$Sn$_2$O$_7$ and Pr$_2$Zr$_2$O$_7$, we find an even more pronounced separation of time scales signalling the likelihood of coherent many-body dynamics that is likely to have signatures in the behaviour of these systems.

Spectroscopy of Spin Fluctuations in Spin Ices*

Ritika Dusad (Presenter), Cornell University, Franziska Kirschner, Oxford University, Jesse Hoke, Benjamin Roberts, Anna Eyal, Cornell University, Felix Flicker, Oxford University, Graeme Luke, McMaster University, Stephen Blundell, Oxford University, James C Davis, Cornell University — In the past decade, the theoretical prediction of emergent magnetic charges in several lanthanide-pyrochlore magnetic insulators has spawned renewed experimental interest in the study of these elusive particles, albeit in a condensed matter system. Thermodynamic and transport studies of of the spin ice of Dy$_2$Ti$_2$O$_7$ and Ho$_2$Ti$_2$O$_7$ are the focus of research. We report new studies of the spin fluctuation spectrum in these materials and analyze the data in the context of theories for thermally generated magnetic monopole pairs.

Monopole equilibration in spin ice

David Tennant (Presenter), MSTD, Oak Ridge National Laboratory, Anjana Samarakoon, NSCD, Oak Ridge National Lab, Santiago Grigera, CONICET La Plata Argentina, Qiang Zhang, NSCD, Oak Ridge National Lab, Bastian Klemke, Helmholtz Center Berlin, Alexander Kirste, PTB Berlin, Claudio Castelnovo, Dept of Physics, University of Cambridge, Roderich Moessner, MPIPKS Dresden — Spin ice shows remarkably rich behavior due to its monopole quasiparticles and coulombic interactions. In actual materials quantum tunneling provides millisecond spin flip times which bring out-of-equilibrium states into reach for experimental and computational study. Recently there has been interest in using neutrons and noise as probes of such behaviors. We present computational and experimental studies of the magnetic states in Dy$_2$Ti$_2$O$_7$ under out-of-equilibrium conditions. These cover the feasibility of noise and neutron measurements to assess the states in the material under thermal and field quenching.
10:24AM R37.00011: Anomalous magnetic ground state behaviour of the mixed B-site pyrochlore Dy$_2$ScNbO$_7^*$
MEGAN RUTHERFORD (Presenter), Physics and Astronomy, McMaster University, COLE D MAUWS, Chemistry, University of Manitoba, CASEY MARJERRISON, Physics and Astronomy, McMaster University, SARA HARAVIFARD, Duke University, JAMES BEARE, GRAEME LUKE, Physics and Astronomy, McMaster University, HAIDONG ZHOU, University of Tennessee, Knoxville, CHRISTOPHER R WIEBE, Chemistry, The University of Winnipeg — The spin ice state, which is of great interest due to observed residual Pauling entropy, has been observed in rare-earth pyrochlores such as Dy$_2$Ti$_2$O$_7$, and Dy$_2$Sn$_2$O$_7$. In an effort to explore the robustness of the spin ice state in dysprosium based pyrochlores, a new species Dy$_2$ScNbO$_7$ has been synthesized and single crystals have successfully been grown. Early physical characterization has shown unique behaviour arising from the disordered b-site, with faster spin dynamics and an anomalous low ordering temperature. In an effort to further explore the unique behaviour of Dy$_2$ScNbO$_7$, heat capacity measurements have been performed with an applied magnetic field along the [111] kagomé ice plane and the [110] direction of the cubic unit cell. The phase diagrams constructed from these measurements and other recent physical characterization results show an unexpected divergence from spin ice behaviour, which is the focus of this presentation.

10:36AM R37.00012: The magnetism of novel pyrochlores with a known muon site studied using muon-spin rotation*
STEPHEN BLUNDELL (Presenter), FRANZ LANG, University of Oxford, TOM LANCASTER, Department of Physics, Durham University, DHARMALINGAM PRABHAKARAN, University of Oxford — Pyrochlore oxides with the formula A$_2$B$_2$O$_7$ display a rich variety of ground states and novel magnetic phenomena, encompassing cooperative paramagnetism, all-in-all-out (AIAO) states and spin-ice behaviour. The magnetic ions on the A or B sites occupy sublattices of corner sharing tetrahedra. In muon experiments on pyrochlores, it is important to consider the extent to which an implanted muon may perturb its local environment and whether it is capable of altering the intrinsic properties of the material under investigation, a significant effect for Pr-based pyrochlores [1]. We have determined the muon site in the pyrochlore structure and use this to understand experimental data obtained on Tm$_2$Ti$_2$O$_7$ (singlet ground state), Y$_2$V$_2$O$_7$ and Lu$_2$V$_2$O$_7$ (candidate topological magnon insulator), and Lu$_2$Ir$_2$O$_7$ (insulator, with AIAO structure). 10:48AM R37.00013: Antisymmetric transport coefficients of magnetic monopoles in quantum spin ice under an electric field*
SHIGEKI ONODA (Presenter), RIKEN — Unambiguously detecting magnetic monopoles in classical or quantum spin ice has been an intriguing issue. Of our interest is the bosonic U(1) quantum spin liquid phase of quantum spin ice, which accommodates emergent magnetic monopoles as fractionalized quasiparticles and hosts deconfined emergent U(1) gauge fields. It has recently been recognized that the emergent electric gauge flux in this quantum spin liquid can be generated by a real electric field and electric polarization [1,2]. Here, solving the Harper equation [3] for a prototypical quantum spin ice, we show that magnetic monopoles can form Landau levels under an electric field, bending the orbital motion of magnetic monopoles and thus producing antisymmetric transport coefficients in response to the temperature gradient and the magnetic field gradient [4]. Possible experimental setups are also discussed.

*The work was partially supported by the JSPS Grant No. 15H03692 and by the RIKEN iTHEMS project. Calculations were partly performed on HOKUSAI at RIKEN.

Thursday, March 7, 2019 8:00 AM - 10:48 AM
8:00AM R38.00001: First-principles Study on Ferromagnetism in Two-dimensional Fe$_3$GeTe$_2$  
JINGZHAO ZHANG (Presenter), The Chinese University of Hong Kong, JING WANG, YUANBO ZHANG, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, JUNYI ZHU, The Chinese University of Hong Kong — Identifying new magnetic materials is key to better device performance and new device paradigm. Recently, the discoveries of two-dimensional (2D) ferromagnetic (FM) insulators have drawn a lot of attention to the searching of 2D magnetic materials. Here, by density functional theory calculation with different functionals as well as effective Hubbard U parameters, we symmetrically studied layered metallic magnet Fe$_3$GeTe$_2$ (FGT) from bulk to monolayer. Generally, LDA functional can give a correct description of the interlayer FM coupling, which is consistent with our experimental results. We simulated the ionic gate by electron doping in tri-layer FGT, explaining the mechanism of $T_C$ dispersion as a function of doping level revealed in experiments, by applying Stoner model. Moreover, by obtaining the intralayer and interlayer exchange parameters, we found that the itinerant ferromagnetism persists in FGT down to monolayer with an out-of-plane magnetocrystalline anisotropy. Finally, the calculated $T_C$ by mean field calculation is consistent with the experimental value.

8:12AM R38.00002: Above-room-temperature Ferromagnetism in Wafer-scale Two-dimensional Fe$_{3+x}$GeTe$_2$ Films  
SHANSHAN LIU (Presenter), ZI Han LI, KE YANG, HUA WU, FAXIAN XIU, Fudan University — Recently, 2D ferromagnetic materials have been discovered with tunable magnetism and nodal-line features. Controlling 2D magnetism in exfoliated nanoflakes via electric-field enables the boosted Curie temperature ($T_C$). One of the most intriguing challenges, however, is the realization of high $T_C$ materials that are tunable, robust and compatible with the commercial-level manufacturability. Here, we report the above-room-temperature ferromagnetic order in wafer-scale 2D Fe$_{3+x}$GeTe$_2$ films through a non-equilibrium growth process in molecular beam epitaxy. The perpendicular magnetic anisotropy in Fe$_{3+x}$GeTe$_2$ is found to persist up to 320 K, significantly higher than the stoichiometric bulk counterpart (Fe$_3$GeTe$_2$, $T_C$~220 K). By controlling the atomic ratio, we found a largely-modulated $T_C$ that depends on carrier density. Corroborated with DFT calculations, we demonstrated that the higher atomic ratio further stabilizes the FM ground state by yielding a larger energy difference of $E_{AFM}$-$E_{FM}$, therefore enabling the enhanced ferromagnetic order in this system. Our results show an effective approach, i.e., the element doping, to produce a robust ferromagnetic order beyond room temperature in wafer-scale Fe$_{3+x}$GeTe$_2$ films, which may render practical applications for 2D spintronic devices.

8:24AM R38.00003: Anomalous magnetotransport in Van der Waals ferromagnet Fe$_2$GeTe$_3$  
SIQI WANG (Presenter), YANG XIA, University of California at Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, YUAN WANG, XIANG ZHANG, University of California at Berkeley — Ferromagnetic Van der Waals (VdW) materials have been discovered with tunable magnetism and nodal-line features. Controlling 2D magnetism in exfoliated 2D magnet with an intrinsically-high Curie/Neel temperature remains a challenge. Here we show experimental evidence of ferromagnetic ordering around temperature in thin flakes of cleavable van der Waals magnet Fe$_2$GeTe$_2$. Anomalous Hall effect measurements and magneto-optic Kerr effect point towards out of plane anisotropy. Furthermore, our devices exhibit high metallicity and a rich phase diagram.

8:36AM R38.00004: Magnetism near room temperature in thin flakes of Fe$_5$GeTe$_2$  
DMITRY OVCHINNIKOV (Presenter), University of Washington, ANDREW MAY, Oak Ridge National Laboratory, BEVIN HUANG, ZAIYAO FEI, University of Washington, QIANG ZHENG, MICHAEL A MCGUIRE, Oak Ridge National Laboratory, XIAODONG XU, University of Washington — Two-dimensional (2D) magnets are an emerging class of materials that exhibit intrinsic magnetic order in the ultrathin limit. An immediate challenge is to realize 2D magnetic order at high temperature. Indeed, molecular beam epitaxy has successfully synthesized monolayers that are magnetically ordered at room temperature. Controlled intercalation of Li ions into a few layers of Fe$_5$GeTe$_2$ also increases magnetic order from low temperature up to room temperature. However, obtaining an exfoliated 2D magnet with an intrinsically-high Curie/Neel temperature remains a challenge. Here we show experimental evidence of ferromagnetic ordering around temperature in thin flakes of cleavable van der Waals magnet Fe$_5$GeTe$_2$. Anomalous Hall effect measurements and magneto-optic Kerr effect point towards out of plane anisotropy. Furthermore, our devices exhibit high metallicity and a rich phase diagram.
Imaging magnetic structure in Van der Waals ferromagnets using nanoSQUID microscopy

CHARLES TSCHIRHART (Presenter), MAREC SERLIN, JIACHENG ZHU, University of California, Santa Barbara, AVI G SHRAGAI, Physics, Cornell University, YU SAITO, University of California, Santa Barbara, MARTIN E HUBER, Physics, University of Colorado, Denver — Van der Waals ferromagnets have been shown to host a variety of magnetic phenomena, including gate-and-magnetic field-tunable transitions between ferromagnetic and layer antiferromagnetic states. I will present high resolution spatial maps of magnetic structure in exfoliated chromium iodide heterostructures, obtained using a scanning nanoscale SQUID on tip microscope, which provides sub-100 nm spatial resolution of magnetic domains across a wide range of magnetic fields spanning the coercive fields of these materials.

Prediction of a two-dimensional intrinsic ferromagnetic and half-metallic material MnSiTe₃

DECHEN ZHANG (Presenter), AZIZUR RAHMAN, WEI QIN, PING CUI, ZENGMING ZHANG, ZHENYU ZHANG, University of Science and Technology of China — Two-dimensional (2D) transition metal trichalcogenides (TMT) have recently been extensively studied due to their intriguing electronic and magnetic properties. Here, based on first-principles calculations, we predict a new 2D TMT material MnSiTe₃, which possesses both ferromagnetism and half-metallicity. The cleavage energy of the bulk MnSiTe₃ is found to be very low, suggesting its monolayer counterpart can be obtained via direct mechanical exfoliation. More intriguingly, we demonstrate that both the ferromagnetism and half-metallicity are preserved when reducing the dimensions from the bulk to monolayer. For the monolayer MnSiTe₃, we calculate the strengths of exchange interactions between nearest, next-nearest and next-next-nearest neighbors of Mn ions. The long-range ferromagnetic order is further confirmed by Monte Carlo simulations within the Heisenberg model, and the Curie temperature $T_c$ is shown to be $\sim$70K. Apart from the exchange interactions between magnetic atoms, the Ruderman-Kittel-Kasuya-Yosida interaction mediated by itinerant carriers also plays a crucial role in determining the ferromagnetic ground state. These findings provide a new 2D material for exploring applications in nano spintronics.

2D Ferromagnetism in Silicene Materials

DMITRY AVERYANOV, ANDREY TOKMACHEV, OLEG PARFENOV, IGOR KARATEEV, IVAN SOKOLOV, ALEXANDER TALDENKOV, VYACHESLAV STORCHAK (Presenter), NRC "Kurchatov Institute" — The appeal of ultra-compact spintronics drives intense research on magnetism in low-dimensional materials. Recent years have witnessed remarkable progress in engineering two-dimensional (2D) magnetism via defects, edges, adatoms and magnetic proximity. However, intrinsic 2D ferromagnetism remained elusive until recent discovery of magneto-optical response in Cr-based layers[1,2], stimulating the search for novel 2D magnets with tunable properties. We employ a bottom-up approach to produce layered structures of silicene (a Si counterpart of graphene) functionalized by rare-earth atoms, ranging from the bulk down to one monolayer. We track the evolution from the antiferromagnetism of the bulk to intrinsic 2D ferromagnetism of ultrathin layers of GdSi₂ and EuSi₂ [3]. Remarkably, the charge transport is found to be layer-dependent once silicene structures are scaled to a few-monolayers limit: it evolves from a Kondo-like trend to an insulating behavior once a gap opens up in its charge excitation spectrum. The discovery of a class of robust 2D magnets, compatible with the mature Si technology, is instrumental for engineering new spintronic devices.

*We acknowledge support from NRC "Kurchatov Institute" (1381) and RFBR (19-07-00249, 16-29-03027 and 17-07-00170).
**9:48AM R38.00008: Interplay between charge density wave phases and magnetism in transition metal diselenides**

**ADOLFO O. FUMEGA, VICTOR PARDÓ (Presenter)**, University of Santiago de Compostela — In this talk we will describe a series of density-functional-theory-based ab initio calculations carried out on structurally two-dimensional transition metal diselenides. VSe₂ has been reported to show robust magnetism[1], yet ab initio calculations[2] show that the coexistence of a charge-density-wave (CDW) phase with a ferromagnetic one is doubtful, even at the monolayer level. We will analyze how the interplay between magnetism and CDW phase occurs in VSe₂, what effects can cause the material to stabilize a long-range ferromagnetic order, how the magnetic properties change from the 1T-phase to the 2H-phase and also how the properties of the Peierls phase observed at the monolayer limit compare to the small-gap phase in isostructural TiSe₂.

*This work has received financial support from Ministerio de Economía y Competitividad (Spain) under project No. MAT2016-80762-R and (A.O.F. only) via FPU scholarship no. FPU16/02572.

**10:00AM R38.00009: Magnetic interfaces of MnSe₂ monolayers**

**TOMAS ROJAS (Presenter)**, Ohio University, ANH T NGO, Materials Science Division, Argonne National Laboratory, SERGIO E ULLOJA, Ohio University — Until recently, 2D magnetism was thought to occur together with defects or doping on different substrates. This situation changed drastically, as intrinsic Cr-based ferromagnetic monolayer materials were discovered, namely CrI₃ and Cr₂Ge₂Te₆. A different material, MnSe₂, was predicted as stable ferromagnetic monolayer by first-principles calculations, and it has been successfully grown on several substrates [1].

In this study, the authors confirm the intrinsic ferromagnetism of the monolayer, while for thicker samples they report an interface of the MnSe₂ monolayer with bulk α-MnSe(111). This phase of the material is non-magnetic, and yet the observed magnetic moments are of up to twice the value of those in the monolayer alone.

In this work, we present a detailed analysis of the interactions at this interface between the two phases, using the Heyd-Scuseria-Ernzerhof hybrid functional. We have studied the effects on the electronic and magnetic structure of both phases of the material, and the dependence on the sample thickness. We study the role that strain plays at the interface, and how it affects the magnetic moments of the structure.

*Supported by NSF-DMR 1508325, and Ohio Supercomputer Center

**10:12AM R38.00010: Emergent Transition Metal Dichalcogenide Monolayer Ferromagnetism at Terminated Edges**

**VIJAYSANKAR KALAPPATTIL, SADHU KOLEKAR, MANUEL BONILLA, RAJA DAS, TATIANA M EGGER,** University of South Florida, KHANG HOANG, North Dakota State University, MATTHIAS BATZILL, MANH-HUONG PHAN (Presenter), University of South Florida — The recent discoveries of the strong room-temperature ferromagnetism in epitaxially grown transition metal diselenide XSe₂ (X = V, Mn) monolayers have effectively heated up the field of two-dimensional (2D) van der Waals magnets [1,2]. However, the origin of the ferromagnetism in these nanosystems has remained an open question. In this talk, we demonstrate that chalcogenide (Se) atoms at terminated edges play a dominant role in the XSe₂ monolayer magnetism, regardless of the transition metal being a non-magnetic element (X = W, Ti) or a magnetic element (X = V). The ferromagnetic Se edge is responsible for the observed large magnetic moment, which decreases as the size of XSe₂ islands or the number of XSe₂ layers increases. The role played by the magnetic transition metal (X = V) on the ferromagnetic ordering of monolayer XSe₂ is also elucidated. Density functional theory (DFT) based calculations support the experimental findings. This understanding enables controlled nanoengineering of novel two-dimensional van der Waals magnets for next-generation spintronic devices and storage information applications.

**10:24AM R38.00011: Flat bands and Dirac cones in magnetic 2D metal-organic frameworks**

TOMOHIRO SOEJIMA (Presenter), Physics Department, UC Berkeley, RU CHEN, Molecular Foundry, Lawrence Berkeley National Laboratory, CHRISTOPHER H. HENDON, Chemistry Department, University of Oregon, JEFFREY B NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory — Metal-organic frameworks (MOFs) are interesting crystals for exploring new physics due to their tunable structure and chemical composition. 2D magnetic MOFs are of particular interest, and a composite kagome-honeycomb lattice was recently realized in a reported ferrimagnetic iron-semiquinone MOF [1]. Via molecular orbital and tight-binding analysis, and with density functional theory-based calculations, we study the iron-semiquinone MOF and show that its band structure contains multiple flatbands as well as multiple Dirac cones. We find that the MOF is semimetallic, with the Fermi level at a Dirac point; and the calculated magnetization is consistent with the reported experimental value. We also explore the effects of spin-orbit coupling and comment on the magnetism of related 2D MOFs; we also discuss how our tight-binding model might be generalized to other 2D MOFs of interest.

**10:36AM R38.00012: Tuning surface properties of 2D magnetic coordination polymers**

SAMUEL MAÑAS-VALERO (Presenter), JAVIER LÓPEZ-CABRELLES, GUILLERMO MÍNGUEZ-ESPALLARGAS, EUGENIO CORONADO, University of Valencia — Magnetism has been an elusive property in the 2D-land up to date. There are only few recent reports regarding inorganic monolayers of antiferromagnets (FePS₃) [1, 2] and highly unstable ferromagnets such as CrI₃ [2] or Fe₃GeTe₂ [3]. To overcome the present unstabilities of 2D magnetic materials, we take advantage of layered molecular magnets since, thanks to the chemical design, they are excellent candidates in order to bring new magnetic scenarios as well as to overcome the present unstabilities of 2D magnetic materials. Here [4] we present a pre-synthetic method based on the use of magnetic coordination polymers that affords the isolation of crystalline functionalized monolayers. This involves functionalization of the ligand prior to the formation of the 2D material. The concept is illustrated using layered coordination polymers formed by reacting various benzimidazole derivatives with ferrocene. This surface tuneability, together with the robust magnetic and mechanical properties of these 2D materials, make them exceptional candidates for studying the magnetism in the 2D limit, as well as for developing membranes for selective molecular sensing.

**8:00AM R39.00001: Investigation of Diverse Magnetic Materials via Acoustically Driven Ferromagnetic Resonance**
PIYUSH SHAH, DEREK BAS, VLADIMIR SAFONOV, Materials and Manufacturing Directorate, Air Force Research Laboratory, MAKSYM POPOV, Department of Physics, Oakland University, ALEXEI MATYUSHOV, Department of Electrical and Computer Engineering, Northeastern University, ANNE KITTMANN, VIKTOR SCHELL, ECKHARD QUANDT, Institute for Materials Science, Chair for Inorganic Functional Materials, Kiel University, D-24143 Kiel, Germany, NIAN XIANG SUN, Department of Electrical and Computer Engineering, Northeastern University, GOPALAN SRINIVASAN, Department of Physics, Oakland University, BRANDON HOWE, MICHAEL E MCONNEY, MICHAEL PAGE (Presenter), Materials and Manufacturing Directorate, Air Force Research Laboratory — Magnetoelastic coupling has been exploited to detect FMR using surface acoustic waves (SAWs), a technique known as ADFMR. GHz-frequency SAWs are produced and detected electrically using pairs of interdigital transducers (IDTs). A magnetic film is placed in the path of the SAWs, which can then interact with magnetic moments via magnetoelastic coupling. Absorption of the SAWs occurs at FMR, modulating the measured output. Landau-Lifshitz-Gilbert theory describes the interaction in terms of the external magnetic field with a characteristic four-lobe pattern, from which the magnetic anisotropy field, FMR resonance field, and magnetoelastic coupling coefficient can be inferred.

We study the effects of a variety of magnetic materials including Ni, FeCo, FeGaB, and FeCoSiB, to examine the dependence of ADFMR patterns on material parameters and geometries. We use a range of SAW frequencies from ~300 to 2000 MHz to explore spectral effects of the IDT design on transduction efficiency, and the frequency dependence of the resonance field. We also calculate the FMR linewidth and quality factor—figures of merit useful for determining the efficacy of future ADFMR devices.

**8:12AM R39.00002: Enhanced-Spectral-Range Brillouin Light Spectroscopy by sub-diffraction confinement of light**
RYAN FREEMAN (Presenter), ROBERT LEMASTERS, FENG WANG, Emory University, VLADISLAV DEMIDOV, SERGEJ DEMOKRITOV, University of Münster, HAYK HARUTYUNYAN, SERGEI URAZHDIN, Emory University — Microfocus Brillouin Light Spectroscopy (BLS) is a standard optical technique which allows for the direct observation of quasiparticles such as phonons or magnons in magnetic films. A major limitation of the technique is that due to the small wavevector of light, the technique is only sensitive to the dynamical modes near the center of the Brillouin zone, making a large part of the spectrum optically inaccessible. We show that by using a nanoscale optical mask on top of the magnetic film, the BLS signal from short-wavelength spin waves can be enhanced by an order of magnitude. The enhancement is consistent with the broadened distribution of wavevectors caused by the spatial confinement of light, analogous to the uncertainty principle. Additionally, by engineering the geometry of the optical mask, we selectively enhance the sensitivity to specific spin wave modes, allowing us to reconstruct the spin wave dispersion.

*Supported by NSF ECCS-1804198

**8:24AM R39.00003: Coupling of Nitrogen Vacancy Centers to Pinned Domain Walls in Magnetic Nanowires**
JEFFREY RABLE (Presenter), ERIC KAMP, BENJAMIN S PIAZZA, NITIN SAMARTH, Pennsylvania State University — Nanodiamonds containing nitrogen vacancy (NV) centers have emerged as a robust system for measuring magnetic structures on the nanoscale. In addition to their use in studying static magnetic structures, such as stationary domain walls[1], they have recently been used to probe dynamic phenomena, such as ferromagnetic resonance[2] and spin wave propagation[3]. Here, we investigate the coupling of NV centers to pinned domain wall oscillations in a notched ferromagnetic nanowire made of permalloy. To design a nanowire that oscillates at NV resonance frequencies, we used micromagnetic simulations to test various wire sizes and notch geometries. Next, we used a pick-and-place method to position the nanodiamonds at the domain wall pinning site using an atomic force microscope. We then performed measurements using microwaves and a homebuilt confocal microscope. These methods pave the way for future measurements of domain wall dynamics with NV centers and more advanced methods of NV qubit control.

8:36AM R39.00004: NV Diamond Based Broadband Readout of FMR from Organic Magnetic V[TCNE]2 Thin Film*  
BRENDAN MCCULLIAN (Presenter), MICHAEL CHILCOTE, Department of Physics, Ohio State University, VIDYA P BHALLAMUDI, Department of Physics, Indian Institute of Technology Madras, CAROLA PURSER, EZEKIEL JOHNSTON-HALPERIN, P CHRIS HAMMEL, Department of Physics, Ohio State University — Low damping magnetic thin films will play a key role in realizing nanoscale spin based computational elements. Organic-based magnetic films have shown high-quality resonance properties which rival the best oxides, and can be deposited across a wide range of substrates. A local probe of magnetic resonance is desirable for nanoscale characterization since inductive based techniques typically require large samples and can be spatially insensitive. The Nitrogen-Vacancy (NV) defect in diamond can serve as a platform for local, broadband, optical readout of magnetic resonance from a proximal magnetic film. We report broadband optically detected ferromagnetic resonance (ODFMR) from a micron-thick layer of the high quality organic-based ferrimagnet Vanadium Tetracyanoethylene (V[TCNE]2) grown on a diamond substrate. The locally probed FMR exhibits linewidths on the order of 1 Gauss, indicating both the high quality of the VTCNE on the micron scale and of the ability of the NV as a sensor for low damping materials. This work demonstrates the utility of the NV center to measure FMR of low Ms and organic systems.

8:48AM R39.00005: THz Spectrum Analysis Using an Antiferromagnetic Tunnel Junction as a Signal Mixer  
STEVEN LOUIS (Presenter), Electrical and Computer Engineering, Oakland University, PETRO ARTEMCHUK, OLGA SULYMENKO, Radio Physics, Taras Shevchenko National University of Kyiv, VASYL S TYBERKEVYCH, Department of Physics, Oakland University, JIA LI, Electrical and Computer Engineering, Oakland University, OLEKSANDR PROKOPENKO, Radio Physics, Taras Shevchenko National University of Kyiv, ANDREI SLAVIN, Department of Physics, Oakland University — We propose a novel, all-electrical method of performing spectrum analysis between 0.1 THz to 1.0 THz (in the “THz gap”). The method features an antiferromagnetic (AFM) tunnel junction that consists of 4 thin layers (Pt, AFM, MgO, Pt) and functions as follows [1]. First, an in-plane dc bias current \( I(t) \) in the Pt layer creates perpendicular spin Hall current, which excites rotation of the AFM sublattices with a frequency \( f(t) \approx I(t) \). When the bias current \( I(t) \) increases with time, \( f(t) \) can be linearly swept over the THz gap. Due to the tunneling magnetoresistance effect, the resistance \( R(t) \) of the MgO/Pt structure oscillates with the same frequency \( f(t) \). Oscillating resistance \( R(t) \) is mixed with an input signal producing low-frequency output voltage \( V(t) \) that temporally encodes the input spectrum. The spectrum can be extracted from \( V(t) \) using signal processing method described in [2].

9:00AM R39.00006: Incoherent ferromagnetic spinwave spectroscopy using defect spins in diamond*  
CAROLA PURSER (Presenter), Department of Physics, Ohio State University, VIDYA P BHALLAMUDI, Department of Physics, Indian Institute of Technology Madras, DENIS PELEKHOV, Department of Physics, Ohio State University, QIAOCHU GUO, GREGORY FUCHS, School of Applied and Engineering Physics, Cornell University, P CHRIS HAMMEL, Department of Physics, Ohio State University — Optically detected spin transitions in nitrogen vacancy (NV) centers in diamond sensitively detect fluctuating fields at NV transition frequencies. Applied to ferromagnetic dynamics, this has enabled sensing of thermally occupied spinwaves as well as broadband, off-resonant spectroscopy of driven uniform-mode ferromagnetic resonance. We measure the relaxation rates of NV sensor spins to detect thermally excited spinwaves from a thin film of permalloy (Py). Analytical calculations and micromagnetic simulations demonstrate good agreement with measured NV relaxation rate as a function of NV-Py separation and applied field strength. Notably, NV sensors detect field noise from Py at a separation of up to 450 nm, thus demonstrating the suitability of NV probes in the GHz frequency range and submicron length scales of interest for communication and information devices.

A single electron spin to study magnons in a magnetic insulator

TONY X. ZHOU (Presenter), Applied physics, Harvard University; JORIS CARMIGGELT, LISA GACHTER, AMIR YACOBY, Physics, Harvard University — A single electron spin as a quantum sensor is an ideal tool to study novel condensed matter physics. Recently, NV center in diamond has been used as a single electron spin sensor to explore topics of skyrmion\cite{ref1} and spin chemical potential in ferromagnetic insulator\cite{ref2}. In this work, we use a single NV center in scanning probe microscope\cite{ref3} to study magnons in yttrium iron garnet (YIG).

Crossover of tip-sample magnetic couplings in an in-field spin-polarized scanning tunneling microscopy

SOOHYON PHARK (Presenter), Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), DIRK SANDER, Experiment 1, Max-Planck-Institute of Microstructure Physics — We report a crossover between long- and short-range magnetic couplings in an atomic scale magnetic tunnel junction (MTJ), measured from a tip-sample distance $d_{TS}$-resolved spin-polarized scanning tunneling microscopy of a Co nanoisland with Fe tips. We show that superparamagnetic response of tip magnetization \cite{ref1} quantitatively measures the sample-induced field at the tip position $\mu_0 H_S(d_{TS})$, which results in non-zero field offset $H_{off}$ in the field-dependent differential conductance hysteresis. The $H_{off}(d_{TS})$ with a varying $d_{TS}$ quantitatively characterizes a dipole filed of $\sim 60$ mT. On the other hand, a short range coupling, which is characterized as an antiferromagnetic tip-sample coupling, is observed at a small $d_{TS}$. This strongly increases for a decreasing $d_{TS}$ and competes with the dipole field, resultantly, leading to a crossover of the magnetic couplings from parallel to antiparallel. Our works demonstrate a novel method for quantitative measurement of magnetic couplings in an atomic scale MTJ under a simple and precise control of its tunnel barrier thickness.

Spin polarized scanning tunneling microscopy with EuS coated W tip

HOYEON JEON (Presenter), MINJUN LEE, Seoul National University, YOUNG KUK, Center for Quantum Nanoscience, Institute of Basic Science, Ewha Womans University, Seoul, Korea — Various kinds of ferromagnetic or antiferromagnetic tips have been used to measure local magnetic properties of surfaces in spin polarized scanning tunneling microscopy technique. In this study, europium sulfide (EuS) coated tungsten tip is used because EuS coated tip is known to have a Sherman factor of 0.85 due to its exchange splitting \cite{ref1,ref2}. With this tip, we have imaged different magnetic domains on iron islands grown on W(110) surface. The differential conductance was mapped at liquid helium temperature because Curie temperature of EuS is 16K. We were able to manipulate the magnetization orientation of a ferromagnetic domain of Fe island by spin polarized tunneling current. We measured magnetic properties of single-layer FeSe film on SrTiO$_3$ to confirm a theory that predicted antiferromagnetic order on Fe layer in the film.

Determination of $^{167}$Er:YSO Spin Hyperfine and Quadrupole Tensors using Josephson Bifurcation Amplifier

RANGGA BUDOYO (Presenter), KOSUKE KAKUYANAGI, HIRAKU TOIDA, YUICHIRO MATSUZAKI, WILLIAM JOHN MUNRO, SHIRO SAITO, NTT Basic Research Labs — Using an ESR spectrometer based on Josephson Bifurcation Amplifier, we performed spectroscopy of Erbium-doped Y$_2$SiO$_5$ crystal at various magnetic field orientations and strengths. By fitting the resulting spectra, we extracted the ground state hyperfine and quadrupole tensor values for $^{167}$Er:YSO. We discuss these tensor values, and compare them with values obtained using other methods, including conventional ESR spectroscopy, tunable resonators, and optical methods.
10:00AM R39.00011: Neutron Depolarization Microscope for Imaging of Ferromagnetic Phase Transitions: Ni$_3$Al and HgCr$_2$Se$_4$ under pressure* BORIS KHAYKOVICH (Presenter), Massachusetts Institute of Technology, PAU JORBA, MICHAEL SCHULZ, Technische Universitat Munchen, DANIEL HUSSEY, National Institute of Standards and Technology, MUHAMMAD ABIR, Massachusetts Institute of Technology, MARC SEIFERT, Technische Universitat Munchen, VLADIMIR TSURKAN, ALOIS LOIDL, University of Augsburg, CHRISTIAN PFLEIDERER, Technische Universitat Munchen — We performed spatially resolved neutron depolarization imaging of a large Ni$_3$Al crystal, and a small HgCr$_2$Se$_4$ spinel under pressure, to probe bulk magnetic inhomogeneities in the ferromagnetic phase and the transition temperature with the spatial resolution of 100 μm. To obtain such resolution, we employed a new technique, a neutron microscope based on image-forming Wolter optics and a focusing guide. The depolarization images of Ni$_3$Al show that the sample doesn’t homogeneously go through the ferromagnetic transition; the improved resolution allows us to identify previously unidentified high-TC regions. The results on HgCr$_2$Se$_4$ highlight the advantage of this technique especially for complex sample environments such as pressure cells. The improved resolution allows to image domain formation in the sample while decreasing the acquisition time. The novel optical design that enabled acquisition of the high spatial resolution neutron depolarization images is described in detail and image results are compared to a conventional radiography setup without a lens.

10:12AM R39.00012: Imaging Nanoscale Magnetism and its Dynamics at CSX Beamline* WEN HU (Presenter), FELIX BUETTNER, CLAUDIO MAZZOLI, ANDI BARBOUR, STUART B WILKINS, Brookhaven National Laboratory — Imaging magnetic materials and structures as a function of external parameters, including magnetic and electric fields, and temperature will provide detailed insight into their dynamics and behavior. Coherent soft x-ray scattering (CSX) beamline at NSLS-II provide researchers a world leading coherent high photon flux with full polarization control. Coherent diffraction imaging, such as resonant soft x-ray ptychography and holography, are under commissioning at CSX and welcome new users. Very recently, we monitored thermal motions of magnetic domain wall with high magnetic contrast and 10nm spatial resolution using holography imaging. Moreover, a new holography chamber has been developed and installed at CSX beamline and it provided holography imaging capability to study magnetic materials as a function of temperature under in-situ condition (current injection and in-vacuum magnetic field).

Here, we highlight current achievements and discusses the future potential of magnetic soft X-ray imaging with a spatial resolution of sub-10nm at CSX beamline.

*This work was done at CSX beamline of NSLS II, a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Brookhaven National Laboratory under Contract No. DE-SC0012704.

10:24AM R39.00013: Extracting equivalent circuit model of magnetoelectric gyrator using vector network analyzer CHENG TU (Presenter), XIANFENG LIANG, CUNZHENG DONG, HUAIHAO CHEN, ZHAOQIANG CHU, NIAN XIANG SUN, Northeastern University — The magnetoelectric (ME) effect is a polarization change induced by an applied magnetic field, or conversely a magnetization change induced by an applied electric field. The giant ME effect found in coil-wrapped magnetostrictive/piezoelectric laminated composites can be utilized to realize gyrators. Until now, there is little reported work regarding how to extract the equivalent circuit model of such ME gyrator from measurement. In this work, we report an effective method to accurately extract the equivalent circuit model from the measured impedance parameters using a vector network analyzer (VNA). The two-port ME gyrator under investigation consists of a plate type piezoelectric/magnetostrictive laminate, in which the piezoelectric layer (PZT) is sandwiched between two magnetostrictive layers (metglass). A 30-turn coil is wrapped around the laminate serving as port 1. The metal electrodes on the surfaces of PZT layer are used as port 2. All the model parameters of the gyrator were extracted from the measured impedance parameters using a VNA. Good agreement between the model and measured results proves that the proposed extraction method is valid and accurate.
Capturing Nucleation at 4D Atomic Resolution* YONGSOO YANG (Presenter), JIHAN ZHOU, YAO YANG, DENNIS S KIM, ANDREW YUAN, XUEZENG TIAN, Physics and Astronomy, University of California, Los Angeles, COLIN OPHUS, Molecular Foundry, Lawrence Berkeley National Laboratory, FAN SUN, Physics, University at Buffalo, ANDREAS SCHMID, Molecular Foundry, Lawrence Berkeley National Laboratory, MICHAEL NATHANSON, HENDRIK HEINZ, Chemical and Biological Engineering, University of Colorado, Boulder, QI AN, Chemical and Materials Engineering, University of Nevada, Reno, HAO ZENG, Physics, University at Buffalo, PETER ERCIUS, Molecular Foundry, Lawrence Berkeley National Laboratory, JIANWEI MIAO, Physics and Astronomy, University of California, Los Angeles — Nucleation is a ubiquitous phenomenon in many physical and biological processes. However, it is a challenging process to study nucleation due to the lack of experimental tools to directly measure the 3D atomic structure of nuclei. Here, we further advance atomic electron tomography to study the early stage nucleation of FePt nanoparticle system at 4D atomic resolution [1]. We reveal that early stage nuclei are irregularly shaped, each has a core of a maximum order parameter, and an order parameter gradient points from the core to the boundary of the nucleus. We also capture the 3D atomic structure and dynamics of the same nuclei undergoing growth, fluctuation, dissolution, merging and/or division. We find that nucleation dynamics is regulated by the distribution of the order parameter and its gradient. These experimental results differ from classical nucleation theory (CNT), and we propose an order parameter gradient nucleation model which is thermodynamically more favorable than CNT. We further corroborate this model using molecular dynamics simulations of the liquid-solid phase transition of Pt.

*STROBE: NSF STC (DMR-1548924), US DOE (DE-SC0010378), the NSF DMREF (DMR-1437263), and the Molecular Foundry (US DOE DE-AC02-05CH11231)

Cryogenic Amplification of Magnetoresistance in Magnetic Tunnel Junctions with the Aid of SiGe-HBT* JASON DARK (Presenter), HANBIN YING, GRANT H NUNN, JOHN CRESSLER, DRAGOMIR DAVIDOVIC, Georgia Institute of Technology — Cryogenic amplification has been used for qubit readout, single electron transistor operation, and charge sensing with quantum point contacts; however, this useful tool has been missing from electron transport measurements in the broad field of magnetism. Silicon-Germanium Heterojunction Bipolar Transistors were used for cryogenic preamplification of nanoscale magnetic tunnel junctions at 8 K. The preamplification system increased the signal-to-noise ratio of the tunneling magnetoresistance signal by a factor of 6.62. The current gain provided by the preamplification also allowed for a higher bandwidth measurement limited by the external transimpedance amplifier, rather than cryogenic wiring. The high impedance (≈1 MΩ) of the junctions allow for easy migration to study the magnetodynamics of more interesting samples.

*This research was supported in part (J. Dark, G. Nunn, and D. Davidovic) by DOE contract DE-FG0206ER46281, and (H. Ying and J. D. Cressler) by the Laboratory Directed Research and Development (LDRD) Program at Sandia National Laboratories (operated by NTES of Sandia, a wholly owned subsidiary of Honeywell International Inc., for DOE's NNSA under contract DE-NA-0003525).

Session R40 GMAG DMP DCOMP: Complex Oxide Films and Heterostructures III BCEC 208 -

Zhigang Chen, San Francisco State Univ - Tag(s): Focus
8:00AM R40.00001: Phase transitions and magnetic domain coexistence in Nd$_{0.5}$Sr$_{0.5}$MnO$_3$ thin films  I-TING CHIU
(Presenter), Chemical Engineering, University of California, Davis, APURVA MEHTA, Stanford Synchrotron Radiation Lightsource, SLAC National Accelerator Laboratory, ALEXANDER MICHAEL KANE, Materials Science and Engineering, University of California, Davis, RAJESH V CHOPDEKAR, Advanced Light Source, Lawrence Berkeley National Laboratory, CHRISTOPHER ROULEAU, The Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, ALPHA N’DIAYE, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, YAYOI TAKAMURA, Materials Science and Engineering, University of California, Davis — We present a study of the physical properties of perovskite oxide Nd$_{0.5}$Sr$_{0.5}$MnO$_3$ (NSMO) thin films grown on (110)-oriented SrTiO$_3$ substrates. In bulk form, NSMO displays magnetic and electronic transitions from paramagnetic/insulator to ferromagnetic (FM)/metal and then to antiferromagnetic (AFM)/charge-ordered insulating phase with decreasing temperature. In thin films, AFM ordering only occurs in an anisotropic strain state such as those obtained in (110)-oriented substrates which allows for Jahn-Teller distortions of the MnO$_6$ octahedral and MnO$_6$ bond length distortions [1]. In this work, resonant x-ray reflectivity and magnetometry measurements showed that the NSMO film breaks up into three layers with different density and magnetic properties. X-ray magnetic circular dichroism confirmed the FM-AFM transition occurs between 80 K and 160 K for the main portion of the NSMO film, while x-ray magnetic linear dichroism provided a clear signature of the AFM phase at 80 K. At an intermediate temperature of 110 K, photoemission electron microscopy demonstrated the coexistence of FM and AFM domains. These temperature-dependent transitions have strong potential applications in next generation memory devices.

8:12AM R40.00002: Growth and Physical properties of full chemically ordered manganites  LINA DENG (Presenter), Department of Physics, Fudan University — Chemical doping is a widely used method to control materials’ physical properties. The dopants are usually randomly distributed. This unavoidably introduces disordering into the materials, which may affect the physical properties of the materials. This is especially true for electronic phase separation (EPS) phenomena in manganites, which is known to have a close correlation with disordering. In this work, we use superlattice growth to form chemically ordered manganites, and compare with conventional manganites whose chemical dopants are randomly distributed. Specifically, one unit cell LaMnO$_3$ / one unit cell PrMnO$_3$ / one unite cell CaMnO$_3$ tricolor superlattices have been grown on NGO (110) and STO (100) substrates by laser molecular beam epitaxy, forming chemically ordered La$_{1/3}$Pr$_{1/3}$Ca$_{1/3}$MnO$_3$ (O-LPCMO) thin films. In stark contrast to the conventional La$_{1/3}$Pr$_{1/3}$Ca$_{1/3}$MnO$_3$ (R-LPCMO) thin films which are characterized by large scale EPS, the O-LPCMO films show no signs of EPS. This indicates that dopants induced disordering plays a critical role in large scale EPS in manganites. Our experimental results show that the O-LPCMO system is in a charge-ordered insulating state which is consistent with the first principle calculations.

8:24AM R40.00003: The role of extreme configurational disorder in entropy stabilized single crystal perovskite oxides*  THOMAS WARD (Presenter), YOGESH SHARMA, Oak Ridge National Laboratory, ALESSANDRO MAZZA, University of Missouri — The ABO$_3$ perovskite and its derivatives are broadly important to a range of fundamental and applied interests. Modification of the A and B sites through substitutional doping allows for a wide variety of distortions and charge states to be tuned. Local distortions arising from cation size variance are balanced by internal changes to Jahn-Teller distortions and octahedral tilts and rotations. In strongly correlated systems, these shifts to local environment are often central to the emergence of important macroscopic functionalities. In this talk, we will describe our recent work using entropy stabilization to synthesize single crystal ABO$_3$ perovskite films possessing 6 or more cations to begin to explore how extreme levels of microscopic disorder might be used to generate unexpected long-range ordering responses. We will discuss how the element specific magnetic and charge states of the cations in La(Cr$_{0.2}$Mn$_{0.2}$Fe$_{0.2}$Co$_{0.2}$Ni$_{0.2}$)O$_3$ films are impacted by the extreme site to site disorder. Experimental results from STEM-EELs, XRD, XMCD, neutron diffraction, and SQUID magnetometry will be presented.

8:36AM R40.00004: Charge order and phase separation nature of the insulating La$_{0.67}$Ca$_{0.33}$MnO$_3$ thin film on NdGaO$_3$ substrate*  
MINGQIANG GU (Presenter), JAMES M RONDINELLI, Department of Materials Science and Engineering, Northwestern Univ — Doped manganite systems have been intensively studied due to their rich phase diagrams at different temperature, strain, pressure, and composition conditions. La$_{0.67}$Ca$_{0.33}$MnO$_3$ thin film grown on NdGaO$_3$ substrate has found to exhibit abnormal antiferromagnetic (AFM) insulating ground state, which violates the bulk phase diagram. The puzzle that why the ground state of this $g^{3.67}$ system becomes insulating is studied with density functional theory (DFT) calculation. Several potential scheme has been examined, including substrate strain, pinning of Jahn-Teller distortion, and charge order (CO), within different magnetic configurations. We find that without charge order, neither substrate strain nor increased Jahn-Teller distortion are sufficient to induce the insulating state. With Mn$^{4+}$/Mn$^{3+}$ valence states ordered in a stripe type pattern along the $b$ lattice vector, the AFM insulating state can be observed. However, an unrealistic large uniaxial strain is required to assist this phase to beat the ferromagnetic (FM) phase. Further study suggests mixture of the CO [Mn$^{4+}$]$_{0.5}$/[Mn$^{3+}$]$_{0.5}$ and pure LaMnO$_3$ micro regions in the sample.

8:48AM R40.00005: Studying Influence of Normal Metal on Magnetic Properties of Y$_3$Fe$_5$O$_{12}$ Thin Film Locally Using Scanning Ferromagnetic Resonance Force Microscopy  
GUANZHONG WU (Presenter), SHANE WHITE, WILLIAM RUANE, JACK T BRANGHAM, YANG CHENG, FENGYUAN YANG, P CHRIS HAMMEL, Department of Physics, The Ohio State University — We image the boundary separating regions of altered internal magnetic fields in Y$_3$Fe$_5$O$_{12}$(YIG) thin films arising from patterning metal films on the YIG film surface. High quality YIG thin films have proven to be useful for spintronics research. However, detailed investigations of internal magnetic variations in patterned devices are still lacking. Spatial maps of the internal fields were acquired using ferromagnetic resonance force microscopy(FMRFM); a technique allowing for nano to micro-scale spatial resolution and high sensitivity to magnetic fields within the film. FMRFM scans laterally across the YIG-YIG/M (M = Au, Pt) boundary indicate an internal field step that is tens of Gauss. Micromagnetic simulations assuming the presence of uniaxial anisotropy in both the bare YIG and the YIG/M bilayer qualitatively match experimental measurements. We discuss possible physical causes of this field shift, methods used to image the spatial magnetization profile, and implications for future spintronic devices.

9:00AM R40.00006: Effects of the apical-oxygen vacancy and magnetism on the ultra-thin LaNiO$_3$ layer studied using DFT+DMFT  
XINGYU LIAO (Presenter), HYOWON PARK, University of Illinois at Chicago — While the bulk LaNiO$_3$ remains metallic at all temperatures, the ultrathin films of LaNiO$_3$ shows a metal-insulator transition as the layer thickness reduces to 2 unit cells. Recent experiment shows that the NiO$_2$ surface layer without top LaO layer can have higher resistivity than the same NiO$_2$ layer with apical oxygens. In this talk, I will present the density functional theory plus dynamical mean field theory (DFT+DMFT) calculations for the one-layer LaNiO$_3$ slab including the LaAlO$_3$ substrate and the vacuum. The slab geometry with the capping LaO layer is metallic even with DFT+DMFT although Ni eg orbitals are renormalized compared to DFT bands. We also move the top LaO layer away from the surface layer to simulate the effect of apical oxygens on the electronic structure. As the apical oxygen moves away from the Ni ion, an effective charge transfer occurs toward the dz$^2$ orbital and the Wannier orbital level is shifted below the dx$^2$-y$^2$ orbital. Moreover, the DMFT self energy makes the dz$^2$ orbital more incoherent and it eventually becomes Mott insulating in the absence of apical oxygens. We also simulate the antiferromagnetic calculations with the up-up-down-down spin structure as measured in experiment. The results will be also compared with the above paramagnetic calculations.
Synthesis and Characterization of Ru-doped BaSnO$_3$ Thin Films and Heterostructures*  
EMILY LINDGREN (Presenter), URUSA S ALAAN, Materials Science & Engineering, Stanford University, YURI SUZUKI, Department of Applied Physics, Stanford University — Epitaxial doped stannate thin films have been identified recently as high mobility oxide semiconductors that could form the foundation of an all-oxide electronics. Adding magnetic functionality to this class of materials may provide for a spin-based electronics. Toward this end, we have grown epitaxial thin films of Ru doped BaSnO$_3$(BSO) and multilayers of alternating La doped and Ru doped BaSnO$_3$ on (001) SrTiO$_3$ substrates using pulsed laser deposition. X-ray photoelectron spectroscopy was used to verify successful incorporation of both La and Ru into the BSO lattice. X-ray diffraction measurements confirm epitaxial growth of the single layer and multi-layered films. Both single layer and multi-layered films are under epitaxial tensile strain according to X-ray diffraction. Omega rocking curves of both types of samples show excellent crystallinity with typical FWHM values of 0.096° and 0.073°. Both types of films exhibit a paramagnetic response which saturates at approximately 1μ$_B$/Ru$^{4+}$, thus indicating paramagnetism but no ferromagnetic order. Single layer Ru doped BSO films exhibit insulating behavior while layered films have a typical mobility value of 37 cm$^2$/Vs, carrier concentration of $110^{19}$ cm$^{-3}$ and resistivity of 0.4 mΩcm at 300K.

Structural, Electrical and Magnetic Properties of Solid Solution Films between SrRuO$_3$ and BaSnO$_3$  
PINGCHUN WU (Presenter), YING-HAO CHU, National Chiao Tung University — A series of SrRuO$_3$/BaSnO$_3$ solid solutions have been fabricated via laser molecular beam epitaxy. With the help of high-energy electron beam reflection, the ratio of SRO/BSO is precisely controlled in the scale of monolayer. The epitaxial relation was analyzed by x-ray diffraction and transmission electron microscopy. The lattice constants of c-axis varied with the change of the ratio between SRO and BSO, which is consistent with the results calculated by Vegard's law. After successfully fabricate a series of SRO/BSO, temperature-dependent resistances measurement has been carried out. It was found that electrical behavior of SRO/BSO was varied from pure metallic to insulating while the ratio of BSO increased in the solid solutions. A metal-insulating transition can also be found in specific ratio. Further, the increase of BSO will result in an enlarged magnetoresistance in the solid solutions. In the magnetic hysteresis loops, the decrease in saturated magnetic moment, coercivity and the change in anisotropy can also be found. This experiment realizes an accurately control of solid solutions in the scale of monolayer. The structural, electrical and magnetic properties of SRO/BSOs have been systematically analyzed and the origin of these differences has also been discussed.

Magnetic Field Control of the Fermi Surface Topology in EuTiO$_3$  
KAVEH AHADI (Presenter), University of California, Santa Barbara, XUEZENG LU, Northwestern university, SALVA SALMANI-REZAIE, PATRICK MARSHALL, University of California, Santa Barbara, JAMES M RONDINELLI, Northwestern university, SUSANNE STEMMER, University of California, Santa Barbara — Spin-orbit coupling plays a central role in the anomalous Hall effect (AHE) of itinerant ferromagnets and in materials with topologically non-trivial electronic states. Recently, AHE attracted significant attention in antiferromagnetic metals and semiconductors. For example, significant AHEs in non-collinear antiferromagnets have been discovered. The degenerately doped antiferromagnetic semiconductor EuTiO$_3$ is a unique testbed for these ideas for several reasons. Despite a small net magnetization, it exhibits an intrinsic AHE that changes sign as a function of the carrier density. We report on the symmetry of the anisotropic magnetoresistance (AMR) in doped EuTiO$_3$ films as a function of the applied magnetic field. Multiple transitions in the AMR symmetry are observed and are attributed to magnetic field induced changes in the band topology. At high fields a transition from positive to negative magnetoresistance coincides with change from four-fold to two-fold symmetry in the AMR. This indicates a non-trivial phase transition in the electronic structure. We discuss the results in the context of Weyl points that form in the band structure of the EuTiO$_3$.

9:48AM R40.00010: Electronic wave function spatial extension of the oxygen vacancies on EuO$_{1-x}$ surface.*

TE-YU CHIEN (Presenter), AARON WANG, University of Wyoming, GAURAB RIMAL, Rutgers University, ROBERT NIELSEN, YURI DAHNOVSKY, JINKE TANG, University of Wyoming — EuO$_{1-x}$ thin films deposited by pulsed laser deposition on Si(100) were studied by scanning tunneling microscopy and spectroscopy at room temperature. Oxygen vacancies in EuO$_{1-x}$ are visualized through dI/dV mapping and the apparent sizes of the oxygen vacancies are found to be 1.8 nm ± 0.5 nm. These apparent sizes are considered as the spatial extension of the electron wave function originated from the oxygen vacancies. It is further argued that this observed electronic wave function might be the precursor of the bound magnetic polaron formation occurred at lower temperature. Moreover, some of the oxygen vacancies were found (1) hopping to adjacent site; (2) emerging (vacancy creation); and (3) disappearing (vacancy annihilation), indicating that the oxygen vacancies on the EuO$_{1-x}$ surface at room temperature are not extremely stable.

10:00AM R40.00011: Magnetic phase transitions in thin films of the near-itinerant spinel CoV$_2$O$_4$*  

CHRISTIE J THOMPSON, Materials Science and Engineering Program and National High Magnetic Field Laboratory, Florida State University, CHRISTIANNE BEEEKMAN (Presenter), Physics and National High Magnetic Field Laboratory, Florida State University — Spinel vanadates are frustrated antiferromagnets, of interest due to the orbital physics that can be tuned via structural perturbations. The V-V distance determines proximity of the system to a localized-itinerant crossover, with CoV$_2$O$_4$ the closest known material to this transition. Previously, we have shown that CoV$_2$O$_4$ films are orthorhombic rather than cubic. The films undergo a spin canting/orbital order transition at low temperature, i.e., they show very different magnetic properties compared to bulk [1]. Based on recent magnetization measurements as a function of temperature we find signatures of three distinct magnetic transitions in the films. We investigate temperature, field, and film thickness dependence of these transitions, and we discuss the roles that single-ion anisotropy and shape anisotropy play.

10:12AM R40.00012: Room-temperature ferromagnetic insulating state in highly cation-ordered Sr$_2$Fe$_{1+x}$Re$_{1-x}$O$_6$ films*  

CHANG HEE SOHN (Presenter), ELIZABETH SKOROPATA, Materials Science and Technology Division, Oak Ridge National Laboratory, YONGSEONG CHOI, Advanced Photon Source, Argonne National Laboratory, XIANG GAO, ANKUR RASTOGI, Materials Science and Technology Division, Oak Ridge National Laboratory, AMANDA HUON, Department of Materials Science & Engineering, Drexel University, MICHAEL A MCGUIRE, Materials Science and Technology Division, Oak Ridge National Laboratory, LAUREN NUCKOLS, Department of Materials Science and Engineering, University of Tennessee, YANWEN ZHANG, Materials Science and Technology Division, Oak Ridge National Laboratory, JOHN WILLIAM FREELAND, DANIEL HASKEL, Advanced Photon Source, Argonne National Laboratory, HO NYUNG LEE, Materials Science and Technology Division, Oak Ridge National Laboratory — Ferromagnetic insulators with high Curie temperatures are critical components for developing quantum electronic/spintronic devices. However, since ferromagnetism generally accompanies metallicty, ferromagnetic insulators have been very limited in nature. Here, we report a highly insulating ferromagnetic state found in 3d-5d double perovskite Sr$_2$Fe$_{1+x}$Re$_{1-x}$O$_6$ (-0.2<x<0.2) epitaxial films by modifying the Fe/Re ratio. Beyond the original ferromagnetic metallic ground state in a stoichiometric film, Fe-rich films showed demanding ferromagnetic insulating states with three orders of higher room-temperature resistance than that of the metallic film, a high Curie temperature about 400 K, and a large saturated magnetization about 1.8 uB/f.u. In this presentation, we discuss about the growth, related physical properties, and the origin of the emerging ferromagnetic insulating state based on x-ray and optical spectroscopy.

10:24AM R40.00013: Observation of Compensation Temperature in Epitaxial Tm$_3$Fe$_5$O$_{12}$ Thin Films by Polar Magneto-Optic Kerr Effect  

YANJUN MA (Presenter), CHENG CEN, West Virginia University — Since ferrimagnetic rare-earth iron garnets (RIG) R$_3$Fe$_5$O$_{12}$ are excellent insulators with Curie temperatures well above room temperature, such materials have been extensively exploited in spintronics, leading to novel discoveries such as anomalous Hall effect in the heterostructure formed by topological insulator and Tm$_3$Fe$_5$O$_{12}$ (TmIG). While the recent research on TmIG thin films has been focusing on the behavior of their perpendicular magnetic anisotropy (PMA) in high temperature region, the magnetic properties of TmIG thin films at lower temperatures are elusive. In this report, we measured the low temperature magnetic properties of epitaxial TmIG films by polar magneto-optic Kerr effect. The divergence of the out-of-plane coercive filed and the reverse of the sign of out-of-plane magnetization were observed consecutively, indicating the existence of compensation temperature in TmIG. Further investigation showed that the temperature making divergent was dependent on the thickness and strain state of the film. Since the compensation temperature in bulk TmIG has never been established, our findings demonstrate that it is worth investigating low temperature magnetism in low dimensional rare-earth iron garnets to advance the research of RIG-based spintronics.

10:36AM R40.00014: Exotic Ferroelectric and Multiferroic Properties in Epitaxial YFeO$_3$ Thin Films and YFeO$_3$-CoFe$_2$O$_4$ Nanocomposites  

SHUAI NING (Presenter), CAROLINE ANNE ROSS, MIT — Multiferroics have been attracting considerable interest in the past decades, and researchers never stop searching for materials exhibiting multiferroic behavior. For orthoferrites, there should be no ferroelectricity in theory due to their centrosymmetric structure. However, when epitaxially grown, the strain can significantly modify the symmetry and physical properties. Here, we present the exotic ferroelectric properties of epitaxial YFeO$_3$ (YFO) thin films on perovskite substrates prepared by pulsed laser deposition (PLD). A nearly single-domain structure is observed in as-grown 40 nm-thick YFO thin films characterized by Piezoresponse force microscopy (PFM), and it can be fully switched suggested by the ideal ferroelectric hysteresis loop and by domain patterns written by a bias of +/- 8 V. The spontaneous polarization direction is highly dependent on the epitaxial strain, which could be tuned either out-of-plane or in-plane. Via co-deposition by PLD, the nanocomposites consisting of YFO and CoFe$_2$O$_4$ (CFO) have been prepared, in which phase separation is successfully achieved. Both ferroelectricity and ferromagnetism are observed originating from YFO and CFO respectively, indicating a promising magnetoelectric coupling in this 2-phase multiferroic nanocomposite.

Session R41 GMAG DMP: Spin Dynamics II  

8:00AM R41.00001: Nanometer-Thick YIG-Based Magnonic Crystals with Large Tunable Bandgaps  

HUAJUN QIN, GERT-JAN BOTH, SAMPO J. HÄMÄLÄINEN, SEBASTIAAN VAN DIJKEN (Presenter), Department of Applied Physics, Aalto University, Finland — Control of information-carrying spin waves in magnonic crystals is essential for the development of magnon-based computing. Crystals comprised of a periodic array of ferromagnetic metals offer versatility in band structure design, but strong magnetic damping restricts their transmission efficiency. Yttrium iron garnet (YIG) with ultralow damping is the palpable alternative, yet its small magnetization limits dynamic dipolar coupling between discrete units in the technological imperative Damon-Eshbach (DE) geometry. Here, we experimentally demonstrate low-loss spin-wave manipulation in one-dimensional magnonic crystals of physically separated nanometer-thick YIG stripes. We enhance the transmission of DE spin waves in allowed minibands by filling the gaps between the stripes with CoFeB. The thus-formed magnonic crystals exhibit tunable bandgaps of 50 MHz - 200 MHz with nearly complete suppression of the spin-wave signal. We also show that efficient Bragg scattering on just two airgaps or two CoFeB stripes already produces clear frequency gaps in spin-wave transmission spectra.
**8:12AM R41.00002: Ferromagnetic resonance and proximity effect in WTe$_2$/magnetic insulator heterostructure**

PENG LI (Presenter), Department of Applied Physics, Stanford University, EDBERT JARVIS SIE, Department of Materials Science and Engineering, Stanford University, JACOB WISER, LAUREN RIDDIFORD, AARON ALTMAN, Department of Applied Physics, Stanford University, AARON LINDENBERG, Department of Materials Science and Engineering, Stanford University, YURI SUZUKI, Department of Applied Physics, Stanford University — Integration of FMI films with 2D materials or topological insulators has proven to be promising for the demonstration of spin-orbit torque switching and more efficient spintronic devices. As an alternative to YIG, we have identified spinel ferrite MgAl$_{0.5}$Fe$_{1.5}$O$_4$ (MAFO) for the spin source material. The Gilbert damping constant of MAFO is 0.001, similar in magnitude to typical YIG. In this work, we have realized bilayer structures of exfoliated nanometer thick WTe$_2$ flakes on top of low damping MAFO thin films. The samples were post-annealed at 300 $^\circ$C for 5 h at a vacuum pressure, giving rise to strong exchange coupling between the 2D and the MAFO layers. Raman spectroscopy showed that WTe$_2$ maintained the desired phase after processing. Together with atomic force microscopy, the thickness of WTe$_2$ was estimated to be several atomic layers. Magnetoresistance measurements revealed a hysteresis loop that was correlated with the magnetization curves of MAFO. These results suggest proximity-induced ferromagnetism in the WTe$_2$ atoms at the interface. We characterized our samples with spin-torque ferromagnetic resonance. This new WTe$_2$/magnetic insulator system is promising for future spinel ferrite insulator based spin current devices.

**8:24AM R41.00003: The Effect of Defects on Precessional Dynamics in a Magnetic Field and Resulting Spin Wave Modes in Elliptical Nanomagnets with In-Plane Anisotropy**

MD AHSANUL ABEED, Electrical and Computer Engineering, Virginia Commonwealth University, SOURAV SAHOO, Condensed Matter Physics and Materials Science, S. N. Bose National Center for Basic Sciences, DAVID WINTERS, Electrical and Computer Engineering, Virginia Commonwealth University, ANJAN BARMAN, Condensed Matter Physics and Materials Science, S. N. Bose National Center for Basic Sciences, SUPRIYO BANDYOPADHYAY (Presenter), Electrical and Computer Engineering, Virginia Commonwealth University — We have simulated the precessional dynamics of magnetization in elliptical nanomagnets biased with an in-plane magnetic field along the minor axis and perturbed by a small out-of-plane magnetic field. The precessional dynamics gives rise to spin wave modes in the nanomagnets. We first calculate the time-dependent out-of-plane component of the magnetization at a fixed plane of the magnet at various coordinate points and also the spatially averaged magnetization as a function of time. We then find the Fourier transform of the spatially averaged component to find the dominant precessional frequencies (which do not necessarily correspond to the Kittel frequencies) and calculate the power and phase profiles of the spin wave modes at those frequencies. We find that the spin wave modes are significantly affected by the presence of defects in the nanomagnets. We have studied six different types of defects arising from material voids and thickness variations which are realistic defects that arise during fabrication processes. Our results show that the spin wave modes are significantly affected by defects. This has a serious implications for devices that rely on spin wave modes such as oscillators and neuromorphic computers based on phase locked oscillators.

**8:36AM R41.00004: Spin-current-mediated rapid magnon localization and coalescence after ultrafast optical pumping of ferrimagnetic alloys**

EZIO IACOCCA (Presenter), University of Colorado, Boulder, ALEX REID, SLAC National Accelerator Laboratory, ALEXEY KIMEL, THEO RASING, Radboud University, ROY CHANTRELL, University of York, MARK A HOEFER, University of Colorado, Boulder, THOMAS SILVA, NIST, HERMANN DÜRR, Uppsala University — We find evidence of rapid magnetic order recovery via nonlinear magnon processes after ultrafast demagnetization of amorphous GdFeCo thin films with perpendicular magnetic anisotropy. The spatial evolution of the magnetization is measured by time-resolved resonant X-ray scattering and modelled by atomistic and multiscale micromagnetic simulations. We identify both localization and coalescence processes. During localization a paramagnetic state evolves into a collection of localized textures while coalescence describes their growth, break-up, and merging. The characteristic length scale during coalescence is found to grow according to a power law in both experiments and simulations. Our results shed light into the physical mechanisms that are important for the picosecond recovery of magnetic order.

Magnon-mediated Neel torques and magnonic responses to Neel order dynamics

Using the Neel ground state, we formulate a microscopic linear response theory of magnon-mediated Neel torques generated by the thermal gradient in collinear antiferromagnets. We also describe the inverse effects in which spin and heat currents are induced by the Neel order dynamics. We obtain the extrinsic and intrinsic contributions where the intrinsic contributions are related to the mixed space Berry curvature. We derive a closed equation of motion of Neel dynamics in antiferromagnets related to thermal Neel torque from linearized LLG equation. We confirm that the Neel torque effect is related to the inverse effect by the Onsager relations. We apply our theory to honeycomb antiferromagnet and confirm that a net magnon-mediated heat current can be induced by the Neel order precession.

General method for atomistic spin-lattice dynamics with first principles accuracy

A computationally efficient general first-principles based method is presented, with applications for spin-lattice simulations for solids and clusters. The method is based on a combination of atomistic spin dynamics and molecular dynamics, expressed through a spin-lattice Hamiltonian where the bilinear magnetic term is expanded to second order in displacement. The effect of first-order spin-lattice coupling on the magnon and phonon dispersion in bcc Fe is reported as an example, and is seen to be in good agreement with previous simulations performed with an empirical potential approach. In addition, we also illustrate the abilities of our method on a more conceptual level, by exploring dissipation free spin and lattice motion in small magnetic clusters.

Magnetic Vortex as a Spin Wave Filter

In the Landau state, the Néel wall is divided into two regions of opposite magnetization, separated by a vortex. In this work, we show, through micromagnetic simulations, that excitations performed at one region are mostly reflected by the vortex, but they can be transmitted at specific frequencies.

The frequency of the maximum transmitted wave (FTW) can be tuned by changing the uniaxial or shape anisotropy of the system. Considering a (4x1) μm² permalloy rectangle, the FTW has a quadratic behavior with the uniaxial anisotropy energy of the system, passing through a minimum of 500 MHz at 100 kJ/m³. By fixing the aspect ratio of the rectangle, if the area is increased, the FTW decreases exponentially. E.g., for a fixed 4 μm length, the FTW can be tuned between 800 MHz and 2 GHz by varying the width. Therefore, the vortex acts a tunable frequency filter for the channeled spin-waves.

ABSTRACT WITHDRAWN
9:36AM R41.00009: Dynamical amplification of magnetoresistances and Hall currents up to the THz regime* FILIPE GUIMARAES (Presenter), MANUEL DOS SANTOS DIAS, JUBA BOUAZIZ, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, ANTONIO COSTA, ROBERTO B. MUNIZ, Instituto de Física, Universidade Federal Fluminense, SAMIR LOUNIS, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich — The quest for device miniaturization, decreased energy consumption, and improved speeds of processing and storage units naturally led to exploiting the connection between electric currents and magnetization dynamics. In this presentation, I demonstrate that ferromagnetic and antiferromagnetic excitations can be triggered by the dynamical spin accumulations induced by the bulk and surface contributions of the spin Hall effect [1]. I also analyze the general concepts of magnetoresistance and Hall effects together with spin-orbit-related mechanisms to demonstrate how dynamical currents can be dramatically enhanced and precisely controlled by applying ac electric fields and static magnetic fields, in a materials-specific approach [2]. This work may also impact experimental techniques that use currents to probe and quantify magnetization precession and the torques that induce it.

9:48AM R41.00010: Bound-state spin-wave spectroscopy exploiting nonlinear three-magnon processes ZHENYU WANG, BEINING ZHANG, YUNSHAN CAO, PENG YAN (Presenter), University of Electronic Science and Technology of China — One recent breakthrough in the field of magnonics is the experimental realization of reconfigurable spin-wave nanochannels formed by a magnetic domain wall with a width of 10–100 nm. This remarkable progress enables an energy-efficient spin-wave propagation with a well-defined wave vector along its propagating path inside the wall. In the mentioned experiment, a microfocus Brillouin light scattering spectroscopy was taken in a line-scans manner to measure the frequency of the bounded spin wave. Due to their localization nature, the confined spin waves can hardly be detected from outside the wall channel, which guarantees the information security to some extent. In this work, we theoretically propose a scheme to detect/eavesdrop on the spin waves inside the domain-wall nanochannel via nonlinear three-magnon processes [1]. The approach can be parallely applied for probing the Dzyaloshinskii-Moriya interaction in narrow magnetic stripes [2]. The idea is analytically formulated with micromagnetic simulations performed to verify the theoretical predictions.

10:00AM R41.00011: Transverse spin currents carried by surface spin waves in obliquely magnetized magnetic films CODY TREVILLIAN (Presenter), VASYL S TYBERKEVYCH, Oakland University — Properties of spin waves (SWs) are well-studied in perpendicular and in-plane magnetized magnetic films, but are understood much worse in the case of oblique magnetization (OM). Recent studies [1, 2] show an unexpected and interesting effect in OM films, namely, an appearance of transverse spin currents (TSCs) carried by SWs propagating in the backward-volume-type geometry. Here, we theoretically study this effect for surface SWs propagating approximately perpendicularly to the bias magnetic field (Damon-Eschbach-type geometry). We show, that the TSC resonantly depends on the direction of SW propagation, reaching maximum when SWs propagate several degrees away from the normal to the bias field. The maximum TSC of surface SWs significantly exceeds that of volume SWs, which makes surface SWs preferable for experimental study of TSCs.

10:12AM R41.00012: Off-resonance excitation of spin waves by a four-magnon process  ROBERT MCMICHAEL  (Presenter), PAUL HANEY, National Institute of Standards and Technology — Recent experiments have shown that driving ferromagnetic resonance in thin films generates noisy stray fields over a broad frequency spectrum [1-3]. The noise has been attributed to spin waves excited through a four-magnon mechanism, although the specifics of the mechanism have not been identified. In this paper we present modeling of one such mechanism that relies on nonuniform fluctuations in $M_s$ owing to thermal excitation. With $M_s$ fluctuating, a uniform driving field at frequency $f_0$ will excite spin waves at frequencies $f_k$. The uniform processional mode adds a resonant amplification of the driving field. The predicted spin wave noise power is proportional to input microwave power, $T^2$, and $1/f_k^4$ (temperature $T$, spin wave frequency $f_k$). We find the most relevant spin waves for this process are near the bottom of the spin wave band. Numerical evaluation yields spin wave noise power that is roughly a factor of $10^2$ weaker than the noise power due to pure thermal excitation. However, this result can be regarded as a lower bound. The effect may be much larger if the $M_s$ fluctuations are due to spin waves that are excited above equilibrium [3].

10:24AM R41.00013: Berry curvature and topological edge modes for coupled waves between magnons and electromagnetic waves*  AKIHIRO OKAMOTO (Presenter), SHUICHI MURAKAMI, Physics, Tokyo Institute of Technology, RYUICHI SHINDOU, School of Physics, Peking University — The Chern number characterizes existence of the chiral topological edge modes inside the gap. The chiral topological edge modes are well studied in electronic systems, and they can be realized in photonic crystals and magnonic crystals, in which the time-reversal symmetry is broken. In addition to systems with a single kind of particles, systems consisting of more than two kinds of particles or quasiparticles attract much attention recently, in the context of topological phases.

In this presentation, we consider coupled waves between magnons and electromagnetic waves in a ferromagnet. The Berry curvature is enhanced at the crossing point of dispersions, as is the case for other coupled waves such as magnons with the dipolar hybridization and magnetoelastic waves. The Chern number, i.e. the integral of the Berry curvature for the coupled waves between the magnon and the electromagnetic wave is quantized. We find that the hybridization gap in this case is topological. Therefore, there exist topological chiral edge modes inside this gap. We also present an emergence of edge modes at an interface between two topologically different regions.

10:36AM R41.00014: Effects of Carbon Content on Magnetic and Microwave Properties of Iron Gallium Carbon Thin Films  XIANFENG LIANG (Presenter), CUNZHENG DONG, NIAN XIANG SUN, Northeastern University — A systematic investigation of the soft magnetism, delta E effect, magnetostriction, and microwave properties has been carried out on iron gallium carbon (Fe-Ga-C) thin films over a wide carbon content range. The phase transformation of the Fe-Ga-C films from bcc polycrystalline to amorphous phase leads to excellent magnetic softness with a low coercivity of less than 1 Oe, high 4pMs, narrow ferromagnetic resonance (FMR) linewidth at 10 GHz of 20~30 Oe and ultra-low Gilbert damping constant of 0.0027. A record high piezomagnetic coefficient of 9.71 ppm/Oe, high saturation magnetostriction constant of 81.2 ppm, and large delta E effect of -120 GPa at 500 nm are also achieved. The soft magnetism, large delta E effect and piezomagnetic coefficient combined with ultra-low Gilbert damping constant make Fe-Ga-C thin film an attractive alloy for magnetoelectric and other voltage tunable RF/microwave device applications.
It has attracted great interests to explore efficient methods to control both the polarity and chirality of magnetic vortex in last decades. Here we report a new mechanism to control both the vortex chirality and polarity by electrical current, which is through the formation, decoupling and fusion of edge solitons. Our micromagnetic simulation show that the dynamics of the edge solitons at the disk edge can lead to selective switching of the vortex chirality and polarity. A way to directly write any of the four vortex states from any random states is proposed based on the switching diagram. The switching phase diagram as a function of disk diameters shows that the vortex chirality and polarity switching process is highly size-dependent. As the disk diameter scales down to below 160 nm, the vortex chirality and polarity are coupled together and always switch at the same time, resulting in an unchanged handedness before and after switch. Furthermore, the critical switch current can be as low as $3 \times 10^6$ A/cm$^2$. Our work offers an efficient way to control vortex chirality and polarity, which may have great application potential in the low-energy and high-density memory application.

Session R42 DQI: Quantum Annealing: Theory BCEC 210A

8:00AM R42.00001: Adaptive quantum annealing based on weak measurements to suppress the errors due to Landau-Zener transitions* YONGCHAO TANG (Presenter), ANTONIO MARTINEZ, University of Waterloo, SONG ZHANG, JUAN ATALAYA, BIRGITTA K WHALEY, University of California, Berkeley, ADRIAN LUPASCU, University of Waterloo — Quantum annealing is undermined by Landau-Zener transitions from the ground to the first excited state around small energy gaps. This kind of error can be suppressed by slowing down quantum annealing near the minimum gap. We study the relationship between the minimum gap and potential observables that can be used to gain information on the minimum gap using weak measurements. The measurement of energy curvature is promising as a measure of the location of the minimum gap. We apply master equations for the quantum annealing monitored by weak measurements to study the impacts of noise. The simulations show that Landau-Zener type errors can be suppressed by making the rate of quantum annealing dependent on monitoring with weak measurements.

8:12AM R42.00002: Feedback control of a monitored system evolving adiabatically* KA WA YIP (Presenter), DANIEL ALIDAR, University of Southern California — Time evolution of a system evolving adiabatically while coupled weakly to a thermal bath can be described by a quantum adiabatic master equation in Lindblad form. In quantum annealing it is desirable is to maintain the state as the ground state of the time-dependent Hamiltonian. This is difficult due to diabatic or thermal transitions. We devised a quantum feedback control method to reverse the effect of thermal excitation. Under specific continuous measurement schemes, quantum trajectories of the measurement records can be obtained and feedbacks conditioned on these records can be applied to increase the ground state population. We derived the feedback master equation for markovian feedback (feedback delay $\tau \to 0$) and further gave the timescale condition for feedback Markovianity. However, realistic feedbacks are non-markovian and subjected to non-negligible feedback delay, detector efficiency and restrictions of the form of the feedback Hamiltonian. We studied the effectiveness of feedback control under such limitations and explored how the optimized feedback delay time depends on the annealing schedule.

*Based upon work (partially) supported by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA).
Many-body quantum systems provide a mechanism for robust and efficient quantum search

KOSTYANTYN KECHEDZHI (Presenter), VADIM SMELYANSKIY, Google Inc., LARA FAORO, LPHE, CNRS, SERGIO BOIXO, HARTMUT NEVEN, Google Inc., LEV B IOFFE, Department of Physics, University of Wisconsin, BORIS ALTSHULER, Physics Department, Columbia University — Searching low energy subspace of a classical spin glass is computationally hard due to landscape of deep local minima separated by barriers. Applying a transverse field gives rise to tunneling between the quantum states defined within individual spin-glass minima. The number of transitions from a state grows exponentially with the number d of spin flips during the transition. This growth can compensate the decrease of the matrix elements with d leading to a transition from many-body localized to non-ergodic extended phase, where eigenstates are sparse superpositions of spin configurations corresponding to local minima within a narrow energy belt. We demonstrate a remarkable structure in the low energy eigenspectrum: it is partitioned into the alternating sequence of bands of two qualitatively different types, x- and z-, which retain characteristics of transverse field eigenstates and classical spin glass, respectively. We demonstrate this novel intermittency in a "wide band" impurity model with a bi-modal classical density of states with a delta-peak at zero energy containing most states and the second peak containing an exponentially smaller number of states lying at low energy. This non-ergodic structure of the eigenspectrum provides a mechanism for efficient quantum search.

Control of Phase Transitions in Wajnflasz–Pick model

YUYA SEKI (Presenter), Nanoelectronics Research Institute, National Institute of Advanced Industrial Science and Technology, SHU TANAKA, Green Computing Systems Research Organization, Waseda University, SHIRO KAWABATA, Nanoelectronics Research Institute, National Institute of Advanced Industrial Science and Technology — We construct a quantum Wajnflasz–Pick model, and investigate a nature of quantum phase transitions of the model. Quantum phase transition phenomena have drawn attention in the field of quantum computing as well as condensed matter physics, since the phenomena are closely related to the performance of quantum annealing (QA) and quantum adiabatic computation (QAC). Adding a driver Hamiltonian that causes spin flip and state transitions within upper and lower states to the Hamiltonian of classical Wajnflasz–Pick model, we construct the quantum model where phase transitions are controllable. Numerical analysis showed that the model undergoes first-order phase transitions whereas a corresponding spin-1/2 model does not undergo first-order phase transitions. In particular, we observed an anomalous phenomenon that the system undergoes first-order phase transitions twice under certain conditions. The results indicate that the performance of QA and QAC can be affected by the choice of the number of upper and lower states and the parameter in the driver Hamiltonian.

Energy gap scaling of quantum annealing based on Wajnflasz–Pick model

SHOHEI WATABE (Presenter), Tokyo University of Science, YUYA SEKI, SHIRO KAWABATA, Nanoelectronics Research Institute, National Institute of Advanced Industrial Science and Technology — The conventional quantum annealer, transverse field Ising model, is known to suffer from the energy gap shrinkage for the scalable system, which may not provide the solution of the optimization problem within the realistic time scale. An idea for possibly overcoming this problem proposed by Seki, Tanaka, and Kawabata is to employ the Wajnflasz–Pick model, i.e., a qudit. By analyzing the order of the phase transition within the mean-field approach with the uniform interaction, they have found that the performance of quantum annealing is controlled by the number of upper and lower states of the spin. In this study, in order to confirm their claim, we revisit the energy gap of the finite size Wajnflasz–Pick model with all-to-all random interaction.

*This presentation is based on results obtained from a project commissioned by the New Energy and Industrial Technology Development Organization (NEDO), Japan.
FERGUSON, SERGEY NOVIKOV, Northrop Grumman, HUO CHEN, DANIEL A LIDAR, University of Southern California — Annealing terms, as well as the values of the ferromagnetic couplings to be used in the minor embedding problem. In this talk I will focus on the parameter setting problem, that is how to find the optimal weights to be used in penalty hosted at NASA Ames with different values of the parameters will be discussed. Hamiltonian corresponds to the solution of the original problem. Finally, benchmark results using the D-Wave 2000Q chip implemented topology of the chip. These results show how state-of-the-art statistical learning algorithms can quantify the performance of physical quantum annealers, suggest a path towards mitigating the effects of persistent biases inevitably present in every analog device, and guide the design of new hardware architectures.

*This material is based upon work supported by the Intelligence Advanced Research Projects Activity (IARPA) through the Army Research Office (ARO) Contract No. W911NF-17-C-0050. HAYATO GOTO (Presenter), TARO KANAO, Toshiba Corporation — Adiabatic quantum computation (AQC) with Kerr-nonlinear parametric oscillators, or KPOs for short, has been proposed [1-3], which is called bifurcation-based AQC [1]. The Hamiltonian used there is an effective one in a rotating frame and in the rotating-wave approximation. This is a notable difference between this approach and standard AQC using real Hamiltonians. Based on this difference, here we propose a method to improve the performance of bifurcation-based AQC, which is not applicable to standard AQC using real Hamiltonians.

ANDREA DI GIOACCHINO (Presenter), University of Milan - Quantum Artificial Intelligence Lab (QuAIL) @ NASA Ames - Stinger Ghaffarian Technologies (SGT), SALVATORE MANDRA, Quantum Artificial Intelligence Lab (QuAIL) @ NASA Ames - Stinger Ghaffarian Technologies (SGT), ELEANOR RIEFFEL, Quantum Artificial Intelligence Lab (QuAIL) @ NASA Ames — Solving a combinatorial optimization problem with the current generation of adiabatic quantum devices, as the D-Wave 2000Q, requires to express the cost function of the optimization problem in the QUBO form, which in many cases includes penalty terms to enforce hard constraints. A similar problem appears when a minor embedding is necessary to map the QUBO Hamiltonian on a specific hardware graph. Interestingly, the performance of both classical and quantum heuristics is very sensible to the choice of such penalty terms and an optimal choice of parameters could result in much faster computations than those ones performed with sub-optimal parameter values.

In this talk I will focus on the parameter setting problem, that is how to find the optimal weights to be used in penalty terms, as well as the values of the ferromagnetic couplings to be used in the minor embedding problem.

I will also present a method to find the minimum parameter values which guarantee that the ground state of the QUBO Hamiltonian corresponds to the solution of the original problem. Finally, benchmark results using the D-Wave 2000Q chip hosted at NASA Ames with different values of the parameters will be discussed.

*This project has received funding from Università degli Studi di Milano and NASA Ames Research Center.

ANDREY LOKHOV (Presenter), Los Alamos National Laboratory, YAROSLAV KHARKOV, University of New South Wales, CARLETON COFFRIN, MARC VUFFRAY, Los Alamos National Laboratory — Quantum annealers have a potential to provide a breakthrough in hard optimization and machine learning problems. Emerging physical implementations of quantum annealers are extremely sophisticated from the engineering point of view, and prediction of their performance remains a challenging problem. Here, we uncover the probabilistic relation between input and output of quantum annealers using the novel rigorous statistical learning tools. Extensive analysis of the output data allows us to check whether it satisfies the desired features assumed in the initial design of the device, to learn the machine's global response function, and to detect the echo of the chip architecture. In particular, our tests on D-Wave 2X and 2000Q quantum annealers revealed the presence of multi-body interactions and spurious next-nearest neighbor couplings between qubits as compared to the hardware-implemented topology of the chip. These results show how state-of-the-art statistical learning algorithms can quantify the performance of physical quantum annealers, suggest a path towards mitigating the effects of persistent biases inevitably present in every analog device, and guide the design of new hardware architectures.
9:48AM R42.00010: Quantum annealing and thermalization: insights from integrability*  
FUXIANG LI (Presenter), School of Physics and Electronics, Hunan University, NIKOLAI SINITSYN, Theoretical division, Los Alamos National Lab, VLADIMIR Y CHERNYAK, Department of Chemistry and Department of Mathematics, Wayne State University — We solve a model that has basic features that (are desired for quantum annealing computations: entanglement in the ground state,) controllable annealing speed, ground state energy separated by a gap during the whole evolution, and programmable computational problem that is encoded by parameters of the Ising part of the spin Hamiltonian. Our solution enables exact nonperturbative characterization of final nonadiabatic excitations, including scaling of their number with the annealing rate and the system size.

10:00AM R42.00011: The computational complexity of optical quantum annealers and Ising machines*  
RAPHAEL POOSER (Presenter), RYAN BENNNK, Computational Sciences and Engineering Division, Oak Ridge National Laboratory — Quantum annealers hold promise as optimization platforms for quantum machine learning applications and as layered neural networks. Recently, Optical Ising Machines (OIM) have been presented as a straight forward method to achieve this computational model. Relying on optical nonlinearities inside resonators, these devices are a network of coupled optical parametric oscillators (OPOs), a mature and practical technology in the field of continuous-variable quantum computing (CVQC). Despite the use of a key ingredient of CVQC (the second order nonlinearity which facilitates entanglement), the computational model of OIMs remains an open question. Here, we present a study of three different computational models based on physics of increasing complexity. We outline a fully classical nonlinear system of coupled oscillators, a semiclassical model of OPOs in the truncated Wigner representation, and a fully quantum treatment in the positive P representation. We present benchmarks of each model and outline their relative capability to capture the relevant physics responsible for practical computation in OIMs. Using these benchmarks, based on known quadratic optimization problems, we determine the computational complexity of these devices.

10:12AM R42.00012: The power of pausing: advancing understanding of thermalization in experimental quantum annealers*  
JEFFREY MARSHALL (Presenter), University of Southern California and NASA Ames Research Center, DAVID VENTURELLI, NASA Ames Research Center, ITAY HEN, University of Southern California, ELEANOR RIEFFEL, NASA Ames Research Center — We investigate annealing schedules involving an intermediate pause, on the current generation of quantum annealing hardware: the D-Wave 2000Q. We show that a pause mid-way through the anneal can cause a dramatic change in the output distribution, and we provide evidence suggesting thermalization is occurring during such a pause. We demonstrate that upon pausing the system in a narrow region shortly after the minimum gap, the probability of successfully finding the ground state of the problem Hamiltonian can be increased by several orders of magnitude. We relate this effect to relaxation, after excitations occurring in the region near to the minimum gap. For a set of problems of size 500 qubits we demonstrate that the distribution returned from the annealer very closely matches a classical Boltzmann distribution of the problem Hamiltonian, albeit one with a noticeably higher temperature than that of the device.

10:24AM R42.00013: Understanding the Role of Non-stoquastic Catalysts in Quantum Adiabatic Optimization*  
TAMEEM ALBASH (Presenter), University of Southern California — The viability of non-stoquastic catalyst Hamiltonians to deliver consistent speedups in quantum adiabatic optimization remains an open question. Several studies (Crosson et al. (2014), Hormozi et al. (2017)) on random Ising problems have shown that stoquastic catalysts typically outperform non-stoquastic ones. A stark counterexample to this is the exponential speedup of non-stoquastic catalysts over stoquastic ones for infinite-range ferromagnetic p-spin models with p > 3 (Seki & Nishimori (2012)). We provide details on how the non-stoquastic catalyst provides an advantage in these models. We use this insight to then construct a geometrically local 2-body example that exhibits a similar exponential advantage for a non-stoquastic catalyst over a stoquastic one, up to the maximum system size we are able to study.

10:36AM R42.00014: Gap-independent cooling and hybrid quantum-classical annealing (HQCA)*
LUKAS S THEIS, PETER SCHUHMACHER (Presenter), MICHAEL MARTHALER, FRANK K WILHELM, Theoretische Physik, Saarland University — We present an efficient gap-independent cooling scheme for a quantum annealer that benefits from finite temperatures. We choose a system based on superconducting flux qubits as a prominent example of current quantum annealing platforms. We propose coupling the qubit system transversely to a coplanar waveguide to counter noise and heating that arise from always-present longitudinal thermal noise. We provide a schematic circuit layout for the system and show how, for feasible coupling strengths, we achieve global performance enhancements. Specifically, we achieve cooling improvements of about 50% in the adiabatic and a few hundred percent in the non-adiabatic regime, respectively.

*The research is based upon work (partially) supported by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), via the U.S. Army Research Office contract W911NF-17-C-0050.

10:48AM R42.00015: Enhancing quantum adiabaticity in adiabatic quantum computers with multiple local minima*
LIN TIAN (Presenter), University of California, Merced — The adiabatic criterion is a key requirement for the successful implementation of adiabatic quantum computing. However, in interacting many-body systems, the energy gap often decreases quickly with the number of qubits, which results in the violation of the adiabatic criterion and diabatic transition to the excited states. In a recent work [1], we presented an approach to enhance quantum adiabaticity that does not require the spectral knowledge of the adiabatic quantum computers or the construction of unphysical many-body interactions. In this talk, we show that this approach can be applied to adiabatic quantum computers with multiple local minima in the energy separation between the ground and the excited states. We demonstrate this approach with numerical simulation. [1] L. Tian, arXiv:1802.02285.

Session R43 DCMP: Discrete Time Crystal Signatures in Driven Spin Systems BCEC 210B - Tag(s): Invited

8:00AM R43.00001: DTC signatures in NV Centers: Initial Discovery and Late-breaking Results [Invited] MIKHAIL LUKIN (Presenter), Harvard University — TBD

8:36AM R43.00002: Can Prethermal Regimes explain the latest observations of DTC signatures in driven spin systems? [Invited] CHETAN NAYAK (Presenter), Microsoft — TBD
9:12AM R43.00003: Observation of Discrete-Time-Crystal Signatures in an Ordered Dipolar Many-Body System*  
[Invited] JARED ROVNY, ROBERT BLUM, SEAN BARRETT (Presenter), Physics Dept., Yale Univ. — The rich dynamics and phase structure of driven systems include the recently described phenomenon of the discrete time crystal (DTC), a robust phase which spontaneously breaks the discrete time translation symmetry of its driving Hamiltonian. Experiments in trapped ions and diamond nitrogen vacancy centers have recently shown evidence for this DTC order. Here, we report nuclear magnetic resonance (NMR) observations of DTC signatures in a third, strikingly different, system: an ordered spatial crystal. This system is expected to be even farther from the regime of many-body localization (MBL) than those studied in the earlier experiments. We study the 100% occupied crystal lattice of spin-1/2 $^{31}$P nuclei in ammonium dihydrogen phosphate (ADP), with chemical formula NH₄H₂PO₄. ADP also contains spin-1/2 $^1$H nuclei (99.98% abundant) and spin-1 $^{14}$N nuclei (99.64% abundant). Implementing the DTC pulse sequence on the $^{31}$P spins, we observe robust oscillations at half the drive frequency ("DTC oscillations" for brevity) across orders of magnitude in interaction time. We also study the decay mechanism of the DTC oscillations, with two results. First, we show by generating a time-reversed DTC echo that the density matrix is more coherent than the original DTC sequence reveals. Second, we show that the effect of interactions during the nonzero pulse duration of the DTC sequence limits our ability to observe the intrinsic lifetime of the DTC oscillations [1,2]. In this work, we exploited both the long coherence times of our sample, and our ability to use NMR pulse sequences to edit the spin Hamiltonian. This suggests that NMR can be a useful probe of the physics of out-of-equilibrium, driven many-body systems.

10:24AM R43.00005: Temporal Order in Periodically Driven Spins in small NMR spin Clusters*  
[Invited] SREEJITH GANESH JAYA (Presenter), SOHAM PAL, NAVEEN NISHAD, MAHESH T S, Physics, Indian Institute of Science Education and Research - Pune — We present the results of experimental studies on the magnetization response of star-shaped clusters of initially unentangled N=4, 10, and 37 nuclear spin-1/2 moments when subjected to inexact pi-pulse sequences. We find that an Ising coupling between the center and the satellite spins results in robust period-2 magnetization oscillations. On the other hand, control experiments (using alternate Isotopes ) without the Ising coupling do not show a robust time period. The period is stable against bath effects, but the amplitude decays with a timescale that depends on the inexactness of the pulse. Numerical simulations of the system reveal a simple semiclassical picture in which the rigidity of the period is due to a randomizing effect from the Larmor precession due to the magnetization of the surrounding spins. The timescale with stable periodicity increases with the net initial magnetization, even in the presence of perturbations and absence of disorder, indicating a robust temporal ordered phase for large systems with finite magnetization per spin. We also present results of numerical simulations of the system with simple model couplings to a bath.

Session R44 DCMP: Heavy Fermion Systems as a Platform for Strongly Correlated Electronic Topology  
BCEC 210C - Piers Coleman, Rutgers University - Tag(s): Invited
8:00AM R44.00001: Weyl-Kondo semimetals: Symmetries, signatures and nearby quantum phases* [Invited] SARAH GREFE (Presenter), Department of Physics and Astronomy and Rice Center for Quantum Materials, Rice University — In the last few years, manifestations of the long-anticipated Weyl semimetal have been observed in weakly correlated materials. In the context of a global phase diagram for strongly correlated systems with a large spin-orbit coupling, the prototypical heavy fermion systems have emerged as an important platform for topological metals. We have recently advanced a strongly correlated topological phase, the Weyl-Kondo semimetal (WKSM) [1], which exhibits Kondo effect-driven nodal quasiparticles. The Weyl nodes are pinned near the Fermi energy by strong correlations along with space group symmetry. One signature of this WKSM phase is a specific heat varying as $T^3$ below the Kondo temperature, with a colossal prefactor, as observed in the noncentrosymmetric heavy fermion semimetal Ce$_3$Bi$_4$Pd$_3$ [2]. Experiments on Ce$_3$Bi$_4$Pd$_3$ have also demonstrated a nonlinear spontaneous Hall response and an even-in-field Hall resistivity, which are attributed to the large Berry curvature dipole of a WKSM with tilted nodes [3]. Both illustrate that signatures of topological phases driven by strong correlations are often distinct from those typical for weakly correlated systems. Finally, in related models we have found how the WKSM connects with proximate topologically distinct phases, such as a Kondo Insulator and a Dirac-Kondo semimetal, as well as magnetic states. I will present these results, and discuss their place in the heavy fermion global phase diagram that the topological paradigm has enriched.

8:36AM R44.00002: Kondo-Weyl semimetal behavior in Ce$_3$Bi$_4$Pd$_3$* [Invited] SAMI DZSABER (Presenter), GAKU EGUCHI, DIEGO A ZOCCO, ANDREI SIDORENKO, XINLIN YAN, ANDREY PROKOFIEV, LUKAS PROCHASKA, Institute of Solid State Physics, , Wiedner Hauptstr. 8-10, 1040 Vienna, Austria, Vienna University of Technology, T. SHIROKA, ETH Zurich, Paul Scherrer Institut, Switzerland, P. BLAHA, Institute of Materials Chemistry, Vienna University of Technology, 1040 Vienna, Austria, O. RUBEL, Department of Materials Science and Engineering, McMaster University, 1280 Main Street West, Hamilton, Ontario, Canada L8S 4L8, S.E. GREFE, H. H. LAI, Department of Physics and Astronomy, Rice University, Houston, Texas 77005, USA, QIMIAO SI, Department of Physics and Astronomy, Houston, Texas 77005, USA, Rice University, SILKE BUEHLER-PASCHEN, Institute of Solid State Physics, , Wiedner Hauptstr. 8-10, 1040 Vienna, Austria, Vienna University of Technology — In heavy fermion systems the Kondo effect stabilizes strongly renormalized heavy electronic bands, and promotes novel quantum phases and excitations. Recently, the discovery of topologically non-trivial insulators, as well as Dirac and Weyl semimetals with 3D bulk linear electronic dispersion has triggered a lot of interest. So far, investigations have focused on non-interacting settings, but it is of great interest to also explore the interplay of strong correlations and topology. For this purpose we have searched for topologically non-trivial phases in heavy fermion systems. Indeed, by tuning the spin-orbit coupling strength by Pt-Pd substitution in Ce$_3$Bi$_4$(Pt,Pd)$_3$, we have discovered a transformation from a Kondo insulator in Ce$_3$Bi$_4$Pt$_3$ to a semimetal in Ce$_3$Bi$_4$Pd$_3$ [1]. The latter shows the thermodynamic hallmark of strongly renormalized linear electronic bands [1], as recently predicted for a Weyl-Kondo semimetal [2]. Strikingly, as full Kondo coherence sets in, a large spontaneous Hall effect appears. As the material is entirely nonmagnetic, this is direct evidence of a huge Berry curvature dipole in the absence of time-reversal symmetry breaking. We attribute this effect to the topological nature of this noncentrosymmetric material, in the form of tilted Kondo-driven Weyl nodes [3].

9:12AM R44.00003: Evidence for Weyl fermions in a heavy fermion semimetal YbPtBi* [Invited] CHUNYU GUO (Presenter), FAN WU, ZHONGZHENG WU, MICHAEL SMIDMAN, Zhejiang University, CHAO CAO, Department of Physics, Hangzhou Normal University, 310036 Hangzhou, China., AARON BOSTWICK, CHRIS JOZWIAK, ELI ROTENBERG, Advanced Light Source, E.O. Lawrence Berkeley National Lab, Berkeley, CA 94720, USA, YANG LIU, Zhejiang University, FRANK STEGLICH, Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany, HUIQIU YUAN, Zhejiang University — Materials with non-trivial band topology have been extensively studied in weakly correlated electron systems. Consequently, it is of great interest to test the existence of Weyl fermions when the electronic correlations are strong. Here, we report electronic structure calculations, ARPES, magneto-transport and calorimetric measurements of the canonical heavy fermion semimetal YbPtBi[1], we find triply degenerate points existed in band structure, which split into pairs of Weyl nodes under applying magnetic field. At high temperatures, the chiral anomaly effect is detected in the magneto-transport measurements, which becomes negligible when the electronic correlations become stronger at lower temperatures. However, the topological Hall effect and the temperature dependence of specific heat still demonstrate the existence of Weyl nodes. These results suggest that YbPtBi is a Weyl heavy fermion semimetal, where the bands hosting Weyl nodes are strongly renormalized at low temperatures due to the Kondo effect. Our findings provide a suitable platform to explore the interplay between topology and strong electronic correlations.

9:48AM R44.00004: Excitons in topological Kondo insulators: Theory of thermodynamic and transport anomalies in SmB6 [Invited] JOHANNES KNOLLE (Presenter), Blackett Laboratory, Imperial College London — Kondo insulating materials lie outside the usual dichotomy of weakly versus correlated—band versus Mott—insulators. They are metallic at high temperatures but resemble band insulators at low temperatures because of the opening of an interaction-induced band gap. The first discovered Kondo insulator (KI) SmB6 has been predicted to form a topological KI (TKI). However, since its discovery thermodynamic and transport anomalies have been observed that have defied a theoretical explanation. Enigmatic signatures of collective modes inside the charge gap are seen in specific heat, thermal transport, and quantum oscillation experiments in strong magnetic fields. Here, we show that TKIs are susceptible to the formation of excitons and magnetoexcitons. These charge neutral composite particles can account for long-standing anomalies in SmB6.

10:24AM R44.00005: Topological Kondo insulators and semimetals* [Invited] ONUR ERTEN (Presenter), Department of Physics, Arizona State University — The electrons in heavy fermion materials experience strong spin-orbit coupling interactions that greatly exceed their kinetic energy. It has long been known that the spin-orbit coupling stabilizes new kinds of heavy fermion metals, superconductors and Kondo insulators and semimetals. In this talk, I will discuss the new realization that spin orbit coupling changes the topology leading to new kinds of topological orders. I will mainly focus on SmB6, CeNiSn and time permitting CeSb. In particular, I will discuss the puzzling experimental results on topological Kondo insulators and the possibility of a Skyrme insulating phase in SmB6 [1]. Next I will discuss how non-symmorphic symmetries can lead to Mobius-twisted surface states in failed Kondo insulators[2]. Time permitting, I will discuss recent ARPES experiments on gapless Kondo-Weyl semimetals[3].

*Supported by ASU startup grant.
8:00AM R45.00001: Photoemission Spectroscopy Experiments on Metalloporphyrin Architectures for Molecular Electronics  RADWAN ELZEIN (Presenter), RUDY SCHLAF, Electrical Engineering, University of South Florida — Metal Organic Frameworks (MOFs) based on metalloporphyrin architectures combine advantages of both organic and inorganic materials and therefore are interesting candidates for next generation molecular electronic devices and applications. They exhibit unique properties such as highly ordered structures, ultrahigh surface area, tunable nanopore size, and more interestingly tailorable electronic, and ionic properties.

In this work, we present Liquid Phase Epitaxy method to fabricate self-assembled monolayers on gold surfaces which enabled to host conductive MOFs with their ability to facilitate charge transfer and control the growth of the MOF thin films.

We used Photoemission Spectroscopy (PES) to reveal the electronic properties which is crucial for the construction of energy band diagrams of various metalloporphyrin derivatives coordinated to either copper or zinc based metal ions. The energy band diagrams revealed interesting details about the electronic properties when changing various metal ions or conductive ligands. The obtained results show the fabricated films exhibit semiconductor tunability of either p-type or n-type behavior as conducting medium of charge carrier transport which is a key prerequisite to build molecular electronic junctions and elaborated devices.

8:12AM R45.00002: Ultrafast electron dynamics in a thin C60 films observed with time and angle resolved photoemission*  PENG ZHAO (Presenter), CHRISTOPHER CORDER, JIN BAKALIS,MICHAEL GEORGE WHITE, THOMAS ALLISON, Stony Brook University — C60 derivatives are common acceptor materials for organic solar cells. Time- and angle-resolved photoelectron spectroscopy (tr-ARPES) is a powerful way to study the electron dynamics in these systems. However, experiments on perturbatively excited systems are very demanding. By combining an 88 MHz ultrafast XUV source [1] with time-of-flight momentum microscopy [2], we are able to perform experiments at high speed and low excitation fluence. Here we present first demonstration results on C60 films with this technique.

*This work is supported by the U.S. Air Force office of Scientific Research under Award No. FA9550-16-1-0164, the U.S. Dept. of Energy, Office of Science, Office of Basic Energy Sciences, under Award No. DE- SC0016017, and the Stony Brook Foundation Discovery Prize.

8:24AM R45.00003: Waves guided by the surface of a Lorentz model dielectric medium*  S.R. SESHADRI (Presenter), 4502 Phyllis Court, Livermore, CA, Independent Researcher — The wavenumber, the phase velocity, the wave packet velocity, the energy transport velocity, and the attenuation coefficient are obtained for the wave guided by the surface of a Lorentz model dielectric medium.

*None

8:36AM R45.00004: The TEM Studies of Tungsten Irradiated by Helium*  KANGWEI ZHU (Presenter), RUILONG YANG, WENYUAN WANG, YIN HU, Institute of Materials, China Academy of Engineering Physics — Tungsten (W) as one of the potential plasma-facing materials (PFMS) would suffer severe irradiation in nuclear fusion reactor which can results in deterioration of the related mechanical and physical properties. Understanding the irradiation effects on PFMS is then critical to improve their performances. Here, we studied the He ions irradiation effects by focusing on microstructures of the the W surfaces. As the irradiation time increased, the surface morphologies changed from smooth to full of nano-structures. TEM images show that the nano-structures contain lots of He voids, it is noted that the shapes of the he bubbles are faceted, which pointed out that the system prefers to develop low surface energy bubbles. And the nano-structures show good deformation feature although micro-carcks are developed inside.

8:48AM R45.00005: Electronic Structure of Phase Separated Material Revealed by Nanospot Angle-Resolved Photoemission Spectroscopy  CHANGHUA BAO (Presenter), HONGYUN ZHANG, HAOXIONG ZHANG, KENAN ZHANG, YANG WU, Department of Physics, Tsinghua Univ, CHAOYU CHEN, JOSE AVILA, MARIA C. ASENSIO, Synchrotron SOLEIL, SHUYUN ZHOU, Department of Physics, Tsinghua Univ — Phase separation frequently occurs in strong correlated materials. The electronic structures of different phases are very important but difficult to access due to very small grain size. As an electronic structure microscopy, nanospot angle-resolved photoemission spectroscopy (NanoARPES) can measure the electronic structure both in real and momentum spaces and provides the unique ability to measure the electronic structures of different phases in phase separated materials. Here I will present our recent experimental results on the electronic structure of phase separated material by using NanoARPES.
9:00AM R45.00006: Optimization and Characterization of Dip-Coated PEDOT:PSS on CdTe Solar Cells* MICHAEL PATULLO (Presenter), NNAMDI ENE, DANIEL ROGERS, MEHMET ALPER SAHINER, Seton Hall University — Organic thin film solar cells have been identified as viable photovoltaic technology alternatives to conventional power production methods. In this work, we optimize the thin film deposition conditions for high-conductive grade poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) on pulsed laser deposited cadmium sulfide/cadmium telluride/indium tin oxide substrates. In our previous studies, we have determined that this particular substrate and polymer combination significantly improves the photovoltaic conversion efficiency due to a reduction of the Schottky barrier resistance. In this study, we focus on applying a uniform layer of the PEDOT:PSS back contact by optimizing thin film dip-coating parameters such as pulling rate, temperature, application duration, and drying procedures. The resultant back contacts are characterized by scanning electron microscopy, energy dispersive x-ray spectroscopy, and ellipsometry techniques. Electrical conductivity tests on full cells are also performed using a Keithley SourceMeter, and structure and efficiency results are discussed.

9:12AM R45.00007: Effect of illumination on the interplay between Dresselhaus and Rashba spin-orbit coupling in InAs quantum wells* ELENA CIMPOIASU (Presenter), BENJAMIN DUNPHY, Physics, United States Naval Academy, Annapolis MD 21402, SHAWN MACK, JOSEPH A. CHRISTODOULIDES, BRIAN R BENNETT, Naval Research Laboratory, Washington DC 20375 — Illumination of variable wavelength was used to study the dependence on the carrier concentration of the spin-orbit coupling and the semiconducting properties of a thin n-type InAs quantum well. Measurements of the sheet and Hall resistance were performed in variable magnetic field, field orientation, temperature, and under illumination with wavelengths of 400 nm up to 1300 nm. Beats in the Shubnikov-de Haas oscillations indicated the presence of strong spin-orbit coupling and the FFT of the oscillations points towards the presence of both Rashba and Dresselhaus spin-orbit interactions. Here we have used simulations to extract the dependence of the spin-orbit strengths on the carrier concentration. The simulations are based on the Hamiltonian of a 2D electron system with both types of spin-orbit interactions and subject to a perpendicular magnetic field. The results indicate that the Rashba coefficient decreases with increasing the carrier concentration, while the Dresselhaus coefficient remains mainly constant. These results are consistent with observations on similar materials where the carrier concentration was varied using applied gate voltage.

9:24AM R45.00008: Band Structure engineering in epitaxial LuSb thin films via dimensional confinement and bi-axial strain SHOUVIK CHATTERJEE (Presenter), Electrical & Computer Engineering, University of California, Santa Barbara, HADASS INBAR, Materials Department, University of California, Santa Barbara, SHOAIB KHALID, Department of Physics & Astronomy, University of Delaware, ARANYA GOSWAMI, Electrical & Computer Engineering, University of California, Santa Barbara, FELIPE CRASTO DE LIMA, ABHISHEK SHARAN, FERNANDO SABINO, Department of Physics & Astronomy, University of Delaware, TOBIAS L BROWN-HEFT, YU-HAO CHANG, Materials Department, University of California, Santa Barbara, ALEXEI V FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, DANIEL READ, School of Physics & Astronomy, University of Cardiff, ANDERSON JANOTTI, Department of Physics & Astronomy, University of Delaware, CHRIS PALMSTROM, Electrical & Computer Engineering, University of California, Santa Barbara — Observation of extreme magnetoresistance (XMR) in rare-earth monopnictides has raised strong interest in understanding the role of its electronic structure. Here, the first demonstration of epitaxial synthesis of LuSb thin films on GaSb (001) substrates will be presented. Combining the techniques of molecular-beam epitaxy, low-temperature magnetotransport, angle-resolved photoemission spectroscopy, and hybrid density functional theory, we have unveiled the bandstructure of LuSb, where electron-hole compensation is identified as a mechanism responsible for XMR. However, by fabricating ultra-thin films, it is possible to controllably create an imbalance in the band fillings of electron and hole-like carriers in this otherwise compensated semimetal. Moreover, magnetoresistance behavior can also be tuned by application of bi-axial strain by synthesizing thin films of LuSb on lattice mis-matched substrates. Our work demonstrates the efficacy of epitaxial synthesis of rare-earth monopnictides to control its electronic structure, and thereby its physical properties.
9:36AM R45.00009: High quality Bi$_2$Se$_3$ thin films grown on Van der Waals substrate BiInSe$_3$* XIONG YAO (Presenter), Center for Quantum Materials Synthesis and Department of Physics and Astronomy, Rutgers, the State University of New Jersey, RONGWEI HU, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers, the State University of New Jersey, JISOO MOON, Department of Physics and Astronomy, Rutgers, the State University of New Jersey, SANG-WOOK CHEONG, SEONGSHIK OH, Center for Quantum Materials Synthesis and Department of Physics and Astronomy, Rutgers, the State University of New Jersey — We grew high quality BiInSe$_3$ single crystals and developed an exquisite process to prepare these crystals as substrates. Well cleaved BiInSe$_3$ single crystals with subsequent in-situ thermal treatment can obtain atomically flat surface, which is evidenced by the sharp streaky reflection high energy electron diffraction (RHEED) patterns. By optimizing the growth recipe, we successfully grew high quality Bi$_2$Se$_3$ thin films on BiInSe$_3$ single crystal substrates. Owing to the weak Van der Waals bonding between the interlayers of BiInSe$_3$ substrates, we can easily transfer the Bi$_2$Se$_3$ thin films grown on these substrates. The high quality surface morphology and electrical transport characteristics, together with the transferrable feature all prove that BiInSe$_3$ could be a promising substrate for TI films growth. Our discovery could pave a new pathway for improving the sample quality of topological insulator thin films.

9:48AM R45.00010: Very different adsorption pathways of triatomic molecule H$_2$O on isolated and domains of dangling bonds on the Si(100) surface* CHANG-YUAN CHANG, DENG-SUNG LIN (Presenter), National Tsing Hua University — On the ideal clean Si(100) surface, dangling bond pairs (DBPs, denoted as -Si-Si-) cover the entire surface. Each dangling bond is an active adsorption site for adsorption of a gas molecule. In this study, isolated DBPs are prepared on a Si(100) surface as well-defined chemically-reactive sites for chemisorption of the prototypical H$_2$O triatomic molecules. The surrounding dangling bonds are passivated by chlorine-termination. Following saturation exposure to H$_2$O molecules at room temperature, the adsorbate configurations on these reactive sites as well as on the clean surface have been examined in atomic resolution using scanning tunneling microscopy.

The results show that, while the H-Si-Si-OH adsorbate configuration is common on a DBP, other configurations such as H-Si-O-Si-H and H-Si-Si-H are observed. These findings indicate that a seemingly simple chemisorption reaction on reactive sites involves not only the sites themselves but also the relevant surrounding bonds and adatoms.

10:00AM R45.00011: Reversible and Efficient Photo-Switching of Azobenzene Derivatives on an Insulator Surface Investigated by nc-AFM SIMON JAEKEL (Presenter), Institute of Chemistry, University of Graz, ANITJE RICHTER, ROBERT LINDNER, Institute of Physical Chemistry, University of Mainz, CHRISTOPHE NACCI, Institute of Chemistry, University of Graz, ANGELIKA KÜHNLE, University of Bielefeld, STEFAN HECHT, Department of Chemistry, Humboldt-Universität zu Berlin, LEONHARD GRILL, Institute of Chemistry, University of Graz, RALF BECHSTEIN, University of Bielefeld — Studying single molecular switches is of interest for a better understanding of fundamental physical and chemical processes, but also in view of their possible use in smart materials and molecular nanotechnology.

Azobenzene is a prototypical molecular switch, which changes between trans and cis isomers at the central N=N bond upon an external stimulus. Adsorption on solid substrates allows the study on the single molecule scale using scanning probe microscopy, but it has been shown that metallic substrates strongly influence the switching properties[1,2]. Here, we report non-contact atomic force microscopy (nc-AFM) results on the switching of individual Azobenzene derived molecules on an insulating calcite surface. It is demonstrated that unlike on metals [3] the molecules retain their efficient photoisomerization properties known from solution. Furthermore, the photoisomerization is shown to be reversible and selective, depending on the exciting wavelength.

10:12AM R45.00012: Theory of coupled deposition and dissolution of solids, with focus on corrosion  INGE BELLEMAN, Department of Materials, Textiles and Chemical engineering, Ghent University, DIMITRIOS FRAGGEDAKIS (Presenter), Chemical Engineering, MIT, MARTIN BAZANT, Chemical Engineering & Math, MIT — Corrosion affects the durability of metals and structures and has important economic consequences, such as the continuous inspection for and replacement of damaged material. Corrosion often initiates locally and therefore, to increase the sustainable use of metals, a thorough knowledge of corrosion and its localized initiation is crucial. One technique to investigate this experimentally is the gold nanoplating technique on pure copper. This study investigates the pattern formation in this concurrent deposition-corrosion system. First we derive the general model for deposition-dissolution systems and then apply this to the gold-nanoplating example. This is the first model to implement non-linear reaction kinetics based on far-from equilibrium thermodynamics. Effects related to curvature induced diffusion and/or effective phase-separation upon deposition/dissolution are inherently included, phenomena which affect the formation dynamics of deposited film and the corroded bulk material-film interface. Other applications of the model are the passivation of stainless steels, the galvanization protection of Zn with respect to iron, and Li plating during continuous cycling of Li-Ion batteries.

10:24AM R45.00013: Morphological Instability of Grain Boundary under Lateral Applied Strain*  MING-WEI LIU (Presenter), KUO-AN WU, National Tsing Hua University — The morphological instability of symmetrical high-angle tilt grain boundary induced by lateral applied strain is investigated using the phase field crystal model in two dimensions. By studying the growth rate of perturbations, we discover a threshold value of the applied strain below which the instability disappears. Furthermore, we construct the phase diagram of instability which is classified into two groups, namely the grain boundary structural transformation or the dislocation emission, based on the late stage behavior of the grain boundary. A theoretical model is proposed by taking into account a relatively soft solid-solid interface, the elasticity of solid grains, and the interfacial energy of grain boundary. The theoretical prediction of the growth rate and the phase diagram is in quantitatively good agreement with the simulation result. In addition, the theory also explains the inhomogeneous strain distribution observed in simulations.

Session R46 DMP: Complex Oxide Interfaces & Heterostructures -- Strong correlations
BCEC 212 - Hyowon Park, University of Illinois at Chicago - Tag(s): Focus
8:00AM R46.00001: Magnetism and topology in SrRuO$_3$- and SrVO$_3$-based heterostructures: from DFT via DMFT to DΓA*[Invited] KARSTEN HELD (Presenter), Institute for Solid State Physics, TU Wien — Oxide heterostructures based on SrRuO$_3$ are promising candidates for thin film ferromagnetism, but experiments showed time and again that ferromagnetism breaks down below a critical thickness. By means of density functional theory (DFT) plus dynamical mean field theory (DMFT), we show [1] that growing SrRuO$_3$ in the (111) direction instead yields a half-metallic ferromagnetic state with an ordered magnetic moment of 2 $\mu$B/Ru and survives the ultimate dimensional confinement down to a bilayer -- even at elevated temperatures of 500 K. This ferromagnetic state has been confirmed by experiment and also hosts Haldane's quantum anomalous Hall state, without any external magnetic field or magnetic impurities [1]. Similar physics with an even larger gap is also observed in SrRhO$_3$ (111) but not in LaNiO$_3$ (111) [2] bilayers.

For SrRuO$_3$ grown in the (001)-direction, DFT+DMFT instead only yields ferromagnetism if the Ru is doped away from 4 d-electrons. This is possible by applying a gate voltage or, as we will show, by growing SrRuO$_3$ on an appropriate substrate that induces a self-doping between different SrRuO$_3$ layers.

For SrVO$_3$-based heterostructures, on the other hand, the metallic bulk behavior turns insulating below a thickness of 3 SrVO$_3$ layers, which has been proposed to be utilized as a Mott transistor [3]. Using DFT+DMFT and beyond that the dynamical vertex approximation (DΓA) [4], we here show that this insulating state is actually antiferromagnetic at low temperatures and can be switched to a ferromagnetic metallic state through a gate voltage, actually making it a Mott magnetotransistor. Here, strong non-local correlations further induce a Lifshitz transition at low temperatures.

8:36AM R46.00002: Designing new metastable nickelate thin films isostructural to the cuprates QI SONG (Presenter), GRACE PAN, CHARLES BROOKS, Harvard University, HANJONG PAIK, Cornell University, JULIA MUNDY, Harvard University — Despite over thirty years of intense experimental and theoretical effort, there remain outstanding questions on the origin of superconductivity in the cuprates. One strategy for gaining insight into this phase has been to probe materials which are isoelectronic to the cuprates and contain many of the same characteristics of the known high-TC superconductors. Recent work on bulk crystals of layered square planar nickelates, $R_nNi_{3-n}$O$_8$ ($R$ = La, Pr) has re-ignited interest in nickelates for this purpose [1]. Here, we use atomically-precise synthesis to construct a full series of $R_nNi_{n+1}$O$_{3n+1}$ ($n$ = 1 – 5) thin films which we then reduce to form $R_nNi_{n+2}$O$_{2n+2}$. We aim to develop a systematic understanding of these different nickelate thin films and to correlate the electronic behavior with the local crystal structure and nickel valence state.

8:48AM R46.00003: BoSS: Boson Slave Solver software for correlated electrons* SOHRAB ISMAIL-BEIJI (Presenter), MINJUNG KIM, Yale Univ, ALEXANDRU BOGDAN GEORGESCU, Center for Computational Quantum Physics, The Flatiron Institute — We describe the recent release of the open source software "BoSS" or Boson Slave Solver (bitbucket.org/yalebosssolver/boss), written in MATLAB, which solves extended Hubbard models using the slave boson approach. The primary intended application is to study the electronic structure of transition metal oxides which are often affected significantly by strong and localized electron-electron interactions. Examples include renormalization of the mass and spectral weight of low energy quasiparticles and the formation of Hubbard bands: these dynamical effects can not be described by band theory approaches (e.g., DFT, DFT+U or hybrid methods). Slave-boson approaches represent computationally efficient electronic structure methods that can explicitly include such effects. We present an overview of our recent slave boson methodology [1,2], show applications to some transition metal oxides where we can compare to experimental and dynamical mean field theory (DMFT) results.

**9:00AM R46.00004: Study of infinite layer CaCuO$_2$/SrTiO$_3$ interfaces**  
ADRIEN WAELCHLI (Presenter), HUGO MELEY, STEFANO GARIGLIO, JEAN-MARC TRISCONE, Department of Quantum Matter Physics, University of Geneva — Thirty years after its discovery, superconductivity in cuprates still remains a lively field of research since the microscopic mechanisms leading to high $T_c$ are not yet fully identified and understood. Recent work on the infinite layer CaCuO$_2$ [1,2] has shown that superconductivity can occur at the interface with SrTiO$_3$. The conduction at the interface has been related to a chemical doping mechanism with O atoms inserting into the apical position above Cu. We present results on the study of CaCuO$_2$/SrTiO$_3$ bilayer structure. We investigate the influence of different growth parameters on the film quality and electrical properties explored through transport measurements.

**9:12AM R46.00005: Effects of epitaxial strain and oxygen underdoping on superconductivity in manganite/cuprate thin-film heterostructures**  
CHAO ZHANG (Presenter), HAO ZHANG, Department of Physics, University of Toronto, ANH NGUYEN, THOMAS GREDIG, Department of Physics and Astronomy, California State University Long Beach, MIN GU KANG, RICCARDO COMIN, Massachusetts Institute of Technology, Department of Physics, JOHN Y.T. WEI, Department of Physics, University of Toronto — To distinguish the role of magnetism from other factors that affect superconductivity in $c$-axis La$_{2/3}$Ca$_{1/3}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-δ}$ (LCMO/YBCO) heterostructures, we grow and characterize various perovskite/YBCO/perovskite trilayers, using ferromagnetic LCMO, paramagnetic LaNiO$_3$ (LNO), and orthorhombic PrBa$_2$Cu$_3$O$_{7-δ}$ (PBCO) as the sandwiching layers. LCMO and LNO trilayers show similarly large superconducting $T_c$ reductions with decreasing YBCO layer thickness, whereas this $T_c$ reduction is not seen in the PBCO trilayers. Our results indicate that epitaxial strain has a stronger effect on the $T_c$ of LCMO/YBCO heterostructures than any long-range magnetic proximity effect present. [1] Using this system, we also study how the $T_c$ reduction varies with oxygen underdoping by deoxygenating the cuprate layer. We discuss our results in the wider context of multiple competing orders, in particular the recent observation by resonant x-ray scattering of robust charge-density-wave order in LCMO/YBCO multilayers. **9:24AM R46.00006: Multi-band, two-dimensional superconductivity above the Pauli limit in Sr$_{1-x}$Nd$_x$TiO$_3$**  
YILIKAL AYINO (Presenter), JIN YUE, TIANQI WANG, BHARAT JALAN, VLAD S PRIBIAG, University of Minnesota — We present evidence of two-dimensional, multi-band superconductivity in Sr$_{1-x}$Nd$_x$TiO$_3$ thin films from the temperature dependence of the resistive upper critical field. The out-of-plane upper critical field shows pronounced positive curvature, which extends substantially below the critical temperature, and further exhibits a change in curvature at low temperatures. Quite unusually, the out-of-plane upper critical field exceeds the Pauli paramagnetic limit, by almost a factor of two. We attribute this unusual observation to the enhancement of critical field due to two-band superconductivity and the presence of strong spin-orbit coupling. We propose a model for the critical field of a two-band superconductor that includes paramagnetic breaking of Copper pairs and spin-orbital coupling in the dirty limit and find good agreement of this model with our data. Our results suggest that in SrTiO$_3$ intra-band superconducting coupling dominates over inter-band coupling.

9:36AM R46.00007: Prospects for creating complex oxide quantum electronic heterostructures via solid phase epitaxy: PrAlO3/SrTiO3 model system  YAJIN CHEN (Presenter), Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, WI 53706, USA, WATHSALA WADUGE, Department of Chemistry, Wayne State University, Detroit, MI 48202, USA, PENG ZUO, Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, WI 53706, USA, THOMAS F. KUECH, Department of of Chemical and Biological Engineering, University of Wisconsin-Madison, Madison, WI 53706, USA, SUE E. BABCOCK, Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, WI 53706, USA, CHUCK H. WINTER, Department of Chemistry, Wayne State University, Detroit, MI 48202, USA, PAUL G EVANS, Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, WI 53706, USA — Various oxide interfaces with composition \( \text{RAlO}_3/\text{SrTiO}_3 \) (\( \text{R} = \text{La, Pr, Nd} \)) can produce a two-dimensional electron gas (2DEG). Crystallization from amorphous precursors, termed solid phase epitaxy (SPE), is an approach for synthesizing these interfaces that complements vapor-phase epitaxy techniques. Atomic layer deposition (ALD) is a promising route for forming the amorphous films because it allows oxide interfaces to be created in non-planar geometries. SPE can be used with patterned substrates to grow epitaxial thin films in complex geometries, which may enable the creation of 2DEG beyond planar geometries. The creation of PrAlO3 thin films via SPE has required developing new ALD procedures, understanding crystallization kinetics, and probing the microstructure and interface structures of the crystallized thin films. Nearly stoichiometric amorphous PrAlO3 thin films were grown via ALD at 300 °C using tris(isopropylcyclopentadienyl)praseodymium, AlMe3, and water with a growth rate of 2.0 Å/cycle on TiO2-terminated STO (001) substrates. The as-deposited amorphous PrAlO3 crystallized via SPE to form an epitaxial layer on STO upon annealing at 800 °C for 3h. Our work provides new opportunities to form polar/nonpolar oxide interfaces, and the accompanying 2DEG in novel geometries.

9:48AM R46.00008: Suppression of Metal-Insulator Transition in VO2 by Interfacial Oxygen Migration  QIYANG LU (Presenter), CHANGHEE SOHN, Materials Science and Technology Division, Oak Ridge National Laboratory, GUOXIANG HU, PANCHAPAKESAN GANESH, PAUL KENT, Center for Nanophase Materials and Sciences, Oak Ridge National Laboratory, OLLE HEINONEN, Materials Science Division, Argonne National Laboratory, GYULA ERES, Center for Nanophase Materials and Sciences, Oak Ridge National Laboratory, HO NYUNG LEE, Materials Science and Technology Division, Oak Ridge National Laboratory — Oxygen defects are essential building blocks for designing functional oxides with remarkable properties, ranging from electrical and ionic conductivity to magnetism and ferroelectricity. Oxygen defects therefore can profoundly alter crystal and electronic structures and enables emergent phenomena. In this work, we achieved tunable metal-insulator transition (MIT) in oxide heterostructures by inducing interfacial oxygen vacancy migration. We chose VO2-x as a model system due to its near room temperature metal-insulator transition temperature. We found that depositing a TiO2 capping layer on an epitaxial VO2 thin film can effectively suppress the MIT in VO2. We systematically studied the TiO2/VO2 heterostructures by structural and transport measurements, resonant inelastic x-ray scattering, X-ray photoelectron spectroscopy, and first principles calculations and found that that oxygen vacancy migration from TiO2 to VO2 is responsible for the suppression of MIT. Our findings underscore the importance of the interfacial oxygen “diode” effect in determining electronic structure and functionality, and provide new pathways of designing oxide heterostructures for novel ionotronics and computing devices.

10:00AM R46.00009: Tailoring the low-energy physics of RuO2 by epitaxial strain  JACOB RUF (Presenter), HANJONG PAIK, JASON KAWASAKI, BETUL PAMUK, HARI NAIR, NATHANIEL SCHREIBER, LUDI MIAO, DARRELL G. SCHLOM, KYLE M SHEN, Cornell University — Rutile ruthenium dioxide (RuO2) was long presumed to be a paramagnetic metal with weak electronic correlations, until recent measurements of antiferromagnetism in bulk single crystals by Berlijn et al. Motivated by this discovery to better understand its electronic structure, we synthesized RuO2 thin films by molecular-beam epitaxy on rutile TiO2 substrates and characterized these films using \textit{in situ} angle-resolved photoemission spectroscopy (ARPES). Comparing our ARPES data with density-functional calculations, we find that: (1.) electron-phonon coupling accounts for most of the modest quasiparticle mass renormalizations observed in RuO2, and (2.) a sizable crystal field splitting in the rutile structure lifts the threefold degeneracy of the t_{2g} manifold spanning the Fermi level (\( E_F \)), causing strong departures from the prototypical Hund's metal behavior observed in perovskite-based ruthenates, despite having the same electron count of 4d^4. Guided by this understanding of the effective low-energy physics, we explain how epitaxial strain modifies the orbital occupations in RuO2 films grown on different orientations of TiO2 substrates, and discuss how concomitant changes to the density of states near \( E_F \) feed back into the instability of strained RuO2 towards superconductivity.
10:12AM R46.00010: Physical properties of LaFeO$_3$ and Pr$_{2-x}$Ce$_x$CuO$_4$ superstructures* GUILLAUME HARDY, PRIYANKA BROJABASI, PATRICK FOURNIER (Presenter), Universite de Sherbrooke — Charge transfer in electron-doped Sm$_2$CuO$_4$ (SCO) and LaFeO$_3$ (LFO) superstructures (SS) grown by RF sputtering was predicted based on their band structure. STEM-EELS measurements revealed the presence of extra electrons at the interface between SCO and LFO[1]. However, the growth conditions left open questions regarding the actual doping of the SCO layers. We have grown SS of electron-doped Pr$_{2-x}$Ce$_x$CuO$_4$ (PCCO) and LaFeO$_3$ by pulsed-laser deposition with various thicknesses and annealing conditions. X-ray diffraction confirms the coherent growth of PCCO/LFO SS. Superconductivity is confirmed for selected samples by magnetic susceptibility and resistivity measurements, while the Hall Effect of low resistivity samples was carried out for all temperatures. A strong dependence of carrier density and the critical temperature as a function of annealing conditions and thickness of the SS subcomponents is observed. Our results indicate that charge transfer might not be the only source of charge carriers in these structures as annealing conditions are playing a central role in our PLD-grown superstructures.

*We acknowledge the technical support of B. Rivard and the financial support from NSERC, FRQ-NT, CFREF and CFI.

10:24AM R46.00011: X-ray imaging of ionically-controlled nanoscale phase separation in cobaltites* GEOFFERY IAN RIPPY, LACEY L TRINH, ALEXANDER MICHAEL KANE, ALEKSEY IONIN, MICHAEL STEVEN LEE, RAJESH V CHOPDEKAR, Materials Science and Engineering, University of California Davis, DUSTIN GILBERT, ALEXANDER GRUTTER, NIST Center for Neutron Research, NIST Gaithersburg, PEYTON MURRAY, Physics, University of California Davis, MARTIN HOLT, ZHONGHOU CAI, Advanced Photon Source, Argonne National Laboratory, KAI LIU, Physics, University of California Davis, YAYOI TAKAMURA, ROOPALI KUKREJA (Presenter), Materials Science and Engineering, University of California Davis — Controlling ionic distributions and stoichiometry provides a unique way for manipulating functional properties in perovskite oxides (ABO$_3$). This talk will focus on Gd/La$_{0.67}$Sr$_{0.33}$O$_3$ (LSCO) heterostructures due to high oxygen ion conductivity, as well as the coupled magnetic and electronic properties of LSCO, which are strongly dependent on the oxygen stoichiometry. This enables the ionic control of the functional properties of LSCO thin films through the presence of oxygen getter layers such as Gd. We utilize x-ray nanodiffraction to directly image the nanoscale morphology of LSCO thin films as they are progressively transformed from the equilibrium perovskite phase to the metastable brownmillerite (ABO$_{2.5}$) phase with increasing Gd thickness. Our studies show the coexistence of perovskite and brownmillerite phases with a critical oxygen vacancy concentration threshold which leads to the formation of extended brownmillerite filaments. In addition to lateral phase separation, we observed phase separation along the thin film thickness due to pinning of perovskite or brownmillerite by substrate/LSCO or Gd/LSCO interface respectively. Our measurements highlight local structural effects and provide insights into nanoscale strain behavior in Gd/LSCO heterostructures

10:36AM R46.00012: Lifshitz transition and emergence of Van Hove singularity at the complex oxide heterostructure* RYO MORI (Presenter), University of California, Berkeley, PATRICK MARSHALL, KAVEH AHADI, University of California, Santa Barbara, JONATHAN DENLINGER, Lawrence Berkeley National Laboratory, SUSANNE STEMMER, University of California, Santa Barbara, ALESSANDRA LANZARA, University of California, Berkeley — Electronic correlations strongly depend on the topology of a given electronic structure. A Van Hove singularity (VHS), where the curvature of the electronic bands has opposite sign in two orthogonal directions, is a critical point for a change in electronic topology (Lifshitz transition). It has been considered to be the key to inducing many new unconventional states, especially when it is close to the Fermi level. By using angle-resolved photoemission spectroscopy, we will show the direct evidence of Lifshitz transition and an emergence of VHS in the oxide heterostructures with the different quantum well structures, revealing a new pathway to tune VHS and the corresponding electronic topology at a complex oxide heterointerface.

8:00AM R47.00001: Mapping experimental electronic transport measurements on appropriate band structure models*  
T. ETHAN STEARNS (Presenter), ANDREW R SUPKA, Department Physics and Science of Advanced Materials Program, Central Michigan University, NICHOLAS A MECHOLSKY, Department of Physics, Catholic University of America, MARCO BUONGIORNO NARDELLI, Department of Physics, University of North Texas, STEFANO CURTAROLO, Department of Mechanical Engineering and Materials Science, Duke University, MARCO FORNARI, Department Physics and Science of Advanced Materials Program, Central Michigan University — For several years, established guiding principles based on effective masses, carrier density, and constant relaxation time have been heuristically used to interpret trends in the power factor. In spite of many simplifying assumptions, the Sommerfeld model has became a standard for thermoelectricity. To verify and validate this interpretative approach we have developed a software tool that, using experimental electronic transport data, leads to band structure parameters that can then be compared with first principles calculations. We present our software tool by illustrating few specific examples for complex sulfides.

8:12AM R47.00002: Selective breakdown of phonon quasiparticles across superionic transition in CuCrSe2*  
OLIVIER DELAIRE (Presenter), Duke University, JENNIFER L NIEDZIELA, Oak Ridge National Laboratory, DIPANSHU BANSAL, Duke University, ANDREW MAY, Oak Ridge National Laboratory, JINGXUAN DING, TYSON LANIGAN-ATKINS, Duke University, GEORG EHLERS, DOUGLAS L ABERNATHY, Oak Ridge National Laboratory, AYMAN SAID, Argonne National Laboratory — Superionic crystals exhibit ionic mobilities comparable to liquids while maintaining a periodic crystalline lattice. The atomic dynamics leading to large ionic mobility have long been debated. A central question is whether phonon quasiparticles - which conduct heat in regular solids - survive in the superionic state, where a large fraction of the system exhibits liquid-like behaviour. Here we present the results of energy- and momentum-resolved scattering studies combined with first-principles calculations and show that in the superionic phase of CuCrSe2, long-wavelength acoustic phonons capable of heat conduction remain largely intact, whereas specific phonon quasiparticles dominated by the Cu ions break down as a result of anharmonicity and disorder. The weak bonding and large anharmonicity of the Cu sublattice are present already in the normal ordered state, resulting in low thermal conductivity even below the superionic transition. These results demonstrate that anharmonic phonon dynamics are at the origin of low thermal conductivity and superionicity in this class of materials.

8:24AM R47.00003: Is AgCrSe2 really a phonon-liquid electron-crystal?  
SERCAN ARSLAN (Presenter), Physics Department, Royal Holloway University of London, DAVID VONESHEN, ISIS Pulsed Neutron and Muon Source, Science and Technology Facilities Council, PAUL STEFFENS, Institut Laue-Langevin, UTHAYAKUMAR SIVAPERUMAL, Physics Department, Royal Holloway University of London, ROBIN S. PERRY, Physics Department, University College London, JON GOFF, Physics Department, Royal Holloway University of London — The phonon liquid concept, in which superionic diffusion prevents the propagation of transverse acoustic phonons, has proved a popular view in the hunt for materials with ultra-low thermal conductivity. Recent inelastic neutron scattering results on AgCrSe2 have found a quasielastic signal (QENS) around 2 Å\(^{-1}\), and suppression of the transverse phonons above the superionic transition. The QENS scattering has been attributed to the melting of the Ag lattice and it is observed to increase dramatically above the superionic transition. Now, using polarised inelastic neutron scattering we determine the origin of this QENS below and above the superionic transition. The validity of a phonon-liquid in AgCrSe2 will be discussed in light of these results.

8:36AM R47.00004: Nanoscale thermal metrology using SEM, TEM, and confocal microscopy [Invited]  
CHRIS DAMES (Presenter), University of California, Berkeley — Nanoscale thermal transport plays a fundamental role in several current research directions in thermoelectric materials, from nanocrystalline composites to transport in thin films and nanowires. However, experimental measurements of the thermal properties of such materials at the nanoscale is challenging. In this talk I will present several collaborative efforts to develop new non-contact methods for heating and thermometry at the nanometer scale, techniques which could eventually be applied to characterize thermoelectric materials. Examples to be discussed include methods based on SEM (e-beam as a point heater; secondary electron yield as a thermometer), TEM (thermometry using the Debye-Waller effect), and confocal microscopy (luminescence thermometry of individual nanoparticles).
Thermoelectric Properties of Carbon-rich Boron Carbide Nanocomposites* YUCHENG LAN, JESSE DAMPARE, MOBOJAJI ZONDODE, Department of Physics and Engineering Physics, Morgan State University, HUA DENG, Department of Chemistry, Morgan State University, SZ-CHIAN LIOU, Advanced Imaging and Microscope Laboratory, Maryland NanoCenter, University of Maryland, SAROJ PRAMANIK, Department of Biology, Morgan State University, ABDELLAH LISFI, Department of Physics and Engineering Physics, Morgan State University, CHUNDONG WANG, School of Optical and Electronic Information, Huazhong University of Science and Technology, YONG-LE PAN, U. S. Army Research Laboratory, WINNIE WONG-NG (Presenter), Materials Measurement Science Division, National Institute of Standards and Technology — Boron carbide is widely used in industry and military because of its low mass-density, super high hardness, good electric conductivity, and excellent mechanical properties. The material is also one high-temperature thermoelectric compound capable for applications above 1000 °C. However, its thermoelectric properties, such as Seebeck coefficient and figure-of-merit, are low and need to be enhanced significantly for high-efficiency energy applications. Nanostructuring is an effective approach to improve thermoelectric properties. Here boron carbide nanomaterials with various chemical composites are prepared and their physical properties (crystallinity, chemical composition, band-gap, defects etc) are characterized. The as-synthesized nanomaterials are then bottom-up-ed to bulk nanocomposites. Thermoelectric properties of the bulks are measured. Their microstructures are characterized by X-ray powder diffraction, scanning electron microscopy, transmission electron microscopy, Raman scattering, and UV-vis spectroscopy etc. The enhanced performances of the carbide nanocomposites are like a result of their unique nanostructures.

*The work is partially supported by W911NF-12-2-0022 and NSF DMR 1206380.

Resolving Thermal Conductivity Spectrums through Time-resolved Spatial-Temporal Imaging* DING DING (Presenter), KEDAR HIPPALGAONKAR, Institute of Materials Research and Engineering — With the advent of nano-engineered and 2D materials, quasiballistic and anisotropic effects have become more commonplace in thermal properties of these material systems. However, current methods to measure these properties through thermal conductivity generally requires variation of spatial or temporal parameters, or measurement of multiple samples with tedious fabrication procedures. Here, we numerically propose an optical pump-probe technique that uses time-resolved spatial and temporal temperature profile to characterize both quasiballistic and anisotropic thermal transport with no variation of experimental parameters. By performing heat-flow analysis of the thermal profile with multi-parameter optimization, we are able to obtain the thermal conductivity spectrums of both the in-plane and cross-plane heat transport as a function of temporal and spatial frequencies, respectively. Such spectrums can then be used to derive the anisotropy in thermal conductivity and the phonon mean-free-path spectrums within a single experiment. We believe that this technique can enable high throughput screening of thermal properties for nano-engineered and 2D materials.

Right Definition of Thermoelectric Figure of Merit toward the Thermoelectric Efficiency Prediction for Segmented Devices* BYUNGGI RYU (Presenter), JAYWAN CHUNG, SUDONG PARK, Korea Electrotechnology Research Institute — The dimensionless figure of merit zT has been considered as a good metric for thermoelectric efficiency. But, due to the strong temperature dependence of material properties, the relation between the material properties and device performances is not clear. Here, we generalize the definition of device figure of merit $Z_{gen}T$. Since the thermoelectric leg acts as a electric and a thermal circuit, the $Z_{gen}$ should be written as $Z_{gen} = (V/\Delta T)^2/RK$, where V, R, and K are generated voltage, electric resistance, and the thermal conductance. Thus V, R, and 1/K should be computed as integrals of material properties ($-\alpha, \rho, \kappa$) on position x, not on temperature T. Using the temperature approximation of zero-electric-current condition, the $Z_{gen}$ is simply approximated as $Z_{gen}^{(0)} = <\alpha^2>/<\rho\kappa>$, where <> is a temperature average. Also we reveal that the $Z_{gen}^{(0)}$ is a good rank-preserving-parameter for efficiency prediction even for the segmented devices.

9:48AM R47.00008: NMR investigation of filled skutterudites \(\text{Ba}_x\text{Yb}_y\text{Co}_4\text{Sb}_{12}\) and \(\text{A}_x\text{Co}_4\text{Sb}_{12}\) (\(A = \text{Ba, Sr}\)) \(^{*}\)  

YEFAN TIAN (Presenter), ALI SIRUSI, Department of Physics and Astronomy, Texas A&M University, SEDAT BALLIKAYA, Department of Physics, Istanbul University, NADER GHASSEMI, Department of Physics and Astronomy, Texas A&M University, CTIRAD UHER, Department of Physics, University of Michigan, JOSEPH HANSBRO ROSS, Department of Physics and Astronomy, Texas A&M University —

Considered as one of the most promising thermoelectric families, skutterudite \(\text{CoSb}_3\) shows a high \(ZT\) value when prepared with filler atoms such as \(\text{Ba, Sr, Yb, etc.}\) We report \(^{59}\text{Co}\) NMR and transport measurements on \(\text{BaxYbyCo}_4\text{Sb}_{12}\) and \(\text{AxCo}_4\text{Sb}_{12}\) (\(A = \text{Ba, Sr}\)) as promising thermoelectric candidates. To analyze the experimental results, we developed a formalism for the NMR shifts and \(T_1\), allowing for arbitrary carrier densities rather than treating the extreme metallic or non-degenerate limit. We find that a model in which a large density of defect states located just below the conduction band edge dominate the electrical behavior works very well, providing a consistent picture of both the NMR and transport results. The carrier effective masses and \(g\)-factors estimated from NMR fitting results are in close agreement with each other. Additional contributions observed in shift and \(1/T_1\) measurements are shown to correspond to the susceptibility of electrons in localized states.

10:00AM R47.00009: Rattling dynamics under a planar coordination in tetrahedrites  

CHUL-HO LEE (Presenter), National Institute of Advanced Industrial Science and Technology, KOICHIRO SUEKUNI, Kyushu University, EIJI NISHIBORI, University of Tsukuba, HITOSHI MORI, HIDETOMO USUI, MASAYUKI OCHI, Osaka University, TAKUMI HASEGAWA, Hiroshima University, MITSUTAKA NAKAMURA, SEIKO OHIRA-KAWAMURA, KOJI KANEKO, Japan Atomic Energy Agency, KATSUAKI HASHIKUNI, Hiroshima University, KAZUHIKO KUROKI, Osaka University, TOSHIRO TAKABATAKE, Hiroshima University — Suppressing lattice thermal conductivity \((k_L)\) as low as possible is essential to achieve high thermoelectric performance. One of effective methods is to use the rattling which is large anharmonic vibration of atoms. Typically, rattling atoms locate in oversized atomic cages of caged compounds. Recently, we found several new thermoelectric materials that contain rattling atoms without oversized cages. In \(\text{LaOBiS}_{2}\) and tetrahedrites, \(\text{Bi}\) and \(\text{Cu}\) atoms having a planar coordination vibrate largely toward out of plane [1-3]. We investigated crystal structures and phonon dynamics of tetrahedrites to clarify the driving force for the occurrence of rattling in a planar coordination. We found that the amplitude of \(\text{Cu}\) rattling increases with decreasing \(\text{S}_3\)-triangle area. The rattling energy observed by inelastic neutron scattering decreases with decreasing the \(\text{S}_3\)-triangle area and finally damped demonstrating an enhancement of anharmonicity. The results suggest that chemical pressure is essential for the appearance of planar rattling in contrast to caged compounds where free space is essential. [1] Y. Mizuguchi et al., J. Appl. Phys. 119, 155103 (2016). [2] C. H. Lee et al., Appl. Phys. Lett. 112, 023903 (2018). [3] K. Suekuni, C. H. Lee et al., Adv. Mater. 30, 1706230 (2018).

10:12AM R47.00010: Enhancement of thermoelectric figure of merit by pressure-driven electronic topological transition  

LIUCHENG CHEN (Presenter), Center for High Pressure Science and Technology Advanced Research, PEI-QI CHEN, Science, Mathematics, Computer Science Program,Poolesville High School, VIKTOR V STRUZHKA, ALEXANDER GONCHAROV, Geophysical Laboratory, Carnegie Institution of Washington, QIAN ZHANG, ZHIFENG REN, Department of Physics and TcSUH University of Houston, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research — The world is currently facing a state of energy shortage, and thus the alternative green energy is ultimately in demand. Thermoelectric generators, which can generate electricity directly from waste heat with the advantages of reliability and compactness, are considered as potential devices for waste heat recovery. The thermoelectric performance is usually evaluated by a parameter named as the figure of merit \(ZT\). So far, the maximum \(ZT\) at room temperature has remained around 1.0 over sixty years. For practical technological applications, it is highly desired to break this barrier. Here, we choose a Cr doped PbSe with the maximum \(ZT\) less than 1.0 at high temperature of about 700 K. By simply applying external pressure, we obtain the record high \(ZT\) value of 1.74 at room temperature. Pressure-driven electronic topological transition is proposed to account for such a huge enhancement. These results and findings point to a new direction in the improvement of \(ZT\) in the existing thermoelectric materials through the lattice compression.
10:24AM R47.00011: Impressive enhancement of thermoelectric performance in CuInTe2 upon compression  
HAO YU (Presenter), LIUCHENG CHEN, HONGJIE PANG, Center for High Pressure Science & Technology Advanced Research, XIAOYING QIN, Key Laboratory of Materials Physics, Institute of Solid State Physics, Chinese Academy of Sciences, PENGFEI QIU, XUN SHI, LIDONG CHEN, Chinese Academy of Sciences, XIAO-JIA CHEN, Center for High Pressure Science & Technology Advanced Research — Thermoelectric materials can directly generate electric power by converting waste heat, and the efficiency is appraised by the figure of merit $zT$. A high $zT$ value larger than 3 is required to achieve comparable efficiency of the traditional heat engines. Despite great efforts over a century, the desired value of 3 is seemingly an upper limit and many existing thermoelectric materials have the $zT$ values less than 1. If their $zT$ values can be improved for several times to break through the upper limit, the energy revolution could be expected. Here, a p-type CuInTe2 is chosen as an example to show the extremely important role of pressure played in enhancing the thermoelectric performance. Over 5 times increase of the $zT$ value is realized by the application of pressure. Both the enhancement of the power factor and the reduction of the thermal conductivity account for this impressive enhancement. The former is due to the optimization of the carrier concentration and band structure, and the latter is attributed to the enhanced phonon anharmonicity. Our results offer an effective method to improve $zT$ of the existing materials for the future technological applications.

10:36AM R47.00012: Thermoelectric sulfides with the colusite structure: theory and experiments*  
VENTRAPATI PAVAN KUMAR, ENSICAEN, UNICAEN, CNRS, CRISMAT, Normandie Univ, ANDREW R SUPKA, Dept. of Physics and Science of Advanced Materials Program, Central Michigan University, PIERRIC LEMOINE, CNRS, ISCR, Univ. Rennes, OLEG I. LEBEDEV, BERNARD RAVEAU, ENSICAEN, UNICAEN, CNRS, CRISMAT, Normandie Univ, KOICHIRO SUEKUNI, Dept. of Applied Science for Electronics and Materials, Kyushu University, VIVIAN NAASSIF, CNRS, Univ. Grenoble Alpes, RABIH AL RAHAL AL ORABI, MARCO FORNARI (Presenter), Dept. of Physics and Science of Advanced Materials Program, Central Michigan University, EMMANUEL GUILMEAU, ENSICAEN, UNICAEN, CNRS, CRISMAT, Normandie Univ — We have achieved extraordinary power factors in bulk thermoelectric sulfides with the colusite structure without compromising the low lattice thermal conductivity. Using a synergy between high-throughput calculations and experiments we learned a possible strategy to engineer the electron relaxation time. The protocol is based on the “conductive network paradigm”, it has been applied to a variety of compositions and lead to power factors up to 1.86 mW m$^{-1}$ K$^{-2}$ at 700K and $zT$=0.86 before any optimization procedure.

10:48AM R47.00013: Thermoelectric transport properties with non-parabolicity, degeneracy and multiplicity of band edges: The case of anisotropic p-type SnSe*  
ANDERSON CHAVES (Presenter), John A. Paulson School of Engineering and Applied Sciences, Harvard University, JUAN J MELENDEZ, Physics Department, University of Extremadura, ROBERT L GONZALEZ-ROMERO, Departamento de Sistema Físicos, Químicos y Naturales, Universidad Pablo de Olavide, ALEX ANTONELLI, Gleb Wataghin Institute of Physics, University of Campinas — Efficient ab initio computational methods for the evaluation of transport properties of thermoelectric (TE) materials, are highly important for the development of energy harvesting technologies. The BOLTZTRAP code [1] has been widely used for this aim. However, its current version relies only on the constant relaxation time (RT) approximation, within the Boltzmann transport equation. Here, we extend the implementation of the BOLTZTRAP code by incorporating realistic k-dependent RT models of the main scattering processes, namely, screened polar and nonpolar scattering by optical phonons, scattering by acoustical phonons, and scattering by screened ionized impurities. The RT models are based on a smooth Fourier interpolation of the Kohn-Sham eigenvalues and its derivatives, thus, taking into account non-parabolicity, degeneracy and multiplicity of the band edges on equal footing, at a very low computational cost. To test our approach, we determined the anisotropic TE transport properties of the Pnma phase of p-type SnSe. Our results for the evolution of TE coefficients with both temperature and chemical potential are in agreement with the experimental data.

8:00AM R48.00001: Marangoni convection in an evaporating sessile droplet depending on the substrate temperature.* LEV BARASH (Presenter), Landau Institute for Theoretical Physics, ALEXANDRA GAVRILINA, National Research University Higher School of Economics — We investigate numerically quasi-steady internal flows in an axially symmetrical evaporating sessile droplet of capillary size. The hydrodynamics of an evaporating sessile drop and effects of the thermal conduction in the droplet and substrate have been taken into account jointly. The equations have been solved by finite element method using ANSYS Fluent. Temperature distributions and the corresponding vortex structures in evaporating sessile droplets are obtained. The phase diagrams containing information on the number and orientation of the vortices depending on the ratio of substrate to fluid thermal conductivities and the contact angle, are presented and analyzed for different values of parameters. Depending on the substrate temperature, we obtain both axisymmetric and asymmetric fluid flow patterns.

*This work was supported by the Russian Science Foundation (project No. 18-71-10061).

8:12AM R48.00002: Spreading and contracting three-component droplets for cleaning high energy surfaces DIETER BAUMGARTNER (Presenter), ETH Zurich, SHAYANDEV SINHA, NATE J. CIRA, Rowland Institute at Harvard — Marangoni flows are a well established mechanism for inducing droplet spreading and contraction. In this work, we study the behavior of a three-component mixture (ethanol, water, and propylene glycol) on high energy surfaces. Evaporation of the ethanol (most volatile, lowest surface tension) results in a higher surface tension around the perimeter of the droplet and rapid spreading. After ethanol evaporation, water evaporation (next most volatile component, highest surface tension) from the perimeter induces a reversal in the direction of Marangoni flow and droplet contraction. We investigate this ternary parameter space to unravel the interplay of Marangoni flow, capillary flow, and evaporation. The self-expansion and contraction of these droplets make them suitable for cleaning even high energy surfaces.

8:24AM R48.00003: Binary Droplets Walking With Their Feet.* JEHAN CHARLIER (Presenter), ALEXEY REDNIKOV, SAM DEHAECK, PIERRE COLINET, DENIS TERWAGNE, Universite libre de Bruxelles — We shed new light on paramount but so far highly elusive morphological features of perfectly wetting binary sessile droplets evaporating into air with a more volatile component possessing higher surface tension (water + propylene glycol). By both interferometric measurements of the detailed shapes of the drops and theoretical developments, we show that there is a narrow high-curvature zone due to the solutal Maranoni effect localized near the edge (foot) of the droplet that dictates the overall droplet shape and behavior by means of induced apparent contact angles. The phenomenon is studied as a function of the mass fraction of the components in the droplet and the ambient relative humidity. We devise a local model, based on the lubrication approximation and Marangoni-flow-related Taylor dispersion, that enables to predict the apparent contact angles without any fitting parameters or invoking any microphysics. Motion dynamics of such droplets in a humidity gradient is also studied.

8:36AM R48.00004: Tears of Wine PRERANA RATHORE (Presenter), CHENXIAN XU, VIVEK SHARMA, University of Illinois at Chicago — `Tears of wine` refer to the rows of wine-drops that spontaneously emerge within a glass of strong wine. Evaporation-driven Marangoni flows near the meniscus of water-alcohol mixtures drive liquid upward forming a thin liquid film, and a rim or ridge forms near the moving contact line. Eventually, the rim undergoes an instability forming drops, that roll back into bulk reservoir forming so-called tears or legs of wine. Most studies in literature argue the evaporation of more volatile, lower surface tension component (alcohol) results in a concentration-dependent surface tension gradient that drives the climbing flow within the thin film. Though it is well-known that evaporative cooling can create temperature gradients that could provide an additional contribution to the climbing flows, the role of thermocapillary flows is less well-understood. Furthermore, the patterns, flows and instabilities that occur near the rim, and determine the size and periodicity of tears, are not well-studied. Using experiments and theory, we visualize and analyze the formation and growth of tears of wine. The sliding drops, released from the rim towards the bulk reservoir, show oscillations and a cascade of fascinating flows that are analyzed for the first time.
Efforts to numerically model droplet-resolved, nonwetting emulsions in complex environments have been stymied, chiefly as multiphase flow through fibrous materials, packed beds with complex pellet shapes, and tortuous subsurface settings. Emulsions are encountered in a variety of environments, such as multiphase flow through fibrous materials, packed beds with complex pellet shapes, and tortuous subsurface settings. Efforts to numerically model droplet-resolved, nonwetting emulsions in complex environments have been stymied, chiefly due to the extremely close approach of fluid-fluid interfaces to solid surfaces. A multimesh desingularization technique is introduced to model the flow of tight-squeezing drops through arbitrary Lyapunov surfaces, i.e., smooth solid obstacles, using a boundary-integral formulation. The method utilizes a hierarchy of embedded mesh resolutions to approximate analytical single- and double-layer contributions from solid particles, for use by the high-order singularity subtraction scheme introduced by Zinchenko and Davis (2006). We present a fully three-dimensional study of drop squeezing through parallel cylindrical particles. Squeezing behavior through a fibrous material using this model is characterized with respect to capillary number, viscosity ratio and droplet size. The critical capillary number, below which trapping occurs, is found to lie between those of two-sphere and three-sphere constrictions.

9:36AM R48.00009: A versatile 3D-printed droplet-on-demand generator NIKOLAY P IONKIN (Presenter), DANIEL M HARRIS, School of Engineering, Brown University — There is a rapid and persistent growth in the study of dynamical behavior of droplets, however, the precise generation of these droplets over a range of sizes can be challenging. A versatile 3D-printed droplet-on-demand generator is presented for laboratory use. The design is modeled off of an existing design [Harris et al., Experiments in Fluids, 56:83 (2015)] but is tested with an extended range of working fluids and the manufacturing process is greatly simplified by 3D-printing the principal components. The present device is tested with deionized water and water-glycerol mixtures, and was reliably able to produce single droplets-on-demand of diameters 0.65-1.32 mm with an overall variability of less than 1%. Tips for fabrication, operation, and maintenance as well as potential applications will be discussed throughout.
9:48AM R48.00010: Axisymmetric Ellipsoidal Droplet Impact on a Horizontal Solid Surface*  XUAN ZHANG (Presenter), XIN LIU, XIAOMIN WU, JINGCHUN MIN, Tsinghua University — Droplet impact process on a solid surface exists in fields such as coating chemistry, inkjet printing, aerospace, etc. In many cases, the initial shape before a droplet impacts on the surface will be effected by the surroundings including flow, gravity and electric field and so on. Thus, a droplet with irregular initial shape will have a quite different impact process from a spherical droplet. In this work, the impact processes of spherical droplets are first simulated using VOF multiphase model coupled with Kistler's dynamic contact angle model, which is verified by the results in our experiment and reference. Then, simulations are conducted on the impact processes of axisymmetric ellipsoidal droplets with different aspect ratios (0.5~2.0) under serials of contact angle (30°~150°) and We number (10~90). It is found that the maximum spreading factor and its corresponding time increases with increases of We number and aspect ratio and decrease of contact angle. Based on an approximate theoretical analysis, an correlation between the maximum spreading factor and We number, contact angle and aspect ratio is proposed, aimed to improve the understanding of the mechanism of droplet impact.

Session R49 DPOLY DBIO DFD GSNP: Polymer and Polyelectrolyte Rheology I: Molecular Sequence and Architecture  BCEC 252A - Samanvaya Srivastava, University of California, Los Angeles - Tag(s): Focus

8:00AM R49.00001: Elasticity of Self-Assembled Block Copolymers in Water and Oil Mixtures*  SAHAR QAVI (Presenter), Chemical and Materials Engineering, New Mexico State University, MILLICENT FIRESTONE, Los Alamos National Laboratory, REZA FOUDAIZI, Chemical and Materials Engineering, New Mexico State University — Amphiphilic block copolymers self-assemble at water/oil interface and form different mesomorphic structures such as lamellar, micellar cubic, normal hexagonal and reverse hexagonal. Usually, these structures are polycrystalline and their elasticity depends on the orientation of their constituent's single crystals. We provide a model to predict the elasticity and yielding of mesophases from their characteristic length and intermicellar interactions. Shear modulus of each structure has been calculated as a function of deformation (strain) applied in one direction. Zero shear modulus, G0, depends on the inverse of intermicellar distance with a power-law model. The power-law index for each structure is about n+2 where n is the degree of confinement in mesophase. Rheological properties of different mesophases of Pluronic P84 in the presence of water and p-xylene are used as case study. Our model is in good agreement with experimental data in the linear viscoelastic region. However, the yield strain value of experimental data is slightly lower than that of the model. Frequency sweep measurements were done to further characterize each mesophase structure and cooperative model was used to fit the frequency sweep data of mesophases.

8:12AM R49.00002: Exploring dynamics of polymerlike wormlike micelles in high shear flow*  PAUL SALIPANTE, ALEX CONTE, VISHNU DHARMARAJ, STEVEN HUDSON (Presenter), National Institute of Standards and Technology — Wormlike micelle solutions entangle and flow like polymers, yet micelles can break and reform. Stress may influence breakage dynamics and the microscopic behavior of these fluids at high stress is not understood. We explore this behavior in pressure-driven microchannel flow. Velocity profiles are measured with high resolution using holographic 3D microparticle tracking velocimetry, to determine the relationship of stress and shear rate. As reported by others, this relationship depends on wall stress and channel dimensions and suggests diffusive processes whose rate depends on channel dimension. We therefore are measuring the local solution concentration with fluorescence microscopy, to explore molecular diffusion. We compare our velocity and concentration profiles to theoretical models that include a diffusive term in the stress balance, which becomes relevant at small channel dimensions.

*The National Institute of Standards and Technology on a Chip funding is gratefully acknowledged.
observed, demonstrating high fiber stiffness (increased by 104) with minimal water consumption. The fibers swell to a diameter of 600% in a gel-like structure at low pH. At neutral pH, the ionization degree is at least 79% and deswelling is along the fibers. The fibers demonstrate pH-responsive behavior with 17% ionization degree and an increase in fiber macromolecular orientation along the fiber axis which implies a better packing of macromolecules due to their orientation confining this solution by electrospinning results in 300-600 nm fibers. Polarized FTIR demonstrates preferred The PECs in aqueous medium was opaque but at 40% ethanol solution was transparent. Extensive stretching and of water/ethanol. Rheological investigation of semi-dilute solution demonstrated maximal relative viscosity at 40% ethanol. studied with 1:1 (by monomer ratio) poly(acrylic acid) (PAA) and poly(allylamine hydrochloride) (PAH) dissolved in a mixture (solid) to coacervates (elastic liquid) to dissolved solutions with increasing salt concentration. In case one of the PEs is dilute solutions of highly charged oppositely polyelectrolytes (PEs) generally yields compositions spanning complexes (solid) to coacervates (elastic liquid) to dissolved solutions with increasing salt concentration. In case one of the PEs is weakly charged, the PE pair can be dissolved without salt by adding an organic co-solvent. Such a system was recently studied with 1:1 (by monomer ratio) poly(acrylic acid) (PAA) and poly(allylamine hydrochloride) (PAH) dissolved in a mixture of water/ethanol. Rheological investigation of semi-dilute solution demonstrated maximal relative viscosity at 40% ethanol. The PECs in aqueous medium was opaque but at 40% ethanol solution was transparent. Extensive stretching and confining this solution by electrospinning results in 300-600 nm fibers. Polarized FTIR demonstrates preferred macromolecular orientation along the fiber axis which implies a better packing of macromolecules due to their orientation along the fibers. The fibers demonstrate pH-responsive behavior with 17% ionization degree and an increase in fiber diameter of 600% in a gel-like structure at low pH. At neutral pH, the ionization degree is at least 79% and deswelling is observed, demonstrating high fiber stiffness (increased by $10^4$) with minimal water consumption.

Effect of edge disturbance on shear banding in polymeric solutions

SEUNGHWAN SHIN (Presenter), KEVIN DORFMAN, XIANG CHENG, University of Minnesota — Edge-induced instabilities have been suggested as one of the possible causes of experimentally observed shear-banding in well-entangled polymer solutions/melts. Using a high-aspect-ratio planar-Couette shear cell, we study the penetration length ($L$) of edge disturbance and the development of bulk shear profiles in highly entangled DNA solutions by measuring shear profiles while varying the locations from near-edge to center of the shearing plates. Under a weak oscillatory shear flow, where the corresponding Weissenberg number ($Wi$) > 1 and the DNA solutions display linear shear profiles with strong wall-slip, we find that $L$ is comparable to the gap ($H$) between the plates. On contrary, under a stronger oscillatory shear ($Wi$ > 1) that produces shear-banding profiles, $L$ is an order-of-magnitude larger than $H$ and the region of the stabilized shear-banding profiles becomes anisotropic. Moreover, a well-developed shear-banding profile persists farther away from the edge, where the edge effect is negligible, which implies its true bulk nature. Our results clarify a surprisingly long penetration of the edge disturbance and the bulk nature of shear-banding flows in entangled polymeric solutions under large amplitude oscillatory shear.

Viscoelastic Response of Branched Polyethylene Combs: A Molecular Dynamics (MD) Simulation Study

SIDATH WIJESINGHE (Presenter), Department of Chemistry, University Of North Carolina, DVORA PERAHIA, Clemson University, GARY GREST, Sandia National Laboratories — Polymers exhibit distinctive rheological behavior depending on their architecture. Addition of small number of branches is sufficient to affect the rheology of polymers compared to their linear counterpart with the same molecular weight. Here, using coarse grained molecular dynamics simulations we resolve the effects of the branch length and branch density on the viscoelastic response of entangled polyethylene (PE) melts with branch lengths above and below the entanglement length. The stress relaxation behavior is measured following a small perturbation and from the stress autocorrelation function using the Green-Kubo relation. We find that the plateau modulus is sensitive to both branch length and branch density and decreases with decreasing branch length, consistent with reduction in entanglement length and increase in tube diameter. This study contributes to the nanometer level insight into long-lived problems in viscoelastic responses of polymers.

We kindly acknowledge NSF DMR 1611136

Flow behavior and impact of shear fields on structural transitions in diblock and triblock copolymer aqueous solutions

CONNOR S VALENTINE, LYNN WALKER (Presenter), Carnegie Mellon University — Low molecular weight diblock and triblock polymers in selective solvents form disordered micellar phases at low concentration and liquid crystal phases at high concentration (or low solvent to amphiphile molar ratio in the case of water). The energetic barriers between different lyotropic states and structures are large enough for systems to become kinetically trapped, but low enough for weak external fields to alter the nanoscale structure. We have been able to align ordered structures and anneal out defect texture in polycrystalline materials. Results for two different block copolymers in aqueous solution will be shown and rheological features correlated with structural measurements (through SANS and SAXS). The use of weak shear fields to align lyotropic structures and then transition to other low and high symmetry structures will be demonstrated.

Accelerated diffusion and entanglement evolution during relaxation of aligned polymer melts

MARCO GALVANI (Presenter), AUSTIN HOPKINS, Johns Hopkins University, THOMAS O’CONNOR, Sandia National Laboratories, MARK OWEN ROBBINS, Johns Hopkins University — The dynamics of entanglement formation and loss has long been recognized as a fundamental mechanism behind the macroscopic rheological properties of polymer melts. Models based on entanglements and a confining tube have been very successful in describing equilibrium diffusion and low rate viscous flow, but it is not yet clear how to extend these tube models to highly aligned states produced by shear or elongational flow and experiments cannot directly measure entanglements. Here we use molecular dynamics simulations to follow the motion of monomers and chains and the evolution of entanglements during relaxation from highly aligned states produced by shear and elongational flow. Polymers are modeled with the coarse-grained FENE potential with varying chain stiffness and entanglements are followed with both Primitive-Path Analysis and the Z1 code. Chain retraction occurs over the equilibrium Rouse time and chains reorient on the equilibrium disentanglement time. In sharp contrast to existing theories, the entanglement density does not decrease during chain retraction. A monotonic increase in entanglement density is observed that can be understood from the chain dynamics.

10:24AM R49.00011: Filled Rubbers Missing High Harmonics in LAOS  SHAN JIANG (Presenter), School of Chemical Science and Engineering, Tongji University, XIAORONG WANG, Institute for Advanced Study, Tongji University — In the present work, the rheological properties of a number of filled elastomers under large amplitude oscillatory shear conditions are investigated. In the nonlinear regime the stress outputs of filled rubbers are surprisingly sinusoidal and essentially absent of any high harmonics. Fourier transform analysis shows that the ratio of the third to the first harmonic responses (I₃/I₁) in the range when G’ loses 70% of its original value and G” passes through its maximum is typically less than 4%. As the strain amplitude increases the ratio I₃/I₁ also displays a maximum and can be linearly corrected with the damping factor tanδ. Such a relationship is independent of the filler content and may reveal some important fundamentals behind this phenomenon.

10:36AM R49.00012: The positions and trajectories of deformed polymers and networks  KAIAI ZHENG (Presenter), YIFAN ZHANG, Institute for Basic Science, LINGXIANG JIANG, Jinan University, JIANG ZHAO, Chinese Academy of Sciences (CAS), STEVE GRANICK, Institute for Basic Science — This laboratory is interested to understand the heterogeneity that underpins an overall rheological response. To this end, we are integrating fluorescence and phosphorescence imaging with controlled rheological polymer deformations. Integrating epifluorescence imaging with a rheometer, we image individual molecules. Integrating new mechanophores with polymerized networks, we image individual stressed chains. Integrating polymer deformation with a newly-designed approach for fast STED (super-resolution) imaging, we also go below diffraction limitations. Result findings will be discussed.

Session R50 DPOLY: Ion Transport Mechanisms in Poly(ionic liquids) and Polymer Electrolytes BCEC 252B - Pinar Akcora, Stevens Institute of Technology - Tag(s): Focus

8:00AM R50.00001: Decoupling Conductivity and Segmental Motion in Polymerized Ionic Liquids*  JORDAN KEITH (Presenter), VENKATRAGHAVAN GANESAN, University of Texas at Austin — We characterize diffusion trends in polymerized ionic liquids using atomistic molecular dynamics simulations of a number of anion species and imidazolium cations, both tethered to and implanted in poly-alkyl backbones, to develop design guidelines for polymerized ionic liquids with highly decoupled conductivity and polymer segmental dynamics. We use glass-transition-normalized temperature to compare conductivity for similar segmental dynamics behavior across a variety of chemical species. Results suggest that ion mobility decoupling depends on two distinct modes: 1) a small-ion ion-pairing mode where conduction relies heavily on an ion-hopping mechanism that has been explored previously, and 2) a large-ion free-volume diffusion mode that utilizes large, interconnected gaps in the polymer matrix for diffusion in the absence of segmental motion.

*The authors acknowledge the Texas Advanced Computing Center (TACC) at The University of Texas at Austin, and funding in part by grants from the Robert A. Welch Foundation (Grant F1599), the National Science Foundation (DMR-1721512 and CBET-1706968), and the Donors of the American Chemical Society Petroleum Research Fund (56715-ND9).

8:12AM R50.00002: Molecular design of precise network polymerized ionic liquids to control aggregation and conductivity  QIUJIE ZHAO (Presenter), Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, CHENTHIAN SHEN, Department of Chemistry, University of Illinois at Urbana-Champaign, CHRISTOPHER EVANS, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — Polymerized ionic liquids (PILs) are promising energy storage materials due to their high ionic conductivity and great thermal stability. The structure-property relationships of linear PILs have been extensively studied, yet little is known about other polymer architectures such as networks. We synthesized linear and network PILs containing precise linker lengths between charges using step-growth polymerization. Two different linkers were incorporated, either an 11 carbon chain (C11) or a tetra(ethylene oxide) chain (EO, also 11 atoms), to vary the network polarity. Wide-angle X-ray scattering measurements showed that the ion aggregation peaks were less intense in the EO systems, suggesting that the polar backbone provides better ion solvation. Network PILs had more pronounced ion aggregation peaks than their linear counterparts, indicating a role of polymer architecture on ion clustering. In addition, the EO network showed a two orders of magnitude increase in conductivity relative to the linear analogue at Tg+10°C. We hypothesize that the cross-linked structure provides greater correlation of conduction pathways. This systematic study provides a fundamental understanding on how polymer architecture and polarity can influence the aggregation and transport of ions in PILs.
8:24AM R50.00003: Competitive structural and cooperative dynamical heterogeneities of hydrogen bonding and π-type interactions in imidazolium bis(oxalato)borate and polymers  YONGLEI WANG (Presenter), AATTO LAAKSONEN, Department of Materials and Environmental Chemistry, Stockholm University, MICHAEL DAVID FAYER, Department of Chemistry, Stanford University, JIAYIN YUAN, Department of Materials and Environmental Chemistry, Stockholm University — Delicate intermolecular features like hydrogen bonding (HB) and π-type interactions play pivotal roles in stabilizing molecular structures in ionic liquids (IL) bearing ring planes and HB sites. The nature of these interactions is distinct depending on specific ion types. HB and π-type interactions simultaneously occur in ILs consisting of imidazolium cations coupled with small anions. However, both HB and π-type interactions are considerably weakened when imidazolium cations are associated with large anions. The trade-off between HB and π-type interactions becomes more complicated if anions are featured with ring planes. We performed first-principles and atomistic simulations to explore HB and π-type associations in imidazolium bis(oxalato)borate ILs. Preferential HBs and π-type coordinations among ring planes coexist in ILs. Lengthening alkyl chains in cations leads to a substantial increase in HB strength but decrease in π-π stacking stability between ring structures, indicating a competitive structural feature between HB and π-type associations. A cooperative character is observed in HB dynamics and in reorientations of rings with lengthening alkyl chains in cations. We will explore additional structural and dynamical heterogeneities in polymerized ILs in our ongoing work.

8:36AM R50.00004: The Role of Polymer Backbone Chemistry on Ionic Aggregation and Conductivity in Metal-Ligand Coordinating Polymers*  NICOLE MICHENFELDER-SCHAUSER (Presenter), University of California, Santa Barbara, MY LINH LE, Mount Holyoke College, RAM SESHAHRI, RACHEL SEGALMAN, University of California, Santa Barbara — Polymeric ionic liquids capable of conducting multivalent ions are based on metal-ligand coordination interactions. This work explores the roles of polymer backbone chemistry, metal-ligand coordination, and ion concentration on ionic conductivity. In these systems, multivalent ion transport is facilitated via ligands pendant to the polymer backbone. While previous results suggest the matrix dielectric constant affects ion dissociation and aggregate structure, this has been studied only in systems where ions interact directly with the polymer backbone. In the case of pendant ligands, it is not clear immediately that the dielectric constant of the backbone would be relevant in determining ion transport. We show for polymers with pendant imidazole ligands, the local dielectric properties of the polymer backbone, based on either poly(ethylene oxide) (PEO) or poly(butadiene) (PBD), still affect ion aggregation and ionic conductivity. While no aggregation is observed at low salt concentration for the PEO-based polymer, Li+, Zn2+ and Cu2+ show aggregation in the PBD polymer resulting in reduced ionic conductivity. This highlights the importance of backbone dielectric properties even in polymer electrolytes with tethered solvating groups.

*This work is funded by an NSF MRSEC (DMR 1720256).

8:48AM R50.00005: Polymerization of a Imidazolium Ionic Liquid Under 2D Confinement and the Resulting Effects on Ion Dynamics*  THOMAS KINSEY (Presenter), KAITLIN GLYNN, JOSHUA SANGORO, University of Tennessee — We have employed broadband dielectric spectroscopy to probe ion dynamics in 1-ethyl-3-vinylimidazolium bis(trifluoromethylsulfonyl)imide ionic liquid (IL) under confinement within ~7nm nanoporous silica membranes. The IL was then polymerized within the pores to a maximum monomer conversion of ~70% as determined using Raman spectroscopy. Compared to the pure systems in bulk, the confined PIL displayed increased ionic conductivity, while the IL displayed decreased ionic conductivity under confinement. To unravel the effects of unconverted monomer and the effects of confinement on the increased ion conduction in the PIL system, a blend of the IL and PIL was prepared at the same monomer to polymer ratio as was achieved during polymerization within the membranes. Decreased conductivity in bulk compared to confinement is described due to aggregation of the IL in the blend with that does not occur within the membranes due to free volume effects. These results are also compared to recent theoretical results from the literature.

**9:00AM R50.00006: Polymer-Grafted Nanoparticles in Ionic Liquids**

SIQI LIU (Presenter), Stevens Institute of Technology, NARESH OSTI, Chemical and Engineering Materials Division, Oak Ridge National Laboratory, CLEMENS LIEDEL, Max Planck Institute of Colloids and Interfaces, PINAR AKCORA, Stevens Institute of Technology — The newly synthesized zwitterionic liquid (ZIL) 1-butyl-3-methyl imidazole-2-ylidene borane, has superior properties to existing ionic liquids such as good stability in ambient environment. Because it is a zwitterion, there is no self-dissociation of ions, the ion transport and conductivity measured will be due to dynamics of zwitterionic molecule. In this work, deuterated PMMA-grafted nanoparticles with two grafting densities were synthesized. Their dispersion in aprotic ZIL and protic ionic liquid (1-hexyl-3-methylimidazolium bis(trifluormethylsulfonyl)imide) (IL) were investigated in high resolution electron microscopy. We measured dynamics of IL and ZIL with the addition of grafted particles in quasi-elastic neutron scattering experiments. We found translational ionic diffusion of IL slowed down as result of the good mixing and coupling of IL with grafted chains. With the aggregated system, diffusion was similar in bulk, which was due to the phase separation between IL and particles. Interestingly, diffusivity of ZIL increased with the inclusion of particles, particularly with the particles of higher graft density. The increased diffusivity is explained by the confinement of ZIL within structures of grafted nanoparticles.

**9:12AM R50.00007: Effects of Molecular Architecture on the Simultaneous Enhancement in Modulus and Ionic Conductivity in Polymer Solid Electrolytes**

SPIROS ANASTASIADIS (Presenter), EMMANUIL GLYNOS, PARASKEVI PETROPOULOU, LAMPROS PAPOUTSAKIS, Foundation for Research and Technology-Hellas and Univ. of Crete, Heraklion Crete, Greece, EMMANOUIL MYGIAKIS, ALKMINI D. NEGA, GEORGIOS SAKELLARIOU, National and Kapodistrian University of Athens, Greece, WENYANG PAN, EMMANUEL P. GIANNELIS, Cornell University, USA — In an effort to develop solid polymer electrolytes (SPEs) with enhanced mechanical modulus and ionic conductivity, we utilize PMMA stars with high functionality as rigid nanoparticle additives to a liquid PEO electrolyte, doped with LiTFSI. The resulting SPEs exhibit two orders of magnitude higher conductivity and one order of magnitude higher mechanical strength compared to their linear PMMA blend analogues. In addition, the former remain solid-like over an extended temperature range. This performance is due to the SPE morphology of dispersed PMMA nanoparticles within the liquid electrolyte host, which allows for the formation of a highly interconnected network of pure liquid electrolyte that leads to high ionic conductivity (comparable to that of the neat PEO electrolyte).

**9:24AM R50.00008: Increasing Permittivity in Ion-Containing Polymers: Influence of Zwitterion Additives on Ion-Conduction**

WENWEN MEI (Presenter), JOSH M RINEHART, JOSH E BOSTWICK, ROBERT HICKEY, RALPH H COLBY, Materials Science & Engineering, Pennsylvania State University — An effective approach to improve the ionic conductivity in ion-containing polymers is to increase the dielectric constant of the host, by adding molecules with large dipole moments. With covalently bonded cation and anion on a single molecule, zwitterions are promising candidates. Despite the high ionic conductivity observed by zwitterion addition in polymerized ionic liquids (PILs), the underlying mechanism remains misunderstood. Here, we studied the change in dielectric constant for a series of sulfonate-imidazolium-based zwitterions blended with glycol solvents using dielectric relaxation spectroscopy (DRS). Adding zwitterions drastically increases the permittivity compared with that of the pure glycol solvents. The Landau-Lifshitz mixing rule describes well the measured permittivities of the blends and was further used to extrapolate to the permittivities of pure zwitterions based on their blend behavior. The dependence of measured permittivity on zwitterion structure, composition, and temperature will be discussed in the context of ion conduction in polymeric materials. The work presented here highlights the exceptional ability of zwitterions to increase permittivity and their potential to boost conductivity of PILs by creating a more polar environment.
9:36AM R50.00009: Quantitative Evidence of Mobile Ion Hopping in Polymerized Ionic Liquids*  HONGJUN LIU (Presenter), ALEXEI P SOKOLOV, STEPHEN J PADDISON, University of Tennessee —
We demonstrate the dynamical heterogeneity and cooperative motion of ion transport in polymerized ionic liquids using atomistic molecular dynamics simulations and establish quantitative evidence of mobile ion hopping for the first time. The hopping of anions is dominantly interchain in nature and is generally facilitated by five associating cations from two chains. Intrachain hopping was found to be much less significant being mediating with fewer chains. The mobile anions tend to form string-like structures and move cooperatively; and the string length of concerted motion of mobile anions increases with decreasing temperature. Our results reveal the important role of a distance criterion in defining hopping events to elucidate the ion transport mechanism which has a significant consequence on rationalizing experimental observations and the design of novel polyILs.

9:48AM R50.00010: Ion Transport in Precise Sulfonate Ionomers with Layered, Cylindrical, and Gyroid Morphologies*  LU YAN (Presenter), Department of Chemical and Biomolecular Engineering, University of Pennsylvania, U.S., CHRISTINA RANK, STEFAN MECKING, Department of Chemistry, University of Konstanz, Germany, KAREN WINEY, Department of Materials Science and Engineering, University of Pennsylvania, U.S. — Precise spacing of ionic pendant groups along linear polymers produces well-defined nanoscale ion-aggregate morphologies and allows new insights into the ion transport mechanism. In this study, we investigate a series of new ionomers synthesized by polycondensation having sodium (Na\(^+\)) or tetrabutylammonium ([N(C\(_4\)H\(_9\))\(_4\)]\(^+\)) sulfosuccinate segments precisely placed every 23 or 48 backbone carbons of a linear backbone. X-ray scattering studies suggest that these precise semicrystalline ionomers containing sodium sulfosuccinate segments form layered or bicontinuous cubic gyroid ionic nanochannels at room temperature and transition to hexagonal symmetry upon heating. In contrast, those containing tetrabutylammonium sulfosuccinate segments exhibit layered ionic aggregates and transition to liquid-like morphologies upon heating. The temperature dependence of ion transport includes both VFT and Arrhenius behavior and varies with ion aggregate morphology. Overall, increasing cation size from Na\(^+\) to [N(C\(_4\)H\(_9\))\(_4\)]\(^+\) leads to faster ion transport due to the enhanced ion dissociation. These precise ionomers provide a promising way to design solid polymer electrolytes with interconnected ionic nanochannels for fast ion transport.

*We acknowledge NSF Grant DMR (15-06726).

10:00AM R50.00011: Nanostructured Polymer Particles for High Modulus and High Conductivity Polymer Electrolytes*  EMMANOUIL GLYNOS (Presenter), LAMPROS PAPOUTSAKIS, SPIROS ANASTASIADIS, Institute of Electronic Structure and Laser, Foundation for Research and Technology-Hellas, WENYANG PAN, EMMANUEL P. GIANNELIS, Department of Materials Science and Engineering, US, Cornell University, PETRA BACOVA, VAGELIS HARMANDARIS, Institute of Electronic Structure and Laser, Foundation for Research and Technology-Hellas, EMMANOUIL MYGIAKIS, ALKMINI D. NEGA, GEORGIOS SAKELLARIOU, Department of Chemistry, National and Kapodistrian University of Athens — We will present a facile new approach for the synthesis of all-polymer nanostructured solid electrolytes that exhibit unprecedented combination of high modulus and ionic-conductivity at room temperature. Novel nanostructured polymer particles, composed of mikto-arm star-shaped copolymers, were synthesized and used as additives to liquid electrolytes. The mechanical properties of the resulting SPEs are dramatically improved compared to the pure liquid electrolyte (the shear modulus increased by up to 8-orders of magnitude), while the ionic conductivity was maintained close to that of the pure liquid electrolyte. Key to their performance is their morphology that stems from the ability of the mikto-arm copolymers to self-assembly in highly interconnected structures within the liquid electrolytes host. With the help of atomistic molecular dynamics we will show that our strategy offers a tremendous potential for the design of nanostructured polymeric materials where the morphology of the nanostructured SPEs could be precisely controlled as is encrypted within the macromolecular characteristics of the star-shaped nanoparticles.

Multivalent cation conduction in dual cation-exchanged polyanions

BUMJUN PARK, JENNIFER SCHAEFER (Presenter), University of Notre Dame — Batteries based on active multivalent metal cations are the topic of research worldwide due to the high abundance of these metals. Unfortunately, transport of hard multivalent cations such as Mg$^{2+}$ and Al$^{3+}$ in polymers is known to be very slow, due to the strong interactions of these ions with the polar constituents on solvating polymers resulting in chain crosslinking and sluggish coordination site exchange rates. Here we report on the transport of multivalent cations in certain poly(ionic liquids). The inclusion of bulky organic cations is found to reduce the glass transition temperature of the matrix and screen metal multivalent cation interactions, resulting in enhanced ion transport. Characterization of the structure and dynamics of a family of materials incorporating varying organic cation types will be discussed.

* A portion of this work was supported by the National Science Foundation though grant number DMR-1654162.

Poly(ionic liquid)s: marriage of ionic liquids and polymers for better materials

JIAYIN YUAN (Presenter), Department of Materials and Environmental Chemistry, Stockholm university — This talk will focus on poly(ionic liquid)s (PILs), a class of multifunctional ionic polymers made up from ionic liquid (IL) monomers. The covalent linkage of IL species into polymeric chains or networks incorporates some unique properties of ILs into that of macromolecular architectures. This innovation in structure design catalyzes new chemistry and physics, and in turn expands the property and function window of ILs and traditional polyelectrolytes. However, PILs initially played a merely supplementary role to ILs, the rapid advance in PIL research in the past decade has created a large toolbox of innovative polyelectrolyte structures, making the study of PILs far beyond the scope of IL research. They are of fundamentally important to polymer chemistry and physics, as they offer new elements and features. Meanwhile, benefiting from a large number of cations and anions in IL chemistry, PILs provide a variety of structure choices and materials solutions in other fields. This lecture highlights the behavior and function of ions in PIL bulk or solution, illustrating the importance of ion motion and ion-guest molecule interaction to determine their global materials property and function.

Session R51 DBIO: Artificial Intelligence, Data, and Dynamics: Learning Physical Models of Living Systems

Machine Learning, Statistical Physics, and Ecological Dynamics

PANKAJ MEHTA (Presenter), Boston University — In this talk, I will start by giving an overview of Machine Learning from a physics perspective and highlight open problems where physicists can contribute. I will then discuss the many connections between the statistical physics of disordered systems and ML. Building on this discussion, I will argue that, somewhat surprisingly, ML is also intimately related to ecological dynamics. I will show how many ML methods and concepts have natural counterparts and ecology and argue that these fields can and should cross-fertilize each other.

*The work was supported by NIH NIGMS grant 1R35GM119461, Simons Investigator in the Mathematical Modeling of Living Systems (MMLS) to PM, and the Scialog Program sponsored jointly by Research Corporation for Science Advancement (RCSA) and the Gordon and Betty Moore Foundation.
8:36AM R51.00002: Principles and Possibilities in the Phase Space of Animal Behavior* [Invited] GREG STEPHENS (Presenter), Physics, Vrije Universiteit & OIST Graduate University — We all instinctively recognize behavior: it’s what organisms do, from the motility of single cells to the stunning displays of bird flocks. To understand behavior, however, we must characterize complex, living movement as precisely and completely as its underlying molecular, cellular and network mechanisms. Here, we leverage a low-dimensional but complete representation of the posture of nematode worm C. elegans to reconstruct a continuous 6D phase space of crawling behavior. The reconstruction separates short and long-time dynamics, untangles subtle movement trajectories, and offers a quantitative arena for examining variability and stereotypy. We find that the phase space is organized into 3 conjugate dynamics containing 2 positive Lyapunov exponents which are approximately balanced by dissipative directions. We suggest that a near-Hamiltonian dynamics of coupled, chaotic oscillators underlie the motor control of C. elegans.

*This work was supported by the research program of the Foundation for Fundamental Research on Matter (FOM), which is part of the Netherlands Organization for Scientific Research (NWO), and by funding from OIST Graduate University.

9:12AM R51.00003: The difference between memory and prediction in recurrent networks [Invited] SARAH MARZEN (Presenter), Massachusetts Institute of Technology, ALEXANDER HSU, Mathematics, Claremont McKenna College — Recurrent networks are trained to memorize their input better, often in the hopes that such training will increase the ability of the network to predict. We show that networks designed to memorize input can be arbitrarily bad at prediction. We also find, for several types of inputs, that one-node networks optimized for prediction are nearly at upper bounds on predictive capacity given by Wiener filters, and are roughly equivalent in performance to randomly generated five-node networks. Our results suggest that maximizing memory capacity leads to very different networks than maximizing predictive capacity. We also discuss how well trained recurrent networks can predict, compared to the optimal.

9:48AM R51.00004: Hybrid Forecasting of Complex Systems: Combing Machine Learning with Knowledge-based Models [Invited] MICHELLE GIRVAN (Presenter), University of Maryland, College Park — In recent years, machine learning methods such as "deep learning" have proven enormously successful for tasks such as image classification, voice recognition, and more. Despite their effectiveness for big-data classification problems, these methods have had limited success for time series prediction, especially for complex systems like those we see in weather, solar activity, and brain dynamics. In this talk, I will discuss how a Reservoir Computer (RC) - a special kind of machine learning system that offers a "universal" dynamical system - can draw on its own internal complex dynamics in order to forecast systems like the weather, beyond the time horizon of other methods. The RC provides a knowledge-free approach because it builds forecasts purely from past measurements without any specific knowledge of the system dynamics. By building a new hybrid approach that judiciously combines the knowledge-free prediction of the RC with a knowledge-based, mechanistic model, we demonstrate a further, dramatic, improvement in forecasting complex systems. This hybrid approach can give us new insights into the weaknesses of our knowledge-based models and also reveal limitations in our machine learning system, guiding improvements in both knowledge-free and knowledge-based prediction techniques.

10:24AM R51.00005: Measuring the hidden dynamics of animal behavior* [Invited] GORDON BERMAN (Presenter), Emory University — When we think of animal behavior, what typically comes to mind are actions – running, eating, swimming, grooming, flying, singing, resting. Behavior, however, is more than the catalogue of motions that an organism can perform. Animals organize their repertoire of actions into sequences and patterns whose underlying dynamics last much longer than any particular behavior. How an organism modulates these dynamics affects its success at accessing food, reproducing, and myriad other tasks essential for survival. Animals regulate these patterns of behavior via many interacting internal states (hunger, reproductive cycle, age, etc.) that we cannot directly measure. Studying these hidden states' dynamics, accordingly, has proven challenging due to a lack of measurement techniques and theoretical understanding. In this talk, I will outline our efforts to uncover the latent dynamics that underlie long timescale structure in animal behavior. Looking across a variety of organisms, we find the existence of a non-trivial form of long timescale dynamics that is unexplainable in standard Markovian frameworks. I will present how temporal coarse-graining can be used to understand how these dynamics are generated and how the found course-grained states can be related to internal states governing behavior. Inferring these hidden dynamics presents a new opportunity to generate insights into the neural and physiological mechanisms that animals use to select actions.

Thursday, March 7, 2019 8:00 AM - 11:00 AM
8:00AM R52.00001: STRESS RELAXATION IN EPOXY NANOCOMPOSITES*  SURESH AHUJA (Presenter), xerox corporation — Nanocomposites are formed by the intercalation or exfoliation of nano inorganic fillers into polymers resulting in improvement of physical and mechanical properties relative to the unmodified polymer. In intercalated nanocomposite, the polymer is inserted between the silicate layers forming well-ordered multi-layers, whereas in exfoliated nanocomposite the silicate layers break into single platelets and orient themselves forming a random pattern. The effect of nano filler on strength and toughness appears to depend on the polymer filler interaction, dispersion on the polymer matrix and aggregation of the filler. In terms of polymer chain mobility in a nanocomposite, glass transition has been reported to increase, decrease, or remain unaffected, in comparison with that of the pure polymer, and sometimes a second glass transition has as well been observed. The molecular structure is modeled using a combination of the classical network theory and the elastic dumbbell model for polydispersed polymer segments and localized junctions.

Stress relaxation modulus of epoxy nanocomposites is analyzed. Qualitatively, FENE models can adequately explain experimental results.

8:12AM R52.00002: Coarse-grained Molecular Dynamics Modeling of Epoxy/CNT Nanocomposites*  RALPH ROMERO (Presenter), HAYDEN HOLLENBECK, CHENGYUAN WEN, GARY SEIDEL, SHENGFENG CHENG, Virginia Tech — Modeling fracture in a polymer nanocomposite presents a big challenge at the moment. To enable us to model larger systems over longer time scales that can be bridged to those in continuum mechanics models such as peridynamics, we have developed a coarse-grained molecular dynamics (MD) model of epoxy/carbon nanotube (CNT) nanocomposites. The polymer is described as bead-spring chains with bonded and nonbonded interactions parametrized with atomistic MD simulations. A CNT is represented similarly as a bead-spring chain but with each bond treated as a rod with finite length and radius. Such a treatment leads to a jointed-tube model in which the corrugation issue associated with traditional coarse-grained models of CNTs is removed and the represented CNT behaves as a filament with finite radius. The CNT-CNT and CNT-polymer interactions are further trained with atomistic MD modeling. Using the coarse-grained model, we study the behavior of CNTs in an epoxy matrix including dispersion and bundling and the fracture properties of the epoxy/CNT nanocomposites.

8:24AM R52.00003: QM/MM hybrid simulations of critical failure at the interface in CNT/polymer nanocomposites.  JACEK GOLEBIOWSKI (Presenter), ARASH A MOSTOFI, PETER HAYNES, Imperial College London, JAMES R KERMODE, Warwick Centre for Predictive Modelling, School of Engineering, University of Warwick — Functionalized carbon nanotube (CNT)/polymer composites have received significant interest as promising structural materials with applications in the most demanding areas of industry such as aerospace and ballistic protection. Developing a fundamental understanding of failure mechanisms at the CNT/polymer interface is essential to improving their properties. Here, we use a quantum mechanics/molecular mechanics (QM/MM) hybrid approach to show how chemical structure at the CNT/polymer interface determines its strength and propose candidate chemistries to guide further experimental work.

Computational investigation of interfacial failure in composite materials is challenging because it is inherently multi-scale: the bond-breaking processes that occur at the covalently bonded interface and initiate failure involve QM phenomena, yet the mechanisms by which external stresses are transferred through the matrix occur on length and time-scales far in excess of anything that can be simulated with QM. Here, we demonstrate and validate an adaptive QM/MM simulation method that can be used to address these issues. We demonstrate that the hybrid method results are in excellent agreement with fully-QM benchmark simulations and offers qualitative insights missing from classical simulations.
8:36AM R52.00004: A new strategy for tire tread stocks with high performances*  
AIHUA HE (Presenter), XINPING ZHANG, Shandong Provincial Key Laboratory of Olefin Catalysis and Polymerization, Key Laboratory of Rubber-Plastics (Ministry of Education), School of Polymer Science and Engineerin, RIGUO WANG, HAO WANG, Shandong Huaju Polymer Materials Co. Ltd. — The desire tire tread stocks require satisfied comprehensive performances including good wet-skid resistance, low rolling resistance, good abrasion resistance and excellent anti-fatigue property. In our work, trans-1, 4-poly (butadiene-co-isoprene) copolymer rubber (TBIR) as novel reactive functional rubber is introduced into traditional SSBR and SSBR/BR recipes. Owing to the reinforcement effect of TBIR on the blended polymer matrix, TBIR inclusion could not only inhibit the aggregation of silica during ageing process, but also improve the filler dispersion in the rubber matrix. Furthermore, the TBIR in the form of lamellar fibrils could inhibit crack initiation and deviate crack propagation direction. Consequently, the vulcanized elastomer nanocomposites exhibit significantly improved comprehensive properties, such as enhanced mechanical strengths, outstanding fatigue resistance, improved abrasion resistance and lower rolling resistance with other properties remaining unchanged.

8:48AM R52.00005: The Linear-Nonlinear Dichotomy Behavior for Filled Rubbers in LOAS  
SHAN JIANG, School of Chemical Science and Engineering, Tongji University, XIAORONG WANG (Presenter), Institute for Advanced Study, Tongji University — Filled rubbers display an unusual linear-nonlinear dichotomy of their rheological responses under large amplitude oscillatory shears, where the amplitude of stress output deviates strongly from the linear dependence of strain, but the time-dependence of stress remains sinusoidal. Increasing the cross-linking density in the rubber matrix tends to favor this quasi-sinusoidal responses. Rising the usage of processing oil in a rubber compound tends to disfavor this dichotomy behavior. Varying the amount of reinforcement fillers seems to be ineffective, as long as the filler loading exceeds its percolation threshold. These observations suggest that the topological structure of polymer chain network in the matrix plays an important role in the linear-nonlinear dichotomy rheology. The agglomeration of fillers and the overall characteristics of the fractal structures of filler clusters may have a less important influence on this phenomenon. A summary of recent research activities at Tongji on this subject will be given.

9:00AM R52.00006: Controlling Microstructure in Thermoplastic Polyurethane/Graphene Oxide Nanocomposites via Rigid Segment Length*  
BRANDY GROVE (Presenter), SHAGHAYEGH KHANI, Case Western Reserve University, RICARDO ANDRADE, GUILHERMINO FECHINE, MackGraphe, Mackenzie Presbyterian University, JOAO MAIA, Case Western Reserve University — Thermoplastic Polyurethane (TPU) is a commercially and academically interesting polymer with a wide range of applications. Engineering the micro-structure of the block-copolymers is of crucial importance for achieving desired mechanical properties. Incorporation of nanofillers such as graphene and graphene oxide platelets provides a means to control the phase separation for this material. Dissipative Particle Dynamics (DPD) are preformed to study the phase separation of systems with these nanofillers and determine how much difference functionality makes in a variety of TPUs with hard segments of different lengths. Platelet nanofillers act as a nucleating agent in TPUs with shorter hard segments, inducing local order; as the hard segment length becomes longer, the ordered local structures formed by hard segments break down. Functionalized nanofillers do not aid or hinder the nucleation in TPUs with short hard segments, but may enhance order in TPUs with moderately longer segment length, particularly with a hard segment to nanofiller length that is 1/3 the length of the nanofiller size.

Interphases in polymer nanocomposites - recent insights from NMR studies

— The outstanding performance of modern elastomers is dominated by reinforcement arising from nanometric fillers. The compounds’ peculiar thermo-mechanical properties cannot be explained without consideration of an interphase, i.e., a region of polymer with modified properties [1]. Our, and many others’, work supports a consensus picture of adsorbed components with locally increased $T_g$, reaching the bulk value over a gradient zone of a few nm [1-3]. This talk focuses on more recent results, mostly obtained by proton low-resolution NMR, that challenge the generality of this picture.

First, we present a more detailed investigation of a specific system, poly(ethylene oxide) – silica, which only superficially follows the above rationale [4]. While we do find rigid components forming a layer of up to 2 nm thickness around the particles, the layer thickness is not a function of temperature, and the chains in this layer feature rather fast, possibly uniaxial dynamics [5]. Moreover, small particles with diameters down to 10 nm exhibit much reduced layer thickness that depends on the end groups [5]. For a more complete picture, we have extended this study to a wider range of particle sizes, polymer molecular weight, and preparation conditions.

Second, spin-diffusion NMR experiments, which probe the size of nanometric domains with distinct mobility, indicate that the smooth-mobility-gradient picture of the “glassy layer” must be replaced by a scenario ruled by dynamic heterogeneities associated with the increased glass transition. We find intriguing similarities of filler-related species and interphase components in semicrystalline polymers and block copolymers [6].

Compatibility/Dispersion in Multi-Hierarchical Polymer Nanocomposites

— Commercial polymer nanocomposites such as reinforced elastomers differ significantly from model nanocomposites. Successful commercial products display a complex multi-level hierarchical, nano- to macro-scale structure. We have studied these structures using TEM, small-angle x-ray scattering, and rheology. The multi-hierarchical structure in carbon black reinforced polybutadiene will be described as a function of processing conditions. The filler network in this compound displays a nanoscale aggregate network within nano-clusters that percolate on the micron scale. The nanoscale network develops due to thermodynamic incompatibility of carbon black and polybutadiene which is mitigated by the accumulated strain. The network clusters are limited in size due to incompatibility. On increasing concentration, percolation of these network clusters is observed in scattering, TEM and dynamic rheology. Through this work control over this complex multi-hierarchical structure will be achieved through manipulation of compatibility/incompatibility and processing history.

10:00AM R52.00009: Fabricating Polymer Network Nanocomposites for Recyclability with Full Property Recovery and the Sometimes Complex Roles of Polymer-Nanofiller Interfaces  
XI CHEN (Presenter), LINGQIAO LI, JOHN TORKELSON, Northwestern University — Polymer network nanocomposites cannot be recycled for high-value applications because permanent covalent cross-links prevent melt-state reprocessing. We have developed novel dynamic covalent cross-linking methods that yield recyclability of polymer networks with full recovery of cross-link density. In the fabrication of network nanocomposites, filler surface functionality can provide challenges. With addition-type reversible covalent cross-linking, e.g., a controlled radical polymerization method, surface functionality (e.g., hydroxyl groups) has no significant effect on reprocessability. However, with step-growth-type dynamic covalent cross-linking, e.g., a hydroxyurethane cross-link, surface functionality has deleterious effects. With hydroxyl or amine functionality which can participate in hydroxyurethane chemistry, silica nanoparticles speed the reprocessing but modestly reduce cross-link density and property recovery. Silica nanoparticles with superhydrophobic surfaces (absence of functionality) impact reprocessing kinetics but not recovery of cross-link density. We will also discuss how filler surface functionality combined with dynamic covalent cross-linking may yield novel, well-dispersed nanocomposite networks with especially robust properties.

10:12AM R52.00010: Intrinsic temperature dependence of plasmonic resonances in gold nanorod polymer nanocomposites  
DAVID LIOI, SARAH IZOR, VIKAS VARSHNEY, WILLIAM KENNEDY (Presenter), Air Force Research Laboratory — Optical scattering in plasmonic polymer nanocomposites is strongly influenced by the dielectric properties of both matrix and particles. Since changes in temperature can affect each constituent in fundamentally different ways, interpretation of optical scattering spectra as a function of temperature is not straightforward. Here we present a systematic experimental and analytical study of the optical scattering of gold nanorods embedded in an epoxy matrix. We demonstrate that the temperature dependence of scattering spectra from gold-polymer nanocomposites depends on the relative thickness of the surrounding ligands or inorganic coatings that are typically used to stabilize nanorods in polymer matrices. Using empirical fits for the dielectric functions of gold, epoxy, and coating materials we show that it is possible to correct for temperature effects in the interpretation of scattering spectra. This can greatly enhance the precision and accuracy of material state sensing applications that rely on the plasmonic response of gold nanorods in polymers.

10:24AM R52.00011: The Impact of an Emergent Hierarchical Filler Network on Nanocomposite Dynamics  
KABIR RISHI (Presenter), GREG BEAUCAGE, Chemical and Materials Engineering, University of Cincinnati, VIKRAM K KUPPA, Nonstructural Materials Division, University of Dayton Research Institute, ALEX MCGGLASSON, Chemical and Materials Engineering, University of Cincinnati, JAN ILAVSKY, Advanced Photon Source, Argonne National Laboratory — The performance of nanoscale-filled elastomers is related to the structure of the aggregated filler network in addition to interfacial chemical affinity and filler dispersion. This structure emerges due to a competition between the thermodynamically driven filler immiscibility and the kinetically driven mixing process. A hierarchical filler network model evidenced in x-ray scattering is linked to the dynamic response at low strains in the linear viscoelastic regime. The primary nanoscale network that percolates locally at ~5 vol % displays a mesh-size, which is related to the changes in the dynamic spectrum at frequencies below the Einstein-Smallwood enhancement associated with the elastomer within the network pores in the high frequency region. The secondary micron-scale network associated with the Payne effect and bulk electrical conductivity that percolates globally at ~20 vol %, influences the gel-like dynamic response at very low frequencies. The hierarchical filler network is described by two crossover frequencies in the dynamic spectrum and two related structural scaling regimes.

10:36AM R52.00012: Defect-Mediated Assembly of Liquid Crystal Elastomer Nanocomposites  
XINFANG ZHANG (Presenter), HAO YU, YUBING GUO, TARAS TURIV, O D LAVRENTOVICH, QI-HUO WEI, Advanced Materials and Liquid Crystal Institute, Kent State University, Kent, Ohio, 44242, USA — One holy grail in making polymer nanocomposites is to be able to place the filling particles into designable positions or orientations. In this talk, we will present a new strategy to self-assemble liquid crystal elastomer nanocomposites by employing topological defects in liquid crystals. We show that topological defects with pre-designed shapes and topology can be created by using a photopatterning technique to control the molecular orientations at the boundaries. Nanoparticles dispersed in the liquid crystals are attracted and self-assembled to these topological defects to minimize the elastic energy of the system. With carefully designed molecular orientations, we show the self-assembly of the nanoparticles into loops and web-networks in liquid crystal polymers.

10:48AM R52.00013: **Mesoscale modeling of polymer bigels using Janus particles**  SHENSHENG CHEN (Presenter), XIN YONG, Binghamton University — Polymeric gels composed of chemical-distinct networks may have unique mechanical properties and potential applications in various areas. Nanocomposites of polymer and colloidal particles also draw great attention due to their enhanced strength, stimuli responsiveness, and rheology. To guide the rational design for a bigel contains hydrophilic and hydrophobic networks with predictive properties, we utilize dissipative particle dynamics (DPD) to simulate a model system that incorporate chemistry, physical absorption, and material characterization. To enable the coexistence of hydrophilic and hydrophobic networks, we use Janus particle with corresponding surface chemistries to attract different polymers. A bell model is used to simulate the reversible physical absorption and desorption. Our results show that a bigel is formed when the hybrid polymers are integrated with a high concentration of Janus particles. The bigel exhibits increased Young's modulus and shear thinning behavior. More importantly, the bigel recovers to a homogenous network in a short time after deformation. This integrated approach provides a general path towards functional network materials with enhanced mechanical properties and potential applications in drug delivery and wound dressing.

**Session R53 GSNP: Flow Driven Pattern Formation in Wet Granular Medium I**  BCEC 253C - Arshad Kudrolli, Clark University - Tag(s): Invited

**8:00AM R53.00001: On flow, fracture and getting jammed – Failure modes in dense suspensions**  [Invited] IRMGARD BISCHOFBERGER (Presenter), DOMENICO CAMPANARO, LEOPOLD BEUKEN, Massachusetts Institute of Technology, IVO PETERS, University of Southampton — Dense suspensions are a class of complex fluids that exhibit both shear-thickening and shear-jamming behavior as a response to an applied stress. These dynamic liquid-to-solid transitions have important consequences for the displacement of a dense suspension by another fluid: upon the injection of air, intricate patterns arise in the suspension, leading to flow or fracture of the material. We displace a cornstarch suspension by a pressure-controlled injection of air in a quasi-2D geometry. Depending on the concentration of cornstarch and the applied stress, we observe a variety of patterns: smooth fingering in the fluid regime and different modes of fractures, ranging from slow branched cracks to single fast fractures. Remarkably, there is a regime where, despite the application of pressure, the suspension cannot be displaced. Only upon an increase to a higher pressure, air injection occurs, leading to very thin fractures in the suspension. We hypothesize that in this regime the suspension is in the shear-jammed state. This would imply a novel way of investigating the mechanical properties of a shear-jammed material by probing its fracture behavior.

**8:36AM R53.00002: Multiphase flow in porous media: wetting, disorder, and pattern formation**  [Invited] RUBEN JUANES (Presenter), Massachusetts Institute of Technology — The displacement of one fluid by another in a porous medium gives rise to a rich variety of hydrodynamic instabilities. Beyond their scientific value as fascinating models of pattern formation, unstable porous-media flows are essential to understanding many natural and man-made processes, including water infiltration in the vadose zone, carbon dioxide injection and storage in deep saline aquifers, methane venting from organic-rich sediments, and fracturing from fluid injection. Here, we review a handful of these hydromechanical instabilities, elucidate the key physics at play, and point to modeling frameworks that permit quantitative assessments of their impact at the geologic scale.

**9:12AM R53.00003: Stressing gels out: exploiting gradients in shrinkable packings**  [Invited] H. JEREMY CHO, MICHAEL P HOWARD, NANCY B LU, SUJIT DATTA (Presenter), Princeton University — Diverse biological systems, ranging from actuation to drug delivery, rely on how soft gels respond to environmental stresses. In this talk, I will describe how we combine experiments and poroelasticity theory to investigate the influence of osmotic stresses in hydrogel packings. In some cases, the stresses that develop cause packings to crack. We show how cracking behavior depends on gradients in the stress profile, suggesting a way to control material behavior in this complex system. Ultimately, our work stimulates new findings and questions at the interface of Physics, Biology, Materials Science, and Engineering.

**9:48AM R53.00004: Granular erosion in Stokes flow**  [Invited] NICK MOORE (Presenter), Florida State University — Fluid-mechanical erosion of solid material occurs across many scales, from massive geological structures down to tiny granular constituents. Here, we numerically examine the erosion of a granular medium in the Stokes limit — the regime of groundwater flow. We combine a highly accurate boundary-integral formulation of the Stokes equations with stable interface-evolution methods. A single body erodes into a slender, for-aft-symmetric morphology which can be described analytically. Using the fast multipole method allows the simulation of 10-100 bodies. Many-body erosion naturally leads to the formation of channels and anisotropy in the medium conductivity.

Pattern formation of frictional fingers in a gravitational potential

KNUT MÅLØY (Presenter), JON ALM ERIKSEN, PoreLab, The Njord Center, University of Oslo, RENAUD TOUSSAINT, Institute de Physique de Globe de Strasbourg, University of Strasbourg, EIRIK GRUDE FLEKKØY, OLIVER GALLAND, PoreLab, The Njord Center, University of Oslo, BJØRNAR SANDNES, College of Engineering, Swansea University — This work concerns experiments and simulations of slow drainage in a deformable quasi 2D porous media Hele Shaw. We introduce gravity as a parameter in the experiments where air displaces a liquid–granular mixture during drainage of a Hele-Shaw cell, by imposing shallow tilt angles. The receding interface accumulates a front of granular material, and an instability caused by a competition between surface tension and frictional forces results in an emerging pattern of frictional fingers, canals of air separated by branches of compacted grains, as also observed in horizontal systems. Aligned finger structures, with a characteristic width, emerge during the slow drainage. A transition from vertical to horizontal alignment of the finger structures is observed as the tilting angle and the granular density are varied. An analytical model is presented, demonstrating that the alignment properties are the result of the competition between fluctuating granular stresses and the hydrostatic pressure. The dynamics is reproduced in simulations. We also show how the system may explain patterns observed in nature, created during the early stages of a dike formation.

*We are grateful to the late Henning Knudsen, who made important contributions to the understanding of frictional fingers. We thank Gidon Baer, Einat Aharonov, and Benjy Marks for discussions. Session R54 DPOLY GSOFT GSNP: Confined Polymer Glasses III: Elasticity, Nanoparticles, and Brushes

Enhanced Thermal Stability of Polymers under Extreme Nanoconfinement

HAONAN WANG (Presenter), JYO LYN HOR, AIXI ZHANG, University of Pennsylvania, PRANTIK MAZUMDER, Corning Research and Development Corporation, DAYEON LEE, ZAHRA FAKHRAAI, University of Pennsylvania — It has been shown that the properties of polymers in weakly-interacting polymer nanocomposites (PNCs), such as Polystyrene(PS) and SiO₂ nanoparticles (NP), can deviate from bulk due to segmental and chain confinement. Capillary Rise Infiltration (CaRI) of polymers into densely-packed NP films can produce PNCs with ultra-high NP loadings. Depending on the degree of confinement, the glass transition temperatures ($T_g$) of PS/SiO₂ CaRI films can increase up to ~57 K. In this study, unentangled PS/SiO₂ CaRI films were used to study the thermal degradation of polymers under extreme nanoconfinement. The degree of confinement was controlled by using NPs with different diameters, thus adjusting the effective pore diameter by 3–30 nm. We show that the thermal stability of PS is significantly increased in smaller pores under both thermo-oxidative and pyrolytic conditions. The characteristic degradation time during isothermal degradation at high temperatures is proportional to the viscosity of PS at lower temperatures, indicating an entropic origin of the improved stability. The details of the kinetics of the degradation process through surface or bulk is also explored.

*We acknowledge University of Pennsylvania MRSEC grant (NSF DMR-1720530) for the funding of this study.
8:12AM R54.00002: Unexpected strengthening effect in brush particle-based hybrid materials with intermediate grafting density* JAEJUN LEE (Presenter), Department of Materials Science and Engineering, Carnegie Mellon University, ZONGYU WANG, Department of Chemistry, Carnegie Mellon University, JIANAN ZHANG, School of Chemistry and Chemical Engineering, Anhui University, TINGWEI DENG, Department of Materials Science and Engineering, Carnegie Mellon University, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University, MICHAEL R BOCKSTALLER, Department of Materials Science and Engineering, Carnegie Mellon University — Surface functionalization of nanoparticles with polymers has emerged as a versatile platform to enable hybrid building blocks that can be assembled into functional nanocomposites with controlled microstructure and enhanced mechanical properties. However, the dense functionalization by conventional method presents a barrier to the utilization of this concept due to the limited inorganic content. This contribution will present a systematic analysis of the role of brush architecture on the elastic properties of brush particle films. Material systems with continuous variation of the grafting density as well as bimodal graft architectures were synthesized using modified atom transfer radical polymerization and films were characterized using indentation and thermal analysis. The results reveal that chain interdigitation plays a dominant role for the modulus and strength of the films. In particular, the results demonstrate an ‘optimum degree of functionalization’ to maximize cohesive interactions as a consequence of the enhanced dispersion interactions in interdigitated brush particle assemblies. The results are used to postulate design guidelines for the synthesis of brush particles capable of forming hybrid materials with enhanced performance.

*DOE (CMMI-1662305), NSF (DE-EE0006702)

8:24AM R54.00003: Dramatic Modification of Nanoparticle Surface Mobility in Polymer Colloids with a Core-Shell Structure HOJIN KIM (Presenter), Department of Chemical and Biomolecular Engineering, University of Delaware, EUNSOO KANG, BARTLOMEJ GRACZYKOWSKI, Max Planck Institute for Polymer Research, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University, ERIC M FURST, Department of Chemical and Biomolecular Engineering, University of Delaware, GEORGE FYTAS, Max Planck Institute for Polymer Research — Advances in polymer nanoparticle synthesis and assembly techniques have enabled new applications, from drug delivery carriers to novel coatings. However, the thermal transition of polymer dynamics, especially at the particle surfaces, must be understood in order to realize their potential. Using Brillouin light scattering as a direct probe of the particle surface mobility via polymer nanoparticle vibrations, recent experiments confirm the correlation between the glass transition behavior and surface dynamics of polymer nanoparticles. This raises a challenge of how the glass transition dynamics of polymer nanoparticles can be engineered. To address this need, we modify the surface condition of polystyrene nanoparticles with different shell architecture layers. We demonstrate that a shell layer composed of two polyelectrolytes, as thin as a single polymer chain, is able to eliminate the effect of enhanced particle surface mobility. Other shell structures, such as a single polyelectrolyte layer, enables tailoring the glass transition temperature, softening behavior, and elasticity of the nanoparticles.

8:36AM R54.00004: Materials by Design for Stiff and Tough Nanoparticle Assemblies with Polymeric Hairs* SINAN KETEN (Presenter), Northwestern University — In this work, a computational methodology for predicting the mechanical behavior of assembled hairy nanoparticle systems (aHNPs) using coarse-grained molecular dynamics simulations coupled with Gaussian process metamodeling will be presented (Hansoge et al. ACS NANO,2018). The coarse-graining approach for the polymeric hairs involves systematic parameter development based on the energy renormalization approach, which allows us to describe the behavior of the glassy nanocomposites with greater accuracy at larger length-scales. Simulations reveal that for cellulose nanocrystal-PMMA aHNPs, the Pareto frontier, which marks the optimal trade-offs between modulus and toughness within the design parameter space, can be reached when the weight percentage of nanoparticles is around 60% and the grafted chains exceed the critical length scale governing transition into the semidilute brush regime. A theoretical model with computationally determined parameters based on the Daoud–Cotton model adequately explains the dependence of the critical length scale on graft density and nanoparticle size. The computational results agree well with recent experiments and suggest that high stiffness and high toughness could be achieved by carefully tuning the molecular design parameters, most notably by keeping a relatively low grafting density while having high graft length and nanoparticle volume fraction.

*The authors acknowledge funding from a DoD PECASE award.
Diminishing Interfacial Effects with Decreasing Nanoparticle Size in Polymer-Nanoparticle Composites

HAMED EMAMY (Presenter), Columbia University, FRANCIS STARR, Wesleyan University, SANAT KUMAR, Columbia University — Using molecular simulations on model polymer nanocomposites at fixed filler loading we show that interfacial polymer dynamics are affected less with decreasing nanoparticle (NP) size. However, the glass transition temperature \( T_g \) changes substantially more for extremely small NP. The reason for this apparent contradiction is that the mean NP spacing decreases with decreasing particle size. Thus, all polymers are effectively interfacial for sufficiently small NP, resulting in relatively large \( T_g \) shifts. For larger NP, interfacial relaxations are substantially slower than the matrix for favorable NP-polymer interactions. The minority "bound" polymer dynamically decouples from the polymer matrix, and we only find small changes in \( T_g \), relative to that of the bulk polymer for large NP. These results are used to organize a large body of relevant experimental data, and we propose an apparent universal dependence on the ratio of the face-to-face distance between the NPs and the chain radius of gyration.

Disentangling the Role of Chain Conformation on the Mechanics of Particle Brush Materials

YU CANG, Max Planck Institute for Polymer research, JIARUL MIDYA, Institute of Physics, Johannes Gutenberg University Mainz, SERGEI EGOROV, Department of Chemistry, University of Virginia, KRZYSZTOF MATYJASZEWSKI, Chemistry Department, Carnegie Mellon University, MICHAEL R BOCKSTALLER, Department of Materials Science and Engineering, Carnegie Mellon University, ARASH NIKOUBASHMAN, Institute of Physics, Johannes Gutenberg University Mainz, GEORGE FYTAS (Presenter), Max Planck Institute for Polymer research — The modification of particle surfaces with polymeric ligands is widely used to enhance the interactions between particles, to allow their integration in polymeric matrices or for the processing of particulate materials through techniques such as molding or extrusion. A critical question that is of both fundamental and applied relevance pertains to the role of polymer architecture in controlling the interactions and resulting mechanical properties of polymer-tethered particles. Because of its ability to resolve the mechanical characteristics on submicrometer scale without sample destruction, Brillouin light scattering (BLS) has become an important analytical tool to elucidate the connection between structure, dynamics and macroscopic response in hybrid material systems. In this contribution a combined approach of experimental BLS analysis and coarse-grained simulations is presented to identify the respective contribution of grafting density and degree of polymerization on the macroscopic mechanical properties of films from polystyrene tethered silica colloids. The bulk modulus is maximized in intermediate to low grafting density systems, where the hard silica cores are partially exposed due to conformational fluctuations of the grafted polymers.

Interfacial entropic interactions tunes fragility and dynamic heterogeneity of confined polymer glasses with embedded nanoparticles.

NAFISA BEGAM, NIMMI DAS ANTHUPARAMBIL (Presenter), Department of Physics, Indian Institute of Science, Bangalore., SIVASURENDER CHANDRAN, Institute of Physics, University of Freiburg, 79104 Freiburg, Germany, MOHD IBRAHIM, Department of Physics, Indian Institute of Science, Bangalore., VENKAT PADMANABHAN, Department of Chemical Engineering, Tennessee Technological University, Cookeville, TN 38505, USA., MICHAEL SPRUNG, Deutsches Elektronen Synchrotron DESY, Notkestrasse 85, 22607 Hamburg, Germany., JAYDEEP K BASU, Department of Physics, Indian Institute of Science, Bangalore. — The nature of nanoparticle-polymer interfacial layer is known to play a vital role in determining various physical properties of polymer glasses. The influence of interfacial interactions on viscosity, fragility and dynamical heterogeneity of athermal melts are explored in this study\(^1\). Dynamical parameters are studied using X-ray photon correlation spectroscopy and results are corroborated with molecular dynamics simulations. Influence of various microscopic parameters such as interfacial layer diffusivity, matrix chain penetration depth etc on fragility of polymer glasses are demonstrated combining experiment and simulation results. Thin film-substrate interface adsorbed layer effects on dynamical properties of confined glasses are also investigated. Reduction (enhancement) in viscosity is observed for melts with low (high) entropic compatibility parameter, \( f \) (molecular weight ratio of graft to matrix chains). Fragility is found to increase with increasing \( f \). Anticorrelation between fragility and dynamical heterogeneity is found in these systems, which are contrary to various earlier studies on glass forming polymers.

Authors would like to thank the DST-Nanomission, India for the financial support.
9:48AM R54.00008: Interactions of Ligand-Coated Nanoparticles at a Liquid Surface*  
DAVID HOAGLAND (Presenter), PAUL KIM, YIGE GAO, ALEXANDER RIBBE, THOMAS RUSSELL, University of Massachusetts Amherst — The pair interaction potential of ligand-coated silica nanoparticles (NPs) at a liquid surface were determined by scanning electron microscopy, exploiting the nonvolatility of ionic liquids to stabilize the liquid specimens against microscope vacuum. Even at near contact, individual, two-dimensionally well-dispersed NPs were resolved. The potential of mean force, reduced to the pair interaction potential for dilute NPs, was extracted with good accuracy from the radial distribution function as both NP diameter and poly(ethylene glycol) ligand length varied. While NP polydispersity broadened the core repulsion, the pair potential well-approximated a hard sphere interaction. For short (5 kDa) ligands, a weak (<kT) long-range attraction was discerned, and for ligands of identical length, the potentials overlapped for NPs of different diameter; the attraction is suggested to arise from ligand-induced menisci. To probe the factors underlying the potential, NP surface-binding energies were measured by interfacial tensiometry, and NP contact angles were assessed by new atomic force microscopy and transmission electron microscopy methods.

*NSF/DMR-1807255

10:00AM R54.00009: Switching mixed polymer brushes surfaces through external stimulation  
MINGXIAO LI, CHRISTIAN PESTER (Presenter), Pennsylvania State University — Binary and mixed brushes are comprised of two (or more), chemically distinct polymers randomly grafted to a surface in close proximity. This approach is considered a potent means to manufacture responsive surfaces with tunable physical properties. We highlight recent work in using orthogonal polymerization techniques to tailor such mixed surfaces, comprised chemically disparate polymers covalently grafted to a silica surface. A combination of X-ray photoelectron spectroscopy, synchrotron hard (GISAXS) and soft resonant X-ray techniques (RSoXS), as well as Infrared Atomic Force Microscopy (AFM-IR) was used to provide evidence for responsiveness towards external stimuli. The choice of selective solvents for either of the two species resulted in reversible microphase segregation and can provide a direct pathway towards switchable surface properties.

10:12AM R54.00010: The TUFF Method: Stretching Free-Standing Ultra-Thin Glassy Polymer Films*  
REED BAY (Presenter), ALFRED CROSBY, Polymer Science and Engineering, University of Massachusetts Amherst — TUTTUT (The Uniaxial Tensile Tester for Ultra-Thin films) is a recently developed method for quantifying the complete uniaxial stress-strain relationship for ultra-thin polymer films. The key to TUTTUT is the use of liquids to help support ultra-thin, often fragile, films. Although this method has provided new insights into mechanical properties and deformation mechanisms for dimensionally-confined polymer systems, for some polymers the presence of a liquid may influence the ultra-thin properties. Here, we introduce a new method, TUFF (Tensile tester for Ultra-thin Freestanding Films) to directly measure the uniaxial stress-strain response of freestanding polymer thin films. Using polystyrene thin films, with thickness 20nm-100nm, we observe and quantify large strain deformation mechanisms, as well as yield stress and elastic moduli, and compare these results to TUTTUT measurements. These results provide new fundamental insights into how the surface interactions can alter polymer behavior in thin confined polymer films.

10:24AM R54.00011: Unveiling the Elasticity of Confined Multilayer Hybrid Materials*  
ZUYUAN WANG (Presenter), KONRAD ROLLE, Max Planck Institute for Polymer Research, THERESA SCHILLING, Department of Inorganic Chemistry I, University of Bayreuth, MARKUS RETSCH, Department of Chemistry, University of Bayreuth, JOSEF BREU, Department of Inorganic Chemistry I, University of Bayreuth, GEORGE FYTAS, Max Planck Institute for Polymer Research — The superior elasticity and processing easiness of polymers render them promising as an interfacial filler material. With the progress in hybrid materials fabrication and manufacturing precision, the thickness of interfacial polymer layers has gone down to the nanometer range that can feature strong confinement. A critical question of scientific and applied importance is how the confined polymer layers affect the effective mechanical properties of the hybrid material. In this contribution, we utilize Brillouin light scattering experiments and a continuum-mechanics based model to examine the anisotropic elastic properties of confined hybrid materials composed of alternating polyvinylpyrrolidone and hectorite nanolayers. The clear resolution of the direction-dependent quasi-longitudinal, quasi-transverse, and pure-transverse phonon modes from the Brillouin scattering experiments leads to the full elastic properties of these highly anisotropic samples. We find that as the polymer layer thickness increases from about 1 to 3 nm, the material's Young's moduli in the directions parallel and perpendicular to the layers drop by nearly 50%, implying the crucial role of polymer confinement on the sample's mechanical properties.

*ERC AdG (SmartPhon No. 694977)
Tensile elastic modulus of free-standing single-layer and bilayer polymer films* PAK MAN YIU (Presenter), HAILIN YUAN, Department of Physics, Hong Kong University of Science and Technology, QIAO GU, PING GAO, Department of Chemical and Biological Engineering, Hong Kong University of Science and Technology, OPHELIA TSUI, Department of Physics, Hong Kong University of Science and Technology — Studies have shown that the elastic modulus, $E$, of polymer films may vary with the film thickness, $h$, when $h$ is tens of nanometers. For polystyrene (PS) supported by a polydimethylsiloxane (PDMS) substrate, $E$ had been found to decrease with decreasing $h$ below ~60 nm. For free-standing PS films, however, $E$ was found to be constant with $h$ for $h < ~80$ nm. In this experiment, we conducted uniaxial tensile tests on free-standing PS films (with a molecular weight, MW, of 1,049 kg/mol and $h = 40$ to 150 nm) and bilayer films of PS-PDMS (with various MW from 151 to 1,049 kg/mol and $h = 12$ to 150 nm). The measured elastic modulus of the films agreed with published value of bulk PS, showing insignificant dependences on $h$ or MW.

Surface and Interfacial Tension of Graft Polymer Melts* MICHAEL JACOBS (Presenter), The University of Akron, BRANDON PUGNET, Department of Physics, Lafayette College, HEYI LIANG, ANDREY DOBRYNIN, The University of Akron — Understanding surface properties of polymer melts is crucial for designing new polymeric coatings, adhesives, and composites. Here, we study the effect of molecular architecture on surface and interfacial tension of graft and linear polymer melts by molecular dynamics simulations. In particular, we elucidate the effect of the degree of polymerization of the side chains $n_{sc}$ and their grafting density $1/n_g$ on the surface tension of the graft polymer/vacuum interface, and the interfacial tension of the interface between graft and linear polymer melts. For the case of the graft polymer/vacuum interface, our simulations confirm that the surface tension is a linear function of the fraction of the backbone ends $f_{be}$ and side-chain ends $f_{se}$. This dependence of the surface tension highlights the entropic origin of the surface tension corrections associated with the redistribution of the grafting points and ends at the interface. However, the interfacial tension between graft and linear polymer melts does not show any significant dependence on the molecular structure of the graft polymers, thus pointing out the dominance of the enthalpic contribution to the interfacial tension.

Session R55 DPOLY: Polymer Crystallization II: Packing Assembly, Chip Calorimetry and Simulations 8CEC 254B - Claudio De Rosa, University of Naples Federico II Rufina Alamo, Florida A&M and Florida State University - Tag(s): Focus

Isodimorphic biodegradable copolyesters: Structure and crystallization behavior* [Invited] ALEJANDRO J. MULLER (Presenter), POLYMAT and University of the Basque Country UPV/EHU, Spain — Random copolymers with crystallizable components can crystallize in three modes: (a) comonomer exclusion, in which the comonomer is excluded from the crystal lattice of the other component, (b) isomorphism (i.e., strict molecular requirements should be met), in which a single crystalline phase is observed for all compositions, because of comonomer inclusion, and (c) isodimorphism, where two crystalline phases are formed depending on the composition, and both phases allow comonomer inclusion. In the present invited lecture, the detailed structure, morphology, nucleation and crystallization behavior of isodimorphic biodegradable copolyesters will be presented as a function of their comonomer ratio. This information is very significant as it allows tailoring the properties of random copolymers as well as their applications. The materials exhibit a pseudo-eutectic type phase behavior. To the left and to the right of the pseudo-eutectic a single phase is formed, rich in the corresponding parent comonomer. However, near the pseudo-eutectic point, two crystalline phases can be formed. In this way, double crystalline materials with interesting spherulitic superstructures that contain both types of lamellar thickness can be generated. The applications of these materials are potentially very interesting as superstructures with different sensitivities to biodegradation could be prepared and their lifetime can be tailored from their structural characteristics.

8:36AM R55.00002: Packing Selection of a Helical Semicrystalline Polymer in Solution and Melt-Grown Crystals*
TOSHIKAZU MIYOSHI (Presenter), The University of Akron — Correlation between packing and chain-folding structures of semicrystalline polymers has not been clearly addressed in existing literature. We investigate kinetics effects on chain packing as well as chain-folding structure of a helical chiral polymer in solution- and melt-grown crystals. We will provide a novel concept of intramolecular and intermolecular packing to understand kinetics effects on packing selection in the melt and solution-grown crystals.

*NSF DMR 1708999

8:48AM R55.00003: Semicrystalline polyethylene measurement by Polarized Resonant Soft X-ray Scattering  
DEAN DELONGCHAMP (Presenter), ELIOT H GANN, CHAD RAY SNYDER, National Institute of Standards and Technology — Orientation and conformation in nanoscale amorphous regions often dominates the properties of soft materials such as composites and semicrystalline polymers. In polyethylene (PE), interlamellar amorphous tie chains have been shown to substantially reduce the rate of slow crack growth, which is important for long service life in infrastructure elements such as potable water pipes. I will describe polarized resonant soft X-ray scattering (P-RSoXS) measurements of semicrystalline polyethylenes. The P-RSoXS of PE is highly anisotropic with respect to electric field vector and orientation of the amorphous interlamellar chains is a significant contributor. Real space models reproduce salient features of the P-RSoXS pattern including trends in anisotropy with energy, trends in anisotropy with q, and a clear long period peak. Prospects for correlating interlamellar orientation measurements by P-RSoXS with tie chain population and crack growth will be discussed.

9:00AM R55.00004: Polymorphism in nanolayered comb-like and linear precision polymers*  
VARUN DANKE (Presenter), GAURAV KUMAR GUPTA, MARIO BEINER, Polymeric Material Design, Business Unit Polymer Applications, Fraunhofer Institute for Microstructure of Materials and Systems IMWS — Comb-like polymers with rigid backbones and flexible alkyl side chains are a class of functional materials which often exhibit long range ordered states wherein main and side chains form an alternating layered arrangement on length scales of 1-3 nm. Similarly, linear precision polymers synthesized by ADMET polymerization, incorporating ring-like units placed at regular intervals along a polyethylene backbone also typically show nanolayered structures[1]. Here we present results of a comparative study using X-ray scattering and calorimetry highlighting similarities and differences in structure formation in these two material classes. Of special interest is the competition of the individual packing tendencies of rings and methylene sub-units that drive polymorphic behavior which is a commonly encountered phenomenon in such nanolayered systems. The role of substrates and interfaces on their crystallization behavior is also briefly discussed.

*Financial support within the framework of Sonderforschungsbereich SFB TRR 102 ‘Polymers under multiple constraints’ (projects A03 and B14) is highly appreciated.

9:12AM R55.00005: Unusual crystallization kinetics of long-spaced polyacetals  
XIAOSHI ZHANG (Presenter), SIDNEY CAMERON, RUFINA ALAMO, FAMU-FSU College of Engineering, Florida State University, XIAOBIN ZUO, X-ray Science Division, Argonne National Laboratory, PATRICK ORTMANN, STEFAN MECKING, Department of Chemistry, University of Konstanz — The overall crystallization kinetics of the major polymorphs of a series of polyethylenes with acetal groups precisely placed on each and every 12th, 18th, 19th and 23rd backbone carbon (PA-12, PA-18, PA-19, and PA-23) have been studied by DSC and FSC with parallel studies using FTIR, real-time X-ray and POM. The crystallization kinetics is unusual because multiple minima of isothermal crystallization rates are observed at polymorphic transition temperature regions, which is reminiscent of previous observations of crystallization minima in precision polyethylenes with halogen. The inversion is mainly associated with a confinement effect that the kinetically favored Form I makes on the growth of the more stable Form II. Besides the effect on growth, data of induction time for crystallization indicates that the presence of Form I also retards the nucleation of Form II.
9:24AM R55.00006: Homogeneous crystal nucleation in polymers: New insights from fast scanning calorimetry

EVGENY ZHURAVLEV, Institute of Physics, University of Rostock, RENE ANDROSCH, IWE TFN, Martin Luther University Halle-Wittenberg, RUSLAN ANDRIANOV, Institute of Chemistry, Kazan Federal University, CHRISTOPH SCHICK (Presenter), Institute of Physics, University of Rostock — Crystallization commonly starts from a (sub)nanoscale nucleus which eventually grows to a crystal. Classical nucleation theory (CNT) provides a qualitative description of these processes. Homogeneous nucleation, to become dominant over heterogeneous nucleation, requires deep undercooling of the polymer melt. At cooling rates of several thousand K/s such states can be reached and the kinetics of homogeneous nucleation becomes accessible. Fast scanning calorimetry (FSC), in combination with polarized optical (POM) and atomic force (AFM) microscopy, provides a tool to study homogeneous nucleation and even the thermodynamic stability of the formed nuclei as a function of nucleation temperature and time.

9:36AM R55.00007: Using chip-based calorimetry to monitor crystallization during polymer processing

KENNETH KEARN (Presenter), THOMAS R FIELTZ, RAJEN M PATEL, SHRIKANT DHODAPKAR, TRAVIS MCINTIRE, JIN WANG, CHRISTOPHER M THURBER, ROBBYN PRANGE, Dow Chemical Company — Polymer processing often involves rapid changes in temperature and strain, which significantly modify the properties and thus performance. Advancements in chip-based calorimetric techniques overcome temperature scanning rate and instrument response limitations of conventional differential scanning calorimeters, enabling off-line probing of commercially relevant process conditions. In this talk we will describe how we have used commercial, chip-based calorimetric instrumentation to monitor crystallization under process conditions. Using a chip-based calorimeter we can monitor the crystallization of semi-crystalline polyolefins as they move through the pelletization step of the manufacturing process. Mapping time-dependent crystallization covering up to 1000 seconds was possible. Blown film processing, which undergoes cooling at rates approaching 100 °C/s, could be mimicked using the chip calorimeters. By coupling this data to at-line monitoring schemes, strain-induced crystallization can be deduced.

9:48AM R55.00008: Visualization of Polymer Crystallization by a Combination of Atomic Force Microscopy with Fast Scanning Calorimetry

RUI ZHANG (Presenter), EVGENY ZHURAVLEV, CHRISTOPH SCHICK, Institute of Physics, University of Rostock — Abstract: The chip-sensor of fast scanning calorimetry (FSC) is directly mounted on the scanner of an atomic force microscope (AFM). By combining AFM with FSC (AFM-FSC) this way, AFM can illustrate the crystal structures on the nanoscale, as well as, FSC can treat the sample at any annealing temperature without unexpected crystallization during heating or cooling at scanning rates up to 1,000,000 K/s. First results on crystals' morphologies, spherulites' growth rates and the influence of crystal nuclei by Tammann's two stage method are shown.

Keywords: Fast Scanning Calorimetry, Atomic Force Microscopy, Morphology, Crystal Growth, Tammann's method

10:00AM R55.00009: Slip-link modeling of a crystallizing entangled polymer melt

MARAT ANDREEV (Presenter), GREGORY C RUTLEDGE, Massachusetts Institute of Technology — Modeling of polymer processing is a subject of continuing industrial and theoretical interest. Many industrial polymer melts are entangled and undergo crystallization during processing. Experimental data for the rheology of crystallizing entangled polymers are available in a number of published studies on this topic. In particular, the 'inverse quench' technique allows one to stop crystallization in effect, and to measure the dynamic modulus over a wide range of frequencies. Meanwhile, over the past few years, slip-link models have been demonstrated to be very capable for describing the rheology of entangled melts. In this work, we present a modification of the slip-link model to capture the rheology of an entangled melt during the early stages of crystallization. The model captures the emergence of a secondary, low-frequency plateau observed in the linear regime. The advantage of this approach is the capability to predict the effect of on-going crystallization during non-linear deformation.
10:12AM R55.00010: Monte Carlo simulations of stress-induced polymer crystallization*  WENBING HU (Presenter), JIPING WANG, School of Chemistry and Chemical Engineering, Nanjing University — We developed the previous approach of dynamic Monte Carlo simulations of bulk lattice polymers for strain-induced crystallization [1-3] by incorporating the stress relaxation, and investigated the competition between strain rate and stress relaxation rate. The results reproduce the basic experimental observations and promise a molecular-level understanding of stress-induced polymer crystallization via our new approach.

10:24AM R55.00011: Monte Carlo Simulation of Stress-Induced Polymer Crystallization during Cold Drawing*  JIPING WANG (Presenter), YIHUAN YU, WENBING HU, Nanjing University — Jiping Wang, Yihuan Yu, Wenbing Hu*

Polymers are stretched with stress relaxation in the common industrial processing such as fiber spinning, plastic molding, film stretching and film blowing. Recently we develop a new simulation method which could reproduce the typical stress relaxation behaviors of polymers. Based on this model we investigated polymer crystallization during the drawing process from high to low temperatures. The high temperature results reproduced our previous observations on strain-induced polymer crystallization [1-3]. Since we took the conformational energy barrier and the monomer adhesive barrier into consideration, the low temperature results revealed the stress-induced fragmentation in company with crystallization. This work could help us to understand the semi-crystalline structures in the cold drawing process of polymer materials.

10:36AM R55.00012: Polymer Crystallization during shear flow*  GO MATSUBA (Presenter), Grad. Sch. of Organic Materials Engineering, Yamagata University — We evaluated the effect of molecular weight on the formation of a shish–kebab morphology on a wide spatial scale. Here we examined blended polyethylene with 97 wt% deuterated polyethylene and 3 wt% protonated polyethylene comprising molecules with a range of molecular weights. Measurements were conducted with various X-ray and neutron scattering techniques. The nanometer-scale analysis revealed that the crystal lattice is also independent of the molecular weight. Moreover, small-angle X-ray and neutron scattering measurements did not reveal any influence of molecular weight. On the other hands, strong streak-like neutron scattering was observed perpendicular to the drawing direction. The multicore-shell cylinder model was used to evaluate the parameters of the shish structure: the radius of the core cylinders increased with the molecular weight while the number of core cylinders decreased with the molecular weight. On the other hand, the micron-scale analysis using ultra-small-angle X-ray and neutron scattering measurements revealed that the micrometer-scale fibril structure is independent of the molecular weight.

10:48AM R55.00013: Modeling the melting of a semicrystalline polymer*  
KIRAN IYER (Presenter), MARZBED MARGOSSIAN, MURUGAPPAN MUTHUKUMAR, University of Massachusetts Amherst — The melt state of a semicrystalline polymer is known to have several dependencies on process variables such as melt temperature and annealing time; it is by itself a rich system, possibly consisting of several topological constraints like entanglements. All of these contribute towards the mechanism of melting, resulting in several intriguing observations in experiments. In this work, we study the melting of a pre-formed polymer crystal by use of coarse-grained parallel tempering Langevin dynamics simulations, guided by experimental findings of the melting of a single polyethylene crystal. By investigating the melting of a single crystal, we determine the kinetics of the process. We also determine the kinetics of an aggregate formed by multiple polymer chains, and find that the kinetics is dependent on the polymer chains being able to cross an entropic barrier.

Session R56 GSNP GSOFT: Discrete Structures: Geometry, Mechanics, Graphics, and Computation II  
BCEC 255 - Christian Santangelo, University of Massachusetts Amherst

8:00AM R56.00001: Geometric defects, weak forces, and self-similar buckling in non-Euclidean elastic sheets*  
KENNETH YAMAMOTO (Presenter), SHANKAR VENKATARAMANI, University of Arizona — Non-Euclidean elastic sheets (like lettuce, flowers, and sea slugs) exhibit extreme properties including an inherent floppiness, which we argue is governed by and may, in turn, be quantified by non-smooth geometric defects. The presence and interaction of these localized defects in hyperbolic sheets may be modelled and explored with rough solutions via discrete differential geometry (DDG) based on taking a singular limit that assumes a no-stretching constraint. Non-smooth geometric defects are identified by a skeleton of intersecting asymptotic curves which, along with geometric data along the curves, enables constructing complex morphologies with intricate wrinkling shapes. By computing various energies on discretized elements, numerical simulations using this novel DDG framework reveal the significant impact of non-smooth geometric defects on elastic energy as well as the non-negligible role of weak forces, i.e., effects other than stretching or bending, and associated scaling laws. Ultimately, these modeling techniques have the potential to explain real-world sheets and enable the control/design of thin soft structures.

8:12AM R56.00002: Discrete PolyCube Surface Flows  
PAUL ZHANG (Presenter), Computer Science, MIT, JOSH VEKHTER, University of Texas System, JUSTIN SOLOMON, Computer Science, MIT, ETIENNE VOUGA, University of Texas System — Discrete flows have been of particular interest to researchers in discrete differential geometry, computational geometry, and computer graphics, due to their connection to the Plateau problem in mathematics, mechanical behavior of various shells and membranes, and their application to shape science problems such as surface fairing, parameterization, collision modeling, registration, and interpolation. We study a new flow, formulated as a variational problem on certain bundles of quotient spaces of rotations over the surface, and describe algorithms to discretize and simulate it. The flow has the following property: stationary surfaces of the flow are polycubes, polyhedra whose facets meet only at right angles. Spheres flow to cubes, and more generally, surface features sharpen or flatten. Moreover the flow is intrinsic to the surface itself, and does not require a choice of preferred planes or directions in the ambient space. This flow has potential applications in crystallography, as well as simplification, discretization, and hexahedralization of shapes.

8:24AM R56.00003: Spatial and Network Effects in Distributed System Design*  
ANDREI A. KLISHIN (Presenter), Physics, University of Michigan, DAVID J. SINGER, Naval Architecture and Marine Engineering, University of Michigan, GREG VAN ANDERS, Physics, Engineering Physics, and Astronomy, Queen's University — Designing a modern complex system requires keeping track of the interplay of the system's logical topology, spatial arrangement, and functionality. Existing frameworks mostly focus on how one of these aspects influences others in a single direction, rather than keeping track of the mutually deterministic nature of design elements. We demonstrate how to determine mutual influences of topology and spatial constraints on each other for a whole ensemble of possible system arrangements. We cast this problem in the modern graphical language of tensor networks, which facilitates computation and allows for extracting a variety of ensemble observables. We demonstrate the power of the approach on a model system routing problem from Naval Engineering, however the method is easily generalizable to other problems.

*U.S. Office of Naval Research Grant no. N00014-17-1-2491.
Physics-inspired optimization for quadratic unconstrained problems using a digital annealer

MALIHEH ARAMON, GILI ROSENBERG, ELISABETTA VALIANTE, 1QB Information Technologies Inc., TOSHIYUKI MIYAZAWA, HIROTAKA TAMURA, Fujitsu Laboratories Ltd., HELMUT KATZGRABER (Presenter), Microsoft Quantum — The Fujitsu Digital Annealer is designed to solve fully connected quadratic unconstrained binary optimization (QUBO) problems. It is implemented on application-specific CMOS hardware and currently solves problems of up to 1024 variables using a parallel-trial algorithm based on simulated annealing. We compare the performance of the Digital Annealer to simulated annealing and parallel tempering Monte Carlo with isoenergetic cluster moves on different spin-glass problems. Our results show that the Digital Annealer currently exhibits a time-to-solution speedup of roughly two orders of magnitude for fully connected spin-glass problems, over the single-core implementations of simulated annealing and parallel tempering Monte Carlo used in this study. This, however, is not the case for sparse two-dimensional problems. We also benchmarked an early implementation of the Parallel Tempering Digital Annealer. Our results suggest an improved scaling over the other algorithms for fully-connected problems of average difficulty with bimodal disorder. The use of specialized hardware paired with fast algorithms thus allows for a more detailed study of statistical physics Hamiltonians in the near future.

Deployable and Mechanical Properties of An Origami Spring Structure*

SOPHIE USHERWOOD (Presenter), CONGRAN JIN, SHICHENG HUANG, Dartmouth College, XIAOHE LIU, Brown University, ZI CHEN, Dartmouth College — Origami has recently been studied intensively by physicists, mathematicians, and engineers due to its deployability, versatility and low cost in potential engineering applications. Examples include self-deployable solar arrays in space and self-folded origami inspired robots. To understand deployable properties of an origami structure, models of an origami “spring” were investigated. Origami spring structures may be useful in robotics and structural designs as their length can vary, while maintaining structural rigidity. Mathematical methods based on the geometry of these spring structures are used to predict ideal maximum height, formulate a relationship between the angle of rotation and the spring height, and to obtain a Poisson’s ratio of the spring structure. We show that the Poisson’s ratio is not constant and is scalable with respect to different geometric parameters. Elastic modulus of the spring structures are also predicted using models based on Hooke’s law and the stationary principle. By studying origami spring models, we discovered interesting and potentially practical engineering designing insights that are embedded in this smart structure.

Discrete Geometric Simulation of Elastic Ribbons*

WEICHENG HUANG (Presenter), Department of Mechanical and Aerospace Engineering, University of California, Los Angeles, XILAI ZHANG, Department of Electrical and Computer Engineering, University of California, Los Angeles, MOHAMMAD KHALID JAWED, Department of Mechanical and Aerospace Engineering, University of California, Los Angeles — We report a discrete differential geometry based numerical simulation for elastic ribbons. Ribbon is a mechanical structure whose three dimensions are very different: length >> width >> thickness. In our framework, we use the elastic energy form, with two essential geometric constraints, of a one-dimensional model of the ribbon [Dias and Audoly, J. Elast. 2015]. As non-zero natural curvature in both in-plane (geodesic curvature) and out-of-plane directions have been considered, this model allows a unified treatment of various types of ribbons, e.g. annular and rectangular. This continuous model is discretized into a mass-spring system in a manner similar to well established Discrete Elastic Rods algorithm for simulation of elastic rods. A system of discrete equations of motions are developed that can be solved implicitly using Newton’s method. In parallel with simulations, we perform experiments with several test cases, e.g. large deformation of elastic ribbons under gravity, coupling of twisting and bending in rectangular ribbons, shape of Mobius strips, and buckling in annular ribbons. Quantitative comparison between experiments and simulations validates the correctness of our numerical method.

*We acknowledge support from HSSEAS, University of California, Los Angeles.
Numerical Simulations for Physics-based Training of Robots for Manipulation of Flexible Rods*

LONGHUI QIN (Presenter), YAYUN DU, WEICHENG HUANG, MOHAMMAD KHALID JAWED, Department of Mechanical & Aerospace Engineering, University of California, Los Angeles — Robotic manipulation of flexible ropes has wide ranging application from advanced manufacturing to robot-assisted surgery. We report a physics-based scheme to deploy elastic ropes along a prescribed trajectory with a collaborative robot. A numerical simulation tool, based on the Discrete Elastic Rods method, is developed for the modeling of elastic rods including contact and friction. Given the stochastic nature of the friction between the rope and the ground, avoiding friction is a key to repeatability of experiments with the robot. Exploiting the robustness and efficiency of the computational framework, we generate training data in the numerical simulator. This data is used to plan the optimal path for the robotic arm such that friction is minimized during deployment of ropes on a given trajectory. Compared with physics-blind methods that require empirical training by humans for every single rope, our proposed scheme remains valid for any elastic rope regardless of the geometric and material properties. Moreover, vast amount of data can be produced from the simulator in a few hours on a contemporary CPU to train a general neural network with high accuracy.

*We acknowledge support from Henry Samueli School of Engineering and Applied Science, University of California, Los Angeles.

A Discrete Geometric Approach to Simulation of Soft Multi-limbed Robots

MOHAMMAD KHALID JAWED, University of California, Los Angeles, XIAONAN HUANG (Presenter), CARMEL MAJIDI, Carnegie Mellon University — Because they are primarily composed of mechanically compliant and deformable materials, soft limbed robots can navigate through unstructured terrain and confined spaces without dependency on highly articulated motion and sensing. However, design and control requires a painstaking trial and error process owing to the absence of an accurate and efficient simulation and modeling tools. Here, we present a numerical simulation tool for limbed soft robots inspired by a discrete differential geometry-based computational framework that can run faster than real-time on a single thread of a contemporary desktop processor. The simulation incorporates an implicit method to account for the elasticity of the structure, contact with an uneven surface, and Coulombic friction between the soft robot limbs and ground. To validate the simulation, we build a novel, shape memory alloy driven star-shaped soft robot comprised of seven compliant limbs that can cyclically change shape through electrical Joule heating and passive cooling. Our experiments and simulations show reasonable quantitative agreement and indicate the potential role of this discrete geometric approach as a computational framework in predictive simulations for soft robot design and control.

Topological Characterization of Meta-stable States in Weakly Non-linear Diffusion Processes on Networks

NIMA DEHMAMY (Presenter), ALBERT-LASZLO BARABASI, Northeastern University — Complex networks are ubiquitous. Many dynamical processes on networks, including spreading processes such as SIR and SIS, are generally weakly non-linear and the core of the process consists of a diffusion process. However, while the diffusion may have a trivial fixed point where the probability distributions over all nodes becomes uniform or proportional to their degree, the nonlinearity generally results in the trivial fixed point becoming unstable, yielding non-trivial outcomes. Especially in real networks with modular and other internal structures, characterizing these outcomes requires numerical simulations. Here we report discovering a deep connection between these solutions and symmetry groups. In particular, we consider a multi-dimensional weakly non-linear dynamical process on a network and show that it is equivalent to a force-directed layout problem. We then show how the topology of the embedding space and its symmetry group can be used to characterize the low-energy solutions, which turn out to be topological in nature. Often the trivial fixed-point of the dynamics, where the field over all nodes collapses to zero, is unstable due to constraints arising from non-linear interactions among nodes, resulting in topological low-energy states becoming the dominant.
**9:48AM R56.00010:** Connecting discrete to the continuum: continuum-level simulation of shear-banding in metallic glasses on transforming grids with Lees-Edwards boundary conditions*  
NICHOLAS BOFFI (Presenter), CHRISTOPHER RYCroFT, Harvard University — We simulate a three-dimensional continuum-level elasto-plastic model of a bulk metallic glass based on the shear transformation zone (STZ) theory of amorphous plasticity. The simulation utilizes a new projection method valid in the quasi-static limit based on a mathematical correspondence between the Navier-Stokes equations for incompressible fluid flow and the equations of quasi-static hypoelastoplasticity. We emphasize a variation of the method based on a coordinate transformation that permits the use of Lees-Edwards boundary conditions at the continuum scale, enabling direct comparisons between continuum and discrete simulation. We consider several interesting numerical examples, including simple and pure shear boundary conditions imposed in the transformed frame.

**10:00AM R56.00011:** Maxwell Force Shaping of Dielectric Liquid Films on Curved Conducting Substrates  
CHENGZHE ZHOU (Presenter), SANDRA TROIAN, MC 128-95, CALTECH, Pasadena, CA 91125 — The dynamical behavior of thin dielectric films on curved substrates is critically important to a range of processes fundamental to the coating industry, micro-lithography and biological flows. Substrate curvature can strongly affect film shape and stability, especially when the local film thickness couples to an external field. For thin dielectric films on planar domains, accurate solutions can be obtained by exploiting the gradient flow structure of the governing equation and appealing to the Helmholtz minimum dissipation principle. Here we show how this minimization principle can be extended to include thin films on curved substrates wherein the local film thickness is *actively coupled* to an external electric field and whose response is only mitigated by capillary forces. Accurate approximate solutions are obtained by invoking a variational principle and restricting trial solutions to polynomial functions in the direction normal to the substrate. We demonstrate this approach for a thin dielectric film coating a cylindrical conductor using a boundary/finite element method. We find that this solution method offers keen physical insight into allowable film configurations not accessible to planar geometries.

**10:12AM R56.00012:** Cross-Influence of Thermodynamic Driving Forces in Confined Environment  
YU QIAO (Presenter), MENG WANG, University of California, San Diego — The second law of thermodynamics dictates that under a certain condition, the cross-influences of thermodynamic driving forces (tdf) must be balanced. For a galvanic cell, it is equivalent to the well-known Nernst equation; for a double-layer supercapacitor, it is consistent with the classic Gouy-Chapman model. In our recent experiment on confined large pivalate ions in carbon nanopores, however, it was measured that the cross-influences of the electromotive force and the chemical potential were different from each other by an order of magnitude. We attribute this remarkable phenomenon to the confinement effect of the electrode inner surfaces, which forbids the formation of diffuse layer. We argue that in general, in a low-dimensional environment, in the large dimension(s), the laws of classic statistical physics can be applied; but in the small dimension(s) wherein two tdf interact, the governing equations can be distinct. With this unique mechanism, the second law of thermodynamics may break down, in a dissimilar manner to “Maxwell’s demon”. The concept of unbalanced cross-influence of tdf is further examined through a theoretical analysis on a model system comprising of randomly moving elastic particles restricted in a two-dimensional transition zone in a gravitational field.

**Session R57 GSNP DBIO: Noise-driven Dynamics in Far-from-equilibrium Systems II**  
- Stephen Teitsworth, Duke University
8:00AM R57.00001: Enhancing noise-induced escape in systems with distributed delays* IRA SCHWARTZ (Presenter), Nonlinear System Dynamics Section, United States Naval Research Laboratory, YULIYA N. KYRYCHKO, Department of Mathematics, University of Sussex — Many real world dynamical systems exhibit complex behavior often induced by intrinsic time delays, as well as influenced by random perturbations. An important problem, therefore, is to understand how random disturbances are organized such that the dynamics escape from a stable attractor and exhibit new behavior. Although the noise amplitudes are small, the result is a large fluctuation out of the basin of attraction. Here we study the influence of noise-induced large fluctuations on dynamical systems, where the time delay is not taken as a constant but is rather chosen from a given distribution. We use a variational approach to calculate the escape rates out of the basin of attraction for a general kernel of the delay distribution, as well as general nonlinearity. We illustrate the theory by taking two particular examples of the distribution kernel, namely, the uniform and bi-modal kernels, and analyze how the width of the distribution affects the switching rates. Our results show that the switching is affected not only by the mean time delay but also by the width of the delay distribution. Specifically, if the distribution width is increased, this leads to an increase in the switching times.

8:12AM R57.00002: A study of rare-event extinction phenomena in three species cyclic predation games.* SHANNNON SERRAO (Presenter), Center for Soft Matter and Biological Physics, Virginia Tech, DARRA LABAVIC, Laboratoire de Physique des Lasers, Atomes et Molécules, Université Lille 1 Sciences et Technologies, HILDEGARD MEYER-ORTMANNS, Physics and Earth Sciences, Jacobs University Bremen gGmbH — In the modified May-Leonard model with cyclically competing three species, we compute the statistics of rare-event two species extinction process from a long lived metastable three-species coexistence state due to large fluctuations. We employ a master equation based eikonal quasi-stationary approximation of the metastable state effectively reducing the problem to the classical dynamics evolution of a Hamiltonian in six degrees of freedom. We then solve the evolution of this system by applying the Iterative Action Minimization Method(IAMM) and compute the action along the optimal path across the transcritical bifurcation. Our results are compared with action computed from the generating function based Hamiltonian of the said (3,1) game. The results obtained are validated for regions across the transcritical bifurcation in the system and investigated for different values of the system size parameter $V$.

8:24AM R57.00003: Scaling laws governing stochastic death of individual cells and the extinction of populations. SRVIDYA IYER-BISWAS (Presenter), KUNAAL JOSHI, Purdue University — In this talk I will discuss the scaling laws governing stochastic death of individual cells and the extinction of populations, bridge the timescales of single-cell and population dynamics under conditions when there is significant mortality, and make connections to ongoing experiments on *C. Crescentus* cells.

8:36AM R57.00004: Intergenerational dynamics of individual cells reveal rules governing stochastic cell-size homeostasis KUNAAL JOSHI (Presenter), SRVIDYA IYER-BISWAS, Department of Physics and Astronomy, Purdue University — In this talk I will first establish that cell size homeostasis is maintained under appropriate growth conditions, using multigenerational data from our experiments on individual *C. Crescentus* cells. I will then discuss how our data on intergenerational dynamics of cell size, cell shape and cell division times, obtained under several growth conditions, reveal the rules governing stochastic cell-size homeostasis.

8:48AM R57.00005: Kinetic inversion of repressors and activators in gene expression regulation. ZHIYUE LU (Presenter), CHUDONG WU, AARON DINNER, University of Chicago — In gene expression regulation, repressors and activators compete to bind with the gene's regulatory element, and the chance of activators binding with the regulatory element dictates the activation level of the gene. In a thermal equilibrium regime, this chance of binding is well determined by the concentrations of activators and repressors as well as their binding free energies to the regulatory element -- a high level of repressor will result in a low chance of activator binding. However, inspired by the experimental observations of cooperativity between activators and repressors, we propose a non-equilibrium dynamics model to describe the gene regulatory dynamics when the concentration of the repressor changes rapidly over time. We demonstrate a minimal Markov model where a rapidly changing level of repressor significantly increases the level of activation beyond predicted by equilibrium theory and effectively enhance the activator. Our model introduced an internal degree of freedom of the regulatory element, and its kinetic barrier allows the system to harnesses the chemical work done by the rapidly changing concentration of the repressor and use it to boost the level of gene activation beyond the equilibrium prediction.
9:00AM R57.00006: A partial differential equation for the mean first-return-time phase of a stochastic oscillator

BENJAMIN LINDNER (Presenter), Humboldt University of Berlin, ALEXANDER CAO, PETER J. THOMAS, Mathematics, Case Western Reserve University — Phase reduction of limit cycle dynamics provides a low-dimensional representation of high-dimensional oscillator dynamics. For a deterministic dynamical system with a stable limit cycle, the change to a phase variable is well established. In contrast, for stochastic limit cycle systems, a phase reduction can be defined in several nonequivalent ways (e.g. Schwabedal and Pikovsky Phys. Rev. Lett. 110, 205102 (2013), Lindner and Thomas Phys. Rev. Lett. 113, 254101 (2014)). Schwabedal and Pikovsky introduced a phase for stochastic oscillators based on a foliation of the basin of attraction, with the property that the mean transit time around the cycle from each leaf to itself is uniform and developed a numerical procedure to estimate the corresponding isochrons. For robustly oscillating planar systems driven by white Gaussian noise, we establish a partial differential equation with a mixture of reflecting and jump boundary conditions that governs this phase function. We solve this equation numerically for several examples of noisy oscillators. In addition, we obtain an explicit expression for the isochron function, for the rotationally symmetric case, and compare this analytical result with oscillators that have been studied numerically in the literature.

9:12AM R57.00007: Fitness landscapes as predictor of noise-driven self-organized pattern formation on surfaces

ZG�N YAVUZ, ONUR TOKEL, FATIH ILDAY, SERIM ILDAY (Presenter), Bilkent University — Pattern formation far from equilibrium often exhibits a richness that is quite distinct from near-equilibrium dynamics. Perhaps the most visible consequence is the formation of different patterns in addition to the one favored at or near equilibrium. Can these, then, be controlled, and selected, externally? Here, we adopt the concept of "fitness landscapes" from evolutionary biology to show how nonlocal feedback gain of tailored defects controls and steers the evolution of nanopatterns using Nonlinear Laser Lithography (Iliday, Nat. Photon., 2013), an optical method that forms feedback-regulated patterns with nanometer uniformity. Through numerical simulations and experimental demonstration, we show that stimulated symmetry breaking can direct these nanopatterns to all possible 2D Bravais lattices.

9:24AM R57.00008: Wavenumber Selection in Pattern Forming Systems

SALONI SAXENA (Presenter), JOHN MICHAEL KOSTERLITZ, Brown University — Pattern forming systems are characterized by the emergence of a band of stable spatially periodic states as a control parameter is varied. Wavenumber selection refers to the evolution of such systems to one of these states at long times, irrespective of initial conditions. Numerical studies of pattern forming phenomena indicate that the presence of noise is a mechanism for wavenumber selection at long times. We investigate this for the noisy Stabilized Kuramoto Sivashinsky (SKS) equation. Computational difficulties restricted earlier numerical simulations of this equation to small system sizes and a narrow range of control parameters[1]. Our aim now is two-fold: to determine whether wavenumber selection occurs for larger system sizes and to do so for a broader range of control parameter values. With the use of spectral methods of integration, we have been able to simulate larger system sizes and obtain a crude probability distribution of final states. We present our results for various system sizes and demonstrate a possible connection to large deviation theory[2]. The drawbacks of our approach and possible improvements are also discussed.

9:36AM R57.00009: Crossover between parabolic and hyperbolic scaling, oscillatory modes and resonances near flocking*

CAROLINA TRENADO (Presenter), LUIS BONILLA, Carlos III University of Madrid — A stability and bifurcation analysis of a kinetic equation indicates that the flocking bifurcation of the two-dimensional Vicsek model exhibits an interplay between parabolic and hyperbolic behavior. For box sizes under a certain large value, flocking appears continuously from a uniform disordered state at a critical value of the noise. Bifurcation equations contain two time scales and, due to mass conservation, comprise a scalar equation for the density disturbance from the homogeneous state and a vector equation for a current density. At the shorter scale, they are a hyperbolic system in which time and space scale in the same way. The equations are diffusive at the longer time scale. The bifurcating solution depends on the angle and is uniform in space as in the normal form of the usual pitchfork bifurcation. We show that linearization about the latter solution is described by a Klein-Gordon equation in the hyperbolic time scale. Then there are persistent oscillations with many incommensurate frequencies about the bifurcating solution that may resonate with a periodic forcing of the alignment rule. These predictions are confirmed by direct numerical simulations of the Vicsek model.

**9:48AM R57.00010: Spin lattices of walking droplets**

PEDRO SAENZ (Presenter), Massachusetts Institute of Technology, GIUSEPPE PUCCI, Institut de Physique de Rennes, SAM E TURTON, ALEXIS GOUJON, RODOLFO R ROSALES, JORN DUNKEL, JOHN BUSH, Massachusetts Institute of Technology — In this talk, we will introduce a hydrodynamic analog system that allows us to investigate simultaneously the wave-mediated self-propulsion and interactions of effective spin degrees of freedom in inertial and rotating frames. Millimetric liquid droplets can walk across the surface of a vibrating fluid bath, self-propelled through a resonant interaction with their own guiding wave fields. A walking droplet, or `walker', may be trapped by a submerged circular well at the bottom of the fluid bath, leading to a clockwise or counter-clockwise angular motion centered at the well. When a collection of such wells is arranged in a 1D or 2D lattice geometry, a thin fluid layer between wells enables wave-mediated interactions between neighboring walkers. Through experiments and mathematical modeling, we demonstrate the spontaneous emergence of coherent droplet rotation dynamics for different types of lattices. For sufficiently strong pair-coupling, wave interactions between neighboring droplets may induce local spin flips leading to ferromagnetic or antiferromagnetic order. Transitions between these two forms of order can be controlled by tuning the lattice parameters or by imposing a Coriolis force mimicking an external magnetic field.

**10:00AM R57.00011: Observation of Stochastic Resonance Induced by Dichotomous Noise in a Liquid Crystal Light Valve with Optical Feedback**

YOSHITOMO GOTO (Presenter), Department of Materials Science and Production Engineering, Oita University, TOMOYUKI NAGAYA, Division of Natural Sciences, Oita University, HIROSHI ORIHARA, Division of Applied Physics, Hokkaido University — Noise-induced phenomena are widely observed in nature and are of great interest in the field of nonlinear dynamics. Stochastic resonance (SR), which is one of the most well-known noise-induced phenomena, has been discussed intensively [1], [2]. SR is a phenomenon in which the response of a nonlinear bistable system to a weak signal is enhanced by the addition of noise. In the present study, we focus on a liquid crystal light valve (LCLV) with optical feedback as one of the bistable systems. In the LCLV with optical feedback, the average orientation of the LC molecules, so-called director, shows bistability in some conditions [3], [4]. In this report, we discuss SR in LCLV with optical feedback system induced by the dichotomous noise (DN), characterized by an autocorrelation time.

**10:12AM R57.00012: Boundary Effects in Stochastic Cyclic Competition Models on a Two-Dimensional Lattice**

M. LAZARUS ARNAU (Presenter), SHANNON SERRAO, UWE CLAUS TAUBER, Virginia Tech — We study noise-induced and stabilized spatial patterns in two distinct stochastic population model variants for cyclic competition of three species, namely the Rock-Paper-Scissors (RPS) and the May-Leonard (ML) models. In two dimensions, it is well established that the ML model can display (quasi-)stable spiral structures, in contrast to simple species clustering in the RPS system. Our ultimate goal is to develop local control schemes which allow us to affect the formation of these spatio-temporal patterns. To this end, we have employed MC simulations to investigate how changing the microscopic rules in a subsection of a two-dimensional lattice influences the macroscopic behavior in the rest of the lattice. Specifically, we implement the ML reaction scheme on a torus, except on a ring-shaped patch, which is set to follow the cyclic Lotka-Volterra predation rules of the RPS model. At the RPS-ML interface we observe a marked disruption of the usual spiral patterns in the form of plane waves emanating from the RPS region. Also, we report a distinct decrease in local population density near the interface in comparison to the bulk of the ML region.

Measurement and feedback are integral components for efficient functioning of physical systems in the microscopic as well as macroscopic world. We will analyze and quantify the thermodynamic costs of performing bit level measurements and energetics of feedback action. The thermodynamic system of interest studied is a Brownian particle in a bi-stable well, which is often used as a model for a single bit memory in the study of erasure of information. Landauer states that the minimum amount of heat dissipation for erasing a memory bit is $k_B T \ln 2$, which provides the Landauer limit. Recent experiments demonstrate that the erasure can be achieved with energetics close to the Landauer's bound. The protocols in prior art are open-loop, where the information on the state of the memory is not employed in the erasure protocol. Here, we quantify the energetics of erasure protocols with feedback; experimentally as well as via Monte Carlo simulations. Results indicate that the deficit between the heat dissipation in the feedback based erasure protocol and the $k_B T \ln 2$ can be accounted for quantitatively by the measurement and feedback mechanisms. Non-conservative bounds are obtained on the deficit.

*The research was supported by the National Science Foundation under the grant NSF ECCS 1809194.

We present a model of a Brownian asymmetric simple exclusion process (BASEP) with overdamped Brownian dynamics that resembles properties of the asymmetric simple exclusion process (ASEP) on a lattice [1]. In this BASEP, particles of size $\sigma$ with hardcore interaction are driven by a constant drag force through a one-dimensional cosine potential with period $\lambda$. The character of the non-equilibrium steady states in the BASEP is strikingly different from that in the ASEP. Compared to the particle current in a system of non-interacting particles, we observe an enhancement for small $\sigma/\lambda$ ratios, caused by a barrier reduction effect arising from multi-occupation of potential wells. Larger $\sigma/\lambda$ ratios lead to a suppression of the current because of blocking effects. Surprisingly, an exchange-symmetry effect causes the current-density relation to be identical to that of non-interacting particles for commensurable lengths $\sigma=\lambda$. A current-density relation similar to the ASEP is obtained only for a limited parameter regime. The rich behavior of the current-density relation leads to phase diagrams of NESS in open systems with up to five different phases. The topology of these phase diagrams changes with varying $\sigma/\lambda$ ratio.

In biological systems, a key concept of interest is the energy required to induce changes in the state of a system. The modern approach to this problem is to identify the energy cost of such control with entropy dissipation. For systems with deterministic control, the lower bounds on entropy dissipation are well known. However such analyses tend to ignore the cost associated with the method of control which becomes crucial at the biological scale. Here we extend such analyses to take into account the entropy cost of exerting control on a system when the control itself is stochastic in nature and subject to fluctuations. Using the formalism of stochastic thermodynamics, we find an intriguing non-trivial unification of previous results for a realizable controlled non-equilibrium steady state system driven at a finite rate around a loop in thermodynamic space. In particular we show that for a model system, the lower dissipation bound is almost the sum of two previously found bounds. Despite this, our result suggests that even for an infinitely long control protocol, it is still impossible to reach the adiabatic limit for stochastic systems.
8:00AM R58.00001: Influence of Elastic Modulus of a Soft Elastomer on Adhesion to Rough Surfaces  SIDDHESH DALVI (Presenter), Department of Polymer Science, The University of Akron, ABHIJEET GUJRATI, Department of Mechanical Engineering and Materials Science, University of Pittsburgh, ALI N DHINOJWALA, Department of Polymer Science, The University of Akron, TEVIS JACOBS, Department of Mechanical Engineering and Materials Science, University of Pittsburgh, LARS PASTEWKA, Department for Microsystems Engineering, University of Freiburg — In the field of adhesion science, it is of practical importance to understand how roughness affects adhesion. This is of direct relevance in designing adhesives for applications in the areas of microelectronics, biomedical devices, and composites. The main idea is to have the adhesives conform to the roughness and approach close enough for van der Waals (or other electrostatic) interactions to be effective. The first complete mathematical formulation for roughness was put forward by Greenwood and Williamson using a single-length-scale model describing the surfaces as hemispherical asperities with a Gaussian distribution of heights. Bo Persson has proposed a multi-scale model to calculate the adhesion energy as a function of modulus and roughness, as described using the power spectral density of topography. Here we have performed contact and fracture mechanics experiments for smooth cross-linked polydimethylsiloxane with varying elastic modulus on polycrystalline diamond surfaces with varying roughness, which have been characterized to obtain accurate multi-scale power spectral densities. We will present the comparison between the predicted adhesion energies calculated using Persson's theory and the experimental adhesion energy measured during approach and separation.

8:12AM R58.00002: Gluing polymer interfaces with nanoparticles: insights from molecular dynamics  NICOLA MOLINARI, BORIS KOZINSKY, Harvard University, STEFANO ANGIOLETTI-UBERTI (Presenter), Department of Materials, Imperial College London — In recent years, nanoparticles have been shown to have the potential to answer the centuries-old question of how to mechanically strengthen an interface between soft materials. A deeper understanding of the mechanism and parameters resulting in the mechanical reinforcement, or lack thereof, would help rationalize experimental findings and, ultimately, guide the design of adhesive solutions. Building on our previous work on polymer in bad solvent conditions [DOI: 10.1021/acs.nanolett.8b00586], we investigate the trends, and the fundamental drivers of, the mechanical properties of polymer interfaces glued with spherical nanoparticles. Using a coarse-grained model, we simulate polymer network structures with different degrees of swelling. The interface between two networks is filled with nanoparticles, and the overall system is then uni-axially strained to construct the stress-strain curve for a given set of parameters. The results from this investigation help disentangling the contributions to the strengthening of the interface and can be used as a guide to experimental design of nanoparticles-based adhesives.

8:24AM R58.00003: Ultra-soft textured substrates*  MARTIN COUX (Presenter), JOHN KOLINSKI, Ecole Polytechnique Fédérale de Lausanne — Droplets deposited on soft elastomers or gels with elastic moduli ~ 1 – 10 kPa induce a micro-scale elastic deformation at the contact line. This significantly modifies the wetting properties of the solid - for example, a droplet deposited on an inclined soft surface will slide downward driven by its weight at velocities orders of magnitude less than a droplet on a similarly inclined rigid solid. Here, we confine the contact between water and a soft silicone gel to micrometric patches by texturing the solid, inducing superhydrophobicity for materials with elastic moduli as low as 3 kPa. The coupling between surface texture and surface compliance strongly influences the behavior of the droplet at both macro- and micro- scales, leading to a giant speed up during descent, and potentially affecting the stability of the Cassie state.

8:36AM R58.00004: Hydrogel menisci: Shape and interaction  ANUPAM PANDEY (Presenter), CHARLOTTE NAWIJN, JACCO SNOEIJER, University of Twente — The interface of a soft hydrogel is easily deformed when it is in contact with particles, droplets or cells. Here we compute the intricate shapes of hydrogel menisci due to the indentation of point particles. The analysis is based on a free energy formulation, by which we also assess the interaction laws between neighboring particles on hydrogel interfaces, similar to the “Cheerios effect”. It is shown how the meniscus formed around the particles results from a competition between surface tension, elasticity and hydrostatic pressure inside the gel. We provide a detailed overview of the various scaling laws, which are governed by a characteristic shear modulus $G^* = \sqrt{\gamma \rho g}$ that is based on surface tension $\gamma$ and gravity $\rho g$. Materials with shear modulus larger than $G^*$ exhibit a solid-like response while softer materials are more liquid-like.
8:48AM R58.00005: Equilibration time, swelling, and the tangential contact-line force on a partially immersed gel thread

SHIH-YUAN CHEN (Presenter), AARON R BARDALL, MICHAEL SHEARER, KAREN DANIELS, North Carolina State University — When a liquid contacts a sufficiently soft material, the surface tension of the liquid deforms the substrate at the contact line, forming a ridge. The height of this ridge is on the order of \( y/E \), known as the elastocapillary length. The precise stress boundary condition at the contact line has a significant effect on this mechanism, but is as yet unresolved. A complicating factor is that liquids also interact with gels by swelling and/or contamination from the uncrosslinked oil in the gel. Hence, it is crucial to distinguish these different mechanisms when conducting an elastocapillary experiment. In our talk, we present experiments with a poly(vinyl siloxane) gel thread partially immersed in liquids of different wettability and swellability. We show that when making stress-strain measurements via fluorescent bead microscopy, the positions of the beads only equilibrate after 12 to 24 hrs. This timescale is incompatible with the use of ethanol as the immersion fluid, since it swells the PVS thread; we find that using FC-40 allows the thread to reach equilibrium without swelling. Once these two effects are resolved, the evidence for a tangential force at the contact line is weak.

*National Science Foundation DMR-1608097

9:00AM R58.00006: Using droplet shapes to study the surface tension of soft gels

KATRINA SMITH-MANNSCHOTT (Presenter), QIN XU, ERIC DUFRESNE, ROBERT STYLE, ETH Zurich — Surface tension is a phenomenon typically associated with liquids, rather than with solids. However, interest in interfaces of soft solids has revealed the importance of surface tension, for instance in controlling small-scale adhesion behavior. Here, we aim to develop a new technique to investigate the surface tension of soft gels through the analysis of droplets on a stretched substrate. In particular, we find that small droplets on a stretched surface elongate along the stretch direction. We will show how this is consistent with the presence of strongly strain-dependent surface stresses.

*SNSF Grant 200021-172827

9:12AM R58.00007: Adhesion-Based Measurements of Strain-Dependent Surface Stress in Soft Solids

JEREMY THALLER (Presenter), MINWOO KANG, KATHARINE JENSEN, Williams College — Surface stress, or surface tension, is a fundamental material property of interfaces. However, our understanding of solid surface tension and how it changes with deformation remains limited because it is difficult to measure in traditional stiff materials. Soft materials, including gels, provide a unique opportunity to measure these fundamental properties because they can be stretched elastically to very large strains. In this work, we use an adhesion-based approach to measure the solid surface stress of compliant materials as a function of applied strain. This approach is applicable to a wide range of soft materials.

9:24AM R58.00008: Interfacially Driven Plastic Deformation of Soft Solids

CHRISTOPHER O’BRYAN (Presenter), THOMAS ANGELINI, University of Florida — Capillary forces acting on the surface of a solid result in elastic deformation on the scale of the elastocapillary length. While these elastic deformations may be negligible in stiff materials, they can dominate the behavior of soft solids, including rubbers, hydrogels, and biological tissues. In the extreme case, capillary forces may exceed the material's yield stress, resulting in plastic deformation near the contact line. Although this elastocapillary effect has been theorized, experimental exploration into this phenomenon have remained limited. Understanding the role of interfacial forces on the deformation of soft surfaces is necessary as new methods for manufacturing soft materials with low moduli and yield stresses are developed. Here, we investigate interfacial instabilities of 3D printed microbeams, using jammed granular microgels swollen in aqueous and organic solvents as both sacrificial support materials and as printed inks. By leveraging the highly tunable material properties of these microgel systems and the structural control offered by 3D printing, we systematically explore a range of yield stresses and beam widths to understand how elastocapillary effects can drive mechanical instabilities and material failure in soft solids.

9:36AM R58.00009: Poking a peach: Is testing for ripeness confounded by the skin

DOMINIC VELLA (Presenter), FINN BOX, University of Oxford, MOKHTAR ADDA-BEDIA, ENS Lyon — To test whether soft fruit is ripe, one often pokes with a finger. However, the flesh of the fruit itself is significantly softer than when the skin remains intact. In this talk we will address the question of when the indentation stiffness of a soft material coated by a thin, but significantly stiffer, material is affected by the presence of the coating. We demonstrate a substrate-dominated regime and a mixed regime (in which both coating and substrate are important) and show that the size of the indenter is a key parameter separating the two.

*ERC StG 637334
9:48AM R58.00010: Direct observations of dewetting relaxation at the interface of soft gels [Invited]  QIN XU (Presenter), ETH Zurich, LAWRENCE WILEN, Yale University, ROBERT STYLE, ERIC DUFRESNE, ETH Zurich — Wetting of liquid droplets on soft gels (E~3kPa) deforms gel interface significantly: a wetting ridge grows under the balance between liquid surface tension and solid surface stress near contact line. Using interference microscopy and fast camera imaging, we directly observe the recovery of gel surface from this wetting-induced deformation after removing liquid droplet. We show experimentally that surface relaxation of soft gels cannot be simply modelled by their viscoelastic rheology. Instead, the relaxation behaviour is a consequence of interplay between different restoring stresses near the interface, including solid capillarity and elasticity, and resisting stresses from the bulk, such as osmotic pressure across the network and local viscous stresses. By measuring scaling of wetting shapes under relaxation, we can determine which stress dominates the dissipation. Our results further extend the current understanding of elastocapillarity with the effect of bulk porosity, and bring new insight into the study of wetting dynamics on soft materials.

10:24AM R58.00011: Surface waves and wakes on soft solids  ROBERT HAUSSMAN (Presenter), ADITI CHAKRABARTI, LAKSHMINARAYANAN MAHADEVAN, Harvard University — Understanding the response of soft matter surfaces to dynamical disturbances is critical for a variety of applications, such as ultrasound and needleless injections. Motivated by this, here we explore the dynamical response of a very large, very soft solid due to impulsive and moving pressure disturbances on its surface. In particular, we describe the conditions under which Kelvin wake-like patterns should appear and derive perturbative corrections due to soft elasticity about the well-known inviscid limit, and describe the results of experiments to probe this limit.

10:36AM R58.00012: Measuring the dispersion relation of capillary waves using differential dynamic microscopy*  JING WANG (Presenter), RYAN J. MCGORTY, Department of Physics and Biophysics, University of San Diego — With a recently-developed method for measuring capillary wave dynamics at the interface of fluids we examine non-equilibrium interfacial fluctuations. We use a colloidal-polymer mixture that separates into colloid-rich and colloid-poor fluid phases with an ultra-low surface tension and capillary velocities on the order of a micron per second. We use differential dynamic microscopy (DDM) to measure the two-dimensional dispersion relation of capillary waves at spatial frequencies spanning over an order of magnitude. Using temperature-responsive colloidal particles (pNIPAM) to tune the phase diagram we investigate the interfacial fluctuations between non-equilibrium phases.

10:48AM R58.00013: How suction cups fail  CHON U CHAN (Presenter), MICHELLE WALSH, L MAHADEVAN, Paulson School of Engineering and Applied Sciences, Harvard University — Suction cups occur in nature and technology, and are widely used in a range of situations across many length scales. They often cannot afford to fail owing to catastrophic consequences associated with examples such as lifting large glass sheets, and in manipulating delicate tissues and organisms. But how do they fail? We report an experimental study that captures the failure dynamics of soft suction cups that involves an interplay of elastic deformation, viscous lubrication flows and interfacial instabilities over time scales that range from milliseconds to hours. Our study allows us to propose a design to prolong the holding time till failure.

Thursday, March 7, 2019 8:00 AM - 10:48 AM

Session R59 GSOFT: Actuation in Soft Matter I BCEC 257B - Tag(s): Focus

8:00AM R59.00001: Actuation in soft matter [Invited]  ROBERT SHEPARD (Presenter), Cornell University — It has recently been shown that elastic materials may be architected to display remarkable functionality when harnessing mechanical instabilities. These so called mechanical-metamaterials are however often passive elastic structures, which undergo deformations when prompted by external loading. Different modes of actuation have been proposed, such as pressure controlled grabbing fingers in soft-robotics, swelling in shape-morphing gels, electrostatics in dielectric elastomers or temperature in liquid cristal polymers or shape memory alloys. How can these different solution be integrated in future manufactured devices? We are seeking contributions studying the fundamental and practical aspects of the integration of actuation in the design of soft materials. Particularly, we are interested in the (1) the mechanisms of amplification of an input via the architecture of the materials and (2) the programability of a complex response using a simple mode of actuation. This session would be in the core of recent GSOFT topics as illustrated in the previous editions of the March meeting, eg Soft Interfaces Mechanics, Robophysics, Extreme Mechanical Instabilities, Origami and kirigami of metamaterials.
Sequential actuation of deformable actuators, producing a complex preprogrammed response with just a single and simple input. Through a combination of experiments and numerical simulations we demonstrate that the transition waves propagating in a system comprising several bistable dome-shaped membranes that enclose fluid filled cavities can be exploited to trigger the sequential actuation of deformable actuators, producing a complex preprogrammed response with just a single and simple input.

*Prof. K. Bertoldi acknowledges support from the National Science Foundation under Grant No. DMR-1420570

Mechanically programmable sequential actuation of fluid-driven soft actuators

LUUK VAN LAAKE (Presenter), JOHANNES OVERVELDE, AMOLF — Fluid-driven actuators show great promise for robotics operating alongside human beings, for handling delicate and irregularly shaped objects, and for medical implants such as artificial muscles and even potentially heart prostheses. While soft actuators can be produced from materials that exhibit mechanical compliance close to that of human tissue, control of these actuators typically requires rigid elements such as electronic sensors, valves, and wires that may cause stress concentrations limiting the lifetime of the system. To circumvent this issue, we aim to replace the electronics by other modes of control using only soft elements that are embedded in the fluid that drives the soft actuators. Specifically, we focus on elastic hysteretic valves that allow us to program complex actuation patterns. We analyze the dynamic behavior using the electronic-hydraulic analogy and show that these circuits can deliver complex flows (e.g. pulsatile) to individual actuators, while fluidic power to the system is provided by a continuous fixed flow. We furthermore show that we can change the behavior of the soft system by varying the initial conditions, such that we can produce a soft robot that can be mechanically programmed to move using multiple gaits, without the need for electronics.

Walking Sheets: Locomotion in chemo-mechanically driven, non-Euclidean elastic plates

PEARSON MILLER (Presenter), Physics, Massachusetts Institute of Technology, JÖRN DUNKEL, Mathematics, Massachusetts Inst of Tech-MIT — Spatio-temporally varying chemical patterns are an essential mechanism for coordinating force generation in biological systems. Inspired by this, the use of active materials driven by self-oscillating reaction-diffusion equations is increasingly being explored for engineering applications. This talk describes recent investigations into the locomotion of chemically-driven, deformable surfaces from the perspective of non-Euclidean elastic plate theory. Through a combination of numerical and analytical results, we examine the geometric and mechanical characteristics which optimize gait velocity in an elastic sheet driven along a frictional surface. Further, locomotion on non-uniform terrain is considered, in particular the conditions in which external geometry can inhibit or promote robust motion. Overall, we develop insights into how best to utilize incompatible geometry in the design of soft robotics and other applications.

Untethered Soft Machines and Robots by Printing Ferromagnetic Domains in Soft Materials

YOONHO KIM (Presenter), HYUNWOO YUK, Soft Active Materials Lab, Department of Mechanical Engineering, Massachusetts Institute of Technology, RUIKE ZHAO, Department of Mechanical & Aerospace Engineering, The Ohio State University, SHAWN A. CHESTER, Department of Mechanical and Industrial Engineering, New Jersey Institute of Technology, XUANHE ZHAO, Soft Active Materials Lab, Department of Mechanical Engineering, Massachusetts Institute of Technology — Soft active materials capable of transforming into programmed shapes in a remotely controllable manner can bring promising applications in diverse fields such as soft robotics and biomedicine. Several types of shape-programmable soft matter have been proposed but often limited to simple geometries and thus with limited functionalities. We introduce a method of printing ferromagnetic domains in soft materials to realize highly responsive and fully programmable soft active materials that quickly transform into multiple desired shapes in applied magnetic fields. We also discuss the mechanics of our printed magnetic soft materials and the model-based simulation, which enable us to design complex structures with multiple modes of programmed actuation while guiding the material design for optimal actuation performance. Combined with the flexibility in design and fabrication, the fast and dynamic response of our printed soft machines and robots provides a range of potential applications, especially in biomedical areas where remote actuation of such untethered devices can be useful. To open this new avenue, we present a set of demonstrations that exemplify the concept of untethered soft machines and robots in biomedical applications such as magnetically steered catheters and guidewires.
9:24AM R59.00006: Energy Release Through Volume Snapping in Soft Inflatable Actuators* BENJAMIN GORISSEN (Presenter), DAVID MELANCON, NICK VASIOS, MEHDI TORBATI, KATIA BERTOLDI, SEAS, Harvard University — Traditionally, the actuation speed of soft inflatable actuators is limited by the influx of fluid, resulting in slow moving soft robots. To overcome this limitation, we have developed a bistable elastic actuator with an isochoric snap-through. As no external fluid input is needed to pass through this instability, the resulting actuator deformation happens quasi-instantaneous and is characterized by energy release. Besides optimizing the actuator's design for energy release, we also demonstrate its ability to be reset to the initial, undeformed state, enabling cyclic energy release.

*This research was supported by the Fund for Scientific Research-Flanders (FWO).

9:36AM R59.00007: Soft Robot Actuated by Electrostatic Force CONGRAN JIN (Presenter), Thayer School of Engineering, Dartmouth College, JINHUA ZHANG, XI'AN JIAOTONG UNIVERSITY, IAN TRASE, SHICHENG HUANG, ZHE XU, LIN DONG, JOHN X.J. ZHANG, ZI CHEN, Thayer School of Engineering, Dartmouth College — Conventional robots are rigid, powerful and robust, and hence they have been serving as trustworthy tools to assist humans in a variety of activities. However, due to their rigid body, they lack flexibility to cope with situations where space is confined, terrain is complex, or the environment is constantly changing. To solve these problems, researchers have focused on developing soft robots that can adapt to different environments. Nevertheless, most of the current locomotive actuation methods and materials have limited applications due to either large size, heavy weight, low speed, or complicated fabrication. We have designed, prototyped, and tested a thin-film-based electrostatic soft actuator that overcomes many of these drawbacks. A robotic bug based on this electrostatic actuator was designed and showed its (1) climbing ability through ascending inclines up to 30°, (2) flexibility through shape-recovery after crushing, (3) adaptability through walking on both rough and smooth surfaces and (4) maneuverability by precisely steering into a designated space. The development of such light weight flexible soft robotics will enable tasks such as surveillance, search-and-rescue, and detection that are challenging if not impossible for traditional robots in a cost-effective manner.

9:48AM R59.00008: Artificial Muscle by Tailoring Compliance in Magneto-kirigami Lattice YI YANG (Presenter), DOUGLAS PETER HOLMES, Mechanical Engineering, Boston University — The emerging research in soft robotics and micro-robotics has sparked new opportunities for developing artificial muscles of variable length scales and in various working environments. The essential challenge lies in controlling the deformability and compliance of its structural component. In this presentation, we demonstrate a novel approach to precisely control the compliance and deformability via perturbing the elastic energy state of metastable kirigami lattices. Each metastable kirigami lattice has two stable configurations corresponding to two distinct local energy minima. Switching between these two minima leads to either stiffening or softening in lattice structures, which when cycled between these states produces an artificial muscle. Through a combination of experiments and mechanical modeling, we interpreted the stiffening or softening mechanism and characterized the performance of the designed artificial muscle. Since the underlying physics of the metastable kirigami lattice is scale invariant, this kirigami architecture may path a new way to design and fabricate low cost, lightweight artificial muscle at multiple scales.

10:00AM R59.00009: Elastomeric focusing enables portable microvalves* NATE CIRA (Presenter), Harvard University — A continuing challenge in material science is creating active materials in which shape changes or displacements can be generated electrically or thermally. Here we borrow principles from hydraulics, in particular that confined geometries can be used to focus expansion into large displacements, to create solid materials with amplified shape changes. Specifically, we confined an elastomeric poly(dimethylsiloxane) sheet between two more rigid layers and caused focused expansion into embossed channels by local resistive heating, resulting in a 10x greater relative displacement than the unconfined geometry. We used this effect to create electrically controlled microfluidic valves that open and close in less than 100 ms, can cycle >10,000 times, and operate with as little as 20 mW of power. We investigate this mechanism and establish design rules by varying dimensions, configurations, and materials. We show the generality of elastomeric focusing by creating additional devices where local heating and expansion are generated either wirelessly through inductive coupling or optically with a laser, allowing arbitrary and dynamic positioning of a microfluidic valve along the channels.

ANDREW GILLMAN, UES, Inc, GREGORY WILSON, University of Texas A & M, KAZUKO FUCHI, University of Dayton Research Institute, DARREN HARTL, University of Texas A & M, ALEXANDER PANKONIEN, PHILIP BUSKOHL (Presenter), Air Force Research Laboratory — The integration of soft actuating materials within origami-based mechanisms is a novel method to amplify the actuated motion and tune the compliance of the system for low stiffness applications. Origami structures provide natural flexibility given the extreme geometric difference between thickness and length, and the energetically preferred bending deformation mode can naturally be used as a form of actuation. However, origami fold patterns with specific actuation motions and mechanical loading scenarios are needed to expand the library of fold-based actuation strategies. In this study, an optimization framework is utilized to predict actuator topologies with different symmetry groups of input and output conditions with respect to the boundary conditions. Utilizing the patterns discovered through the optimization, the multistability of the actuator is further characterized through computational tracking of the bifurcating equilibrium branches and through empirical demonstration with actuator prototypes. This survey of origami mechanisms, comparison of actuation efficiency, and characterization of multistability provides a new set of origami actuators for future integration with soft actuating materials.

JI-HWAN KANG (Presenter), CHRISTIAN SANTANGELO, RYAN HAYWARD, University of Massachusetts Amherst — Self-folding of responsive polymer networks represents a powerful tool to form arbitrary 3D shapes from an initially flat 2D sheet. For example, our groups have previously developed trilayer polymer films that reversibly fold into complex origami designs due to swelling of a temperature-responsive hydrogel mid-layer. However, the configuration space of even very simple origami designs features multiple branches bifurcating from the flat state, meaning that self-folding structures can easily become trapped in an undesired state. Here, we evaluate two methods to avoid such misfolding. First, as suggested by Tachi and Hull (J. Mech. Robot. 2017), we design a set of driving forces that renders the flat state a local minimum along undesired geometrically allowed branches. While we find the approach to be effective for a single degree-6 vertex, this approach is inherently limited to a highly restricted set of crease patterns. Second, we seek to locally program the buckling direction of each vertex by incorporating an orthogonally-addressable (pH-sensitive) element that pre-biases the structure along the desired branch. As this approach should be applicable for generic crease patterns of high complexity, it represents an important step in the design of robustly self-folding structures.

MARY ELIZABETH LEE (Presenter), CHRISTIAN SANTANGELO, Physics, University of Massachusetts, Amherst — Self-folding origami, flat sheets that use mechanical instabilities to fold into three-dimensional structures, have been actuated using swelling polymer gels, surface tension, and more. A universal problem with these structures is that there can be multiple fold configurations for one origami pattern, resulting in the possibility that the structure folds into a configuration other than the one desired. Using an energy model for the structures, we show that the configuration space of a generic origami structure takes the form of nested cones, and that the number of conical branches increases with the number of internal vertices. We will use this geometry to investigate misfolding, with a focus on origami with 5 external vertices.

Session R60 FIP: Condensed Matter/Materials Science Solutions to Environmental Problems BCEC 258A - Abhishek Kumar, NIST - Tag(s): Invited
8:00AM R60.00001: Perovskites for Energy Harvesting* [invited] MARINA LEITE (Presenter), University of Maryland, College Park — The extraordinary performance of perovskite solar cells (> 20%) is still hampered by their dynamic optical and electrical responses, which often lead to degradation. The individual and combined effects of water, oxygen, temperature, bias, and light must be controlled for their future commercialization. To unravel the contribution of each parameter on materials’ properties and devices’ performance, we combine advanced scanning probe methods. We investigate a series of hybrid perovskites, including MAPbI3, MAPbBr3, CsxFA1−xPb(lyBr1−y)3, and triple cation Cs-mixed. Using environmental PL microscopy we elucidate a humidity-induced PL hysteresis, strongly dependent on the Cs/Br ratio. Through Kelvin-probe force microscopy we elucidate the dynamic open-circuit voltage response as a function of chemical composition and illumination treatments. We propose a machine learning (ML) paradigm to identify the influence of each aforementioned parameter on perovskite’s stability and device performance. Our functional microscopy platform, combined with ML, can be leveraged to assess Pb-free perovskites.

8:36AM R60.00002: John Wheatley Award Talk: Multifunctional Materials for Emerging Technologies [invited] FEDERICO ROSEI (Presenter), INRS-EMT — As the age of fossil fuels is coming to an end, now more than ever there is the need for more efficient and sustainable renewable energy technologies. This presentation will give an overview on recent developments in solar technologies that aim to address the energy challenge. In particular, nanostructured materials synthesized via the bottom–up approach present an opportunity for future generation low cost manufacturing of devices. We demonstrate various multifunctional materials, namely materials that exhibit more than one functionality, and structure/property relationships in such systems, including new strategies for the synthesis of multifunctional nanoscale materials to be used for applications in photovoltaics, solar hydrogen production, luminescent solar concentrators and other emerging optoelectronic technologies. [1-22].

9:12AM R60.00003: Nanomanufacturing: An enabler for environmental technologies [invited] JAMES LIDDLE (Presenter), National Institute of Standards and Technology — From clean water to clean energy, many environmental technologies rely upon nanoscale phenomena, and consequently on our ability to control and manipulate material structure, composition, and function at that scale. While we have achieved unprecedented control over matter using the tools of integrated circuit manufacturing, the volumes and price points required to meet the demands of environmental technologies mean that the semiconductor manufacturing toolset cannot be used. I will describe the economic landscape relevant to nanomanufacturing in the context of environmental technologies and a selection of those nanostructuring methods that may meet the boundary conditions of scale and cost.

8:00AM R61.00001: Chiral electrophoresis: a new steering wheel* [invited] THOMAS A WITTEN (Presenter), James Franck Institute, University of Chicago — Even rigid colloidal objects in conventional fluids in general respond chirally to external gradients such as electric fields. They twist around the gradient direction in a sense dictated by the object. Do real objects have enough chiral response to make a difference? Any chiral response requires either a chiral (non-inversion-symmetric) shape or a chiral charge distribution. But no shape can give chiral electrophoresis if it is uniformly charged. Nor can a sphere respond chirally even with the most chiral charge distribution. Here we demonstrate a new approach for calculating chiral responses of asymmetric objects. It represents the sheath of electrically-driven flow over the object as a superposition of stokeslet sources. Insights from this approach show how symmetric shapes can show strongly chiral response. We illustrate using a cube-shaped object. Chiral response is a handle by which a dispersion can be manipulated in powerful ways using time-varying electric fields.

8:36AM R61.00002: Orientation of spheroidal colloids near a charged surface* YOAV TSORI (Presenter), Ben-Gurion University of the Negev — We look at an uncharged spheroidal colloid in a water near a charged flat surface. We solve the nonlinear Poisson-Boltzmann equation outside of the colloid for various tilt angles θ with respect to the surface. The colloid's size is assumed to be comparable to the Debye's length and hence field gradients are essential. The Maxwell stress tensor, including a contribution from the ideal gas of ions, can be integrated along the colloid's surface to give the total force and torque on the colloid. The calculation is for a static colloid but if it were to move translation and rotations would be coupled via the tilt angle. From the torque we calculate the effective angular potential u(θ). The colloid tends to align in the direction perpendicular to the surface (parallel to the field, θ=0) if it is far enough from it. Surprisingly, we find that at short separations or large voltages the colloid will align parallel to the surface (θ=90 degs). Interestingly, colloid orientation parallel to the surface is promoted at a finite value of the eccentricity. Lastly, and this needs to be yet verified, the nonuniform forces on the surface of the colloid seem to amount to a net translational force along the surface although the system is invariant in this direction.

8:48AM R61.00003: The Electrohydrodynamic Magnus Effect: Coupling between Electrophoresis and Quincke Rotation Propels Colloids Orthogonal to a Driving Electric Field ZACHARY SHERMAN (Presenter), JAMES W SWAN, Massachusetts Institute of Technology — Colloids dispersed in electrolytes polarize the surrounding ion cloud when exposed to an electric field. For sufficiently strong fields, an instability occurs that causes spherical colloids to break symmetry and spontaneously rotate about an axis orthogonal to the applied field, a phenomenon named Quincke rotation. If the colloids also have a net charge, the electrophoretic motion couples to Quincke rotation and propels particles in a direction orthogonal to both the driving field and the axis of rotation, an electrohydrodynamic analogue to the Magnus effect. The orthogonal Magnus velocity is of a comparable magnitude to the electrophoretic velocity. Typically, motion orthogonal to the field requires anisotropy in particle shape, dielectric properties, or geometry of boundaries. Here, the electrohydrodynamic Magnus effect occurs for bulk, isotropic spherical particles, with the Quincke rotation instability providing broken symmetry driving orthogonal motion. The direction of the Magnus velocity is not changed by flipping the sign of the field, so net orthogonal motion persists in AC electric fields. This orthogonal motion acts as a type of “self-propulsion”, and colloids with an electrohydrodynamic Magnus velocity can be used to create a new type of active matter.
Recent work shows that colloidal dimers with asymmetric geometric or interfacial properties can propel due to the unbalanced electrohydrodynamic (EHD) flow around the particles, offering a new avenue to engineer active particles. In this work, we present experimental studies on the active motion behaviors of boomerang-shaped colloidal particles driven by the EHD flow. We show that by breaking the symmetry of particle shapes, the boomerang particles exhibit several different modes of active motions which can be either translation and/or rotation, and these modes of motions can be fine-tuned or switched by the frequency and initial phase of the electrical fields.

*Funding Acknowledgement: NSF CMMI-1663394 and CBET 1454095

We experimentally create different potential energy landscapes using extended laser light fields, ranging from periodic patterns (laser fringes) to random patterns (speckle patterns). The dynamics of colloidal particles in these potential energy landscapes are followed by video microscopy. Diffusive as well as sub- and super-diffusive behavior can be observed with the extent of the different regimes depending on the specific situation, such as the shape and modulation amplitude of the potential but also the composition of particle mixtures and the particle concentrations. We will review our findings from different experimental conditions and compare the experimentally observed behavior to simulation and theoretical results.

Light can be a powerful tool to mechanically manipulate matter, as evidenced by concepts such as optical tweezers and optical traps utilized across biology, colloidal science, microfluidics, and elsewhere. Advances in nanofabrication have enabled the ability to engineer the phase front of light as well as structure the shape of the target object for more advanced mechanical manipulation. We show how the combination of phase-space topology and particle asymmetry can provide a powerful degree of freedom in designing nanoparticles for optimal external manipulation. In particular, we find counterintuitive dynamics where optically asymmetric particles become stable nanoscale motors even in a light field with zero angular momentum. Here, the wavelength of the incident light can be used to externally control the number, orientation, and the stability of the equilibrium states. Finally, we discuss how structural complexity on the nano-scale can enable rich dynamics of optical manipulation of objects much larger than a wavelength in size.

This work was funded by a FY2015 postdoctoral standard fellowship from the Japanese Society for the Promotion of Science (JSPS).
While complex fluids are traditionally studied by imposing bulk forces on a macroscopic samples, here we explore the response of a colloidal dispersion to a local, microscopic driving; a microscale version of rheometry. In particular, we examine the response of a two dimensional layer of Brownian particles to a flow field induced by a circular motion of a probe particle driven by optical tweezers. We observe that particles migrate from high to low strain rate regions and form strong gradients in the density profiles. This non-homogeneity in the density profile is localized and the emerging length scale is set by the competition between the Brownian and shear forces. We further demonstrate that our measurements are quantitatively described, over a large range of strain rates and particle densities, by a phenomenological two phase fluid constitutive model previously discussed in the literature.

Increases up to 80% resulting in significant changes in the flow paths and diversion of the flow towards unexplored hydrogels swell up to 6 times. Hence, by injection of a small amount of the suspension, the resistance of the medium injection of the nano-hydrogels. After injection of the suspension of nano-hydrogels, the shells degrade and nano-phase is created by the leakage of CO2 through the permeable PDMS walls. Mathematical models for early stage particle sorting applications. The behavior of the systems is highly robust and controllable and thus allows it to be used to a wide range of particle focusing and the traveling pulse will be compared with the experimental observations.

10:36AM R61.00012: Spontaneous pulse generation in a steady channel flow of a colloidal suspension*  
SUIN SHIM (Presenter), HOWARD A STONE, Princeton University — We present experiments demonstrating the spontaneous generation and traveling of a colloidal pulse in a steady channel flow. When deionized (DI) water with suspended positively-charged particles flows steadily through a single channel, a pulse of particles is generated, which then flows through the channel at a slower speed than the mean flow velocity. With detailed experimental investigations and quantified results, we rationalize our observations by considering CO2 driven diffusiophoresis. The concentration gradient of ions in the liquid phase is created by the leakage of CO2 through the permeable PDMS walls. Mathematical models for early stage particle focusing and the traveling pulse will be compared with the experimental observations.

Session R62 DQI: Noisy Intermediate-Scale Quantum Computers  
BCEC 258C - David McKay, IBM T J Watson Res Ctr - Tag(s): Invited

8:00AM R62.00001: Quantum Computing in the NISQ era and beyond  
JOHN PRESKILL (Presenter), Caltech — Noisy Intermediate-Scale Quantum (NISQ) technology will be available in the near future. Quantum computers with 50-100 qubits may be able to perform tasks which surpass the capabilities of today's classical digital computers, but noise in quantum gates will limit the size of quantum circuits that can be executed reliably. NISQ devices will be useful tools for exploring many-body quantum physics, and may have other useful applications, but the 100-qubit quantum computer will not change the world right away --- we should regard it as a significant step toward the more powerful quantum technologies of the future. Quantum technologists should continue to strive for more accurate quantum gates and, eventually, fully fault-tolerant quantum computing.

8:36AM R62.00002: Advances in quantum simulation on the path towards post-supremacy, pre-fault-tolerant applications  
JARROD MCCLEAN (Presenter), Al Quantum, Google LLC — Quantum simulation looks to be one of those most promising applications for near-term quantum computers. However, even in an optimistic mindset, it is clear that utilizing a post-supremacy device for near-term applications will present a number of challenges. To date, the maximum number of utilized qubits for such applications is significantly smaller than a post-supremacy device, and direct application of previous methods with no modifications could simply prohibit more qubits from giving a better or more interesting answer. In this talk I will discuss some of these challenges and recent advances in both the algorithms for simulating these problems with lower overheads and mitigating some of these difficulties directly.
9:12AM R62.00003: Simple tricks to squeeze more out of your noisy quantum device* [Invited] KRISTAN TEMME (Presenter), IBM Research — Near-term applications of early quantum devices rely on accurate estimates of expectation values to become relevant. Decoherence and gate errors lead to wrong estimates. This problem was, at least in theory, remedied with the advent of quantum error correction. However, the overhead that is needed to implement a fully fault-tolerant gate set with current codes and current devices seems prohibitively large. In turn, steady progress is made in improving the quality of the quantum hardware and we believe that we can build machines in the near term that cannot be emulated by a conventional computer. We discuss simple techniques that increase the quality of short-depth quantum simulations. In light of these advances, it becomes interesting to ask what these noisy devices can be used for. In this talk we will present our advances in the search for quantum algorithms for noisy quantum computers that may be relevant to problems in quantum simulation and quantum machine learning.

9:48AM R62.00004: Photonic quantum networks* [Invited] IAN A WALMSLEY (Presenter), Physics, Imperial College London — Hybrid light-matter networks offer the promise for delivering robust quantum information processing technologies, from sensor arrays to quantum simulators. Recent developments in new quantum light sources, reconfigurable and modular circuit design and fabrication, novel waveguide-based detectors and low-noise photonic memories have all contributed in progress towards a resilient, scalable photonic quantum network. Purely photonic quantum simulators have been demonstrated, and better understanding of the role of imperfections in degrading the performance of such devices has been made, although concrete limits are known in only a few cases. Meanwhile progress in hybrid networks indicates that scalable performance should be possible, albeit only when a number of engineering challenges have been met.

*This work was funded by the UK Engineering and Physical Sciences Research Council (project EP/K034480/1 and the Networked Quantum Information Technology Hub), the Fondation Wiener Anspach, the John Templeton Foundation (Grant 60469), and the European Commission (H2020-FETPROACT-2014 grant QUCHIP; ERC Advanced Grant MOQUACINO).

10:24AM R62.00005: Scaling Ion-trap Quantum Computing [Invited] THOMAS MONZ (Presenter), Experimental Physics, University of Innsbruck — Scalability is tied to the notion of being able to take individual components, combine an increasing number of these components, and be able to predict the performance of the larger system from its constituents. Verifying scalability is thus tied to routines that allow us to both investigate the performance of building blocks as well as larger systems. In this presentation I will present recent work on investigating the performance of the Innsbruck-based ion-trap quantum computer as the quantum register size increases, provide an ongoing project to extend quantum error correction capabilities including loss and outline changes to the apparatus to push towards a 20-qubit quantum processor with parallel processing capabilities.

Thursday, March 7, 2019 8:00 AM - 11:00 AM

Session R63 DBIO DPOLY: Physics of Proteins and Nucleic Acids I: Structures, Dynamics, Interactions, and Energetics BCEC 259A - Huan-Xiang Zhou, Florida State University - Tag(s): Focus
GAVIN KING (Presenter), Physics and Astro., Joint w/ Biochemistry, University of Missouri-Columbia — How are proteins transported across membranes? The general secretory (Sec) system of *E. coli* exports precursor proteins via a translocase comprising the peripheral ATPase SecA and the translocon, SecYEG. Structural changes of active translocases underlie the translocation process. Yet, the mechanistic details of this complex and dynamic system have proven challenging to study. The atomic force microscope (AFM) is well suited for imaging membrane proteins in near-native conditions and can achieve molecular-scale (~10 Å) lateral resolution coupled with ~1 Å vertical resolution (i.e., normal to the bilayer surface). We imaged individual components of the Sec system as well as active translocases at work in lipid bilayers. In this talk I will review our single molecule results in the context of conventional models in the field, which are based on bulk assays. In addition to imaging, AFM can be used in force spectroscopy mode, providing access to energy landscapes. Our group has applied precision AFM-based force spectroscopy techniques to study a peptide-lipid interaction underlying Sec system activity. Together with analytical modeling and simulations, the results represent a step towards a more detailed understanding of the protein export process in *E. coli*, and more generally, of the stochastic kinetic pathways driving peptide-lipid interactions.

SOLANGE FLATT, Institute of Physics, École Polytechnique Fédérale de Lausanne, LE YAN, Kavli Institute of Theoretical Physics, CAROLINA BRITO, Instituto de Física, Universidade Federal do Rio Grande do Sul, MATTHIEU WYART, Institute of Physics, École Polytechnique Fédérale de Lausanne — Allostery is responsible for the activity regulation of many proteins essential for life. We will discuss a minimal model examining the effect of global motions and long-range interactions on protein functions that involve molecular information processing.

RICCARDO RAVASIO (Presenter), SOLANGE FLATT, Institute of Physics, École Polytechnique Fédérale de Lausanne, LE YAN, Kavli Institute of Theoretical Physics., University of California Santa Barbara, STEFANO ZAMUNER, Institute of Physics, École Polytechnique Fédérale de Lausanne, CAROLINA BRITO, Instituto de Física, Universidade Federal do Rio Grande do Sul, MATTHIEU WYART, Institute of Physics, École Polytechnique Fédérale de Lausanne — Allostery is responsible for the activity regulation of many proteins essential for life. Many efforts on understanding this long-range communication have been made, but the physical picture of allosteric mechanics is not yet clear. Recent progress employing in-silico evolutions studied mechanical networks of harmonic springs with allosteric behaviors. These networks are found to share common principles for the long-range communication to occur. Specifically, the stiffness of the allosteric response scales with the system size with a nontrivial power law. In this work, we test these principles in real systems, using a large set of X-ray structural data of allosteric proteins. Overall, we find that the functional allosteric response of each protein is related to a “mechanism”, a soft and extended mode with strong strain. By extending the theory of allosteric materials to include nonlinearities, we identify two scalings of stiffness setting a regime where the allosteric cooperative binding is optimal. A new scaling exponent appears, in addition to the one from the linear theory. The stiffness from the X-ray structural data falls in this predicted range, suggesting that proteins actually work at optimal cooperativity.
9:12AM R63.00005: Finding the Optimal Folding Routes of self-entangled Proteins via Coarse-Grained Molecular Dynamics*  
CLAUDIO PEREGO (Presenter), Polymer Theory Department, Max Planck Institute for Polymer Research, Mainz (Germany), RAFFAELLO POTESTIO, Physics Department, University of Trento, Trento (Italy) — Among the known protein motifs, several structures exhibit a self-entangled backbone topology. Understanding how polypeptides can efficiently and reproducibly attain such topologies is a crucial biophysical challenge, which might shed new light on our general understanding of protein folding.

In this work we present a molecular dynamics methodology for the study of the possible folding pathways travelled by self-entangled proteins. The method is based on a Coarse-Grained, minimalistic representation of the polypeptide chain, driven by a structure-based angular potential. The heterogeneity of the potentials acting among residues is optimized by means of an evolutionary strategy, aimed at maximizing the folding probability of the model.

The purpose of our approach is two-fold. On the one hand we aim at constructing a simple protein model, capable of attaining the entangled structure in a reproducible and efficient way. On the other hand we mimic an evolutionary mechanism that might have selected a specific folding pathway among the possible routes.

Applying the method to relevant test cases we retrieve indications on the optimal folding pathways of self-entangled proteins, and useful guidelines for simulations via more detailed molecular models.

*EU MSC No 796969

9:24AM R63.00006: Molecular mechanisms for protein-denaturation in urea and guanidinium chloride mixtures*  
PRITAM GANGULY (Presenter), JOAN-EMMA SHEA, University of California, Santa Barbara — Using replica-exchange molecular dynamics simulations, we have studied the thermodynamic stability and the conformational changes of two synthetic mini-proteins, Trp-cage and Trp-zip1, in pure and mixed denaturant solutions of guanidinium chloride (GdmCl) and urea. We have found that urea, which denatures proteins through favorable preferential interactions with protein sidechains and backbone, is more effective in destabilizing and elongating alpha-helical secondary structures of proteins than beta-hairpin structures. Contrarily, GdmCl, which denatures proteins by inhibiting salt-bridge formations between charged amino acids, is more effective in destabilizing beta-hairpin structures than alpha-helical structures. The extent of GdmCl-induced protein-denaturation is not determined by protein-GdmCl preferential interactions. In mixed denaturant conditions, our results indicate that GdmCl may however enhance the overall denaturing effects of urea by promoting protein-urea preferential interactions when full-length proteins are considered, but it may also potentially lead to local compaction of smaller segments of proteins, partially counteracting urea-induced extension of the protein segments.

9:36AM R63.00007: Large-scale, automated prediction of protein-ligand binding structures  
ZHIWEI MA (Presenter), XIANJIN XU, RUI DUAN, XIAOQIN ZOU, University of Missouri — Molecular docking is a useful and important approach for the prediction of protein-ligand structures and for structure-based drug design. The growing number of protein-ligand complex structures, particularly the structures of proteins co-bound with different ligands, in the Protein Data Bank helps us tackle two major challenges in molecular docking studies: the protein flexibility and the energy scoring function. Here, we introduced a systematic strategy by using the information embedded in the known protein-ligand complex structures to improve binding mode predictions. We also developed and integrated several methods for large-scale binding mode prediction, and systematically tested these methods on the weekly Continuous Evaluation of Ligand Pose Prediction (CELPP) competition, an automated workflow to process and evaluate the challenge of ligand pose prediction. Up to October 26, 2018, the quantitative analysis of our docking results for over 3000 targets released by CELPP revealed that our methods improve the success rates of ligand pose prediction.

Inferring protein dynamics through experiment and simulation: collective modes from atomic trajectories  LAUREN MCGOUGH (Presenter), RAMA RANGANATHAN, Center for Physics of Evolving Systems and Department of Biochemistry and Molecular Biology, University of Chicago — Proteins are evolved molecular machines that carry out the essential chemical reactions necessary for life. Like machines designed by humans, proteins execute their functions through an orderly set of motions and fluctuations - their “reaction coordinate”. However, proteins are also marginally stable, with the expectation that functional dynamics are embedded in small subspace of a high dimensional pattern of overall motions. Here, we aim to discover the embedded functional dynamics using experiment and simulation.

One approach to studying intramolecular fluctuations is computational simulation of atomic trajectories. Recent advances in experimental protein dynamics open up the ability to test, validate, and possibly improve the process of molecular simulation through direct comparisons between prediction and data. We describe two such comparative analyses using data from X-ray diffraction studies reporting electric field-stimulated excited state motions and evolutionarily conserved room-temperature conformational fluctuations. The goal is then to use both simulation and experiment to infer the effective variables describing functional, collective motions in proteins. This work initiates a path towards understanding the physics of protein function and evolution.

Temperature dependent studies of proteins and their hydration shell properties using megahertz-to-terahertz dielectric spectroscopy*  ALI CHARKHESHT (Presenter), DJAMILA LOU, BEN SINDLE, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — The low-frequency collective vibrational modes in proteins and the protein–water interface playing an important role in biochemical reactions and biological energy transport strongly depend on the temperature and conditions of the environment. However, capturing a precise picture of collective vibrational dynamics under temperature variations is challenging due to the strong absorption of water. For this reason, we have employed a highly sensitive dielectric megahertz-to-terahertz frequency-domain system to probe the vibrational dynamics of proteins in aqueous solutions from 50 MHz to 2 THz. With this approach, we have performed an exclusive temperature dependent study on myoglobin and lysozyme in water by means of complex dielectric analysis. We have focused on protein collective vibrational processes and atypical surrounding water molecules to outline comprehensive images of aqueous solutions. The results help us to clarify protein dynamics and protein-water interfaces in temperature dependent environment that determine biochemical functions and reactivity of proteins.

Protein Structural Fluctuations at Criticality in the Temperature-pressure-crowding Folding Phase Diagram*  ANDREI G GASIC (Presenter), CALEB M DAUGHERTY, MARGARET CHEUNG, Department of Physics, University of Houston; Center for Theoretical Biological Physics, Rice University — In the cell, proteins perform complex biological functions through large-scale motion, which are induced by slight environmental perturbations. This characteristic of having high susceptibility is similar to a physical system near a critical point. Indeed, recent experimental and computational findings demonstrate that protein folding transitions in the temperature (T), pressure (P), and crowding volume-fraction (φc) phase diagram point toward signatures of criticality, where distinct folding phases merge. Here, using coarse-grained molecular dynamics simulations, we theoretically show that at the critical regime, fluctuations exhibit high susceptibility and long-range correlations up to the size of the protein. Meaning that near criticality, the dynamics of each residue is influenced by each other residue even across the entire protein. We investigate the structural origin and the effect of macromolecular crowding on this critical behavior. Furthermore, this study leads us one step closer to developing universal principles of protein folding and function in vivo.

Neighbourhood preference based energy function and its applications in structure prediction and protein evolution*  SIYUAN LIU, XILUN XIANG, school of software engineering, university of science and technology of China, HAIGUANG LIU (Presenter), complex systems division, beijing computational science research center — Based on the statistics from known structures in the protein data bank, a statistical energy function is derived to reflect the amino acid neighbourhood preferences. The neighbourhood of one amino acid is defined by its contacting residues, and the energy function is determined by the neighboring residue types and relative positions. A scoring function, Nepre, has been implemented and its performance was tested with several decoy sets. The results show that the Nepre program can be applied in model ranking to improve the success rate in structure predictions. We also applied this empirical energy function in the understanding of protein evolution and the designability of protein structures.

10:36AM R63.00012: Protein Structure Prediction with MELD x MD* JAMES ROBERTSON (Presenter), Stony Brook University, ALBERTO PEREZ, Stony Brook University (currently University of Florida), KEN DILL, Stony Brook University — Predicting protein structures from their amino acid sequences is a major challenge, especially with atomistic molecular dynamics (MD) simulations. The two major limitations to MD are poor sampling due to high computational cost and inaccurate force fields. Bioinformatics-based methods are an alternative approach to structure prediction that rely on databases of structures or structural fragments, as in threading. Threading has been very successful in predicting protein structures, but about 15% of proteins are not amenable to threading, the so-called nonthreadables. The nonthreadables provide a test set for MELD x MD, which does not rely on bioinformatics databases. We show that MELD x MD accurately predicts 20/41 nonthreadables and give high Boltzmann populations for successful predictions. We also discuss MELD x MD structure prediction on a larger set of proteins, particularly how the method is limited by sampling and force fields, but also how MELD x MD can overcome these limitations.

10:48AM R63.00013: Dynamic Allosteric Residue Coupling (darc) Spots Shed Light on Functional Changes from Sequence Variation PAUL CAMPITELLI (Presenter), Center for Biological Physics, Arizona State University, LISKIN SWINT-KRUSE, Department of Biochemistry and Molecular Biology, The University of Kansas Medical Center, BANU OZKAN, Center for Biological Physics, Arizona State University — Defining the functional impact of protein sequence variation presents a major challenge in biology and genomics and the importance has grown dramatically as unprecedented advances in sequencing complete exomes have yielded tens of thousands of non-synonymous single nucleotide variants (nSNVs) on the human proteome. Currently there are no consistent methods to capture the mechanisms of functional changes as a result of sequence variations, particularly at non-conserved positions and in the absence of large structural changes. We present the dynamic flexibility index (dfi), a measure of residue-specific flexibility and the dynamic coupling index (dci), a technique determining coupling strength between amino acids. We apply our approach to the lactose repressor protein LacI, where substitutions at non-conserved position V52 produce progressive effects on function. dfi captures changes in flexibility in the DNA binding domain and is correlated with binding affinity. We also use dci to identify important dynamic allosteric residue coupling (darc) spots, distally located to the DNA binding domain. darc spot dfi correlates strongly with changes in repression rate as well as DNA binding affinity and shows conformational dynamics at distal sites plays an important role in LacI function.

Session R64 DBIO: Physics of Intracellular Transport BCEC 259B - Jing Xu, Univ of California - Merced - Tag(s): Focus

8:00AM R64.00001: The complexity of microtubule-based motility* [invited] MICHAEL VERSHININ (Presenter), University of Utah, JUN ALLARD, STEVEN GROSS, UC Irvine, JAMES KEENER, JARED BERGMAN, University of Utah, MATTHEW BOVYN, UC Irvine, OLAOLU OSUNBAYO, West Physics, CHRIS MILES, New York University, BABU J.N. REDDY, UC Irvine, MANASA GUDHETI, Bruker, FLORENCE DOVAL, ABHIMANYU SHARMA, University of Utah — The tug of war between multiple molecular motors driving the same cargo can take many forms and result in many observable motility phenotypes. I will discuss some of the relevant cases, from movement across microtubule intersections to a minimal tug of war system on a single microtubule. I will show that the overall range of behaviors is remarkably large and in particular that cargos can remain in a tug of war state for extremely long times and that this has significant implications for both cargo routing in cells and for our ability to tell tug of war processes from other pathways to immotility such as diffusion. Finally, I will discuss viable approaches for identifying tug of war in biological systems.

*NSF ENG/CMMI #1563280
suggest the use of crowding as a control parameter to study kinesin's mechanochemical cycle. The importance of motor-motor interactions in cargo transport, explain the long observed variability of cargo velocity, and results from the individuals' increased sensitivity to hindering load in a crowded medium. Our results highlight the teams of motors, while having no effect on single motor velocity. We find that this emergent property of kinesin teams results from the individuals' increased sensitivity to hindering load in a crowded medium. Our results highlight the importance of motor-motor interactions in cargo transport, explain the long observed variability of cargo velocity, and suggest the use of crowding as a control parameter to study kinesin's mechanochemical cycle.

9:12AM R64.00003: Intracellular transport is accelerated in early apoptotic cells*  HUI LI (Presenter), CAS Key Lab of Soft Matter Physics, Institute of Physics, Chinese Academy of Sciences — Apoptosis is a process of programmed cell death with dramatic changes in cell morphology and organization, during which signaling molecules are transported within the cells between different organelles. However, how the intracellular transport changes in cells undergoing apoptosis remains unknown. Here, we study the dynamics of intracellular transport by using single-particle tracking method, and find that both the directed motion and diffusive motion of endocytic vesicles are accelerated in early apoptotic cells. With careful elimination of the other factors involving in the intracellular transport, the reason for the acceleration is attributed to be the elevation of ATP concentration. More importantly, we show that the accelerated intracellular transport is critical for apoptosis. Apoptosis is delayed when the dynamics of intracellular transport is regulated back to the normal level. Our results demonstrate the important role of transport dynamics in apoptosis and shed light on the apoptosis mechanism from a physical perspective.

9:24AM R64.00004: Doppler Spectroscopy of Intracellular Motion in Revived Flash-Frozen Cancer Tissues  ZHEN HUA (Presenter), ZHE LI, JOHN TUREK, MICHEAL CHILDRESS, DAVID NOLTE, Purdue University — Biodynamic imaging is a high-content optical imaging technology based on Doppler spectroscopy and digital holography that uses dynamic speckle as high-content image contrast to probe living tissue. The multimode mixing of Doppler signals produces a fluctuation spectrum that is a function of the acquisition time relative to the persistence time of intracellular transport and hence provides a measure of cellular activity. Creating Doppler spectrograms of tumor tissues responding to anticancer agents usually relies on patient enrollment in IRB-approved trials, which is slow and inefficient. However, if flash-frozen biopsies could be revived and measured, then a large reservoir of tissue-banked samples could become available for phenotypic library building. We have performed biodynamic imaging measurements of flash-frozen canine B-cell cancer tissue and compared the drug-response spectrograms to results from fresh tissues from the same dogs. By compensating for tissue trauma in the frozen sample, we demonstrate a high accuracy for patient clustering between the fresh and frozen samples when correlating with clinical outcomes, identifying resistance or sensitivity to their prescribed chemotherapy.

9:36AM R64.00005: A model of diffusion through a potential captures the effect of competition on the efficiency and speed of nucleocytoplasmic transport  TIANTIAN ZHENG (Presenter), ANTON ZILMAN, University of Toronto — The nuclear pore complex (NPC) facilitates the selective transport of materials between the nucleus and cytoplasm in eukaryotic cells. Typically, many cargo are simultaneously present within the NPC during transport, and it is not fully understood how the NPC can function efficiently despite the crowding in the channel. In this study, we simulate transport through an NPC-like channel with coarse-grained cargoes and NPC-associated intrinsically disordered proteins (FG nucleoporins). From the results of this simulation, we show that cargo densities and trajectories along the direction of transport can be captured by a model of 1-dimensional diffusion through a potential, which is an effective potential arising through the interactions between cargoes and NPC components, and is modified by the non-equilibrium density profiles of cargoes inside the channel. With this framework, we are able to account qualitatively for previously unexplained experimental data which show that an increased number of cargo results in both increased efficiency and speed of transport. Our model therefore provides an explanation for why crowding does not necessarily affect the functioning of the NPC in a negative way, which can explain how the NPC can achieve both high specificity and high throughput.
9:48AM R64.00006: A Semi-Analytical Model to Investigate Cargo Transport by Bi-Directional Molecular Motor Ensemble*  
RACHIT SHRIVASTAVA (Presenter), SHREYAS BHABAN, JAMES MELBOURNE, SIVARAMAN RAJAGANAPATHY, MURTI SALAPAKA, Department of Electrical and Computer Engineering, University of Minnesota, Twin Cities — Deciphering mechanism of transportation of organelles by molecular motors is crucial to understand the genesis of neurodegenerative diseases. We model the ensemble behavior of motors using a semi-analytical approach. This approach uses an individual motor's model to predict their ensemble behavior. The process of cargo transportation is modeled as Markov process with molecular motor arrangements being as its state which satisfies Markov property. Exact probabilities distribution functions of the relative configurations of motor is determined in order decipher the cargo transportation process. When only unidirectional motors are carrying a cargo, this approach has revealed insights such as relative configurations approaching a unique steady state distribution, enforcing the robustness of the motor-cargo assembly. Also it has been observed that as the load on the cargo increases, motors tend to cluster together. We attempt to extend this analysis to ensembles with bidirectional motors such as both kinesin and dynein. This will aid to suggest new hypothesis about motor behavior and drive the design and realization of new experiments. Finally, we attempt to determine the factors responsible for deciding the “tug-of-war” vs coordinated movement.

10:00AM R64.00007: Two-Species Active Transport along Cylindrical Biofilaments is Limited by Emergent Topological Hindrance  
PATRICK WILKE (Presenter), EMANUEL REITHMANN, ERWIN FREY, Physics, Ludwig Maximilian University of Munich — Motivated by recent experimental studies that have addressed the stepping behavior of kinesins, we investigate a lattice gas model for simultaneous transport of two species of active particles on a cylinder. The species are distinguished by their different gaits: While the first species moves straight ahead, the second follows a helical path. We show that the collective properties of such systems critically differ from those of one-species transport. This is most evident in a jamming transition far below full occupation, as well as in nonequilibrium pattern formation. The altered behavior arises because—unlike the case in single-species transport—any given position may be targeted by two particles from different directions at the same time. However, a particle can leave a given position only in one direction. This simple change in connectivity significantly amplifies the impact of steric interactions and thus becomes a key determinant of mixed species transport. We computationally characterize this type of hindrance and develop a comprehensive theory for collective two-species transport along a cylinder. Our observations show high robustness against model extensions that account for additional biomolecular features which suggests relevance also in a biological context.

10:12AM R64.00008: Simulation of membrane-bound cargo transport by teams of kinesin motors*  
NIRANJAN SARPANGALA (Presenter), AJAY GOPINATHAN, Physics, University of California, Merced — In eukaryotic cells, membrane-bound cargoes are transported by teams of molecular motors. Motors on such cargoes diffuse on the lipid membrane. How the fluidity of the membrane affects transport characteristics is still not well understood. Here we develop a stochastic dynamical simulation of kinesin-based cargo transport along microtubules that explicitly considers the Langevin dynamics of motors on the surface of cargo. We study how the number of bound motors, run length, the velocity of cargo and binding rates are influenced by parameters like the diffusion coefficient of motors on cargo surface, ATP concentration, and the cargo size. We show that the distribution of free motors on microtubule-bound cargo surface depends on these parameters and affects the rebinding of cargo to microtubule after its detachment, thus affecting overall transport. Our work suggests that the consideration of motor diffusivity should be important in the cellular context.

*We acknowledge support from National Science Foundation NSF grant DMS-1616926, NSF-CREST:Center for Cellular and Bio-molecular Machines at UC Merced (NSF-HRD-1547848) and computing time on the Multi-Environment Computer for Exploration and Discovery (MERCED) cluster at UC Merced, (National Science Foundation Grant No. ACI-1429783).
subjected to a simple exclusion process. We consider the analytical solution of velocity (V) of a collection of N processive and non-processive motors stepping along one and multiple microtubule filaments in stochastic simulations using Monte Carlo methods. The motor dynamics follow biased random walks along and switching between multiple filaments. In this case, the applied load is shared between the leading motors on each filament. We also show the simulation results of F-V relations of non-processive motors stepping along and switching between multiple filaments. In this case, the applied load is shared between the leading motors on each filament.

**Session R65 DBIO: Biomaterials: Structure, Function, Design IV**

**8:00AM R65.00001: Biomimetic Mineralization via Polymer-Induced Liquid Precursors** [Invited] LAURIE GOWER (Presenter), Materials Science & Engineering, University of Florida — The hallmark of biomineralization is the ability of organisms to form non-equilibrium crystal morphologies. Our group has been using in vitro model systems to examine the physicochemical mechanisms that might be involved in biomineralization, with emphasis on the role that biopolymers play. We have discovered that many of the long-standing enigmatic biomineral features can be reproduced in the beaker using a non-classical crystallization process we call the Polymer-Induced Liquid-Precursor (PILP) process. This process entails adding charged polymers to supersaturated salt solutions which then sequester ions/clusters/phases to induce phase separation of a hydrated amorphous mineral precursor. Interaction of these PILP colloids with various organic templates and matrices leads to a variety of non-equilibrium morphologies and composite textures, many of which emulate those seen in biominerals. We argue that a PILP type process may lie at the foundation of biomineralizing systems ranging from invertebrate exoskeletons to vertebrate bones and teeth. This argument is based on the diversity of features that can be emulated, and their distinct mineralogical signatures of formation mechanism, such as incorporation of high magnesium into calcite, transition bars and shrinkage patterns, and remnant colloidal textures within single-crystalline composites. Through this enhanced understanding of biomineralization processes, we are now developing biomimetic processing methods that enable the fabrication of hard-tissue biomaterials which emulate bone.

**8:36AM R65.00002: Cell contraction induces long-ranged stress stiffening in the extracellular matrix** YULONG HAN (Presenter), Massachusetts Institute of Technology, PIERRE RONCERAY, Princeton Center for Theoretical Science, Princeton University, CHASE P. BROEDERSZ, Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-Universität München, MING GUO, Massachusetts Institute of Technology — Animal cells in tissues are supported by biopolymer matrices, which typically exhibit highly nonlinear mechanical properties. While the linear elasticity of the matrix can significantly impact cell mechanics and functionality, it remains largely unknown how cells, in turn, affect the nonlinear mechanics of their surrounding matrix. Here, we show that living contractile cells are able to generate a massive stiffness gradient in three distinct 3D extracellular matrix model systems: collagen, fibrin, and Matrigel. We decipher this remarkable behavior by introducing nonlinear stress inference microscopy (NSIM), a technique to infer stress fields in a 3D matrix from nonlinear microrheology measurements with optical tweezers. Using NSIM and simulations, we reveal large long-ranged cell-generated stresses capable of buckling filaments in the matrix. These stresses give rise to the large spatial extent of the observed cell-induced matrix stiffness gradient, which can provide a mechanism for mechanical communication between cells.

Contaminated Water*  9:12AM R65.00005: Modeling and Design of Adsorption Based Filters and the Bio-remediation of Heavy Metal Contaminated Water*   CHRIS MCCARTHY (Presenter), Mathematics, BMCC City University of New York — I will discuss kinetic models of adsorption, as well as our mathematical models of such filters. These mathematical models have been developed in support of our interdisciplinary lab group and can be used in filter design. Our group conducts research into bio-remediation of heavy metal contaminated water via filtration. The filters are constructed out of biomass, such as spent tea leaves. The spent tea leaves are available in large quantities as a result of the industrial production of tea beverages. The heavy metals bond with the surfaces of the tea leaves (adsorption). I will compare the models’ predictions to data obtained from computer simulations and experimentally by our lab group.

Mucus and mucin biopolymer environments reduce the efficacy of polymyxin and fluoroquinolone antibiotics*  9:24AM R65.00006: Mucus and mucin biopolymer environments reduce the efficacy of polymyxin and fluoroquinolone antibiotics*   TAHOURA SAMAD (Presenter), JULIA Y CO, JACOB WITTEN, KATHARINA RIBBECK, Massachusetts Institute of Technology — Mucus, a biopolymer hydrogel that covers all wet epithelia, is one of the primary arenas for microbes in the body, including the microbiome and pathogenic microbes that can cause serious infections. Mucus has the potential to bind small molecules and influence bacterial physiology, two factors that might affect the efficacy of antibiotics. Despite this, the impact of mucus on antibiotic efficacy has not been thoroughly characterized. We investigated the efficacy of polymyxin and fluoroquinolone antibiotics against the opportunistic pathogen Pseudomonas aeruginosa in native mucus and purified mucin biopolymer environments. We found that mucus reduces the efficacy of polymyxin and fluoroquinolone antibiotics against P. aeruginosa. MUC5AC, MUC2, and MUC5B mucin biopolymers, the gel-forming components of mucus, are primary contributors to this reduced efficacy. Our findings highlight that inclusion of the biomaterial environmental context is an important consideration when evaluating antimicrobial efficacy in vitro.

*This work was supported by the National Institutes of Health (R01-EB017755) and the National Science Foundation (PHY-1454673, DMR-14-19807), National Science Foundation Graduate Research Fellowship (1122374), the Siebel Scholarship and the MIT Collamore-Rogers Fellowship.
9:36AM R65.00007: Morphological change of the phospholipid vesicle induced by actin polymerization of the artificial photosynthetic protocellular system. KEEL YONG LEE, John A. Paulson School of Engineering and Applied Sciences, Harvard University, SUNGJIN PARK, Emory University, A SETIAWATI, SUNGWOO JUNG, HUONG NGUYEN, Chemistry, Sogang University, KEVIN PARKER, John A. Paulson School of Engineering and Applied Sciences, Harvard University, KWAN HWAN JUNG, Sogang University, Kwan Shin (Presenter), Chemistry, Sogang University — We designed, built, and tested a light-harvesting encapsulated artificial organelle system that provides both a sustainable energy source and a means of controlling intracellular reactions. With the reconstitution into lipid vesicles, an ATP synthase and two photoconverters (plant-derived photosystem II [PSII] and bacteria-derived proteorhodopsin [PR]) enabled orchestration of ATP synthesis. Independent activation of the two photoconverters, which respond to different light wavelengths, allowed dynamic regulation of ATP synthesis. The resulting system was able to simulate a ubiquitous process in cells—cytoskeleton formation through ATP-dependent actin polymerization in a giant vesicle. Optical stimulation initiated ATP synthesis and induced ATP-dependent actin polymerization, leading to growth of three-dimensional actin filaments. Cytoskeleton formation and manipulation successfully induced morphological change of the outer membrane of the protocellular system by tuning the attraction–repulsion interactions between actin filaments and phospholipids.

9:48AM R65.00008: Dual-gel Dual-porosity 3D ECM Mimics for Studying flow-induced mechanotransduction* ALIMOHAMMAD ANBARI (Presenter), City College of New York, HUNG-TA CHIEN, Texas A&M, CHUN-WEI CHI, SIHONG WANG, JING FAN, City College of New York — Interstitial flow in the Extracellular Matrix (ECM) has been postulated to play a key role in regulating behaviors of cells. Among the cellular behaviors, cell migration is hypothesized to be influenced by interstitial flow via two mechanisms: autologous chemotaxis and integrin-mediated focal adhesion activation. It is commonly accepted that the effectiveness of the former depends on interstitial fluid velocity and the effectiveness of the latter depends on the flow-induced force on a cell, which relates to both interstitial fluid velocity and matrix permeability. The two mechanisms have never been rigorously verified using the traditional single hydrogel-based models due to the inevitable correlation between matrix permeability and stiffness. In this work, we developed a dual-gel dual-porosity 3D ECM mimics to address this challenge. With the new model, one can individually control the interstitial flow and matrix permeability without affecting the primary matrix stiffness. We also conduct preliminary studies on the efficiency of our model in studying the effect of interstitial flow on cancer cell migration.

10:00AM R65.00009: Targeted photothermal lysing of E. Coli via a geometrically-modified Au-binding M13 virus ZAIRA ALIBAY (Presenter), TAM-TRIET NGO-DUC, Materials Science and Engineering Program, University of California, Riverside, JOSHUA M PLANK, Department of Electrical and Computer Engineering, University of California, Riverside, JOSEPH CHEENEY, Materials Science and Engineering Program, University of California, Riverside, ELAINE D. HABERER, Department of Electrical and Computer Engineering, University of California, Riverside — Increasing antibiotic resistance (ABR) in bacteria is a continuing public threat to human health. Antibody functionalized nanoparticles (NPs) in conjunction with photothermal lysis have been successful in targeting and eradicating these pathogens. Yet, synthesis of antibodies is an expensive and time-consuming process. Alternative approaches capable of selectively delivering photothermally-active NPs to ABR bacteria are essential. In our work, a geometrically-modified, Au-binding M13 bacteriophage offers a novel solution to this challenge. Rod-shaped and spherically-shaped viral templates were created via chloroform interaction with the filamentous bacteriophage. Decorated with Au NPs, both of these scaffolds were capable of targeting E.Coli bacteria via attachment of exposed minor coat protein to the pathogen. Bactericidal studies of rods and spheroids were executed under a range of 532 nm laser irradiation conditions: power (0 - 60 mW) and time (0 - 20 min). Using geometrically-modified M13 scaffolds up to 65% of E.Coli were killed within 20 min. Through genetic modification of the minor coat protein the bactericide effects of these templates could be extended to target other pathogens. These findings advance efforts to engineer versatile and low-cost strategies to tackle ABR.
10:12AM R65.00010: Gold Binding by Design: A Combined Theoretical/Experimental Study of Biohybrid Systems
MARGARET HURLEY (Presenter), MEAGAN C. SMALL, US Army Research Laboratory - APG, MD, DEBORAH A. SARKES, HONG DONG, JUSTIN P. JAHNKE, DIMITRA N. STRATIS-CULLUM, US Army Research Laboratory - ALC, MD — Biomolecular-inorganic hybrid materials have many potential applications in medicine, electronics, and nanotechnology. It is therefore of great interest to design peptides that have predictable and controllable binding to inorganic surfaces, requiring a detailed understanding of biotic/abiotic interactions. Computational models have provided key insight into the underlying intermolecular interactions in such systems. However, owing to limited computational resources, these studies are often performed using periodic models where care must be taken to understand the effects of model size and periodicity, as well as any possible additional limitations in the method. Here we perform DFT calculations exploring the binding interactions between amino acid residues and the Au(111) surface. Results are presented in the context of experimental results from bacterial display studies of engineered E. coli binding to gold surfaces with applications including development of viable E. coli/AuNP hybrid systems and microbial fuel cells.

10:24AM R65.00011: A Comparative Study on Interspecies Blood Rheology*
JEFFREY HORNER (Presenter), ANTONY N BERIS, NORMAN J. WAGNER, DONNA WOULFE, University of Delaware — Blood is a complex suspension of red blood cells (RBCs), white blood cells, and platelets in an aqueous plasma phase with several dissolved proteins. Despite a consistent makeup, with minor changes in constituent sizes and volume fractions, blood from different species exhibits significantly different rheological signatures. Blood from some species including horse, pig, and human exhibit a yield stress at low shear rates, while blood from other species including cow, sheep, and guinea pig exhibit no yield stress. This is attributed to the presence or absence of microstructural RBC aggregates at low shear rates. Moreover, blood samples across all species may exhibit unique transient behavior which enables insight into how blood evolved to the specific organism. In this work, we present new steady and transient rheological data on blood from several species. We show that a previously developed thixotropy model can be used to model blood rheology across species and discuss the similarities and differences. This study improves the understanding of how blood changes across species, which is important for drug clinical testing and elucidates the connection between physiology and blood rheology.

10:36AM R65.00012: Early onset of kinetic roughening due to finite step width in hematin crystallization*
KATY OLAFSON, JEFFREY RIMER, PETER VEKILOV (Presenter), University of Houston — Crystallization is an example of a highly non-equilibrium process, in which the flows of mass and energy are governed by dynamic structures comprising a two-dimensional interface between adjacent three-dimensional semi-spaces. During crystal growth, the structure of its interface with the growth medium dictates the molecular mechanism of solute incorporation, the response of the growth dynamics to temperature and composition gradients, the action of impurities and dopants, and, ultimately, the crystal perfection. Interfaces that are smooth at equilibrium may become rough during growth at elevated supersaturation. We observed a smooth to rough transition during the growth of hematin crystals from a biomimetic mixed organic-aqueous solvent. Hematin crystallization is the main pathway employed by malaria parasites to sequester toxic hematin, released during hemoglobin digestion; its inhibition is considered the most successful target for antimalarial drugs. We show that the transition occurs at a supersaturation significantly lower than that predicted by published criteria.

**8:00AM R66.00001: Mitotic traveling waves in the Drosophila embryo** [Invited] STEFANO DI TALIA (Presenter), Cell Biology, Duke University Medical Center — Early embryogenesis of most metazoans is characterized by rapid and synchronous cleavage divisions. While diffusion is too slow for synchronization of mitosis across large spatial scales, traveling waves represent a possible process of synchronization. I will discuss our recent work dissecting the molecular and physical mechanisms for the generation of traveling waves of activity of Cdk1, the master regulator of the cell cycle. I will show that the *in vivo* dynamics of Cdk1 are captured by a transiently bistable reaction-diffusion model, where time-dependent reaction terms account for the growing level of cyclins and Cdk1 activation across the cell cycle. I will discuss two distinct regimes. The first one is observed in mutants of the mitotic switch. There, waves are triggered by the classical mechanism of a stable state invading a metastable one. Conversely, waves in wild type reflect a transient phase that preserves the Cdk1 spatial gradients while the overall level of Cdk1 activity is swept upward by the time-dependent reaction terms. This unique mechanism generates a wave-like spreading (sweep-waves) that differs from bistable waves for its dependence on dynamic parameters and its faster speed. I will also discuss how the integration of biochemical and mechanical processes is required for the early establishment of synchronization of the cell cycle.

**8:36AM R66.00002: Tuning the Xenopus mitotic oscillator in artificial cells** [Invited] QIONG YANG (Presenter), Biophysics and Physics, University of Michigan Ann Arbor — We study biological oscillations and self-organization phenomena in both artificially constructed mitotic cells and live zebrafish embryos. We focus on how the network structures of biological clocks are linked to their functions, such as tunability and robustness, and how individuals coordinate through biochemical and mechanical signals to generate collective spatiotemporal patterns. To pin down the physical mechanisms that give rise to these complex phenomena, we integrate modeling, time-lapse fluorescence microscopy, microfluidics, and systems and synthetic biology approaches.

Although central architectures drive robust oscillations, networks containing the same core vary drastically in their potential to oscillate. We computationally generate an atlas of oscillators and found that, while certain core topologies are essential for robust oscillations, local structures substantially modulate the degree of robustness. Strikingly, two key local structures, incoherent inputs and coherent inputs, can modify a core topology to promote and attenuate its robustness, additively (Cell Systems 2017). Experimentally, we developed an artificial cell-cycle system to mimic the real mitotic oscillations in microfluidic droplets (eLife 2018). The artificial cells can perform self-sustained oscillations for 40 cycles over multiple days. The oscillation period and number of cycles can be reliably tuned by the amount of clock regulators or droplet sizes. Such innate flexibility makes it key to studying clock functions of tunability and stochasticity at the single-cell level. With nanofabrication and long-term time-lapse fluorescence microscopy, this system enables a high-throughput, single-cell analysis of clock dynamics and functions. We now combine this platform with mathematical modeling to elucidate the topology-function relation of biological clocks.

**9:12AM R66.00003: Identifying How Single Cells Modulate Population-Wide Pattern Formation** [Invited] ALLYSON SGRO (Presenter), Departments of Biomedical Engineering and Physics and the Biological Design Center, Boston University — One of the key outstanding challenges in understanding multicellular pattern formation is identifying what single cells tune within themselves to change population-wide patterns. A major driver of multicellular patterns is oscillations in single-cell signaling networks, but it is unknown what features single cells naturally modulate in these oscillations to change global patterns. An ideal system for addressing this challenge exists in the social amoeba, *Dictyostelium discoideum*. *Dictyostelium* uses travelling waves of chemoattractant molecules between cells to drive aggregation into a multicellular state when starving. These waves originate within single cells that release this molecule to the environment, and the single-cell signaling network phenomena that drive the creation of these waves are well-characterized. However, it is still unknown what parameters a single cell naturally controls to change the observed population pattern. Using new experimental data in conjunction with an existing phenomenological model, I explore what parameters single cells can modulate to control signaling oscillations and pattern formation.

9:24AM R66.00004: Single-Mode Turbulence in Pattern-Forming Protein Systems* JONAS DENK (Presenter), JACOB HALATEK, FRIDTJOF BRAUNS, KORBINIAN PÖPPEL, ERWIN FREY, Ludwig Maximilian University of Munich — Protein pattern formation often relies on proteins that cycle between a cytosolic bulk and a membrane at which they undergo molecular interactions. On a flat membrane, this cycling can lead to intriguing protein patterns including spiral waves as well as more irregular dynamics such as chemical turbulence. While theoretical approaches have been able to reproduce various experimentally observed protein patterns, the underlying mechanisms for pattern selection remain poorly understood. Motivated by the bacterial Min protein system, we present a spatially reduced reaction-diffusion model to study pattern selection in protein systems with bulk-membrane coupling. Remarkably, we find that already a single-mode instability can lead to turbulent dynamics at the onset of pattern formation. Further away from this onset, we observe a transition from turbulent to coherent patterns, which can be explained on the basis of diffusively coupled local equilibria. Our study yields insights into a novel route to chaos for a widespread class of mass-conserving reaction-diffusion systems with bulk-boundary coupling.

9:36AM R66.00005: Directed and Spiral Wave Propagation in Communities with Correlated Heterogeneity XIAOLING ZHAI (Presenter), Purdue University, JOSEPH LARKIN, GUROL SUEL, University of California, San Diego, ANDREW MUGLER, Purdue University — Directed signal propagation in cellular communities is an important and ubiquitous phenomenon. However, heterogeneity in these communities may pose a challenge to directed propagation. Additionally, spatial correlations in the heterogeneity may alter the dynamic behavior. In general, the relationship between correlated heterogeneity and wave propagation is poorly understood. Here we use a FitzHugh Nagumo-type model to investigate wave propagation in a two-dimensional heterogeneous community. Our model predicts three dynamic regimes in which waves either propagate directly, die out, or spiral indefinitely. In some parameter regimes, correlations in the heterogeneity enhance directionality and suppress spiraling, as expected. In contrast, in other regimes, correlations promote spiraling, a surprising feature that we explain by demonstrating that these spirals form by a second, distinct mechanism. Finally, we characterize the dependence of the spiral period on the degree of heterogeneity and connect our results to percolation theory. Our work reveals that the spatial structure of cell-to-cell heterogeneity can have important consequences for directed signal propagation in cellular communities, and provides predictions that can be tested in experiments.

9:48AM R66.00006: Coexistence and coupling of Min protein patterns in heterogeneous systems JACOB HALATEK (Presenter), Biological Computation Group, Microsoft Research, Cambridge, FRIDTJOF BRAUNS, Physics, Ludwig-Maximilians Universitaet Muenchen, GRZEGORZ PAWLIK, Kavli Institute of Nanoscience, TU Delft, LAESCHKIR HASSAN, Physics, Ludwig-Maximilians Universitaet Muenchen, CEES DEKKER, Kavli Institute of Nanoscience, TU Delft, ERWIN FREY, Physics, Ludwig-Maximilians Universitaet Muenchen — In the past two decades, the Min protein system has been established as paradigmatic model system for self-organized protein pattern formation. Much of this success is owed to the advances made in the reconstitution of Min protein patterns in vitro, which allowed precise control over experimental conditions and thereby the pattern forming phenomena. However, up until recently a theoretical description for in vitro Min protein patterns has been missing. Lately, we proposed a novel theoretical framework for pattern formation in mass-conserved reaction-diffusion systems [1]. One of the key predictions are transitions between chaotic, standing, and travelling wave patterns induced by variations in the system geometry or protein numbers. Here, we present the first experimental confirmation of these predictions. An extension of the theoretical framework enables us to forecast the entire time evolution of patterns and their dynamic transitions in systems with heterogeneous geometry or kinetic parameters. Strikingly, the theory predicts the coexistence of patterns in large heterogeneous systems, which we confirm experimentally.

10:00AM R66.00007: Rectified adaptation - a variance sensor for processing time-varying inputs* KABIR HUSAIN, JACKSON D O’BRIEN, WEERAPAT PITTAYAKANCHIT, PARTHIV PATEL, SAVAS TAY, ARVIND MURUGAN (Presenter), University of Chicago — The role of chemical identity and spatial distribution of biomolecules in pattern formation and cell fate decision making has long been appreciated. However, recent experiments have revealed that the temporal dynamics of molecular concentrations also plays an important role and can affect gene regulation, cell fate decisions and accelerate pattern formation. We identify a general phenomenological behavior - "rectified adaptation" - that plays a critical role in processing oscillatory, pulsatile and fluctuating temporal signals in these diverse biological contexts. Like conventional adaptation, rectified adaptation describes a transient response to step changes in an input signal but the response to step ups and step downs is strongly asymmetric. We show how simple implementations of rectified adaptation can sense the variance of an input signal on specific timescales, helping make decisions in immune response and in embryonic patterning.

10:12AM R66.00008: Critical dynamics in bursts of δ and θ-rhythms across the sleep-wake cycle FABRIZIO LOMBARDI (Presenter), Boston University, MANUEL GOMEZ-EXTREMERÁ, PEDRO BERNAOLA-GALVAN, University of Malaga, THOMAS E SCAMMELL, Harvard Medical School, PLAMEN CH IVANOV, Boston University — Solid evidences indicate that different cortical rhythms characterize distinct phases (sleep stages) of the sleep-wake cycle. Sleep stages are not stable, and sleep periods exhibit numerous transitions among different stages, including short awakenings/arousals. Nature and dynamics of such transitions, as well as origin and functions of arousals, remain elusive. Recently, it has been shown that brief awakenings/arousals do not have a characteristic duration and consistently follow a power-law distributions across different species. Since arousals can be viewed as 'active' states of the brain that interrupt the 'inactive' phase represented by sleep periods, such a scale-free statistics has been interpreted as a fingerprint of criticality in sleep dynamics, suggesting that arousals are an integral part of sleep regulation. In this talk, I will present recent results on the dynamics of relevant cortical rhythms across the sleep-wake cycle that seem to support such a hypothesis. I will show that wake-related θ- and sleep-related δ-bursts exhibit a robust scale invariant temporal organization closely reminiscent of other non-equilibrium phenomena, and discuss their dynamics and coupling in relation to the neuronal circuitry responsible for wake and sleep control in rats.

10:24AM R66.00009: Phase space geometry of reaction--diffusion systems FRIDTJOF BRAUNS (Presenter), JACOB HALATEK, ERWIN FREY, Ludwig Maximilian University of Munich — Self-organized pattern formation — typically studied in terms of spatially extended dynamical systems — is as ubiquitous in nature as it is difficult to deal with conceptually and mathematically. We build on the phase space geometric methods of Nonlinear Dynamics, using geometric structures like nullclines and fixed points, to develop a comprehensive theory for two-component mass-conserving reaction–diffusion systems — a paradigmatic model class for pattern formation, e.g. intracellular polarization. A dissection of space into (notional) compartments enables us to characterize the spatio-temporal dynamics based on the ODE phase space of local reactions. Diffusive coupling leads to mass redistribution between the compartments which, in turn, changes the local phase space properties.

We show that all aspects of pattern formation, from linear instability and excitability to the bifurcations of stationary patterns, can be extracted from the geometric features of the line of chemical equilibria in phase space. Furthermore, our analysis points towards a deep connection between the far from equilibrium reaction–diffusion dynamics to phase separation of binary mixtures near equilibrium, and thus offers a new perspective on phase separation far from equilibrium.
Emergence of traveling waves in linear arrays of electromechanical oscillators

YONG DOU (Presenter), SHASHANK PANDEY, Chemical Engineering, Columbia University, CHARLES CARTIER, OLIVIA MILLER, Chemical Engineering, Pennsylvania State University, KYLE J. M. BISHOP, Chemical Engineering, Columbia University — Traveling waves of mechanical actuation provide a versatile strategy for locomotion and transport in both natural and engineered systems across many scales. These rhythmic motor patterns are often orchestrated by systems of coupled oscillators such as beating cilia or firing neurons. Here, we show that similar motions can be realized in linear arrays of electromechanical oscillators that move and interact via electrostatic forces. Conductive spheres oscillate between biased electrodes through cycles of contact charging and electrostatic actuation. The combination of repulsive interactions among the particles and spatial gradients in their natural frequencies lead to phase locked states characterized by gradients in the oscillation phase. The frequency and wavelength of these traveling waves can be specified independently by varying the applied voltage and the electrode separation. We demonstrate how traveling wave synchronization can enable the directed transport of material cargo. Our results suggest that simple energy inputs can power complex patterns of mechanical actuation with potential opportunities for soft robotics and colloidal machines.

Progress on functional connectivity measurement and modeling in C. elegans

FRANCESCO RANDI (Presenter), ANUJ K SHARMA, ANDREW M LEIFER, Department of Physics, Princeton University — Advances in microscopy and optogenetics now permit “functional connectivity” experiments in which some neurons are optogenetically stimulated while the responses of other neurons in the network are simultaneously measured, ideally giving access to the strengths and the dynamical properties of the interactions between neurons. Currently, the nematode C. elegans is an ideal candidate in which to perform such experiments, because of its small nervous system, the known anatomical connectivity map between the neurons, and the graded nature of their activity. I will present progress on such measurements on the whole brain of the worm. Additionally, how should a mathematical description of C. elegans’ neural network be structured so as to be able to best incorporate such measurements of functional connectivity? I will introduce a framework for the description of the neural activity in C. elegans based on Green's functions, which can be directly related to the quantities measured in the above experiments.

Bridging severed nerves in a mouse using Carbon Nanotubes (CNTs): Identifying artifact vs. neural signals suggests transmission was partially restored

VINEET MATHUR (Presenter), Chemistry, University of California Berkeley, ZACHARIAH HENNIGHAUSEN, SWASTIK KAR, Physics, Northeastern University — Stimulation and recording of neural tissue are hallmarks of investigation of neural activity, especially the detection of action potentials. In this context, accurate analysis of curve-shapes holds significant value in distinguishing between neural activity compared to background noise and instrument artifacts. We report the remarkable observation that when probed using an electric field stimulation technique (EFS) in an in-vitro setting, control experiments that contain no neural tissue reproducibly produce curves in-distinguishable from experiments containing sources of neuronal activity. We additionally provide a physical model to explain the origin and behavior of such false-positive signals in relation to the buffer and neural circuits in the system. Lastly, we present data and analysis on in-vivo experiments using a mouse and carbon nanotubes (CNTs). Our experiments detected a previously unreported dominant secondary pulse delayed over 16ms after the artifact signal. Comparing the intact, severed, and bridged (with CNTs) spinal cord suggests transmission of neural signals was partially restored.

8:24AM R67.00003: Nonlinear synchronization of neuronal firing on a random graph: Application to breathing rhythm formation in the preBötzinger complex. VALENTIN SLEPUKHIN (Presenter), ALEXANDER JACOB LEVINE, Physics and Astronomy, Univ of California - Los Angeles, JACK L FELDMAN, SUFYAN ASHHAD, Neurobiology, Univ of California - Los Angeles — The preBötzinger complex is a network of a few thousands of neurons that produces the rhythmic signal controlling mammalian breathing (inspiration). In vitro experiments demonstrated that the activation of small group of neurons in this network results in a “burstlet” of neuronal firing that propagates through the network after some delay (Kam et al., 2013). We consider a simple model burstlet dynamics based on the nonlinear synchronization of imprecise neuronal oscillators interacting on a random graph. The numerical simulations based on this model reproduce features observed in the experiment, such as (i) the probability of systemic synchronization in response to a given number of stimulated neurons, and (ii) the time lag between stimulation and systemic synchronization as a function of the number of stimulated neurons. We conclude by discussing how the topology of the neuronal connectivity affects the robustness of the emergent rhythm dynamics of the network in response to local damage (cell death).

8:36AM R67.00004: Modularity as an order parameter for speech reception FENGDAN YE (Presenter), COLIN NOE, SIMON FISCHER-BAUM, MICHAEL DEEM, Rice University — Recent work in cognitive neuroscience has focused on analyzing the brain as a network, rather than as a collection of independent regions. Prior studies taking this approach have found that individual differences in the degree of modularity of the brain network relate in a complexity-dependent way to performance on cognitive tasks. In the current study, we study the effect of modularity in the context of speech perception. We calculate modularity of whole brain EEG data collected during a lexically biasing phoneme categorization task from 20 subjects, and correlate modular activity of the brain with subjects' responses to audio stimuli with varying ambiguity. We find that modularity is correlated with how quickly and decisively a subject switches from one category of phoneme to another. This correlation is also mediated by lexical bias and place of articulation in each pair of phonemes. The results presented here provide a framework for linking measures of whole brain organization from network neuroscience to cognitive processing.

8:48AM R67.00005: Global synchronization due to cluster size heterogeneity in balanced neural networks ABHIJIT CHAKRABORTY (Presenter), GREG MORRISON, Department of Physics, University of Houston — Synchronized brain rhythms have been associated with various cognitive functions as well as neurological disorders, and comprehending how the network connectivities give rise to these behaviors is essential for a better understanding of the importance of network topology on functional brain dynamics. Previous studies have shown that cortical networks with clustered connections give rise to correlated dynamics in individual clusters. However, this same model applied to a network with highly heterogeneous cluster sizes leads to a clear breakdown of the balanced state. In this talk, using a formal definition of the balance matrix, we show why the balance condition breaks and propose a solution to restore balance in the heterogeneous networks. In doing so, we also observe that global synchronization in firing dynamics appears due to cluster size heterogeneity. This modified balance matrix applied to a homogeneous network results in the disappearance of the synchronization. Diversity in cluster sizes has not previously been shown to produce such a global effect in a network of excitatory and inhibitory leaky integrate and fire neurons, and may have important implications in real world cortical networks.

9:00AM R67.00006: Statistical properties of the optimal sensitivity matrix for compressed sensing with nonlinear sensors* SHANSHAN QIN (Presenter), QIANYI LI, CHAO TANG, Peking University, YUHAI TU, IBM Thomas J. Watson Research Center — Natural odors are typically sparse mixtures of a few types of odorants each with a wide range of concentrations. How to encode a large number of sparse odor mixtures with a relatively small number of nonlinear olfactory receptor neurons (ORNs) — the nonlinear compressed sensing problem — remains a puzzle. Here, by using an information theory approach, we study the optimal coding strategies that enable ORNs to best represent olfactory information. Our results show that the optimal odor-receptor sensitivity matrix is sparse and the nonzero sensitivities follow roughly a log-normal distribution, both of which are consistent with existing experiments. We also show that odor-evoked inhibition increases coding capacity, providing a plausible explanation for experimental observation in the fly olfactory system. Furthermore, we show that the optimal sensitivity matrix can enhance accuracy of the downstream decoding tasks. Our results may shed light on understanding the peripheral olfactory sensory system and improving performance of artificial neural networks.

GORDON BERMAN, Emory University — Social behavior is an important aspect of life for humans and many other animals. Oxytocin, a neurotransmitter often associated with social behavior, is involved in pair bonding. Further, our results suggest the role of model neurons driven by oscillatory input. Our results show that changes in the input to the network and in the excitability of the neurons play an important role in bond formation. Furthermore, our results suggest the role of the phase-amplitude-coupling (PAC) between mPFC drive to NAcc is pivotal for the formation of a bond in Microtus ochrogaster. Key brain areas in this process are the medial prefrontal cortex (mPFC) and the nucleus accumbens (NAcc). It was shown that the phase-amplitude-coupling (PAC) between mPFC drive to NAcc is pivotal for the formation of a bond in voles. Experimental measurements from NAcc suggest non-trivial relations between the input to the network and the resulting PAC features. Using simulations and analytical methods we study the emerging coupling in networks of model neurons driven by oscillatory input. Our results show that changes in the input to the network and in the excitability of the neurons play an important role in the bond formation process. Furthermore, our results suggest the role of oxytocin, a neurotransmitter often associated with social behavior, in pair bonding is to modulate the excitability of certain neurons.

9:24AM R67.00008: Chaotic itinerancy in reservoir computing* HIROMICHI SUETANI (Presenter), Faculty of Science and Technology, Oita University — Recently, the paradigm of reservoir computing (RC) has attracted attention as a new way of recurrent neural network (RNN) training [1]. Especially, Sussillo and Abbott proposed a version of RC, called FORCE-learning[2] and they showed how chaotic activity in a RNN is useful for generating various temporal patterns. In this study, we construct a machine based on the FORCE-learning scheme for generating a set of temporal patterns that are selectable by the combination of trigger pulses through multiple channels. We show that this machine can be actually realized, depending on the adequate choice of parameters of the reservoir. When the machine shows optimal performances, it also shows intermittent transitions among several typical patterns without any trigger inputs, i.e., spontaneous mode, which reminds us chaotic itinerancy [3]. We characterize this pliability of chaos in terms of the large deviation fluctuations of Lyapunov exponents and visualize the itinerant dynamics using the manifold learning such as t-SNE.

9:36AM R67.00009: The role of neural excitability and coupling in the formation of social bonds ITAI PINKOVIEZKY (Presenter), AHMED ROMAN, Emory University, ELIZABETH AMADEI, Neuroinformatik u. Neuronale Syst, ETH, ROBERT C LIU, GORDON BERMAN, Emory University — Social behavior is an important aspect of life for humans and many other animals. Yet, our understanding of the biological mechanisms giving rise to it is limited. Although extensive research has been done on the neural basis of social impairment, few studies have attempted to explain the formation of positive behaviors. Here, we report results on the mechanisms responsible for a positive social behavior, pair bonding in prairie voles (Microtus ochrogaster). Key brain areas in this process are the medial prefrontal cortex (mPFC) and the nucleus accumbens (NAcc). It was shown that the phase-amplitude-coupling (PAC) between mPFC drive to NAcc is pivotal for the formation of a bond in voles pair. Experimental measurements from NAcc suggest non-trivial relations between the input to the network and the resulting PAC features. Using simulations and analytical methods we study the emerging coupling in networks of model neurons driven by oscillatory input. Our results show that changes in the input to the network and in the excitability of the neurons play an important role in the bond formation process. Furthermore, our results suggest the role of oxytocin, a neurotransmitter often associated with social behavior, in pair bonding is to modulate the excitability of certain neurons.

9:48AM R67.00010: Precise Spatial Memory in Local Random Networks* JOSEPH NATALE (Presenter), H G E HENTSCHEL, ILYA NEMENMAN, Emory University — Self-sustained, elevated neuronal activity persisting on time scales of ten seconds or longer is vital for working memory. The most prevalent models for persistent activity, known as attractor networks, have come under criticism for their severe reliance on fine-tuning of synaptic architectures. While alternative frameworks exist, many of these invoke fine-tuning implicitly. Here we elaborate a model with local learning rules, and can be derived from principled objective functions. We test these algorithms on data generated from several alternating autoregressive-moving-average (ARMA) models and find very good performance in detecting changes in the generating process within just dozens of samples from the transition point. We compare this to similar methods from control theory that are not directly interpretable as neural models.

10:00AM R67.00011: A physical model for pattern completion of highly overlapping patterns for Human Episodic Memory  
ZAHRA GHASEMI ESFAHANI (Presenter), MARC HOWARD, Boston University — Patterns of neural activity in the hippocampus change very slowly, perhaps in a scale-invariant manner. 
Episodic memory is a consequence of retrieval of a pattern of activity corresponding to a specific event in the past. The physics of attractor networks have been extensively studied. However, it is well known that attractor networks have a small capacity when storing the correlated patterns. This coupled with the strong overlap in patterns of neural activity in the hippocampus makes attractor networks ill-suited to describe human episodic memory. 
Using a concise description of hippocampal time cells, we develop a formal model for pattern completion of hippocampal representations. The model overcomes pattern similarity by relying on the coupling between different temporal scales. Because the model uses the recency of the desired memory as part of the retrieval process, it can be understood as an ‘`address-addressable`` memory. In this sense, time serves as a scaffolding to organize different experiences. We study the capacity and dynamics of this model for memory retrieval and compare to properties of human episodic memory.

10:12AM R67.00012: Novel strategies for holographic optical activation of neurons*  
SAMIRA AGHAYEE (Presenter), PATRICK KANOLD, WOLFGANG LOSERT, University of Maryland, College Park — In-vivo two photon imaging of neuronal activity in the higher sensory cortical layers has revealed that the spatial arrangements of neurons involved in processing sensory stimuli is complex. Recent advances in optogenetics have allowed for optical manipulation of neurons, and holographic microscopy has enabled us to selectively target neurons for activation. Here we introduce the use of extended holographic patterns with high planar selectivity for photo activation of neurons. Our approach takes advantage of a lens function to reduce off-target speckles. We find that in addition to reducing speckles, our approach also generates target patterns with a higher degree of uniformity. We demonstrate the feasibility of this method for in vivo studies of the auditory cortex.

10:24AM R67.00013: Wiring economy constrains olfactory glomerulus placement in fly larva  
GUANGWEI SI (Presenter), MATTHEW E BERCK, YU FENG, ARAVINTHAN SAMUEL, Harvard University — Olfactory sensory neurons expressing the same receptor converge their axons to a common locus called a glomerulus. The glomeruli placement are largely stereotyped. A plausible theory to explain the placement is the wiring economy principle, where neuronal placement is an optimal solution to minimizing the wiring cost given a synaptic connectivity pattern. Recently, the complete wiring diagram of a glomerular olfactory system, the insect antennal lobe, has been reconstructed using serial section electron microscopy and the fly larva. The reconstruction provides a detailed map of glomerulus placement as well as the underlying synaptic connectivity. Interneuron synaptic connectivity patterns within the antennal lobe are strikingly and consistently heterogeneous in their glomerular innervations. We developed a coarse-grained model to describe the glomeruli placement and calculate the wiring cost to generate this synaptic connectivity. The wiring cost of observed glomerular position is significantly smaller than random glomerular arrangements. We also searched for the theoretical minimal wiring cost, which compares well with the observed glomerular arrangement. Wiring economy provides an explanation in terms of physical optimization for the organization of an olfactory system.

10:36AM R67.00014: Generation of scale-invariant sequential activity in recurrent neural circuits*  
YUE LIU (Presenter), MARC W HOWARD, Department of Physics and Center for Systems Neuroscience, Boston University — Sequential neural activity has been observed in many parts of the brain. Sequential activity can be generated by recurrent neural networks, which have been extensively studied (White and Sompolinsky, 1996, Goldman, 2009, Rajan et al., 2016, Chaudhuri et al., 2016).
Inspired by Weber-Fechner law in the sensory domain and scalar timing in psychophysics, we study the requirements for scale-invariant sequences in linear recurrent neural networks. It is found that 1) the eigenvalues of the connectivity matrix must be geometrically spaced, and 2) the eigenvectors have to have a translation-invariant structure composed of the same motif.
Together the relationship between the eigenvectors and eigenvalues can be thought of a logarithmic mapping from a ratio scale to an interval scale (Luce, 1959). Geometrically spaced network eigenvalues can generically emerge from multiplicative cellular processes (Amir et al., 2012). We are now seeking to extend these results to nonlinear recurrent networks.

Exploring the energy landscape of C. elegans neural activities

XIAOWEN CHEN (Presenter), FRANCESCO RANDI, ANDREW M LEIFER, WILLIAM BIALEK, Princeton University — Recent advances in experimental techniques and application of the maximum entropy principle have allowed us to build models for joint probability distribution of activity in groups of up to 50 neurons in *Caenorhabditis elegans*, a nematode with 302 neurons. These models, which are equivalent to the Boltzmann distribution for a family of Potts glasses, successfully predict the static observables of the network. The energy landscape defined by these models exhibits curious signatures of collective behavior, including a large number of energy minima, as in models for memory, and a clustering of energy barriers that is reminiscent of the dynamical transitions in disordered systems. While these models describe the distribution of network states at a single time, the observed neural dynamics are not consistent with a simple Brownian-like motion on the energy landscape. In particular, the real dynamics exhibit much longer correlation times than predicted from the heights of energy barriers alone. We will show progress towards understanding how the nematode actually explores the energy landscape of its neural network.

Session S01 DCMP: Fractional Quantum Hall Effect: Novel States and Excitations

Lucia Steinke, Texas A&M University

11:15 AM S01.00001: Zero modes, Bosonization and Topological Quantum Order: Composite Fermions in Second Quantization  
LI CHEN (Presenter), Florida State University, SUMANTA BANDYOPADHYAY, Washington University, St. Louis, KUN YANG, Florida State University, ALEXANDER SEIDEL, Washington University, St. Louis — We develop recursion relations, in particle number, for all (unprojected) Jain composite fermion (CF) wavefunctions. These recursions generalize a similar recursion originally written down by Read for Laughlin states, in mixed first-second quantized notation. In contrast, our approach is purely second-quantized, giving rise to an algebraic, `pure guiding center'' definition of CF states that de-emphasizes first quantized many-body wave functions. Key to the construction is a second-quantized representation of the flux attachment operator that maps any given fermion state to its CF counterpart. An algebra of generators of edge excitations is identified. In particular, in those cases where a well-studied parent Hamiltonian exists, its properties can be entirely understood in the present framework, and the identification of edge state generators can be understood as an instance of `microscopic bosonization'. The intimate connection of Read's original recursion with `non-local order parameters'' generalizes to the present situation, and we are able to give explicit second quantized formulas for non-local order parameters associated with CF states.

11:27 AM S01.00002: Variational principle for an incompressible fluid with Hall viscosity and gapless surface modes*  
GUSTAVO M MONTEIRO (Presenter), UNICAMP-Univ de Campinas, ALEXANDRE ABANOV, Stony Brook University — Hydrodynamics is a powerful tool to study strongly interacting systems, including for example the fractional quantum Hall effect (FQHE). The main features of the quantum Hall hydrodynamics are the incompressibility of the electron flow, due to the gap separation between the FQH ground state and the excited states, and the relation between the density of the fluid and its vorticity. Motivated by this example, we focus in this work on the variational and Hamiltonian formulations of incompressible two-dimensional fluid dynamics with free surface and nonvanishing Hall viscosity. We show that within the variational principle the Hall viscosity contribution corresponds to a purely geometric boundary term. This term modifies effective boundary conditions on the free surface. The modified boundary conditions have a interpretation describing an additional pressure at the free surface proportional to the angular velocity of the surface itself. These boundary conditions are believed to be universal since the proposed hydrodynamic action is fully determined by the symmetries of the system. The extension of this variational principle to compressible flows will be also considered in this talk.

11:39AM S01.00003: Geometric quench in the fractional quantum Hall effect: exact solution in quantum Hall matrix models and comparison with bimetric theory* MATTHEW LAPA (Presenter), Physics, University of Chicago, ANDREY GROMOV, Physics, University of California, Berkeley, TAYLOR HUGHES, Physics, University of Illinois at Urbana-Champaign — We investigate the recently introduced geometric quench protocol for fractional quantum Hall (FQH) states within the framework of exactly solvable quantum Hall matrix models. In the geometric quench protocol a FQH state is subjected to a sudden change in the ambient geometry, which introduces anisotropy into the system. We formulate this quench in the matrix models and then we solve exactly for the post-quench dynamics of the system and the quantum fidelity (Loschmidt echo) of the post-quench state. Next, we explain how to define a spin-2 collective variable \( g_{ab}(t) \) in the matrix models, and we show that for a weak quench (small anisotropy) the dynamics of \( g_{ab}(t) \) agrees with the dynamics of the intrinsic metric governed by the recently discussed bimetric theory of FQH states. We also find a modification of the bimetric theory such that the predictions of the modified bimetric theory agree with those of the matrix model for arbitrarily strong quenches.

*Kadanoff Center for Theoretical Physics and Materials Research Science and Engineering Center at University of Chicago, U.S. National Science Foundation DMR 1420709 and DMR 1351895-CAR, U.S. Department of Energy DE-AC02-05CH11231, Institute for Condensed Matter Theory at University of Illinois at Urbana-Champaign.

11:51AM S01.00004: Interlayer fractional quantum Hall effect in a coupled graphene double-layer XIAOMENG LIU, ZEYU HAO (Presenter), Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, BERTRAND I. HALPERIN, PHILIP KIM, Harvard University — In two-dimensional (2D) electron systems under strong magnetic fields, interactions can cause fractional quantum Hall (FQH) effects. Bringing two 2D conductors to proximity, a new set of correlated states can emerge due to interactions between electrons in the same and opposite layers. Here we report interlayer correlated FQH states in a system of two parallel graphene layers separated by a thin insulator. Current flow in one layer generates different quantized Hall signals in the two layers. This result is interpreted by composite fermion (CF) theory with different intralayer and interlayer Chern-Simons gauge-field coupling. We observe FQH states corresponding to integer values of CF Landau level (LL) filling in both layers, as well as “semi-quantized” states, where a full CF LL couples to a continuously varying partially filled CF LL. Remarkably, we also recognize a quantized state between two coupled half-filled CF LLs, attributable to an interlayer CF exciton condensate.

12:03PM S01.00005: Microwave photo-excited transport in the GaAs/AlGaAs 2DES* ANNIKA KRIISA, Georgia State University, CHRISTIAN REICHL, WERNER WEGSCHEIDER, ETH-Zurich, RAMESH MANI (Presenter), Georgia State University — Collective bulk plasmon excitations of a two dimensional electronic system (2DES) evolve into magnetoplasmons in the presence of a perpendicular magnetic field, with a low frequency cutoff determined by the dispersion relation \( \omega_{MP} = (\omega_C^2 + \omega_P^2)^{1/2} \), where the plasmon frequency \( \omega_P = (ne^2 / 2\varepsilon_{eff}\varepsilon_{om^*})k \), with \( k \) the plasmon wave vector, and \( \omega_C \) the cyclotron resonance frequency. Studies of narrow Hall bar type GaAs/AlGaAs specimens of width, \( w \), have long ago suggested that localization of the plasmon within the boundaries of the sample can lead to the wave vector selection \( k = n\pi/w \) and the observation of the corresponding resonance in magnetotransport under photoexcitation. The observation of zero-resistance states and associated radiation induced magnetoresistance oscillations under microwave/mm-wave/terahertz photoexcitation has brought new interest in the role of the magnetoplasmon, if any, in the ultra high mobility GaAs/AlGaAs 2DES and its interaction with this photo-excited transport phenomena mentioned above. In this study, we re-examine through experiment the role of the magnetoplasmon in the GaAs/AlGaAs magnetotransport and report the results.

12:15PM S01.00006: Microwave-induced resistance oscillations in a tunable-density GaAs quantum well* XIAOJUN FU (Presenter), MICHAEL ZUDOV, University of Minnesota, QI QIAN, JOHN WATSON, MICHAEL MANFRA, Purdue University — We report on microwave-induced resistance oscillations (MIRO) in a tunable-density 30 nm-wide GaAs/AlGaAs quantum. When the second subband becomes populated, we observe that the MIRO amplitude significantly decreases compared to the single-subband regime, the effective mass increases, while the quantum lifetime shows little change. We also find that the MIRO prefactor, which depends on the disorder characteristics and the inelastic relaxation, first decreases and then grows with the carrier density, behaving much the same as the carrier mobility. These findings will be compared to theoretical expectations.

*The work at Minnesota (Purdue) was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award No. ER 46640-SC0002567 (DE-SC0006671).
Pairing and Pair Tunneling of Electrons at the Edge of a GaAs Quantum Dot Two-Dimensional Electronic System  

AHMET DEMIR, NEAL STALEY, Massachusetts Institute of Technology, K. W. BALDWIN, KENNETH WEST, LOREN PFEIFFER, Princeton University, RAYMOND ASHOORI (Presenter), Massachusetts Institute of Technology — We have large (diameter ~0.8 μm) ultra-clean quantum dots that act as mini-2D electron systems and studied their single electron addition spectra at ~45 mK using capacitive sensing. Single electrons tunnel from an n+ GaAs electrode across an AlGaAs tunnel barrier into an otherwise electrically floating quantum dot. We measured the magnetic field dependence of electron addition energies from a completely empty dot, up to dot occupancies of ~2000 electrons. Here, we report the observation in the addition spectra of individually localized states, incompressible Landau gaps, and isolated tunneling to edge states. We see electron additions to the edge states between filling factors ν = 1 and ν = 2 with single flux quantum (h/e) periodicity in magnetic field. Remarkably, between filling factors ν = 2 and ν = 5, we observe the pairing of electron additions to states at the edges of the quantum dots with a corresponding 2e charge tunneling and with (h/2e) periodicity in magnetic field. These results are consistent with interferometry work from the group of Heiblum[1] showing an unexpected h/2e periodicity around the same filling factors, and they suggest that the same correlated electron physics is creates a novel pair tunneling effect.

Study of spin splitting of Shubnikov de Hass oscillations under microwave photoexcitation in the GaAs/AlGaAs 2DES*  

THARANGA NANAYAKKARA (Presenter), RASANGA SAMARAWEERA, BINUKA GUNAWARDANA, C. RASADI MUNASINGHE, U. KUSHAN WIJEWARDENA, SAJITH WITHANAGE, ANNIKA KRIISA, RAMESH MANI, Department of Physics and Astronomy, Georgia State University, Atlanta, Georgia 30303, USA, CHRISTIAN REICHL, WERNER WEGSCHEIDER, ETH Zürich, CH-8093 Zürich, Switzerland, Laboratorium für Festkörperphysik — We perform magneto transport measurements on GaAs/AlGaAs 2D electron system to understand the influence of the microwave photoexcitation on the spin splitting of the Shubnikov-de Haas oscillations at liquid helium temperatures. The aim of the study is to determine the magnitude of the electron heating under microwave photo-excitation by examining observable spin splitting- and variation thereof under photoexcitation- at high filling factors. Thus, we apply a Lifshitz-Kosevevich type formula to describe the magneto transport data and report here the relevant results.

Collective excitations in the Moore-Read phase: view from superspace*  

ANDREY GROMOV (Presenter), UC Berkeley, SHINSEI RYU, EMIL J MARTINEC, University of Chicago — We present a microscopic theory of the neutral collective modes supported by the Moore-Read fractional quantum Hall state. The theory is formulated in terms of the trial states describing the Girvin-MacDonald-Platzman (GMP) mode and its fermionic counterpart, known as the “Neutral Fermion” mode. To access both modes simultaneously the Moore-Read state is first lifted to the superspace. These modes are created by the same operator which acts in the superspace. The Grassman variables are auxilliary and are integrated over in the end.

One-plaquette Chern number: Many-body Chern number without integration*  

KOJI KUDO (Presenter), University of Tsukuba, HARUKI WATANABE, University of Tokyo, TOSHIKAZE KARIYADO, National Institute for Materials Science, YASUHIRO HATSUGAI, University of Tsukuba — The Niu-Thouless-Wu formula defines the many-body version of the Chern number that characterizes the quantized Hall conductance in the presence of disorders or interactions. In this talk, we provide numerical evidence that the integration by twisted angles in the Niu-Thouless-Wu formula is unnecessary if the system size and the excitation gap are sufficiently large. The Berry curvature itself is effectively quantized and the error decays exponentially with the system size. The lack of integration reduces the computational cost, which is advantageous in the interacting many-body problems for a sufficiently large system size. We also discuss the accuracy of the effective quantization in the vicinity of quantum phase transitions.

1:15PM S01.00011: Search for exact local Hamiltonians for general fractional quantum Hall states

SREEJITH GANESH JAYA (Presenter), Physics, Indian Institute of Science Education and Research Pune, MIKAEL FREMLING, Institute of theoretical physics, Utrecht University, GUN SANG JEON, EWAH Womans University, JAINENDRA JAIN, Physics, Penn State — We report on our systematic attempts at finding local interactions for which the lowest-Landau-level projected composite-fermion wave functions are the unique zero energy ground states. We study in detail the simplest non-trivial system beyond the Laughlin states, namely bosons at filling factor 2/3 and identify local constraints among clusters of particles in the ground state. By explicit calculation, we show that no Hamiltonian up to (and including) four particle interactions produces this state as the exact ground state, and speculate that this remains true even when interaction terms involving greater number of particles are included. Surprisingly, we can identify an interaction, which imposes an energetic penalty for a specific entangled configuration of four particles with relative angular momentum of 6, that produces a unique zero energy solution (as we have confirmed for up to 12 particles). This state is not identical to the projected CF state, but have high overlaps with the CF state and the same root partition, quasiparticle and neutral excitation spectrum as the CF state. On the quasihole side, the quantum numbers of the low energy states agree with the CF state but these states are not separated from the others by a clearly identifiable gap.

1:27PM S01.00012: Prediction of a new non-Abelian state at ν = 1/4 in Wide Quantum Wells

WILLIAM FAUGNO (Presenter), Pennsylvania State University, AJIT COIMBATORE BALRAM, Niels Bohr Institute, MAISSAM BARKESHLI, Physics, University of Maryland, JAINENDRA JAIN, Pennsylvania State University — For zero width systems, the ground state at filling factor 1/4 is described by the fully polarized composite fermion Fermi sea. However, fractional quantum Hall effect (FQHE) has been observed at 1/4 in wide quantum well samples [1]. We consider several single-component candidate states, and conclude that the non-Abelian “22111-parton” state is the most likely candidate. Our calculated phase diagram as a function of the quantum well width and the density is in very good agreement with experiments. We suggest further experiments that can confirm the nature of the 1/4 state and, in particular, distinguish it from other candidate states. We also consider a bilayer system at total filling 3/4 as a function of the interlayer separation and predict that it does not support any incompressible FQHE state.

1:39PM S01.00013: Stripe Pairing Order in the 5/2-filling Fractional Quantum Hall State

LUIZ SANTOS (Presenter), Emory University, YUXUAN WANG, University of Florida, EDUARDO HECTOR FRADKIN, University of Illinois at Urbana-Champaign — The nu=5/2 fractional quantum Hall (FQH) state can be effectively described by a paired state of composite fermions with a chiral p-wave order parameter. Motivated by recent works showing an instability of this FQH state towards a phase with broken rotation symmetry, we study the properties of a p-wave pair density wave (PDW) state. We show that the domain walls (DWs) of the PDW order parameter support a pair of counter-propagating Majorana modes whose properties depend on the competition between the Fermi energy and the strength of the PDW order parameter. At weak coupling, the hybridization of DWs generically gives rise to a Majorana Fermi surface (MFS) that is protected by inversion and particle-hole symmetries. A uniform p-wave component gaps the MFS causing the system to enter a striped non-Abelian state with a chiral edge Majorana. At strong coupling, on the other hand, the system is described by a gapped phase without chiral Majorana edge states, which we identify with an striped Abelian paired state. The striped paired FQH state is therefore a fertile arena to study transitions between different topological orders tunneled by the strength of the PDW order parameter.

1:51PM S01.00014: Composite fermions mass in an anisotropic two-dimensional electron system

KEVIN VILLEGAS ROSALES (Presenter), EDWIN CHUNG, HAO DENG, KENNETH WEST, K. W. BALDWIN, LOREN PFEIFFER, MANSOUR SHAYEGAN, Princeton University — Recent advances in molecular beam epitaxy capabilities have established a new record in the quality of AlAs two-dimensional electron systems (2DESs). This breakthrough allows us to study the temperature dependence of fractional quantum Hall states up to ν = 7/15 and 7/13 in the extreme quantum limit. We report on the energy gaps and Shubnikov-de Haas mass (mCF) of composite fermions in samples with density n = 1.04 x 10^11 cm^-2 and quantum well widths of 35 and 50 nm. The measured mCF are 0.68 and 1.2 (in units of free electron mass) for the 35 and 50 nm wide quantum well near ν = 1/2, respectively. We contrast our results with the previously reported energy gaps and mCF of 2DESs in GaAs and ZnO, and the 2D hole system in GaAs. Our experiments on AlAs 2DESs demonstrate the important role of electron layer thickness in determining the energy gaps and mCF.
Parton states as unique ground states of frustration free quantum Hall Hamiltonians with Fibonacci anyon excitations

MOSTAFA TANHAYI AHARI (Presenter), Indiana University Bloomington, SUMANTA BANDYOPADHYAY, ZOHAR NUSSINOV, ALEXANDER SEIDEL, Physics, Washington University in St.Louis, GERARDO ORTIZ, Indiana University Bloomington — We develop a general formalism to systematically derive frustration-free fractional quantum Hall (FQH) Hamiltonians in the presence of Landau level (LL) mixing. Their ground state correlations organize according to entangled Pauli principles, encoding the fluid’s DNA and, dictating the fractional nature of the statistics of their topological excitations. As we will show, the densest ground state - conjectured to be an incompressible quantum liquid - can be uniquely associated to a certain (closed-shell) parton state. Using S-duality, we show that for the case of 4 LLs, excitations of a filling fraction 2/3 liquid admit non-Abelian statistics and correspond to Fibonacci anyons.

Session S02 DMP GMAG: Topological Materials -- Magnetic Materials

11:15AM S02.00001: Theoretical study of topological materials for spintronics

WEI JIANG (Presenter), TONY LOW, Electrical and Computer Engineering, University of Minnesota — Enabling highly efficient current-induced magnetization switching is critical to future spintronic applications, and many proposals relies on topological effects for the conversion of charge current to spin current. Recently, the intrinsic spin-Hall effect (SHE) in the topological materials has been intensely studied and was proposed to play a more important role in the field, because of their extremely large spin Berry curvature. Here, we carried out theoretical studies of different topological materials ranging from topological insulator, Dirac/Weyl semimetal, to topological superconductor, and calculated their intrinsic spin-Hall conductivity (SHC). The figure of merit for charge-to-spin conversion is defined as the SHC over the density of state, based on which we propose a family of topological materials for the spintronics devices.

11:27AM S02.00002: Structural and Physical Properties of Magnetic EuMnSb2 Single Crystals

SILU HUANG (Presenter), XIN GUI, WEIWEI XIE, RONGYING JIN, Louisiana State University — Layered EuMnPn2 (Pn = Sb, Bi) has generated immense interest because of the interplay between complex magnetism (Eu and Mn forming two magnetic sublattices) and topological properties. We have successfully grown EuMnSb2 single crystals, which form the tetragonal structure (space group P4/nmm) containing Sb square net. Both in-plane (ρab) and c-axis (ρc) resistivities show semiconductor-like behavior with an anomaly at TN ~ 20 K. Magnetization measurements indicate that there is an antiferromagnetic (AFM) transition at TN. Upon the application of the magnetic field along the c axis, the in-plane magnetoresistance (MRab) changes sign from positive at T > TN to negative at T < TN, while MRc reveals the opposite trend. This indicates that magnetic interactions are different between the ab plane and c direction. Further discussion will be presented.

11:39AM S02.00003: Crossover of Quantum Anomalous Hall to Topological Hall Effects in Magnetic Topological Insulator Sandwich Heterostructures

JUE JIANG (Presenter), DI XIAO, FEI WANG, JAEOH SHIN, JIANXIAO ZHANG, Department of Physics, Pennsylvania State University, DOMENICO ANDREOLI, Department of Physics, University of New Hampshire, RUN XIAO, YIFAN ZHAO, MORTEZA KAYYALHA, LING ZHANG, Department of Physics, Pennsylvania State University, JIADONG ZANG, Department of Physics, University of New Hampshire, CHAO-XING LIU, NITIN SAMARTH, CUI-ZU CHANG, MOSES H. W. CHAN, Department of Physics, Pennsylvania State University — Electronic band structures with non-trivial topology in momentum space and magnetic spin textures in real space have attracted enormous attention in the past decade since they harbor elegant physics relevant to the Berry curvature. The quantum anomalous Hall (QAH) effect, which is induced by the Berry curvature in the momentum space, supports dissipation-free chiral edge states. The topological Hall (TH) effect is a transport signature of the chiral spin textures that are a consequence of Berry curvature but in real-space. Both QAH and TH effects have been separately reported in magnetically doped TI materials and thus it is natural to ask if both phenomena can coexist in a single sample. Here, by inserting a TI layer between two magnetic TI layers to form a sandwich heterostructure, we observed the crossover from the QAH to TH effects through tuning electrostatic gate voltage. Our theoretical modeling suggests that the inserted TI layer decouples the two magnetic TI layers. As a consequence, the strong Dzyaloshinskii-Moriya interaction in each magnetic TI layer can give rise to chiral spin textures and lead to the TH effect. Our study provides us a new understanding of the interplay between the momentum-space and real-space Berry curvatures in magneto-transport phenomena.

**This work is supported by NSF through Grant Number DMR-1504226**
11:51AM S02.00004: Quantum anomalous Hall effect at the interface between magnetic and topological crystalline insulators*  JINWOONG KIM (Presenter), DAVID VANDERBILT, Rutgers University, New Brunswick — By employing tight-binding and first-principles calculations, we investigate the possible appearance of the quantum anomalous Hall (QAH) effect at the interface between topological crystalline insulators (SnTe, SnSe) and magnetic insulators (EuO, EuS, EuSe). For a surface Dirac cone associated with a band inversion in the bulk, a mass gap acquisition via an effective Zeeman field is a subject of broad interest because of the potential for exotic thin-film states such as the QAH and axionic phases. A number of studies have demonstrated the appearance of such states by using diverse interfacial and magnetic-element-doped systems in agreement with predictions. Although achieving a large mass gap is critical for further investigations and room temperature devices, the microscopic mechanisms determining the size of the mass gap have not been clearly addressed. In this study, we enumerate several combinations of topological crystalline insulators and magnetic insulators in a search for an optimal electronic structure, where a large mass gap is isolated inside a bulk insulating gap. The underlying mechanisms and their dependence on factors such as magnetization orientation will be discussed.

*This work was supported by the National Science Foundation under Grant No. DMR-1408838.

12:03PM S02.00005: Local magnetism in a correlated Kagome magnet with massive Dirac Fermions*  YANGMU LI (Presenter), CMPMS, Brookhaven National Laboratory, QI WANG, Physics Department, Renmin University of China, RYAN DESAUTELS, Neutron Scattering Division, Oak Ridge National Laboratory, QIANHENG DU, CMPMS, Brookhaven National Laboratory, WEIJUN REN, ZHIDONG ZHANG, Institute of Metal Research, Chinese Academy of Sciences, CEDOMIR PETROVIC, CMPMS, Brookhaven National Laboratory, LISA DEBEER-SCHMITT, Neutron Scattering Division, Oak Ridge National Laboratory, IGOR ZALIZNYAK, WEIGUO YIN, CMPMS, Brookhaven National Laboratory, HECHANG LEI, Physics Department, Renmin University of China, JOHN TRANQUADA, CMPMS, Brookhaven National Laboratory — Recent photoemission and scanning tunneling experiments revealed that Fe₃Sn₂, a strongly-correlated Kagome magnet, features massive Dirac fermions and an intrinsic electronic nematicity [1, 2]. DFT calculations show that the Dirac mass depends significantly on the local magnetic moment. The electronic nematicity also relates to local magnetism through the spin-orbital coupling. Here, we present our small-angle neutron scattering and angle-resolved charge transport results in combination with DFT calculations to characterize the complex role of local magnetism in Fe₃Sn₂.

*Work at BNL was supported by Office of BES, U.S. DOE under Contract No. DE-SC0012704. Research conducted at ORNL's SNS was sponsored by the SUFD, Office of BES, U.S. DOE.

12:15PM S02.00006: Anomalous Hall Effect in Intrinsic Antiferromagnetic Topological Insulator MnBi₂Te₄*  SENG HUAT LEE (Presenter), 2D Crystal Consortium, Materials Research Institute, The Pennsylvania State University, YANGLIN ZHU, Department of Physics and Engineering Physics, Tulane University, YU WANG, ZHIQIANG MAO, Department of Physics, The Pennsylvania State University — MnBi₂Te₄ has recently been predicted to be an intrinsic antiferromagnetic topological insulator (AFMTI)¹. This material is also predicted to show ferromagnetism if its dimensionality is reduced to 2D and support other topological states, including type-II magnetic Weyl semimetal state under magnetic fields and Majorana fermions at the interface with a superconductor. Its surface states and magnetic phase transition have been experimentally observed in both bulk² and thin-film samples³. The material provides an excellent platform to study various exotic physics as well as the realization of the quantum anomalous Hall effect at higher temperatures. Here, we report the synthesis of high-quality bulk single crystals of MnBi₂Te₄ by melt-growth technique. Magnetic-transport measurements on bulk samples demonstrated the first observation of the anomalous Hall effect.

*The authors acknowledge funding by NSF through the Penn State 2D Crystal Consortium—Materials Innovation Platform (2DCC-MIP) under NSF cooperative agreement DMR-1539916. Y. Z. is supported by the US DOE under EPSCoR Grant No. DE-SC0012432 with additional support from the Louisiana Board of Regents.
12:27PM S02.00007: Antiferromagnetic topological insulator MnBi$_2$Te$_4^*$  
MIKHAIL OTROKOV (Presenter), IKERBASQUE, Basque Foundation for Science, 48011 Bilbao, Spain, IGOR P RUSINOV, Saint Petersburg State University, 198504 Saint Petersburg, Russia, MARIA BLANCO-REY, Departamento de Fisica de Materiales, UPV/EHU, 20080 Donostia-San Sebastian, Basque Country, Spain, MARTIN HOFFMANN, Institut fur Theoretische Physik, Johannes Kepler Universitat, A 4040 Linz, Austria, ALEXANDRA YU VYAZOVSKAYA, Tomsk State University, 634050 Tomsk, Russia, SERGEY V EREMEEV, YURY M KOROTEEV, Institute of Strength Physics and Materials Science, Russian Academy of Sciences, 634021 Tomsk, Russia, ARTHUR ERNST, Max-Planck-Institut fur Mikrostrukturphysik, Weinberg 2, D-06120 Halle, Germany, PEDRO M ECHENIQUE, Donostia International Physics Center (DIPC), 20018 Donostia-San Sebastian, Basque Country, Spain, ANDRES ARNAU, Centro de Fisica de Materiales (CFM-MPC), Centro Mixto CSIC-UPV/EHU, 20018 Donostia-San Sebastian, Basque Country, Spain, EVGUENI CHULKOV, Donostia International Physics Center (DIPC), 20018 Donostia-San Sebastian, Basque Country, Spain — Using ab initio and Monte Carlo calculations we predict the van der Waals layered compound MnBi$_2$Te$_4$ to be antiferromagnetic (AFM) topological insulator [1], which is further confirmed experimentally [1]. MnBi$_2$Te$_4$ appears to be invariant with respect to the combination of the time-reversal and primitive-lattice translation symmetries, giving rise to the Z$_2$ topological classification of AFM insulators, and Z$_2$=1 for MnBi$_2$Te$_4$. Its (0001) surface, breaking the combined symmetry, shows a giant gap in the topological surface state thus representing a promising platform for the quantized magnetoelectric effect observation. In the 2D limit, MnBi$_2$Te$_4$ shows a unique set of thickness-dependent magnetic and topological transitions, which drive it through FM and (un)compensated AFM phases, as well as quantum anomalous Hall (QAH) and intrinsic zero plateau QAH states [2].

*The supports by the Spanish Ministerio de Economia y Competitividad (FIS2016-75862-P), Academic D.I. 12:39PM S02.00008: Large anomalous Hall effect in topological insulators with a proximitized ferromagnetic insulator*  
MASATAKA MOGI (Presenter), Applied Physics, University of Tokyo, TARO NAKAJIMA, RIKEN CEMS, VICTOR UKLEEV, PSI, ATSUSHI TSUKAZAKI, IMR Tohoku University, RYUTARO YOSHIMI, MINORU KAWAMURA, KEI TAKAHASHI, RIKEN CEMS, TAKAYASU HANASHIMA, KAZUHISA KAKURAI, CROSS, TAKA-HISA ARIMA, GSFS, University of Tokyo, MASASHI KAWASAKI, University of Tokyo, YOSHINORI TOKURA, RIKEN CEMS — Ferromagnetism in topological insulators could lead to exotic quantum phenomena such as quantum anomalous Hall effect. A predominant requirement for such phenomena is the formation of an exchange gap at the Dirac surface states, being realized not only by magnetic doping but also by proximitizing ferromagnetic insulators. Here, we report on the effective gap formation driven by proximity coupling via detection of large anomalous Hall conductivity in heterostructures consisting of ferromagnetic insulator Cr$_2$Ge$_2$Te$_6$ and topological insulator (Bi,Sb)$_2$Te$_3$. While no discernible magnetization in the (Bi,Sb)$_2$Te$_3$ layer is probed by spin-polarized neutron reflectometry, the emergence of large anomalous Hall effect implies that the wavefunction of the Dirac surface state gains an exchange field by penetrating into the Cr$_2$Ge$_2$Te$_6$ by approximately 2-3 nm, finally activating a large Berry curvature. The presently verified mechanism of strong ferromagnetic proximity effect paves a way to enrich the proximity coupling phenomena in versatile topological quantum materials.

12:51PM S02.00009: Anisotropic magnetotransport and planar Hall effect in the quantum anomalous Hall regime

MICHELLE TOMCZYK (Presenter), DI XIAO, CUI-ZU CHANG, ANTHONY R. RICHARDELLA, CHAO-XING LIU, NITIN SAMARTH, Pennsylvania State University — Perturbations to the metallic surface states of topological insulators (TIs) through interactions with magnetism or superconductivity can result in novel phenomena. For example, magnetically-doped TIs realize the theoretically-predicted quantum anomalous Hall (QAH) insulator, in which the surface states are gapped while current is carried in quantized chiral edge states even in zero magnetic field. Understanding the transition between the QAH insulator and dissipative metallic conduction regimes is of fundamental importance. We study this transition by measuring electrical transport while rotating an external magnetic field in different planes relative to the surface. Using scaling plots of the Hall and longitudinal conductance, we find an equivalency in the phase transition created by either rotating the field in the perpendicular plane or by increasing the temperature. Additionally, the angle-dependent in-plane transverse magnetoresistance, the planar Hall effect, exhibits anomalous behavior when perturbed by a small out-of-plane magnetic field. We interpret these observations in terms of the interplay between magnetization, dissipation-free chiral edge states, and dissipative surface states.

*We acknowledge support from the Eberly Research Fellows Program, ONR, and NSF-MIP/2DCC.

1:03PM S02.00010: Berry Phase Engineering in Magnetic Topological Insulator Heterostructures

FEI WANG (Presenter), YIFAN ZHAO, DI XIAO, Department of Physics, The Pennsylvania State University, WENBO WANG, Department of Physics and Astronomy, Rutgers University, JUE JIANG, LING ZHANG, Department of Physics, The Pennsylvania State University, WEIWEI ZHAO, School of Materials Science and Engineering, Harbin Institute of Technology, CHAO-XING LIU, Department of Physics, The Pennsylvania State University, WEIDA WU, Department of Physics and Astronomy, Rutgers University, MOSES H. W. CHAN, NITIN SAMARTH, CUI-ZU CHANG, Department of Physics, The Pennsylvania State University — The Berry phase, both in momentum-space and real-space, plays a key role in nontrivial transport phenomena such as the anomalous Hall (AH) and topological Hall (TH) effects. The AH effect is induced by Berry curvature in momentum space. The TH effect is a transport hallmark of chiral magnetic textures that are a consequence of Berry curvature in real space. In order to engineer the Berry phase, we have fabricated magnetic TI films and heterostructures and systematically studied their magneto-transport properties. We found that the sign of the AH effect in a magnetic TI film can be reversed through proximity to an undoped TI layer. By fabricating magnetic/nonmagnetic/magnetic TI sandwich heterostructures, we realized a square-shaped “hump” feature in the Hall traces, which is usually known as the TH effect. Combining transport measurements with magnetic force microscopy, we demonstrated that the TH effect-like “hump” feature observed here is not due to chiral magnetic textures but from the superposition of two AH effects with opposite signs. Our study provides a new route to engineer the Berry curvatures in magnetic TI heterostructures and facilitate the understanding of the interplay between the AH and TH effects.

*This work is supported by the ARO, DOE, and NSF 2DCC-MIP.

1:15PM S02.00011: Magneto-transport and Magnetism in Antiferromagnetic GdSbTe

TSUNG-CHI WU (Presenter), AKHILESH SINGH, MING-CHIN CHEN, Institute of Physics, Academia Sinica, RAMAN SANKAR, FANGCHENG CHOU, Center for Condensed Matter Sciences, National Taiwan University, WEI-LI LEE, Institute of Physics, Academia Sinica — The crystal structure of GdSbTe belongs to the PbFCl-type family that is known for exhibiting a possible topological nodal-line phase. The spin-7/2 Gd$^{3+}$ ions form a square lattice in the ab plane with large moments. Recently, a Dirac-like state was observed in GdSbTe by ARPES measurement [1]. Magnetization and specific heat measurements also revealed an antiferromagnetic (AFM) transition with a Néel temperature of around 12 K [2], making it a suitable system to study the interplay between AFM and topological states. Here, we report the angular dependence of the magneto-transport properties in GdSbTe. Several features in magnetoresistance (MR) measurements were uncovered while sweeping an in-plane magnetic field, including abrupt increases of MR occurs at 2 T and 6 T and an unusual hysteretic giant magnetoresistance (GMR)-like behavior at higher magnetic fields. We remark that those features are absent when the magnetic field is applied perpendicular to the ab-plane direction. The magneto-transport and magnetization measurements up to a magnetic field of 14 T will be presented and compared to several metallic spin systems.

1:27PM S02.00012: Magneto-Transport Study of Magnetic/Nonmagnetic Topological Insulator Heterostructures*
DI XIAO (Presenter), FEI WANG, RUN XIAO, LING ZHANG, Physics, The Pennsylvania State University, HAIZHOU LU, Physics, Southern University of Science and Technology, CHAO-XING LIU, MOSES H. W. CHAN, CUI-ZU CHANG, NITIN SAMARTH, Physics, The Pennsylvania State University — Breaking time-reversal symmetry in a topological insulator (TI) by a magnetic perturbation can give rise to a variety of exotic quantum phenomena such as quantum anomalous Hall effect. Since the surface states of TIs have a spin helical massless Dirac structure, undoped TI films usually show weak antilocalization (WAL) quantum corrections to diffusive transport, characterized by a positive magnetoresistance (MR). Here, we fabricate magnetically doped TI films on pristine TI films with different thicknesses to form magnetic/nonmagnetic TI heterostructures and systematically study their magneto-transport properties. When the thickness of the TI layer is ≤ 2QL, the MR shows a typical butterfly shape due to domain wall scattering. However, when the thickness of the TI layer is ≥ 3QL, the MR is suppressed, similar to the WAL cusp, but near the magnetization reversal regime. We speculate that this “dip” in MR near the coercive field is a result of the coexistence of the gapless surface state of the TI layer and the ferromagnetic order in the magnetic TI layer. Our study provides new insights into magneto-transport phenomena in the presence of a superposition of gapped and gapless surface states.

1:39PM S02.00013: HoBi: The Effect of Magnetism on Extreme Magnetoresistance*
HUNG-YU YANG (Presenter), Department of Physics, Boston College, JONATHAN GAUDET, Department of Physics and Astronomy, McMaster University, ADAM ACZEL, Oak Ridge National Laboratory, DAVID E GRAF, National High Magnetic Field Lab, PETER BLAHA, Institute of Materials Chemistry, Vienna University of Technology, BRUCE GAULIN, Department of Physics and Astronomy, McMaster University, FAZEL FALLAH TAFTI, Department of Physics, Boston College — Since the discovery of extreme magnetoresistance (XMR) in the topological semimetal WTe2, this phenomenon, featuring extremely high and non-saturating MR, has been found in many topological materials. In some cases, it is shown that XMR does not necessarily connect to topology and can be explained by electron-hole compensation unambiguously [1]. Although we have better understood the role of topology in XMR, the effect of magnetism on XMR remains elusive. Previous studies showed the power-law field dependence of XMR holds in both non-magnetic and magnetic XMR materials and is robust against magnetism. In this work [2], we focus on HoBi in the rare-earth monopnictide material family, which has an antiferromagnetic ground state with huge moments. We find an exact correspondence between the phase diagrams mapped by magnetization and transport measurements. Interestingly, we also find the XMR of HoBi is significantly affected by its magnetic order with ordering vector (1/6,1/6,1/6), in strong contrast to its family members like CeSb. The interplay between magnetism and transport makes HoBi a great platform to understand XMR in magnetic semimetals with trivial or non-trivial topology.

1:51PM S02.00014: Neutron scattering study on a topological antiferromagnet
WEILIANG YAO (Presenter), Peking University, YANGMU LI, Brookhaven National Laboratory, KAZUKI IIDA, Neutron Science and Technology Center, Comprehensive Research Organization for Science and Society (CROSS), TAKASHI OHHARA, Japan Atomic Energy Research Agency, AKIKO NAKAO, Neutron Science and Technology Center, Comprehensive Research Organization for Science and Society (CROSS), BARRY L. WINN, Oak Ridge National Laboratory, JOHN TRANQUADA, IGOR ZALIZNYAK, Brookhaven National Laboratory, CHENYUAN LI, Peking University, CHEN FANG, Institute of Physics, Chinese Academy of Sciences, YUAN LI, Peking University — As analogue of Dirac fermions in topological semimetals, magnon Dirac points have recently been proposed [1] and observed [2,3] in a three-dimensional antiferromagnet, Cu3TeO6. Motivated by the expected presence of Dzyaloshinskii-Moriya interactions in this system [1], we have performed a detailed magnetic neutron diffraction measurement on a single crystal, aiming to detect possible non-collinear spin arrangements in the magnetically ordered state. The result in turn allows for an estimate of the sizes of the topological nodal lines that are represented by the Dirac points in the U(1)-symmetric approximation. Furthermore, we have attempted the first inelastic neutron scattering experiment in search of the putative topological magnon surface states [1,2].

2:03PM S02.00015: Sign Reversal of the Anomalous Hall Effect in Magnetically Doped Topological Insulator Thin Films* YIFAN ZHAO (Presenter), LING ZHANG, FEI WANG, JUE JIANG, MOSES H. W. CHAN, CUI-ZU CHANG, Department of Physics, Pennsylvania State University — Inducing magnetic orders in a topological insulator (TI) to break its time reversal symmetry has revealed many exotic topological quantum phenomena such as quantum anomalous Hall (QAH) effect. The QAH effect has been experimentally realized in the thin films of Cr- and/or V-doped (Bi,Sb)2Te3. The V-doped Sb2Te3 is one of two parent systems for the QAH state. Recently, we fabricated the V-doped Sb2Te3 films with varying V doping concentration and systematically studied their magneto-transport properties. We observed the sign reversal of the anomalous Hall (AH) effect in the V-doped Sb2Te3 films with increasing the V doping concentration. For low doping level, the sign of the AH effect is negative; When the V doping level reaches ~ 3% of Sb, the AH effect starts to show positive sign, consistent with that of the V-doped QAH samples. The observation of the sign reversal of the AH effect in the V-doped Sb2Te3 films opens a new route to understand the interplay between the topological states and magnetism in magnetic doped TI films and facilitates the exploration of the underlying mechanism of the V-doped QAH system.

Session S03 DCMP: Topological Phases and Their Excitations BCEC 107B - Kunal Tiwari, Univ of Texas, Arlington

11:15AM S03.00001: Growth of a predicted two-dimensional topological insulator based on InBi-Si(111)-√7×√7 CHIA-HSIU HSU, ZHI-QUAN HUANG, Physics, National Sun Yat-sen University, CHO-YING LIN, Physics, National Tsing Hua University, GENNEVIEVE M. MACAM, Physics, National Sun Yat-sen University, YU-ZHANG HUANG, DENG-SUNG LIN, Physics, National Tsing Hua University, TAI-CHANG CHIANG, Physics, University of Illinois, HSIN LIN, Physics, Academia Sinica, FENG-CHUAN CHUANG (Presenter), Physics, National Sun Yat-sen University, LI HUANG, Physics, Southern University of Science and Technology — Using combined scanning tunneling microscopy (STM) measurements and first-principles electronic structure calculations, we extensively studied the atomic and electronic properties of a √7-InBi overlayer on Si(111). We propose and demonstrate an effective experimental process to successfully form a large well-ordered √7 surface by depositing Bi atoms on the In-Si(111)-4×1 substrate. The STM images exhibit a honeycomb pattern. After performing an exhaustive computational search, we identified the atomic structures of the surface at In and Bi coverages of 6/7 and 3/7 monolayers, respectively. We discovered a trimer model with a lower energy than the previously proposed model. The simulated STM images of trimer models confirm the presence of the honeycomb pattern in accord with our experimental STM images. Most importantly, we found that the surface is robust, preserving the topologically nontrivial phase. Our edge state calculations verify that the InBi overlayer on Si(111) is indeed a two-dimensional topological insulator (TI). Moreover, hybrid functional calculations result in band gaps up to 70 meV, which is high enough for room-temperature experiments. Our findings lay the foundation for the materials realization of 2D TIs by growing an InBi overlayer on a Si(111) substrate.

11:27AM S03.00002: Topological Phase Transition from a Quantum Spin Hall Insulator to a Chern Insulator* ZHONGDONG HAN (Presenter), Peking University, TINGXIN LI, Cornell University, GERARD SULLIVAN, Teledyne Scientific and Imaging, RUI-RUI DU, Rice University — The effect of magnetic field on electronic transport in InAs/GaSb quantum spin Hall systems is investigated. As theoretical works [1-3] indicate, the system will undergo an insulator-metal-insulator phase transition at a critical magnetic field where the lowest Landau Levels (LLs) of electron and hole cross. Here we observe a distinct bulk conductance peak emerging around 12T in InAs/GaSb double layer systems. Both its temperature dependence and abruptly increasing signal fluctuation is consistent with a metallic phase arising from the topological phase transition between a QSHI phase and a Chern insulator phase. In the meanwhile the response of helical edge state is also systematically studied and the results will be presented.

11:39AM S03.00003: Shift insulators: rotation-protected two-dimensional topological crystalline insulators*
SHANG LIU (Presenter), ASHVIN VISHWANATH, ESLAM KHALAF, Harvard University — We study a two-dimensional tight-binding model of a topological crystalline insulator protected by rotation symmetry. The model is built by stacking two Chern insulators with opposite Chern numbers which transform under conjugate representations of the rotation group, e.g. $p_x$ orbitals. Despite its apparent similarity to the Kane-Mele model, it does not host stable gapless surface states. Nevertheless the model exhibits topological responses including the appearance of quantized fractional charge bound to rotational defects (disclinations) and the pumping of angular momentum in response to threading an elementary magnetic flux, which are described by a mutual Chern-Simons coupling between the electromagnetic gauge field and an effective gauge field corresponding to the rotation symmetry. We show that although the filled bands of the model do not admit a symmetric Wannier representation, this obstruction is removed on addition of appropriate atomic orbitals, which implies ‘fragile’ topology. As a result, the response of the model can be derived by representing it as a superposition of atomic orbitals with positive and negative integer coefficients.

11:51AM S03.00004: Scanning tunneling microscopy and spectroscopy on strong spin-orbit coupling chalcogenides*
SHEKHAR DAS (Presenter), ANSHU SIROHI, Department of Physical Sciences, Indian Institute of Science Education and Research Mohali, GAURAV KUMAR GUPTA, Department of Physics, IISc Bangalore, SUMAN KAMBOJ, AASTHA VASDEV, SIRSHENDU GAYEN, Department of Physical Sciences, Indian Institute of Science Education and Research Mohali, PRASENJIT GUPTASARMA, Department of Physics, University of Wisconsin, Milwaukee, TAMMOY DAS, Department of Physics, IISc Bangalore, GOUTAM SHEET, Department of Physical Sciences, Indian Institute of Science Education and Research Mohali — A large number of A$_2$B$_3$ type chalcogenides with strong spin-orbit coupling like Bi$_2$Se$_3$, Bi$_2$Te$_3$, and Sb$_2$Te$_3$ etc. are topological insulators (TI) whereas Sb$_2$Se$_3$ is an exception in this group. In this talk, I will show, as the TI Bi$_2$Se$_3$, Sb$_2$Se$_3$ displays generation of highly spin-polarized current by point contact Andreev reflection spectroscopy. However, unlike in Bi$_2$Se$_3$, in case of Sb$_2$Se$_3$, a prominent quasiparticle interference (QPI) pattern could be observed in STM conductance mapping which contradicts the above experiment. According to the band structure calculation, there are two trivial surface states available and among them, one shows large splitting due to Rashba type spin-orbit coupling. In addition, we observe a large negative and anisotropic magnetoresistance in Sb$_2$Se$_3$. Experimental data reveal Sb$_2$Se$_3$ to be a trivial band insulator under ambient conditions with high spin-polarization due to Rashba type spin-orbit coupling.

12:03PM S03.00005: A new topological crystalline insulator state in the TaAs$_2$materials class
BAOKAI WANG (Presenter), Physics, Northeastern University, Boston, Massachusetts 02115, USA, BARUN GHOSH, Physics, Indian Institute of Technology Kanpur,Kanpur 208016, India, WEI-CHI CHIU, Physics, Northeastern University, Boston, Massachusetts 02115, USA, BAHADUR SINGH, Department of Physics, Northeastern University, Boston, Massachusetts 02115, USA /SUZU-NUS Collaborative Center and International Collaborative Laboratory of 2D Materials for Optoelectronic Science & Technology, Engineering Technology Research Center for 2D, AMIT AGARWAL, Physics, Indian Institute of Technology Kanpur,Kanpur 208016, India, HSIN LIN, Institute of Physics, Academia Sinica, Taipei 11529, Taiwan, ARUN BANSIL, Physics, Northeastern University, Boston, Massachusetts 02115, USA — Crystalline symmetries drive a variety of topological crystalline insulator (TCI) phases in materials. Here, based on first-principles calculations combined with associated symmetry analysis, we identify a new rotational-symmetry protected TCI state in the TaAs$_2$ family of compounds. The low-energy band structure consists of two bulk nodal lines in the absence of spin-orbit coupling (SOC) effects. Turning on the SOC opens a continuous band gap in the spectrum and drives the system into a $C_3$ symmetry protected TCI state. On the (010) surface, we show the presence of rotational-symmetry-protected nontrivial Dirac cone states within a local bulk energy gap of 300 meV. Our results indicate that the TaAs$_2$ materials family provides an ideal setting for exploring unique physics associated with the rotational-symmetry protected TCIs.
12:15PM S03.00006: Conductance Oscillations in Gated Topological Insulator Heterostructures*  EKLAVYA THAREJA (Presenter), ILYA VEKHTER, MAHMOUD ASMAR, Louisiana State University — Recent theoretical studies have shown that the properties of the surface state of 3D Topological Insulators (TIs) may be different from the topological interface states in a heterostructure containing TIs [1]. Directly accessing these interface states is, however, challenging. We propose that a transport measurement on a gated double junction sandwich device yields critical information about the topological interface states. We show that the conductance oscillations as a function of the gating potential can be used to extract the Fermi velocity and other parameters characterizing their dispersion. Crucially, these results are only weakly dependent on the boundary conditions at the lateral sandwich junctions. We discuss relevance of our results to proposed applications of TIs in functional devices.

*Supported in part by NSF via DMR Grant 1410741

12:27PM S03.00007: Tunable skyrmion-skyrmion interactions on the surface of a three dimensional topological insulator*  KUNAL TIWARI (Presenter), JULIETTE LAVOIE, WILLIAM COISH, TAMI PEREG-BARNEA, Department of Physics, McGill University — The surface of a three-dimensional topological insulator is characterized by a gapless two-dimensional Dirac cone dispersion. In a magnetic topological insulator, this surface dispersion is gapped by a Zeeman term proportional to the local magnetization. Magnetic skyrmions—stable, low energy excitations in chiral planar magnetic systems—lead to sign changes in this Zeeman term and, consequently, topologically protected bound states. It has been shown previously [1] that magnetic skyrmions on the surface of a topological insulator may result in a discrete set of localized orbitals—skyrmion bound states. We study the skyrmion-skyrmion interaction mediated by the hybridization of these orbitals. In particular, we consider the effective interaction between a pair of skyrmions in the presence of their hybridized orbitals. We show that the skyrmions form a bound state for high chemical potential. For low chemical potential their interaction is strictly repulsive. For intermediate chemical potential, both the bound and the unbound configurations locally minimize the free energy. We support our phenomenological theory with numerical calculations.

12:39PM S03.00008: Strain-driven topological phase transitions and tunable topological states in the Bi2Se3 family.*  HUGO ARAMBERRI (Presenter), M. CARMEN MUÑOZ, Instituto de Ciencia de Materiales de Madrid, ICMM-CSIC — Strain allows for a controlled manipulation of the topological order and Dirac states in three-dimensional Bi-chalcogenide topological insulators. Based on ab-initio density functional methods, we predict a universal phase diagram for the Bi2Se3 family. Under elastic strain these compounds present metallic, topological and trivial insulating phases. Furthermore, by strain engineering we built realistic topological homojunctions (THs) in Bi2Se3. We show how the topological interface states arising in such THs can be reversibly tuned along with their electron doping, spatial localization and mutual interaction. A TH contains the simplest topological interface, and hence constitutes the ‘Hydrogen atom’ of topological states of matter. Our findings show a route to tune the topological states within the field of straintronics.

**12:51PM S03.00009: Closing the surface bandgap in thin Bi$_2$Se$_3$/graphene heterostructures**  

JIMIN CHAE (Presenter), Department of Physics, Yonsei University, SEOUNG-HUN KANG, Korea Institute for Advanced Study, SANG HAN PARK, Pohang Accelerator Laboratory, HANBUM PARK, KWANGSIK JEONG, TAE-HYEON KIM, SEOK-BO HONG, KEUN SU KIM, Department of Physics, Yonsei University, YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung-Hee University, JWONG WON KIM, Division of Industrial Metrology, Korea Research Institute of Standards and Science, MANN-HO CHO, Department of Physics, Yonsei University — Topological insulator (TI), a band insulator with topologically protected edge states, is one of the most interesting materials in the field of condensed matter. For application, suppression of the bulk effect is crucial, but in ultrathin TI materials, with thicknesses less than 3 QL, the surface band has a finite bandgap because of the hybridization between the top and bottom surface states. Here, we studied the gapless top surface Dirac state of strained 3 QL Bi$_2$Se$_3$/graphene heterostructures. A strain caused by the graphene layer reduces the bandgap of surface states, and the band bending resulting from the charge transfer at the Bi$_2$Se$_3$/graphene interface induces localization of surface states to each top and bottom layer to suppress the overlap of the two surface states. In addition, we verified the independent transport channel of the top surface Dirac state in Bi$_2$Se$_3$/graphene heterostructures by measuring the magneto-conductance. Our findings suggest that the strain and the proximity effect in TI/non-TI heterostructures may be feasible ways to engineer the topological surface states beyond the physical and topological thickness limit.

**1:03PM S03.00010: Surface states of topological crystalline insulators**  

ESLAM KHALAF (Presenter), SHANG LIU, Department of Physics, Harvard University, HOI CHUN PO, Department of Physics, Massachusetts institute of Technology, HARUKI WATANABE, Department of Applied Physics, University of Tokyo, ASHVIN VISHWANATH, Department of Physics, Harvard University — We study topological crystalline insulator (TCI) phases hosting anomalous surface states. These include traditional surface states with two-dimensional Dirac dispersion as well as one-dimensional hinge modes characteristic of higher-order phases. Both of these can be captured by analyzing a general surface theory with multiple flavors of Dirac fermions and identifying global symmetry obstructions to achieving a fully gapped surface. This method is used to obtain a full classification of TCIs protected by time-reversal symmetry in the presence of strong spin-orbit coupling in the 230 space groups as well as TCIs protected by inversion in the ten different Altland-Zirnbauer symmetry classes. Furthermore, we establish a correspondence between the existence of surface states in a TCI and the existence of a stable (rather than fragile) obstruction to finding a basis of symmetric localized Wannier functions. Finally, we discuss possible extension of the results to magnetic space groups.

**1:15PM S03.00011: THz spectroscopy of ultralow carrier density topological insulator thin films**  

DIPANJAN CHAUDHURI (Presenter), Johns Hopkins University, MARYAM SALEHI, Rutgers, the State University of New Jersey, MINTU MONDAL, Johns Hopkins University, JISOO MOON, DEEPTI JAIN, SEONGSHIK OH, Rutgers, the State University of New Jersey, PETER ARMITAGE, Johns Hopkins University — Sb$_2$Te$_3$ is one of the earliest known examples of a 3D topological insulator with a single Dirac cone on the surface. Pure Sb$_2$Te$_3$ is generally p-doped with the Fermi level embedded in the bulk valence band which makes it challenging to study surface state dynamics through transport and optical measurements. Only recently, bulk insulating Sb$_2$Te$_3$ thin films have been grown using molecular beam epitaxy via chemical doping and buffer layer engineering. In addition, the carrier densities in these films are exceptionally low, nearly an order of magnitude lower than the best results obtained in Bi$_2$Se$_3$. Here we report the magneto-optical response of regular and bulk insulating (p-type and n-type) Sb$_2$Te$_3$ films at THz frequencies using time-domain polarimetry. While undoped, bulk conducting samples exhibit usual semiclassical behaviour, the bulk insulating samples show unusual optical properties and quantized response in presence of magnetic fields.
and temperature ($T$) using high-quality Bi$_{2-x}$Sb$_x$Te$_{3-y}$Sey single crystal thin films. Integrals of the Berry curvature. In this presentation, we consider what happens to the glide-Z$_2$ invariant, when the combination of the glide-Z$_2$ invariant and the Chern number. From the irreducible representations at high-symmetric points in this case, we can only know possible combinations of the glide-Z$_2$ invariant and the Chern number. Moreover, we show that in both cases the Z$_4$ strong topological invariant for inversion symmetric systems is directly related to the glide-Z$_2$ invariant and the Chern number. Finally, we also investigate topological invariants for glide-symmetric systems with nonprimitive lattice with and without inversion symmetry.

Thursday, March 7, 2019 11:15 AM - 2:15 PM
11:15AM S04.00001: Entropy changes and caloric effects driven by charge transfer: Application to YbInCu₄*
NILSON DE OLIVEIRA (Presenter), Instituto de Física, Universidade do Estado do Rio de Janeiro, AMÓS TROPER, Centro Brasileiro de Pesquisas Físicas — In this work, we propose a new physical mechanism based on charge transfer to produce large entropy and caloric effects even in non magnetic solid materials. In order to carry out the calculations, we use a two subband model in which a strongly correlated narrow band is coupled with a wide conduction electrons band. In the model, the charge transfer is controlled by the energy bandwidth and the hybridization parameter. The entropy and the caloric functions are calculated using the standard relations [1].
We apply the model to YbInCu₄ which exhibits an itinerant behavior at low temperature and a local magnetic moment profile at temperatures larger than the valence temperature $T_V$ around 42 K [2]. Our theoretical results, show that YbInCu₄ presents a large entropy change around 42 K due to the charge transfer from the 4f band to the electron sea. Besides, the isothermal entropy change upon pressure variation exhibits sizeable values in a wide temperature range. This outstanding result, which needs experimental data to be confirmed, can be very important for solid state refrigerators tecnology.

*We acknowledge financial support from CNPq and FAPERJ

11:27AM S04.00002: High field magnetostriction and magnetization of uranium monoantimonide single crystals*
XIAOXIN DING (Presenter), KESHAV SHRESTHA, DANIEL ANTONIO, Idaho National Laboratory, FRANZISKA WEICKERT, NHMFL, FSU, MARCELO JAIME, NEIL HARRISON, MYRON B SALAMON, Los Alamos National Laboratory, TOMASZ DURAKIEWICZ, National Science Foundation, JAMES L SMITH, Los Alamos National Laboratory, KRZYSZTOF GOFRYK, Idaho National Laboratory — Uranium monoantimonide (USb) crystallizes in the cubic NaCl-type crystal structure and is known to order antiferromagnetically with a triple-k magnetic structure, with a wave vector $(1,0,0)$, below $T_N$ = 213 K. In addition, the extent of hybridization that occurs between the uranium's 5f electrons with conduction electrons and its role for magnetism is not fully understood. During the talk we will present results of our recent magnetization and magnetostriction measurements of high-quality single crystals of USb at pulsed magnetic fields up to 65 T. The magnetization measurements help us to reveal the energy scales that are important in USb. In addition, the magnetostriction measurements performed in wide temperature range provides better microscopic understanding of the spin-lattice coupling and its strength in this material. We will discuss implications of these results.

*Work supported by DOE's Early Career Research Program (K.G., K.S. and D.A.). High field measurements have been performed at the National High Magnetic Field Laboratory, which is supported by the National Science Foundation Cooperative Agreement No. DMR-1157490 and DMR-1644779 and the State of Florida.

11:39AM S04.00003: Pressure-Driven 5f Localized-Itinerant Transition and Valence Fluctuation in Californium
LI HUANG (Presenter), HAIYAN LU, Institute of Materials, China Academy of Engineering Physics — A combination of the density functional theory and the single-site dynamical mean-field theory is employed to study the pressure dependence of electronic structure for cubic phase californium. We predict that its 5f electrons could undergo an orbital-selective localized-itinerant transition under moderate pressure. The volume contraction causes remarkable charge redistribution and valence fluctuation behaviors, which are the driving forces of the divalent-trivalent transition. Additionally, we find that the angular momentum coupling mechanism is hardly affected by pressure. The 5f orbital occupancy is well described by the intermediate coupling scheme.
11:51AM S04.00004: Effective Coulomb interaction in actinides from linear response approach* RUIZHI QIU (Presenter), BINGYUN AO, LI HUANG, Institute of Materials, China Academy of Engineering Physics — The effective on-site Coulomb interaction (Hubbard $U$) between $5f$ electrons in actinide metals (Th-Cf) is calculated with the framework of density-functional theory (DFT) using linear response approach. The $U$ values seldom rely on the exchange-correlation functional, spin-orbital coupling, and magnetic states, but depend on the lattice volume and actinide element. Along the actinide series, the Coulomb parameter $U$ of α-phase first decreases slowly, followed by a jump in the vicinity of Pu and then a monotonous increase. For light actinides, the lattice volume has a sizeable influence on $U$ while the localization of $5f$ electrons is almost constant. But for transplutonium metals, $U$ is almost independent of the lattice volume but the electronic localization increases rapidly. The calculated lattice parameters from DFT+$U$ with the Coulomb parameters as input are in better agreement with the experimental values than those from DFT within local density approximation or Perdew-Burke-Ernzerhof approximation for solids (PBEsol). In particular, the agreement between PBEsol+$U$ and experiment is remarkable.

*We would like to acknowledge the financial support from the Science Challenge Project of China (Grant No. TZ2016004), NSFC (Grant No. 21771167), and the CAEP project (Grant No. TCGH0708).

12:03PM S04.00005: Unifying DFT+$U$ approach for plutonium modeling BORIS DORADO, BERNARD AMADON, MARC TORRENT (Presenter), FRANCOIS BOTTIN, JOHANN BOUCHET, CEA, DAM, DIF — The theoretical description of the plutonium phase diagram still represents a major challenge to modern electronic structure methods. For the δ phase, a comprehensive knowledge has gradually been building up and the correct description of spectroscopic, magnetic, structural properties could be obtained using the DMFT approach. Effective Coulomb interactions in Pu were calculated very recently with DMFT and were found to be around 1 eV, which is much smaller than the "commonly accepted value" of 4 eV. It was also shown that the Hunds exchange, together with the spin-orbit coupling, yields an improved description of all phases, thus opening the way to a unifying theory of Pu.

In the present study, we investigate the influence of these weaker electron correlations on the ground state properties of the α, δ and ε phases of Pu, calculated with DFT+$U$ (GGA), which is a static approximation of the DMFT. We first show that the GGA+$U$+SOC and DMFT approaches yield similar structural properties. This allows us to use the "more simple" DFT+$U$ approximation instead of the "expensive" DMFT to perform ab initio molecular dynamics calculations and extract temperature-dependent phonon spectra. GGA+$U$+SOC approximation allows for an improved description of all phases of Pu at high temperature.

12:15PM S04.00006: Crystal structure and thermal stability of uranium nitride* XIAOFANG WANG (Presenter), RUILONG YANG, QIFA PAN, YIN HU, KEZHAO LIU, Institute of Materials, China Academy of Engineering Physics — Uranium nitrides are among the most promising fuels for Generation IV nuclear reactors, but until now, very little has been known about their thermal stability properties under nonequilibrium conditions. In this work, thermal decomposition of nitrogen-rich uranium nitride (denoted as UN$_{2-x}$) under ultrahigh-vacuum (UHV) conditions was investigated by thermal desorption spectroscopy (TDS). It has been shown that the nitrogen TDS spectrum consists of two peaks at about 723 and 1038 K. The X-ray diffraction, scanning electron microscopy, and X-ray photoelectron microscopy results indicate that UN$_{2-x}$ (UN$_2$ phase) decomposed into the α-U$_2$N$_3$ phase in the first step and the α-U$_2$N$_3$ phase decomposed into the UN phase in the second step. Further studies are needed to fully understand the thermal decomposition kinetics of the UN$_{2-x}$ film, and work is in progress.

*The work was supported by NSAF (Grant U1630250)

12:27PM S04.00007: Plutonium in high magnetic fields.* MARK WARTENBE (Presenter), PAUL H TOBASH, MST-16, Los Alamos National Laboratory, NEIL HARRISON, JOHN SINGLETON, MPA-MAG, Los Alamos National Laboratory, LAUREL WINTER, JESSICA HEBERT, MST-16, Los Alamos National Laboratory — High magnetic field studies of plutonium have been limited up until now. The complex behavior of plutonium's 5f electrons are thought to be responsible for the elements unusual behavior, making it possibly the strangest element in the periodic table. Here we review data from a new set of various experiments involving high magnetic field and extremes of temperature. High magnetic fields are especially effective in probing electronic states and is the highlighted method of this study. We present the data in the context of gaining in site into the 5f electrons physics of the material.

*LANL LDRD Program
Nuclear graphite, is a synthetic graphite typically manufactured by isostatic pressure moulding. It is used in the core structural components of the UK’s nuclear reactors. This material contains many interesting atomic and mesoscale features. Recent TEM imaging shows that in-plane boundaries between misaligned basal planes within the graphite crystallites occur. Our previous work describes this “crazy paving” structure, which consists of nearly perfect slabs of graphite laminae, with nearly parallel c-axis. These slabs range in size from 100-1000 nm, with a thickness of ~30 nm.

Dynamical MD simulations are performed using a recent ReaxFF potential fitting, as well as, the AIREBO potential model. A geometric relaxation method is used to construct these graphite “crazy paving” structures. The optimised structures show that the lowest energy interfaces comprise of 5, 6 and 7 carbon atom rings, with formation energies in the region of 0.5-1.0 eV.

The mechanical properties of these structures are investigated by performing MD simulations of nano-indentation and scratching. The simulated indenter tips are controlled by spring constraints, instead of a rigid moving surface, in order to more closely model the experimental procedure.

*EDF energy funded lectureship.

Graphite has been used for neutron moderation from the beginning of the nuclear reactor era. While research activities have abated over the years, there is renewed interest in graphite motivated by its use in Very High Temperature Reactors (VHTRs) and Molten Salt Reactors (MSRs). Retention of the activated fission products is paramount during normal operating and accident conditions, and a mechanistic understanding of the bonding and diffusion properties of fission products is imperative for predicting the release rates and designing appropriate barriers.

While the simulation, via Density Functional Theory, of the diffusion and adsorption of a number of elements on graphene has received some attention, to the best of our knowledge little work has been conducted on the bonding and diffusion properties of many elements in bulk graphite. We have performed high-accuracy DFT simulations of nuclear fission products on graphene and in bulk graphite using LDA, GGA and van der Waals exchange-correlation functionals. The bonding, structural and diffusive properties have been extracted. These simulations form a basis for the understanding of the diffusion and retention of such products in nuclear graphite.

*We would like to acknowledge the support of EPSRC grant number EP/R005745/1.

The family of actinide compounds \( AX \), where \( A = \text{actinides} \) and \( X = \text{N, P, As, Sb, S, Se, and Te} \) have drawn great interest in research of actinide compounds because of their simple structure and rich magnetic properties. Recent study of \( \text{UO}_2 \) and \( \text{UN} \) revealed the effectiveness in probing the magneto-structural coupling in actinides by high magnetic field magnetostriction. Uranium monosulfide (US) crystalizes in simple cubic rock salt structure and exhibits the highest ferromagnetic transition temperature in uranium monochalcogenides (\( T_C = 177 \text{ K} \)) with easy axis along [111] direction. At the magnetic phase transition the crystal structure undergoes a rhombohedral distortion along one of the [111] directions with a large magnetic anisotropy. This might imply that strong magneto-elastic interactions play important role in this material. In this talk, our recent measurements of the magnetostriction and magnetic torque of uranium monosulfide single crystals will be presented.

1:15PM S04.00011: Extreme Fermi surface smearing in a maximally disordered concentrated solid solution*  
STEPHEN DUGDALE (Presenter), HANNAH ROBARTS, THOMAS E MILLICHAMP, DANIEL A LAGOS, JUDE LAVEROCK, HH Wills Physics Laboratory, University of Bristol, United Kingdom, DAVID BILLINGTON, SPring-8, Japan Synchrotron Radiation Institute, Japan, JONATHAN DUFFY, DANIEL O’NEILL, Department of Physics, University of Warwick, United Kingdom, SEAN GIBLIN, School of Physics and Astronomy, Cardiff University, United Kingdom, JONATHAN TAYLOR, DMSC, European Spallation Source, Denmark, GRAZYNA KONTRYM-SZNAJD, MALGORZATA SAMSEL-CZEKALA, Institute of Low Temperature and Structure Research, Polish Academy of Science, Poland, HONGBIN BEI, SAI MU, GERMAN SAMOLOYUK, GEORGE MALCOLM STOCKS, Materials Science and Technology Division, Oak Ridge National Laboratory — The impact of extreme chemical disorder on the Fermi surface of the equiatomic alloy Ni0.25Fe0.25Co0.25Cr0.25 was probed by high-resolution X-ray Compton scattering. Such experiments probe the Fermi surface via the occupied momentum states, meaning that such measurements are ideally suited to revealing the electronic structure of such disordered alloys. The smearing of the Fermi surface is rather strong, reaching up to 40% of 2π/a, but nevertheless a Fermi surface can be clearly identified in the experimental data and the extent of the smearing and its variation on and across different sheets has been investigated. By connecting this smearing with the coherence length of the quasiparticle states, estimates of the electronic mean-free-path and residual resistivity have been made. It is found that the mean-free-paths are in the range 0.7 - 0.9 nm.

*The Compton scattering experiment was performed with the approval of the Japan Synchrotron Radiation Research Institute (JASRI, proposal no. 2016A1323). H.R. and D.A.L. gratefully acknowledge the financial support of the UK EPSRC (EP/L015544/1), and the National Secretariat of Higher Education, Science, Technology and Innovation of Ecuador (SENESCYT), respectively.

1:27PM S04.00012: Ballistic effects in squares and crosses of the ultra-pure delafossite PtCoO2*  
PHILIPPA MCGUINNESS (Presenter), ELINA ZHAKINA, VERONIKA SUNKO, MARKUS KOENIG, SEUNGHYUN KHIM, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids — The delafossite PtCoO2 is a layered oxide material with a single-band, hexagonal Fermi surface. This metal is extremely conductive, with a room temperature resistivity of 1.8 μOhmcm and a low-temperature mean free path of 5 μm [1]. Using focused ion beam microstructuring, we have created PtCoO2 square and cross devices which demonstrate strong ballistic behavior when their dimensions are similar to this mesoscopic length scale. These ballistic signals, in a weaker form, persist to structure sizes of at least 50 μm. Novel magnetoresistance effects, not observed in materials with circular Fermi surfaces, are also present within these devices, suggesting an influence of the hexagonal Fermi surface on ballistic transport.

*Max Planck Society, EPSRC studentships (grant number EP/L015110/1)

1:39PM S04.00013: Optical properties of the delafossite PdCoO2*  
CHRISTOPHER HOMES (Presenter), CMPMS, Brookhaven National Laboratory, Upton, New York, USA, SEUNGHYUN KHIM, ANDREW P. MACKENZIE, Chemical Physics of Solids, Max Planck Institute, Dresden, Germany — The delafossite PdCoO2 is remarkable for its extremely low in-plane residual resistivity at low temperature [1]. The in-plane optical properties have been determined over a wide frequency range at a variety of temperatures. At 295 K the reflectance of this material is extremely high (>99%) before encountering a sharp plasma edge at ~ 6000 cm⁻¹, above which it decreases rapidly. The real part of the optical conductivity reveals that the free-carrier (intraband) response falls well below the interband excitations, allowing the plasma frequency to be determined from the f-sum rule, ω_p ~ 33500 cm⁻¹; this value is in good agreement with first principle results. The Drude model for the optical properties of a metal may be used to estimate the free-carrier scattering rate, 1/τ ~ 80 cm⁻¹ at 5 K, which is well above the transport estimate of 1/τ < 0.2 cm⁻¹; this suggests that the scattering rate is strongly renormalized with frequency, and that the optical value is an average of these scattering rates. Structure is observed in the region of the expected infrared-active modes; however, the location and strength of these features suggests that some are not simple vibrations.

*Supported by DOE-BES under DE-SC0012704.
1:51PM S04.00014: Controlled introduction of defects to delafossite metals by electron irradiation* VERONIKA SUNKO, PHILIPPA MCGUINNESS, ELINA ZHAKINA, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, MARCIN KONCZYKOWSKI, JÉRÉMIE LEFEVRE, Laboratoire des Solides Irradiés, Ecole Polytechnique, Palaiseau, France, JÖRG SICHELSCHMIDT, ANDREW MACKENZIE (Presenter), Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — The delafossite metals PdCoO$_2$ and PtCoO$_2$ are among the highest conductivity materials known. At room temperature the mean free path is at least twice as long as those of silver or copper, and at low temperature mean free paths of tens of microns are observed in as-grown single crystals, enabling searches for unusual regimes of ballistic and hydrodynamic electrical transport. In parallel with that class of experiments, we wish to understand the microscopic mechanisms for the existence of these extraordinary mean free paths. Somewhat paradoxically, one route to obtaining more insight is to deliberately introduce point defects and study their effect on the electrical transport properties. We report on a systematic study in which both bulk single crystals and focused ion beam sculpted mesostructures are irradiated with 0.8 - 2.5 MeV electrons and their transport properties studied both in- and ex-situ.

*Max Planck Society, EMIR Network and UK EPSRC through grant EP/L015110/1

2:03PM S04.00015: Local Analysis of Disorder Driven Insulator-to-Metal Transition in the 2D Mott-Hubbard Model. JOSEPH SZABO (Presenter), KYUNGMIN LEE, NANDINI TRIVEDI, Ohio State University, JARED O’NEAL, Mathematics and Computer Science Division, Argonne National Laboratory — We show that increasing the number of disordered sites drives an insulator-to-metal transition in 2D Mott-Hubbard insulator. In our numerical approach we treat the spatial disorder exactly and use real-space Hartree-Fock mean-field decomposition for electron-electron interactions. These numerical methods provide insight into the localization physics as it relates to the interplay between disorder and interactions. Our results reveal an asymmetric closing of the Mott-gap and formation of a pseudogap in the density of states arising from inhomogeneous disorder potential mediated screening of the Hubbard interaction. Global lattice transport properties exhibit a transition from an insulating, gapped optical conductivity to an ungapped, metallic phase. A local picture consisting of magnetic order, compressibility, and charge mobility evolves toward a paramagnetic, metallic state with increasing disorder number due to correlations with regions of greater effective disorder. We present these local measurements to explain and provide avenues to characterize disorder induced transitions in ongoing experimental efforts.

Session S05 DMP: Topological Superconductivity: Nanowires BCEC 108 - Anushya Chandran, Boston University - Tag(s): Focus

11:15AM S05.00001: Surface superconductivity in gold – a material platform for Majorana bound states* [Invited] PENG WEI (Presenter), University of California, Riverside, SUJIT MANNA, Physics, Massachusetts Institute of Technology, MARIUS EICH, Solid State Physics Laboratory, ETH Zurich, PATRICK LEE, Physics, Massachusetts Institute of Technology, JAGADEESH MOODERA, Department of Physics, Plasma Science and Fusion Center, and Francis Bitter Magnet Lab, Massachusetts Institute of Technology — Proximity effect in multilayer heterostructures allows the creation of new quasiparticles with mixed physical characters. In particular, it may lead to the emergence of Majorana bound states (MBS) by mixing superconductivity, ferromagnetism, and spin-orbit coupling at material interfaces. Inducing superconductivity and magnetic exchange interactions in well-defined Shockley surface states (SS) of high quality ultrathin Au(111) layers has been predicted as an excellent platform for MBS [1]. In this talk, I will first present our device based heterostructure platform for creating and investigating such hybrid superconducting states in Au(111) [2]. By means of electron tunneling spectroscopy, I will demonstrate signatures of superconductivity induced in the two-dimensional SS of Au(111) thin film, as well as the behavior of such superconducting state under a planar Zeeman field. Unlike conventional proximity effects, the induced superconductivity in SS that are physically separated from a bulk superconductor may be governed by indirect quasiparticle scattering processes, which would further allow the manipulations of SS for MBS. Our results on planar tunneling devices made of scalable nanowires fabricated from such Au(111) heterostructures will be discussed.

*The work is supported by John Templeton Foundation Grant No. 39944, ONR Grant N00014-16-1-2657 and NSF (DMR 1700137). Peng Wei acknowledges the funding support from UCR.
11:51AM S05.00002: Backbones of a Topological Qubit – High Quality Selective-Area Grown InSb Nanowire Networks using MBE* GUANZHONG WANG (Presenter), PAVEL ASEEV, LUCA BINCI, AMRITA SINGH, LIEUWE STEK, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, FRENK BOEKHOUT, Netherlands Organisation for Applied Scientific Research (TNO), SENJA RAMAKERS, JIE SHEN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, JOHN WATSON, LEO P KOUWENHOVEN, GIJS DE LANGE, PHILIPPE CAROFF, Microsoft Quantum Delft — Nanowires (NW) made from III-V semiconductors are arguably the most mature platform for studying topological superconductivity and realizing Majorana bound states. So far progress on this front has been restricted to single NWs grown with conventional vapor-liquid-solid method. Although this growth mechanism is capable of producing free-standing NW crosses and hashtags, realization of more complex networks calls for an in-plane strategy to achieve new lithographically defined structures. Here, we implement such in-plane synthesis of InSb NW networks by selective area growth (SAG) using molecular-beam epitaxy (MBE). We perform structural and transport characterization to assess the crystal quality and electronic properties. The high quality of electron transport in InSb NWs and crosses are verified by both classical mobility and quantum transport measurements, with Hall mobility reaching 17,000 cm²/(V*s) and well-defined quantum point contact conductance plateaus at finite magnetic field. We also demonstrate phase coherent transport by studying Aharonov-Bohm interference in loops and induced superconductivity in an Al-covered sample. These results combined make InSb SAG a promising material platform for realizing a topological qubit.

*We acknowledge Microsoft for funding support.

12:03PM S05.00003: Demonstration of Majorana Fermion Pairs in Superconducting gold Surface States* SUJIT MANNA (Presenter), Massachusetts Institute of Technology, PENG WEI, Physics and Astronomy, UCR, YINGMING XIE, KAM TUEN LAW, Physics, HKUST, PATRICK LEE, JAGADEESH MOODERA, Massachusetts Institute of Technology — We present strong evidence for the emergence of Majorana bound states (MBS) in gold nanowires with proximitized superconductivity, as theoretically predicted. The interplay between superconductivity, spin-orbit coupling (SOC) and Zeeman field laid the foundation to realize MBS. We have experimentally achieved novel heterostructures, achieving these three interactions, and developed a unique method to fabricate such heterostructures into scalable nanowires. Using high-resolution scanning tunneling microscopy (STM) under in-plane magnetic field, we show that MBS appears in pairs at the opposite edges of a magnetic nanostructure on Au nanowire at 350 mK. Such spatially resolved pair of bound states, confirmed by further theoretical modeling, provides strong support for the observation of MBS in Au nanowire systems. It opens up the possibility for realizing MBS manipulations in stable and scalable metallic thin-film nanostructures, where strong SOC ensures much more robust MBS compared to other analogous semiconductor-based schemes.

12:15PM S05.00004: From Spintronics to Majorana Bound States* IGOR ZUTIC (Presenter), TONG ZHOU, Department of Physics, University at Buffalo, NARAYAN MOHANTA, Wayne State University, JONG E HAN, Department of Physics, University at Buffalo, ALEX MATOS ABIAGUE, Wayne State University — Magnetic textures, widely used to store information, can also provide synthetic spin-orbit coupling and confinement, supporting the creation of topologically nontrivial states, such as skyrmions and Majorana bound states (MBS) [1,2]. By a careful design of an array of magnetic nanopillars (MNPs), based on finite-element simulations, the resulting magnetic textures modify a proximity-induced superconductivity in the nearby 2D electron gas to form effective topological wires with MBS emerging at their ends [3]. Using spin-transfer torque, common to spintronics, to control magnetic textures [4], these topological wires can be reconfigured to implement fusion and braiding of MBS [2]. We show that a generalized topological condition for MBS formation [2] can also guide the understanding of the MBS evolution in realistic MNP arrays [3].

12:27PM S05.00005: Interacting Shiba States on Proximitized Superconducting Surface of Bi

YUWEN HU (Presenter), HAO DING, MALLIKA RANDERIA, ALI YAZDANI, Princeton University — Magnetic atoms on the surface of a superconductor induce in-gap Shiba states that can be hybridized to create a topological superconducting phase when placed in one-dimensional chains, with Majorana zero modes localized at their ends [1,2]. We have performed measurements of magnetic adatoms deposited on the surface of epitaxially grown Bi(110) thin films on a superconducting Nb(110) surface using a dilution refrigerator scanning tunneling microscope (STM). Our spectroscopic measurements show the Bi surface to exhibit a hard superconducting gap of 1.6 meV and the presence of Shiba states near magnetic adatoms. Using atomic manipulation techniques with the STM, we have built dimers of magnetic atoms with varying distance and geometry and detected the hybridization of individual in-gap states into “Shiba molecules”. We will report on these results and our efforts to build chains of magnetic atoms on the surface of superconducting Bi. The strong spin-orbit coupling and the large induced superconducting gap by the Nb substrate make this Bi surface an attractive platform for creation of atomic chains that host Majorana zero modes.

*We acknowledge funding from ONR, Moore foundation, NSF-DMR, and NSF-MRSEC.

12:39PM S05.00006: De-localized states in three-terminal InSb nanowire devices

PENG YU (Presenter), JUN CHEN, University of Pittsburgh, MOIRA HOCEVAR, Institut Néel CNRS, GHADA BADAwy, SASA GAZIBEGovic, ROY OP HET VELD, Eindhoven University of Technology, SEBASTIEN PLISSARD, LAAS CNRS, ERIK P. A. M. BAKKERS, Eindhoven University of Technology, SERGEY M FROLOV, University of Pittsburgh — Majorana bound states (MBS) has been predicted to emerge in 1D nanowire with induced superconductivity, spin-orbital coupling and external magnetic field. Although zero bias peak (ZBP) has been observed in different systems for years, no tunneling spectroscopy has verified the existence of the two Majorana bound states that should appear at the boundaries of the topological regime. We fabricated three-terminal devices with 400nm long superconducting contact in the middle and de-localized states have been observed from two sides measured simultaneously. On the contrary of the regime where the ZBP usually be observed in two terminal devices, those de-localized states appear in more open regime with more subbands available. Ongoing measurements will be dedicated to answer whether ZBP could appear in that regime and be observed from two sides.

12:51PM S05.00007: Flux-induced Majorana modes in full-shell nanowires

SAULIUS VAITIEKENAS (Presenter), MINGTANG DENG, PETER KROGSTRUP, CHARLES M MARCUS, Center for Quantum Devices and Microsoft Quantum Lab-- Copenhagen, Niels Bohr Institute, University of Copenhagen — We demonstrate a novel means of creating Majorana zero modes using magnetic flux applied to a full superconducting shell surrounding a semiconducting nanowire core, unifying approaches based on proximitized nanowires and vortices in topological superconductors. In the destructive Little-Parks regime, reentrant regions of superconductivity are associated with an integer number of phase windings in the shell. Tunneling into the core reveals a hard induced gap near zero applied flux, corresponding to zero phase winding, and a gapped region with a discrete zero-energy state for flux around $\Phi_0 = \hbar/2e$, corresponding to $2\pi$ phase winding. Coulomb peak spacing in full-shell islands around one applied flux shows exponentially decreasing deviation from $1e$ periodicity with device length, consistent with the picture of Majorana modes located at the ends of the wire.

1:03PM S05.00008: Advanced hybrid InSb/Al nanowires devices for topological parity readout (Part 2)* SEBASTIAN HEEDT (Presenter), Delft University of Technology, MARINA QUINTERO PEREZ, Microsoft Station Q at Delft University of Technology, FRANCESCO BORSOI, Delft University of Technology, ALEXANDRA FURSINA, Microsoft Station Q at Delft University of Technology, NICK VAN LOO, JIE SHEN, CHIEN-AN WANG, Delft University of Technology, KEVIN VAN HOOGDALEM, Microsoft Station Q at Delft University of Technology, BADAWY GHADA, SASA GAZIBEGOVIC, ERIK P. A. M. BAKKERS, Eindhoven University of Technology, LEO P KOUWENHOVEN, Microsoft Station Q at Delft University of Technology — Majorana bound states (MBS) are expected to enable topological qubits that encode quantum information with particularly long coherence times. The qubit state is stored non-locally in the fermion parity of multiple pairs of MBS hosted on a semiconducting-superconducting charge island. Interferometric readout of these qubits requires phase-coherent loops that comprise high-mobility InSb nanowires and Al to enable proximity-induced superconductivity in the semiconductor. Here, we introduce a fundamentally new approach for the realization of these hybrid devices based on a novel technique for the selective deposition of the Al thin films. We combine this technique with atomic hydrogen cleaning of the nanowires to remove native oxide prior to the Al deposition. The induced superconductivity in the nanowires is demonstrated via voltage-bias spectroscopy and by probing the critical currents in InSb Josephson junctions. Moreover, Cooper pair tunneling is studied in mesoscopic InSb/Al islands and parity transitions are investigated as a function of the applied magnetic field. Finally, advanced circuits are introduced that allow to study basic elements of the prospective topological qubit.

*European Research Council, Dutch Organization for Scientific Research, and Microsoft Corp. Station Q

1:15PM S05.00009: Quantum-Transport in Semiconductor Nanowire Josephson Junctions PRAVEEN SRIRAM (Presenter), SANDESH S KALANTRE, Electrical Engineering, Indian Institute of Technology Bombay, KAVEH GHARAVI, JONATHAN D BAUGH, Institute for Quantum Computing, University of Waterloo, BHASKARAN MURALIDHARAN, Electrical Engineering, Indian Institute of Technology Bombay — Semiconductor nanowire-superconductor hybrid systems provide a promising platform for hosting unpaired Majorana fermions and thus realizing fault-tolerant topological qubits. In this study, we employ the Non-Equilibrium Green’s Function (NEGF) Formalism to model quantum transport in normal (N)-superconductor(S) junctions. We analyze Josephson junctions based on semiconductor nanowires and derive the Andreev bound state spectrum and current-phase relations. Recently, [1], and [2] have reported oscillations in the critical supercurrent with an axial magnetic field. Our simulations indicate that this phenomenon arises from the interference of orbital angular momentum modes of the cylindrical nanowire. We add disorder and study its effect on the critical current oscillations, with an aim to gain a thoroughgoing understanding of the experiments.

1:27PM S05.00010: Hysteresis from Nonlinear Dynamics of Majorana Zero Modes in Topological Josephson Junctions JIA-JIN FENG, School of Physics, Sun Yat-sen University, ZHAO HUANG, Department of Physics, The University of Houston, ZHI WANG (Presenter), School of Physics, Sun Yat-sen University, QIAN NIU, Department of Physics, The University of Texas at Austin — We reveal that topological Josephson junctions provide a natural platform for the interplay between the Josephson effect and the Landau-Zener effect through a two-level system formed by coupled Majorana modes. We build a quantum resistively shunted (RSJ) junction model by modifying the standard textbook RSJ model to take account of the two-level system from the Majorana modes at the junction. We show that the dynamics of the two-level system is governed by a nonlinear Schroedinger equation and solve the equations analytically via a mapping to a classical dynamical problem. This nonlinear dynamics leads to hysteresis in the I-V characteristics, which can give a quantitative explanation to recent experiments. We also predict coexistence of two interference patterns with periods h/e and h/2e in topological superconducting quantum interference devices.
1:39PM S05.00011: Current-Controlled Majorana Bound States in Hybrid Semiconductor-Superconductor Nanowires Deposited on Magnetic Stripe Domains*  
NARAYAN MOHANTA (Presenter), Department of Physics and Astronomy, Wayne State University, TONG ZHOU, JONG E HAN, Department of Physics, State University of New York at Buffalo, ANDREW D KENT, JAVAD SHABANI, Department of Physics, New York University, IGOR ZUTIC, Department of Physics, State University of New York at Buffalo, ALEX MATOS ABIAGUE, Department of Physics and Astronomy, Wayne State University — The fringing fields created by magnetic stripes formed in magnetic films [1] generate inhomogeneous magnetic textures on length scales as large as 2 microns. A hybrid semiconductor-superconductor nanowire deposited on the top of a magnetic film in the stripe phase experiences a large synthetic spin-orbit coupling resulting from the fringing fields [2] of the striped domains. We show that such a system can support the formation of Majorana bound states (MBS) localized at the ends of the wire. We investigate the transition to the topological superconducting phase as a function of the stripes size and orientation, which can be tuned by applying a charge current through the magnetic film. This produces changes in the fringing magnetic texture acting on the nanowire and eventually leads to a topological phase transition with the corresponding emergence or destruction of MBS [2]. The proposed platform is promising for electrically tuning MBS in a non-invasive way and without the need for external magnetic fields.

1:51PM S05.00012: Quantized zero bias conductance plateaus in hybrid nanowire topological quantum information processing platforms without non-Abelian Majorana zero modes*  
CHRISTOPHER MOORE (Presenter), CHUANCHANG ZENG, Clemson University, TUDOR DAN STANESCU, Department of Physics and Astronomy, West Virginia University, SUMANTA TEWARI, Clemson University — Braiding operations in topological quantum computations inherently rely on the spatial separation between Majorana bound states (MBSs), as a result a method of distinguishing between these quasi-Majorana states and true Majorana zero modes (MZMs), localized at the ends of a semiconductor-superconductor (SM-SC) nanowire, is essential in the creation of a topological quantum bit. Here we show that recently observed, 2e^2/h-quantized zero-bias conductance plateaus, may arise in SM-SC nanowires due to the presence of quasi-Majorana states, for which the constituent MBSs are specially separated on the order of the Majorana decay length. Because these quasi-Majoranas form rather generically within the topologically trivial regime, our results establish that the observation of 2e^2/h-quantized zero-bias conductance plateaus does not represent sufficient evidence of the existence of non-Abelian MZMs localized at the opposite ends of a wire. Thus, we conclude that localized charge tunneling measurements, so far considered the primary probe for the existence of MZMs, have exhausted their potential to reveal useful information in distinguishing MZMs from low energy Andreev bound states within SM-SC hybrid structures.

*ARO Grant No. W911NF-16-1-0182

2:03PM S05.00013: Onset of the 4π-periodic Josephson effect and dissipative response at the Majorana phase transition in a semiconducting nanowire junction*  
CHAITANYA MURTHY (Presenter), Physics, UCSB, BERNARD VAN HECK, Microsoft Station Q, UCSB, LEONID GLAZMAN, Physics, Yale University, CHETAN NAYAK, Microsoft Station Q, UCSB — We study the appearance of the 4π-periodicity of the Josephson energy in a single-channel semiconducting nanowire junction much shorter than the coherence length. We compute analytically the Josephson energy of the junction as a function of magnetic field, taking into account the contributions of both discrete and continuous spectrum. We show that, in the limit of perfect transmission, the spectrum of the junction is gapless for a finite range of phase difference and a finite range of magnetic fields on the topological side of the transition. We also study the finite-frequency admittance of the junction, paying particular attention to the critical regime. We show that the expected critical behavior near the phase transition only appears in the current-current correlation function at sub-leading order in the ratio of the induced superconducting gap to the spin-orbit energy, a fact that can be understood within the critical theory of a helical, neutral Majorana mode.

Session S06 DCMP: Quantum Criticality: Theory BCEC 109A - Zhen Bi, Massachusetts Institute of Technology
11:15AM S06.00001: Instabilities of 2d quantum critical metals in the $N_f \to 0$ limit

Petter Säterskog (Presenter), Nordic Institute for Theoretical Physics — We study a Fermi surface coupled to fluctuations of one or more critical order parameters in 1+2 dimensions. The limit of vanishing fermion flavor number gives a controlled way of studying this strongly coupled theory. In this talk I show results for charge, spin and pairing susceptibilities and find that the critical fluctuations may induce charge/spin density wave order or pairing depending on the types of critical order parameter fluctuations and their interplay.

*This work was support by the grant "Exact Results in Gauge and String Theories" from the Knut and Alice Wallenberg foundation.

11:27AM S06.00002: Itinerant Quantum Critical Point with Fermion Pockets and Hot Spots

Zihong Liu (Presenter), Gaopei Pan, Chinese Academy of Sciences, Xiao Yan Xu, Department of Physics, Hong Kong University of Science and Technology, Kai Sun, Department of Physics, University of Michigan, Zi Yang Meng, Chinese Academy of Sciences — Combining determinantal quantum Monte Carlo (DQMC) and elective momentum ultra-size quantum Monte Carlo (EQMC) methods, we systematically investigated the itinerant quantum critical point on a 2D square lattice with antiferromagnetic spin fluctuations at wavevector $Q = (\pi, \pi)$. System sizes of $60 \times 60 \times 320$ ($L \times L \times L_t$) are comfortably accessed, and the quantum critical scaling behaviors are revealed with unprecedented high precision. We found that the antiferromagnetic spin fluctuations introduce effective interactions among fermions and the fermions in return render the bare bosonic critical point into a new universality, different from the bare Ising universality class and the Hertz-Mills-Moriya RPA prediction. At the quantum critical point, a finite anomalous dimension $\eta \sim 0.125$ is observed in the bosonic propagator, and fermions at hot spots evolve into a non-Fermi-liquid. In the antiferromagnetically ordered metallic phase, fermion pockets are formed as energy gap opens up at the hot spots.

11:39AM S06.00003: Emergent O(4) Symmetry and Conserved Current Continuum at a Deconfined Quantum Critical Point in Shastry-Sutherland Model

Jong Yeon Lee (Presenter), Harvard University, Yizhuang You, Physics, University of California, San Diego, Ashvin Vishwanath, Harvard University — In this work, we investigate a possibility of deconfined quantum phase transition in the two dimensional Shastry-Sutherland spin model. Using the level-crossing technique for correlation length spectrum in the infinite DMRG simulation, we demonstrate the evidence for a deconfinement and emergent O(4) symmetry at the phase transition between the plaquette valence bond solid and Neel order. Such a phase transition has been observed in the recent experiment, and we propose experimental signatures for this deconfined quantum criticality that can be measured in both phonon and magnon spectra.

11:51AM S06.00004: Quantum criticality in Ising chains with random hyperuniform couplings

Philip Crowley (Presenter), Christopher Laumann, Boston University, Sarang Gopalakrishnan, CUNY College of Staten Island; The Graduate Center, CUNY — In critical Ising chains, independent random disorder localises almost all excitations, and drives the system to an infinite randomness critical point. However, correlations in the disorder can change the universality, and even make the disorder irrelevant.

We show this in the critical hyperuniform random Ising chain, where increasing hyperuniformity yields a line of Griffiths-free infinite-randomness critical points with continuously varying exponents, this line terminates at the Ising class “critical Ising insulator”.

12:03PM S06.00005: Deconfined quantum criticality from the $QED_3$-Gross-Neveu-Yukawa model: the $1/N$ expansion revisited

Rufus Boyack (Presenter), Ahmed Rayyan, Joseph Maciejko, Physics, University of Alberta — Quantum phase transitions involving dynamical gauge fields are an important class of transitions beyond the standard Landau-Ginzburg-Wilson paradigm. Two subcategories are those where (i) the gauge field deconfines only at the critical point itself, and (ii) the gauge field deconfines in one of the phases separated by the critical point. The latter subcategory is exemplified by the $QED_3$-Gross-Neveu-Yukawa (GNY) model in which there has been great interest recently due to a conjecture relating its critical point to the Néel-to-valence-bond-solid (VBS) deconfined critical point in the first subcategory. Motivated by this, we use the $1/N$ expansion to study the $QED_3$-GNY model in fixed three spacetime dimensions, with $N$ flavors of two-component Dirac fermions. We find new contributions to critical exponents arising from Aslamazov-Larkin diagrams missed by previous epsilon- and $1/N$-expansion studies in arbitrary dimensions. For the specific case of $N = 2$, when the duality is conjectured to hold, we find that the bosonic anomalous dimension and adjoint fermion bilinear scaling dimension are in reasonable agreement with numerical studies of the Néel-to-VBS transition.
12:15PM S06.00006: Dynamical spin susceptibility of a Fermi liquid without conservation law  
PRACHI SHARMA (Presenter), DMITRII MASLOV, University of Florida — Galilean invariance along with the conservation of charge and total spin guarantees that the corresponding susceptibilities vanish at an infinitely long wavelength (q=0) and finite frequency. But the susceptibility of nematic fluctuations or that of spin fluctuations in the presence of spin-orbit interaction (SOI) is not protected by any conservation laws and hence leads to finite spectral weight outside the particle-hole continuum even at q=0 and finite \( \omega \) [1,2]. Finite width of the chiral spin modes for a Fermi liquid (FL) with Rashba SOI was studied at q=0 by Maiti and Maslov [3]. Here, we study the effect of residual interaction on the chiral spin modes of a FL with weak Rashba SOI for a model of dynamic screened Coulomb potential at finite q by going beyond the random phase approximation (RPA). We also study the interplay between the plasmon and chiral spin modes due to their coupling for the non-RPA corrections.

12:27PM S06.00007: Critical strange metal from fluctuating gauge fields in a solvable random model*  
AAVISHKAR PATEL (Presenter), SUBIR SACHDEV, Harvard University — Building upon techniques employed in the construction of the Sachdev-Ye-Kitaev model, which is a solvable (0+ 1)-dimensional model of a non-Fermi liquid, we develop a solvable infinite-ranged random-hopping model of fermions coupled to fluctuating U (1) gauge fields. In a specific large-N limit, our model realizes a gapless non-Fermi-liquid phase, which combines the effects of hopping and interaction terms. We derive the thermodynamic properties of the non-Fermi-liquid phase realized by this model and the charge transport properties of an infinite-dimensional version with spatial structure. We also describe a Higgs transition from this non-Fermi-liquid "strange metal" phase to a weakly-interacting "pseudogap" phase with a relatively reduced low-energy fermion density of states, and gapped gauge field fluctuations.

12:39PM S06.00008: Fermion-induced quantum critical points in a generalized SU(N) fermion model  
BOHAI LI (Presenter), Tsinghua University, ZIXIANG LI, University of California, Berkeley, HONG YAO, Tsinghua University — The non-Landau quantum criticality dubbed as "fermion-induced quantum critical point" (FIQCP) was proposed in Ref. [1], where it was shown for 2D SU(N) Dirac fermions with Na2. Here we investigate the nature of quantum phase transition for case of N=1. Our sign-problem-free Majorana quantum Monte Carlo simulations show that, by introducing longer-range interactions, our model exhibits transitions among Dirac semimetals, CDW, and Kekule-VBS phases. This can further provide support for the critical value of N for the occurrence of FIQCP predicted by previous RG studies.

12:51PM S06.00009: Incommensurate 2k_F charge density wave quantum critical points in two-dimensional metals*  
MATTHIAS PUNK (Presenter), JOHANNES HALBINGER, DIMITRI PIMENOV, Ludwig Maximilian University of Munich — We study two-dimensional metals in the vicinity of a quantum critical point, where incommensurate 2k_F charge density wave (CDW) order develops. Starting from a model of two antipodal hot spots at the Fermi surface which are connected by a 2k_F wavevector, we perform a controlled, perturbative renormalization group analysis in the spirit of earlier work by Dalidovich and Lee [1]. We show that the charge density wave transition is indeed continuous and described by a non-Fermi liquid fixed point with a dynamically nested Fermi surface. Our results are potentially relevant to understand the onset of incommensurate CDW order in Cu_xTaS_2 and NbSe_2 at high pressure.

1:03PM S06.00010: Quantum criticality of a quantum nonlinear sigma model with Kondo coupling: a renormalization group study  
CHIA-CHUAN LIU (Presenter), QIMIAO SI, Rice University — Quantum criticality has been an active research topic in condensed matter physics, with a lot of effort being made into the heavy fermion material in which local moments are coupled with itinerant electrons through Kondo coupling [1]. From a theoretical perspective, the interplay between different kinds of degrees of freedom makes it challenging to develop a unified framework to study the quantum criticality of such systems [2]. Here we approach the problem from the magnetically ordered side, using a quantum non-linear sigma model with an additional coupling to itinerant fermions [3]. By treating the renormalization of the bosonic and fermionic degrees of freedom on an equal footing, we analyze the effect of the Kondo coupling on the criticality. Our results shed new light on the global phase diagram of the heavy fermion systems.

1:15PM S06.00011: Incoherent metal in the quantum critical region of SU(2) symmetric model*  
PETER CHA (Presenter), Cornell University, OLIVIER PARCOLLET, ANTOINE GEORGES, CCQ, Flatiron Institute, Simons Foundation, EUN-AH KIM, Cornell University — Incoherent metals have recently garnered much interest in their relation to quantum criticality, high-temperature superconductivity, quantum chaos, and holography. In this context, considerable recent interest has been devoted to the SYK model and its variants, as a paradigmatic model for metallic behaviour without quasiparticles.

With the aim at exploring the robustness of this physics beyond the large-N limit, we consider an SU(2) symmetric spin-1/2 model with disordered magnetic exchange and repulsive Hubbard local interaction, in the framework of dynamical mean-field theory. In the insulating regime, we recover the spin-glass and local moment phases of the spin-1/2 disordered Heisenberg Hamiltonian, while deep in the metallic regime we find Fermi liquid behaviour. We discuss the effect of the disordered spin coupling on the metal-insulator transition, and the presence of a quantum-critical non-Fermi liquid in the phase diagram.

1:27PM S06.00012: Deconfined Quantum Critical Points in 3+1D*  
ZHENG BI (Presenter), SENTHIL TODADRI, Massachusetts Institute of Technology — Continuous quantum phase transitions that are beyond the conventional paradigm of fluctuations of a symmetry breaking order parameter are challenging for theory. These phase transitions often involve emergent deconfined gauge fields at the critical points as demonstrated in 2+1D. Examples include phase transitions in quantum magnetism as well as those between Symmetry Protected Topological phases. In this work, we present several examples of Deconfined Quantum Critical Points between Symmetry Protected Topological phases in 3+1D for both bosonic and fermionic systems. These critical theories can be formulated as non-abelian gauge theories either in their Infra-Red free regime, or in the conformal window when they flow to the Banks-Zaks fixed points. We will talk about several interesting quantum critical phenomena. We describe situations in which the same phase transition allows for multiple universality classes controlled by distinct fixed points. We exhibit the possibility - which we dub “unnecessary quantum critical points” - of stable generic continuous phase transitions within the same phase.

1:39PM S06.00013: Quantum-critical conductivity of the Dirac fluid in graphene  
TAIRU LYU (Presenter), PATRICK R GALLAGHER, CHANSAN YANG, FENG WANG, University of California, Berkeley — Graphene near charge neutrality is expected to behave like a quantum-critical, relativistic plasma—the “Dirac fluid”—in which massless electrons and holes rapidly collide at a rate proportional to temperature. We measure the frequency-dependent optical conductivity of clean micron-scale graphene encapsulated in hexagonal Boron Nitride at electron temperatures between 77 and 300 K using on-chip terahertz spectroscopy. At charge neutrality, we observe the quantum-critical scattering rate characteristic of the Dirac fluid. At higher doping, we uncover two distinct current-carrying modes with zero and nonzero total momenta, a manifestation of relativistic hydrodynamics. Our work reveals the quantum criticality and unusual dynamic excitations near charge neutrality in graphene.
Emergent Spacetime Supersymmetry at Superconducting Quantum Criticality of a single Dirac Cone

ZIXIANG LI, Tsinghua University, ABOLHASSAN VAEZI, CHRISTIAN MENDL, Stanford University, HONG YAO (Presenter), Tsinghua University — No definitive evidence of spacetime supersymmetry (SUSY) that transmutes fermions into bosons and vice versa has been revealed in nature so far. Moreover, whether spacetime SUSY in 2+1 and higher dimensions can emerge in generic lattice microscopic models remains open. Here, we introduce a lattice realization of a single Dirac fermion in 2+1 dimensions with attractive interactions that preserves both time-reversal and chiral symmetries. By performing sign-problem-free determinant quantum Monte Carlo simulations, we show that the interacting single Dirac fermion in 2+1 dimensions features a superconducting quantum critical point (QCP). More remarkably, we demonstrate that the N=2 spacetime SUSY in 2+1D emerges at the superconducting QCP by showing that the fermions and bosons have identical anomalous dimensions 1/3, a hallmark of the emergent SUSY [1]. We further show some experimental signatures which may be measured to test such emergent SUSY in candidate systems such as the surface Dirac cone of 3D topological insulators.

Session S07 DCMP: Metal/Insulator and Superconductor/Insulator BCEC 109B - Nandini Trivedi, Ohio State University

11:15AM S07.00001: Spin and charge dynamics of an interacting gas of small (bi)polarons across the mobility edge
GAYAN HETTIARACHCHI (Presenter), Rutgers University, YOSHIFUMI NISHIDA, YUSUKE MASAKI, Osaka University, MOHD NAZLAN MOHD MUHID, HALIMATON HAMDAN, University of Technology Malaysia — We performed electron spin resonance (ESR) and optical studies on a model system that is used to investigate the discontinuous metal-insulator transition in a deformable lattice. The ESR signal below the mobility edge has no correlation to the conductivity and arises purely from a minority of magnetic polarons. Above the percolation threshold of the system and below the mobility edge, the intensity of the ESR signal shows a decrease suggesting that small polarons form paired states, i.e., small bipolarons, with increasing interactions. The conducting transition is marked by the appearance of an asymmetric ESR line shape simultaneously with a decrease in the small bipolaron optical absorption band. The delocalized states result from a partial dissociation of the small bipolarons. Immediately above the mobility edge, competing phases of delocalized (extended) states, small polarons, and small bipolarons coexist. Based on the experimental results, we propose a phase diagram that adds to the theoretical studies and highlight that the polaron density and local interactions are important parameters that determine the balance among competing states in a many-polaron system.

11:27AM S07.00002: Renormalization group analysis of superconductor-insulator transition with disorder
CHAO-JUNG LEE (Presenter), Caltech, MICHAEL C MULLIGAN, Physics and Astronomy, Univ of California - Riverside — A recent experiment [1] indicates the magnetic field-tuned superconductor-insulator transition (SIT) in thin films can exhibit particle-vortex self-dual electrical conductivity. With the aim of understanding this quantum critical behavior, we consider a manifestly self-dual theory consisting of a Dirac fermion coupled to a Chern-Simons gauge field [2] in the presence of quenched disorder. We derive renormalization group fixed points of this theory in the presence of disorder and gauge fluctuations, which are controlled in an expansion in the number of fermion flavors. We then discuss the quantum critical conductivity of these fixed points. This formalism can also be used to understand quantum Hall plateau transitions.

11:39AM S07.00003: New microscopic paradigms in the doped Fermi-Hubbard model
FABIAN GRUSDT (Presenter), ANNABELLE BOHRDT, MICHAEL KNAP, Physics Department, Technical University of Munich, EUGENE DEMLER, Physics Department, Harvard University — The interplay of mobile dopants with anti-ferromagnetic spin correlations is at the heart of high-temperature superconductivity. Here we present a microscopic trial wavefunction describing individual dopants as spinon-chargon composites. We derive the correlations of the charges with their spin environment and reveal short-range hidden string order, which manifests in genuine higher-order correlations developing around the dopants and can be directly observed in state-of-the-art quantum simulations. Our microscopic model explains the observations of string patterns and the dressing cloud of magnetic polarons in recent measurements performed with ultracold atoms in optical lattices. Our approach can be applied at finite doping and paves the way for a microscopic description of the exotic metallic phases in strongly correlated cuprate compounds.
11:51 AM S07.00004: Magnetism and correlation effects in titanium phosphate at high pressure  
JOHAN JÖNSSON (Presenter), MARCUS EKHOLM, IGOR ABRIKOSOV, Linköping University — Titanium phosphate exhibits interesting properties as pressure and temperature is varied e.g., the spin-Peierls transition. We have investigated the influence of magnetism and electron correlation on this behaviour upon compression.

At ambient pressure TiPO₄ forms the orthorhombic structure called phase I, with TiO₆ octahedra forming chains along the c-axis. As pressure is increased these chains begin to dimerise, leading to the incommensurate phase II, further increases of pressure locks the dimerisation in the chains, forming the commensurate and dimerised phase III. Even higher pressures leads to two new phases, IV and V, that show a noticeable increase in density.[1]

The chains in phase III exhibit a behaviour similar to what has been observed in VO₂, as a function of temperature. This suggests that TiPO₄ may be useful to investigate the correlation effects in VO₂ at room temperature but at high pressure.

At high pressure phase III undergoes a transition from a Mott insulating state into a metallic one. This Mott transition triggers another phase transition revealing two new, Mott insulating, phases, one non-magnetic and dynamically stabilised and another antiferromagnetic with strong local magnetic moments.

12:03 PM S07.00005: Quantum electrodynamics of a superconductor-insulator quantum phase transition I: theory  
VLADIMIR MANUCHARYAN (Presenter), ROMAN KUZMIN, RAY MENCIA, NICHOLAS GRABON, NITISH JITENDRASKUMAR MEHTA, YEN-HSIANG LIN, University of Maryland, College Park — We report on our experimental probing of the superconductor-insulator quantum phase transition (QPT) in a 1D Josephson chain in the high-frequency and short-wavelength limit [1]. By contrast, traditional experiments focus on finding a universal scaling of resistance with temperature and other system parameters. The quantum BKT transition resisted this approach for two decades. In part I, we overview the possible issues with the DC transport measurements and describe the advantages of viewing a QPT from the high-energy side. In part II, we show the results of our microwave spectroscopy of long chains of Al/AIOx/Al tunnel junctions. First, we find that an insulating chain can carry AC currents (in a GHz-band) as a near-perfect superconductor. Second, deviations from perfect superconductivity can be resolved. These deviations appear as frequency-dependent linewidths of the collective modes and as a scattering of their frequencies. Both effects arise from interactions and constitute the high-frequency footprint of the insulating phase near the critical point. Our new approach can help bridge theory with the experiments in chains, thin films, nanowires, and cold atom realizations of 1D systems.

12:15 PM S07.00006: Quantum electrodynamics of a superconductor-insulator quantum phase transition II: experiment  
NICHOLAS GRABON (Presenter), ROMAN KUZMIN, RAY MENCIA, NITISH JITENDRASKUMAR MEHTA, YEN-HSIANG LIN, VLADIMIR MANUCHARYAN, University of Maryland, College Park — We report on our experimental probing of the superconductor-insulator quantum phase transition (QPT) in a 1D Josephson chain in the high-frequency and short-wavelength limit [1]. By contrast, traditional experiments focus on finding a universal scaling of resistance with temperature and other system parameters. The quantum BKT transition resisted this approach for two decades. In part I, we overview the possible issues with the DC transport measurements and describe the advantages of viewing a QPT from the high-energy side. In part II, we show the results of our microwave spectroscopy of long chains of Al/AIOx/Al tunnel junctions. First, we find that an insulating chain can carry AC currents (in a GHz-band) as a near-perfect superconductor. Second, deviations from perfect superconductivity can be resolved. These deviations appear as frequency-dependent linewidths of the collective modes and as a scattering of their frequencies. Both effects arise from interactions and constitute the high-frequency footprint of the insulating phase near the critical point. Our new approach can help bridge theory with the experiments in chains, thin films, nanowires, and cold atom realizations of 1D systems.

12:27PM S07.00007: Structural investigation of the insulator-metal transition in NiS$_2-x$Sex compounds
SUNGKYUN CHOI (Presenter), Department of Physics and Astronomy, Rutgers University, GARAM HAN, HWANBEOM CHO, BYUNGMIN SOHN, JE-GUEU PARK, CHANGYOUNG KIM, Department of Physics and Astronomy, Seoul National University (SNU) —
We report [1] on a combined measurement of high-resolution x-ray diffraction on powder and Raman scattering on single crystalline NiS$_2-x$Sex samples that exhibit the insulator-metal (IM) transition [2] with Se doping. Via x-rays, an abrupt change in the bond length between Ni and S (Se) ions was observed at the transition temperature, in sharp contrast to the almost constant bond length between chalcogen ions. Raman scattering, a complementary technique with the unique sensitivity to the vibrations of chalcogen bonds, revealed no anomalies in the phonon spectrum, consistent with the x-ray diffraction results. This indicates the important role of the interaction between Ni and S (Se) in the IM transition. The potential implication of this interpretation is discussed in terms of current theoretical models.

12:39PM S07.00008: Quasi-periodic metal-insulator phase separation in strain engineered La$_{0.66}$Sr$_{0.33}$MnO$_3$ thin films
XINZHONG CHEN (Presenter), Stony Brook University, LIN LI, XIAODONG FAN, USTC, ZHIJING NIU, MENGKUN LIU, Stony Brook University, CHANGGAN ZENG, USTC — We report the electronic phase separation in the prototypical double exchange ferromagnet La$_{0.66}$Sr$_{0.33}$MnO$_3$ (LSMO) thin films grown on LaAlO$_3$ (LAO) substrate. We discovered a peculiar mesoscale stripe pattern that only occurs at specific film thickness, using the scattering-type scanning near-field optical microscope (s-SNOM) at the mid-infrared (mid-IR) frequencies. These novel quasi-periodic mesoscale metal-insulator-metal stripes are contributed to a subtle and delicate balance between the epitaxial strain and surface twin structure of the LAO substrate. Our work strongly suggests the possibility to control the metallicity via interface and strain engineering in strontium doped manganites.

12:51PM S07.00009: Observation of a new collective mode involved in the Verwey transition in magnetite
CARINA BELVIN (Presenter), EDOARDO BALDINI, OZGE I OZEL, Massachusetts Institute of Technology, JOSÉ LORENZANA, Institute for Complex Systems, Italy and University of Rome “La Sapienza”, NUH GEDIK, Massachusetts Institute of Technology — Magnetite (Fe$_3$O$_4$), the oldest known magnetic material, is a strongly correlated transition metal oxide that exhibits complex electronic and structural properties. Below the Verwey transition, the low-temperature insulating phase displays rich features, including the coexistence of charge and orbital orders whose detailed nature is still under debate. Using pump-probe spectroscopy, we photoexcite the system out of equilibrium with a tailored femtosecond laser pulse and examine the evolution of the coherent oscillations due to the system's collective modes in the time domain. We observe signatures of a new mode that undergoes a dramatic softening as a function of laser fluence. We discuss the implication of this collective mode on the understanding of the Verwey transition.

1:03PM S07.00010: Electron localization in 2D extended Hubbard model
HANNA TERLETSKA (Presenter), Middle Tennessee State University, JOSEPH PAKI, SERGEI ISAKOV, University of Michigan, THOMAS MAIER, Oak Ridge National Lab, EMANUEL C GULL, University of Michigan — We use the Dynamical Cluster Approximation to study the finite temperature phase transitions in 2D extended Hubbard model. We find that non-local electron-electron interactions screen the local Hubbard interactions, stabilizing the Mott metal-insulator transition in 2D extended Hubbard model. We also investigate the effect of the temperature and non-local interactions on the competition between antiferromagnetism and charge order. We show that non-local correlations are important, and hence the non-local methods are needed for proper analysis of the phase transitions in this model.
1:15PM S07.00011: Amplitude (Higgs) mode at the superfluid-Mott glass transition*  
JACK CREWSE (Presenter), THOMAS VOJTA, Missouri University of Science and Technology —  
We investigate the amplitude (Higgs) mode of a diluted quantum rotor model in two and three space dimensions close to their respective superfluid-Mott glass quantum phase transitions [1,2]. After mapping the Hamiltonians onto appropriate classical XY models, the systems are simulated by means of large-scale Monte Carlo simulations. The scalar susceptibility of clean, undiluted systems exhibit sharp spectral peaks associated with the amplitude mode that show the expected scaling behavior close to the critical point. However, the diluted systems do not exhibit such sharp peaks. Instead, the scalar susceptibility is dominated by broad, non-critical peaks which obscure any potential amplitude mode. To understand the fate of the amplitude mode in diluted systems we study the localization behavior of the mode by calculating dispersion relations near the critical point, for varying dilution strengths. We also calculate conductivity as an indirect measure of the amplitude modes existence in diluted systems.  

*This work was supported in part by the NSF under grants No. DMR-1506152 and DMR-1828489.

1:27PM S07.00012: Resistive Switching as Nonequilibrium Phase Transition*  
JONG E HAN (Presenter), JIAJUN LI, University at Buffalo, The State University of New York, CAMILLE ARON, Department of Physics, Ecole Normale Superieure, CNRS, Paris, France, GABRIEL KOTLIAR, Department of Physics, Rutgers University — We investigate the quantum mechanical origin of resistive phase transitions in solids driven by a constant electric field in the vicinity of a metal-insulator transition [1]. We perform a nonequilibrium mean-field analysis of a driven-dissipative symmetry-broken insulator, which we solve analytically for the most part. We find that the insulator-to-metal transition (IMT) and the metal-to-insulator transition (MIT) proceed by two distinct electronic mechanisms: Landau-Zener processes and the destabilization of the metallic state by Joule heating, respectively. Our analytic approach enables us to formulate testable predictions on the nonanalytic behavior of I-V relation near the insulator-to-metal transition. Building on these successes, we propose an effective Ginzburg-Landau theory which paves the way to incorporating spatial fluctuations and to bringing the theory closer to a realistic description of the resistive switchings in correlated materials.  

*We acknowledge financial support form National Science Foundation with Grant No. DMR-1733071.

1:39PM S07.00013: Interplay between superconducting and magnetic fluctuations in the doped 2D Hubbard model*  
ANNA KAUCH (Presenter), FELIX HORBINGER, Institute of Solid State Physics, TU Wien, GANG LI, School of Physical Science and Technology, ShanghaiTech University, KARSTEN HELD, Institute of Solid State Physics, TU Wien — The importance of antiferromagnetism for d-wave type superconductivity has already been established within various theoretical methods [1]. In this work we focus on the doped regime, where the magnetic fluctuations become incommensurate [2]. The solution of the Hubbard model by parquet equations gives us the unique opportunity to treat fluctuations in all channels on equal footing. Using the victory parquet equations solver [3] we compute two-particle quantities in the 2D Hubbard model on square lattice in the parquet (PA) and dynamical vertex (DΓA) approximations [4][5]. In the parquet flavour of DΓA, the fully irreducible vertex is assumed to be local and it is obtained from dynamical mean-field theory (DMFT). The analysis of the particle-particle vertex as well as of the leading eigenvalues of the Bethe-Salpeter equations allow us to identify the dominant fluctuations and the symmetry of the pairing.  

*Fonds zur Förderung der wissenschaftlichen Forschung (FWF) project P 30997
1:51PM S07.00014: Effect of Spin-Selective Disorder on the Hubbard model. RAJESH NARAYANAN (Presenter), MADHUPARNA KARMAKAR, SHASHIKANT SINGH KUNWAR, Indian Institute of Technology Madras, PRABUDDHA CHAKRABORTY, Chennai Centre, Indian Statistical Institute — We use a combination of Monte-Carlo techniques to study the effect of spin-selective disorder for both the repulsive and attractive Hubbard models. For the repulsive Hubbard model with spin-selective disorder, by using a determinant quantum Monte-Carlo scheme we show evidence for the existence of a metal-insulator transition for fillings away from half-fillings. We show that the metal-insulator transition is accompanied with a net-polarization of the fermionic fluid and a consequent saturation behavior in the susceptibility. For the case of the attractive Hubbard model at half-filling in the presence of spin-selective disorder, we use a real space based Monte-Carlo scheme to completely elucidate the ground state phase diagram. In particular, we compare and contrast the behavior at weak and strong disorder: In the limit of weak disorder gapless superconductivity obtains whereas in the limit of strong disorder a spin-selective Anderson transition is realized. The effect of thermal fluctuations on the phase diagram is also studied within this approach.

2:03PM S07.00015: Percolative transport in the metal-insulator phase coexistence region of Mott organics* YUTING TAN (Presenter), VLADIMIR DOBROSAVLJEVIC, Department of Physics and NHMFL, Florida State University — The Mott metal-insulator transition of the organic triangular-lattice system $k$–$(ET)_2Cu_2(CN)_3$ has recently been re-examined through low temperature DC [1] transport experiments. These results, displaying striking non-monotonous temperature dependence for a family of resistivity curves, have been previously interpreted in terms of the "continuous" (spinon-based) scenario for the transition. Here we theoretically re-examine the transport properties in this regime, and show that an alternative viewpoint [2], based in the dynamical mean-field theory (DMFT) and a percolation picture [3], naturally explains all the observed anomalies. According to this scenario, the transition assumes first-order character at low temperature, leading to percolative transport in the coexistence regime, which we study theoretically, reproducing the experimental trends.

Session S08 DCMP: Superconductivity in EM fields BCEC 150 - Catalin Martin, Ramapo College

11:15AM S08.00001: Debye mechanism of giant microwave absorption in superconductors* MICHAEL SMITH (Presenter), ANTON V ANDREEV, BORIS SPIVAK, University of Washington — We present a theory of microwave absorption in conventional superconductors and show that in the presence of a superfluid velocity $V_s$ the microwave absorption coefficient can be orders of magnitude larger than at $V_s = 0$. The reason for this is that the $V_s$-dependent contribution is proportional to the inelastic scattering time rather than the elastic scattering time. The mechanism responsible for this larger contribution is similar to the Debye mechanism for microwave absorption in molecules. Further, the $V_s$ dependence of the absorption coefficient is non-analytical, and measurement of this contribution to the absorption coefficient will give direct information about the inelastic scattering time in superconductors which in general has been difficult to directly measure. In the absence of the superfluid velocity we identify a new mechanism of non-linear conductivity with anomalously low threshold.

11:27AM S08.00002: A nonlinear THz study of strong light-matter coupling between plasmonic metamaterials and a superconducting Josephson Plasmon in $\text{La}_2\text{xSr}_x\text{CuO}_4$.* JACOB SCHALCH (Presenter), University of California, San Diego, CHUNXU CHEN, XIAOGUANG ZHAO, department of mechanical engineering, boston university, DIMITRI BASOV, department of physics, columbia university, MICHAEL FOGLER, University of California, San Diego, XIN ZHANG, department of mechanical engineering, boston university, RICHARD DOUGLAS AVERITT, University of California, San Diego — The Josephson plasma resonance (JPR) in layered high temperature superconducting cuprates provides a useful probe of the superconducting condensate, as well as an avenue to couple incident electromagnetic fields to the condensate. We enhance this light-matter coupling by applying interchangeable metamaterial tapes to a c-axis single crystal of $\text{La}_2\text{xSr}_x\text{CuO}_4$ and perform linear THz time domain spectroscopy in reflection in order to identify anti-crossing behavior characteristic of strong coupling. We then drive the hybrid superconducting metamaterial system with large single cycle THz fields in excess of 100kV/cm in order to explore emergent nonlinear behavior of the coupled system. This work informs future possibilities of utilizing strong coupling effects in conjunction with large transient fields to achieve coherent control of a superconducting condensate and an avenue towards light enhanced superconductivity.

11:39AM S08.00003: Cavity Quantum Enhancement of Superconductivity* JONATHAN CURTIS (Presenter), ZACHARY RAINES, ANDREW ALLOCCA, MOHAMMAD HAFEZI, VICTOR GALITSKI, University of Maryland, College Park — Standard superconductors are known to exhibit a number of fascinating and potentially useful phenomena when driven away from thermal equilibrium by coherent classical electromagnetic radiation. These non-equilibrium effects can often lead to an enhancement in the strength of the superconducting gap and its manifestations. We aim to understand what happens when the classical electromagnetic field is replaced by a fluctuating quantum electromagnetic field, as may be found in a microwave cavity resonator. We show that in the lossy regime non-equilibrium cavity photons can rid the superconductor of deleterious quasiparticles, thereby enhancing the superconducting gap strength. This proposed quantum enhancement of superconductivity opens the door to the study of more exotic phenomena which may arise when superconductors are subjected to cavity quantum electrodynamic environments.

11:51AM S08.00004: Modulating Superconductivity with Metamaterial Plasmonic Structures – Theory TYLER DODGE (Presenter), XUEYUAN WU, MARK SCHILLER, MICHAEL J NAUGHTON, KRZYSZTOF KEMPA, Department of Physics, Boston College — In 1972, Kirzhnits et al. reformulated the BCS superconductivity theory in terms of a dielectric response function1. The conclusion of this theory was that the strength of the Cooper pairings can be controlled by the dielectric environment. A demonstration of this effect was recently given in a metamaterial composite made of Al nanoparticles2, designed to have suppressed dielectric function at the Eliashberg function maximum, leading to threefold increase of superconductivity critical temperature. In this work, we have studied theoretically, two-dimensional Babinet metamaterials made of Pb, properly designed to have the Cooper pairing strength systematically controlled (enhanced or suppressed). This work, has been coupled to the parallel effort to determine these effects theoretically.

12:03PM S08.00005: Modulating Superconductivity with Metamaterial Plasmonic Structures – Experiment. MARK SCHILLER (Presenter), TYLER DODGE, XUEYUAN WU, KRZYSZTOF KEMPA, MICHAEL J NAUGHTON, Physics, Boston College — In 1972, Kirzhnits et al. reformulated the BCS superconductivity theory in terms of a dielectric response function,1 concluding that the strength of Cooper pairing can be controlled by the dielectric environment. A demonstration of this effect was recently given in a metamaterial composite made of Al nanoparticles2, designed to have suppressed dielectric function at the Eliashberg function maximum, leading to threefold increase of superconductivity critical temperature. We report fabrication and experimental measurements of thin film Babinet metamaterials made of Pb, designed to have the Cooper pairing strength systematically controlled (enhanced or suppressed). This work is coupled to a parallel effort to determine these effects theoretically.

12:15PM S08.00006: Strong Plasmonic Enhancement of Photoelectric Quantum Efficiency of Nb using In Nano islands  SHOKOUFEH ASALZADEH (Presenter), JOHN ZASADZINSKI, MARK WARREN, LINDA KLAMP SPENTZOURIS, NOAH SAMUELSON, Illinois Institute of Technology — The development of superconducting photocathodes is presented which explores thin film coatings to enhance the quantum efficiency (QE) of superconducting Nb above its bulk value of < 10^-6. Deposition of a 10nm layer of Mg (work function = 3.6 eV) onto Nb after UHV anneal increases QE by a factor of 10. Deposition of ultra-thin islands of In (4 nm) on top of Nb/Nb oxide or Nb/Mg/Mg oxide leads to overall enhancements of QE by up to 400 times. We attribute this latter enhancement to plasmonic effects where the stored EM fields in the In islands couple to Nb electrons

12:27PM S08.00007: Theory of coherent plasmon in one dimensional insulators* JAY SAU (Presenter), University of Maryland, College Park — Recent microwave reflection measurements of Josephson junction ladders have suggested the presence of nearly coherent collective charge oscillations deep in the insulating phase. Here we develop a qualitative understanding of such coherent charge modes by studying the local dynamical charge susceptibility of the insulating phase of the Sine-Gordon model. By considering parameters near the non-interacting Fermion limit where the charge operator dominantly couples to soliton-antisoliton bound states of the Sine-Gordon model, we find that the local charge susceptibility shows an array of sharp peaks in frequency representing coherent plasma oscillations on top of an incoherent background. The strength of the coherent peaks relative to the incoherent background increases as a powerlaw in frequency whose exponents depend on system parameters. The charge susceptibility also clearly shows the insulating gap. We then compare the controlled results in the high frequency limit to phase-slip-induced decay of plasmons in the Josephson junction ladder.

12:39PM S08.00008: Application of metamaterial nano-engineering for increasing the superconducting critical temperature* MICHAEL OSOFSKY (Presenter), United States Naval Research Laboratory, VERA SMOLYANINOVA, Department of Physics Astronomy and Geosciences, Towson University, JOSEPH PRESTIGIACOMO, United States Naval Research Laboratory, PETER ROSEN, MATTHEW DICKSON, BRIAN WOODFIELD, Chemistry and Biochemistry Dept., Brigham Young University, Brigham Young University, JEFFREY W LYNN, NICHOLAS BUTCH, HEATHER CHEN-MAYER, NIST Center for Neutron Research, National Institute of Standards and Technology, IGOR SMOLYANINOV, Department of Electrical and Computer Engineering, University of Maryland — In previous work, we demonstrated that the metamaterial approach to dielectric response engineering increases the critical temperature of a composite superconductor-dielectric system in the epsilon near zero (ENZ) and hyperbolic regimes. To create such metamaterial superconductors three approaches were implemented: 1) mixtures of tin and barium titanate nanoparticles of varying composition and tin and strontium titanate nanoparticles, 2) composite Al_2O_3-coated aluminium nanoparticles, and 3) thin Al/Al_2O_3 heterostructures that form a hyperbolic metamaterial superconductor. IR reflectivity measurements confirmed the predicted metamaterial modification of the dielectric function thus demonstrating the efficacy of the metamaterial approach to T_c engineering. In this talk, we present specific heat data on samples of the composite Al_2O_3-coated aluminium nanoparticle superconductors showing that the normal state density of states (DOS) is similar to that of pure aluminum, thus precluding the DOS from being responsible for the observed enhanced T_c. We will also discuss other features in the specific heat results that are consistent with results of neutron scattering experiments.

*This work was supported in part by DARPA W911NF1710348 and ONR N00014-18-1-2681 grants.

12:51PM S08.00009: Observation of plasmon-phonons in a metamaterial superconductor using inelastic neutron scattering* VERA SMOLYANINOVA (Presenter), Towson University, JEFFREY W LYNN, NICHOLAS BUTCH, HEATHER CHEN-MAYER, NIST, JOSEPH PRESTIGIACOMO, MICHAEL OSOFSKY, NRL, IGOR SMOLYANINOV, Saitenna LLC — Recent experiments have demonstrated that the metamaterial approach is capable of drastically increasing the critical temperature, T_c, of composite metal-dielectric epsilon near zero (ENZ) metamaterial superconductors. For example, a tripling of the critical temperature was observed in bulk Al-Al_2O_3 ENZ core-shell metamaterials. A theoretical model based on the Maxwell-Garnett effective medium approximation provides a microscopic explanation of this effect in terms of electron-electron pairing mediated by a hybrid plasmon-phonon excitation in the composite metal-dielectric metamaterial. We report the first observation of a hybrid plasmon-phonon excitation in Al-Al_2O_3 ENZ core-shell metamaterials using inelastic neutron scattering. These results provide strong support for this novel mechanism of superconductivity in ENZ metamaterials and provide an explanation for the 50 year old mystery of enhanced T_c in granular aluminum thin films.

*This work was supported in part by DARPA W911NF1710348 and ONR N00014-18-1-2681 grants.
1:03PM S08.00010: Interference experiments with superconducting microwave beam splitter*  IULIIA ZOTOVA (Presenter), Moscow Institute of Physics and Technology, YU ZHOU, RUI WANG, Tokyo University of Science, OLEG ASTAFIEV, Moscow Institute of Physics and Technology, JAW-SHEN TSAI, Tokyo University of Science — Superconducting quantum circuit is one of the most promising way for realization of quantum systems. Quite interesting effects in superconducting quantum systems can be observed involving single photons interference[1]. To conduct these type of experiments, different devices like single-photon sources and an element for entanglement generation are required. The most natural realization for such element is a beam splitter [2]. In microwave range, it is convenient to use a hybrid beam splitter [1]. It is natural to use a beam splitter on-chip for less insertion losses. In the talk, the investigation of this kind of beam splitter with proposed interference experiments will be reported.

*We would like to acknowledge the support of JST CREST, ImPACT and NEDO IoP project.

1:15PM S08.00011: Transient optical response of correlated electrons*  ANKIT KUMAR (Presenter), ALEXANDER KEMPER, North Carolina State University — Recent discoveries of non-equilibrium higher order harmonic response of the superconducting condensate in cuprates, enhancement of the transient superconductivity in organic superconductor K$_2$C$_60$ and signature of the Higgs mode in BCS superconductor has attracted much attention. To understand the underlying physics behind such collective response of correlated electrons to electromagnetic field requires an understanding of response functions in the time domain. In our work, we calculate transient optical conductivity using a non-equilibrium Green's function method. We study a phonon mediated superconducting state. In the equilibrium state, we observe the normal superconducting gap in the real part of conductivity, and the $1/\omega$ divergence in the imaginary part. In a pump driven non-equilibrium state we observe suppression and the oscillatory recovery of the order parameter - the Higgs amplitude mode. We use different quantities – probe current, phonon-valley, coherence peak and the gap edge – to study the Higgs mode and the transient superconducting state. Our calculation helps in the understanding of transient superconducting state and provide a general framework to analyze the transient response of correlated electrons.

1:27PM S08.00012: Manifestation of vibronic dynamics in infrared spectra of Mott insulating fullerides  NAOYA IWAHARA (Presenter), KU Leuven, YUKI MATSUDA, KATSUMI TANIGAKI, Tohoku University, LIVIU F CHIBOTARU, KU Leuven — In order to probe the nature of Jahn-Teller dynamics in alkali-doped fullerides, the fine structure and temperature evolution of infrared spectra have been intensively used last years [1,2]. At the same time, theoretical framework to adequately extract the information on the complicated vibronic dynamics from infrared spectra is still lacking. In this work, the first-principles theory of the infrared spectra of dynamical Jahn-Teller system is developed and applied to the Mott-insulating Cs$_3$C$_60$ [3]. With the calculated coupling parameters for Jahn-Teller and infrared active vibrational modes, the manifestation of the dynamical Jahn-Teller effect in infrared spectra is elucidated. In particular, the temperature evolution of the infrared line shape is explained. The transformation of the latter into Fano resonance type in metallic fulleride [2] is discussed on the basis of obtained results.

Session S09 DCMP: Nanoparticles and Nanoplatelets: Structural and Optoelectronic Properties and Phenomena  BCEC 151A - Chen-Yen Lai, Los Alamos National Laboratory
Second harmonic generation from nanoparticles of noncentrosymmetric geometry

RAKSHA SINGLA (Presenter), W LUIS MOCHAN, Instituto de Ciencias Físicas, Universidad Nacional Autónoma de México — The nonlinear polarization resulting in generation of second harmonic (SH) radiation from centrosymmetrical (CS) media mostly takes place at the surface where the inversion symmetry is lost. This local disruption of symmetry disappears globally for a symmetrical particle, suppressing its total SH polarization. In this work, we explore SHG from particles of CS materials with non-CS geometry. We choose an isolated cylindrical particle with a deformed circular cross-section in the presence of an external field with a long wavelength. Assuming a small deformation parameter, a perturbative scheme is employed to analytically solve the linear and quadratic field equations, employing the dipolium model [1] to calculate the SH bulk and surface polarization. We report the SH dipolar and quadrupolar hyperpolarizability tensors, their spectra, the radiation patterns, and the conversion efficiency.

Quantum Dot Supercrystals: Assembly and properties

EMANUELE MARINO (Presenter), Institute of Physics, University of Amsterdam, TOM KODGER, Physical Chemistry and Soft Matter, Wageningen University, PETER SCHALL, Institute of Physics, University of Amsterdam — The assembly of semiconductor nanoparticles, quantum dots (QD), into dense crystalline nanostructures holds great promise for future optoelectronic devices. Emulsion-templated assembly has recently been shown to provide three-dimensional quantum-dot supercrystals of excellent crystal quality. We combine emulsion-templated assembly with in situ small-angle X-ray scattering to obtain direct insight into the nanoscale interactions underlying the nucleation, growth and densification of quantum dot supercrystals. We show that while hard-sphere behaviour governs their initial nucleation, at later stages the ligands play a crucial role in balancing steric repulsion against attractive van der Waals attraction. We also elucidate the optoelectronic properties of these supercrystals. We show that the supercrystals exhibit Mie resonances that can lead to absorption efficiencies larger than one, beneficial for photovoltaic applications. Ultrafast spectroscopy reveals energy transfer processes due to quantum-dot coupling in these supercrystals.

Electronic, Optical and Transport Properties of PbS Nanocrystal Superlattices

YUN LIU (Presenter), NOLAN PEARD, JEFFREY C GROSSMAN, Massachusetts Institute of Technology — Optoelectronic devices made from colloidal quantum dots (CQDs) often take advantage of the combination of tunable quantum confined optical and electronic properties and carrier mobilities of strongly coupled systems. For lattices of connected CQDs, of interest is the interplay between confinement effects and band-like behavior. In this work, first-principles calculations are applied to investigate the electronic, optical and transport properties of PbS CQD superlattices. Our results show that even in the regime of strong necking between CQDs, quantum confinement can be preserved. In the bandlike regime, computed carrier mobilities for simple cubic and 2D square lattices fused along the (100) facets are 2-4 orders of magnitude larger than those of superlattices fused along (110) and (111) facets. The relative magnitude of the electron and hole mobilities strongly depends on the crystal and electronic structures. We also find that the carrier mobilities of CQD solids increases as the size of the quantum dot increases due to the stronger coupling between neighboring CQDs. Our results illustrate the importance of understanding the effects of crystal structure and connectivity of CQD films.

The authors acknowledge the funding from Tata GridEdge Program at MIT.
measurements reveal that significant diffusional mixing occurs starting at a temperature between 300 and 400° C and involves core/shell nanoparticles to a homogeneous Cu-Ni alloy as a function of both the temperature and the time. These ex-situ x-ray diffraction measurements have been used to follow the conversion of the as-prepared core/shell nanoparticles to a homogeneous Cu-Ni alloy occurring at a temperature of 600° C. We believe that the nanoscale core-shell HMM paves a way to enlarge the development of applications, such as highly optoelectronic conversion efficiency of solar cells, great power extraction of light emitting diodes and wide spectra photodetectors.

*This work was financially supported by the "Advanced Research Center for Green Materials Science and Technology" from The Featured Area Research Center Program within the framework of the Higher Education Sprout Project by the Ministry of Education (107L9006) and the Ministry of Science and Technology in Taiwan (MOST 107-3017-F-002-001).

11:51AM S09.00004: Nanoscale Core-Shell Hyperbolic Metamaterial for Ultralow Threshold Laser Action* HUNG-I LIN (Presenter), KANCHAN YADAV, KUN-CHING SHEN, GOLAM HAIDER, YIT-TSONG CHEN, YANG-FANG CHEN, National Taiwan University — We develop the nanoscale core-shell hyperbolic metamaterial (HMM) possessing a remarkably coupling effect in between the multishell components, which is due to the formation of higher density of states and longer time of collective oscillations of the electrons than the plasmonic-based pure metal nanoparticles. Subsequently, a giant localized electromagnetic wave of surface plasmon resonance is formed at the surface causing the pronounced out-coupling effect. The nanoscale core-shell HMM confines the energy well without being decayed, reducing the propagation loss and then achieving the stimulated emission (e.g., random lasing action by dye molecule) with an ultralow lasing threshold (~30 μJ/cm²). We believe that the nanoscale core-shell HMM paves a way to enlarge the development of applications, such as highly optoelectronic conversion efficiency of solar cells, great power extraction of light emitting diodes and wide spectra photodetectors.

12:03PM S09.00005: Hot-electron generation and energy transfer in plasmonic metastructures with hot spots: Quantum and Classical mechanisms ALEXANDRE GOVOROV (Presenter), LUCAS VAZQUEZ BESTEIRO, ZHIMING M WANG, Institute of Fundamental and Frontier Sciences, University of Electronic Science and Technology of China — Generation of energetic (hot) electrons is an intrinsic property of any plasmonic nanostructure under illumination. Simultaneously, a striking advantage of metal nanocrystals over semiconductors lies in their very large absorption cross sections. Therefore, metal nanostructures with strong and tailored plasmonic resonances are very attractive for photocatalytic applications, which often involve excited electrons. However, the central questions in the problem of plasmonic hot electrons are quantifying the number of optically excited energetic electrons in a nanocrystal and finding out how to extract such electrons. Here we develop a theory describing the generation rates and the energy distributions of hot electrons in nanocrystals with various geometries. Hot-electron generation [1] together with non-radiative plasmonic transfer [2] represent efficient mechanisms to transport and localize optical and photo-chemical energies.

12:15PM S09.00006: Solid-state diffusion in Cu core/Ni shell nanoparticles* JIE REN, ROBERT E SCHMIDT, KLAUS H THEOPOLD, KARL UNRUH (Presenter), University of Delaware — Cu core/Ni shell nanoparticles with nominal Cu/Ni atomic ratios of 2/1, 1/1, 1/2, and 1/3 have been prepared in a microwave reactor by the sequential reduction of Cu acetate (at 100° C) and Ni acetate (at 175° C) in ethylene glycol using sodium hypophosphite as the reducing agent. The measured room temperature lattice parameters of the as-prepared samples are slightly smaller/larger than the corresponding bulk Cu and Ni lattice parameters indicating a small amount of diffusional mixing at the Cu/Ni interface during sample preparation. Ex-situ vacuum annealing experiments followed by room temperature x-ray diffraction measurements and in-situ high temperature x-ray diffraction measurements have been used to follow the conversion of the as-prepared core/shell nanoparticles to a homogeneous Cu-Ni alloy as a function of both the temperature and the time. These measurements reveal that significant diffusional mixing occurs starting at a temperature between 300 and 400° C and complete mixing with the formation of a homogeneous Cu-Ni alloy occurs at a temperature of 600° C.

*This material is based upon work supported by the National Science Foundation under Grant No. DMR140076.

12:27PM S09.00007: Growth and Shape Stability of Bi-metallic Nano-particles SONDAN DURUKANOGLU (Presenter), School of Engineering and Natural Sciences, Kadir Has University, EFE ILKER, PSL Research University, MINE KONUK, Piri Reis University, MELIHAT MADRAN, Sabanci University — Controlling the morphology of non-noble bi-metallic nano-crystals has become the focus of several studies as these nano-structures can provide a great opportunity to improve their performance and activity in catalytic reactions. Although much of the focus has been on the overall macroscopic description of synthesis processes, it is still a great challenge to identify the leading factors in a typical crystal growth process at atomic-scale. Here we report results of atomic scale calculations on shape evolution and stability of grown bi-metallic Cu-Ni nano-particles using molecular static and dynamic simulations. Our growth simulations on bare Cu and Ni nano-cubes reveals that single-atom diffusion characteristics play an important role in utilizing the particle with specific morphology and architecture.
12:39PM S09.00008: Interface Modification in Type-II ZnCdSe/(Zn)CdTe QDs for High Efficiency Intermediate Band Solar Cells* VASILIOS DELIGIANNAKIS (Presenter), SIDDHARTH DHOMKAR, MARCEL CLARO, City College of New York, IGOR KUSKOVSKY, Queens College, MARIA TAMARGO, City College of New York — Intermediate band solar cells have been proposed as being able to overcome the Shockley-Queisser limit for single junction solar cells.1 Our group has been devolving a II-VI based material system using type-II submonlayer quantum dots (QDs) composed of (Zn)CdTe embedded in a ZnCdSe host. These materials, when lattice matched to InP closely match the theoretically predicted requirements. However, do to the dissimilar group VI elements and Cd desorption that occurs during the formation of the quantum dots a highly strained interfacial layer is formed.2 A new growth process is proposed to avoid formation of a strain-inducing ZnSe interfacial layer. We show that the new growth sequence allows for improved control of the interfacial composition and simplifies the fabrication of the intermediate band solar cell device structure based on these QDs, since additional strain balancing schemes are no longer required to grow stress-free structures.

12:51PM S09.00009: Observation of optical referigeration on CdSe/CdS quantum dots MUCHUAN HUA (Presenter), RICARDO SANTIAGO DECCA, Indiana University - Purdue University Indianapolis — Optical refrigeration on CdSe/CdS (core/shell) quantum dots (QDs) was observed for the first time. From the observed temperature drop and the experimental conditions, the effective cooling power in our experiment was estimated to be ~10^{-14} W per dot. Experiments were done with samples (colloidal QDs suspension) synthesized in our lab following the method recently developed at Peng's group (DOI: 10.1021/jacs.6b02909), which can effectively eliminate the excitonic non-radiative decay path inside the QDs. The cooling effect comes from the significant up-conversion of the mean emission energy (typical up-conversion of the mean emission energy is >25 meV) observed in the photoluminescence spectra of our samples under sub-band excitation (excitation energy is much lower than the energy band gap of the QDs). Details of the experiments and the observation will be discussed in the presentation.

1:03PM S09.00010: Confined excitons in CdSe/CdMnS and CdSe/ZnMnS nanoplatelets ARMAN NAJAFI (Presenter), PEIYAO ZHANG, TENZIN NORDEN, ARINJOY BHATTACHARYA, Department of Physics, University at Buffalo SUNY, Buffalo, NY, JAMES PIENTKA, Department of Physics, St. Bonaventure University, St. Bonaventure, NY, SUSHANT SHENDRE, SAVAS DELIKANLI, HILMI VOLKAN DEMIR, LUMINOUS! Centre of Excellence for Semiconductor Lighting and Displays, School of Electrical and Electronic Engineering, Nanyang Technological University, Singapore, ATHOS PETROU, Department of Physics, University at Buffalo SUNY, Buffalo, NY — We have used absorption and PL spectroscopies to study the magneto-optical properties of colloidal CdSe/CdMnS and CdSe/ZnMnS core-shell nanoplatelets. We observe three absorption features tentatively attributed to the e_{1}h_{1}, e_{1}l_{1}, and e_{2}h_{2} confined excitons. In the presence of a magnetic field B applied normal to the substrate surface, the PL from e_{1}h_{1} becomes circularly polarized as \( \alpha_{+} \), indicating the presence of exchange interaction between the carrier spins and the spins of the Mn^{2+} ions. The circular polarization initially increases with B and saturates at 4T. At a fixed B the circular polarization decreases with increasing temperature and vanishes around 50K. The circular polarization peak, unlike previously studied samples [1], coincides with the e_{1}h_{1} exciton. This is attributed to the smaller thickness (2ML) of the CdSe core compared to the previously studied samples (5ML). We also measured the e_{1}h_{1} exciton magnetic splitting from the magneto-transmission spectra. Saturation splittings up to 5 meV have been observed.

First-Principles Calculations of Nanoplatelet Heterostructures: Surface Ligands and Strain

SERGIO MAZZOTTI (Presenter), Optical Materials Engineering Laboratory, Department of Mechanical and Process Engineering, ETH Zurich, ARIN R GREENWOOD, Institute for Molecular Engineering, University of Chicago, DAVID J NORRIS, Optical Materials Engineering Laboratory, Department of Mechanical and Process Engineering, ETH Zurich, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — Nanoplatelets (NPLs) – highly anisotropic, quasi-two-dimensional semiconductor nanostructures – exhibit optoelectronic properties that are governed by their precisely tunable thickness of a few atomic layers. However, the atomistic structure of NPLs is not completely known and is expected to depend on the passivating ligands. Here we determine the structure of both CdSe-core and CdSe/CdS-core/shell NPLs, using Density Functional Theory (DFT) and the Qbox code[1]. For both core and core/shell NPLs with different thicknesses and ligands, we determined the equilibrium positions and the in-plane strain. We found that NPL thickness, different ligands and the presence of a shell are all factors affecting the axial atomistic structure and they are responsible for inducing an in-plane strain field, which in many studies has been neglected. We show that, compared to CdSe NPL of the same thickness, the lattice constants of the core-shell NPLs expand in the axial direction, in agreement with recent experiments[2]. We rationalize our first principles findings by a continuum elastic model including surface-stress terms that account for the surface passivation of NPLs.

*Supported by DOE grant No. DE-FG02-06ER46262.

First Principles Calculations of Nanoplatelet Heterostructures: Optoelectronic Properties

ARIN R GREENWOOD (Presenter), Institute for Molecular Engineering, University of Chicago, SERGIO MAZZOTTI, Optical Materials Engineering Laboratory, Department of Mechanical and Process Engineering, ETH Zurich, ABHIJIT HAZARIKA, IGOR COROPCEANU, DMITRI TALAPIN, Department of Chemistry and James Franck Institute, University of Chicago, GIULIA GALLI, Institute for Molecular Engineering and Materials Science Division, University of Chicago and Argonne National Laboratory — Two-dimensional, atomically precise core-shell nanoplatelets (NPLs) have recently been synthesized with no sample inhomogeneity, leading to remarkable photoluminescence quantum efficiencies and tunable electronic properties dependent on NPL thickness [1]. Here we use Density Functional Theory and the Qbox code [2] to investigate the unique optoelectronic properties of CdS/CdSe core-shell NPLs. We show that, compared to a pure CdSe NPL of the same thickness, the band gap and dielectric constant of the core-shell NPLs decrease consistent with experimental results, corresponding to a larger exciton binding energy by approximately 30%. We attribute our findings to an expansion of the lattice constant of the core-shell NPLs in the axial direction, leading to a strain-induced modification of the electronic properties of the system. In contrast to nanoparticles, where the optoelectronic properties are governed by quantum confinement, we find that the properties of NPLs depend on a subtle interplay between quantum confinement and strain induced in the NPLs by the heterostructured interfaces.

*Supported by DOE grant No. DE-FG02-06ER46262.
1:39PM S09.00013: Low-temperature photoluminescence spectroscopy of single core/shell nanoplatelets  
LINTAO PENG (Presenter), Center for Nanoscale Materials, Argonne National Laboratory, IGOR COROPECEANU, DMITRI TALAPIN,  
Department of Chemistry and James Franck Institute, University of Chicago, XUEDAN MA, Center for Nanoscale Materials, Argonne National Laboratory — With promising applications in lasing, light-emitting diodes, as well as quantum photonics, semiconducting nanoplatelets (NPLs) with atomically controlled thickness and giant oscillator strength has attracted considerable interest in the past few years. Our previous studies\(^1\) have revealed that with excitons in NPLs being strongly confined in the thickness direction, an increase in their lateral size and a weakening in the in-plane confinement has complex effects on their photon emission statistics and carrier dynamics. These properties are unique to NPLs due to their quasi-two-dimensional structures.

While room temperature studies of single NPLs provide valuable information, the spectrum is broadened by carrier-phonon interactions, making the assignment of optical transitions and the related electronic structures challenging. Here, we perform single NPL spectroscopic measurements at cryogenic temperatures. Spectral linewidth and diffusion are investigated systematically. In addition, we observe rich spectral fine structures from the NPLs. These results will shed new light on the intrinsic electronic structures of the NPLs, and help understand the origin of the much debated side emission peak observed in ensemble measurements.

1:51PM S09.00014: Tuning the Photophysical Properties of Colloidal Two-Dimensional Nanoplatelets*  
QUNFEI ZHOU (Presenter), Materials Research Center, Northwestern University, YEONGSU CHO, Department of Chemistry, University of Chicago, SHENYUAN YANG, Institute of Semiconductors, Chinese Academy of Sciences, EMILY A WEISS, Department of Chemistry, Northwestern University, TIMOTHY BERKELBACH, Department of Chemistry, University of Chicago, PIERRE DARANCET, Center for Nanoscale Materials, Argonne National Laboratory — Two-dimensional colloidal semiconductor nanoplatelets (NPLs) are promising optoelectronic materials with outstanding photophysical properties, such as large optical cross-sections and high photoluminescence quantum yield.

Using first-principles density functional theory calculations, we demonstrate strong tunability of NPL band edge energies through surface passivation by common organic molecules. We develop a simple quantitative electrostatic theory describing this effect through dipole-dipole interactions mediated by platelet-ligand interactions and ligand-dependent dielectric function. Finally, using parameter-free self-energies and an effective mass model of the excitons, we show that the band-edge tunability of NPLs together with the strong dependence of the optical bandgap of NPL on thickness can lead to favorable, and controlled tunability of photochemical and optoelectronic properties.

Session S10 DMP: Fe-based Superconductors -- Nematicity II  
BCEC 151B - Qing-Ping Ding, Ames Laboratory - 
Tag(s): Focus

11:15AM S10.00001: Interplay between nematicity and superconductivity in iron-based superconductors* [Invited]  
JIAN KANG (Presenter), Florida State University — The iron-based high-T\(_c\) superconductors exhibit several remarkable features, including the multi-orbital character and the ubiquity of the nematic phase. One consequence of the multi-orbital Fermi surface is that the spin-fluctuation mediated pairing interactions are sensitive to the orbital spectral weight at the Fermi surface, leading to several different possible gap structures, such as nodeless s\(_±\), nodal s\(_±\), and d-wave. Focused on the orbital order induced in the nematic phase, I will discuss how the nematic order can manipulate the properties of SC. Our calculation shows that not only \(T_c\) is enhanced, but more importantly, the gap structure becomes a mixture of nearly degenerate s and d-wave states by increasing the external strain. This mixture of s and d wave pairing channels has been recently found in the superconducting phase of the bulk FeSe, when SC occurs deeply inside the nematic phase.

* JK was supported by the National High Magnetic Field Laboratory through NSF Grant No. DMR-1157490 and the State of Florida.
11:51AM S10.00002: Probing nematic fluctuations in iron-based superconductors with pair distribution function analysis*  
BENJAMIN FRANDSEN (Presenter), Brigham Young University, KEITH TADDEI, Oak Ridge National Laboratory, DANIEL BUGARIS, Argonne National Laboratory, RYAN STADEL, Northern Illinois University, MING YI, Rice University, QISI WANG, JUN ZHAO, Fudan University, RAYMOND OSBORN, STEPHAN ROSENKRANZ, Argonne National Laboratory, OMAR CHMAISSEM, Northern Illinois University, ROBERT J BIRGENEAU, University of California, Berkeley — The origin and implications of nematicity in iron-based superconductors remain among the most pressing questions in the field. Recent efforts to address this topic have focused not only on the nematic phase itself, but also on the nematic fluctuations that exist outside the region of static nematicity. Pair distribution function (PDF) analysis of x-ray and neutron total scattering data is a proven method of studying local, short-range structural correlations that deviate from the average structure, such as the orthorhombic distortions associated with nematic fluctuations in the high-temperature tetragonal phase of iron-based superconductors. Focusing primarily on the representative hole-doped system (Sr,Na)Fe2As2, we present PDF analysis that reveals a remarkably large region of nanometer-scale local orthorhombic distortions in temperature-composition space, reaching up to approximately 500 K for the parent compound and extending to doping levels beyond the C2 dome near optimal superconductivity. These results offer a rich and detailed view of nematic fluctuations in iron-based superconductors and should be helpful in guiding future experimental and theoretical work.

*Support came primarily from the U.S. Department of Energy under Contract No. DE-AC02-05-CH11231.

12:03PM S10.00003: Spin correlations and B2g nematicity in extremely hole doped iron pnictides  
RONG YU (Presenter), Department of Physics, Renmin University of China, QIMIAO SI, Rice University — There is growing experimental evidence for B2g nematic correlations in the extremely hole doped iron pnictide compounds AFe2As2 (A=K,Rb,Cs). In this work, we construct a general Ginzburg-Landau theory for the nematic transitions driven by incommensurate spin correlations. We find various nematic orders depending on the nature of the incommensurate spin correlations, and demonstrate a unified description of the nematicity in both the parent and doped iron pnictides. For the extremely hole doped iron pnictides, our analysis provides a mechanism for a B2g nematic order developing from the pertinent incommensurate spin fluctuations. We further study an extended bilinear-biquadratic Heisenberg model, which provides additional evidence for the proposed mechanism.

12:15PM S10.00004: Doping-dependent nematic susceptibility and strain-tunable Tc in FeTe1-xSex*  
QIANNI JIANG (Presenter), Physics, University of Washington, YUE SHI, Materials Science & Engineering, University of Washington, JJUN-HAW CHU, Physics, University of Washington — In comparison to the end member FeSe, the role of nematicity in the FeTe1-xSex family is less explored. Using the elastoresistivity technique, we measured the nematic susceptibility of FeTe1-xSex over a wide range of doping, and revealed the presence of strong B2g nematic fluctuations despite the absence of static nematic order. We also studied the effects of anisotropic strain on the superconducting transition temperature, providing insight into the interplay between nematic fluctuations and the superconductivity.

12:27PM S10.00005: Anisotropy in Superconducting CsCa2Fe4As4F2 Single Crystals*  
ZHICHE NG WANG (Presenter), YI LIU, SI-QI WU, YE-TING SHAO, Zhejiang University, ZHI REN, Institute of Natural Science, Westlake University, GUANG-HAN CAO, Zhejiang University — CsCa2Fe4As4F2 is a typical example of 12442-type iron-based superconductors. The novel materialsuperconducts at 29.5 K without extrinsic chemical doping. It contains double Fe2As2 layers that are separated by insulating CaF2 layers. The structural feature may lead to the weak interlayer coupling and strong anisotropy. In this work we successfully synthesized high quality CsCa2Fe4As4F2 single crystals with CsAs flux. Measurements of X-ray diffraction, anisotropic magnetotransport and magnetization were carried out to characterize the single crystals. The anisotropic superconducting upper Hc2 (T), lower critical field Hc1 (T), the anisotropy parameter γ (T) and other related parameters were obtained. The results indicate that CsCa2Fe4As4F2 is one of most anisotropic iron-based superconductors.

12:39PM S10.00006: Unusual nematic behavior of heavily hole-doped AFe$_2$As$_2$* VLADISLAV BORISOV (Presenter), Institute of Theoretical Physics, Goethe University Frankfurt, Frankfurt am Main, Germany., RAFAEL M FERNANDES, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA., ROSER VALENTI, Institute of Theoretical Physics, Goethe University Frankfurt, Frankfurt am Main, Germany. — We investigate via density functional theory calculations the recently reported unusual nematic behavior of heavily hole-doped pnictides AFe$_2$As$_2$ (A = Rb, Cs) [1,2]. In contrast to the B$_{2g}$ nematic order of the parent 122 compounds, characterized by unequal Fe-Fe bonds, in the former systems nematic order is observed in the B$_{1g}$ channel, characterized by unequal Fe-As-Fe bonds. We attribute this behavior to the evolution of the magnetic ground state along the compound series Sr$_{1-x}$Rb$_x$Fe$_2$As$_2$, from single stripes for small $x$ to double stripes for large $x$. Our simulations using the reduced Stoner theory show that fluctuations of Fe moments are essential for the stability of the double-stripe configuration. We discuss the relationship between these magnetic orderings and the nature of nematicity in terms of vestigial orders [3].

12:51PM S10.00007: Nematic fluctuations at nonzero q in FeSe vs. Ba(Fe1-xCox)2As2* ADRIAN MERRITT (Presenter), University of Colorado, Boulder, FRANK WEBER, JOHN-PAUL CASTELLAN, Karlsruhe Institute of Technology, ALFRED Q R BARON, DAI SUKE Ishikawa, RIKEN, SPring-8, AYMAN SAID, AHMET ALATAS, Argonne Nati Lab, TRAVIS WILLIAMS, Oak Ridge Nati Lab, RAFAEL M FERNANDES, University of Minnesota, JOERG SCHMALIAN, Karlsruhe Institute of Technology, DMITRY REZNIK, University of Colorado, Boulder — FeSe and Ba(Fe1-xCox)2As2 (Ba122) have several shared phase transitions such as the tetragonal-to-orthorhombic structural transition associated with nematic electronic order as well as a superconducting transition. There are also important differences, including magnetic order found in the Ba122 but not the FeSe compounds. Our recent inelastic X-ray and neutron scattering measurements of TA phonons in these compounds focused on anomalies in their dispersion. These anomalies reflect nematic fluctuations at nonzero q. We obtained nematic correlation length as a function of temperature from fits to these anomalous dispersions and found that it is similar in FeSe and Ba(Fe0.96Co0.04)2As2: compounds whose structural transition temperatures are close. In addition, we measured TA phonon dispersions and linewidths in optimally-doped Ba122 in detail. I will discuss the implications of the observed phenomena, focusing on the relation between nematic correlation length and the structural transitions, magnetic order, and superconductivity.

1:03PM S10.00008: Nematic fluctuations in Ba(Fe1-xTMx)2As2 (TM = Cr, Mn, V and Cu): Why superconductivity cannot be achieved by these dopants YANHONG GU (Presenter), HUIQIAN LUO, SHILIANG LI, National Laboratory for Superconductivity, Institute of Physics, Chinese Academy of Sciences — We have systematically studied nematic susceptibilities in nonsuperconducting Ba(Fe1-xTMx)2As2 (TM = Cr, Mn, V and Cu) single crystals by measuring the uniaxial pressure dependence of the resistivity along the Fe-As-Fe direction. The nematic susceptibilities in all samples show the Curie-Weiss-like behavior at high temperatures, where the nematic Curie constant $A_n$ can be derived. In Cr, Mn and V doped samples, $A_n$ decreases with the doping level, suggesting the suppression of nematic fluctuations by these dopants. In Ba(Fe1-xCu$_x$)$_2$As$_2$, detailed neutron-diffraction measurements reveal that the collinear antiferromagnetic order persists up to $x = 0.08$ but becomes short-range above $x > 0.04$. Moreover, the nematic susceptibilities in the $x >0.04$ samples are significantly suppressed at low temperatures although $A_n$ obtained by fitting the high-temperature data increases with increasing $x$. Compared with those systems that clearly exhibit superconductivity, such as Co, Ni, K or P doped samples, our results suggest that the reason that no superconductivity is found by doping Cr, Mn, V and Cu in BaFe$_2$As$_2$ may be correlated with the suppression of nematic fluctuations.
Effect of controlled point-like disorder induced by 2.5 MeV electron irradiation on nematic resistivity anisotropy of hole-doped (Ba,K)Fe$_2$As$_2$*  

MAKARIY TANATAR (Presenter), Ames Laboratory US DOE, Ames, Iowa, ERIK TIMMONS, Department of Physics and Astronomy, Iowa State University, Ames, Iowa, KYUIL CHO, YONG LIU, THOMAS ANTONY LOGRASSO, RUSLAN PROZOROV, Ames Laboratory US DOE, Ames, Iowa, MARCIN KONCZYKOWSKI, OLIVIER CAVANI, Laboratoire des Solides Irradiés, École Polytechnique, F-91128 Palaiseau, France — In iron-based superconductors in-plane anisotropy of electrical resistivity in strain-detwinned samples strongly depends on residual resistivity [1]. The mechanism of the electronic transport responsible for sign change of in-plane resistivity anisotropy in hole-doped (Ba,K)Fe$_2$As$_2$ [2] attracts notable interest, since contributions from both elastic scattering due to impurities/defects and inelastic scattering on magnetic excitations and phonons can be anisotropic. We use irradiation with relativistic 2.5 MeV electrons at low temperatures to change residual resistivity and study the contribution of elastic scattering into anisotropic electronic transport. The modification of detwinning technique enabled measurements of the same samples before and after irradiation.

*Nematic Glassy Behavior Probed by NMR under Strain in Iron Pnictide Superconductors  

TANAT KISSIKOV (Presenter), University of California, Davis, MAKARIY TANATAR, PAUL CANFIELD, Ames Laboratory, ERICA CARLSON, Purdue University, KARIN ANDREA DAHMEN, University of Illinois at Urbana-Champaign, NICHOLAS CURRO, University of California, Davis — NMR studies of Ba(M$_x$Fe$_{1-x}$)$_2$As$_2$ (M = Co, Cu) have uncovered inhomogeneous glassy dynamics via stretched exponential relaxation and wipeout of the NMR signal. These signatures emerge below approximately 100-150 K, depending on the doping level, and reach a maximum onset temperature around the nematic quantum critical point. Here we present NMR data under uniaxial strain in Ba(CoxFe1-x)2As2 (x=0.08) at the nematic quantum critical point. The relaxation behavior reveals inhomogeneous relaxation that is strongly temperature-dependent and hysteric with strain. The stretching exponent, which probes the degree of inhomogeneity, remains unchanged under strain. These results suggest that the inhomogeneous relaxation observed by NMR reflects a nematic glass, in which large random strain fields are present and frustrate long-range nematic order.
1:51PM S10.00012: Persistent correlation between superconductivity and antiferromagnetic fluctuations near a nematic quantum critical point in FeSe$_{1-x}$S$_x$ seen by $^{77}$Se NMR*  PAUL WIECKI (Presenter), Karlsruhe Institute of Technology, KHUSBOO RANA, MOUMITA NANDI, Iowa State University, ANNA BOEHMER, Karlsruhe Institute of Technology, SERGEY BUDKO, PAUL CANFIELD, YUJI FURUKAWA, Iowa State University — In the iron-based superconductors, the superconducting pairing interaction is believed to involve antiferromagnetic spin fluctuations. However, fluctuations of the nematic degrees of freedom are also present in these materials and may also be involved in the pairing. A role for electronic nematic fluctuations in achieving high-temperature superconductivity has been suggested by the ubiquitous observation of critical nematic fluctuations near optimal doping in several of the key families. In this context, the FeSe$_{1-x}$S$_x$ system offers an opportunity to study an isolated nematic critical point, as the nematic order of pure FeSe is suppressed by S doping without the appearance of magnetic order. I will present $^{77}$Se NMR measurements which demonstrate that low-energy magnetic fluctuations are well correlated with the superconducting transition temperature $T_c$ in FeSe$_{1-x}$S$_x$, similar to pure FeSe under pressure. These findings confirm that magnetic fluctuations alone are the primary driver of superconductivity, even in the presence of critical nematic fluctuations.

Session S11 DCMP: Group IV- and III-V-Based Low-Dimensional Semiconductor Heterostructures

11:15AM S11.00001: Band engineering of semiconductor artificial graphene and exploration of flat band physics(*)*  LINGJIE DU (Presenter), Department of Applied Physics and Applied Mathematics, Columbia University, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University, SAEED FALLAHI, GEOFFREY GARDNER, Department of Physics and Astronomy, Purdue University, MICHAEL MANFRA, Department of Physics and Astronomy, School of Materials Engineering and School of Electrical and Computer Engineering, Purdue University, VITTORIO PELLEGRINI, Istituto Italiano di Tecnologia, SHALOM WIND, Department of Applied Physics and Applied Mathematics, Columbia University, ARON PINCZUK, Department of Applied Physics and Applied Mathematics and Department of Physics, Columbia University — Semiconductor artificial graphene (AG) has been realized on 2D electron systems in GaAs quantum wells subjected to a lateral potential modulation with honeycomb symmetry [1, 2]. Tunability of the AG band structure is a key property of the artificial systems. Here, we present effective band engineering of semiconductor AG with multiple control knobs that offer flexible and effective exclusive tunability of electron properties. Using the cutting-edge fabrication technology, we fabricated small-period triangular antidot lattices with different honeycomb lattice periods (35 nm to 45 nm) and various AG potentials. The M-point gap, which reveals key characteristics of the AG band structure, was measured by intersubband excitations using resonant inelastic light scattering (RILS) at low temperature. We found that the M-point gap could be tuned from 0.5 meV to 1.2 meV, with the band dispersion near the M point evolving from the Dirac-like case to flat band. Emerging flat-band physics in such tunable system will be discussed. [1] S. Wang, et al. Nature Nanotech. 13, 29 (2018). [2] L. Du, et al., Nature Commun. 9, 3299 (2018).

11:27AM S11.00002: Fabricating shallow 2D systems in GaAs/AlGaAs heterostructures towards the creation of Artificial Graphene  
YONATAN ASHLEA ALAVA (Presenter), OLEH KLOCHAN, QINGWEN WANG, School of Physics, University of New South Wales, ANDREAS D. WIECK, ARNE LUDWIG, JULIAN RITZMANN, Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, ALEX R HAMILTON, School of Physics, University of New South Wales — Patterning ordinary GaAs/AlGaAs heterostructures with a triangular nano-array of quantum anti-dots has been shown to yield Artificial Graphene. The lattice spacing of the patterned quantum anti-dot array must be in the order of 100 nm to enable the observation of Dirac physics. This implies that the GaAs/AlGaAs interface has to be considerably shallower than 100 nm to enable strong modulation of the 2D carriers with surface gates. Fabricating low disorder shallow 2D systems is experimentally challenging due to the close proximity to the surface and the thin barrier to the surface gate, determined by the AlGaAs layer. This thinner barrier increases leakage between the gate and the 2D system, and increases scattering at the interface, damaging the mobility of the 2D carriers.

Here we present results on the fabrication of 2D systems in accumulation mode heterostructures as shallow as 35 nm. We use aluminium gates grown in-situ in the MBE chamber, to avoid exposing the GaAs surface to air. Surprisingly, we find that the 2D mobility with an ‘in situ’ gate is lower than with an ‘ex situ’ gate. We investigate the density dependence of the mobility to identify the underlying scattering mechanisms behind this observation.

11:39AM S11.00003: A novel route to achieve two dimensional (2D) carrier confinement in a wedge-shaped polar semiconductor structure  
SWARUP DEB (Presenter), SUBHABRATA DHAR, Physics, Indian Institute of Technology Bombay — A novel route to achieve two dimensional (2D) carrier confinement in a wedge-shaped polar semiconductor has been demonstrated theoretically. Tapering of the wall along the direction of the spontaneous polarization leads to the development of charges of equal polarity on the two inclined facets of the wall. Negative/positive polarization charges on the facets can push the electrons/holes inward for an n-/p-type material leading to the formation of 2D electron/hole gas at the central plane and depletion regions at the outer edges of the wall. Schrodinger and Poisson equations are solved self-consistently to obtain the potential and charge density distribution in n-type GaN nanowalls, tapered along c-axis by different angles. Carrier mobility in this 2D carrier gas is estimated to be significantly higher than that of bulk. A recent experimental finding indeed shows a very high electron mobility in wedge-shaped GaN nanowall networks. Properties of high mobility and the vertical orientation of the 2D confinement can be exploited in fabricating highly conducting transparent interconnects and high mobility field effect transistors, which can lead to a large-scale integration of 2D devices in future.

11:51AM S11.00004: Classical elements in the magnetoconductance of two-dimensional Lorentz gases*  
BEATE HORN-COSFELD (Presenter), JAKOB SCHLUCK, Condensed Matter Physics, Heinrich-Heine University Düsseldorf, NIMA HAMIDI SIBONI, JÜRGEN HORBACH, Institute of Theoretical Physics II, Heinrich-Heine University Düsseldorf, THOMAS HEINZEL, Condensed Matter Physics, Heinrich-Heine University Düsseldorf — Electrons moving through an array of identically shaped obstacles at random positions form a Lorentz gas. [1] In two-dimensional systems, strong deviations of the magnetoresistance from the Boltzmann model are observed experimentally and in numerical simulations, which have a classical origin. At low magnetic fields, memory effects [2] cause subdiffusive transport, which generates a strong positive magnetococonductivity, while weak localization is absent. At intermediate magnetic fields, the transport develops a superdiffusive character, which is visible as a pronounced maximum in the magnetoconductance at sufficiently large obstacle densities. [3] In dilute two-dimensional Lorentz gases, the interplay between the Lorentz obstacles and the residual background disorder causes strong corrections to the behavior of a clean Lorentz gas.

12:03PM S11.00005: Temperature dependence of transverse magnetic focusing in high-mobility GaAs/AlGaAs*
ADBHUT GUPTA (Presenter), JEAN HEREMANS, Virginia Tech, SAEED FALLAHI, MICHAEL MANFRA, Purdue University — The temperature dependence of the ballistic and mesoscopic transport phenomenon of transverse magnetic focusing (TMF) is investigated in a two-dimensional electron system in a high-mobility GaAs/AlGaAs heterostructure at low temperatures 0.4 K < T < 20 K (electron mean free path ~ 80 μm at 4.2 K). Measurements use in-line configurations with distance between the injector and collector of L = 7 μm, and bent TMF configurations with L = 5 μm horizontal and 2 μm vertical. In both configurations, the TMF amplitude (non-local resistance $R_f$) shows a monotonic decrease as T is increased from 4 K to 20 K, according to $R_f \sim 1/T^2$. The dependence on T is analyzed by fitting $R_f$ according to different scattering mechanisms, with $R_f \sim 1/T^2$ indicating a dominant role for inelastic electron-electron interactions. In the particular temperature range, electron-electron interactions point to the importance of momentum exchange between the ballistic beam and the surrounding carrier fluid, and hence to the existence of a hydrodynamic transport regime, which has recently received increasing attention. The experiments suggest that in addition to ballistic aspects, TMF presents hydrodynamic aspects as well.

12:15PM S11.00006: Studies on the nonlinear optical properties of two-step GaAs/Ga$_{1-x}$Al$_x$As quantum well
JUAN CARLOS MARTINEZ OROZCO (Presenter), Unidad Académica de Física, Universidad Autónoma de Zacatecas, F. UNGAN, Faculty of Technology, Department of Optical Engineering, Cumhuriyet University, K. A. RODRÍGUEZ-MAGDALENO, Unidad Académica de Física, Universidad Autónoma de Zacatecas, A. DEL RÍO-DE SANTIAGO, Unidad Académica de Ingeniería, Universidad Autónoma de Zacatecas — The numerical computation for the absorption coefficient and the relative refactive index change, considering the third order correction nonlinear optical properties, is reported. This study was performed for an interesting symmetric two-step GaAs/Ga$_{1-x}$Al$_x$As quantum well subjected to a constant electric field applied along the growth direction z of strength $F$, an in-plane constant magnetic field of magnitude $B$ and considering also the intense laser field effect. The optical properties study is performed by using the well-studied compact matrix formalism expression for the nonlinear optical properties of interest. In the case of the intense laser field effect on the system, when this is irradiated, we implemented the so-called laser-dressed potential deformation characterized by the laser-dressing parameter $\alpha_0$. In general we find that the structural parameters as the step-potential of the central barrier width, permit to control the resonant peak and the amplitude in an important way, the system becomes more sensible to electric than to magnetic field, and finally the intense, non-resonant, laser field can strongly change the optical properties.

12:27PM S11.00007: Carrier Lifetime Analysis in a Transistor Laser by Using Non-Equilibrium Green's Function Method with Effective Bond-Orbital Model*
FU-CHEN HSIAO (Presenter), University of Illinois at Urbana-Champaign, YIA-CHUNG CHANG, Research Center for Applied Sciences, Academia Sinica, JOHN DALLESASSE, University of Illinois at Urbana-Champaign — Carrier injection and recombination in a single quantum well AlGaAs/InGaP/GaAs/InGaAs transistor laser (TL) is examined theoretically with the non-equilibrium Green's function (NEGF) method. The multi-band effects are incorporated in the NEGF method by applying effective bond-orbital model (EBOM). Carrier-phonon scattering are taken into account within the deformation-potential approximation. The squared momentum matrix elements, scattering rate, and the density of states for the quantum well in a TL are presented. In addition, the simulated I-V characteristics as well as the frequency response of the TL is shown and compared with the experimental data. In the end, the carrier recombination in the quantum well as well as the base region are discussed based on the results calculated by the present model.

Acoustic Nanostructures for Charge Carrier Confinement in GaAs/AlGaAs Multiple Quantum Wells

KEVIN VALLEJO (Presenter), CHRISTOPHER F SCHUCK, KATHRYN E SAUTTER, Micron School of Materials Science and Engineering, Boise State University, TRENT GARRETT, Physics, Boise State University, ARIEL E WELTNER, Micron School of Materials Science and Engineering, Boise State University, BAOLAI LIANG, California NanoSystems Institute, University of California, Los Angeles, ZILONG HUA, DAVID H HURLEY, Idaho National Laboratory, PAUL J SIMMONDS, Micron School of Materials Science and Engineering, Boise State University — Quantum confinement of charge carriers in semiconductors is at the heart of next generation technologies for energy conversion, encryption and computation. We use picosecond-duration surface acoustic phonon pulses to produce lateral 2D and 3D carrier confinement in polar III-V semiconductor quantum wells. Shear strain and dilatation generated by the phonon pulses vary with depth below the sample surface, locally deforming the valence and conduction bands to produce lateral confinement in the plane of a quantum well that is externally controllable. We grew a GaAs/AlGaAs heterostructure containing three quantum wells, 5, 7, and 10 nm wide, at depths of 14, 49, and 112 nm beneath the sample surface respectively, to coincide with different piezoelectric field strengths. We verify carrier confinement and transport using metallic gratings on the surface of the sample to generate and detect surface acoustic phonons. These gratings modulate light absorption on length scales below the optical diffraction limit. Our approach enables a spectrally selective scheme for generating surface acoustic phonons 20 – 200 nm in wavelength. Length scales at the lower end of this range are associated with quantum confinement.

The Effect of Nanostructure on Near-Infrared Absorption in M-Plane AlGaN/(In)GaN Heterostructures

TRANG NGUYEN (Presenter), MOHAMMADALI SHIRAZI-HOSSEINI-DOKHT, YANG CAO, Physics and Astronomy, Purdue University, ALEXANDER SENICHEV, Birck Nano Technology Center, Purdue University, BRANDON DZUBA, Physics and Astronomy, Purdue University, ROSA DIAZ, GEOFFREY GARDNER, Birck Nano Technology Center, Purdue University, OANA MALIS, MICHAEL MANFRA, Physics and Astronomy, Purdue University — Near infrared intersubband (ISB) absorption of nonpolar AlxGa1-xN/(In)GaN is studied due to its broad potential applications into optoelectronic devices. Above 60% Al-composition, m-plane AlGaN alloy becomes kinetically unstable during the plasma-assisted molecular beam epitaxy growth generating unique nanostructures. The nanostructures are imaged with energy dispersive x-ray spectroscopy and scanning transmission electron microscopy. They consist of platforms of higher than expected Al-composition and islands of lower Al-composition AlGaN. We discuss the consequences of these nanostructures on ISB absorption energy and linewidth. We are also investigating strain-balanced AlxGa1-xN/InGaN (x<0.6) as an alternative to AlxGa1-xN/GaN (x>0.6).

Influence of QD Morphology on Photoluminescence in GaSb/GaAs Multilayers

CHRISTIAN GREENHILL (Presenter), ERIC ZECH, ALEXANDER CHANG, Materials Science & Engineering, University of Michigan - Ann Arbor, STEPHEN CLARK, GANESH BALAKRISHNAN, Electrical and Computer Engineering, University of New Mexico - Albuquerque, RACHEL GOLDMAN, Materials Science & Engineering, University of Michigan - Ann Arbor — Due to the predicted composition and strain dependence of type I versus type II band offsets, GaSb/GaAs quantum dots (QDs) are promising for a variety of optoelectronic applications. For GaSb/GaAs multilayers, atomic structures ranging from QDs, quantum rings and clusters have been observed, with photoluminescence (PL) energies ranging from 0.9 to 1.3eV. However, the association of these emission energies with specific nanostructure morphologies remains elusive. We investigate the structural and optical properties of GaSb/GaAs multilayers, with and without 3D nanostructures, using cross-sectional transmission electron microscopy, atom probe tomography (APT), and PL. In both cases, we find PL energies at 1.33eV and 1.49eV, which are attributed to 2D GaSb/As layers and the GaAs matrix, respectively. For the case with 3D nanostuctures, both individual QDs and circular arrangements of QDs, termed QD-rings, are observed. For both cases, Sb-rich cores are apparent, with xSb up to 0.40 (individual QDs) and 0.25 (QD-rings). Thus, we attribute 1.08 eV and 1.2 eV emissions to the individual QDs and QD-rings, respectively. Local measurements of the electronic states using scanning tunneling microscopy will also be presented.

*We gratefully acknowledge support of the NSF, DGE 1256260.
1:15PM S11.00011: Lattice-matched In$_{0.17}$Al$_{0.83}$N/GaN heterostructures for near-infrared intersubband absorption

ALEXANDER SENICHEV (Presenter), TRANG NGUYEN, ROSA DIAZ, BRANDON DZUBA, MOHAMMADALI SHIRAZI-HOSSEINI-DOKHT, YANG CAO, MICHAEL MANFRA, OANA MALIS, Purdue University — Lattice-matched In$_{0.17}$Al$_{0.83}$N/GaN heterostructures are promising platforms for near-infrared optoelectronic devices based on intersubband transitions. Previously, strong near-infrared intersubband absorption (ISBA) was demonstrated in InAlN/GaN superlattices. But, reducing compositional inhomogeneity of InAlN barriers and effective doping of these heterostructures that affect ISBA properties presented open challenges. Here, we demonstrate that InAlN/GaN structures with saturated indium composition of 0.17 can be grown by plasma-assisted molecular beam epitaxy over a wide range of growth conditions and constructed the growth diagram for lattice-matched InAlN layers. Our results indicate that the studied growth conditions alone are not sufficient to eliminate the indium segregation and additional mechanisms are involved. The impact of an indium adlayer and a thin AlN nucleation layer on compositional inhomogeneity of InAlN barriers is discussed. We report the impact of different Si doping profiles and doping levels on structural quality and hence ISBA properties of lattice-matched InAlN/GaN superlattices.

*AS and BD were supported from NSF award ECCS-1607173. TN, YC, and OM acknowledge partial support from NSF grant ECCS-1253720. MS-HD was supported in part by NSF award DMR-1610893.

1:27PM S11.00012: Integrated III-V/Si Visible and IR Nanowire Photodetectors

ARJUN SHETTY (Presenter), EDUARDO BARRERA, FRANCOIS SFIGAKIS, Institute for Quantum Computing, University of Waterloo, MITCHELL ROBSON, NEBILE ISIK, CURTIS GOOSNEY, RAY LAPIERRE, Department of Engineering Physics, McMaster University, JONATHAN D BAUGH, Institute for Quantum Computing, University of Waterloo — Self-assembled nanowires can support optical resonant modes and act as very effective waveguides that concentrate and absorb light over only a few microns of nanowire length, enabling highly efficient photodetection. The resonant absorption shows wavelength selectivity that can be tuned continuously across the visible and IR wavelengths by adjusting the nanowire diameter during molecular beam epitaxy growth on silicon wafers. Thus, ordered arrays of III-V semiconductor nanowires, integrated with standard Si technology, could provide low-cost, high-performance multi-spectral photodetectors.

We realized photodetectors from ordered arrays of InAs (~120 nm diameter) and GaAs (~300 nm diameter) nanowires grown on Si(111) substrates. The nanowires grow out of holes etched into a thin oxide layer down to the Si layer. These holes are lithographically patterned and allow control of the nanowire diameter, pitch and array size, the latter being adjustable down to a single nanowire. The nanowires show a wavelength-dependent response, with a peak centered at ~450 nm for InAs and ~750 nm for GaAs.

1:39PM S11.00013: White-light Emitted InGaN Nanorods Grown on Pyramided Si Substrate

CHUN-YEH LIN (Presenter), CHUNG-LIN WU, SHU-JU TSAI, SHENG-SHONG WONG, NIEN-TING TSAI, National Cheng Kung University — In this study, white-light emitted InGaN nanorods were grown on pyramided Si substrate by plasma-assisted molecular beam epitaxy system (PA-MBE) with fixed In/Ga flux ratio. Due to the textured morphology of pyramided Si substrate, using energy-dispersive X-ray spectroscopy (EDS), we demonstrate that the impingement flux ratios of Ga/In and N-plasma varied with different facets of Si pyramids, which results in different light emission ranges on different facets and mixed into white light emission. By conducting spatial resolved catholuminescence spectroscopy (CL), we have resolved that each facet emits different CL spectrum. This finding could assist the design of nanorods-embedded light emitted devices that can be grown more efficient and compact in structure.
1:51PM S11.00014: Tensile-Strained Ge Quantum Dots on (111) and (110) Surfaces*  KATHRYN SAUTTER (Presenter), CHRISTOPHER SCHUCK, TRENT GARRETT, ARIEL E WELTNER, KEVIN VALLEJO, PAULJ SIMMONDS, Boise State University — Si and Ge are ubiquitous in electronics, but their indirect bandgaps make them unsuitable for light emitting devices. Theory shows that placing Ge under tensile strain will allow us to engineer its electronic band structure. Tensile strains of 2–4% should transform Ge either into a direct band gap semiconductor or a semimetal, with applications from infrared emitters to low-loss tunnel junctions. Researchers have therefore tried various ingenious methods to create tensile-strained Ge, but these attempts typically generate strain-induced defects and do not result in viable optoelectronic materials. Our approach to this problem is to create Ge quantum dots (QDs) that self-assemble as a result of biaxial tensile strains on low-index surfaces. We have previously demonstrated defect-free, tensile GaAs(111) QDs. Given the similar lattice constants of GaAs and Ge, we follow the same approach to produce self-assembled Ge QDs at 3.7% tensile strain, which we anticipate should lead to optically active Ge with a reduced bandgap. We will discuss our control of Ge QD properties with growth parameters, and discuss possible reasons for some of the structural and optical phenomena we observed.

2:03PM S11.00015: Light Emission from Direct Bandgap Hexagonal Silicon Germanium*  ELHAM FADALY (Presenter), ALAIN DIJKSTRA, Applied Physics, Eindhoven University of Technology, JENS RENÈ SUCKERT, Faculty of Physics and Astronomy, Friedrich-Schiller-Universität Jena, MARCEL VERHEIJEN, SEBASTIAN KOELLING, Applied Physics, Eindhoven University of Technology, JONATHAN FINLEY, Physics, Technische Universität München, SILVANA BOTTI, Faculty of Physics and Astronomy, Friedrich-Schiller-Universität Jena, JOS HAVERKORT, ERIK P. A. M. BAKKERS, Applied Physics, Eindhoven University of Technology — Efficient light emission from Si and Ge has been a holy grail due to their indirect bandgap nature. Recently, Ge-rich alloys, with a hexagonal structure have been theoretically predicted to exhibit a direct band gap nature. Density functional theory (DFT) calculations predict a 0.3 eV bandgap for hex-Ge, which can be tuned up to 0.9 eV by alloying with Si. Yet, the fundamental bottleneck is that Ge and its alloys crystallize naturally in the cubic structure which is optically inactive due to its indirect bandgap nature. We have realized hex- SiGe by utilizing wurtzite GaAs nanowire cores as a template to transfer the crystal structure to the SiGe shells in a core-shell geometry. We demonstrate photoluminescence of hex-Ge at 3.5 µm at low temperatures and up to room temperature. In addition, we validate the tunability of the wavelength between 1.8 µm and 3.5 µm via alloying Ge with up to 30% Si. These results reveal the potential of this new material system for SiGe based light emitting devices.

Session S12 DCMP: Adatom and Proximity Driven Electronic Interactions in Graphene

BCEC 153A - Jianhao Chen, Peking University

11:15AM S12.00001: Strained-induced Landau levels in momentum space  ÉTIENNE LANTAGNE-HURTUBISE (Presenter), PASCAL NIGGE, AMY QU, ERIK MÅRSELL, University of British Columbia, STEFAN LINK, Max Planck Institute for Solid State Research, GARY TOM, CHRISTOPHER GUTIERREZ, University of British Columbia, ULRICH STARKE, Max Planck Institute for Solid State Research, DOUGLAS ANDREW BONN, SARAH A. BURKE, ANDREA DAMASCELLI, MARCEL FRANZ, University of British Columbia — It is well known that certain strain patterns in graphene couple to the low-energy Dirac fermions as pseudo-magnetic fields -- i.e. magnetic fields that preserve time-reversal symmetry. This can lead to the formation of quantized Landau levels in the absence of magnetic fields, as first predicted by [Guinea et al., Nat. Phys. 6, 30 (2010)] and subsequently identified in local STM measurements [Levy et al., Science 329, 544 (2010)]. Here we extend this body of work by considering momentum-resolved signatures of large-scale, strain-induced pseudo-magnetic fields in graphene. Our theoretical modeling supports the first observation of Landau levels in ARPES. The corresponding pseudo-magnetic field of 41 T is attributed to strain generated by shallow triangular nanoprisms on our SiC substrates, over which graphene grows without grain boundaries, as revealed by AFM and STM measurements. Our work demonstrates the feasibility of generating strain-induced quantum phases in 2D Dirac materials on a wafer-scale size.
11:27AM S12.00002: Emergence of Kondo Resonance in Graphene Intercalated with Cerium

JINWOONG HWANG (Presenter), Pusan National University, KYOO KIM, Max Planck-POSTECH/Hsinchuen Center for Complex Phase Materials, HYEJIN RYU, Lawrence Berkeley National Laboratory, JINGUL KIM, Pohang University of Science and Technology, JI-EUN LEE, Pusan National University, SOORAN KIM, Pohang University of Science and Technology, MINHEE KANG, Pusan National University, BYUNG IL MIN, Pohang University of Science and Technology, ALESSANDRA LANZARA, UC Berkeley, JINWOOK CHUNG, Pohang University of Science and Technology, SUNG-KWAN MO, JONATHAN DENLINGER, Lawrence Berkeley National Laboratory, BYEONG-GYU PARK, Pohang Accelerator Laboratory, CHOOINGYU HWANG, Pusan National University — The interaction of a magnetic impurity with surrounding electrons has been a core problem in modern physics to understand fundamentals of many-body effects and its relation to magnetism. In particular, antiferromagnetic screening of the local magnetic moment by conduction electrons leads to the formation of a new resonant-type many-body ground state, so-called Kondo resonance. Here we report the realization of the Kondo resonance in a prototypical two-dimensional system, graphene, induced by the presence of cerium with the localized spin of a 4f-electron. The combination of two complementary techniques, angle-resolved photoemission spectroscopy and dynamic mean-field theory, reveals the development of new spectral weight near Fermi energy at lower temperature that is hybridized with the graphene π-band. The observed T-dependence provides not only a direct evidence of the formation of the many-body ground state in graphene, but also novel insight how Kondo physics emerges in the sea of two-dimensional Dirac electrons.

11:39AM S12.00003: Gate Modulated Interaction Between Quantum Dots in a Graphene/hBN Heterostructure

EBERTH QUEZADA (Presenter), FREDERIC JOUCKEN, ZHEHAO GE, JOHN L DAVENPORT, University of California, Santa Cruz, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, JAIRO VELASCO JR., University of California, Santa Cruz — Understanding interactions between atoms is fundamental in condensed matter systems. In heterostructures of graphene and hexagonal boron nitride (hBN) we are able to create tailor-made quantum dots in a background of Dirac fermions. Recent studies have explored the nature of single quantum dots and how their behavior is influenced by the application of a perpendicular magnetic field. However, no efforts have been made towards understanding the interaction between a pair of Dirac fermion quantum dots. We will discuss and present spatially-resolved scanning tunneling spectroscopy studies performed on a pair of quantum dots. We will also show how their behaviour is influenced by changes in their shape, size, and separation attained through the modulation of an electrostatic backgate.

11:51AM S12.00004: Proximity-induced Ising spin orbit coupling in bilayer graphene/WSe2 van der Waals heterostructures

XIAOMENG CUI (Presenter), JOSHUA ISLAND, University of California, Santa Barbara, JUN KHOO, CYPRIAN LEWANDOWSKI, MIT, HAOXIN ZHOU, ERIC SPANTON, University of California, Santa Barbara, DANIEL A RHODES, JAMES HONE, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, LEONID LEVITOV, MIT, MICHAEL ZALETEL, University of California, Berkeley, ANDREA YOUNG, University of California, Santa Barbara — Interlayer proximity effects at van der Waals interfaces provide a tool for engineering electronic phases that do not occur in isolated two-dimensional materials. A longstanding goal is proximity induced spin orbit coupling (SOC) in graphene. While previous experimental efforts have reported signatures of SOC in graphene-transition metal dichalcogenide (TMD) heterostructures, these studies have primarily relied on indirect charge and spin transport measurements preventing definitive resolution of the strength, nature, or origin of the induced SOC. Here we report on the direct observation of proximity induced SOC in bilayer graphene in contact with tungsten selenide (WSe2). Using spin- and layer-resolved broken symmetry Landau levels as a probe of layer specific proximity-induced SOC, we observe rearrangement of these levels consistent with an Ising (valley-Zeeman) type SOC with a strength of ≈2 meV. Our observations pave the way toward new engineered topological phases in van der Waals heterostructures.

12:03PM S12.00005: Strain engineering of a pseudo gauge field superlattice in a suspended graphene nanoribbon studied by scanning probe microscopy

RIJU BANERJEE (Presenter), Pennsylvania State University, VIET-HUNG NGUYEN, Université catholique de Louvain, LAVISH PABBI, TOMOTAROH GRANZIER-NAKAJIMA, Pennsylvania State University, AURELIEN LHERBIER, Université catholique de Louvain, ANNA BINION, MAURICIO TERRONES, Pennsylvania State University, JEAN-CHRISTOPHE CHARLIER, Université catholique de Louvain, ERIC HUDSON, Pennsylvania State University — Engineering exotic electronic states in novel materials, which are unrealizable in traditional systems, has been the focus of intense research over the past decade. Unlike present electronics, which rely on controlling the flow of charges primarily by electric fields, strain, for example, can control electrons by generating pseudo gauge fields in 2D materials. In this talk, we report strain engineering of pseudo electric and magnetic superlattices in suspended graphene nanoribbons by extreme (>10%) strain and study the local electronic density of states by scanning tunneling microscopy. These measurements reveal Landau levels in the presence of highly non-uniform pseudo-magnetic fields. DFT and tight binding calculations imply the existence of counterpropagating snake states along the edges of the nanoribbons reminiscent of topological materials.

*NSF Grant: 1229138
12:15PM S12.00006: Charge density wave induced proximity spin-orbit coupling effects in graphene on 1T-TaS₂*
KAROL SZALOWSKI, University of Lodz, MARTIN GMITRA (Presenter), P. J. Safarik University —
Graphene on transition-metal dichalcogenides (TMDCs) exhibits proximity spin-orbit effects opening new venues for optospintronics [1], and provides route for exploring robust helical edge states [2, 3]. 1T-TaS₂ is a layered TMDC showing metal-insulator transition and the sequence of different charge density wave (CDW) transformations [4]. We present our first-principles results for the electronic band structures of graphene on 1T-TaS₂ in normal state and for periodic lattice distorted David star pattern providing commensurate CDW phase. We discuss the orbital and spin-orbital proximity effects with phenomenological symmetry-based Hamiltonian that we use to fit the first-principles data. The extracted spin-orbit coupling parameters are of the order of meV. A fascinating finding is that induced proximity effects in graphene on 1T-TaS₂ are significantly influenced by the presence of the commensurate CDW in 1T-TaS₂.

12:27PM S12.00007: Synthetic topological phases in bilayer graphene via van der Waals proximity induced spin orbit coupling  JOSHUA ISLAND (Presenter), XIAOMENG CUI, University of California, Santa Barbara, JUN KHOO, CYPRIAN LEWANDOWSKI, Massachusetts Institute of Technology, HAOXIN ZHOU, ERIC SPANTON, University of California, Santa Barbara, DANIEL A RHODES, JAMES HONE, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, LEONID LEVITOV, Massachusetts Institute of Technology, MICHAEL ZALETEL, University of California, Berkeley, ANDREA YOUNG, University of California, Santa Barbara — Spin orbit coupling (SOC) forms the basis of time reversal invariant topological insulators. While graphene provided the first theoretical model for a topological insulator, the small intrinsic SOC in carbon make such phases unobservable. Here we engineer a synthetic topological insulator-like phase in bilayer graphene via proximity induced SOC from WSe2 in a van der Waals heterostructure. At zero magnetic field, we observe a new incompressible phase at charge neutrality due to proximity induced Ising-type SOC, having equal and opposite magnitude on each layer. Transport measurements show enhanced conductance within this new phase, which is rapidly suppressed by an in-plane magnetic field, consistent with modeling that suggests the new phase hosts spin filtered edge states and has a nearly quantized spin Hall conductance. Interestingly, spin is approximately conserved in this system despite large Rashba spin orbit coupling, whose effects are strongly suppressed in the spin-filtered edge states. Remarkably, electric field can be used to tune the system between the quantum spin Hall phase and a trivial insulator, permitting reconfigurable topological edge state circuits.

12:39PM S12.00008: Topological phases in intercalated epitaxial graphene* CAI-ZHUANG WANG (Presenter), MINSUNG KIM, KAI-MING HO, Ames Laboratory — Intercalation is one of the effective methods to functionally manipulate the electronic structure of epitaxial graphene. Here, using first-principles density functional theory calculations, we design 2D topological insulators in epitaxial graphene via intercalation. We find that the electronic band structure near the Fermi energy shows Dirac-cone type or quadratic band dispersion depending on the type of intercalants, and topologically nontrivial band gap opens due to the considerable strength of the spin-orbit coupling. Our results indicate that the intercalation is a promising way to realize topological phases in graphene, and could be important in future nano device applications of graphene.

*This work was supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division. The research was performed at Ames Laboratory, which is operated for the U.S. DOE by Iowa State University under Contract No. DE-AC02-07CH11358.
Effect of High gate-voltage application on the molecular adsorption on Graphene*  KAZUYUKI TAKAI (Presenter), TAICHI UMEHARA, YASUSHI ISHIGURO, Hosei University — The electronic properties of graphene are well tuned by guest chemical species due to its 2D nature. We have clarified that the charge transfer between molecules and graphene proceeds by an electrochemical process based on the fact that the kinetics of the charge transfer decreases with down and up shift of the Fermi energy of graphene for electrons and holes, respectively. In this study, the electrochemical potential is widely varied by graphene FET in order to induce various electrochemical reactions for the charge transfer phenomena. In the case of the hole doping by oxygen adsorption on graphene, the lower gate-voltage, the slower hole doping reactions as we reported [1] and finally no charge doping occurs at enough higher gate-voltage around -80 V. Interestingly, further lowering of the gate-voltage results in the electron doping by the oxygen adsorption on graphene. Even in this condition, the doping kinetics are accelerated by the presence of water molecule. This suggests that different electrochemical reactions are responsible for the charge transfer by oxygen adsorption on graphene between the higher gate-voltage region and lower voltage region.

Graphene-Bi (111) interface: atomic structure and electronic properties*  IVAN NAUMOV (Presenter), PRATIBHA DEV, Physics and Astronomy, Howard University — Interfacial interactions are widely used to engineer desired electronic properties. In this context, the interface between graphene and nanostructured bismuth is especially interesting since both the materials exhibit unique properties associated respectively with the Dirac cones and quantum spin-Hall states along the edges and hinges. In this work, using first-principles calculations, we study the interfacial interaction between graphene and Bi (111) surfaces. Since the actual structure of graphene on Bi (111) can be incommensurate, we investigated a large number of crystal approximants to the incommensurate interface and found the most stable one. Despite hybridization between graphene and substrate orbitals, the graphene-derived Dirac cones are preserved, although shifted with respect to the Fermi level due to the n-doping of graphene. We also find that a small gap opens up at the original Dirac points in these cones due to interface-induced spin–orbit coupling within graphene. At the same time, the bands near the gamma point are mostly Bi-derived and resemble the corresponding surface states in pure Bi. Using the obtained results, we discuss possible applications of graphene/Bi interfaces in future electronic devices.

Comparative Mapping of the Local Potential of Graphene/hBN Systems Using Scanned Probe Techniques  WYATT BEHN (Presenter), VICTOR W BRAR, ZACH KREBS, KEENAN SMITH, GREGORY HOLDMAN, University of Wisconsin - Madison — Mapping the local electrostatic potential of 2D materials is an important step in understanding how defects and strain affect local electrostatic structure. Potential mapping can also reveal the strength of el-el interactions in a material, and – when performed under transport conditions – can directly probe the nature of electronic flow. Specifically, probing the local potential gradient of a current-driven graphene sheet could provide insight into how electronic transport shifts between ballistic and diffusive regimes. We present preliminary results comparing three scanned probe methods for mapping electrostatic potential of a graphene sheet: Kelvin probe force microscopy (KPFM), scanning tunneling potentiometry (STP), and scanning tunneling spectroscopy (STS). We discuss the comparative advantages of each technique, describing how each method performs when measuring a graphene/hBN system with current applied in situ.

Concomitant enhancement of electron-phonon coupling and electron-electron interaction in graphene decorated with ytterbium  MINHEE KANG (Presenter), JINWOONG HWANG, JEUN LEE, Pusan National University, ALEXEI V FEDOROV, Lawrence Berkeley Natl Lab, CHOONGYU HWANG, Pusan National University — The presence of foreign atoms induces exotic many-body physics in a condensed matter system. Especially, a two-dimensional system is very sensitive to such an external perturbation to lead metal-insulator transition, Kondo effect, strongly enhanced electron-phonon coupling, etc. Here we report that the presence of Yb results in the enhancement of not only electron-phonon coupling, but also electron-electron interaction in graphene. When the band structure of graphene with Yb exhibits the characteristics of electron-phonon coupling that is not clearly observed in as-grown graphene, the slope of the energy-momentum dispersion was also found to decrease by the presence of Yb using angle-resolved photoemission spectroscopy. Within the Fermi liquid theory, the decreased slope indicates enhanced electron-electron interaction, suggesting possibility interplay between electron-phonon coupling and electron-electron interaction in graphene decorated with foreign atoms.
1:39PM S12.00013: Nanoscale distribution of strains and defects in graphene transferred onto polymethylmethacrylate

DMITRY VOYLOV (Presenter), Mechanical Engineering, Tufts University, IVAN VLASSIOUK, Energy & Transportation Science Division, Oak Ridge National Laboratory, NICK LAVRIK, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, ALEX KISLIUK, ALEXEI P SOKOLOV, Chemical Sciences Division, Oak Ridge National Laboratory — Graphene has attracted a wide interest over the last decade and deeper understanding of formation of defects and strains controlling its properties is one of the major goals. One of the commonly used methods for transferring graphene on a substrate of interest utilizes polymethylmethacrylate (PMMA) as a temporary support. While several studies demonstrated that the length scale of strain can be as small as a few nm for graphene on SiO₂ substrates [1], the strain coherence length and distribution of defects on a nanoscale for graphene laying on PMMA remains poorly understood. Here we present tip-enhanced Raman Spectroscopy (TERS) study of single layer graphene on top of PMMA. Our results provide a clear experimental evidence that the locations of defects correlate with topological features of PMMA, which on the other hand replicates topological structure of copper foil. We found that the strain is anisotropically distributed with a length scale varies from tens hundred nm.

1:51PM S12.00014: Deposition of single-molecule magnets on graphene quantum dots.

LUKE ST. MARIE (Presenter), Physics, Georgetown University, JAKUB HRUBY, CEITEC, JAMES HUNT, Physics, Georgetown University, PETR NEUGEBAUER, IVAN NEMEC, CEITEC, A EL FATIMY, Physics, Georgetown University, RACHAEL MYERS-WARD, DAVID KURT GASKILL, US Naval Research Laboratory, MATTIAS KRUSKOPF, YANFEI YANG, RANDOLPH E ELMQUIST, National Institute of Standards and Technology, PAOLA BARBARA, Physics, Georgetown University — Gapless graphene is a single-atom-thick material that yields ultra-broadband photodetectors for applications that require high sensitivity. These applications include spectroscopy of single molecule magnets (SMMs), metal-ion complexes that exhibit quantum behavior at low temperatures and have great potential as components for quantum computing and molecular spintronics. By grafting small amounts of SMMs directly to the surface of a graphene quantum dot, we can utilize the high sensitivity of a graphene hot-electron bolometer to perform spectroscopy on the SMMs. We have investigated various methods of grafting transition-metal-based SMMs to the graphene and characterizing the deposited molecules.

Session S13 DMP GMAG: 2D Materials (General): Transport and Optical Phenomena -- Magnetism

BCEC 153B - TeYu Chien - Tag(s): Focus

11:15AM S13.00001: Magneto-optical properties of bilayer transition metal dichalcogenides

MUHAMMAD ZUBAIR (Presenter), Physics, Concordia University, MUHAMMAD TAHIR, Colorado State Univ, PANAGIOTIS VASILOPOULOS, Physics, Concordia University — In transition metal dichalcogenides (TMDCs) the spin-orbit interaction affects differently the conduction and valence band energies as functions of the wave vector k and the band gap is usually large except in few TMDCs that are metallic without band gaps. Consequently, when a perpendicular magnetic field B is applied, the conduction and valence band Landau levels are also different and this leads to a splitting of the interband optical absorption lines in both the absence and presence of an external electric field Ez. When B and Ez are present, the peaks in the imaginary part of the Hall conductivity give two distinct contributions of opposite sign to the interband spectrum. The real part of the right- and left-handed interband conductivity, however, retains its two-peak structure but the peaks are shifted in energy and amplitude with respect to each other in contrast with graphene.

*M.Z. and P.V. acknowledge the support of the Canadian NSERC Grant No. OGP0121756 and Concordia University Graduate Fellowship. The work of M.T. was supported by Colorado State University.
Magneto-Raman Spectroscopy of Layered Transition-Metal Dichalcogenides

JEFFREY SIMPSON (Presenter), Towson University, HEATHER M. HILL, SUGATA CHOWDHURY, FRANCESCA TAVAZZA, ANGELA HIGHT WALKER, NIST — Raman spectroscopy offers a non-contact, non-destructive, and high-throughput optical technique to probe the fundamental physics of two-dimensional (2D) layered materials. We discuss our unique magneto-Raman capability, which affords measurement of Raman spectra with simultaneous variation of temperature (4K to 400K), laser excitation wavelength (tunability from UV to near-IR), and magnetic field (up to 9 T). Coupling to a triple-grating spectrometer provides measurement of low-frequency phonons. Recent results on novel 2D materials will be presented to highlight instrumentation capabilities, including metallic TaSe2, which exhibits transitions between commensurate and incommensurate charge-density wave (CDW) phases, and related, layered materials. The dependence of the observed Raman-active phonons in TaSe2 on temperature and magnetic field will be presented and compared with earlier results on MoS2 and calculations using density functional theory. Specifically, we observe the appearance of low-frequency, zone-folded modes in the CDW state. The phase, amplitude, and previously unanalyzed zone-folding modes are assigned to specific phonons observed in experimental spectra and DFT. Uniquely, the calculations show Ta-rich stripes emerge in the commensurate CDW phase.

Magnetoplasmons in the pseudospin S=1 \(\alpha\)-T3 lattice

ANTONIOS BALASSIS (Presenter), Physics, Fordham University, DIPENDRA DAHAL, Graduate Center, CUNY, GODFREY GUMBS, Hunter College, CUNY — We calculate the dynamical polarizability and the dispersion relation for magnetoplasmons for the \(\alpha\)-T3 model at zero temperature at integer filling. In the absence of magnetic field, the low energy spectrum described by a Dirac-Weyl Hamiltonian consists of a pair of Dirac cones and a dispersionless (flat) band in the K and K' valleys. We use the Peierls substitution to generate the Landau level spectrum for this structure with pseudospin \(S = 1\) which is characterized by a parameter \(\alpha\) for measuring the coupling strength between an additional atom at the center of the honeycomb graphene lattice and the A and B atoms of graphene. We present results for a doped layer for various \(\alpha\) and magnetic fields in the random-phase approximation. These modes may be observed with the aid of inelastic light-scattering experiments.

Negative Magnetoresistance from Berry Curvature and Orbital Magnetic Moment

HAILONG ZHOU (Presenter), CONG XIAO, QIAN NIU, University of Texas at Austin — Longitudinal negative magnetoresistance has attracted tremendous amount of attention since the emergence of three-dimensional topological materials, e.g. Weyl semimetals, due to the effect of chiral anomaly in these systems. In contrast to the extensively studied longitudinal negative magnetoresistance, transverse magnetoresistance in topological systems has been somewhat overlooked. We formulate transverse magnetoresistance for topological systems with non-zero Berry curvature based on semiclassical Boltzmann theory. Model calculation based on gapped two-dimensional valley systems shows explicitly that magnetoresistance is negative in large range of magnetic field, stemming from Berry curvature and orbital magnetic moment.

Electrical and Magneto Transport Properties in Weyl Semimetal MoTe2

LEI WANG (Presenter), Materials Characterization Core, Yale University West Campus, JOSHUA PONDICK, JOHN WOODS, PENGZI LIU, MILAD YARALI, SAJAD YAZDANI, Energy Sciences Institute, Yale University West Campus, MIN LI, Materials Characterization Core, Yale University West Campus, JUDY CHA, Energy Sciences Institute, Yale University West Campus — Molybdenum ditelluride MoTe2, a type II Weyl semimetal, has attracted intense interest due to novel properties such as large magnetoresistance, quantum spin Hall effect and massless carriers. Here we report on electrical and magneto transport studies of exfoliated multilayer MoTe2. Weak antilocalization is observed at low magnetic fields due to strong spin-orbit coupling. We also investigate layer dependent magnetoresistance at various temperatures. A back-gate voltage is applied to change the carrier density and Fermi level. It is shown such electronic properties can be effectively tuned by gate voltage.
12:15PM S13.00006: Magnetotransport in monolayer 2H-MoTe2*  

DANIEL RHODES (Presenter), Columbia Nano Initiative, Columbia University, AUGUSTO GHIOTTO, Department of Physics, Columbia University, ABHINANDAN ANTONY, BUMHO KIM, JAMES HONE, Department of Mechanical Engineering, Columbia University — Monolayer transition metal dichalcogenides (TMD) have been investigated for a variety of interesting aspects: valley Hall effect, biexcitons, and 2-D superconductivity. In magnetotransport, monolayer TMDs break inversion symmetry and as a result have degenerate K/K’ bands which are spin-split. In MoS2, this spin-splitting between the lower and upper K/K’ bands in the conduction band is around 15 meV, 5x larger than expected, and similar results have been extracted from monolayer WSe2. In both cases, neither system can be investigated via electrical transport in both the n- and p-type carrier regime due to the large bandgap and issues with contacts. Monolayer, 2H-MoTe2 however, has a much smaller bandgap of 1.1 eV. Though there has been much work done on electrical characterization in MS2 and MSe2 (M = Mo or W), there has been almost no work done on 2H-MoTe2 as the monolayer is air sensitive and more difficult to contact than like 2-D air sensitive materials such as InSe or black phosphorus. In this study we report the magnetotransport of monolayer 2H-MoTe2 in the ultra-clean limit.

*We would like to acknowledge the support of the National Science Foundation MRSEC program through Columbia in the Center for Precision Assembly of Superstratic and Superatomic Solids (DMR-1420634).

12:27PM S13.00007: Theory of magnetotransport for a cavity-embedded two-dimensional electron gas

NICOLA BARTOLO (Presenter), CRISTIANO CIUTI, Laboratoire MPQ, Université Paris Diderot - Paris 7 — We present a theory pointing out the crucial role of virtual polariton excitations in controlling the dc charge transport properties of cavity-embedded systems. Specifically, we consider the linear magnetotransport of a cavity-embedded two-dimensional electron gas (2DEG) in the regime where no real photons are injected or created in the resonator [1]. Our theory shows that, for a cavity photon mode with in-plane linear polarization, the dc bulk magnetoresistivity of the 2DEG is anisotropic. For high filling factors of the Landau levels, we predict a profound modification in the envelope of the Shubnikov-de Haas oscillations, with the resistivity being increased or reduced depending on the system parameters (an effect observed in recent experiments [2]). In the limit of low magnetic fields and in the ultrastrong light-matter coupling regime, the resistivity along the cavity-mode polarization direction is enhanced.

12:39PM S13.00008: Coordinate-shift induced electron transport in strong magnetic field*

JINGJING FENG (Presenter), University of Texas at Austin, YANG GAO, Department of Physics, Carnegie Mellon University, QIAN NIU, University of Texas at Austin — In a strong magnetic field, electrons primarily execute cyclotron motion, with transverse transport in an electric field from the drifting of cyclotron orbits. We present a classical-Boltzmann theory of longitudinal transport in terms of coordinate shifts of such orbits upon scattering with impurities. During the electron-impurity scattering, the guiding centers suddenly shift their positions, which accumulatively contribute to a longitudinal current. Along with coordinate shifts, the cyclotron orbit radius are also changed, accounting for energy dissipation in the electric field. The resulting longitudinal conductivity is in agreement with the Drude phenomenological theory even beyond the weak scattering limit.

*Welch Foundation

12:51PM S13.00009: Investigation on the Non-trivial Photoluminescence in 2D Antiferromagnetic Layers*

XINGZHI WANG (Presenter), JUN CAO, HIKARI KITADAI, WEIJUN LUO, XI LING, Department of Chemistry, Boston University — Two-dimensional (2D) magnetic systems have attracted intense attention due to potentially applications in low-dimensional spintronic and magnetic devices. Recently, we observe a non-trivial photoluminescence in metal phosphorus chalcogenides, which are 2D antiferromagnetic materials. Multiple photoluminescence peaks are observed and some of them show a strong dependence on the excitation-wavelength and temperature in both the bulk and few-layer cases, which are different from the emission in conventional 2D semiconductors. A rational model based on the special electronic structures and transitions of the materials is proposed to explain this phenomenon. Our studies reveal the intrinsic electronic and magnetic properties in 2D crystals, and suggest the potential functionalities and applications of 2D magnetic layers.

*This work is supported by Boston University. We acknowledges the membership of the photonics center at Boston University.
Spin filter and spin-polarized electric current in silicene nanoribbons induced by point defects

LUIS ROSALES (Presenter), CESAR D. NUÑEZ, PEDRO ORELLANA, Departamento de Fisica, Universidad Tecnica federico Santa Maria, FRANCISCO DOMÍNGUEZ-ADAME, Departamento de Fisica de Materiales, Universidad Complutense de Madrid, RUDOLF ROEMER, 2Department of Physics, University of Warwick — Half-metals, in which one spin channel is conductive but the other one is insulating or semiconducting, is the key ingredient to achieve spin-polarized currents. Hybrid structures of 2D materials and ferromagnetic insulators, like EuO, provide a route to induce half-metallicity and pave the way for spintronic applications. The ferromagnetic insulator induces a proximity exchange interaction between the spins in the material that results in a spin modulation of the structures. In this context, in this work we address the effects of a random distribution of adatoms on the electron transport properties of silicene nanoribbons. The tunnel coupling between adatoms and silicon atoms induces an electronic Fano effect that makes the conductance vanish when the Fermi level matches the resonant energy induced by the adatoms. The resonant energy is independent of the random distribution of adatoms, provided that they do not cluster. When the nanoribbon is in close proximity to a ferromagnetic insulator, the resonant energy depends on the electron spin and consequently the electric current can be highly spin polarized. Our results expand the base of available materials to designing a tunable source of polarized electrons for spintronics.

Anisotropic spin relaxation in graphene/hBN heterostructures

KLAUS ZOLLNER (Presenter), Institute for Theoretical Physics, University of Regensburg, MARTIN GMITRA, Institute of Physics, P. j. Safarik University in Kosice, JAROSLAV FABIAN, Institute for Theoretical Physics, University of Regensburg — Measurements show a large and tunable anisotropy in the spin relaxation of hBN encapsulated bilayer graphene1,2, similar to what is observed in graphene/TMDC heterostructures3. Combining systematic first principles calculations for graphene/hBN heterostructures with a minimal tight-binding model, we extract spin-orbit coupling parameters of graphene in the µeV range. The extracted model parameters depend on (i) interlayer distances, (ii) stacking configurations, and (iii) an external electric field, resulting in a rich parameter space. Based on the Dyakonov-Perel formalism we calculate spin relaxation times for graphene, in the nanosecond range, in agreement with recent experimental measurements. A very important finding is that the spin relaxation anisotropy is maximum close to the charge neutrality point, decreasing with the doping level. In addition, we also show that the anisotropy can be tuned by means of an external electric field, via the precise control of the Rashba SOC.

Bilayer silicene in a magnetic field: spin localization and its effect on the integer and fractional Hall conductivity

THI NGA DO (Presenter), Dept. of Physics, National Cheng Kung University, GODFREY GUMBS, Department of Physics and Astronomy, Hunter College of the City University of New York, POHSIN SHIH, Dept. of Physics, National Cheng Kung University, DANHONG HUANG, US Air Force Research Laboratory — The Hall conductivity of many condensed matter systems presents step structure when a uniform perpendicular magnetic field is applied. We report the emergence of fractions of the Hall conductivity due to the grouping in pairs of an electron with a bilayer silicene sublattice site due to strong spin-orbit coupling. The collective behavior of this pairing causes the conductivity to exhibit steps of \( e^2/h \) or \( 4/5 \ e^2/h \) high for the low-lying spectrum, depending on the dominating sublattices of Landau levels. This coexistence of integer and fractional Quantum Hall States arises from the interplay of lattice geometry, atomic interaction, spin-orbit coupling, and external magnetic field. We also report the significant effect of an external electric field on the evolution of integer and fractional quantum Hall effects.

1:39PM S13.00013: Fano Resonance in Two-Dimensional Magnetic Semiconductor CrPS₄  
PINGFAN GU (Presenter), School of Physics, Peking University, QINGHAI TAN, Institute of Semiconductors, Chinese Academy of Sciences, ZILING LI, YI WAN, XIAOHAN YAO, School of Physics, Peking University, JUN ZHANG, Institute of Semiconductors, Chinese Academy of Sciences, YU YE, School of Physics, Peking University — The two-dimensional (2D) magnetic materials have attracted extensive research interests, not only because of their novel physical properties induced by quantum confinement, but also for their promise for spintronic devices. Chromium thiophosphate (CrPS₄) is a promising ternary antiferromagnetic semiconductor with a Neel temperature of 36 K. We synthesized CrPS₄ single crystals by chemical vapor transport method and performed spectroscopy study at different temperature. The spectra at low temperature showed an asymmetric Fano-resonance shape, which can be explained by coupling between a discrete state and continuum state. This is the first observation of Fano resonance in 2D magnetic materials in near infrared spectrum region. Moreover, we also studied Fano resonance of layered CrPS₄ on dependence of magnetic field, excitation power, laser polarization, etc. Our findings may provide insight of the electronic transition of CrPS₄, which is related to its intrinsic magnetic properties.

1:51PM S13.00014: Si-doped Defect in Monolayer Graphene: Magnetic Quantization*  
POHSIN SHIH (Presenter), THI NGA DO, BOR-LUEN HUANG, Dept. of Physics, National Cheng Kung University, GODFREY GUMBS, Department of Physics and Astronomy, Hunter College of the City University of New York, DANHONG HUANG, US Air Force Research Laboratory, MING-FA LIN, Dept. of Physics, National Cheng Kung University — We explore the rich and unique magnetic quantization of Si-doped graphene defect systems for various concentrations and configurations using the generalized tight-binding model. This model takes into account simultaneously the non-uniform bond lengths, site energies and hopping integrals, as well as a uniform perpendicular magnetic field. The magnetic quantized Landau levels (LLs) could be classified into four different groups based on the probability distributions and oscillation modes. The magneto-optical selection rules, reflecting the main characteristics of LLs, cover Δn = |n⁺−n⁻| = 0 and 1. These rules for inter-LL excitations arise from the non-equivalence or equivalence of the and sublattices in a supercell. The spectral intensity can be controlled by oscillator strength using a canonical momentum as well as by density of states using concentration and distribution of doped Si atoms.

Session S14 DMP: 2D Materials (Metals, Superconductors, and Correlated Materials) -- Twisted Graphene II  
BCEC 153C - Roland Koch - Tag(s): Focus

11:15AM S14.00001: Electronic compressibility of magic-angle graphene superlattices  
SPENCER TOMARKEN (Presenter), YUAN CAO, AHMET DEMIR, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, NIMS, PABLO JARILLO-HERRERO, RAYMOND ASHOORI, Massachusetts Institute of Technology — Recent calculations and measurements have revealed that the superlattice formed by twisting and stacking two monolayers of graphene at particular small twist angles (dubbed ‘magic angles’) relative to their crystallographic axes can form an electronic system with substantially reduced Fermi velocity compared to monolayer graphene. Moreover, exotic insulating [1] and superconducting phases [2] near fractional filling of the moiré miniband have been observed in initial transport and capacitance measurements, drawing comparisons to the high-Tc cuprates and other superconducting platforms with analogous phase diagrams. Here we report the first thermodynamic compressibility measurements of magic angle twisted bilayer graphene in the low frequency limit. We find strongly incompressible features at quarter- and half-filling of the electron-doped regime, whereas we find substantially weaker features at the equivalent hole-doped densities. We extract the thermodynamic gaps at fractional filling and compare our results to recent transport studies.

11:27 AM S14.00002: Multicomponent Superfluidity and Screening in Biased Electron-Hole Double Bilayer Graphene with Realistic Bands. ANDREA PERALI, Fisica, University of Camerino — Superfluidity has recently been reported in double electron-hole bilayer graphene. The multiband nature of the bilayers is expected to be very important because the band gaps between conduction and valence bands are small. Here we report on a detailed mean-field study that takes into account the effects of multichannel electron-hole pairing, including Josephson-like pair transfer between bands; screening from both intraband and interband excitations; and effects of the non-parabolic band dispersion that accompanies the variable band gaps in bilayer graphene. From the self-consistent calculation based on the random phase approximation in superfluid state, we obtain a density range for superfluidity consistent with the density range reported in the recent experiments. We find for non-zero gaps, that the boost of the density of states from the flattening of the bands strengthens the superfluidity. We also find that the superfluidity modifies the intraband screening in a fundamentally different way from the interband screening. Surprisingly, the net effect of the screening is to restrict the superfluid pairing entirely to the conduction band - even for very small band gaps. This makes the system behave almost analogously to a one-band superfluid.

11:39 AM S14.00003: Symmetry, maximally localized Wannier states, and low energy model for the twisted bilayer graphene narrow bands* JIAN KANG (Presenter), OSKAR VAFEK, Florida State University — We build symmetry adapted maximally localized Wannier states, and construct the low energy tight binding model for the four narrow bands of the twisted bilayer graphene. We do so when the twist angle is commensurate, near the "magic" value, and the narrow bands are separated from the rest of the bands by energy gaps. On each layer and sublattice, every Wannier state has three peaks near the triangular Moire lattice sites. However, each Wannier state is localized and centered around a site of the honeycomb lattice that is dual to the triangular Moire lattice. Space group and the time reversal symmetries are realized locally. The corresponding tight binding model provides a starting point for studying the correlated many-body phases.

11:51 AM S14.00004: Maximally Localized Wannier Orbitals and the Extended Hubbard Model for Twisted Bilayer Graphene* MIKITO KOSHINO (Presenter), Osaka University, FANQUI YUAN, MIT, TAKASHI KORETSUNE, Tohoku University, MASAYUKI OCHI, KAZUHIKO KUROKI, Osaka University, LIANG FU, MIT — We develop an effective extended Hubbard model to describe the low-energy electronic properties of the twisted bilayer graphene. By using the Bloch states in the effective continuum model and with the aid of the maximally localized algorithm, we construct the Wannier orbitals and obtain an effective tight-binding model on the emergent honeycomb lattice. We find that the Wannier state takes a peculiar three-peak form in which the amplitude maxima are located at the triangle corners surrounding the center. We estimate the direct Coulomb interaction and the exchange interaction between the Wannier states. At the filling of two electrons per supercell, we find an unexpected coincidence in the direct Coulomb energy between a charge-ordered state and a homogeneous state, which could possibly lead to an unconventional many-body state.

12:03 PM S14.00005: Collisionless transport close to a fermionic quantum critical point in Dirac materials VLADIMIR JURICIC (Presenter), NORDITA, the Nordic Institute for Theoretical Physics, Stockholm University and KTH, Stockholm, Sweden, BITAN ROY, Max-Planck-Institut für Physik komplexer Systeme, Dresden, Germany — Quantum transport close to a critical point is a fundamental, but enigmatic problem due to fluctuations, persisting at all length scales. In this talk, we discuss the scaling of optical conductivity (OC) in the collisionless regime ($\omega \gg T$) in the vicinity of a relativistic Gross-Neveu-Yukawa quantum critical point, separating two-dimensional ($d=2$) massless Dirac fermions from a fully gapped insulator or superconductor. In particular, we show that close to such a critical point a universal suppression of both the inter-band OC and the Drude peak (while maintaining its delta function profile) inside the critical regime occurs due to strongly coupled gapless fermionic and bosonic excitations [1]. We carry out the computation to the leading order in $1/N_F$ and $\varepsilon$-expansions, where $N_F$ counts fermion flavor number and $\varepsilon=3-d$. Correction to the OC at such a non-Gaussian critical point due to the long-range Coulomb interaction and generalizations of these scenarios to a strongly interacting three-dimensional Dirac or Weyl liquid are also presented.

importance. In many novel superconductors of interest, fluctuations of the phase of the SC order parameter determines the highest valence band, thus reinforcing our microscopic approach to the superconductivity of twisted bilayer graphene. To the superconducting phase, and whose onset typically takes place for a Hubbard repulsion below the bandwidth of the shape close to the magic angle. We also consider the competition with charge and spin-density-wave instabilities, adjacent in a channel with odd parity under the exchange of the two mirror patches of the Fermi line, which develop a universal belonging to different K valleys. The highly anisotropic screening of the Coulomb interaction induces an effective attraction electronic spectrum. This leads to extended saddle points and energy contours with almost perfect nesting between states first magic angle is approached, we find two consecutive transitions between different topologies in the highest valence band of the twisted bilayers, driven by the doubling and subsequent strong coupling of van Hove singularities in the graphene near the "magic angle". The non-local interaction terms are novel and their form can be traced to the topologically non-trivial nature of the narrow bands. In the strong coupling limit and at the filling of two electrons/holes per moire unit cell, the ground state can be found exactly; it is SU(4) ferromagnetic with exactly one electron/hole on each honeycomb lattice site. The kinetic terms break the SU(4) symmetry and select the ground state in which the two valleys with opposite spins are equally mixed. Although such an insulating state is not quite a spin singlet, the magnetic moment per particle vanishes in the thermodynamic limit and therefore its Zeeman coupling to an external magnetic field also vanishes at linear order. We also find gapped extended excited states with a gap that decreases in an external magnetic field. Finally, we propose that an insulating stripe ferromagnetic phase could be the ground state for the filling of one electron/hole per unit cell, with a gap that does not decrease in an external magnetic field.

**12:27PM S14.00007: Strong coupling phases of partially filled twisted bilayer graphene narrow bands**

OSKAR VAFEK (Presenter), JIAN KANG, Florida State University — We identify the many-body insulating states favored by the Coulomb interactions projected onto the microscopically constructed Wannier basis of the four narrow bands of the twisted bilayer graphene near the "magic angle". The non-local interaction terms are novel and their form can be traced to the topologically non-trivial nature of the narrow bands. In the strong coupling limit and at the filling of two electrons/holes per moire unit cell, the ground state can be found exactly: it is SU(4) ferromagnetic with exactly one electron/hole on each honeycomb lattice site. The kinetic terms break the SU(4) symmetry and select the ground state in which the two valleys with opposite spins are equally mixed. Although such an insulating state is not quite a spin singlet, the magnetic moment per particle vanishes in the thermodynamic limit and therefore its Zeeman coupling to an external magnetic field also vanishes at linear order. We also find gapped extended excited states with a gap that decreases in an external magnetic field. Finally, we propose that an insulating stripe ferromagnetic phase could be the ground state for the filling of one electron/hole per unit cell, with a gap that does not decrease in an external magnetic field.

**12:39PM S14.00008: Gate-Tunable Mott Insulator in Trilayer Graphene-Boron Nitride Moiré Superlattice**

GUORUI CHEN (Presenter), LILI JIANG, Physics, UC Berkeley, SHUANG WU, Electrical Engineering and Computer Sciences, UC Berkeley, BOSAI LV, HONGYUAN LI, Physics, Shanghai Jiaotong University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ZHIWEN SHI, Physics, Shanghai Jiaotong University, YUANBO ZHANG, Fudan University, FENG WANG, Physics, UC Berkeley — Mott insulator plays a central role in strongly correlated physics, where the repulsive Coulomb interaction dominates over the electron kinetic energy and leads to insulating states with one electron occupying each unit cell. A tunable Mott insulator, where the competition between the Coulomb interaction and the kinetic energy can be varied in situ, can provide an invaluable model system for the study of Mott physics. Here we report the realization of such a tunable Mott insulator in the ABC trilayer graphene (TLG) and hexagonal boron nitride (hBN) heterostructure with a Moiré superlattice. The Moiré superlattice in TLG/hBN heterostructures leads to narrow electronic minibands that are gate-tunable. The Mott insulator states emerge at 1/4 and 1/2 fillings, corresponding to one electron and two electrons per site, respectively. Moreover, the Mott states in the ABC TLG/hBN heterostructure exhibit unprecedented tunability: the Mott gap can be modulated in situ by a vertical electrical field, and at the meantime the electron doping can be gate-tuned to fill the band from one Mott insulating state to another. Our observation opens up tremendous opportunities to explore novel strongly correlated phenomena in two-dimensional Moiré superlattice heterostructures.

**12:51PM S14.00009: Kohn-Luttinger Superconductivity in Twisted Bilayer Graphene**

JOSE GONZALEZ (Presenter), Instituto de Estructura de la Materia, CSIC, Spain, STAUBER TOBIAS, Instituto de Ciencia de Materiales de Madrid, CSIC, Spain — We propose that the superconductivity observed in twisted bilayer graphene can be explained as the consequence of a Kohn-Luttinger instability, which leads to an effective attraction between electrons with originally repulsive interaction. As the first magic angle is approached, we find two consecutive transitions between different topologies in the highest valence band of the twisted bilayers, driven by the doubling and subsequent strong coupling of van Hove singularities in the electronic spectrum. This leads to extended saddle points and energy contours with almost perfect nesting between states belonging to different K valleys. The highly anisotropic screening of the Coulomb interaction induces an effective attraction in a channel with odd parity under the exchange of the two mirror patches of the Fermi line, which develop a universal shape close to the magic angle. We also consider the competition with charge and spin-density-wave instabilities, adjacent to the superconducting phase, and whose onset typically takes place for a Hubbard repulsion below the bandwidth of the highest valence band, thus reinforcing our microscopic approach to the superconductivity of twisted bilayer graphene.
1:03PM S14.00010: Magnetotransport properties in twisted bilayer graphene at magic angle*  EVAN LAKSONO (Presenter), Centre for Advanced 2D Materials and Graphene Research Centre, National University of Singapore, ALEXANDER REAVES, MANRAAJ SINGH, Yale-NUS College, XINGYU GU, JIA NING LEAW, NIMISHA RAGHUVANSHI, SHAFFIQUE ADAM, Centre for Advanced 2D Materials and Graphene Research Centre, National University of Singapore — Recent experimental works on magic-angle twisted bilayer graphene have pointed to the existence of insulating and superconducting phases when the flat bands are half-filled. Among the mysteries in the experiments is the observed Landau fan diagram which shows a reduction in degeneracy close to the charge neutrality point compared to that at larger twist angle. These features are a remarkable departure from theoretical expectations. In this work, we use our recently developed theory for the non-interacting band structures [1, 2] to understand the behaviors of twisted bilayer graphene under the influence of magnetic field, and offer the possible scenarios that lead to the unconventional features in the magnetotransport at charge neutrality and at half-filling.

1:15PM S14.00011: Strong Correlations and d+id Superconductivity in Twisted Bilayer Graphene*  JOHANNES LISCHNER (Presenter), Imperial College London, DANTE KENNES, CHRISTOPH KARRASCH, Freie Universitaet Berlin — We compute the phase diagram of twisted bilayer graphene near the magic angle where the occurrence of flat bands enhances the effects of electron-electron interactions and thus unleashes strongly-correlated phenomena. Most importantly, we find a crossover between d+id superconductivity and Mott insulating behavior near half-filling of the lowest electron band when the temperature is increased. This is consistent with recent experiments. Our results are obtained using unbiased many-body renormalization group techniques combined with a mean-field analysis of the effective couplings.

1:27PM S14.00012: Topological and strong correlation physics in orbital-active honeycomb lattice materials -- applications to twisted bilayer graphene, bismuthene, transition-metal oxide film, etc  CONGJUN WU (Presenter), Department of Physics, University of California, San Diego, CA 92093, USA, SHENGLONG XU, Condensed Matter Theory Center and Department of Physics, University of Maryland, College Park, Maryland 20742, USA — We apply the symmetry principle to analyze the physical properties of orbital-active honeycomb systems which include a large class of materials (e.g. the twisted-bilayer graphene, transition-metal-oxide layer, bismuthene, stanene, metal-organic framework, and quantum dot array). Their orbital degree of freedom transforms as a two-dimensional irreducible representation of the lattice symmetry group, which results in band structures consisting of both the dispersionless flat bands and orbital-active Dirac bands. The flat bands amplify strong correlation effect to yield Wigner crystal and flat-band ferromagnetism. The active-orbital degree of freedom boosts the topological gap of the Dirac bands to the order of atomic scale spin-orbit coupling, i.e. at the scale of 1eV, as observed experimentally in bismuthene. In the Mott-insulating states, the orbital exchange becomes heavily frustrated as described by a novel 120 degree model whose classic ground states are mapped to all possible loop configurations covering the lattice, and quantum fluctuations select the closest packed loop configuration. The orbital degree of freedom also facilitate an f-wave superconductivity in which the gap nodal lines are determined by the orbital symmetry independent of the concrete pairing interactions.

Session S15 DMP: 2D Materials (Semiconductors) -- Emerging Materials I  BCEC 154 - Kristie Koski, University of California, Davis - Tag(s): Focus
11:15AM S15.00001: An Orbitally-Derived Single Atom Magnetic Memory  BRIAN KIRALY (Presenter), Scanning Probe Microscopy, Radboud University, ALEXANDER N. RUĐENKO, School of Physics and Technology, Wuhan University, WERNER M. J. VAN WEERDENDURG, DANIEL WEGNER, Scanning Probe Microscopy, Radboud University, MIKHAIL KATSNELSON, Theory of Condensed Matter, Radboud University, ALEXANDER A. KHAJETOORIANS, Scanning Probe Microscopy, Radboud University — Single atoms at the surfaces of solids have demonstrated rich electronic, chemical, and magnetic properties. In this direction, we show that we can manipulate the valency of a single cobalt atom on a crystalline black phosphorus surface. Using the local electric field generated from an STM tip, individual cobalt atoms residing at the same hollow site can be reversibly switched between two stable states, which correspond to the different valencies. Consistency between experimentally observed charge densities and density functional theory calculations reveal distinct high and low total magnetic moments for each state. We investigate the stability of each configuration, as well as compare the experimentally measured impurity states with DFT calculations. Finally, we probe the switching dynamics to determine the underlying mechanism and energy scale of the switching. This system opens up the horizon to explore complex memory based on both the orbital and spin degrees of freedom.

11:27AM S15.00002: Anisotropic Quantum Transport in Black Phosphorus Two-dimensional Hole Gas  FANGYUAN YANG, ZUOCHENG ZHANG, Fudan University, NAI ZHOU WANG, University of Science and Technology of China, SHUAIFEI GUO (Presenter), Fudan University, HAO WANG, Southern University of Science and Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, XIN WAN, Zhejiang University, XIANGHUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Fudan University — High-mobility two-dimensional (2D) electron system in black phosphorus van der Waals heterostructures has provided a new platform for studying electron-electron interaction in 2D. In particular, the large anisotropy distinguishes black phosphorus from other high-mobility two-dimensional (2D) electron systems. Here, we observed that new anisotropic states emerge at fractional filling factors for spin-split Landau levels $N > 4$. The new states manifest as resistance maxima or minima when current flows in different directions. Our results indicate the formation of charge-density-wave stripe phase in black phosphorus 2D hole gas that is surprisingly robust against thermal fluctuation and impurity scattering.

11:39AM S15.00003: "Resonant Tunneling in Black Phosphorus Homojunction"  YASIR HASSAN (Presenter), SAINT, Sungkyunkwan University Suwon Korea, PAWAN KUMAR SRIVASTAVA, School of Mechanical Engineering, Sungkyunkwan University Suwon Korea, BUDHI SINGH, Inter University Accelerator Center, New Delhi, India, CHANGUU LEE, School of Mechanical Engineering, Sungkyunkwan University Suwon Korea — Most common resonant tunnel devices (RTDs) consist of a quantum well formed between double barrier structures. Here for the first time, we demonstrate the RTD in a homojunction. By taking highly anisotropic nature of black-phosphorous (BP) into account, we have fabricated RTDs by sandwiching a thin (4-7 nm)-BP layer between two thick (40-72 nm)-BP flakes. We have observed that RTD could be realized in a BP homojunction by careful alignment of BP flakes. Moreover, a formation of a quantum well at the junction derives from the work function tunability of BP with flake thickness. Work function difference of thick-BP and sandwiched thin-BP layers results in band bending near the junction creating a quantum well. Under certain bias conditions, an electron can tunnel from one side to other through bound states in the quantum well. Such RT has been manifested by observation of negative differential resistance (NDR) in the current-voltage characteristics. The observed NDR peak in the current-voltage characteristics shifts to a higher voltage with decreasing quantum well thickness. Temperature-dependent current-transport reveals that momentum conservation for resonant tunneling is satisfied with acoustic/optical phonon scattering of electrons in the quantum well.

11:51AM S15.00004: Strain Tuning of the Electronic Structures of Few-Layer Black Phosphorus  SHENYANG HUANG (Presenter), GUOWEI ZHANG, FENG-REN FAN, FANJIE WANG, QIAOXIA XING, CHONG WANG, HUA WU, HUGEN YAN, Fudan University — Black phosphorus (BP) is a Van Der Waals material consisted of puckered atomic layers coupled together by the weak Van Der Waals force. Although Van Der Waals force is weak, it plays an important role in their bandstructure evolution. In this work, we tune the bandstructures of few-layer (2-10 layer) black phosphorus by applying in-plane biaxial strain. A large tunability has been observed for all of the few-layer BP samples. Careful examination reveals that the strain effect has layer dependence and transition order dependence, which can be accounted by the interlayer coupling effect. Meanwhile, Raman studies for the strained BP have been performed as well, which corroborate our observations.
**12:03PM S15.00005: Layer-Dependent Ultrafast Carrier and Coherent Phonon Dynamics in Black Phosphorus**

XIANCHONG MIAO (Presenter), MINBIAO JI, Fudan University — Black phosphorus is a layered semiconducting material, demonstrating strong layer-dependent optical and electronic properties. Probing the photophysical properties on ultrafast time scales is of central importance in understanding many-body interactions and nonequilibrium quasiparticle dynamics. Here, we applied temporally, spectrally, and spatially resolved pump–probe microscopy to study the transient optical responses of mechanically exfoliated few-layer black phosphorus, with layer numbers ranging from 2 to 9. We have observed layer-dependent resonant transient absorption spectra with both photobleaching and red-shifted photoinduced absorption features, which could be attributed to band gap renormalization of higher subband transitions. Surprisingly, coherent phonon oscillations with unprecedented intensities were observed when the probe photons were in resonance with the optical transitions, which correspond to the low-frequency layer-breathing mode. Our results reveal strong Coulomb interactions and electron–phonon couplings in photoexcited black phosphorus, providing important insights into the ultrafast optical, nanomechanical, and optoelectronic properties of this novel two-dimensional material.

**12:15PM S15.00006: Prolonged photo-carriers generated in Black Phosphorus**

MUNISA NURMAMAT (Presenter), Department of Physics Science, Graduate School of Science, Hiroshima University, Japan, YUKIAKI ISHIDA, Institute for Solid State Physics, the University of Tokyo, Japan, RYOHEI YORI, KAZUKI SUMIDA, SIYUAN ZHU, Department of Physics Science, Graduate School of Science, Hiroshima University, Japan, MASASHI NAKATAKE, Aichi Synchrotron Radiation Center, Aichi Science & Technology Foundation, Japan, YOSHIFUMIUEDA, MASAKI TANIGUCHI, Hiroshima Synchrotron Radiation Center, Hiroshima University, Japan, SHIK SHIN, Institute for Solid State Physics, the University of Tokyo, Japan, YUICHI AKAHAMA, Graduate School of Material Science, University of Hyogo, Japan, AKIO KIMURA, Department of Physics Science, Graduate School of Science, Hiroshima University, Japan — Transient electron-hole pairs generated in semiconductors can exhibit unconventional excitonic condensation. By optical pumping, photoexcited carriers facing across the band gap form excitons due to the Coulomb interaction between electrons and holes. As being a direct band gap and highly anisotropic semiconductor, black phosphorus (BP) can be expected to form excitons due to the nonequilibrium electron and hole populations after optical pumping. However, the electrons excited in the conduction band and their carrier dynamics which can offer hints on e-h pair condensation have not yet been clarified.

Here we employ time-resolved ARPES to explore the dynamics of photo-generated carriers in BP. The electronic structure above the Fermi level has been clearly observed, where a massive-and-anisotropic Dirac-type dispersions are confirmed. Importantly, we have directly observe that the photo-carriers generated across the direct band gap have the life time exceeding 400 ps. Such a long duration can be attributed to the stabilized e-h pairs between conduction and valence bands and confirms that the BP is a suitable platform for excitonic condensations.

**12:27PM S15.00007: Strain-engineered p-type to n-type transition in mono-, bi- and tri-layer phosphorene**

ANASS SIBARI (Presenter), ZINEB KERRAMI, Physics, Mohammed V University - Rabat, ABDEIKADER KARA, Physics, University of Central Florida, OMAR MOUNKACHI, Physics, Mohammed V University - Rabat, MOHAMMED HAMEDOUN, ABDELILAH BENYOUSSEF, MASciR Foundation, MOHAMMED BENAÏSSA, Physics, Mohammed V University - Rabat — Using density functional theory, a detailed computational study is performed to explore the structural and electronic properties of a phosphorene monolayer, bilayer and trilayer under a uniaxial strain along the armchair (b axis) and zigzag (a axis) directions. In the case of a monolayer phosphorene, it is found that strain along the armchair direction slightly affects the a lattice parameter and the puckering height (Δ). Along the zigzag direction, however, variation of the a lattice parameter is compensated by both the a and b lattice parameters while the parameter Δ remains unaffected. In terms of electronic properties, strain along the armchair and zigzag directions changes the nature of the Γ point in the bandgap from a direct to an indirect electronic transition as a function of the strain value. In the strain range from -14% to +6%, all phosphorene structures behave like most semiconductors under strain. However, size and strain combined effect significantly affects the Fermi energy position. Around 0% strain, all phosphorene structures are of p-type, while they switch to an n-type semiconductor in the range of strain values from +2% up to +14%. This p-type to n-type transition may have a major technological impact in fields where mono- and hetero-junctions are needed.
12:39PM S15.00008: Probing topology through optical response in group V monolayers*  
GAOFENG XU (Presenter), TONG ZHOU, University at Buffalo, The State University of New York, BENEDIKT SCHARF, University of Würzburg, IGOR ZUTIC, University at Buffalo, The State University of New York — Experiments on Bi monolayers on a SiC substrate reveal an interplay between a huge topologically nontrivial gap ~0.8 eV and strong spin-orbit coupling (SOC), leading to striking transport properties such as a robust quantum spin Hall effect (QSHE)[1]. With a suitable choice of substrates it is also possible to remove valley degeneracy and realize multiple Hall effects in a single materials system [2]. In contrast to transport properties, much less is known about how an optical response could yield topological signatures in these group V monolayers. By combining first-principles calculations for different substrates and a careful inclusion of strong SOC and Coulomb interaction in effective models for these monolayers on various substrates, we show that the changes in optical response reveal topological properties inherent to these systems. We explain how these findings offer new opportunities for proximitized materials [3]. [1] F. Reis, et al., Science 357, 287-290 (2017); F. Dominguez, et al., Phys. Rev. B 98, 161407(R) (2018). [2] T. Zhou, et al., npj Quant. Mater. 3, 39 (2018). [3] I. Zutic, et al., Materials Today (2018).

12:51PM S15.00009: Multiple Hall Effects in Functionalized Bismuth Monolayers*  
TONG ZHOU (Presenter), Department of Physics, University at Buffalo, JIAYONG ZHANG, School of Mathematics and Physics, Suzhou University of Science and Technology, HUA JIANG, School of Physical Science and Technology, Soochow University, IGOR ZUTIC, Department of Physics, University at Buffalo, ZHONGQIN YANG, Department of Physics, Fudan University — Advances in (quantum) spin and anomalous Hall effect, as well as (anomalous) valley Hall effect suggest the electronic degrees of freedom (spin, charge, and valley) can be used as different information carriers [1,2]. The realization of multiple Hall effects in a single 2D material provides a fascinating opportunity to manipulate the implementation of such information [3]. Motivated by the experiments [4], we combine a tight-binding model with first-principles calculations to reveal that with a large nontrivial gap, quantum spin Hall effects (QSHEs) and valley Hall effects appear simultaneously in the functionalized bismuth monolayers [5]. A staggered exchange field is introduced to realize the spin-valley polarized QSHEs. With gate control, QSHE and anomalous charge, spin, valley Hall effects can be observed in the single system [5]. These predicted multiple Hall effects could enable applications of the functionalized bismuth monolayers in electronics, spintronics, and valleytronics.

1:03PM S15.00010: Properties and Device Prospects of Emerging Two-Dimensional Materials* [Invited]  
HAN WANG (Presenter), Ming Hsieh Department of Electrical Engineering, University of Southern California — In this talk, I will discuss our recent research in studying the electronic, optical and ferroelectric properties of emerging low-dimensional materials, and in developing them for electronic and photonic device applications. The first part of the talk will focus on discussing the basic properties of emerging 2D materials such as black phosphorus and its applications in mid-infrared optoelectronics. Our recent research on the ferroelectric monolayer materials will also be presented. In the second part of the talk, I will discuss our work on applying advanced 4-dimensional imaging technique to study the carrier transport in low dimensional materials and in studying optical phenomenon. I will conclude with remarks on promising future research directions of low-dimensional material properties and devices, and how the emerging materials may benefit future generations of electronics and photonics technology in sensing, imaging and communications.

1:39PM S15.00011: Electronic structures and unusually robust bandgap in an ultrahigh-mobility layered oxide semiconductor, Bi$_2$O$_2$Se

CHENG CHEN (Presenter), MEIXIAO WANG, shanghaiTech University, JINXIONG WU, peking university, HUIXIA FU, Weizmann Institute of Science, HAIFENG YANG, ZHEN TIAN, shanghaiTech University, TENG TU, peking university, HAN PENG, University of Oxford, YAN SUN, Max Planck Institute, XIANG XU, tsinghua university, JUAN JIANG, shanghaiTech University, NIELS SCHROTER, YIWEI LI, DING PEI, University of Oxford, SHUAI LIU, shanghaiTech University, SANDY ADHITIA EKAHANA, University of Oxford, HONGTAO YUAN, Nanjing University, JIAMIN XUE, GANG LI, shanghaiTech University, JINFENG JIA, shanghai jiao tong university, ZHONGKAI LIU, ShanghaiTech University, BINGHAI YAN, Weizmann Institute of Science, NIELS SCHRÖTER, YIWEI LI, DING PEI, University of Oxford, SHUAI LIU, shanghaiTech University, SANDY ADHITIA EKAHANA, University of Oxford, HONGTAO YUAN, Nanjing University, JIAMIN XUE, GANG LI, shanghaiTech University.

Semiconductors are essential materials that affect our everyday life in the modern world. Two-dimensional semiconductors with high mobility and moderate bandgap are particularly attractive today because of their potential application in fast, low-power, and ultrasmall/thin electronic devices. We investigate the electronic structures of a new layered air-stable oxide semiconductor, Bi$_2$O$_2$Se, with ultrahigh mobility (~2.8 × 10$^5$ cm$^2$/V.s at 2.0 K) and moderate bandgap (~0.8 eV). Combining angle-resolved photoemission spectroscopy and scanning tunneling microscopy, we mapped out the complete band structures of Bi$_2$O$_2$Se with key parameters (for example, effective mass, Fermi velocity, and bandgap). The unusual spatial uniformity of the bandgap without undesired in-gap states on the sample surface with up to ~50% defects makes Bi$_2$O$_2$Se an ideal semiconductor for future electronic applications. In addition, the structural compatibility between Bi$_2$O$_2$Se and interesting perovskite oxides further makes heterostructures between Bi$_2$O$_2$Se and these oxides possible platforms for realizing novel physical phenomena.

1:51PM S15.00012: Stable holey two-dimensional C$_2$N structures with tunable electronic structure*

RAPHAEL LOBATO (Presenter), JENAINA RIBEIRO SOARES, Departamento de Física, Universidade Federal de Lavras — We investigate the phonon stability of several bulk C$_2$N holey two-dimensional crystals (C$_2$N-h2D), a recently synthesized carbon nitride layered material, by using first-principles calculations. Among the polytypes addressed, only one does not display phonon instabilities. The electronic structure evolution of dynamically stable C$_2$N-h2D from monolayer to bilayer and to bulk is unveiled. The direct band gap at Γ can be decreased by 34% from monolayer to bulk, offering opportunities in optoelectronics. The effective masses of both carriers become smaller as the number of layers increases, and their anisotropy along in-plane directions displayed in the monolayer is reduced, which suggest that the carrier mobility may be tuned as well. These effects are then explained according to the interaction of the orbitals in neighboring layers.

2:03PM S15.00013: Chlorine termination of Silicene on Silver (111)

JENNIFER DEMELL (Presenter), MICHAEL DREYER, ROBERT E BUTERA, Laboratory for Physical Sciences — Silicene is the 2D form of silicon, which grows readily on silver (111) as single layers or even bi-layers, showing several surface reconstructions in scanning tunneling microscopy images. Discrete Fourier transform calculations of halide-terminated single and multi-layers predict superconducting as well as topological behavior. In fact, a previous study [1] found possible superconductivity in plain silicene/silver, which – so far – we have been unable to confirm. We successfully grew silicene on silver (111) crystals and imaged them using scanning tunneling microscopy/spectroscopy at 4.2 K. The topographic and spectroscopic results on chlorine-terminated surfaces will be presented.

Session S16 DMP: Transport in Nanostructures -- 2D Materials and Their Heterostructures BCEC 155 - Shixiong Zhang, Indiana University Bloomington - Tag(s): Focus
11:15AM S16.00001: Electron transport in III-VI and IV-VI mono-chalcogenide nanostructures* [invited] XUAN GAO (Presenter), Case Western Reserve University — One focal point in recent studies of 2D semiconductors beyond transition metal dichalcogenides (e.g. MoS2) is non-transition metal based III-VI and IV-VI monochalcogenides. In this talk, I will highlight our transport studies of monochalcogenide InSe, SnS and SnSe for future 2D semiconductor applications. First, few and multilayer InSe nanoflakes are demonstrated to be promising 2D semiconductor nanostructures with high electron mobility and gate tunable Rashba spin-orbit coupling for high-performance n-type transistor and spintronic devices. Then I will discuss the gate and doping control of nanostructured IV-VI monochalcogenide SnS and SnSe's electrical and thermoelectric transport properties. In particular, the impact of SnS and SnSe's intrinsic p-type nature in the device behavior will be addressed. References: Nano Letters 15, 3815 (2015); Nano Letters 18, 4403 (2018); Nanoscale 8, 19050 (2016); Jour of Appl Phys, 123, 115109 (2018).

* The author acknowledges NSF CAREER Award (grant number DMR-1151534) for funding support.

11:51AM S16.00002: Inducing transport-anisotropy in graphene with 1D superlattices YUTAO LI (Presenter), SCOTT A DIETRICH, CARLOS FORSYTHE, SHAOWEN CHEN, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science (Japan), JAMES HONE, CORY DEAN, Columbia University — Graphene devices subjected to one-dimensional periodic superlattice potential have been studied extensively over the last decade. Previous experimental studies on such systems interpreted their data in fundamentally different ways: either based on commensurate effects such as Fabry-Perot interference, or a band structure based picture. Here we exploit our recently developed technique of dielectric superlattices to pattern graphene with a 1D superlattice, with periodicity as low as as low as 55nm. We observe strong anisotropy in electrical transport features along directions parallel versus perpendicular to the SL basis vector. For transport parallel to the SL basis vector, we see features consistent with Fabry-Perot interference at zero magnetic field, and Hofstadter butterfly-like features at high field that suggest band structure modifications. Possible interplay between commensurability effects and band structure modifications in such systems are discussed.

12:03PM S16.00003: Commensurate Lattice Vector Dependent Thermal Conductivity of Twisted Bilayer Graphene* CHENYANG LI (Presenter), BISHWAJIT DEBNATH, ROGER LAKE, University of California, Riverside — The in-plane thermal conductivity, as well as phonon dispersion of twisted bilayer graphene (TBG), are investigated as a function of temperature and rotation angle using both nonequilibrium molecular dynamics (NEMD) and density functional theory (DFT) combined with the phonon Boltzmann transport equation. The central result from the NEMD calculations is that the thermal conductivity decreases approximately linearly with the increasing lattice constant of the commensurate TBG unit cell. Comparisons of the phonon dispersions from both the DFT and NEMD calculations show that misorientation has the negligible effect on the low-energy phonon frequencies and velocities. However, the larger periodicity of TBG reduces the Brillouin zone size to the extent that the zone edge acoustic phonons are thermally populated allowing Umklapp scattering to reduce their lifetimes. This explanation is supported by DFT calculations of phonon-phonon lifetimes.

12:15PM S16.00004: Anomalous Hall effect in strain-engineered graphene systems SHENG-CHIN HO (Presenter), CHING-HAO CHANG, YI-CHIANG HEISH, SHUN-TSUNG LO, THI-HAI-YEN VU, TSE-MING CHEN, Department of Physics, National Cheng Kung University — The pseudo-magnetic field in graphene is of significant interest because it provides a means to modify the band structures and consequently the electronic properties through mechanical deformations or, more precisely, by engineering the strain1,2. Here, we report the observation of a non-vanishing Hall conductivity in a strain-engineered graphene system in the absence of an external magnetic field.

**12:27PM S16.00005: Probing spin fluctuations in graphene nanoribbons with STM tunnelling spectroscopy**
RICARDO ORTIZ CANO (Presenter), University of Alicante, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory — We address the question of how scanning electron tunnelling spectroscopy can be used to probe spin excitations that emerge in localized states in atomically precise graphene ribbons. We consider both sequential and cotunnelling regimes, and discuss how the dI/dV curves provide information about the fluctuating local moments that are expected to occur in zigzag edges and other zero modes that occur in graphene ribbons. We model the graphene nanoribbons with a Hubbard model and we obtain the relevant electronic states by numerical diagonalization in a reduced active space. We conclude that inelastic electron tunnelling spectroscopy provides an image, with atomic scale resolution, of the spectral function of the low energy spin excitations in nanographene, and should provide unambiguous evidence of the emergence of local moments in this class of systems.

**12:39PM S16.00006: High efficiency thermoelectricity with indirect excitons in a transition-metal dichalcogenide nanostructure**
CHUNJING JIA (Presenter), KAI WU, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory — High thermoelectric efficiency requires a large Seebeck coefficient and electric conductivity while maintaining low thermal conductivity. Recent development of modern synthesis techniques in nanomaterials provides new approaches to conquer such limits and usher the study of the thermoelectric effect into a new era. We propose to use indirect excitons (IEs) in two-dimensional TMDC nanostructures as a highly efficient thermoelectric device. We develop the exciton transport theory and numerically simulate the thermoelectric transport coefficients based on materials-specific parameters obtained from ab initio density functional theory calculations and experiments. Our numerical simulation shows that the excitons in bilayer TMDCs can dramatically enhance the figure of merit and the power factor an order of magnitude compared with those of separated TMDC monolayers. These enhancements are general consequences of increasing the Seebeck coefficient and electric conductivity of IEs simultaneously, thus demonstrating robustness for enhancing the thermoelectric effect.

**12:51PM S16.00007: Spin Hall effect for polaritons in a TMDC monolayer embedded in a microcavity**
OLEG Berman (Presenter), ROMAN KEZERASHVILI, Physics Department, New York City College of Technology, City University of New York, New York, USA, YURIII LOZOVIK, Laboratory of Nanophysics, Institute of Spectroscopy, Troitsk, Russia — The spin Hall effect (SHE) for polaritons in a transition metal dichalcogenides (TMDC) monolayer embedded in a microcavity is predicted. We demonstrate that two counterpropagating laser beams incident on a TMDC monolayer can deflect a polariton flow due to generation the effective gauge vector and scalar potentials. The components of polariton conductivity tensor for a weakly-interacting Bose gas of polaritons in the presence of Bose-Einstein condensation (BEC) and superfluidity and for non-interacting polaritons without BEC are obtained. We propose to study the superfluidity of microcavity polaritons by experimental measurement of components of a total conductivity tensor as functions of the effective gauge magnetic field at different temperatures. It is shown that the concentrations of the normal and superfluid components and the Kosterlitz-Thouless temperature of occurrence of superfluidity can be determined by experimental measurement the components of the total conductivity tensor. The possible experimental observation of the SHE for microcavity polaritons is proposed, which provides the signature of the superfluidity of microcavity polaritons.

Quantum scattering in two-dimensional nanostructures using a novel method of sources and absorbers

SATHWIK BHARADWAJ (Presenter), Department of Physics, Worcester Polytechnic Institute, Worcester, MA 01609, L RAMDAS RAM-MOHAN, Department of Physics, Electrical and Computer Engineering and, mechanical engineering, Worcester Polytechnic Institute, Worcester, MA 01609 — There have been several attempts in the literature to provide a variational approach to solve quantum scattering problems. However, the asymptotic boundary conditions (BCs) used in such methods do not take crucial evanescent modes into account, making them unsuitable for applications in meso- and nano-scale devices. Further, widely used atomistic models are computationally expensive for any device scale applications. We develop a method based on sources and absorbers to study quantum scattering in two-dimensional systems. The Cauchy BCs that are essential in the action integral formulation of scattering are reduced to simpler Dirichlet BCs by introducing totally absorbing “stealth regions.” Solutions decay within the stealth regions, thereby vanishing at the finite boundaries. A Green's function source is constructed to provide incident plane waves in the active scattering regime. This method overcomes the limitations of the currently prevalent approaches to provide a complete non-asymptotic variational description for scattering in confined as well as open domain quantum systems. We also discuss the applications of our method in simulating nanoscale rectifiers and enhancement of the thermoelectric power in quantum waveguides with embedded defects.

Strong exciton-plasmon coupling in two-dimensional transition metal dichalcogenides

AARON ROSE (Presenter), JEREMY R DUNKLIN, HANYU ZHANG, Chemistry & Nanoscience Center, National Renewable Energy Laboratory, JUAN M. MERLO, MICHAEL J NAUGHTON, Physics, Boston College, JAO VAN DE LAGEMAAT, Chemistry & Nanoscience Center, National Renewable Energy Laboratory — Two-dimensional transition metal dichalcogenides (2-D TMDs) show promise as photocatalytic materials for water splitting due to their strong light-matter interactions and favorable band gaps and band alignments. Incorporation of plasmonics into these systems is expected to enhance performance due to a variety of effects including large exciton-plasmon coupling.

Here, we show that strong exciton-plasmon coupling is possible in many 2-D TMD systems as evidenced by Rabi splitting in modeled photonic dispersion of thin films of 2-D TMDs coupled to tunable surface plasmons. The results show coupling in every metal-TMD combination between the metals Au, Al, Ag, and Cu and the 2-D TMDs MoS2, MoSe2, WS2, and WSe2. Finally, we discuss current experimental progress on such systems.

Phonon-Dislocation Interaction Mediated Thermal Transport in Polycrystalline MoS2

CHANGPENG LIN (Presenter), Shenzhen Geim Graphene Center (SGC), Tsinghua–Berkeley Shenzhen Institute (TBSI), Tsinghua University, XIAOBIN CHEN, School of Science, Harbin Institute of Technology, Shenzhen, XIAOLONG ZOU, Shenzhen Geim Graphene Center (SGC), Tsinghua–Berkeley Shenzhen Institute (TBSI), Tsinghua University — Phonon-dislocation interaction plays an important role in minimizing the lattice thermal conductivity in thermoelectric materials historically. Here, we implemented a systematic study of heat transport in polycrystalline MoS2 by molecular dynamics simulation and atomic Green’ s function method. Simulation results indicate that thermal boundary conductance of diverse grain boundary in MoS2 scales quasi-linearly to grain boundary energy. The existence of grain boundary strongly scatters the phonons with frequency larger than 3 THz, below which transmission function remains almost unchanged. Furthermore, the breakdown of classical Casimir model is observed by directly comparing to the thermal conductivity results obtained from realistic polycrystalline MoS2 with different grain size, and the detailed phonon dynamics should be taken into account to accurately describe the phonon scattering at grain boundary. Our findings will provide crucial guidelines for designing efficient thermoelectrics by phonon-dislocation interaction.

This work was supported by the Development and Reform Commission of Shenzhen Municipality under the "Low Dimensional Materials and Devices Discipline", the Youth 1000-Talent Program of China, and the Tsinghua-Berkeley Shenzhen Institute (TBSI).
1:39PM S16.00011: Frequency-Domain Magneto-Optical Kerr Effect for thermal property measurements of anisotropic 2-dimensional materials  SIMONE PISANA (Presenter), Department of Electrical Engineering and Computer Science, York University, Toronto, ON, Canada, MIZANUR RAHMAN, Department of Physics and Astronomy, York University, Toronto, ON, Canada, MOHAMMADREZA SHAHZADEH, Department of Electrical Engineering and Computer Science, York University, Toronto, ON, Canada — The rapidly increasing number of 2-dimensional materials that have been isolated or synthesized provides an enormous opportunity to realize new device functionalities. Whereas optical and electrical characterization has been more readily applicable to these new materials, quantitative thermal characterization is more challenging due to the difficulties with localizing heat flow. Optical pump-probe techniques that are well-established for the study of bulk materials or thin-films have limited sensitivity to lateral heat transport, and the characterization of the thermal anisotropy that is common in 2-dimensional materials is therefore challenging. Here we present a new method to quantify the thermal properties based on the magneto-optical Kerr effect that yields enhanced sensitivity to in-plane heat transport. Using a magnetic material as transducer for heat transport allows the use of semi-transparent layers that are very thin, increasing the in-plane thermal gradients. We apply this approach to measure the thermal properties of a range of 2-dimensional materials which are of interest for device applications, including single layer graphene and h-BN, multilayer h-BN and MoS₂, and bulk MoSe₂.

1:51PM S16.00012: Quantum Dragon Solutions for the Tight Binding Model of 2D Ribbon Nanodevices. GODFRED INKOOK (Presenter), MARK NOVOTNY, Mississippi State University, TOMAS NOVOTNY, Mathematics and Physics., Charles University — We present quantum dragon solutions for electron transport for the tight binding model with strong disorder in nanoribbons based on 2D hexagonal, rectangular, and square-octagonal graphs. When the nanodevice is connected between two thin semi-infinite leads, the Landauer formula gives the electrical conductance, \( G \). The electron transmission probability, \( T(E) \) from the solution of the time-independent Schrödinger equation, yields \( G = \frac{2e^2}{h} T(E) \). In the presence of uncorrelated randomness, \( T(E) \ll 1 \) for most electron energies, \( E \). Recently, the theoretical discovery of a large class of nanostructures called quantum dragons has been published [1]. Quantum dragon nanodevices have strong, correlated randomness but have \( T(E) = 1 \) for all \( E \) of electrons which propagate through the leads. Here, we show that both uniform leads and dimerized leads coupled to hexagonal, rectangular, and square-octagonal graphs with different boundary conditions can have the quantum dragon property [2]. We discuss how added disorder affects \( T(E) \) near a quantum dragon solution, and discuss experiments relevant to quantum dragon nanodevices.

Thursday, March 7, 2019 11:15 AM - 2:03 PM

Session S17 DCOMP: Matter in Extreme Environments: Theoretical Methods and Applications III BCEC 156A - Shuai Zhang, Lawrence Livermore National Laboratory

11:15AM S17.00001: Many-body molecular dynamics force fields for chemistry at extreme conditions* LAURENCE FRIED (Presenter), REBECCA LINDSEY, CONG HUY PHAM, NIR GOLDMAN, Lawrence Livermore Natl Lab — Molecular materials at high pressures and temperatures, such as those produced by a shock wave or detonation, often undergo rapid chemical reactions. There has been significant progress in understanding chemical processes at extreme conditions through simulations based on Kohn-Sham density function theory (DFT). DFT simulations, however, are typically limited in size to less than 1000 atoms and in time to less than 100 ps. We have developed a reactive molecular dynamics force field, called ChIMES, that retains much of the accuracy of density functional theory, while allowing application to much larger systems and longer time scales. The ChIMES approach has been recently extended to treat 4 body interactions and charge fluctuations. We find that these additions significantly enhance the accuracy of the force field, but require more sophisticated calibration methods to maintain accuracy and stability for a wide range of conditions. Effective calibration methods will be presented based on techniques adapted from the machine learning community. Applications to liquid carbon, H₂O, and N₂H will be discussed.

*This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
11:27AM S17.00002: Modeling High Strain Rate Plasticity in BCC Lead* ROBERT RUDD (Presenter), LIN YANG, ANDREW KRYGIER, PHILIP D POWELL, HYE-SOOK PARK, Lawrence Livermore Natl Lab, PETER GRAHAM, AWE — High-energy lasers have enabled the determination of constitutive properties of metals at very high pressures and strain rates. Here we consider the strength (flow stress) of lead in the high-pressure body-centered cubic (bcc) phase. There were two models of high-strain-rate lead strength available previously. Both models were constructed using data from the low-pressure, face-centered cubic phase of lead. Plasticity in bcc and fcc crystals can be very different. Experiments conducted at the National Ignition Facility have used ramp-compression to drive Rayleigh-Taylor instability and measured the ripple growth to infer lead strength in the bcc phase. We have developed an Improved Steinberg-Guinan model for bcc lead strength [1] using ab initio calculations of the shear modulus at pressure. We compare the predictions of the model with those from the two previous models and results from experiment. We also discuss the effect of alloying.

*This work was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344.

11:39AM S17.00003: Role of “soft” wall confinement in the particle dynamics of supercritical fluids* KANKA GHOSH (Presenter), KRISHNAMURTHY C.V, Department of Physics, Indian Institute of Technology Madras, India — Supercritical fluids (SCF), having a heterogeneous phase behavior (“liquid-like” and “gas-like”) across the Frenkel line (FL) [1], seem to be a promising candidate for the study of the effect of wall softness on the particle dynamics. Recently, structural features of SCF have been found to vary significantly as the walls became “softer”[2].

Molecular dynamics simulations are carried out to understand the effect of softness of the walls on the particle dynamics of a supercritical fluid using mean-squared displacement (MSD) and the velocity autocorrelation function (VACF). Walls are systematically made “softer” by lowering the stiffness coefficient of the springs attached to each of the wall particles. The existence of non-diffusive modes, and the effect of wall softness on it, is investigated through the vibrational density of states (DoS). We discuss the contrasting trends observed in self-diffusion parallel to the walls, on the either side of the FL, as a function of the wall-stiffness. The effect of the “softness” of the walls to support or disrupt collective motion will also be discussed.

*Department of Science and Technology(DST), INSPIRE Fellowship.

11:51AM S17.00004: Maximum initial growth-rate of strong-shock-driven Richtmyer-Meshkov instability* AKLANT K BHOWMICK (Presenter), ARUN PANDIAN, Carnegie Mellon University, ROBERT F STELLINGWERF, Stellingwerf Consulting, SNEZHANA ABARZHI, Univ of Western Australia — We focus on the classical problem of the dependence on the initial conditions of the initial growth-rate of strong shock driven Richtmyer-Meshkov instability (RMI) by developing a novel empirical model and by employing rigorous theories and Smoothed Particle Hydrodynamics simulations to describe the simulation data with statistical confidence in a broad parameter regime. For the given values of the shock strength, fluid density ratio, and wavelength of the initial perturbation of the fluid interface, we find the maximum value of the RMI initial growth-rate, the corresponding amplitude scale of the initial perturbation, and the maximum fraction of interfacial energy. This amplitude scale is independent of the shock strength and density ratio and is characteristic quantity of RMI dynamics. We discover the exponential decay of the ratio of the initial and linear growth-rates of RMI with the initial perturbation amplitude that excellently agrees with available data.

*National Science Foundation (USA)
12:03PM S17.00005: Water and hydrocarbon desorption from rapidly-heated metal oxide surfaces  JASON P KOSKI (Presenter), KEVIN LEUNG, AIDAN THOMPSON, J MATTHEW D LANE, Sandia National Labs — Understanding and controlling water and hydrocarbon desorption from steel surfaces under vacuum are crucial for high-voltage pulsed power applications. Ohmic heating in Sandia's Z-machine conductors can drive temperature rises of 1000 K over nanoseconds, leading to plasma formation and current loss. We apply reactive and non-reactive classical molecular dynamics (MD) and grand canonical Monte Carlo (GCMC) methods to study the thermodynamics and kinetics of fast desorption from hematite Fe2O3 surfaces. MD simulations are conducted using thermodynamically consistent coverages deduced from GCMC. For water, the resulting time- and temperature-dependent desorption profiles on the Fe2O3 (0001) and (1-102) surfaces show cooperative behavior. Results are in reasonable agreement with simple Temkin isotherm model estimates. Similar reduced models will be discussed for hydrocarbons desorption. The effect of external electric field on desorption profiles will also be discussed.

12:15PM S17.00006: Sweeping wave impact on tantalum plate* DUAN ZHANG (Presenter), CURT A BRONKHORST, Los Alamos National Laboratory — The tensile plasticity (TEPLA) model is extended to study sweeping wave impact, where the material undergoing large deformation, pore growth, and failure. We start with the ensemble phase averaging method to derive averaged equations for inhomogeneous material. For a given time and spatial position, it only averages over the material configurations in which the given spacetime is occupied by the specified material. The averaging method leads to the decomposition of the velocity gradient into intrinsic part representing the gradient experienced by the solid material and the plastic part caused by deformations related to slipping planes, void growth, and sliding on the crack surfaces.

To compute large plastic deformation, while accurately tracking the material history Dual Domain Material Point (DDMP) method is employed. The DDMP method uses both Eulerian and Lagrangian descriptions. We use the Eulerian capability to compute the large deformation of the solid caused by a sweeping shock wave and the Lagrangian capability to track history dependent plastic pore growth. Numerical results are compared to an experiment to show the needed improvements on both the physical models and numerical techniques.

* Work performed under the auspices of the United States Department of Energy.

12:27PM S17.00007: Effects of alloying elements on defect production and evolution in Fe-based alloys  YAXUAN ZHANG (Presenter), CURT A BRONKHORST, Los Alamos National Lab, XIAN-MING BAI, Material Science and Engineering, Virginia Polytechnic Institute and State University — Fe-based alloys are important structural and cladding materials for current and future nuclear reactors. Radiation-induced defect production and subsequent defect evolution play important roles in microstructural evolution in these alloys. In this work, the effects of alloying elements on defect production and evolution in Fe-based alloys have been investigated using molecular dynamics simulations. Primary damage simulations have been conducted for pure Fe and Fe-based alloys, including Fe-Cr, Fe-Cu, and Fe-W. It is found that Cr or Cu do not affect the total number of produced Frenkel pairs, while oversized W increases the total number of Frenkel pairs. In addition, Cr interstitials are over-produced while Cu and W interstitials are under-produced comparing to their solute concentrations. Both dislocation loops and C-15 clusters have been found in these alloys but their population is affected by the alloying elements. Interstitial cluster evolution is studied in these alloys. It is found that Cr and W suppress the growth of dislocation loops. Finally, the defect energetics are calculated to interpret these simulation results.

12:39PM S17.00008: Dynamic recrystallization in adiabatic shear banding: an entropic, effective-temperature model  CHARLES K LIEOU (Presenter), HASHEM MOURAD, CURT A BRONKHORST, Los Alamos National Laboratory — Dynamic recrystallization (DRX) is often observed in conjunction with adiabatic shear banding (ASB) in polycrystalline materials. The recrystallized nanograins in the shear band have few dislocations compared to the material outside of the shear band. We reformulate the recently developed Langer-Bouchbinder-Lookman (LBL) continuum theory of polycrystalline plasticity and include the creation of grain boundaries. While the shear-banding instability emerges because thermal heating is faster than heat dissipation, recrystallization is interpreted as an entropic effect arising from the competition between dislocation creation and grain boundary formation. We show that our theory closely matches recent experimental results in sheared ultrafine-grained titanium and in compressed AISI 316L stainless steel. The theory thus provides a thermodynamically consistent way to systematically describe the formation of shear bands and recrystallized grains therein.
12:51PM S17.00009: Crack deflection-penetration at a nanoscale interface of graphene/hBN heterostructure
TOUSIF AHMED (Presenter), MD Z HOSSAIN, Mechanical Engineering, University of Delaware — We investigate crack deflection-penetration behavior at an interface of two elastically dissimilar 2D nanomaterial taking an interface between graphene and hexagonal boron nitride (hBN) as an example test case. Growth of an edge crack from graphene towards hBN and similar growth of crack from hBN towards graphene are considered in two separate cases. Crack deflection-penetration (DP) criterion for continuum study is redefined in terms of cohesive energies of individual solids in this MD study. In case of graphene/hBN heterostructure, crack typically prefers to penetrate either material over deflection when it reaches the interface. Ratios of cohesive energies of interface and material ahead of the crack are 0.67 (when crack in graphene) and 1.0 (when crack in hBN). As these ratios lie in the crack penetration zone of the DP criterion, crack penetration is the only logical choice. However, in some cases slight deflection has been observed. This phenomenon occurs when crack bifurcates into several branches and the mother crack interacts with defects formed at the interface due to lattice constant mismatch. This initial study indicates that at nanoscale crack growth, DP criterion developed for continuum studies cannot be directly applied due to the role of crystallography itself.

1:03PM S17.00010: Assessing the Impact of Strength Model Parameters on Simulated Cerium Flyer Plate Behavior*
JOANNE BUDZIEN (Presenter), Los Alamos National Laboratory — Cerium flyer plate experiments were simulated using the LANL Lagrangian hydrodynamics code FLAG and results were compared to experimental results. The range of experiments examined includes shocking through the cerium γ-α phase transition. Several sets of parameters for the Preston-Tonks-Wallace strength model have been produced through fits to experimental Hopkinson bar data. We will present simulation results showing the effect of varying the strength parameter sets including simulations with no strength. This process may aid in differentiating the various parameter sets by testing them under conditions different from the calibration experiments.

*Los Alamos National Laboratory, an affirmative action/equal opportunity employer, is operated by Los Alamos National Security, LLC, for the National Nuclear Security Administration of the U.S. Department of Energy under contract DE-AC52-06NA25396.

1:15PM S17.00011: Update on the Development of a Multiscale Friction Model
MARVIN ZOCHER (Presenter), MARK KENAMOND, JAMES EDWARD HAMMERBERG, Los Alamos National Laboratory — Two sets of experiments designed to produce dry sliding of metal-on-metal resulting in normal pressures up to tens of GPa and sliding velocities up to hundreds of meters per second are simulated numerically for the purpose of evaluating a new multiscale friction model. These experiments involve the impact of a cylindrical copper flyer onto a composite cylindrical target composed of an aluminum inner core and a stainless steel circumferential confinement. The primary diagnostic in these experiments is a measurement of free-surface velocity. Numerical simulations are conducted using the Los Alamos finite volume continuum mechanics code FLAG. The primary metric of evaluation is a comparison of predicted free-surface velocities to those measured. The importance of accounting for friction in the simulation of these experiments is clearly demonstrated. It is shown that the FLAG implementation of the new multiscale friction model provides capabilities that are essential in the modeling of dry sliding friction.

1:27PM S17.00012: Uncertainty Quantification of Velocimetry-Based Load Current Inferences for 100 ns Multi-Mega-Amp Pulsed Power Experiments
ANDREW PORWITZKY (Presenter), JUSTIN BROWN, CHRISTOPHER JENNINGS, Sandia National Laboratories — Accurate determination of the electric current delivered to the load region is critical to the success of various multi-mega-amp pulsed power experiments. Magnetic inductance (B-dot) probes often fail over ten mega-amps, and when successful can only infer current centimeters from the load region, before major current loss mechanisms kick in. This has prompted interest in velocimetry-based load current inferences. The present work is part of a systematic uncertainty quantification effort. Here we apply Bayesian statistics to a series of synthetic experiments. Tens of thousands of multiphysics simulations were run with perturbed drive currents to determine correlations between input current and output surface velocity (our experimental measurable). We find that for very short pulses (100 ns rise time) relevant to cylindrical platforms significant uncertainties, not typical of planar dynamic materials experiments, can be introduced around peak current if the velocimetry measurement is not well matched to the current pulse. All regions of enhanced uncertainty are explained physically, and compensating strategies are developed in order to increase confidence and certainty in load current inferences.
1:39PM S17.00013: Numerical modeling of the phase transition kinetics for the sub-microsecond solidification of water under dynamic compression*  DANE STERBENTZ (Presenter), University of California, Davis, PHILIP MYINT, Lawrence Livermore National Lab, JEAN-PIERRE DELPLANQUE, University of California, Davis, JONATHAN BELOF, Lawrence Livermore National Lab — Several landmark experimental studies on the solidification of liquid water to the high-pressure ice VII phase under multiple-shock and ramp dynamic compression have been carried out over the past two decades, yet modeling this rapid phase transition has proven challenging. The application of classical nucleation theory (CNT)-based approaches to rapid phase transition kinetics occurring under extreme temperatures and pressures presents a variety of new opportunities for predictive computational modeling. This work attempts to model the liquid water-ice VII phase transformation using a numerical discretization scheme to solve the Zel'dovich-Frenkel partial differential equation, an underlying CNT-based kinetic equation describing the statistical time-dependent behavior of solid cluster formation. One major result of this research is that the Zel'dovich-Frenkel equation is able to accurately determine—the duration of the induction time prior to the onset of the phase transformation.  

*This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. We thank A. Arsenlis, D.P. McNabb, and B. Wallin for funding and project support.

1:51PM S17.00014: Li-ion battery material under high pressure: amorphization and enhanced conductivity of Li$_4$Ti$_5$O$_12$*  LIN WANG (Presenter), High Pressure Science and Technology Advanced Research — Li$_4$Ti$_5$O$_12$ (LTO), a “zero-strain” anode material for lithium-ion batteries, exhibits excellent cycling performance. However, its poor conductivity highly limits its applications. Here, the structural stability and conductivity of LTO were studied using in situ high-pressure measurements and first-principles calculations. LTO underwent a pressure-induced amorphization (PIA) at 26.9 GPa. The impedance spectroscopy revealed that the conductivity of LTO improved significantly after amorphization compared with its starting phase. Furthermore, our calculations demonstrated that the different compressibility of the LiO$_6$ and TiO$_6$ octahedra in the structure was crucial for the pressure-induced amorphization. The amorphous phase promotes Li$^+$ diffusion and enhances its ionic conductivity by providing defects for ion migration. Our results not only provide an insight into the pressure depended structural properties of a spinel-like material but also facilitate exploration of the interplay between pressure-induced amorphization and conductivity.

11:15AM S18.00001: van der Waals density functional with corrected long-range behavior*  TIMO THONHAUSER (Presenter), Department of Physics, Wake Forest University, KRISTIAN BERLAND, Department of Physics, University of Oslo, DEBAJIT CHAKRABORTY, Department of Physics, Wake Forest University — A new van der Waals density functional, i.e. vdw-DF3, has been developed by maintaining an accurate balance between short- and long-range contributions to the non-local correlation in the original vdw-DF scheme. We stay entirely true to the original design criteria of vdw-DF, adhering to the exact same physical constraints. But, we take advantage of some freedom in defining the plasmon-dispersion model ω$_Q$ which allows us to significantly improve the asymptotic behavior and the resulting calculated C$_6$ coefficients, overcoming the problem of unreliable C$_6$ coefficients from previous vdw-DF functionals. Our functional predicts very well the binding energies (<5% error) and separation for molecular dimers of commonly used reference datasets (such as S22, A24, X40, S66 etc.); performance in solids, layered structures, and noble gas dimers is also good.  

*This work has been funded by NSF grant No. DMR-1712425.
**11:27 AM S18.00002: A fitted van der Waals density functional with accurate short and long-range interactions**

DEBAJIT CHAKRABORTY (Presenter), Department of Physics, Wake Forest University, KRISTIAN BERLAND, Department of Physics, University of Oslo, TIMO THONHAUSER, Department of Physics, Wake Forest University — A fitting scheme has been developed to create a new van der Waals density functional, called vdW-DF-fit. The original vdW-DF kernel, as well as the plasmon dispersion model, are numerically modified and fitted to minimize the binding energy and separation errors with respect to experimental/RPA/high-level quantum chemistry results of a list of commonly used reference datasets (S22, A24, X40, S66 etc.). We are also pursuing automated fitting schemes using machine-learning techniques. This is work in progress and we are reporting first, promising results.

*This work has been funded by NSF grant No. DMR-1712425

**11:39 AM S18.00003: A Generalized Gradient Approximation with Local Parameters.** ANGEL ALBAVERA MATA (Presenter), Departamento de Química, Centro de Investigación y de Estudios Avanzados, KARLA BOTELLO MANCILLA, Escuela Superior de Ingeniería Química e Industrias Extractivas, Instituto Politécnico Nacional, DANIEL MEJIA-RODRIGUEZ, Quantum Theory Project, Department of Physics, University of Florida, SAM B TRICKEY, Quantum Theory Project, Department of Physics and Department of Chemistry, University of Florida, JOSE L GAZQUEZ, Departamento de Química, Universidad Autónoma Metropolitana, ALBERTO VELA, Departamento de Química, Centro de Investigación y de Estudios Avanzados — The dependence of typical generalized gradient approximations (GGA) for exchange-correlation (XC) on fixed, global parameters makes them incapable of providing good accuracy in predicting, simultaneously, molecular and solid properties. This drawback has motivated recent interest in constructing more flexible GGAs incorporating XC parameters that depend on the density, bounding their values to those for the high- and low-density regimes. In this work we explore a scheme to couple X and C functionals through the density-dependence of the gradient expansion coefficient derived beyond the random phase approximation [1,2] employed in different C functionals [3-5]. We discuss the implications of such local dependence of the gradient coefficient and show results of these GGAs for various properties involving test sets of atoms, molecules, and solids.

**11:51 AM S18.00004: Neural-Network Implementation of Transferable Kohn-Sham Exchange-Correlation Functionals**

RYO NAGAI (Presenter), Institute of Solid State Physics, University of Tokyo, RYOSUKE AKASHI, SHU SASAKI, SHINJI TSUNEYUKI, Department of Physics, University of Tokyo, OSAMU SUGINO, Institute of Solid State Physics, University of Tokyo — The accuracy of Kohn-Sham density functional theory [1] depends crucially on its approximated exchange-correlation functional. Structures of conventional density functionals depend on, however, combination of a number of physical constraints, making thereby the construction technically demanding and systematic improvement of their accuracy difficult. In order to overcome this difficulties, we present a new strategy free from the use of complicated physical constraints: representing the functional structure with Neural-network (NN), which is an extremely flexible function with a large number of parameters.

We demonstrate two types of NN-based functional. (i)Non-local functionals, which is made to reproduce the exact exchange-correlation potential of 1D model systems consisting of two electrons applied with various external potentials [2], (ii)Semi-local functionals, which is made to reproduce densities provided by an accurate quantum chemical calculation of only a few molecules [3]. We show potentials of the NN-based functionals for high accuracy and out-of-training transferability.

Theory will be presented, and only passing familiarity is assumed. The uniform electron gas in three and two dimensions is treated exactly by popular Kohn-Sham density functional approximations. However, no general-purpose semi-local functional can find the correct behavior of a 3D electron gas undergoing extreme compression in one dimension. In this talk, I will present our recent work [1] applying the SCAN functional to this perennial problem. While the exact exchange-correlation energy per electron tends to a finite 2D limit, the local density and generalized gradient dimension. In this talk, I will present our recent work [1] applying the SCAN functional to this perennial problem. While the exact exchange-correlation energy per electron tends to a finite 2D limit, the local density and generalized gradient approximations to it diverge to minus infinity. SCAN tends to a finite limit that is however an order of magnitude too negative. These errors at high compression are in one sense harmless, since the noninteracting kinetic energy, treated exactly in Kohn-Sham density functional theory, overwhelms them. Relevant background in Kohn-Sham density functional theory will be presented, and only passing familiarity is assumed.

We discuss two sets of response functionals for estimating the local, non-negative kinetic energy density of initially free electrons that are perturbed by a static external potential. We begin with first- and second-order functionals of the perturbing potential, which are directly analogous to known response functionals for the electron density and the integrated kinetic energy. We provide reciprocal-space formulations of these functionals that complement previously known real-space expressions. We then present alternate first- and second-order response functionals that operate on the induced electron density and do not depend explicitly on the applied potential. The structure of these latter functionals will help guide the design of the more sophisticated kinetic energy functionals that enable orbital-free density functional theory simulations of materials. We examine the performance of the response functionals, in density-functional form, when applied to electron densities generated from local pseudopotential calculations for Li, Al, and Si solids.

12:51PM S18.00009: Koopmans compliance: a functional theory for spectral properties  ANDREA FERRETTI (Presenter), Nanoscience Institute, S3 Center, National Research Council, NICOLA COLONNA, NGOC LINH NGUYEN, NICOLA MARZARI, THEOS, Ecole Polytechnique Federale de Lausanne — Energy functionals which depend explicitly on each individual orbital density, rather than the total charge density, appear naturally when applying self-interaction corrections to density-functional theory. Rather than a limitation, we argue that this is a powerful feature, and show how it is possible to interpret the orbital-dependency of densities and potentials as an effective frequency dependency. Such a frame is naturally amenable to describe electronic spectroscopies [1], and is free from e.g. the constraint of having derivative discontinuities in the exact formulation. Excellent agreement is achieved for ionization potentials and affinities, fundamental gaps, and deeper orbital levels (photoemission) for both molecules and solids [2-4]. We believe that a functional theory for the spectral density is therefore emerging, able to address at the same time total energies and spectral properties.

1:03PM S18.00010: The Self-Consistent Field in Kohn-Sham Density Functional Theory: A Review of Methods and Algorithms* NICK WOODS (Presenter), MICHAEL C PAYNE, Department of Physics, University of Cambridge, PHIL HASNIP, Department of Physics, University of York — Software that computes the electronic structure of a material by searching for an infimum of the Kohn-Sham energy functional - achieving self-consistency - requires the use of an algorithm that iterates an initial estimate of the particle density toward the self-consistent particle density. We present a review of methods and algorithms that solve this problem in the context of plane-wave, pseudopotential density functional theory. This review involves first identifying features intrinsic to the Kohn-Sham framework that produce sources of numerical difficulty for self-consistency algorithms. A test suite of over fifty Kohn-Sham inputs is then designed in order to exploit these difficulties and target weaknesses in contemporary algorithms. In order to utilise this test suite, a sample of methods from literature are then implemented in the plane-wave, pseudopotential density functional theory code, CASTEP. These methods are then benchmarked on the test suite, and a novel set of analysis tools allow us to determine the effectiveness of each method. We believe this study will not only elucidate the current state of the literature, but also assist future method development by providing a systematic work-flow for presenting new methods and assessing their effectiveness.

1:15PM S18.00011: Obtaining Stationary States in Density Functional Theory Using Imaginary Time Propagation* CEDRIC FLAMANT (Presenter), GRIGORY KOLESOV, Harvard University, EFSTRATIOS MANOUSAKIS, Florida State University, EFTHIMIOS KAXIRAS, Harvard University — Density functional theory (DFT) is widely successful for determining electronic and structural properties of materials and molecules. In order to perform a DFT calculation, the Kohn-Sham nonlinear equations must be solved self-consistently, a task usually achieved using self-consistent field (SCF) loops. However, for large systems SCF can occasionally struggle to find the ground state. Using time-dependent DFT in imaginary time, a given starting state can be purified into its lowest-energy component with reliable monotonic convergence. With appropriate constraints, it is also possible to obtain excited states with imaginary time propagation (ITP). We compare and analyze the performance of ITP and SCF in a few difficult systems, and present a few excited state calculations performed with the method.

1:27PM S18.00012: Path-integral imaginary-time TDDFT simulation of the hydrogen-bonded systems*  
GRIGORY KOLESOV (Presenter), Harvard University, EFSTRATIOS MANOUSAKIS, Department of Physics and National High Magnetic Field Laboratory, Florida State University, EFTHIMIOS KAXIRAS, Harvard University — We have recently developed a new imaginary-time time-dependent density-functional theory (iTDDFT)-based approach for computing the ground-state electron-ionic structure of atomistic systems[1]. In this method the ionic degrees of freedom are treated in the path-integral formalism, whereas electronic degrees of freedom are treated with iTDDFT. Our method, given an exact functional of the electronic density, is in principle exact in the zero-temperature limit. With approximate functionals it offers a practical path to direct \textit{ab initio} simulation of molecular and condensed matter systems going beyond the Born-Oppenheimer approximation. In this work we apply our method to study properties of hydrogen-bonded and tautomeric molecules: hydrogen sulfide, formic acid and terephthalic acid dimers. We compare the results of our simulations to known experimental and theoretical results.

1:39PM S18.00013: Benchmarking the structure selection performance of the SCAN functional relative to PBE and PBE+D3*  
JULIA YANG (Presenter), Materials Science and Engineering, University of California, Berkeley, DANIIL KITCHAEV, Materials, University of California, Santa Barbara, GERBRAND CEDER, Materials Science and Engineering, University of California, Berkeley — The ability of first-principles computational methods to reproduce ground-state crystal structure is key to their application in the study of structural phase transitions and the discovery of new materials. In assessing the reliability of structure selection made on the basis of density-functional theory, it is critical to understand the impact of various errors on structure stabilization arising from the choice of density functional. Here, we evaluate the SCAN functional performance in structure selection relative to widely-used PBE and PBE+D3 functionals and build on recent reports that the SCAN functional significantly improves crystal structure selection across a wide range of main group compounds [1]. We demonstrate that the origin of this improvement is to a large extent the inclusion of van der Waals interactions.

1:51PM S18.00014: From one to three, exploring the rungs of Jacob’s ladder in magnetic alloys*  
MATTHIEU VERSTRAETE (Presenter), University of Liege, ALDO H ROMERO, Physics and Astronomy, West Virginia University — Magnetic systems represent an important challenge for electronic structure methods, in particular Density Functional Theory (DFT). We benchmark different exchange correlation (xc) functionals with respect to each other, and with respect to available experimental data, on two families of binary iron alloys. We climb three rungs in Jacob’s ladder of DFT (i) the local density approximation, (ii) the industry standard approximations due to Perdew, Burke and Ernzerhof, and PBEsol, and finally (iii) the meta-GGA functional SCAN. More than 400 structures in ferromagnetic and antiferromagnetic configurations were considered. We compare the Convex Hull, magnetic moment, structure, and formation energy. None of the functionals work in all conditions: the GGAs and mGGA give a fair crystal structure, but SCAN strongly overestimates the formation energy (wrt PBE and experiment). Magnetic moments are better predicted by PBE as well. Our results show that magnetic and strongly correlated materials are a tough litmus test for DFT, and that they represent the next frontier towards a truly universal xc functional.

Session S19 DMP: Computational Materials Design and Discovery -- Data-Driven Electronic Structure BCEC 156C - Alexander Urban - Tag(s): Focus
11:15 AM S19.00001: Data-driven design of electronic band structure for materials [Invited]  ERIC ISAACS (Presenter), Northwestern University — Designing a material with a desired electronic band structure is an outstanding challenge in materials physics. In this talk, I will describe an approach using materials database screening with materials attributes based on the constituent elements, nominal electron count, atomic coordination environment, and thermodynamics. Using the over half a million real and hypothetical inorganic crystals of the Open Quantum Materials Database, this approach is applied to two disparate band structure design problems. In the first, we seek a “pudding-mold” band structure containing both flat and dispersive components, which leads to large thermoelectric power factor. One of the identified compounds, BaPdS_2, exhibits ultralow lattice thermal conductivity in addition to the pudding-mold band structure, leading to remarkable thermoelectric figure-of-merit approaching 3. In the second, we search for materials with a single correlated d band at low energy, an important yet rare property of the cuprates, to search for possible superconductors and benchmarks for the one-band Hubbard model. Several Cu compounds, including bromide, oxide, selenate, and pyrophosphate chemistries, achieve the desired electronic structure and exhibit properties such as Mott insulating behavior and antiferromagnetism.

11:51 AM S19.00002: Discovery of Novel Dielectric Materials With Large Energy Bandgaps Using Statistical Optimization*  ABHIJITH GOPAKUMAR (Presenter), CHRISTOPHER WOLVERTON, Northwestern University — We present results from a feedback-based materials design work-flow to find novel materials with optimized dielectric properties. The objective is to improve the performance of electrical devices that depend on charge bearing capacity, which directly depends on dielectric constants and band-gap energies of the compounds. A data-set containing data of dielectric tensors for 1864 materials was extracted from MaterialsProject.org¹ to train the statistical deep-learning models. The set of thermodynamically stable materials from OQMD.org² was used as the search-space to discover novel materials with large values for dielectric constants and bandgap energy. A reliable neural network model was built over the small training data and combined it with statistical optimization strategies. Dielectric properties of predicted materials were computed using Density Functional Perturbation Theory and fed back into subsequent generations of neural network models. Each design cycle in this approach successfully picked up new promising materials from the large search-space, including mixed anion compounds with very large bandgap and dielectric constants - a highly optimized scenario for industrial applications.

*Samsung GRO 2017

12:03 PM S19.00003: Designing Materials with High Refractive Index and Wide Band Gap: A First-Principles High-Throughput Study*  FRANCESCO NACCARATO (Presenter), Faculty of Science, Technology and Communication, University of Luxembourg, FRANCESCO RICCI, Institute of Condensed Matter and Nanoscience, Université Catholique de Louvain, JIN SUNITIVICH, Department of Materials Science and Engineering, Cornell University, GEOFFROY HAUTIER, Institute of Condensed Matter and Nanoscience, Université Catholique de Louvain, LUDGER WIRTZ, Faculty of Science, Technology and Communication, University of Luxembourg, GIAN-MARCO RIGNANESE, Institute of Condensed Matter and Nanoscience, Université Catholique de Louvain — Materials combining both a high refractive index and a wide band gap are of great interest for optoelectronic and sensor applications. However, these two properties are typically described by an inverse correlation with high refractive index appearing in small gap materials and vice-versa. Here, we conduct a first-principles high-throughput study on more than 4000 semiconductors (with a special focus on oxides). Our data confirm the general inverse trend between refractive index and band gap but interesting outliers are also identified. It turns out that the negative effect of a large band gap on the refractive index can be counterbalanced by the presence of weakly dispersive states for transitions between the top of the valence band and the bottom of the conduction band. Focusing on oxides, we use our data to investigate how the chemistry influences this inverse relationship and rationalize why certain classes of materials would perform better. Our findings can be used to search for new compounds in many optical applications both in the linear and non-linear regime (waveguides, optical modulators, laser, frequency converter, etc.).

*EJD-FunMat project
12:15PM S19.00004: Rational Design and Discovery of Novel High Temperature Superconductors* ONYEDINACHI IRONKWE (Presenter), HTSC Design & Search Division, RTSD Technologies, San Diego, CA — Rational design of high temperature superconductors, (HTSCs), with predicted stoichiometry and transition temperature, Tc, is a major challenge in superconductivity. We presented in previous APS meetings (2015, 2016, 2017 and 2018), our computational design model called Material Specific Characterization Dataset (MSCD) Framework, and also design algorithms, and generalized periodic system (GPS), for superconductors. Over the past year, we have put to experimental test, our designs of oxide, oxy-sulfide and oxy-chloride systems predicted by MSCD Framework to be HTSCs. At this March 2019 meeting, we present the experimental results of this great challenge and announce the discovery, at ambient pressure of new classes of HTSCs without copper.

*This research is funded by Dr. M.J. Schaffer and RTSD Technologies, San Diego, CA

12:27PM S19.00005: Building and browsing ab initio computational databases in quest of materials with exceptional opto-electronic properties [Invited] GEOFFROY HAUTIER (Presenter), Universite catholique de Louvain — Essential materials properties can now be assessed through ab initio methods. When coupled with the exponential rise in computational power, this predictive power provides an opportunity for large-scale computational searches for new materials. We can now screen thousands of materials by their computed properties even before the experiments. This computational paradigm allows experimentalists to focus on the most promising candidates, and enable researchers to efficiently and rapidly explores new chemical spaces.

In this talk, I will present the challenges and opportunities in materials discovery offered by high-throughput ab initio computing in searching for materials with exceptional optical and electronic properties. Examples from the fields of transparent conducting oxides and electrides will be especially highlighted. As high-throughput computing generates large amounts of data, I will finish my talk by giving an update on the new properties recently added to the Materials Project (http://www.materialproject.org), including electronic transport but also phonon and vibrational properties.

1:03PM S19.00006: Classification models for high-throughput electronic band structures using feature extraction BRADLEY MAGNETTA (Presenter), VIDVUDS OZOLINS, Yale Univ — Applying machine learning techniques to aid materials engineering has become possible due to the existence of large databases of materials data. While models can be built using only scalar data, these databases also provide higher-dimensional data, such as high-throughput electronic band structures, which contain important information for many applications. For instance, the efficiency of thermoelectric materials is known to benefit from certain features in the band structure. We demonstrate how feature extraction techniques can be used to build classification models for band structures and show how these models can be used to aid materials innovation.

1:15PM S19.00007: Fully-automated construction of Maximally Localized Wannier Functions: High-Throughput calculations of material properties* VALERIO VITALE (Presenter), Cavendish Laboratory, Department of Physics, University of Cambridge, GIOVANNI PIZZI, ANTIMO MARRAZZO, Theory and Simulation of Materials (THEOS), École Polytechnique Fédérale de Lausanne, JONATHAN YATES, Department of Materials, University of Oxford, NICOLA MARZARI, Theory and Simulation of Materials (THEOS), École Polytechnique Fédérale de Lausanne, ARASH A MOSTOFI, Departments of Materials and Physics, and the Thomas Young Centre for Theory and Simulation of Materials, Imperial College London — Maximally localized Wannier functions (MLWFs) are increasingly used in the computation of advanced properties of materials from first principles and as a localized basis for accurate beyond-DFT methods [1].

Conventionally, MLWFs are obtained by performing a multi-objective non-convex optimization [1]. In the case of MLWFs that represent so-called "entangled bands", e.g. for metals, the MLWFs may depend on the trial orbitals used to initiate the optimization. Consequently, automatic generation of MLWFs within high-throughput workflows is hindered by the need for user intervention in the selection of the initial guess.

A recently developed approach, the "selected columns of density matrix" (SCDM) algorithm [2] for obtaining localized Wannier functions does not require any initial guess and, by introducing only two parameters, is also applicable to the case of entangled bands.

We have implemented SCDM in a fully-integrated framework that combines the AiiDA workflow management platform, Quantum ESPRESSO and Wannier90 to achieve user-intervention-free construction of MLWFs. This work paves the way for high-throughput computation of advanced materials properties with Wannier functions.

1:27PM S19.00008: Universal $d=1$ flatband generator from compact localized states*

WULAYIMU MAIMAITI (Presenter), SERGEJ FLACH, ALEXEI ANDREANOV, Center for Theoretical Physics of Complex Systems, Institute for Basic Science — The band structure of some translationally invariant lattice Hamiltonians contains strictly dispersionless flatbands (FB). These are induced by destructive interference, and typically host compact localized eigenstates (CLS) which occupy a finite number $U$ of unit cells. FBs are important due to macroscopic degeneracy and consequently due to their high sensitivity and strong response to different types of weak perturbations. We use a recently introduced classification of FB networks based on CLS properties, and extend the FB Hamiltonian generator introduced in Phys. Rev. B 95, 115135 (2017) to an arbitrary number $v$ of bands in the band structure, and arbitrary size $U$ of a CLS. The FB Hamiltonian is a solution to equations that we identify with an inverse eigenvalue problem. These can be solved only numerically in general. By imposing additional constraints, e.g. a chiral symmetry, we are able to find analytical solutions to the inverse eigenvalue problem.

1:39PM S19.00009: Coupling of lattice distortions to bands near the Fermi level in ABC compounds from first principles*

KONRAD GENSER (Presenter), Rutgers University, New Brunswick, CYRUS DREYER, Stony Brook University, JASON KAWASAKI, Univ of Wisconsin, Madison, KARIN RABE, Rutgers University, New Brunswick — ABC intermetallic compounds exhibit a rich variety of crystal structures and electronic properties. In this work, we use first-principles calculations to elucidate the coupling of lattice distortions to the electronic bands near the Fermi level in a family of hexagonal P6mm and P63mc ABC compounds, where A is a rare earth, B is a transition metal and C is a main group element. In particular, we have shown that in certain compounds in this family, a polar distortion that buckles the honeycomb layers can open a gap at the Fermi level. In addition, we show that epitaxial strain couples to the bands near the Fermi level directly, as well indirectly through polarization-strain coupling. These results have a number of implications for the targeted design of functional properties in these class of materials, which have been previously proposed as novel candidate ferroelectrics and piezoelectrics.

1:51PM S19.00010: Material design of indium-based compounds: possible candidates for charge, valence and bond disproportionation and superconductivity

CHANG-JONG KANG (Presenter), GABRIEL KOTLIAR, Rutgers University, New Brunswick — We design and investigate the physical properties of new indium compounds AInX$_3$ (A = alkali metals, X = F or Cl). We find nine new indium-based materials in their ground state and are thermodynamically stable but are not reported in Inorganic Crystal Structure Database (ICSD). We also discuss several metastable structures. This new series of materials display multiple valences, charge and bond disproportionation, and dimerization. The most common valence of In is 3+. We also find two rare alternatives, one has In$^{2+}$ with In-In dimerization and the other shows valence disproportionation to In$^{1+}$ and In$^{3+}$ with bond disproportionation. We study the possibility of superconductivity in these new In compounds and find that CsInF$_3$ has a transition temperature of about 24 K with sufficient hole doping and pressure.

Session S20 DMP: Hybrid Perovskites -- Photovoltaics

BCEC 157A - Joseph Berry, National Renewable Energy Laboratory - Tag(s): Focus
We demonstrate that at the intrinsic limit, the mobility of charge-carriers is predominantly governed by interaction of carriers with optical vibrations of the lead halide lattice (Fröhlich interaction). In the absence of trap-mediated charge recombination, band-to-band recombination will dominate losses near the Shockley-Queisser limit. We show that in methylammonium lead triiodide perovskite, such processes can be fully explained as the inverse of absorption, and exhibit a dynamic that is heavily influenced by photon reabsorption inside the material. Finally, we demonstrate that in the absence of degradation, perovskite solar cells can exhibit appreciably higher energy-conversion efficiencies under solar concentration, where they exceed the Shockley-Queisser limit and exhibit elevated open-circuit voltages.

Unraveling the role of low-frequency phonon modes in carrier relaxation and regeneration in lead-halide perovskites

EE MIN CHIA (Presenter), Nanyang Technological University — Carrier-phonon scattering, a ubiquitous effect in all condensed matter systems, has been discussed in the halide perovskites in the context of placing an upper limit to the carrier mobility. Using time-resolved terahertz spectroscopy on a formamidinium-based perovskite system, we will show that phonons play a much larger role than thought previously. The combination of phonon emission during carrier relaxation, phonon-assisted exciton dissociation, and free-carrier screening, ensure a large and long-lived carrier population in the material. Our work reveals the delicate interplay among carriers, phonons and excitons, that affect the photo-physical properties of the halide perovskites, that ultimately determines the photovoltaic performance of halide perovskite-based solar cells.

Electron and Hole Mobilities in Organic-Inorganic Hybrid Perovskites

YAXIN ZHAI (Presenter), MATTHEW C BEARD, National Renewable Energy Laboratory — One of the fundamental semiconducting properties, charge-carrier mobilities have been widely studied in the organic-inorganic hybrid perovskites. However, the reported values of mobilities ranges widely from 0.4 to 600cm²(V s)⁻¹ and most of the experimental methods cannot distinguish the electron and hole mobilities. Other than photoluminescence quenching (PLQ) methods that requires the presence of an extractor layer, here we report an optical method to determine the electron and hole mobilities individually in organic-inorganic hybrid perovskite films and single crystals.

*We gratefully acknowledge support from the Center for Hybrid Organic Inorganic Semiconductors for Energy (CHOISE) an Energy Frontier Research Center funded by the Office of Basic Energy Sciences, Office of Science within the U.S. Department of Energy through contract number DE-AC36-08GO28308.
12:15PM S20.00004: Direct Measurement of the Carrier Diffusion in CH$_3$NH$_3$PbI$_3$ Hybrid Thin Films and How It Compares with Other Inorganic Thin Film Materials* JOSE CASTANEDA (Presenter), FAN ZHANG, University of North Carolina at Charlotte, WUQIANG WU, JINSONG HUANG, University of North Carolina at Chapel Hill, YONG ZHANG, University of North Carolina at Charlotte — Large charge carrier diffusion lengths are believed to be one of the critical reasons for the high efficiencies demonstrated with organic-inorganic perovskite solar cells, as large diffusion lengths are often viewed as a necessity to maximize collection efficiencies of photovoltaic devices. Using energy selective PL imaging, diffusion lengths for carriers with different kinetic energies can be measured directly under focused laser excitation [1]. In this work, we directly measured the carrier diffusion length of surface passivated polycrystalline CH$_3$NH$_3$PbI$_3$ thin films under CW 532 nm excitation as a function of power density, which was found to be on the order of ~1 µm in approximately 7 – 40 W/cm$^2$ or 70 – 400 sun illumination density. Further comparisons were then made to other prominent thin film materials such as CdTe and GaAs, which tend to exhibit significantly longer diffusion lengths when as double-heterostructures. The carrier diffusion length in CH$_3$NH$_3$PbI$_3$ is also found to increase systematically with reducing kinetic energy, suggesting that carriers are localized due to disordering and not properly thermalized along with the existence of energy transfer among different emitting sites. [1] Zhang et al., J. Lumin. 185, 200 (2017).

*UNC/ROI

12:27PM S20.00005: Long Exciton Diffusion Length in Single Crystal Halide Perovskites* LUKE MCCLINTOCK (Presenter), RUI XIAO, CLINTON GIBSON, YASEN HOU, University of California, Davis, SONG JIN, Chemistry, University of Wisconsin-Madison, LIANG TAN, Lawrence Berkeley National Laboratory, DONG YU, University of California, Davis — Hybrid inorganic-organic halide perovskites have garnered an incredible amount of attention over the last few years, thanks to power conversion efficiencies climbing from 3% to now 22.7% in less than a decade. The majority of published work thus far has focused on creating higher quality thin films, while the underlying carrier transport processes are not well understood. By studying single crystal methylammonium lead iodide (MAPbI$_3$) samples, we avoid the issues caused by thin film grain boundaries and shed light on the inherent carrier transport mechanisms of this revolutionary material. We determined the carrier diffusion lengths via scanning photocurrent microscopy (SPCM). We observed excitonic behavior through electric field independent photocurrent distributions as well as a measured exciton diffusion length that increased abruptly below the phase transition temperature from the room temperature tetragonal phase to the low temperature orthorhombic phase. The low temperature phase diffusion reached up to 100 µm at 80 K. We attributed the long exciton diffusion length to the reduced carrier scattering because of the suppressed ion rotation in the orthorhombic phase.

12:39PM S20.00006: Comparative photovoltaics studies of prominent PV materials, organometal halide perovskite, CdTe, and GaAs with direct comparison of carrier recombination through power dependent photoluminescence* FAN ZHANG (Presenter), JOSE CASTANEDA, University of North Carolina at Charlotte, WUQIANG WU, JINSONG HUANG, The University of North Carolina at Chapel Hill, YONG ZHANG, University of North Carolina at Charlotte — Comparative Photovoltaics refers to the study of material properties of different PV materials by making direct and meaningful comparison to reveal their relative strength and weakness. Although the hybrid perovskite based solar cell has reached up to 23.3% energy conversion efficiency, it remains unclear what the enabling factors are for the impressive performance, in particular how it differs from the better-known PV materials CdTe and GaAs. Power dependent PL measurements show that perovskite samples tend to have stronger PL than the inorganic counterparts in the very low excitation density region (e.g., 0.1 – 1 sun), indicating that Shockley-Read-Hall (SRH) recombination is relatively less effective in the perovskite. PL lineshape analysis suggests that carriers in the perovskite are not in thermal equilibrium due to structural disordering, which in turn suppresses the nonradiative recombination. Both relatively low effective point defect density and moderate crystalline disordering in the perovskite contribute to the low nonradiative recombination loss, thus, high cell efficiency.

*UNC/ROI
The energy level alignment that occurs at the interfaces in planar-hetero structured perovskite photovoltaic devices strongly influences the charge transport across the interface and thus plays a role in overall device performance. To directly observe the energy level alignment requires pristine homogeneous surfaces that are free of contamination. Coevaporation has been employed to grow perovskite films. The method involves thermally evaporating the perovskite precursors such as PbI₂ and CH₃NH₃I, and some early reports have shown that the perovskite film formation and stoichiometry are problematic at ultralow coverages. Using photoemission spectroscopy, we investigated the perovskite precursors PbI₂ and MAI on gold and highly oriented pyrolytic graphite (HOPG) surfaces. Results show that the nature of the surface and the deposition conditions can strongly influence the film formation. Excessive iodine observed in the initial evaporation stages appears to be substrate dependent, and this may influence the overall energy level alignment.

The present work focuses on halide-related defects, the main contributors to ionic conductivity [2]. We use first principles density functional theory calculations to simulate the migration of halide vacancies in CsPbBr₃ perovskite. The well-established nudged elastic band method [3] is used to compute minimum-energy pathways and energy barriers of halide-related defects. We systematically study the change of migration activation energies upon moving from the surface into the bulk. Our results show that ions migrate more easily in soft lattices showing a pronounced dependence on surface proximity, depending on the availability and size of interstitial sites.

Organic-inorganic hybrid perovskites have been intensively studied in recent years as a very promising next-generation photovoltaic technology. Surface and interfacial engineering have been a focus for performance improvement. The microstructure-property relationship, particularly at the surface, has yet to be resolved. Here we investigated the intrinsic structural and electrical properties of single perovskite layers. The associated microstructure, which depends on the depth inside the layer, changes from a layer of randomly oriented grains at the surface to grains with a preferential orientation in the bulk with a post treatment. This structural change leads to a uniform bandgap for the entire system and an efficient hole accumulation at the surface that is concentrated at the grain boundaries. The established relationship between the surface and bulk, and the switch in the role of the grain boundaries between ideal charge transport highways and non-ideal defect locations enrich the understanding of the working mechanism of the devices, opening a pathway to increased efficiencies.

Raman spectroscopy as a probe of local strain in perovskite solar cells

Vibrational frequencies are shifted due to strain in a material and we want to enable use of this phenomenon to map local stress-strain behavior within a perovskite material via Raman spectroscopy, as is done in crystalline silicon and other materials [D. A. Strubbe et al., Phys. Rev. B 92, 241202(R) (2015)]. We study vibrational properties of different phases of methylammonium lead iodide (CH₃NH₃PbI₃) structures and calculate the slope of the shift of each mode for applied strains along different crystal directions to provide a calibration curve for measuring local strain. Our study also gives insight into the interaction between strain, structural changes and vibrational modes which may help to understand the degradation that plagues these materials.
Direct Optical Characterization of Subgrain Boundaries and Carrier Diffusion Rates in Perovskites

WENHAO LI (Presenter), SRINIVAS YADAVALLI, JUAN LIZARAZO FERRO, NITIN PADTURE, RASHID ZIA, Brown University — Perovskite solar cells (PSCs) have attracted considerable attention in recent years due to their rapidly increasing power conversion efficiency (PCE), which currently exceeds 23%. An important feature in organic–inorganic halide perovskites (OIHPs) that limits PCE is their defect densities. Here we report an optical spectroscopy method for identifying subgrain special boundaries that introduce defects and limit carrier diffusion. These subgrain boundaries do not exhibit clear surface morphology features that can be recognized by scanning electron microscopy (SEM) or atomic force microscopy (AFM). Such special boundaries may explain why PSC performance has not scaled with apparent grain size. Furthermore, in order to quantitatively study the role of defects, we establish a method to estimate defect density by directly studying the spatial and temporal distribution of carriers in OIHP thin films.

Session S21 DMP: Nanostructures and Metamaterials -- Functional Systems

11:15AM S21.00001: Plasmonic Aerosols: a novel phase of plasmonic matter*  JAKE FONTANA (Presenter), United States Naval Research Laboratory, JEFFREY GELDMEIER, PAUL JOHNS, ASEE-NRL Postdoctoral Fellow, NICHOLAS J. GREYBUSH, NRC-NRL Postdoctoral Fellow, JAWAD NACIRI, United States Naval Research Laboratory — The field of plasmonics has given rise to many innovative optical materials over the years, however these plasmonic materials are limited to only a few phases of matter, either as 2D solids or dilute liquids. Here, we introduce a novel phase of plasmonic matter by aerosolizing gold nanorods into the gas phase from liquid suspensions and simultaneously measure their optical spectra. We show by controlling the aspect ratio of the nanorods that the aerosol absorption peaks are tunable from visible to mid-wave infrared wavelengths. We find for large aspect ratio nanorods extraordinary sensitivity to changes in the refractive index of the host gas (~4,000 nm per refractive index unit). Utilizing this sensitivity dependence, we demonstrate the feasibility to use these plasmonic aerosols as environmental sensors.

*This material is based upon work supported by the Office of Naval Research under (N0001418WX00122) & (N0001417WX00884)

11:27AM S21.00002: Controlling light using dynamic plasmonic pixels*  NICHOLAS J. GREYBUSH (Presenter), NRC-NRL Postdoctoral Fellow, KRISTIN M. CHARIPAR, NICHOLAS CHARIPAR, United States Naval Research Laboratory, PAUL JOHNS, JEFFREY GELDMEIER, ASEE-NRL Postdoctoral Fellow, JAWAD NACIRI, JAKE FONTANA, United States Naval Research Laboratory — With the end of Moore's law, information needs to move from electron- to photon-based systems, if computational processing power is going to continue to increase. To enable this paradigm shift, optical elements are needed to dynamically control the propagation of light. Here we demonstrate the spatial, spectral and temporal control of light using electric field aligned plasmonic nanorods. We show these suspensions are color tunable from visible to infrared wavelengths, with microsecond switching times, and can be spatially tuned using lithographically defined electrodes. These suspensions may lead to novel dynamic plasmonic pixel devices for optical display, filter and spatial light modulators applications.

*This material is based in part upon work supported by the Office of Naval Research under (N0001418WX00122) & (N0001417WX00884)
11:39AM S21.00003: Finite-thickness effects in plasmonic films with periodic cylindrical anisotropy*  IGOR BONDAREV (Presenter), Math & Physics, North Carolina Central University, USA — Using the earlier developed Lagrange formalism[1], the plasma frequency and the dielectric response function are derived for finite-thickness plasmonic films formed by periodic parallel arrays of metallic cylinders embedded in a host dielectric matrix[2]. The plasma frequency of the system is shown to have the unidirectional square-root-of-momentum and quasilinear momentum spatial dispersion for the thick and ultrathin films, respectively. This spatial dispersion and the unidirectional dielectric response nonlocality associated with it can be adjusted by the film material composition, the film thickness, the cylinder length, the cylinder-radius-to-film-thickness ratio, and by an appropriate choice of substrates and superstrates of the film. The theory developed is discussed in application to the finite-thickness periodically aligned carbon nanotube film system as a potential candidate for the new generation of flexible multifunctional metasurfaces[3], for which the importance of the nondispersive interband plasmon modes of individual nanotubes is stressed in the ultrathin film regime. -- [1]I.V.Bondarev & V.M.Shalaev, Opt. Mater. Expr. 7, 3731 (2017); [2]I.V.Bondarev, arXiv1810.07303; [3]A.L.Falk, et al, Phys. Rev. Lett. 118, 257401 (2017).

11:51AM S21.00004: Realization of A Novel Fibonacci Metasurface and K-space Imaging of Interference Pattern of Surface Plasmon Polariton*  CHUN YUAN WANG (Presenter), Department of Physics, The University of Texas at Austin, Austin, Texas, 78712, USA., SHANGJR GWO, Department of Physics, National Tsing-Hua University, Hsinchu 30013, Taiwan, CHIH-KANG SHIH, Department of Physics, The University of Texas at Austin, Austin, Texas, 78712, USA. — Metasurface is an artificial surface structure which are composed of, in general, period structure of metal or dielectric material to enable a spatially varying electromagnetic response, molding optical wavefronts or modulating surface plasmon polaritons (SPPs) [1, 2]. A Fibonacci sequence is defined mathematically as \( \{S_n\} \) where \( S_{n+1} = S_n, S_{n-1} \). If one creates a real space structure following the Fibonacci sequence, then the structure would not be periodic yet containing a long range order, in a manner similar to a quasicrystal whose structure is ordered but not periodic [3]. In this work, we fabricated Fibonacci sequence nanogrooves on epitaxial silver film via focus ion beam. Based on the angle-resolved reflectance mapping, we show multiple scattering of in-plane lattice-SPPs resulting from the hierarchial Fourier components of the Fibonacci sequence. It opens a way to understand coherent scattering in an ordered yet non-periodic structure.

12:03PM S21.00005: A generative model for the inverse design of metamaterials  ZHAOCHENG LIU (Presenter), WENSHAN CAI, Georgia Institute of Technology — The advent of metamaterials in recent years has ushered in a revolutionary means to manipulate the behavior of light on the nanoscale, and thereby enabling diverse applications in optical imaging, beam steering, light modulation, dispersion engineering, holography, and many more. However, the design of such structures, to date, has relied on the expertise of an optical scientist to guide a progression of electromagnetic simulations that iteratively solve Maxwell’s equations until locally optimized solution can be attained. Here, we develop a framework leveraging a deep generative model to identify the photonic structures in arbitrary topology from a geometric dataset given target optical response. Furthermore, if black-box optimization methods are incorporated, the framework is able to automate the inverse design and generate patterns of photonic structure with few interventions of human. The evaluation shows that over 95% average accuracy can be achieved in less than 5 seconds for all the unit patterns of the nanostructure tested. Our work introduces a generic approach for the design of photonic and optical structures in response to the near-field and far-field requirements, with broad applications in large-scale photonic design requiring trial-and-error practices.
Divacancy spin defects coupled to photonic crystal cavities in 4H-SiC

ALEXANDER CROOK

(Presenter), CHRISTOPHER P ANDERSON, KEVIN MIAO, ALEXANDRE BOURASSA, HOPE LEE, University of Chicago, DAVID BRACHER, XINGYU ZHANG, Harvard University, HIROSHI ABE, TAKESHI OHSHIMA, National Institutes for Quantum and Radiological Science and Technology (QST), EVELYN L HU, Harvard University, DAVID AWSCHALOM, University of Chicago — Silicon carbide (SiC) has recently been developed as a platform for optically addressable spin defects in the form of the neutral divacancy, most notably in the 4H polytype [1-3]. Here we present progress in the fabrication and characterization of 4H-SiC photonic crystal cavities coupled to neutral divacancies. We use a combination of nanolithographic techniques and a dopant-selective photoelectrochemical etch to produce suspended cavities. For divacancies in the cavity mode, the Purcell effect enhances near-infrared optical emission from the defect. This results in increased photon count rates due to reduced excited state lifetimes, and for cavity wavelengths matched with the defect, the Purcell enhancement increases emission into the zero-phonon line. This enhancement has applications for the scalability of long-distance entanglement schemes that require the interference of indistinguishable photons from spatially separated defects.

Photothermal Effect and Circular Dichroism in Chiral Plasmonic Metamaterials and Bolometers

LAROUSSE KHOSRAVI KHORASHAD (Presenter), XIANG-TIAN KONG, ALEXANDER O. GOVOROV, Department of Physics and Astronomy, Ohio University, USA — Chiral nanostructures have already shown their promising chiro-optical properties in many areas of plasmonic science and photonics. Simultaneously, plasmonic nanostructures are suitable tools to efficiently enhance light absorption and increase temperature as a result of the light-matter interaction. In this project, we couple chirality and a strong plasmonic photothermal effect to present a new type of chiral spectroscopy. We utilize the idea of chiral planar superabsorber to enhance the chiro-optical effect. Our simulation models show that the hybrid nanostructure introduces high chiral light sensitivity that leads to the polarization-sensitive local temperature distributions and to strong photothermal circular dichroism in a nanostructure. These ideas can be applied for polarization-sensitive photochemistry, plasmonic thermal switches and chiral bolometers [1].

Air-Spaced Triple Band Metamaterial Perfect Absorber

CHUNXU CHEN (Presenter), XIAOGUANG ZHAO, Boston University, JACOB SCHALCH, UC San Diego, SULTAN CAN, GUANGWU DUAN, Boston University, RICHARD DOUGLAS AVERITT, UC San Diego, XIN ZHANG, Boston University — We present a polarization insensitive air spaced triple band metamaterial perfect absorber (MMPA) consisting of a metamaterial layer and metallic ground plane. For our MMPA, the three near unity-absorption peaks can be individually specified by selecting the size of the ring resonators within one metamaterial unit cell – that is, inter-unit cell coupling is negligible. For our MMPA design, the coupling between the metamaterial layer and the ground plane is very strong. As a result, near-field interactions must be taken into account to properly analyze the electromagnetic response (EMR). Interference theory is often used to model the EMR of MMPAs. To account for near-field coupling we incorporate a correction term into our interference model. Our approach is in agreement with full-wave numerical simulations and experimental measurements. These findings demonstrate that a capacitance increase and an inductance decrease due to the coupling between the metamaterial layer and the ground plane are the primary causes for the difference between the standard interference theory and the experimental results.

Photonic Forces on Dielectric Metasurfaces for Passive Stabilization of Laser Propelled Spacecraft

JOEL SIEGEL (Presenter), ANTHONY WANG, University of Wisconsin - Madison, SERGEY MENABDE, KAIST, MIKHAIL A. KATS, University of Wisconsin - Madison, MIN SEOK JANG, KAIST, VICTOR W BRAR, University of Wisconsin - Madison — In this talk, we will show that the ability of metasurfaces to create arbitrary reflected/transmitted wavefronts leads to complex – and measurable – optical forces on the metasurface. We will show how these forces manifest on the microscopic scale for individual resonators (the base elements of the metasurface) and on the macroscopic scale. In addition, we will discuss the non-intuitive behavior these forces can exhibit and the challenges that result in controlling these forces. Finally, we will demonstrate the potential value of a metasurface to serve as a ‘laser sail’ for a recently proposed relativistic spacecraft. To this end, photonic forces are used to passively stabilize the metasurface in a high power laser beam.
room temperature also facilitate their application potential. Their robustness for a wide range of parameters and thus can dramatically tune the complex correlation between the spin- and charge-density waves, giving rise to a number of novel phases with distinct unusual magnetic and electronic features. Under the electric field in the ribbon width direction. Such setting imposes strong tendency to charge inhomogeneity and theoretical studies of the electronic and magnetic properties of lightly doped zigzag-edged graphene nanoribbons [1].

The electric field is one of the ideal ways for spintronics device applications due to its precise controllable nature. We report engineering magnetism on graphene nanoribbons by electric field* YUAN ZHOU (Presenter), Department of Physics, Nanjing University, WEIGUO YIN, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, SHUNLI YU, WENCHAO CHEN, Department of Physics, Nanjing University, CHANGDE GONG, Center for statistical and theoretical condensed matter physics, Zhejiang Normal University — Manipulating magnetism by means of the electric field is one of the ideal ways for spintronics device applications due to its precise controllable nature. We report theoretical studies of the electronic and magnetic properties of lightly doped zigzag-edged graphene nanoribbons [1] under the electric field in the ribbon width direction. Such setting imposes strong tendency to charge inhomogeneity and thus can dramatically tune the complex correlation between the spin- and charge-density waves, giving rise to a number of novel phases with distinct unusual magnetic and electronic features. Their robustness for a wide range of parameters and room temperature also facilitate their application potential.

1:51PM S21.00014: Wafer-scale photolithography of ultra-sensitive nanocantilever force sensors* YING PAN (Presenter), CALDER MILLER, KAI TREPKA, YE TAO, Harvard University — The detection of small forces using singly-clamped cantilevers is a fundamental feature in ultrasensitive versions of scanning probe force microscopy. In these technologies, silicon-based nanomechanical devices continue to be the most widespread high-performance nanomechanical sensors for their availability, ease of fabrication, inherently low mechanical dissipation, and good control of surface-induced mechanical dissipation.

Here, we develop a robust method to batch fabricate extreme-aspect-ratio (10^3), singly-clamped scanningnanowire mechanical resonators from plain bulk silicon wafers using standard photolithography. We discuss the superior performance and additional versatility of the approach beyond what can be achieved using the established silicon-on-oxide (SOI) technology.

T. acknowledge support from the Harvard Physics Department, the Harvard Office of Undergraduate Research and Fellowships, and the Rowland Institute. This work was supported by a Rowland Fellowship to Y. T.. The sample fabrication was carried out at the Center for Nanoscale Systems (CNS) at Harvard University.

2:03PM S21.00015: Resolution of Ultra-thin Piezoresistive Silicon Nanomechanical Resonators for Single Molecules Mass Spectrometry JARVIS LI (Presenter), WARREN FON, MICHAEL ROUKES, Caltech — Nanoelectromechanical-system mass spectrometry (NEMS-MS) measures the mass of single particles, one at a time, through determining the shift in the frequency of a nanomechanical resonator due to adsorption of molecules. This allows rapid identification and stratification of bio-molecules and individual analytes, as an alternative to conventional mass spectrometry. To achieve broad applications in native mass spectrometry, which focuses on large protein complexes over 1MDa, a mass resolution of less than 5kDa is desired. Ultra-thin silicon resonators provide a viable platform to achieve this desired resolution, as well as the ability for scaled up operation. Here we demonstrate optimizations in the mass sensitivity of ultra-thin silicon piezoresistive devices through dimensional scaling and cryogenic operations. We also discuss practical advantages and limits of this device architecture as it relates to single molecule analysis.

Session S22 DCOMP DMP: Electrons, Phonons, Electron-Phonon Scattering and Phononics VI BCEC 157C - Yan Li, American Physical Society APS - Tag(s): Focus

11:15AM S22.00001: An Ab-Initio Study of the Effect of Impurities on Electron-Phonon Energy Transfer in Niobium* NATHAN SITARAMAN (Presenter), JAMES MANISCALCO, TOMAS ARIAS, MATTHIAS ULF LIEPE, Cornell University — A precise understanding of electron-phonon energy transfer is crucial to the optimization of superconducting radio frequency (SRF) cavities, photocathodes, and other material systems in which electrons are out of thermal equilibrium with phonons. The role played by interstitial impurities is a point of particular interest; SRF scientists have long believed that impurities affect electron-phonon energy transfer in niobium cavities, but it is difficult to distinguish this effect from other impurity-induced effects. An inability to precisely control impurity concentrations and directly measure electron temperature further complicates the problem.

In order to shed light on this rich and important topic, we take an ab-initio approach, using recently developed packages for our in-house density functional theory software JDFTx to explore the dependence of electron-phonon energy transfer on electron and phonon temperatures, and on the concentrations of common impurities such as H, C, N, and O. We perform our calculations using a Wannier representation of the electronic state, which makes possible the dense k-space sampling necessary to study processes at cryogenic temperatures in the large unit cells necessary to study impurities.

11:27AM S22.00002: Understanding the chemical enhancement mechanism of graphene-enhanced Raman Spectroscopy (GERS) – A first principles study.  KANCHAN ULMAN (Presenter), SU YING QUEK, National University of Singapore — Surface-enhanced Raman spectroscopy (SERS), involving the enhancement of Raman signals for molecules on metal substrates, is a well-established field that has enabled the detection of trace concentrations of molecules. In recent years, graphene was found to be a candidate substrate for SERS, giving rise to a rapidly expanding field of graphene-enhanced Raman spectroscopy (GERS), and opening doors for other two-dimensional materials to be used for SERS. In conventional SERS, the Raman signal is enhanced by a combination of the dominant electromagnetic enhancement effect, and the smaller chemical enhancement effect, which stems from electron-phonon coupling in the system. The latter chemical enhancement effect is thought to play a dominating role in GERS, thus enabling detailed studies of electron-phonon coupling effects for organic-graphene interfaces. Yet, the details of the chemical enhancement effect in GERS are not well understood. Using first principles calculations, we study the GERS chemical enhancement mechanism using typical probe molecules such as pyridine adsorbed on graphene. We uncover a novel ground state enhancement mechanism that is distinct from the typical ground state charge transfer mechanism in conventional SERS.

11:39AM S22.00003: Kagome modes, a new route to ultralow thermal conductivity?* DAVID VONESHEN (Presenter), ISIS Pulsed Neutron and Muon Source, Science and Technology Facilities Council, MONICA CIOMAGA HATNEAN, Physics Department, University of Warwick, TOBY PERRING, HELEN C WALKER, ISIS Pulsed Neutron and Muon Source, Science and Technology Facilities Council, KEITH REFSON, Physics Department, Royal Holloway University of London, GEETHA BALAKRISHNAN, Physics Department, University of Warwick, JON GOFF, Physics Department, Royal Holloway University of London — From next generation gas turbines to scavenging waste heat from car exhausts, finding new materials with ultra-low thermal conductivity (κ) has the potential to lead to large gains in device efficiency. Crystal structures with inherently low κ are consequently desirable, but candidate materials are rare and often difficult to make. Using first principles calculations and inelastic neutron scattering we have studied the pyrochlore La2Zr2O7 which has been proposed as a next generation thermal barrier. We find that there is a highly anharmonic, approximately flat, vibrational mode associated with the kagome planes. Our results suggest that this mode is responsible for the low thermal conductivity observed in the pyrochlores and that kagome compounds will be a fruitful place to search for other low κ materials.

11:51AM S22.00004: Thermodynamics of Tin Using AFLOW-APL* MATEO RONQUILLO (Presenter), MICHAEL MEHL, United States Naval Academy, COREY OSES, STEFANO CURTAROLO, CORMAC TOHER, Duke University — Tin is one of the more interesting metallic elements, with a 13.2°C phase transition from diamond-like “gray” (α-Sn) to “white” (the eponymous β-Sn). Density Functional Theory (DFT) finds a simple hexagonal phase (sh-Sn, hP1) nearly degenerate with the other phases, although it is never seen. sh-Sn is very close in energy to β-Sn at all volumes, as found by a variety of density functionals. While the simple hexagonal structure is a high pressure phase of Si, there it is not close to the ground-state structure at normal pressures.

To understand this behavior we used the high-throughput AFLOW-APL (AFLOW Harmonic Phonon Library) to find the energy-volume relationship, phonon spectra and free energy for tin in the α-, β-, and sh-phases. Our results showed significant discrepancies between DFT and experiment. We find that DFT predicts the β-Sn phase as the ground state of tin, and a transition from β-Sn to sh-Sn at 200\,K. Both of these results contradict experiment. Our results are thus a cautionary tale about the use of DFT for understanding the behavior of systems with nearly degenerated crystal structures.

12:03PM S22.00005: Hybridization of Localized Surface Phonon Polaritons via Symmetry Breaking in Dolmen Nanostructures  
SWATHI IYER (Presenter), CHASE ELLIS, ALEXANDER GILES, United States Naval Research Laboratory, DMITRY CHIGRIN, Dept of Physics, Institute of Physics (IA), RWTH Aachen University, Aachen, Germany, RICHARD KASICA, CNST, National Instrumentation Science and Technology (NIST), Maryland, USA, MICHAEL MEEKER, United States Naval Research Laboratory, JOSHUA D CALDWELL, Mechanical Engineering Dept, Vanderbilt University, Nashville, TN, USA, JOSEPH G TISCHLER, United States Naval Research Laboratory —  
Subdiffractional confinement of light coupled with low optical losses mediated through surface phonons polaritons (SPhPs) in polar dielectric materials such as SiC have enabled infrared based nanophotonic applications. By utilizing a nano-Dolmen architecture, we experimentally and theoretically demonstrate hybridization between localized, sub-diffractional SPhP modes via spatial symmetry breaking. The substrate mediated, extended coupling nature of the vertically oriented monopole leads to gap-tunable symmetric and antisymmetric modes with high quality factors (200-250) and field localization in the coupled oscillator. By theoretical modelling we demonstrate monopolar excitation, otherwise excited so far only by off-normal light, through dipolar nearfields via normal incidence by overcoming the selection rules leading to direct and indirect excitation pathways for monopolar activation in the Dolmen system. Further, in contrast to the plasmonic systems, despite strong coupling the bound continuum states in narrow SPhP modes do not exhibit Fano interference. By controlling nanoscale geometry, spacing and excitation, we are able to obtain highly tunable optical responses resulting in strong phonon polariton hybridization and large near-field enhancements in these high-Q resonators.

12:15PM S22.00006: Nonlinear Physics for the Engineering of Phononic Frequency Combs*  
ADARSH GANESAN (Presenter), ASHWIN SESHIA, University of Cambridge — Phononic frequency combs (PFC) represent a new nonlinear phenomenon in the physical domain of micromechanical resonators [1]. The emergence of PFC is mediated by nonlinear modal coupling. Through a series of experiments with micromechanical resonators, various features of PFC have now been identified. These include drive parameters for comb operation, hysteresis for comb spectrum tailoring and evolving spectral envelopes of combs. Potential applications of PFC include high-precision sensing, spread spectrum information processing and other applications in timing and frequency control. However, for the successful realization of such applications, the nonlinear physics of micromechanical resonators underlying the evolution of PFC must be fully elucidated. Specific future directions include developing experimental protocols for engineering frequency combs at low drive power levels; resonant and off-resonant excitation; understanding comb frequency fluctuations; tailoring combs for broadband multi-octave spanning spectra; and modelling sensitivity to system parameters and physical perturbations.

12:27PM S22.00007: Studying the correlations and solubility of hydrogen in niobium using Density Functional Theory calculations  
ARVIND RAMACHANDRAN (Presenter), School of Sustainable Engineering and the Built Environment, Arizona State University, DR. HOULONG ZHUANG, School for Engineering of Matter, Transport & Energy, Arizona State University, KLAUS S LACKNER, School of Sustainable Engineering and the Built Environment, Arizona State University — In this work, we present a Density Functional Theory (DFT) study of hydrogen correlations and solubility in niobium. Finding the preferred interstitial site for single hydrogen atoms, calculating the pair-wise hydrogen correlations, and the treatment of many hydrogen atoms in a niobium cell are parts of this work. By studying how the pair-wise hydrogen-hydrogen interaction energy varies as a function of their distance, we develop the theoretical counterpart of the empirical Westlake criterion, a rule that states that hydrogen atoms cannot simultaneously occupy pairs of interstitial sites closer than 0.21 nm. Based on this inference, we provide a systematic way of populating many (>3) hydrogens in the niobium lattice. Using the differential binding energies and vibrational frequencies of dissolved hydrogens at varying hydrogen concentrations, we estimate the solubility of hydrogen in niobium. Apart from the conventional way of calculating the entropy of interstitial hydrogens under the harmonic oscillator approximation, this work includes a new approximation that treats the hydrogens as a monatomic ideal gas. The solubility predictions are in good agreement with experimental data.

12:39PM S22.00008: A simple method to determine lattice constants  
CHEN XIAO-FAN (Presenter), Department of Physics, Harbin Institute of Technology — A simple method to determine lattice constants is proposed. The method is based on the relation between electric conductivity and the lattice constants. A way to solve a puzzle in high-temperature superconductivity is also presented.
Purely electronic instabilities versus Peierls instabilities in semi-metallic 1D atomic chains*

MATTEO BARBORINI, SVEN REICHARDT, PIER LUIGI CUDAZZO, Physics and Materials Science Research Unit, University of Luxembourg, MATTEO CALANDRA, Institut des Nanosciences de Paris, Université Pierre et Marie Curie, FRANCESCO MAURI, Dipartimento di Fisica, Università di Roma La Sapienza, LUDGER WIRTZ (Presenter), Physics and Materials Science Research Unit, University of Luxembourg — In 1929 Peierls hypothesized that a semi-metallic linear chain of equally spaced single electron atoms is unstable due to electron-phonon coupling at T=0: periodic lattice distortions along the longitudinal mode of vibration lead to the opening of an electronic band gap, lowering the symmetry of the lattice and stabilizing a semiconducting ground state. The origin of the symmetry breaking and of the formation of a charge density wave (CDW) state, was thus directly linked to the ionic displacement.

Here we study two equidistant semi-metallic linear chains, the (hypothetical) hydrogen chain and the carbon chain (carbyne), by means of accurate ab initio calculations based on quantum Monte Carlo and density functional theory (DFT). For both chains we find that the CDW state is more stable than the metallic phase even without any lattice distortion. This means that the ground state is electronically unstable. In DFT we show that the presence of the electronic instability is directly related to the non-locality of the Hartree-Fock exchange term that appears in the hybrid functionals. These results suggest that in 1D semi-metals there exists a pure electronic instability that opens a gap, leading to a CDW phase which is prior to Peierls distortion.

We acknowledge funding by FNR and ANR.

Magnetoelastic coupling, phonon and magnons in inverse spinel NiFe2O4*

QIANG ZHANG (Presenter), Louisiana State University & Oak Ridge National Laboratory (current affiliation), ROSHAN NEPAL, Physics and astronomy, Louisiana State University, ASHFIA HUQ, ALEXANDER I KOLESNIKOV, STEPHEN NAGLER, Oak Ridge National Laboratory, RONGYING JIN, Physics and astronomy, Louisiana State University — The inverse spinel NiFe2O4 has attracted enormous interest due to the potential applications in several important fields such as electronic devices and catalysis. NiFe2O4 exhibits a cation distribution of (Fe3+)A(Ni2+Fe3+)B04, with Fe3+ occupying the tetrahedral(A) sites forming a diamond lattice, and Ni2+ and Fe3+ sharing the octahedral(B) sites forming a pyrochlore lattice. Powder neutron diffraction reveals the cubic spinel structure persisting down to 5 K. A collinear ferrimagnetic order with antiparallel moments between A and B sites is found below T_N ≈ 860 K with a magnetoelastic coupling at T_N. Magnetization measurements further reveal NiFe2O4 enters a state with the coexistence of a ferrimagnetic order and a spin glass like state below the freezing temperature T_f ≈ 40 K. A few branches of phonons and magnons with a crossing feature are observed via single-crystal inelastic neutron scattering at 100 K (T_f < T < T_N) and 5 K (T < T_f). All these results and magnetic exchange constants will be compared to the well-known magnetite Fe3O4 to reveal the distinct spin, lattice and orbital degrees of freedom.

The work has been supported by the U.S. DOE under EPSCoR Grants No. DESC0012432, DE-SC0016315 and US DOE Basic Energy Sciences Division of Scientific User Facilities.

First-principles calculation of Seebeck coefficient of transition-metal elements

HISAZUMI AKAI (Presenter), University of Tokyo, SONJU KOU, Graduate School of Engineering Science, Osaka University — Calculation of the Seebeck coefficient S of transition metal elements is challenging. The difficulties are that, first, at T=0K, the conductivity of pure metal diverges. Second, the Fermi surfaces of transition metals composed of many different states, For this a formal cancelation of the relaxation time appearing in L_{12} and L_{11} in the expression of S=C(L_{12}/L_{11}) cannot be applied. To overcome the difficulties, we included the effects of electron-phonon scattering in the calculation of S. We exploited the Korringa--Kohn--Rostoker (KKR) Green's function method combined with the coherent potential approximation (CPA, KKR-CPA) and linear response theory. The approach combines three components: linear response theory in the framework of the KKR method; ab-initio phonon calculations; and an alloy analogy applied to the local static phonons using the KKR-CPA. The calculated Cu resistivity and the Seebeck coefficients for various transition-metal elements at finite temperature show reasonably good overall agreements with experiments. The present approach provides us with a framework applicable to a wide range of materials, including pure metals, compounds, ordered and disordered alloys, opening up the possibilities of computational design of useful thermoelectric materials.
1:27PM S22.00012: Nonlinear Anomalous Thermoelectric Current*  
YANG GAO (Presenter), DI XIAO, Carnegie Mellon University — Using the concept of the orbital magnetic quadrupole, we derive a nonlinear anomalous thermoelectric current, i.e. a current quadratic in temperature gradient and perpendicular to its direction. In the system that breaks time reversal, inversion, and one mirror symmetry, but has the combined time reversal and inversion symmetry, the linear anomalous thermoelectric current vanishes but the nonlinear current we obtained does not vanish and hence can be used to probe such system. We demonstrate this nonlinear current in the loop-current model in the pseudogap phase.

*This work is supported by the Department of Energy, Basic Energy Sciences, Grant No.—DE-SC0012509.

1:39PM S22.00013: Nanosecond Shape-driven Localized Surface Plasmon Resonance Switching in Silver Nanoparticles*  
VENKATANARAYANA P SANDIREDDY, Department of Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, KRISHNA KOIRALA, Department of Physics and Astronomy, University of Tennessee, Knoxville, RAMKI KALYANARAMAN (Presenter), Department of Material Science and Engineering, University of Tennessee, Knoxville — The ability to tune the localized surface plasmon resonance (LSPR) in a fast and repeatable manner could form the basis for a hypothetical optical switch. Here we demonstrate a reversible change in the LSPR wavelength of Ag nanoparticles based on nanosecond melting induced shape effects. When Ag nanoparticles are melted by nanosecond laser pulses, the resulting contact angle is determined by the fluid environment during melting. For instance, Ag nanoparticles on quartz substrates melted in air are near hemispherical in shape (with contact angle ~ 96°), while those melted under water and glycerol have larger contact angles of ~127° and ~172° respectively. This shape or contact angle change significantly modifies the intensity and wavelength of the dipolar and quadrupolar plasmonic signals. We have utilized this shape change to switch the plasmonic signals over multiple cycles of irradiation and determined the fatigue limit of LSPR switching between air and glycerol environments. Such shape control and repeatable modification of the plasmonic wavelength could serve as a useful system for biological sensing and optical tuning applications.

1:51PM S22.00014: Theory of time-resolved resonant inelastic x-ray scattering for studying material dynamics  
YUAN CHEN (Presenter), Department of Applied Physics, Stanford University, YAO WANG, Department of Physics, Harvard University, CHUNJING JIA, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, JAMES FREERICKS, Department of Physics, Georgetown University, ANDRIJ SHVAIKA, Institute for Condensed Matter Physics, National Academy of Sciences of Ukraine, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory — With recent progress in the X-ray beamline and pump-probe instrumentation, time-resolved RIXS (tr-RIXS) promises to detect the nonequilibrium dynamics of collective modes, which play significant roles in quantum materials. Here we present a theory for evaluating the tr-RIXS cross-section. This time-domain theory is based on nonequilibrium linear response and can reproduce the common Kramers-Heisenberg formula at equilibrium. We numerically evaluated tr-RIXS cross-section for some example systems out of equilibrium, including a graphene nanoribbon and the 2D single-band Hubbard model. We show that tr-RIXS can capture the dynamics of multi-particle Floquet excitations in a momentum-resolved way, revealing underlying physics such as Floquet band renormalization, topological edge states, and pump-induced collective excitations.

2:03PM S22.00015: Polarized Raman spectroscopy at the edges of exfoliated GeS and GeSe crystals*  
HENRIQUE BUCKER RIBEIRO (Presenter), MackGraphe, Mackenzie Presbyterian University, SÉRGIO L. L. DE MORAES RAMOS, Centro de Tecnologia em Nanomateriais (CTNano), Universidade Federal de Minas Gerais, LEANDRO SEIXAS ROCHA, CHRISTIANO DE MATOS, MackGraphe, Mackenzie Presbyterian University, MARCOS ASSUNÇÃO PIMENTA, Departamento de Física, Universidade Federal de Minas Gerais — Germanium sulfide (GeS) and germanium selenide (GeSe) are layered crystals which structure bears a strong resemblance to that of black phosphorus (BP). As recently observed and reported, BP exhibits atomic rearrangements at crystal terminations, which lead to the activation of Raman modes that are otherwise forbidden by polarization selection rules. Considering the similarities in the crystalline structure of BP, GeS, and GeSe, the same behavior would be expected at the edges of these crystals. In this work, the Raman modes GeS and GeSe edges were experimentally studied using polarized Raman spectroscopy. We show, at the edges, the appearance of modes that are symmetry-forbidden. By carrying out DFT calculations, we conclude that the anomalous behavior is a consequence of edge atomic rearrangements. Such rearrangements, therefore, appear to be a general feature in lamellar crystals with the crystalline structure of BP.

L.S. acknowledges support from FAPESP (2017/00486-1) and computational facilities from SDumont/LNCC supercomputer.
Quantitatively accurate numerical modeling of amplitude and phase contrast in broadband near-field infrared spectroscopy

Patrick Mcardle (Presenter), David Lahneman, Muhammad M. Qazilbash, Department of Physics, College of William & Mary, Amlan Biswas, Department of Physics, University of Florida. Proper modeling of near-field infrared spectroscopy data is critical to extracting useful material properties. Current analytical models make underlying assumptions about the probe geometry that makes their use applicable in only limited situations. When strong coupling between probe and sample exists, a more robust solution method must be used. A full-wave numerical method for calculating broadband demodulated near-field amplitude and phase contrast will be presented. Our method captures the probe geometry accurately and is thus essential for obtaining quantitative results free of underlying assumptions and tunable parameters. We will present simulation results on SiO$_2$ and SrTiO$_3$, both of which exhibit surface phonon-polariton modes, and will compare the simulation results to experimental data.

* M.M.Q acknowledges support from NSF DMR-1255156. The simulation work was performed, in part, using computing facilities at the College of William and Mary which are supported by contributions from the National Science Foundation, the Commonwealth of Virginia Equipment Trust Fund, and the Office of Naval Research.

Tunable narrow band sources for anisotropic THz spectroscopy

Deepu George (Presenter), Physics, University at Buffalo, Ian Mcnee, Patrick Tekavec, Vladimir Kozlov, MicroTech Instruments, Peter Schunemann, BAE Systems, Andrea Markelz, Physics, University at Buffalo. THz spectroscopy is well suited for material identification and characterization in many different fields due to unique molecular vibrational signatures in this range. Recently this has been extended to feature identification in large biomolecules like proteins and DNA, using the newly developed time domain Anisotropic Terahertz Microscopy (ATM)[1]. ATM measures polarization dependent changes in THz absorption and thus generates a comprehensive map of the vibrational modes, featuring their frequencies as well as their directions. Despite these advances, proliferation of THz systems is hindered by low dynamic ranges of measuring systems, large footprints and cost. Therefore, development of high power, compact THz sources and their characterization are critical. In this study we investigate the suitability of using quasi CW THz radiation generated by pumping Orientation Patterned Gallium Phosphide with a 1064 nm fiber laser for identifying anisotropic signatures of molecular crystals. THz generation from 0.5 to 4 THz is achieved. Results compared with that obtained using a broadband time domain spectrometer. The results show that new narrow band sources are suitable for high dynamic range THz systems.

Terahertz Coherent Acoustic Phonons in SrRuO$_3$/SrTiO$_3$ Superlattices

Chiyuan Yang (Presenter), Department of Physics, National Taiwan University, Pingchun Wu, Yings-Hao Chu, Department of Materials Science and Engineering, National Chiao Tung University, Kung-Hsuan Lin, Institute of Physics, Academia Sinica. We utilized time-resolved pump-probe spectroscopy to generate and detect coherent acoustic phonons (CAPs) in SrRuO$_3$/SrTiO$_3$ superlattices with frequencies according to the spatial modulation of the heterostructures. Thanks to the pulse laser deposition techniques, precise manipulation of atomic layers enables the fabrication of high-quality heterostructures and generation of CAPs in THz regime. Dynamics of CAPs from hundreds of GHz to 1 THz were investigated. By introducing a control pulse, coherent control of CAPs was also demonstrated. Since many complex oxides with perovskite structures can be deposited on the SrRuO$_3$/SrTiO$_3$ superlattices, our demonstrated technique can be used to study their coherent acoustic properties in THz regime.
11:51AM S23.00004: Near Field Optical-Pump-Terahertz-Probe Experiments on Graphene/InAs Heterostructure
ZHENG YAO, JIAWEI ZHANG (Presenter), SCOTT MILLS, Stony Brook University, XIAOGUANG ZHAO, Boston University, XINZHONG CHEN, RYAN MESCALL, Stony Brook University, VYACHESLAV SEMENENKO, Skolkovo Institute of Science and Technology, HAI HU, Nanophotonics Research Division, National Center for Nanoscience and Technology, THOMAS P CIAVATTI, Stony Brook University, STEPHAN MARCH, SETH BANK, Electrical and Computer Engineering, The University of Texas at Austin, HU TAO, Shanghai Institute of Microsystem and Information Technology, State Key Laboratory of Transducer Technology, VASILI PEREBEINOS, Skolkovo Institute of Science and Technology, XIN ZHANG, Boston University, QING DAI, Nanophotonics Research Division, National Center for Nanoscience and Technology, XU DU, MENGKU LIU, Stony Brook University — We show that graphene is a perfect terahertz reflector in the high q regime with terahertz s-SNOM. We also demonstrate optical pump terahertz near-field probe (n-OPTP) and optical pump terahertz near-field emission (n-OPTE) experiments on graphene/InAs heterostructure. Femtosecond pulse laser is used to both pump samples and to generate terahertz pulses. We show that in the near-field regime a single layer graphene is transparent to near-IR (800 nm) optical excited terahertz emission from InAs but completely “screens” the photo-induced carrier dynamics in InAs probed by a separate THz pulse.

12:03PM S23.00005: Developing Wide-angle Spherical Neutron Polarimetry at Oak Ridge National Laboratory
NICOLAS SILVA (Presenter), TIANHAO WANG, HARISH K AGRAWAL, FANKANG LI, LISA DEEBER-SCHMITT, MASAAKI MATSUDA, JILLIAN RUFF, Neutron Science Directorate, Oak Ridge National Laboratory, ROGER PYNN, Physics, Indiana University Bloomington, XIN TONG, BARRY L. WINN, CHENYANG JIANG, Neutron Science Directorate, Oak Ridge National Laboratory — Spherical Neutron Polarimetry (SNP) analyzes complex magnetic structures through distinguishing contributions from nuclear-magnetic interference and chiral structure in addition to nuclear magnetic scattering separation. This analysis is achieved through determining all components in the polarization transfer process. Currently, wide-angle SNP is being realized at Oak Ridge National Laboratory (ORNL) for multiple beamlines including: the polarized triple-axis spectrometer (HB-1) and general-purpose small angle neutron scattering instrument (CG-2) at the High Flux Isotope Reactor (HFIR), as well as the hybrid spectrometer (HYSPEC) at the Spallation Neutron Source (SNS). The SNP device consists of three units: incoming/outgoing neutron polarization, sample environment and a zero-field chamber. The incoming/outgoing neutron polarization regions use high-Tc superconducting YBCO films and mu-metal to achieve full control of neutron polarization. The sample environment is a dilute refrigerator with a customized tail piece placed into the zero-field chamber. The device is under construction with performance simulations complete and calibration and demonstration experiments scheduled for next year.

TIANHAO WANG (Presenter), CHENYANG JIANG, HASSINA Z BILHEUX, INDU DHIMAN, JEAN-CHRISTOPHE BILHEUX, MORRIS LOWELL CROW, LANDEN MCDONALD, LEE ROBERTSON, Oak Ridge National Laboratory, NIKOLAY KARDJILOV, Institute Applied materials, Helmholtz Zentrum berlin, ROGER PYNN, Department of Physics, Indiana University Bloomington, XIN TONG, China Spallation neutron Source — Polarized Neutron Imaging (PNI) visualizes magnetic field distribution through interactions between the neutron polarization and the magnetic field. The PNI technique creates unique imaging contrast related to magnetic properties in comparison to traditional absorption-based neutron imaging. Furthermore, quantitative PNI provides a nondestructive measurement on internal magnetic structures. At the Oak Ridge National Laboratory, a new PNI capability was implemented on the CG-1D neutron imaging beamline at the High Flux Isotope Reactor (HFIR). The PNI setup at ORNL uses an in-situ optical pumping $^3$He neutron spin filter to provide a non-distorted radiographs with a stable 90% neutron polarization. The polarized beamline operates in either polychromatic or monochromatic mode, with a field of view of 50mm×50mm and 350μm spatial resolution. Based on the new capability, a series of experiments were performed investigating the magnetic field distortion caused by Meissner effect of superconductors. The results of these experiments combined with modeling will be presented. The PNI team at ORNL is now seeking collaborations to utilize the PNI technique at CG-1D.
12:27PM S23.00007: Cross-Section and Measurement Considerations for Polarized Neutron Scattering from NMR Spin-Modulated Systems  MICHAEL KOTLARCHYK (Presenter), GEORGE THURSTON, Rochester Institute of Technology — We present a development of theoretically predicted cross sections, along with potential measurement scenarios, associated with the scattering of polarized thermal neutrons from target nuclei whose spins are modulated using nuclear magnetic resonance (NMR). Specifically, we investigate the modulation of the polarized differential scattering cross sections under the following two scenarios: (i) Measurements that take place during the time-interval between the application of radio-frequency (RF) pulses that repeatedly impart transverse rotations to selected sets of spin-1/2 target nuclei, and (ii) Measurements that take place during continuous RF irradiation of these nuclei. The aim of this work is to provide foundational knowledge and necessary considerations to explore, and ultimately achieve, the design of instrumentation that would provide enhanced scattering signals from selected nuclei in liquids and solutions by leveraging the use of NMR techniques. We discuss our in-progress calculations which are aimed at evaluating signal-to-noise for a prototypical molecular mixture in the context of NMR/neutron scattering protocols such as those outlined in our recent paper (1).

12:39PM S23.00008: Designs of neutron microscopes for high-resolution imaging*  MUHAMMAD ABIR, BORIS KHAYKOVICH (Presenter), Massachusetts Institute of Technology, DANIEL HUSSEY, National Institute of Standards and Technology — We demonstrate designs of two types of neutron microscopes. Like an optical microscope, the neutron microscope consists of a condenser and an image forming optics. Neutrons are focused at the sample by a condenser optic. An image forming optic focuses transmitted neutrons at the detector. The condenser optic is designed to maximize the neutron flux and to obtain desired beam divergence at the sample. The condenser consists of axisymmetric confocal paraboloid and a hyperboloid mirrors, which are concentrically nested. The image-forming optics are designed using two different types of Wolter mirrors, confocal nested ellipsoid and hyperboloid sections. The design of magnification-10 mirrors should achieve the spatial resolution of about 10 μm. Importantly, the resolution of the microscope is determined by the mirrors rather than by the beam collimation as in conventional pinhole imaging, leading to possible dramatic improvements in the signal rate and resolution. Also in contrast with pinhole imaging, in the microscope the samples are placed far from the detector to allow for bulky sample environment.

*The work at MIT was supported by the award 60NANB15D361 from U.S. Department of Commerce, National Institute of Standards and Technology.

12:51PM S23.00009: Portable Mid-IR Spectrometer  TAEYOON JEON (Presenter), AMIRHOSSEIN NATEGHI, AXEL SCHERER, Caltech — We describe a mid-IR spectrometer by combining a commercial thermal imaging camera with a Diesel engine glow-plug and a micromachined hyperspectral filter. Our hyperspectral mid-IR filter consists of two silicon/air mirrors that form an optical cavity. A small angle between the two high-reflectivity mirrors provides us with a gradual variation of the cavity resonance peak and we obtain a position-dependent transmission filter. The linear variation of resonance frequency with position enables the ~40,000 pixels in the thermal bolometer camera to be converted into an optical multichannel spectrometer. Filters are made of multiple layers of silicon and air, and the high refractive index and transparent properties of silicon in the mid-IR region provide a wide free spectral range of up to 10 micrometers. Different wavelengths can be assigned to each pixel in the microbolometer array, enabling rapid spectral acquisition in our compact spectrometer. This allows us to measure the mid-IR spectra of various types of polymers, biomolecules and medications in a compact system. Here we show mid-IR molecular absorption spectra from different materials measured with this spectrometer and compare them to Fourier-Transform Infrared Spectroscopy (FTIR) results.

Session S24 DAMOP DCMP: Topological States in AMO Systems I  BCEC 159 - Chao-Xing Liu - Tag(s): Focus
11:15AM S24.00001: Topological triply-degenerate points in ultracold atoms and photonic hyperbolic metamaterials* [Invited] CHUANWEI ZHANG (Presenter), University of Texas at Dallas — Topological states of matter provide a fertile ground for discovering new quasiparticles in condensed matter physics, such as Weyl and Dirac fermions, which were originally predicted in high-energy physics and recently observed in solid-state materials. In topological semimetals, Weyl and Dirac points correspond to two- and fourfold degenerate linear band crossing points, hallmarks of relativistic particles with half-integer spins. Remarkably, the recent discovery of triply degenerate points (TDPs) in semimetals has opened an avenue for exploring new types of quasiparticles that have no analog in quantum field theory. Such TDPs possess effective integer spins while preserving Fermi statistics and linear dispersions. In previous studies, the emergence of such protected nodes was often attributed to spin-vector-momentum couplings. In this talk, I will discuss three new types of TDPs that are classified by different monopole charges (C = +/- 2, 1, 0) and induced by the interplay between spin-tensor- and spin-vector-momentum couplings. I will discuss how to realize these new types of TDPs using ultracold atoms in optical lattices and photons in non-Hermitian hyperbolic metamaterials. These proposed atomic and photonic systems may provide highly controllable platforms for exploring and engineering novel quasiparticles without counterparts in quantum field theory.

11:51AM S24.00002: A Bose-Einstein Condensate on a Synthetic Hall Cylinder* CHUAN-HSUN LI (Presenter), YANGQIAN YAN, SAYAN CHAUDHURY, DAVID BLASING, QI ZHOU, YONG CHEN, Purdue University — Interplay between matter and fields in physical spaces with nontrivial geometries gives rise to many exotic quantum phenomena. However, their realizations are often impeded by experimental constraints. Here, we realize a Bose-Einstein condensate (BEC) on a synthetic cylindrical surface subject to a net radial synthetic magnetic flux, topologically equivalent to a two-dimensional (2D) Hall ribbon with two edges connected. This cylindrical surface comprises a real spatial dimension and a curved synthetic dimension formed by cyclically-coupled spin states. The BEC on such a Hall cylinder has counterintuitive properties unattainable by its counterparts in 2D planes. We observe Bloch oscillations of the BEC with doubled periodicity of the band structure, analogous to traveling on a Möbius strip, reflecting the BEC’s emergent crystalline order with nonsymmorphic symmetry-protected band crossings. We further demonstrate such topological operations as gapping the band crossings and unzipping the cylinder. Our work opens the door to engineering synthetic curved spaces and observing intriguing quantum phenomena inherent to the topology of spaces.

12:03PM S24.00003: Topological Phases of Fermions in Kagome Optical Lattices* VITO SCAROLA (Presenter), MENGSU CHEN, HOI-YIN HUI, Physics, Virginia Tech, SUMANTA TEWARI, Physics, Clemson University — Frustration can favor topological states of matter over conventionally ordered states. We use numerical diagonalization and mean field theory to study models of fermionic atoms and molecules placed in kagome optical lattices. We show that just the long range part of dipolar interactions between fermions can drive the creation of a topological Mott insulator. We also study applications of applied synthetic fields using optical flux lattices and laser assisted tunneling. We find that effective magnetic fields lead to topological phases, including the chiral spin liquid, even for atoms interacting with only the contact interaction. Experimental challenges for realizing these topological states with atomic gases in optical lattices are discussed.

*We acknowledge support from AFOSR (FA9550-18-1-0505) and ARO (W911NF-16-1-0182).
We propose a realistic scheme for the full characterization of Floquet topological insulators realized in optical lattices. We construct a family of drives that connects the target Hamiltonian to a topologically trivial reference point for the periodically driven systems that we identify as the high-frequency regime. Our proposal relies on the detection of topological singularities in the Floquet spectrum with respect to the reference point as the drive parameters are varied within a specific drive family. Bypassing the difficulties of adiabatic preparation through a topological transition, we show how the topological charge of individual singularities can be measured using state tomography techniques. We demonstrate our scheme by using two concrete examples of periodically driven systems in two dimensions relevant to experiments. Our proposal paves the way to full experimental characterization of nonequilibrium topological phases in driven systems with the measurement of both regular and anomalous Floquet topological invariants.

Work supported by the DFG-Research Unit 2414, the NSF CAREER grant DMR-1350663, the BSF Grant 2014245, and the College of Arts and Sciences at Indiana University.
Wavefunction localization is a characteristic phenomenon occurring in disordered and quasiperiodic systems as well as with edges states in topological phases. We study the quasiperiodic Aubry-Andre-Harper (AAH) model, known to exhibit a unique localization-delocalization transition in one dimensions, defying standard Anderson localization. Generalizations of the AAH model include next-nearest neighbor (NNN) hopping, or additional incommensurate on-site terms and have so far been studied numerically. For such extended models the appearance of a mobility edge i.e. an energy cut-off dictating which wavefunctions undergo the localization-delocalization transition is expected. To study properties of these models, we employ transfer matrices which are known to characterize localization physics through Lyapunov exponents. We use the symplectic nature of transfer matrices to represent them as points on a torus. Related wavefunctions then form toroidal curves. We obtain distinct toroidal curves for localized, delocalized and critical wavefunctions, thus demonstrating a geometrical characterization of localization physics. Applying the transfer matrix method to the NNN AAH model, we formulate a geometrical picture that captures the emergence of the mobility edge in a visually striking way.

1:51PM S24.00012: Geometric phases enable real-world models of classical and quantum dynamics in Hall effects and in three-body molecular dynamics*  
F. J. LIN (Presenter), F. J. Lin Research — Almost sixty years ago, Aharonov and Bohm pointed out that electrons could be affected by vector potentials without an external magnetic field. They described an \textit{ad hoc} phase shift required for wave functions in vector potentials, e.g., representing magnetic fields. The phase shift exemplifies a geometric phase (or Berry's phase). In classical and quantum dynamics, vector potentials producing \textit{coupled} overall rotation lead to geometric phases. Instead of neglecting it, now the coupling is used to create a frame with \textit{decoupled} overall rotation and vanishing classical and quantum geometric phases. A general formulation of classical dynamics describes both the dynamics of topological matter, such as Hall effects, and three-body molecular dynamics. A quantum extension describes the quantum dynamics of topological matter and the three-body molecular dynamics in the Born-Oppenheimer approximation. Real-world models with or without magnetic fields contribute to developing optoelectronic and photonic devices. Real-world models for three-body dynamics contribute to developing optimal molecular reaction dynamics.

Topological phases in 1D bosonic Bogoliubov bands with dynamical instability

TERUMICHI OHASHI (Presenter), SHINGO KOBAYASHI, YUKI KAWAGUCHI, Applied physics, Nagoya University — Topological phases of matter have attracted much attention in solid-state physics, but most of studies treat Hermitian Hamiltonians [1]. Recently, there has been growing interest in non-Hermitian topological phases [2], which exhibit exotic phenomena absent in Hermitian ones [3]. Non-Hermitian Hamiltonian describes an open quantum system in which loss and gain of particles coexist. Here, we note that bosonic Bogoliubov quasiparticles, which are elementary excitations from a Bose-Einstein condensate (BEC), are also described with a non-Hermitian Hamiltonian, where a BEC works as a particle bath. In this sense, topological classification of BECs is an open question. In the case when the non-Hermitian Hamiltonian has real eigenvalues, the topological properties of quasiparticles is discussed [4].

In this talk, we consider more general cases of 1D BECs and find topological invariants in 1D BDI and D classes. As concrete examples, we discuss topological properties in a 1D Kitaev model [4] and in a 1D SSH model.

11:15AM S25.00001: Microgravity experiments with radiofrequency-dressed Bose-Einstein condensates aboard NASA's Cold Atom Laboratory

NATHAN LUNDBLAD (Presenter), MAXWELL GOLD, XIAOLE JIANG, RYAN CAROLLO, Bates College — Microgravity conditions present opportunities for studying ultracold atomic systems free of gravitational perturbation. One such opportunity is the study of shell- or bubble-like Bose-Einstein condensates, which have not been observed terrestrially due to gravitational effects dominating condensate mean-field energy in typical experimental conditions. We present recent measurements using NASA's Cold Atom Laboratory facility aboard the International Space Station focusing on both preliminary characterization of the CAL atom-chip magnetic trap and on the physics of radiofrequency (rf) dressed magnetic traps in a microgravity environment, and discuss model predictions of bubble-BEC properties in such an environment.

*NASA Fundamental Physics / JPL RSA No. 1597429

11:27AM S25.00002: Proposal for measuring Big G using the NASA Cold Atom Lab aboard the International Space Station

COLSON SAPP (Presenter), Georgia Southern University, CHARLES W CLARK, JQI and NIST, MARK EDWARDS, Georgia Southern University — We propose an atom interferometry (AI) experiment to measure Big G constant in a microgravity environment. Our experiment is assumed to be conducted in NASA's Cold Atom Laboratory currently deployed to the International Space Station. The idea is to carry out an AI sequence many times, first with a source mass present and then with no source mass. The basic AI sequence is to split a Bose-Einstein condensate (BEC) into two pieces using pulsed optical lattice potentials. These pieces fly apart in the presence of an harmonic potential and finally stop after one quarter trap period. The trap is then turned off for a wait time. The pieces acquire a relative velocity difference due to the differential gravitational pull of the source mass. The trap is turned back on and the pieces then recombine and are split again. The result is two clouds left nearly motionless near the trap center creating an interference pattern due to their relative velocity. We have simulated this sequence using the Lagrangian Variational Method (LVM) where the trial wave function is a sum of Gaussian clouds. We show how big G can be extracted from the interference pattern that results and present an approximate error budget for the measurement.

11:39AM S25.00003: Measurement induced dynamics and defect stabilization in spinor condensates*  
HILARY HURST (Presenter), I. B. SPIELMAN, Joint Quantum Institute and National Institute of Standards and Technology — Weakly measuring many-body systems and allowing for feedback in real time can simultaneously create and measure new phenomena in quantum systems. We study weak measurement and classical feedback in spinor Bose-Einstein condensates, focusing on the trade-off between usable information obtained from measurement and quantum backaction. As a prototype example, we consider the dynamics of a domain wall in a two-component BEC and show that quantum backaction due to measurement causes two primary effects: domain wall diffusion and overall heating. The system dynamics and signal-to-noise ratio depend on the choice of measurement observable. We describe a feedback protocol to create and stabilize a domain wall in the regime where domain walls are unstable, giving a prototype example of Hamiltonian engineering using measurement and feedback. Finally, we discuss extensions of this idea to higher spin systems.

11:51AM S25.00004: Nonthermal fixed points in a one-dimensional antiferromagnetic spinor Bose gas  
KAZUYA FUJIMOTO (Presenter), RYUSUKE HAMAZAKI, MASAHITO UEDA, Department of Physics, University of Tokyo — Recently, a nonthermal fixed point (NFTP) is proposed as a universal thermalization scenario [1], where a system evolving from a nonequilibrium initial state is attracted to the NTFP and shows a universal dynamical scaling law. We theoretically study quench dynamics in a one-dimensional (1D) antiferromagnetic (AF) spinor Bose gas, finding universal thermalization dynamics characterized by a NTFP induced by two types of solitons. One soliton is a magnetic soliton having a locally magnetized part, and the other is an exotic bound state of magnetic solitons, which we refer to as a Flemish string because of the twisted magnetic structure. We numerically find that the stable magnetic solitons can disappear through formation of the Flemish strings, and that the cooperative soliton dynamics through the Flemish string promotes the relaxation. Then, we elucidate the dynamical scaling regarded as a signature of the NTFP in the quench dynamics. Furthermore, studying the experiment for a trapped 1D AF Bose gas [2], we find that the universal thermalization with the NTFP appear if the applied filed is quenched more strongly compared with the experiment.

12:03PM S25.00005: Universal relations and Tan contact matrix for 1D spinor quantum gases*  
SHAH SAAD ALAM (Presenter), HAN PU, Rice University — The Tan contact and associated Tan relations, such as the tail of the momentum distribution, have been previously studied for a few kinds of spinor quantum gases, such as spin-zero/half fermions, bosons, SU(N) symmetric cases or multicomponent gases. Inspired by our previous work on interacting spinor quantum gases with arbitrary spins, we present results of our investigation of the Tan contact matrix and its connection to the large momentum tail for arbitrary spin cases with spin-dependent interactions at arbitrary strengths. We further discuss the connection of the Tan contact matrix to two body density matrices, energetics and other universal relations.

12:15PM S25.00006: Supercurrent induced by multipoles in nonmagnetic spin-2 Bose-Einstein condensates*  
EMI YUKAWA (Presenter), Center for Emergent Matter Science, RIKEN, MASAHITO UEDA, Department of Physics, University of Tokyo — In spinor Bose-Einstein condensates (BECs), a supercurrent is known to be induced by the magnetic degrees of freedom when the magnitude of the spin vector is finite. On the other hand, when a spinor BEC is nonmagnetic, the supercurrent originating from the magnetic degrees of freedom is absent for a spin-1 BEC; however, it has remained to be clarified if it is essentially zero for any spin degrees of freedom. We show that a supercurrent can be induced by magnetic multipoles for a non-magnetic spin-2 BEC. We analytically derive a superfluid in a nonmagnetic spin-2 BEC that involves components originating from the magnetic degrees of freedom. We also numerically demonstrate that these components can be induced by a spatially dependent magnetic field via the quadratic Zeeman effect.

12:27PM S25.00007: Internal oscillations of a dark-bright soliton in a harmonic potential* MAJED ALOTAIBI (Presenter), LINCOLN CARR, Colorado Sch of Mines — We investigate the dynamics of a dark-bright soliton in a harmonic potential using a mean-field approach via coupled nonlinear Schrodinger equations appropriate to multi-component Bose-Einstein condensates. We use a modified perturbed dynamical variational Lagrangian approximation, where the perturbation is due to the trap, taken as a Thomas-Fermi profile. The wave function ansatz is taken as the correct hyperbolic tangent and secant solutions in the scalar case for the dark and bright components of the soliton, respectively. We also solve the problem numerically with pseudo-spectral Runge–Kutta methods. We find, analytically and numerically, for weak trapping the internal modes are nearly independent of center of mass motion of the dark-bright soliton. In contrast, in tighter traps the internal modes couple strongly to the center of mass motion, showing that for dark-bright solitons in a harmonic potential the center of mass and relative degrees of freedom are not independent. This result is robust against noise in the initial condition and should, therefore, be experimentally observable.

12:39PM S25.00008: Collision of Bose-Einstein Condensates* FABIO LINGUA (Presenter), Physics Departement, Clark University, LUCA LEPORI, INFN, Laboratori Nazionali del Gran Sasso, FRANCESCO MINARDI, LENS European Laboratory for Non-Linear Spectroscopy, VITTORIO PENNA, Dipartimento di Scienza Applicata e Tecnologia, Politecnico di Torino, LUCA SALASNICH, Dipartimento di Fisica e Astronomia Galileo Galilei and CNISM, Università di Padova — We study the collision of two interacting Bose-Einstein Condensates of $^{87}$RB and $^{41}$K in a weak harmonic confinement. The study is performed by means of numerical solution of two coupled Gross Pitaevskii equations. The process is investigated in presence of both attractive and repulsive interaction between the two atomic components, showing various complex phenomena such as the formation of dark and bright solitons, condensate trapping, and coupled oscillations of boson populations.

12:51PM S25.00009: Filamentary Dynamics of Dark Solitons, Vortex Rings and Knots* PANAYOTIS KEVREKIDIS (Presenter), University of Massachusetts Amherst — In the present talk, we will revisit some principal excitations in self-repulsive Bose-Einstein condensates, namely dark solitons, vortex rings and knots. For dark solitons, upon introducing them and explaining their existence and stability properties in 1d, we will extend them both in the form of stripes and in that of rings in two-dimensions, presenting an adiabatic-invariant formulation of their stability and excitations. We will explore their filamentary dynamics, as well as the states that emerge from their transverse (snaking) instability. Then, we will consider these structures even in three dimensions, in the form of planar, as well as spherical shell solitons and generalize our adiabatic invariant formulation to the case of vortex rings and their own filamentary dynamics. Finally, time permitting, we will give some glimpses of how some of these dynamical features in 1d and 2d generalize to the case of vortex rings and their own filamentary dynamics.

*This work is supported by NSF-PHY-1602994.

1:03PM S25.00010: Lattice and continuum model for ultra-cold atoms in a crossed-cavity system* POORNIMA SHAKYA (Presenter), AMULYA RATNAKAR, SANKALPA GHOSH, Indian Institute of Technology Delhi — Recent experiments by ETH and MIT groups have reported on the formation of a super-solid, respectively in scalar and spinorial ultra-cold atomic systems, an enigmatic phase of matter that shows superfluidity and solid-like density modulation, simultaneously. In this paper [1], we derive the extended Bose-Hubbard Hamiltonian for a Bose-Einstein condensate loaded in a crossed-cavity set-up. Subsequently, in the continuum limit, we obtain the Gross-Pitaevskii energy functional and the Gross-Pitaevskii equations for the superfluid order parameters for such a super-solid phase and discuss its significance.

*P.S. is supported by UGC Fellowship and S.G. and A.R. both are supported by BRNS (DAE, Govt. of India) Grant no. 21/07/2015-BRNS/35041 (DAE SRC Outstanding Investigator scheme).
1:15PM S25.00011: Production of smooth flow in racetrack BECs at zero and non-zero temperatures

BENJAMIN ELLER (Presenter), DANIEL FOGARTY, Georgia Southern University, CHARLES W CLARK, JQI and NIST, MARK EDWARDS, Georgia Southern University — We have studied the production of smooth, persistent currents in ultracold (bosonic) gas systems that consist of an atomic BEC and a non-condensate cloud. The BEC is assumed to be strongly confined in a horizontal plane by a vertical harmonic trap and, within this plane, subjected to an arbitrary two-dimensional potential. The racetrack potential is made up of two straight parallel channels connected on both ends by semicircular channels of the same width and energy height as the straightaways. The zero-temperature behavior of the system is simulated using the Gross-Pitaevskii equation and at non-zero temperature by the Zaremba-Nikuni-Griffin model. The flow is realized by stirring along the channel with a rectangular barrier. We conducted simulations of stirring racetrack BECs for a range of different racetrack geometries, barrier speeds and maximum energy heights both at zero and non-zero temperatures. We also investigated the mechanism for producing flow in order to be able to predict the amount of flow and its onset using a 1D model. We will present the results of the simulations and also discuss the effect of temperature on the amount of flow produced.

*This work was funded by NSF grant numbers 1413768 and 1707776.

1:27PM S25.00012: Bistability of Bose-Einstein condensates with a local loss term and pinning potentials

MASAYA KUNIMI (Presenter), Kyoto University, IPPEI DANSHITA, Kindai University — Recent technological advances in ultracold atom experiments allow for introducing couplings to environment, namely dissipation, in a well-controlled manner [1,2]. In particular, the experimental group at Technische Universitat Kaiserslauten has reported the observation of unexpected bistability in a Bose-Einstein condensate in the presence of local one-body dissipation created with an electron beam [1]. To clarify the origin of the bistability under the local particle loss, we construct a simple mean-field model that describes the bistability of superfluids. In this work, we will show that exact solutions of the Gross-Pitaevskii equation with a local particle loss term and pinning potentials of the delta function type. We point out that the pinning potentials play an essential role for the bistability. When there are not the pinning potentials, the bistability does not appear [3]. We also discuss the roles of the pinned solitons for the bistability. [1] R. Labouvie, et al., Phys. Rev. Lett. 116, 235302 (2016). [2] T. Tomita et al., Sci. Adv. 3, e17011513 (2017). [3] D. 1:39PM S25.00013: Dimensional phase transitions from 1D quantum liquids to 3D condensates

SEBASTIAN EGGERT (Presenter), IMKE SCHNEIDER, AXEL PELSTER, POLINA MATVEEVA, DENIS MORATH, University of Kaiserslautern, DOMINIK STRASSEL, Fraunhofer ITWM — We consider weakly coupled strongly interacting quantum chains, such as quantum wires, anisotropic ultracold gases, or quasi-1D spin-chain compounds. It is known that a phase transition from the 1D Luttinger liquid behavior to a 3D ordered states can be qualitatively described by a chain mean field theory to determine the critical temperature, but the quantitative corrections and the range of validity is not well established. We therefore simulate the transition using a fully 3D microscopic model with very large scale quantum Monte Carlo calculations and compare with theoretical prediction including higher order terms in the chain mean field theory. We not only determine the very strong quantitative corrections, but also find a new regime of low density behavior where long range quantum correlations between the chains dominate the behavior, which leads qualitatively different powerlaws as a function of interchain couplings.

1:51PM S25.00014: Robust cat state from kinetic driving of a boson gas

FERNANDO SOLS (Presenter), GREGOR PIEPLOW, CHARLES E. CREFFIELD, Universidad Complutense de Madrid, Madrid, Spain — We investigate the behavior of a one-dimensional Bose-Hubbard gas whose kinetic energy is made to oscillate with zero time-average. The effective dynamics is governed by an atypical many-body Hamiltonian where only even-order hopping processes are allowed. In some parameter range the system has similarities to the Richardson model, which permits a detailed understanding of its key features. The ground state is a cat-like superposition of two macroscopically occupied one-atom states of opposite momentum. Interactions give rise to a reduction (or modified depletion) cloud that is common to both macroscopic options. Symmetry arguments permit a precise identification of the two orthonormal, macroscopically distinguishable many-body states yielding the cat state, each involving a large number of momentum configurations. For a gas between hard walls, the cat correlations are fundamentally robust because the system cannot collapse into a nonzero current state.

Emergence of correlations in the process of thermalization of interacting bosons

FAUSTO BORGONOVI (Presenter), istituto nazionale di fisica nucleare, FELIX IZRAILEV, Istituto de fisica, BUAP, Mexico — The relevance of thermalization to the increase of correlations in the quench dynamics of an isolated system with a finite number of interacting bosons has been studied. Specifically, we analyze how correlations between occupation numbers increase in time resulting in the emergence of the Bose-Einstein distribution. Before saturation, the two-point correlation function increases quadratically in time (as predicted by perturbation theory), while the out-of-time-order correlator (OTOC) increases algebraically with an exponent 2.5 beyond the perturbative region. Our results, that can be confirmed experimentally in traps with interacting bosons, may be also relevant to the problem of black hole scrambling.

Session S26 DQI: Superconducting Circuits: Fluxonium and Superinductance Devices BCEC

160B - Vladimir Manucharyan

11:15AM S26.00001: Cavity-less circuit quantum electrodynamics of a fluxonium artificial atom – Design

HAONAN XIONG (Presenter), YEN-HSIANG LIN, University of Maryland, College Park, NATHANAEL COTTET, Ecole Normale Superieure de Lyon, LONG NGUYEN, RAY MENCIA, AARON SOMOROFF, VLADIMIR MANUCHARYAN, University of Maryland, College Park — In circuit quantum electrodynamics (cQED), a high-quality factor cavity plays a central role: it protects a qubit from spontaneous emission and acts as a buffer system enabling a quantum non-demolition (QND) dispersive readout of the qubit state. Here we experiment with a fluxonium artificial atom capacitively connected to a 1D transmission line. We simultaneously achieved a strong coupling of a high-frequency “cycling” transition (0→3 or 1→2) to the traveling waves and a complete suppression of the spontaneous emission of the low-frequency qubit transition (0→1). This allowed implementing the fluorescence “shelving” readout of a highly-coherent and fully controllable qubit. Unlike in conventional cQED, here the cycling dynamics during the readout is confined to a small Hilbert space and can be understood within a simple optical pumping model. Our system realizes a hardware-efficient interface between qubits and photons and hence can be useful in constructing quantum networks. It can also help understanding the processes leading to the loss of QND-ness in cQED at relatively low photon numbers.

11:27AM S26.00002: Cavity-less circuit quantum electrodynamics of a fluxonium artificial atom - Experiment

YEN-HSIANG LIN (Presenter), HAONAN XIONG, University of Maryland, College Park, NATHANAEL COTTET, Ecole Normale Superieure de Lyon, LONG NGUYEN, RAY MENCIA, AARON SOMOROFF, VLADIMIR MANUCHARYAN, University of Maryland, College Park — In circuit quantum electrodynamics (cQED), a high-quality factor cavity plays a central role: it protects a qubit from spontaneous emission and acts as a buffer system enabling a quantum non-demolition (QND) dispersive readout of the qubit state. Here we experiment with a fluxonium artificial atom capacitively connected to a 1D transmission line. We simultaneously achieved a strong coupling of a high-frequency “cycling” transition (0→3 or 1→2) to the traveling waves and a complete suppression of the spontaneous emission of the low-frequency qubit transition (0→1). This allowed implementing the fluorescence “shelving” readout of a highly-coherent and fully controllable qubit. Unlike in conventional cQED, here the cycling dynamics during the readout is confined to a small Hilbert space and can be understood within a simple optical pumping model. Our system realizes a hardware-efficient interface between qubits and photons and hence can be useful in constructing quantum networks. It can also help understanding the processes leading to the loss of QND-ness in cQED at relatively low photon numbers.
11:39AM S26.00003: Single-Shot Readout of Fluxonium Qubits.* KONSTANTIN NESTEROV (Presenter), University of Wisconsin - Madison, IVAN PECHENEZHSKIY, LONG NGUYEN, YEN-HSIANG LIN, AARON SOMOROFF, RAY MENCIA, VLADIMIR MANUCHARYAN, University of Maryland-College Park, MAXIM VAVILOV, University of Wisconsin - Madison — We discuss the possibility of the single-shot readout of fluxonium superconducting qubits [1] based on the preparation of the "bright" and "dark" cavity states. With a proper choice of parameters, the dispersive shift of the cavity (the distance between its dressed and bare resonance frequencies) for the qubit 0 state can be made much smaller than this shift for the qubit 1 state. Thus, the cavity nonlinearity can be made much weaker for the qubit 0 than for the qubit 1 states. This has a potential to improve two types of single-shot qubit readout schemes that are used in the transmon readout, when the cavity nonlinearity is comparable for the two transmon states. First, for the readout based on microwave photon counters [2], one can achieve a higher cavity occupation in its bright state. Second, for the high-power readout [3], the onset of the bright transmission for one of the qubit states can occur at lower power.

*We acknowledge funding from the U.S. Army Research Office (Grant No. W911NF-18-1-0146).

11:51AM S26.00004: Nanowire Superinductance Fluxonium Qubit* THOMAS HAZARD (Presenter), ANDRAS GYENIS, Electrical Engineering, Princeton University, AGUSTIN DI PAOLO, Institut Quantique and Département de Physique, Université de Sherbrooke, ABRAHAM ASFAW, Electrical Engineering, Princeton University, ALEXANDRE BLAIS, Institut Quantique and Département de Physique, Université de Sherbrooke, STEPHEN APLIN LYON, ANDREW HOUCK, Electrical Engineering, Princeton University — We characterize a fluxonium qubit consisting of a Josephson junction inductively shunted with a NbTiN nanowire superinductance. We explain the measured energy spectrum by means of a multimode theory accounting for the distributed nature of the superinductance and the effect of the circuit nonlinearity to all orders in the Josephson potential. Using multiphoton Raman spectroscopy, we address multiple fluxonium transitions, observe multilevel Autler-Townes splitting and measure an excited state lifetime of $T_1 = 20 \mu$s. By measuring $T_1$ at different magnetic flux values, we find a crossover in the lifetime limiting mechanism from capacitive to inductive losses.

*Army Research Office Grant No. W911NF-15-1-0421 and the Princeton Center for Complex Materials DMR-142052

12:03PM S26.00005: Fast qubit reset of a low frequency fluxonium circuit* NATHANAEL COTTET (Presenter), JEREMY STEVENS, BENJAMIN HUARD, Ecole Normale Superieure de Lyon — The improvement of the lifetime and coherence time of superconducting circuits is a critical step towards the development of quantum processing of information. Recent results demonstrated coherence times and lifetimes above 100 microseconds on the first transition of fluxonium circuits biased at half flux quantum. These timescales can be improved tenfold by decreasing the transition frequencies below 500 MHz, without compromising on the gate time. The drawback is that the qubit is thermally excited at thermal equilibrium in a dilution refrigerator. Fast and efficient initialization processes are therefore crucial to follow that road. We present and characterize two initialization schemes on a low frequency fluxonium circuit. First, we use optical pumping to convert circuit excitations into cavity ones in a process similar to the one demonstrated for transmons. Second, using quantum-limited amplifiers, we use single-shot measurements to herald on the initial qubit state.

*This program is funded by the HiPS program of the ARO.

12:15PM S26.00006: Towards a fluxonium-based quantum processor I: non-interacting qubits AARON SOMOROFF (Presenter), LONG NGUYEN, YEN-HSIANG LIN, RAY MENCIA, IVAN PECHENEZHSKIY, University of Maryland, College Park, KONSTANTIN NESTEROV, MAXIM VAVILOV, University of Wisconsin, Madison, VLADIMIR MANUCHARYAN, University of Maryland, College Park — We describe our progress in experimentally realizing a microwave-activated two-qubit gate with capacitively coupled fluxonium qubits. When biased at the flux sweet-spot, the individual qubits have frequencies around 500 MHz and reproducibly reach long coherence times in excess of 100 us (the best device had $T_2 > 300$ us) [1]. A c-Phase gate can be achieved by sending a short 2π-pulse at the frequency near the 1→2 transition of the target qubit [2]. Our work includes characterization of coherence and parameter fluctuations in multi-qubit chips, modeling and experimentally validating the two-qubit interactions, optimizing the joint readout, and benchmarking of the gate operations.

We describe our progress in experimentally realizing a microwave-activated two-qubit gate with capacitively coupled fluxonium qubits. When biased at the flux sweet-spot, the individual qubits have frequencies around 500 MHz and reproducibly reach long coherence times in excess of 100 us (the best device had $T_2 > 300$ us) [1]. A c-Phase gate can be achieved by sending a short 2π-pulse at the frequency near the $1/2$ transition of the target qubit [2]. Our work includes characterization of coherence and parameter fluctuations in multi-qubit chips, modeling and experimentally validating the two-qubit interactions, optimizing the joint readout, and benchmarking of the gate operations.

A promising alternative for the implementation of superinductors, compared to the predominantly used mesoscopic Josephson junction arrays, is granular aluminum (grAl), with a microstructure consisting of pure aluminum grains embedded in an AlOx matrix, effectively forming a self-assembled Josephson junction network [1]. This material offers a large kinetic inductance, while its non-linearity is orders of magnitude smaller than that of Josephson junction arrays [2]. We present a fluxonium qubit employing a granular aluminum superinductor with coherence times $T_1$ up to 23 μs and $T_2^R$ up to 30 μs at the flux bias sweet spot. The measured $T_2^E$ approaches the limit $2 \times T_1$ [3]. These coherence times recommend granular aluminum for increasingly complex protected superconducting quantum circuits, while they also evidence the need to further investigate and mitigate loss mechanisms in high impedance qubits.

*Funding was provided by the Alexander von Humboldt foundation in the framework of a Sofja Kovalevskaja award endowed by the German Federal Ministry of Education and Research.

We present a superconducting fluxonium qubit employing a superinductor with impedance $Z > R_Q$, fabricated from a grAl thin film, in-situ integrated with a conventional Al/AlOx/Al Josephson junction. The measured qubit spectrum is in good agreement with the fluxonium Hamiltonian [3].

*Funding was provided by the Alexander von Humboldt foundation in the framework of a Sofja Kovalevskaja award endowed by the German Federal Ministry of Education and Research.
1:03PM S26.00010: Circuit-QED Studies of Josephson Junction Arrays in the Quantum Regime* HIROKI IKEGAMI (Presenter), Center for Emergent Matter Science (CEMS), RIKEN, COSMIC RAJ, Research Center for Advanced Science and Technology (RCAST), The University of Tokyo, YASUNOBU NAKAMURA, Center for Emergent Matter Science (CEMS), RIKEN — Josephson junction arrays (JJAs) in superconducting circuits offer model systems for studying various many-body phenomena both in the classical and quantum regimes. One of the remarkable phenomena observed in JJAs is the quantum phase transition between superconducting and insulating phases associated with the competition between the Josephson energy and the charging energy. In our previous study, we used a circuit-QED technique to study dynamics of the superconductor-metal transition of a classical JJA at a single photon level and found that the internal loss of the cavity shows a peak at the transition temperature. Here we use the experimental technique to explore JJAs in the quantum regime. We find that the temperature at which a peak appears in the cavity loss decreases when the charging energy becomes more dominant than the Josephson energy, i.e., the quantum effect becomes more significant. In the talk, we will discuss the result in connection with the quantum phase transition between the superconducting and insulating phases.

*This work was partly funded by ImPACT Program of Council for Science, Technology and Innovation and Matsuo Foundation.

1:15PM S26.00011: Implementation of π-periodic Josephson Elements for Topologically Protected Charge-Parity Qubits* YEBIN LIU (Presenter), KENNETH DODGE, MICHAEL ANTHONY SENATORE, Physics, Syracuse University, SHAOJIANG ZHU, FNU NAVEEN, ABIGAIL J SHEARROW, FRANCISCO SCHLENKER, ANDREY KLOTS, LARA FAORO, LEV B IOFFE, ROBERT F MCDERMOTT, Physics, University of Wisconsin-Madison, B.L.T. PLOURDE, Physics, Syracuse University — Superconducting qubits with topological protection against local noise hold the promise of significantly enhanced coherence times and higher gate fidelities than is possible with conventional qubits. We are developing one such protected design — the hybrid charge-parity qubit that combines arrays of high kinetic inductance nanowires and conventional Josephson junctions and involves the individual flux control in each plaquette. For appropriate values of the Josephson energy and charging energy of the junctions and the inductive energy of the nanowires, the arrays can be tuned between a periodicity of 2π and π by varying the external magnetic flux through the array. We describe the fabrication of these arrays and experiments to characterize the periodicity with phase by incorporating the array into an rf SQUID.

*Supported by the U.S. Government under Grant W911NF-18-1-0106

1:27PM S26.00012: Granular aluminum: A source of non-linearity for superconducting quantum circuits PATRICK WINKEL (Presenter), DENNIS RIEGER, LUKAS GRUENHAUPT, Physikalisches Institut, Karlsruhe Institute of Technology, KIRIL BORISOV, Institute of Nanotechnology, Karlsruhe Institute of Technology, NATALIYA MALEEVA, MARTIN SPIECKER, ALEXEY V. USTINOV, WOLFGANG WERNSDORFER, IOAN-MIHAI POP, Physikalisches Institut, Karlsruhe Institute of Technology — Superconducting granular aluminum (grAl) has already proven its applicability as linear inductor in kinetic inductance detectors and Fluxonium qubit designs [1]. Evaporated in an oxygen atmosphere, aluminum self-assembles into crystalline grains separated by amorphous aluminum oxide, resulting in highly inductive and low-loss superconducting grAl films [2]. We model the cQED properties of grAl microwave resonators using an effective array of Josephson junctions, and obtain self-Kerr coefficients that are inversely proportional to the grAl volume and the critical current density [3]. By shunting a small grAl volume with a thin film aluminum capacitor, we enhance the self-Kerr nonlinearity of the resulting LC mode, $K_{11}$, up to values much larger than the spectral linewidth of the fundamental mode, $\kappa$, with $K_{11} \approx 100\kappa$. By driving the resonator with increasingly larger power, we observe up to 30 multi-photon transitions between the levels of the fundamental mode, from which we extract a value of $K_{11}$ in the MHz range.

1:39PM S26.00013: Phase Transitions and Edge States in Fluxonium Qubit Systems A. BARIS OZGULER (Presenter), Department of Physics, University of Wisconsin - Madison, VLADIMIR MANUCHARYAN, Department of Physics, University of Maryland, MARK DYKMAN, Department of Physics and Astronomy, Michigan State University, MAXIM VAVILOV, Department of Physics, University of Wisconsin - Madison — A chain of fluxonium qubits provides the means for simulating quantum many-body phenomena in spin-1/2 magnets. The available controls allow us to map a qubit chain on an Ising chain in a transverse magnetic field with variable parameters. The role of the transverse field is played by the tunnel-induced splitting between the lowest energy states at the half-flux sweet spot [1]. The interaction comes from the inductive qubit coupling between fluxoniums' superinductors and can exceed the level splitting [2]. The magnetic flux detuning from the sweet spot plays the role of the longitudinal field for an Ising spin. In this talk, we discuss the phase diagram of the fluxonium chain. We demonstrate the quantum phase transition with the varying level splitting and the emergence of the edge states. We compare these states to the Majorana states in a fermion chain. We study how the edge state localization length depends on the disorder in the random longitudinal and transverse fields.

1:51PM S26.00014: Intrinsically Error Protected Superconducting Architecture Based on Superinductance* ANDRAS GYENIS (Presenter), THOMAS HAZARD, Department of Electrical Engineering, Princeton University, AGUSTIN DI PAOLO, Institut Quantique and Département de Physique, Université de Sherbrooke, ANDREI VRAJITOAREA, Department of Electrical Engineering, Princeton University, ALEXANDRE BLAIS, Institut Quantique and Département de Physique, Université de Sherbrooke, JENS KOCH, Department of Physics and Astronomy, Northwestern University, ANDREW HOUCK, Department of Electrical Engineering, Princeton University — Significant effort has been recently devoted to develop qubits with hardware-level protection, where the disjoint nature of the qubit wavefunctions offers protection against various relaxation mechanisms. Among the superconducting architectures, the so-called 0-π qubit [PRA 87, 052306 (2013)] is a promising candidate for realizing such a system. Here, we introduce the soft-0-π qubit: a twist on the original 0-π qubit proposal that relaxes some of the constraints on the qubit design parameters. In this talk, we present spectroscopic and time-domain measurements on this device. Our approach exploits an exponentially small overlap between the qubit logical wave functions and flux sweet spots to render the soft-0-π qubit noise-protected.

2:03PM S26.00015: Characterizing Granular Aluminum in Superconducting Circuits* ALEXANDER PLACE (Presenter), THOMAS HAZARD, ANDRAS GYENIS, ANDREW HOUCK, Princeton University — High kinetic inductance materials are promising candidates for implementing large inductances which are crucial for several proposed qubit designs. These materials also allow for a distributed nonlinear element, opening the door for a new family of qubits. Here, we present a new method to deposit granular aluminum in addition to spectroscopic and time domain measurements of granular aluminum-based superconducting qubits.

Session S27 DQI: Landauer-Bennett Award Session: Quantum Error Correction Theory and Experiment III BCEC 160C - Markus Kesselring - Tag(s): Focus
11:15AM S27.00001: Rolf Landauer and Charles H. Bennett Award in Quantum Computing talk: Repeated parity measurement and feedback in a mixed-species trapped ion register [Invited] JONATHAN HOME (Presenter), ETH Zurich — Quantum error correction is essential for realizing the full potential of large-scale quantum information processing devices. Fundamental to its experimental realization is the repetitive detection of errors via projective measurements of quantum correlations among qubits, as well as corrections using conditional feedback. I will describe experiments in which we demonstrate up to 50 sequential measurements of correlations between two beryllium ion microwave qubits using an ancillary optical-frequency qubit in a calcium ion, and implement feedback that allows us to stabilize two-qubit subspaces as well as maximally entangled Bell states [1]. The use of multiple ion species allows us to completely reset the ancilla after measurement and completely mitigate any unwanted effects. Looking towards further scaling, many apparent challenges appear to lie in the use of radio-frequency traps, including power-dissipation and the need to co-align microscopically varying potentials. I will describe how this might be mitigated using micro-fabricated arrays of Penning traps, which would also provide a powerful tool for implementing trapped-ion quantum simulation on a variety of two-dimensional lattices.

11:51AM S27.00002: Optimality of Gottesman-Kitaev-Preskill (GKP) Codes for Bosonic Quantum Error Correction KYUNGJOO NOH (Presenter), Yale Univ, VICTOR ALBERT, Caltech, LIANG JIANG, Yale Univ — Bosonic quantum error correction has recently risen as a hardware-efficient alternative to the conventional multi-qubit-based quantum error correction. We mainly focus on photon loss error, which is a dominant error source in microwave cavity modes. Previously, it was shown that GKP codes outperform many other bosonic quantum error-correcting codes in correcting photon loss errors, despite the fact that GKP codes are not designed to correct loss errors [1]. Here, we explain why GKP codes perform well against photon loss errors by providing a near-optimal decoding scheme and analyzing its performance. Furthermore, we formulate a biconvex optimization to find the best single-mode bosonic error-correcting code for photon loss errors. In particular, we solve the biconvex optimization heuristically by an alternating semi-definite programming method and show that, starting from Haar random initial codes, our numerical optimization yields a hexagonal GKP code as an optimal encoding in a practically relevant regime [2].

12:03PM S27.00003: High-threshold fault-tolerant quantum computation with GKP qubits and realistically noisy devices KOSUKE FUKUI (Presenter), Kyoto University, AKIHISA TOMITA, Hokkaido University, KEISUKE FUJII, Kyoto University — To implement fault-tolerant quantum computation with continuous variables, the Gottesman-Kitaev-Preskill (GKP) qubit has been recognized as an important technological element. We have proposed a method to reduce the required squeezing level to realize large scale quantum computation with the GKP qubits [Phys. Rev. X. 8, 021054 (2018)]. Although our method can reduce the required squeezing level to less than 10 dB, which is within the reach of the current experimental technology, we have assumed that the CZ gate and an efficiency of the homodyne detection are ideal. In this work, we show that the required squeezing level is around 10 dB under the realistic assumption that the CZ gate and homodyne detection degrade the squeezing level of the GKP qubits, developing a method to reduce a noise on the GKP qubit by using postselection and maximum-likelihood methods.

12:15PM S27.00004: Grid states for encoding and stabilizing a logical qubit in superconducting circuits (Part 1)* ALEC EICKBUSCH (Presenter), STEVEN TOUZARD, PHILLIPE CAMPAGNE-IBARCQ, EVAN ZALYS-GELLER, NICHOLAS FRATTINI, VOLODYMYR SIVAK, SHRUTI PURI, MAZYAR MIRRAHIMI, SHYAM SHANKAR, MICHEL H. DEVORET, Yale Univ — Quantum computation requires that systems preserve quantum information in the presence of noise. The impact of this noise can be mitigated by redundantly encoding a quantum bit of information within a space with a large number of dimensions. Stabilization is done by detecting noise-induced transformations of the system state before the encoded information is lost. In 2001, Gottesman Kitaev and Preskill (GKP) proposed to encode a quantum bit in non-local grid states of a harmonic oscillator. Remarkably, GKP codes have the potential to protect quantum information against all known error channels. In this talk, I will review GKP code properties and present a protocol based on a tunable interaction with an ancillary two-level system to create and stabilize GKP grid states using phase-estimation of the harmonic oscillator field.

*Work supported by ARO, AFOSR and YINQE
12:27PM S27.00005: Grid states for encoding and stabilizing a logical qubit in superconducting circuits (Part 2)*
STEVEN TOUZARD (Presenter), ALEC EICKBUSCH, PHILIPPE CAMPAGNE-IBARCO, EVAN ZALYS-GELLER, NICHOLAS FRATTINI, VOLODYMYR SIVAK, SHRUTI PURI, MAZAR MIRRAHMI, SHYAM SHANKAR, MICHEL H. DEVORET, Yale Univ — Protecting quantum information requires encoding a quantum bit of information into a space with a large number of dimensions. To this end, Gottesman Kitaev and Preskill (GKP) proposed to use a single harmonic oscillator as an alternative to an ensemble of many two-level systems. In this scheme, the information is encoded in grid states of the oscillator. The dispersive interaction between the oscillator and an ancillary two-level system is sufficient to create and stabilize these non-local states, provided that the interaction strength is periodically modulated in time. In this talk, I will show how to engineer such a modulated interaction and I will present our experimental progress towards the creation and stabilization of GKP grid states.

*Work supported by ARO, AFOSR and YINQE

12:39PM S27.00006: Continuous symmetries and approximate quantum error correction* PHILIPPE FAIST (Presenter), California Institute of Technology, SEPEHR GHAZI NEZAMI, Stanford University, VICTOR ALBERT, California Institute of Technology, GRANT SALTON, Stanford University, FERNANDO PASTAWSKI, Freie Universitaet Berlin, PATRICK HAYDEN, Stanford University, JOHN PRESKILL, California Institute of Technology — Quantum error correction and symmetries are relevant to many areas of physics, including many-body quantum systems, holographic quantum gravity, and reference-frame error-correction [Hayden et al., arXiv:1709.04471]. Here, we show that any code is fundamentally limited in its ability to approximately error-correct against erasures at known locations if it is covariant with respect to a continuous local symmetry. Our bound vanishes either in the limit of large individual subsystems, or in the limit of a large number of subsystems, and is approximately tight in these regimes. Furthermore, we prove an approximate version of the Eastin-Knill theorem that quantifies a code's ability to correct erasure errors if it admits a universal set of transversal logical gates. The bound is in terms of the local physical subsystem dimension. We provide a collection of example codes illustrating our bounds in different regimes. In the context of the AdS/CFT correspondence, our approach provides insight into how time evolution in the bulk corresponds to time evolution on the boundary without violating the Eastin-Knill theorem, and our five-rotor code can be stacked to form a covariant holographic code.

12:51PM S27.00007: Numerically optimized quantum error-correcting codes for a bosonic mode MATTI SILVERI (Presenter), KARI MÄKINEN, University of Oulu — Bosonic quantum error-correcting codes, such as cat and binomial codes, provide good performance against photon loss errors and are experimentally realizable e.g. with superconducting circuits. Motivated by this and aiming to broaden the spectrum of bosonic codes, we have numerically searched for bosonic single-mode codes. The codes are constructed from a finite superposition of Fock states. By utilizing numerical methods, the complex coefficients of the Fock states are chosen so that a code protects against L photon loss errors and minimizes the probability for the L+1:th error to occur. We have found codes that are protected up 9 photon loss errors. We present the structure and analyze the performance of these numerically optimized codes.

1:03PM S27.00008: Single-mode bosonic error correcting codes with rotation symmetry* ARNE GRIMSMO (Presenter), Physics, The University of Sydney, JOSHUA COMBES, School of Mathematics and Physics, The University of Queensland, BEN Q BARAGIOLA, Science, RMIT University — Bosonic mode error correcting codes, or mode codes for short, are error correcting codes where a qubit (or qudit) is encoded into one or multiple bosonic modes, i.e., quantum oscillators with an infinite Hilbert space. In this talk I focus on single-mode codes that obey rotation symmetry in phase space, such as the the well known Cat-, Binomial- and GKP codes. I will introduce a universal scheme for this class of codes based only on simple and experimentally well-motivated interactions. The scheme is fault-tolerant in the sense that small errors are guaranteed to remain small under the considered gates. I will also introduce a fault-tolerant error correction scheme based on cross-Kerr interactions and destructive phase measurement (e.g., heterodyne). Remarkably, the error correction scheme approaches the optimal recovery map for Cat and Binomial codes when the ancilla modes are error free. We numerically compute break-even thresholds under loss and dephasing, both with ideal and faulty ancillas.

**1:15PM S27.00009: Simplified mixed-state encoding for quantum computation with continuous-variable systems**

KEVIN MARSHALL, DANIEL JAMES (Presenter), Dept. of Physics, University of Toronto, Toronto, Canada, ALEXANDRU PALER, Institute for Integrated Circuits, Johannes Kepler University, Linz, Austria, HOI-KWAN LAU, Institute for Molecular Engineering, University of Chicago — Recent development of mixed-state encoding (MSE) allows a pure-state logical qubit to be encoded by a continuous-variable system in mixed physical state. Despite interest due to its counter-intuitiveness, the utility of current MSE is limited due to several operational drawbacks, namely probabilistic initialisation, redundant information carrier, and requirement of discrete-variable measurement. In this work, we present a simplified MSE that does not suffer from any of these drawbacks. Specifically, our protocol encodes each qubit by only one mixed-state harmonic oscillator, and the logical basis can be deterministically initialised by displacing a thermal equilibrium state. By using measurement-based quantum computation formalism, logical operations can be performed by only continuous-variable interaction and measurement. Without the necessity of ground state cooling, our proposal could broaden the candidate for quantum computation, and reduce the re-initialisation time of measured qubits. Additionally, the noise tolerance of logical quantum information can be enhanced by treating conventional pure-state encoded qubits as MSE qubits.

**1:27PM S27.00010: Fault-tolerant gates on a logical qubit**

SERGE ROSENBLUM (Presenter), PHILIP REINHOLD, WENLONG MA, LIANG JIANG, LUIGI FRUNZIO, ROBERT J SCHOELKOPF, Yale Univ — A fault-tolerant architecture based on error-corrected qubits requires the implementation of logical gates that do not induce uncorrectable errors. Here, we present a fault-tolerant construction for a gate on a cavity-encoded logical qubit. The scheme uses the multilevel structure of a transmon ancilla, along with RF-tunable transmon-cavity interaction, to apply arbitrary phases to the cavity Fock states. This enables a broad range of gates on a variety of encodings, while protecting the logical qubit against photon loss, as well as ancilla decay and dephasing. Together with the previously demonstrated fault-tolerant syndrome measurements [1], this result further expands the toolbox towards fully fault-tolerant processing of logical qubits.

**1:39PM S27.00011: Optimal condition for a cavity QED-based fault-tolerant quantum computation**

RUI ASAOKA (Presenter), RINA KANAMOTO, Physics, Meiji university, YUUKI TOKUNAGA, NTT SC Labs., TAKAO AOKI, Applied physics, Waseda university — Cavity quantum electrodynamics (QED) has been extensively studied for decades as one of the promising candidates for the realization of quantum computing and quantum network. For example, the controlled phase flip gate between photons assisted by cavity-QED systems was proposed in 2004[1] and demonstrated recently[2]. However, fault-tolerant quantum computing is still difficult because of the infidelity and the losses originated from imperfections of the cavity QED system.

In this work, we theoretically investigate optimal conditions for the cavity-QED-based quantum gate. Controllable experimental parameters are optimized not only to suppress photon loss considered in previous study[3] but also to increase fidelity. As a result, the experimental conditions for achieving the fault-tolerant threshold is much relaxed compared to the previous one. We finally derive the error and loss probability in the optimal condition assuming the typical experimental values of the nanofiber cavity-QED system as a promising candidate for the near future development[4].

1:51PM S27.00012: Simulation of Gaussian channels via teleportation with applications to error correction and secret-key capacities.†  SPYROS TSERKIS (Presenter), JOSEPHINE DIAS, School of Mathematics and Physics, University of Queensland, RICCARDO LAURENZANDA, SAMUEL L BRAUNSTEIN, STEFANO PIRANDOLA, Computer Science, University of York, TIMOTHY RALPH, School of Mathematics and Physics, University of Queensland — Gaussian channels are the typical way to model the decoherence in continuous-variable quantum states. It is known that those channels can be simulated by a teleportation protocol using as a resource state either a maximally entangled state passing through the same channel, i.e., the Choi-state, or a state that is entangled at least as much as the Choi-state. Since the construction of the Choi-state requires infinite mean energy and entanglement, i.e. it is unphysical, we derive instead every physical state able to simulate a given channel through teleportation with finite resources. Finally, we use those states to generalize a previously known error correction protocol by making it able to correct noise coming from thermal loss channels, and we also show how finite-energy resource states are able to provide tight upper bounds to the secret-key capacity of Gaussian channels.

2:03PM S27.00013: Recovering noise-free quantum observables  MATTHEW OTTEN (Presenter), STEPHEN K GRAY, Argonne Natl Lab — We introduce a technique for recovering noise-free observables in noisy quantum systems by combining the results of many slightly different experiments. Our approach is applicable to a variety of quantum systems but we illustrate it with applications to quantum computing and quantum sensing. The approach corresponds to repeating the same quantum evolution many times with known variations on the underlying systems' error properties, e.g. the spontaneous emission and dephasing times, T1 and T2. As opposed to standard quantum error correction methods, which have an overhead in the number of qubits, our method has only an overhead in number of evaluations, allowing the overhead to, in principle, be hidden via parallelization. We show that the effective spontaneous emission, T1, and dephasing, T2, times can be increased using this method in both simulation and experiments on an actual quantum computer. We also show how to correct more complicated entangled states and how Ramsey fringes relevant to quantum sensing can be significantly extended in time. This work was performed at the Center for Nanoscale Materials, a U.S. Department of Energy Office of Science User Facility, and supported by the U.S. Department of Energy, Oce of Science, under Contract No. DE-AC02-06CH11357.

11:15AM S28.00001: Role of nonclassical correlations in quantum parameter estimation assisted by a local measurement scheme in thermal equilibrium†  AKIRA SONE (Presenter), Nuclear Science and Engineering, Massachusetts Institute of Technology, QUNTAO ZHUANG, Physics, University of California, Berkeley, CHANGHAO LI, YI-XIANG LIU, PAOLA CAPPELLARO, Nuclear Science and Engineering, Massachusetts Institute of Technology — We discuss the role of nonclassical correlations in enhancing estimation sensitivity of parameters characterizing the quantum system in thermal equilibrium, in terms of greedy local measurement scheme, where subsystems are measured sequentially with the local optimal measurements. We introduce a practical discord, called discord for local metrology, to measure the nonclassical correlations induced by local optimal measurement, and we explicitly derive its relation to loss in quantum Fisher information in the high-temperature limit. We also demonstrate that discord for local metrology becomes diagonal discord when the estimated parameter is linearly coupled to the Hamiltonian. Practically, this result in the high-temperature limit could provide a measurement or control strategy to utilize nonclassical correlations to achieve a precise sensing or imaging in room-temperature NMR system or living cells.

**11:27 AM S28.00002: Super-sensitive Metrology using Induced Coherence**

WILLIAM PLICK (Presenter), Physics, University of Dayton, NATHANIEL R MILLER, Physics and Astronomy, Louisiana State University — We theoretically analyze the phase sensitivity of the well-known “Induced-Coherence Interferometer”, including the case where the sensitivity is “boosted” into the sub-shot-noise-limit regime with coherent-light seeding. We find scaling which reaches below the standard quantum limit, even when seeding the spatial mode which does not interact with the sample. This allows bright, super-sensitive phase estimation of an object with different light fields for interaction and detection, with various potential applications, especially in cases where the sample may be sensitive to light or is most interesting in frequency domains outside what is easily detected. It is a hybrid of a linear and non-linear interferometers, and aside from the super-sensitivity, is distinguished from other systems by “preferring” an imbalance in the gains of the two nonlinearities, and non-monotonic behavior of the sensitivity as a function of the gain of the coherence-inducing medium. We use an analysis in terms of general squeezing and show that super-sensitivity occurs only in this case - that is, the effect is not present in the spontaneous-parametric-down-conversion regime, which previous analyses and experiments have focused on.

**11:39 AM S28.00003: Oxygenated (113) diamond surface for nitrogen-vacancy quantum sensors with preferential alignment and long coherence time from first principles**

SONG LI (Presenter), JYH-PIN CHOU, JIE WEI, Department of Mechanical Engineering, City University of Hong Kong, MINGLEI SUN, School of Mechanical Engineering, Southeast University, ALICE HU, Department of Mechanical Engineering, City University of Hong Kong, ADAM GALI, Institute for Solid State Physics and Optics, Wigner Research Centre for Physics — Shallow nitrogen-vacancy (NV) center in diamond is promising in quantum sensing applications however its sensitivity has been limited by surface terminators and defects. There is an immediate quest to find suitable diamond surfaces for NV sensors. In this work, the surface terminators of (113) diamond to host shallow NV centers are studied by means of first principles calculations. Results indicate that complete oxygen termination of (113) diamond creates positive electron affinity with no surface states in-gap levels. Combining this with the ~73% preferential alignment of as-grown NV centers in (113) oriented diamond, oxygenated (113) diamond is presently supposed to be the most prospective host for NV quantum sensors.

**11:51 AM S28.00004: Quantum-enhanced rotation measurements – a multiparameter problem**

AARON GOLDBERG (Presenter), DANIEL JAMES, Physics, University of Toronto — Precise rotation measurements have numerous classical and quantum applications. Particular quantum states can be used to dramatically increase sensitivities in estimating rotation angles around a known axis. We present a class of states that offer similar enhanced sensitivities in estimating both the orientation of an unknown rotation axis and the angle rotated about it. We derive a quantum Cramér-Rao bound for simultaneously estimating the three Euler angles of a rotation and discuss states that achieve Heisenberg-limited sensitivities for all three. Our states are “anticoherent” states, for whose identification we provide new geometric insights. This result is immediately useful for shot-noise-limited metrology.

12:03PM S28.00005: Detecting Macroscopic Indefiniteness of Cat States in Bosonic Interferometers* SHANE KELLY (Presenter), EDDY M.E. TIMMERMANS, Los Alamos Natl Lab, SHAN-WEN TSAI, University of California, Riverside — The paradigm of Schrodinger's cat illustrates how specific superposition states preclude the assignment of definite properties to a macroscopic object (realism). In this work we develop a method to investigate the indefiniteness of cat states using currently available cold atom technology. The method we propose, uses observation of a statistical distribution to demonstrate the macroscopic distinction between dead and alive states and the interferometric sensitivity(Fisher Information) to detect the indefiniteness of the vital status of the cat. We show how these two observations can provide information about the quantum state without full quantum state tomography. We test this method using a cat state proposed by Gordon et. al.(PRA 59 4623), which is dynamically produced from a coherent state. As a control, we consider a set of states produced using the same dynamical procedure acting on an initial thermal distribution. Numerically simulating our proposed method, we show that as the temperature of this initial state is increased, the produced state undergoes a quantum to classical crossover where the indefiniteness of the vital status of the is lost, while the macroscopic distinction between dead and alive states of the cat is maintained.

12:15PM S28.00006: Optimal Estimation of Complex Squeezing in Phase Space* JASMINDE SIDHU (Presenter), PIETER KOK, University of Sheffield — All optical fields fluctuate in both phase and amplitude due to stochastic indeterminacy, which imposes a fundamental shot noise uncertainty to measurements. Squeezed states surpass this precision limit in one quadrature at the expense of a concomitant increased uncertainty to the complementary quadrature. These states are heavily used in continuous variable quantum information processing [1], quantum metrology [2], and optical quantum computing. Full characterisation of the squeezed states used is required to envisage the progression of these applications.

We apply quantum estimation theory to optimally characterise the squeezing parameter ξ. Previous works have been limited to estimates of its magnitude r. However, a complete understanding also requires knowledge of its direction θ. We derive the fundamental precision bounds for both parameters for general Gaussian states. We find that saturating these bounds through simultaneous measurements are prohibited, even asymptotically. Despite this, we show how correlated intensity measurements saturate the individual precision bounds for complete characterisation of squeezed light sources.

12:27PM S28.00007: Minimal quantum state representations from denoising auto-encoders* SHIVA LOTFALLAHZADEH BARZILI (Presenter), RAZIEH MOHSENINIA, JUSTIN DRESSEL, Chapman University — As multi-qubit systems increase in size, the state space scales exponentially. This makes accurate state tomography increasingly challenging and places a high demand on computational resources. This problem is compounded by the addition of experimental noise in tomographic measurements. We investigate the use of supervised machine learning, in the form of modified denoising auto-encoders, to simultaneously remove experimental noise while finding minimal latent representations of the quantum state. These representations can be later decoded into more traditional state representations.

12:39PM S28.00008: An implementation of the generalized coherent-state measurements* CHRISTOPHER JACKSON (Presenter), University of New Mexico — Generalized coherent-states are a beautiful theoretical tool for describing quantum systems with Lie group symmetries. The POVM of projectors onto the continuum of generalized coherent-states is also known to be the optimal measurement for estimating unknown states given multiple copies. However, it has been thought that this POVM is in general not practical to realize. We show how one can in principle realize this POVM by a sequence of isotropic weak measurements.

Detecting Dark Matter with Polar Materials using ab initio calculations. 

SINEAD GRIFFIN (Presenter), Lawrence Berkeley National Laboratory, SIMON KNAPE, IAS, Princeton, TONGYAN LIN, Physics, University of California, San Diego, KATHRYN M ZUREK, Physics, University of California Berkeley — Dark matter (DM) comprises ~25% of the mass-energy density of the universe, yet to date has eluded direct detection. Ultra-light DM has emerged as a promising possibility for DM, and is only now becoming experimentally viable for direct searches. In this work we propose the direct detection of DM with polar materials, considering both the scattering of optical and acoustic phonons by light DM, and the absorption of dark photons by optical phonons. Using Density Functional Theory, we calculate the material-specific matrix elements, and show that DM scattering in an anisotropic crystal has a strong directional dependence. We find that phonon-based detectors have comparable or greater sensitivity to sub-MeV dark matter scattering and sub-eV dark matter absorption than other current proposals.

Long-living coherence in 2D and 3D disordered dipolar-coupled spin systems under strong periodic driving

VIATCHESLAV DOBROVITSKI (Presenter), QuTech and Kavli Institute of Nanoscience, TU Delft, the Netherlands, WALTER HAHN, QuTech, TU Delft, the Netherlands — It has been found recently [1] that a 3D dipolar-coupled network of electronic spins under periodic driving shows long-living coherence and signatures of the time-crystal-like order. Similar behavior has also been observed and studied before [2,3], in the 3D networks of the nuclear spins subjected to the spin-echo pulse trains, and has been used for 70,000-fold improvement in NMR spectroscopy [2]. We numerically simulated these effects in 2D and 3D dipolar-coupled spin systems, directly solving the time-dependent Schrodinger equation. We show that the many-body localization is only marginally related to the appearance of the slowly decaying coherence. We identify the simplest Hamiltonian where the long-living coherence are observed in agreement with experiments, and the relevant parameters for 2D spin systems, to enable application of the long-living coherence in advanced sensing and metrology.

Results and model for single-gate ratchet charge pumping

NEIL ZIMMERMAN (Presenter), ROY MURRAY, JUSTIN K PERRON, MICHAEL DAVID STEWART, National Institute of Standards and Technology, MASAYA KATAOKA, STEPHEN GIBLIN, JONATHAN FLETCHER, National Physical Laboratory — Single-gate ratchet pumping is based on a Brownian motor mode, and thus can present subtle behavior. We show experimentally that, in the same devices, we can demonstrate multiple two-gate pumping modes but not the single-gate mode. We propose three mechanisms to explain the lack of plateaus in the single-gate ratchet mode: a large plunger-to-barrier ratio compared to the charging energy (Δptb/EC), nonlinear tunnel barriers, and phase offset leading to nonequilibrium heating. Our analysis shows that each of these could contribute to the lack of plateaus in the 1-gate ratchet pumping, but allow 2-gate pumping methods to work with robust plateaus. We propose several methods to reduce these sources of error, including reducing gate oxide thickness and reducing cross capacitances.

Superparamagnetic reversal of single magnetic nanoparticles near phase transition

NING WANG (Presenter), WENG HANG LEONG, GANG-QIN LIU, XI FENG, CHUFENG LIU, SEN YANG, Department of Physics, The Chinese University of Hong Kong, JOERG WRACHTRUP, Institute of Physics, Research Center SCoPE and IQST, University of Stuttgart, QUAN LI, RENBAO LIU, Department of Physics, The Chinese University of Hong Kong — The magnetic properties of single magnetic nanoparticles, especially the superparamagnetic (SPM) reversal near the phase transition point, are relevant to information storage, biomedicine imaging, and paleology. However, it is challenging to study the SPM reversal of single nanoparticles due to the weak magnetic moment and the sharp temperature dependence of the reversal rate. Here, we utilize nitrogen-vacancy centers in diamond as a quantum probe to study the SPM reversal of individual magnetic particles. Such a configuration enables the verification of the Neel-Arrhenius law and the Stoner-Wohlfarth model at the single-particle level. We observe that the reversal rate changes from 10^{-2} Hz to 10^4 Hz in approximate 10 K temperature range. The SPM reversal rate as a function of temperature indicates that the Neel-Arrhenius law is still valid when the temperature is 1/20 Tc close to the Curie temperature of the magnetic nanoparticle.

OLENDSKI (Presenter), Department of Applied Physics and Astronomy, University of Sharjah — Shannon quantum information entropies $S_{p,γ}$, Fisher informations $I_{p,γ}$, and Onicescu energies $O_{p,γ}$ are calculated in the position (subscript $p$) and momentum (subscript $γ$) spaces for the azimuthally symmetric 2D nanoring that is placed into the combination of the transverse uniform magnetic field $B$ and Aharonov-Bohm (AB) flux $Φ$. Position (momentum) Shannon entropy depends on the field as negative (positive) logarithm of $ω_{\text{eff}} = (ω_c^2 + ω_p^2/4)^{1/2}$, with $ω_c$ being cyclotron frequency, what makes the sum $S_p + S_γ$ a field-independent quantity that increases with the principal $n$ and azimuthal $m$ quantum numbers and satisfies entropic uncertainty relation. Position Fisher information does not depend on $m$, linearly increases with $n$ and varies as $ω_{\text{eff}}$ whereas its Onicescu counterpart changes as $1/ω_{\text{eff}}$. The products $I_{p,γ}$ and $O_{p,γ}$ are both $B$-independent quantities. Dependence of the measures on the thickness of the ring is discussed. It is shown that position Shannon entropy has the same dependence on the AB flux $Φ$ as the energy spectrum. Other analytic and numerical results for all measures are discussed too and their physical meaning is highlighted.

1:51PM S28.00014: Electron spin coherence measurements of high-density silicon vacancy ensembles in silicon carbide  
JOHN ABRAHAM (Presenter), JACOB EPSTEIN, JEREMIAH WATHEN, Applied Physics Laboratory — High density ensembles of defects in solids hold the potential to realize highly correlated states or high sensitivity quantum sensors. To explore the feasibility of this development path for silicon vacancies in silicon carbide, we will present electron spin coherence measurements of neutron irradiated samples of silicon carbide. To date, published measurements of the electron spin coherence time of this system have primarily been with electron or proton irradiated samples where the density of defects is not uniform throughout the sample. Since the density of defects is uniform throughout the sample with neutron irradiation, these measurements will shed light regarding the observed anomalies (Phys. Rev. B 95, 045206 (2017)) in the density dependence of the spin coherence time with silicon vacancy ensembles.

11:15AM S29.00001: Coupling superconducting qubits to traveling surface acoustic wave phonons*  
ETIENNE DUMUR (Presenter), Institute for Molecular Engineering, University of Chicago, KEVIN SATZINGER, Physics, University of California, Santa Barbara, YOUPENG ZHONG, HUNG-SHEN CHANG, Institute for Molecular Engineering, University of Chicago, GREGORY A PEAIRS, Physics, University of California, Santa Barbara, MING-HAN CHOU, AUDREY BIENFAIT, CHRISTOPHER CONNER, JOEL GREBEL, RHYS G POVEY, ANDREW N CLELAND, Institute for Molecular Engineering, University of Chicago — Surface acoustic wave (SAW) devices are heavily used in classical signal processing applications. SAWs have also been proposed as a method to coherently couple disparate solid-state quantum systems, such as superconducting and semiconducting qubits[1-4]. Recently the quantum control of phonons in a SAW resonator has also been demonstrated[5]. In this talk, we report the experimental development of a device coupling two superconducting qubits through SAW phonons. The transduction of the energy quantum is performed by a unidirectional SAW transducer. We examine the influence of the material properties, coupling strategy, acoustic velocity and design on the performance of the state transfer.

11:27AM S29.00002: Quantum State Transfer Using Surface Acoustic Wave Phonons* AUDREY BIENFAIT (Presenter), Institute for Molecular Engineering, University of Chicago, KEVIN SATZINGER, Department of Physics, University of California, Santa Barbara, YOUPENG ZHONG, HUNG-SHEN CHANG, MING-HAN CHOU, CHRISTOPHER CONNER, ETIENNE DUMUR, JOEL GREBEL, Institute for Molecular Engineering, University of Chicago, GREGORY A PEAIRS, Department of Physics, University of California, Santa Barbara, RHYS G POVEY, ANDREW N CLELAND, Institute for Molecular Engineering, University of Chicago — Heavily used in classical signal processing, surface acoustic waves (SAWs) have also been proposed as a means to couple distant solid-state quantum systems. Several groups have reported the coherent coupling of standing SAWs modes to superconducting qubits, opening the door to the control and detection of quantum phonon states. Here, we explore the coherent coupling of superconducting qubits to propagating SAWs. The experimental device comprises a 2-mm-long SAW resonator coupled to two xmon-style qubits. The resonator operates at 4 GHz and sustains 70 standing SAW modes with a free spectral range of 2 MHz. We demonstrate that each qubit reaches the strong multi-mode regime, where the coupling to one standing mode exceeds the resonator free spectral range. We show that in this regime, each qubit can launch a propagating SAW into the resonator and capture it at a later time, showing that the SAW resonator can act as an acoustic communication channel. We perform quantum state transfer as well as remote entanglement generation between the two qubits using this acoustic channel.

11:39AM S29.00003: Giant Atom Bounded in Continuum* SHANGJIE GUO (Presenter), YIDAN WANG, Joint Quantum Institute, University of Maryland, THOMAS PURDY, National Institute of Standards and Technology, JACOB TAYLOR, Joint Quantum Institute, University of Maryland — Tremendous progress in coupling light to matter has enabled strong coupling of qubits to modes of a photonic or phononic resonator. Here we consider what happens in the phononic case when the qubit is coupled to an electromagnetic antenna that enables supersonic propagation of the qubit oscillations. One can consider this as a giant – many wavelength-long – atom from the perspective of the phonons. We find that even in the absence of phononic resonances, as the atom size is increased, new bound states emerge from the continuum. We find a toy model that captures these effects while being exactly solvable. Compared to a sub-wavelength size atom, the bound states of this non-Markovian giant atom has localized wavefunctions, reduced dissipation, and amplified vacuum Rabi frequencies. This result also agrees with our generalized Levinson's theorem, as the number of bound states always equals the winding number of transmission phase. Application of this approach to surface acoustic wave devices will be considered.

11:51AM S29.00004: Solid-state quantum interfaces of spins and photons* METE ATATURE (Presenter), University of Cambridge — Optically active spins in solids offer exciting opportunities as scalable and feasible quantum-optical devices. Numerous material platforms, such as diamond, silicon carbide and semiconductors, are under investigation, where each platform brings advantages along with challenges. For example, diamond nitrogen-vacancy centre is a fantastic host for spins, yet suffers from its optical properties. In contrast, the brightness and the coherence of photons from semiconductor quantum dots remain practically unchallenged today, while the electronic spin coherence is modest owing to the magnetic noise generated by the nuclear spins of the quantum dot. In this talk, I will present an overview of the current progress to overcome such challenges for solid-state spin-photon interfaces in two example platforms: First, I will highlight the diamond group-IV vacancy centres and their promise to combine desirable optical and spin properties. Then, I will finish with the semiconductor quantum dots and their potential to transform their nuclei from nuisance to resource.

12:27PM S29.00005: Tunable coupling of a double quantum dot spin system to a mechanical resonator*  
SAMUEL CARTER (Presenter), ALLAN S BRACKER, MICHAEL K YAKES, MAXIM ZALALUTDINOV, U.S. Naval Research Laboratory, MJIN KIM, KeyW Corporation, CHUL SOO KIM, U.S. Naval Research Laboratory, BUMSU LEE, NRC Research Associate at the U.S. Naval Research Laboratory, DANIEL G GAMMON, U.S. Naval Research Laboratory — Hybrid systems in which a mechanical resonator is coupled to a microscopic quantum system are of strong practical and fundamental interest. Achieving a large interaction strength is vital for many goals in this field, and the ability to tune this coupling is also valuable. This has been challenging in solid state spin systems, where often the coupling is weak and fixed. Here we use pairs of coupled InAs quantum dots embedded within GaAs cantilevers to achieve high spin-mechanical coupling through strain. One electron is injected into each dot, with the tunnel coupling inducing a splitting between the singlet and triplet spin states. While optically driving motion of the cantilever, we measure the time-dependent shifts of the singlet and triplet transitions and find that the spin splitting can be highly sensitive to the motion-induced strain. This sensitivity depends strongly on the electrical bias of the system and can even be tuned to zero. The results can be explained by the difference in strain experienced by the two QDs, due to their different positions in the cantilever, which results in a change in the exchange interaction.

12:39PM S29.00006: Coupling a mechanical oscillator to a parametric amplifier*  
DAVID ZOEPFL (Presenter), MATHIEU L. JUAN, CHRISTIAN SCHNEIDER, GERHARD KIRCHMAIR, University of Innsbruck — In our experiment, we inductively couple a mechanical oscillator to a microwave circuit. We place a magnet on the tip of the mechanical resonator, a cantilever, which leads to a position dependent magnetic field. This field is coupled via a SQUID embedded into a microwave resonator: its resonance frequency depends on flux and consequently on the position of the cantilever. In addition to being a flux sensitive element, the SQUID also constitutes a non-linear element. This non-linear system is modelled with the Duffing model, describing our measurement data with good accuracy. The non-linearity also enables us to use the resonator as a parametric amplifier, and boost the system's sensitivity.

By sideband cooling the cantilever – a macroscopic object – we aim to reach the quantum mechanical ground state. In the future we plan to replace the microwave resonator with a qubit, we can exploit strong single-photon single-phonon coupling for example by preparing the cantilever in a non-Gaussian state. In addition, our system can be used as a highly sensitive acceleration sensor.

12:51PM S29.00007: Hardware-efficient quantum random access memory using hybrid quantum acoustic systems*  
CONNOR HANN (Presenter), Departments of Applied Physics and Physics, Yale Univ, CHANG-LING ZOU, Key Laboratory of Quantum Information, USTC, YAXING ZHANG, YIWEN CHU, ROBERT SCHOELKOPF, STEVEN GIRVIN, LIANG JIANG, Departments of Applied Physics and Physics, Yale Univ — Hybrid quantum systems where acoustic resonators couple to superconducting qubits are promising quantum information platforms. High quality factors and small mode volumes make acoustic modes ideal quantum memories, while the qubit coupling enables the initialization and manipulation of quantum states. In this talk we consider the practical applications of multi-mode quantum acoustic systems as hardware-efficient quantum processors. Quantum gates between different acoustic modes can be implemented using resonant interactions between the phonons and qubit, but such gates are vulnerable to qubit decoherence. As an alternative, we propose the use of off-resonant interactions that only virtually excite the qubit. This virtual approach overcomes limitations placed by qubit decoherence and attains considerably higher fidelities for long-lived acoustic modes. Given advances in performance, we propose a quantum acoustic implementation of a quantum random access memory (qRAM). We show how information can be routed through the system such that data stored in memory modes can be accessed in superposition according to the state of designated address modes—implementing a qRAM on a single chip.

1:03PM S29.00008: Toward the preparation of sub-Poissonian states in a low frequency mechanical oscillator

XIZHENG MA (Presenter), JEREMIE VIENNONT, JILA, Univ of Colorado - Boulder, SHLOMI KOTLER, NIST - Boulder, KONRAD LEHNERT, JILA, Univ of Colorado - Boulder — Preparation of non-classical states of motion in a macroscopic object has been an ambition in the field of opto- and elecro-mechanics. We propose a protocol for the preparation of one type of non-classical state, the sub-Poissonian state. We dispersively couple a Cooper-pair box qubit to a 25 MHz aluminum drumhead mechanical oscillator, and enter the phonon number sensitive regime [1]. In this regime, the motion-induced AC Stark shift on the qubit allows us to address phonon populations with a number resolution of 7, and to extract the phonon distribution via the qubit lineshape. Using sideband transitions between the qubit and mechanics, we demonstrate progress towards preparing the mechanical oscillator in a sub-Poissonian state, where the variance in the phonon distribution is less than the mean phonon number.

1:15PM S29.00009: Resolving Phonon Number States with an Acoustic Ramsey Interferometer+

LUCAS SLETTEN (Presenter), BRADLEY MOORES, K. W. LEHNERT, JILA, University of Colorado at Boulder — The rise of quantum control over surface acoustic waves (SAWs) introduced a novel concept: a “giant atom” many wavelengths long. The large size of the atom, formed by a transmon qubit with a piezoelectric transducer, generates fine frequency features in the qubit-phonon interaction strength that are determined by the shape of the transducer. Here, we combine a multi-mode SAW cavity with a qubit whose transducer is spatially engineered to enter the strong dispersive regime. The transducer comprises two halves separated by 38 wavelengths that, in close analogy to Ramsey interferometry, generate narrow frequency fringes in the qubit-phonon coupling. We observe these fringes both as a sharp frequency dependence in the qubit emission of unconfined phonons and as a modulated coupling strength to acoustic cavity modes. This modulation creates frequency regions of strong coupling in close proximity to windows of vanishing coupling, a combination that enables both dispersive operation and a coupling strength that is comparable to the free spectral range. The strong coupling creates a large dispersive shift that exceeds both qubit and acoustic linewidths.

1:27PM S29.00010: Nonexponential decay of a giant artificial atom

GUSTAV ANDERSSON (Presenter), Microtechnology and Nanoscience MC2, Chalmers University of Technology, BALADITYA SURI, Indian Institute of Science, LINGZHEN GUO, Max Planck Institute for the Physics of Light, THOMAS AREF, PER DELSING, Microtechnology and Nanoscience MC2, Chalmers University of Technology — The interaction between light and atoms has been conventionally studied using small atoms interacting with electromagnetic radiation of wavelengths that are several orders of magnitude larger than the atomic dimensions. In contrast, quantum acoustic experiments allow reaching the giant atom regime, where the coupled field wavelength is orders of magnitude smaller than the atomic dimensions. This is achieved by coupling a superconducting qubit to surface acoustic waves on a piezoelectric substrate at two points with separation on the order of 100 wavelengths. This approach is comparable to controlling the radiation of the atom by attaching an antenna. The slow velocity of sound leads to a significant internal time-delay for the field to propagate across the giant atom, and thus strongly non-Markovian dynamics. We demonstrate signatures of this non-Markovianity in the frequency spectrum as well as time domain relaxation of the giant atom.

1:39PM S29.00011: Strong coupling of a transmon qubit and a phononic crystal cavity array+

PATRICIO ARRANGOIZ-ARRIOLA (Presenter), ALEX EDWARD WOLLACK, MAREK PECHAL, ZHAOYOU WANG, WENTAO JIANG, TIMOTHY MCKENNA, AMIR SAFAVI-NAEINI, Applied Physics, Stanford University — Coupling superconducting circuits to nanomechanical systems opens up new opportunities in quantum acoustics (e.g. QND phonon detection) and the exploration of technologically-relevant devices such as quantum memory elements. In particular, phononic crystal cavities (PCCs), which localize sound at the wavelength scale, show great promise as ultra-compact, long-lived mechanical elements which can be strongly coupled to a superconducting circuit despite being orders of magnitude smaller. Building upon our previous work, we now demonstrate coupling of a transmon qubit to an array of PCCs with mode frequencies in the 2.0-2.4 GHz range. We fabricate the qubit and associated control and readout circuitry on a silicon substrate and the PCCs on a suspended thin film of lithium niobate, effectively forming an array of one-dimensional “phononic wires” with localized resonances at a set of precisely engineered frequencies. The phononic defects sites are coupled to the qubit via superconducting electrodes patterned directly on top of the cavity mirrors. We measure qubit-phonon coupling rates in excess of 10 MHz, putting the system well in the strong coupling regime.

2:03PM S29.00013: Demonstration of the Generalized Kennedy Receiver as a Near Quantum-Optimal Measurement for the Discrimination of Weak Classical Optical States* JONATHAN HABIF (Presenter), ARUNKUMAR JAGANNATHAN, University of Southern California — We describe an experimental testbed demonstrating quantum measurements on a single spatio-temporal, polarization mode, photon-starved classical state of light. The measurements are designed to optimally discriminate between coherent and incoherent optical states at mean photon numbers $n < 2$. A narrow-linewidth, 780 nm laser is used to prepare a coherent state or a thermal state in a single spatio-temporal, polarization mode. Three measurement strategies are implemented for the discrimination problem: photon counting, shot-noise limited coherent detection, and the near-optimal, generalized Kennedy receiver. For each receiver type we present discrimination error probability measurements as a function of the mean photon number of the received optical state.

Session S30 GSNP DBIO: Scaling and Phase Transitions in the Life Sciences - From Proteins to Tropical Forests BCEC 162B - Marek Cieplak, Polish Academy of Sciences - Tag(s): Focus

11:15AM S30.00001: Measuring the multiscale and multi-mass heterogeneity of complex spatial patterns in synthetic and real datasets NEKTARIOS VALOUS (Presenter), Applied Tumor Immunity Clinical Cooperation Unit, National Center for Tumor Diseases, German Cancer Research Center, Im Neuenheimer Feld 460, 69120 Heidelberg, Germany, WEI XIONG, Statistical Physics and Theoretical Biophysics Group, Institute for Theoretical Physics, Heidelberg University, Philosophenweg 16, 69120 Heidelberg, Germany, NIELS HALAMA, INKA ZÖRNING, Department of Medical Oncology, National Center for Tumor Diseases, Heidelberg University Hospital, Im Neuenheimer Feld 460, 69120 Heidelberg, Germany, DENNIS CANTRE, ZI WANG, BART NICOLAI, PIETER VERBOVEN, Division of Mechatronics Biostatistics and Sensors, Department of Biosystems, KU Leuven - University of Leuven, Willem de Croylaan 42, 3001 Heverlee, Belgium, RODRIGO ROJAS MORALEDA, Applied Tumor Immunity Clinical Cooperation Unit, National Center for Tumor Diseases, German Cancer Research Center, Im Neuenheimer Feld 460, 69120 Heidelberg, Germany — Spatial patterns may exhibit scale-dependent changes in structure and are often difficult to characterize. Lacunarity measures how data fill space enabling the parsimonious analyses of patterns. The lacunarity index (monolacunarity) averages the behavior of variable size structures in a binary image. The generalized lacunarity concept (multilacunarity) on the basis of generalized distribution moments is an appealing model that can account for differences in the mass content at different scales. The method was proposed in *Physica A* 388, 4305 (2009). Here, the aim is to provide validation on synthetic images (lacking in the original paper) and to quantify the mesostructural changes in the intercellular air spaces of pome and stone fruit parenchymatous tissue after storage and ripening, respectively. These generalized moments can yield an enhanced measure of the spatial organization of intercellular air spaces which is complementary to the monolacunarity model. Essentially, the multilacunarity morphometric is a multiscale multi-mass measure of spatial heterogeneity that offers insights regarding modifications upon the arrangement of cells and voids. This can further stimulate research interest in analyzing tissue (plant, human) under various metabolic and physiological changes.
11:27AM S30.00002: Percolation in protein cores: a novel approach to protein decoy detection  JOHN TREADO (Presenter), ZHE MEI, ZACHARY LEVINE, LYNNE REGAN, COREY SHANE O’HERN, Yale Univ — Protein cores are regions of densely packed, solvent-excluded residues, and void space inside of cores can often destabilize the structure. Here, we measure the void space in protein cores and find that the void structure is equivalent to that in jammed packings of repulsive residue-shaped particles. A continuum void percolation transition can be defined as when the characteristic void length scale approaches the system size. Using finite-size scaling, we show that the percolation of void space in protein cores belongs to the same universality class as voids in static packings of residue-shaped particles. This result provides a novel approach for evaluating whether computationally designed protein structures will take a desired fold in experiments. Molecular dynamics simulations often generate “decoy” protein structures that have low potential energy, but are not observed experimentally. We argue that decoy protein structures will have a fundamentally different void distribution, i.e. belong to a different universality class than the void distribution in real protein structures. Therefore, by analyzing the universal aspects of connected voids in computationally generated protein structures, we will be able to differentiate experimentally observed structures from protein decoys.

11:39AM S30.00003: Scaling and phase transitions – from proteins to ecology [invited]  JAYANTH BANAVAR (Presenter), University of Oregon — The nature of a phase of matter transcends the microscopic material properties. For example, materials in the liquid phase have certain common properties independent of the chemistry of the constituents: liquids take the shape of the container; they flow; and they can be poured — alcohol, oil and water as well as a Lennard-Jones computer model exhibit similar behaviour when poised in the liquid phase. I will introduce a simple model of a chain molecule with no spurious symmetries and present the results of computer simulations of its ground state phase diagram. Our calculations on relatively short chains (recall proteins are also much shorter than conventional polymers) reveals a hitherto unstudied “phase” that may have a relationship to proteins, the workhorse molecules of living cells. Our findings may be relevant for understanding proteins as well as for the creation of novel bio-inspired nano-machines.

Scaling ideas are most useful, when one is unable to deal with the full complexity of a problem or more importantly, when many of the details are not essential for the type of information that one is seeking. An important example of scaling arises in the field of ecology, when one wishes to understand the threats of losing bio-diversity. I will describe some recent results on the metabolic scaling of individual trees and a forest comprised of many trees. Our scaling framework unifies seemingly distinct trends in a forest and provides a simple yet promising approach to begin to quantitatively understand a bewilderingly complex many-body system with imperfectly known interactions.

12:15PM S30.00004: RG-inspired analyses of activity in networks of real neurons*  LEENOY MESHULAM (Presenter), Massachusetts Institute of Technology, JEFFREY L GAUTHIER, CARLOS D BRODY, DAVID W TANK, WILLIAM BIALEK, Princeton University — The renormalization group (RG) allows us to understand how theories of macroscopic dynamics can be simpler and more universal than the underlying microscopic mechanisms. Inspired by these ideas, we develop an approach to coarse-graining complex biological systems in which highly correlated groups of variables play the role of spatial neighborhoods or block spins. We apply this to experiments on the activity of 1000+ neurons in mouse hippocampus, recorded as the animal navigates a virtual environment. We find power-law dependences of several static and dynamic quantities on the coarse-graining scale, over two decades, with exponents that are strikingly reproducible across experiments. In addition, the probability distribution of coarse-grained variables seems to converge on a non-trivial fixed form. We explore how different coarse-graining schemes affect the scaling behaviors, and construct minimal models for the coarse-grained variables. Finally, we investigate how the coding properties of the neurons change as we move along the RG flow.

**12:27PM S30.00005: Hierarchy Near a Critical Point: From the Ising Model to Gene Networks**

SHUBHAM TRIPATHI (Presenter), MICHAEL DEEM, Rice University — The renormalization group approach involves locally averaging over microscopic variables to obtain coarse-grained variables that describe the macroscopic behavior of the system. We propose that hierarchical clustering corresponds to the same approach. We used the cophenetic correlation coefficient (CCC) to quantify how well the relationships between the components in a system are approximated by a hierarchical construct that captures the macroscopic behavior. Since the behavior of a system near a critical point is dominated by macroscopic variables, we expected the CCC to be higher near such a point. This was verified for the 2D Ising model. We then applied this approach to gene networks with distinct behaviors in different regions of the parameter space, separated by critical surfaces. The CCC was higher near the critical surface for the two gene networks investigated. Further, a higher CCC correlated with higher susceptibility of the networks to perturbations, mirroring the higher susceptibility of physical systems near a critical point. We suggest that the CCC can be a useful quantitative signature of criticality in biological systems.

**12:39PM S30.00006: Collective sensing by cell populations with feedback-induced long-range correlations**

MICHAEL VENNETTILLI (Presenter), Department of Physics and Astronomy, Purdue University, West Lafayette, Indiana 47907, USA, AMIR EREZ, Department of Molecular Biology, Princeton University, Princeton, NJ 08544, USA, ANDREW MUGLER, Department of Physics and Astronomy, Purdue University, West Lafayette, Indiana 47907, USA — Cells sense their environment with remarkable precision, and recent experiments have shown that this precision can be enhanced by cell-cell communication. However, most theoretical investigations of this effect have assumed linear sensing and communication, whereas it is well known that cells use nonlinear feedback to internally amplify sensed signals. Here, using a minimal stochastic model we investigate the interplay of feedback and communication in determining sensory precision. We find that feedback can induce a critical transition and long-range correlations among cells. We investigate the associated sensing tradeoff: on the one hand, we expect long-range order to enhance communication; on the other hand, fluctuations become large at the critical point, so order may come at the cost of precision. We find that depending on the parameters the system can exist in one of two universal regimes, one which permits an ordered phase and one which does not.

*This work was supported by the Simons Foundation.

**12:51PM S30.00007: Chemotaxis: A New Mechanism for Molecular Transport**

FARZAD MOHAJERANI (Presenter), Chemical Engineering, Pennsylvania State University, AYUSMAN SEN, Chemistry, Pennsylvania State University, DARRELL VELEGOL, Chemical Engineering, Pennsylvania State University — In aqueous environments, molecules bounce around through random Brownian walk. However, the environment is often not uniform and there might be a gradient of an interacting solute. In that case, the probe molecules can show directional motion known as chemotaxis. In contrast to diffusion, the chemotactic motion is directional and can be toward or away from high solute concentration which constitutes positive or negative chemotaxis. We have found that enzyme undergoes directional movement towards high concentration of substrate under different conditions, even when the enzyme is not catalyzing the corresponding reaction [1]. In addition to enzymes, we have shown that chemotaxis can happen in a simpler system comprised of dye and interacting polymer molecules [2]. Despite the very different chemistries of the two chemotaxing species (enzyme and dye), the driving force for molecular chemotaxis appears to be similar: the lowering of chemical potential due to a thermodynamically favorable interaction or binding. Based on this thermodynamic insight, we have proposed a general expression to model the observed molecular chemotaxis.

1:03PM S30.00008: Ising model with memory: results and applications to synchronization in population ecology*
VAHINI REDDY NAREDDY (Presenter), Physics, University of Massachusetts Amherst, JONATHAN MACHTA, Physics, University of Massachusetts Amherst, Santa Fe Institute, KAREN ABBOTT, Biology, Case Western Reserve University, ALAN HASTINGS, Environmental Science and Policy, University of California at Davis, Santa Fe Institute — Synchronized oscillations in spatially extended populations can be modeled by coupled noisy, quadratic maps in the two-cycle regime. These dynamical systems exhibit a phase transition from incoherence to synchrony that is in the equilibrium Ising universality class. However individuals in real populations have phase memory that is not contained in the standard Ising model. In this work we analyze a dynamical Ising model with an additional memory term and investigate the phase transition using analytical and numerical approaches. The effective equilibrium model of this dynamical system undergoes a phase transition in the equilibrium Ising universality class with a critical temperature that increases with the strength of the memory. We present results for this system and discuss connections to coupled map systems and also to agricultural data describing oscillations in pistachio production (masting) where tree level data from an orchard in California reveals Ising critical behavior.

Session S31 DCP: Wavefunction Methods (ES3) BCEC 203 - James Shepherd - Tag(s): Focus

11:51AM S31.00002: Localized active-space self-consistent field method: a size-extensive, linear-scaling MC-SCF approach for strongly-correlated materials* MATTHEW HERMES (Presenter), LAURA GAGLIARDI, Chemistry, University of Minnesota — The complete active space (CAS) SCF method and its perturbative corrections are the standard computational strategy in the field of quantum chemistry for computing accurate wave functions of strongly-correlated molecular systems. They are, however, not applicable to materials in a condensed phase because they are not size extensive and/or have exponential cost scaling, and common cost-controlling approximations such as restricted or generalized active space (RAS, GAS) do not resolve this difficulty. However, our recently-developed localized active space (LAS) SCF method, which is based on a union of density matrix embedding theory (DMET) and MC-SCF concepts, generates a wave function which, unlike RAS or GAS, is multiplicatively separable between disjoint, real-space-localized active subspaces. LASSCF is therefore both size consistent and size extensive, and in principle, its computational cost is linear scaling with respect to system size. We test this method on various realistic chemical models of strongly-correlated systems and show that LASSCF gives CASSCF-quality results, implying an attractive possibility for computing wave functions of strongly-correlated condensed systems.

12:03PM S31.00003: Transitioning High-Accuracy Electronic Structure Methods from Molecules to the Solid State* MALTE LANGE (Presenter), TIMOTHY BERKELBACH, University of Chicago — This presentation discusses ongoing work to transfer trusted computational and theoretical tools that are traditionally used in the molecular regime to the rapidly growing field of solid state physics. Specifically, Equation of Motion Coupled Cluster (EOM-CC) is compared to the current state-of-the-art method, the so-called GW approximation for the GW100 test set. Ongoing challenges to the implementation of periodic EOM-CC including finite size effects, basis set effects, and pseudopotentials to reduce computational complexity will be addressed. Preliminary results indicate that this problem is not trivial and requires consideration of many inputs and extrapolation schemes in order to achieve reliable results. In addition to these computational schemes, a systematic hierarchy of approximations is introduced to quantitatively gauge computational cost and accuracy trade-offs, exploring theoretical errors in addition to computational errors.

*This work was supported by:
Midwest Integrated Center for Computational Materials (MICCoM)
NSF Graduate Research Fellowships Program (GRFP)
Development of electronic structure theory methods for periodic systems has been hampered for decades due to the unaffordable scaling with system size. One of the obstacles is the computation of two-electron repulsion integrals, whose near-field interaction can only be computed exactly or approximated using density fitting (DF). In this work, a massively-parallel implementation of an efficient local DF algorithm is presented in which atomic orbital (AO) products are fitted using only auxiliary AOs on one of the nuclei in that product. We applied this approach on the exact exchange term in Hartree-Fock with periodic boundary conditions (periodic HF) based on linear combinations of Gaussian-type AOs. Our algorithm has shown a significant reduction of computational costs with an accuracy below millihartree per atom, and thus will be beneficial to both hybrid density functional theory and post-HF methods.

When a system has semi-periodic boundary condition, caution is needed to remove the interaction between the overall potential and the charge density in the neighboring boxes. For neutral systems, owing to the locality of one-body potential, a common trick in DFT calculations is to use a finite space of vacuum to mimic the free boundary. When moving to the periodic post-HF methods, the effectiveness of this treatment was yet verified. It was known that the finite-size correction to HF needs to be carefully handled in the periodic coupled cluster methods [1]. When the same treatment was applied to low-dimension systems, numerical uncertainty or slow convergence were observed. We compared the effects of vacuum treatments in periodic-MP2, periodic-CCSD calculations. We observed that the finite-size correction at HF level has different effects on different post-HF methods. In this talk, we will analyze the reasons that cause the numerical issues in semi-periodic post-HF methods. For different periodic post-HF methods, different solutions will be presented.

Doped nanocrystals exhibit infrared absorption and are promising candidates for sensors, solar energy conversion, and optical communications. The infrared absorption appears to undergo a transition from a single-particle to plasmonic absorption as a function of doping density and radius. This transition is not well understood from an experimental or theoretical point of view. This talk will present results from correlated quantum chemistry calculations of a particle-in-a-sphere model for a doped nanocrystal. The transition of the infrared absorption from single-particle to plasmonic is found to also depend on the absolute number of doped electrons. In particular, a single-particle transition can be broken into true single-particle, and Coulombically bound, but collective, excitations. These results highlight the importance of many-body exchange and correlation effects in quantum confined nanostructures.

Quasiparticle spectra of polyacetylene using coupled-cluster singles and doubles (CCSD)*

Those to periodic systems, however, suffer from large computational cost for k point sampling. We developed interpolation techniques for reducing the cost for obtaining reliable GFs. We apply them to polyacetylene and examine their validity by comparing the original spectral function and the interpolated ones.

1:27PM S31.00008: Coupled cluster theory for condensed phase spectroscopy*  ALAN LEWIS (Presenter), TIMOTHY BERKELBACH, James Franck Institute, University of Chicago — We use state-of-the-art equation-of-motion coupled-cluster theory with single and double excitations (EOM-CCSD) to calculate the dynamic structure factor of the uniform electron gas. Our calculations are performed at densities corresponding to the valence electron densities of common metals. We compare our results to those obtained using the random-phase approximation, which is known to provide a reasonable description of the collective plasmon excitation. We find that EOM-CCSD, instead of providing a perturbative improvement on the RPA plasmon, predicts a many-state plasmon resonance, where each contributing state has a double-excitation character of 80 percent or more. This finding amounts to an ab initio treatment of the plasmon linewidth and highlights the strongly correlated nature of lifetime effects in condensed-phase electronic structure theory.

1:39PM S31.00009: Effect of basis set on the outcome of external energy mediated chemical reactions*  SHARMA SRKC YAMIJALA (Presenter), ZULFI ALI, BRYAN M WONG, CEE, University of California, Riverside — Directing the energies of an hot-electron or atom or molecule towards a specific vibrational mode to tune the reaction outcomes is an active area of catalytic research and ab initio molecular dynamics is one of the indispensable tools in understanding the mechanistic details of these reactions. In this work, we show that the predicted thermodynamic and catalytic properties of a reaction using an AIMD simulation highly depends on the quality of the employed basis set. To this end, we have considered the reactants and products of the water-gas shift reaction (viz., CO, CO2, H2, and H2O) and studied their interaction with the ZnO(10-10) surface using DFT and Born Oppenheimer Molecular Dynamics (BOMD) simulations. By merely changing the quality of the basis set from double zeta (commonly used in most calculations of these systems) to triple zeta, we show that the reaction outcome of an H2O molecule colliding with a ZnO surface pre-covered with carbon monoxide gives qualitatively different results. Furthermore, we show that the calculated adsorption energies can vary by as much as 380 meV (which is an order of magnitude larger than room temperature) by merely changing the basis.

1:51PM S31.00010: Electronic Structure of NiO from Gaussian-based Periodic Coupled Cluster Theory  YANG GAO (Presenter), MARIO MOTTA, JAMES MCCLAIN, QIMING SUN, GARNET CHAN, AUSTIN MINNICH, Caltech — Accurate description of ground and excited state properties of strongly correlated materials is a grand challenge in ab initio condensed matter simulation. While typical mean field methods performs poorly for these solids, increase in computational power now allows us to employs time-independent perturbation theory in quantum chemistry to systematically improve towards the exact solution for crystalline materials. Here, we present a numerical study of NiO using a Gaussian-based periodic coupled cluster method with single and double excitations. We compute ground-state properties of the antiferromagnetic phase as well as the quasiparticle band structure using the equation of motion ansatz (EOM-CCSD). We compare our results to other ab-initio methods and experimental data.
11:27AM S33.00002: Role of surface reconstruction and passivation mechanisms on the structural and electronic properties of diamond surfaces  BISHWAJIT DEBNATH, Electrical and Computer Engineering, University of California Riverside, MAHESH NEUPANE (Presenter), A. GLEN BIRDWELL, JAMES WEIL, PANKAJ SHAH, TONY IVANOV, US Army Rsch Lab - Adelphi — Diamond is an insulating material in the bulk form which can exhibit two-dimensional p-type conducting characteristics when its surface is passivated with hydrogen. It is postulated that the formation of a conducting channel at the hydrogenated surface is mainly due to charge transfer between the surface and atmospheric adsorbates. A fundamental understanding of the source of p-type conductivity at the hydrogenated surface is key to the realization of diamond surface field effect transistor (FET). Though there have been many experimental studies in this direction, theoretical studies correlating surface termination and reconstruction to structural and electronic properties have been limited. To address these fundamental questions, we have utilized ab initio density functional theory (DFT) and performed systematic studies of surface reconstruction phenomena in (100) and (110) diamond surfaces. Based on the observed structural and electronic properties, we have made an attempt to establish a correlation between the surface reconstruction and passivation with the electronic properties of the diamond surfaces, such as surface energy, electron affinity, and effective mass.

11:39AM S33.00003: Examining the effects of changing film composition and temperature on the optical properties of GaAsBi epitaxial films*  SAMUEL LENNEY (Presenter), MARGARET STEVENS, KEVIN GROSSKLAUS, THOMAS VANDERVELDE, Tufts University — GaAs_{1-x}Bi_x semiconductor alloys are being considered for a range of new infrared optoelectronic applications. This is because small changes in Bi content can produce large decreases in film bandgap, opening up new lattice parameter and bandgap combinations for devices. However, the optical properties of GaAsBi as a function of changing Bi content have not been thoroughly documented and seldom tested at temperatures relevant for infrared detectors or thermophotovoltaics. In this work we study the optical properties of GaAsBi films of varying Bi composition grown by solid source molecular beam epitaxy (MBE). Optical properties are measured by variable angle spectroscopic ellipsometry over a wavelength range from 300 nm to 32 μm and at temperatures ranging from 77K to 600K. The optical properties of the system are modeled so that the GaAsBi optical constants can be separated from those of the underlying substrate. Characterization of GaAsBi optical properties over a range of Bi compositions and temperatures will provide the necessary data for design of future devices and a better fundamental understanding of the material system.

11:51AM S33.00004: A Computational study of Magnetic Field-controlled Acoustic Coherent Phonon Generation and Propagation in Ferromagnetic GaMnAs*  SUNIL THAPA (Presenter), GARY DONALD SANDERS, University of Florida, BRENDEN A MAGILL, GITI KHODAPARAST, Physics, Virginia Tech, STEPHEN A MCGILL, JADE HOLLEMAN, NHMFL, Florida State University, HIRO MUNEKATA, Institute of Innovative Research, Tokyo Institute of Technology, CHRISTOPHER J STANTON, University of Florida — We present a theoretical study of magnetic field-controlled generation and propagation of coherent longitudinal acoustic phonons (CLAP) generated by ultrafast laser pulses in a Ferromagnetic Ga_{1-x}Mn_xAs (x=0.082) thin film grown on an intrinsic GaAs substrate subjected to an in-plane static magnetic field varying between 2-10T. Electron-phonon deformation potential coupling is considered for the generation of the CLAP at the surface as well as at the interface for a pump energy of 3.1 eV with their propagation being governed by a semi-classical wave equation. The field-induced variation in the bandstructure, dielectric functions, and, hence, the CLAP amplitude are calculated using an 8-band Pidgeon-Brown model including the effects of magnetic, Mn impurities. The calculated differential reflectivity at the probe energy 1.55 eV agrees well with experimental time-resolved differential reflectivity measurements and suggests that a substantial contribution to the signal comes from the interface. The magnetic field dependence of the reflectivity amplitude arises from the Seraphin coefficients.

described by a Bose-Einstein factor taking into account electron-phonon interactions. The results of the reciprocal-space

analysis are compared to the parameters determined by a parametric semiconductor fit.

TAKAYAMA (Presenter), Department of Physics, The University of Tokyo, CHANGSU KIM, HIDEFUMI AKIYAMA, Institute of Solid

State Physics, The University of Tokyo, LOREN PFEIFFER, KENNETH WEST, Department of Electrical Engineering, Princeton University,

RYO SHIMANO, Cryogenic Research Center and Department of Physics, The University of Tokyo — The exciton-exciton (ex-ex)

interaction has long been investigated from the viewpoint of excitonic nonlinear optics in a variety of semiconductors [1].

Recently, the problem has gained a renewed interest partly triggered by the progress of researches in the field of polariton

Bose-Einstein condensation in a quantum well system embedded in a microcavity. In contrast to intensive theoretical

studies devoted over decades, however, the quantitative evaluation of ex-ex interaction in bulk system has been lacked.

Here we revisited this long-standing issue with near-infrared optical pump optical-probe/terahertz probe spectroscopy

technique. In bulk GaAs at the lattice temperature 5K, we observed a blueshift of exciton absorption peak caused by the

ex-ex interaction when the pump photon energy tuned to 1s-exciton resonance. Combined with the terahertz

spectroscopy, the density dependence of the excitonic blueshift is evaluated, which allows to determine the ex-ex

interaction strength quantitatively. The value coincides well with that predicted from mean-field theory. The dynamics of

the excitonic blueshift will also be discussed with respect to the thermalization of cold exciton gas.

12:51PM S33.00009: Moments analysis of the dielectric function  
ERIC SHIRLEY (Presenter), JOHN VINSON, National Institute of Standards and Technology — For many purposes, the random-phase approximation (RPA) is an adequate approximation for dielectric screening when the latter is required within a calculation. Therefore, an efficient approximation to the RPA is similarly useful in a wide range of situations. In this talk, we will describe a model for the same based on knowledge of several approximate frequency moments of the irreducible polarizability function. These models rely, in part, on the Fourier transform of the two-point, one-electron density matrix. We test our model calculations against numerical density-function theory (DFT) calculations in isolated atoms, the homogeneous electron gas, and a wide variety of metals, semiconductors, and insulators.

1:03PM S33.00010: Electronic Transport Studies of Boron-Doped Diamond-on-Graphene Heterostructures*  
ADRIAN NOSEK (Presenter), Physics, University of California, Riverside, ROBERT BOGDANOWICZ, MATEUSZ FICEK, MICHAL SOBASZEK, LUKASZ GOLUNSKI, Metrology and Optoelectronics, Gdansk University of Technology, JAKUB KARCZEWSKI, Applied Physics and Mathematics, Gdansk University of Technology, ANDRES JARAMILLO-BOTERO, WILLIAM GODDARD, Materials and Process Simulation Center, California Institute of Technology, MARC BOCKRATH, Physics, Ohio State University, TADEUSZ OSSOWSKI, Analytical Chemistry, University of Gdansk — Diamond-on-graphene heterostructures are a promising route for operating novel electronic devices at high temperatures due to their excellent thermal properties. For this purpose, boron-doped diamond thin films were grown in a microwave plasma-assisted chemical vapor deposition (CVD) system on a tantalum substrate which allows us to peel off diamond films [1]. Successive mechanical transfer of the diamond films onto CVD graphene on either Si/SiO₂ or quartz results in our heterostructure devices. We will present current-voltage characteristics as a function of temperature and their tunable gate dependence at specific temperatures. Varying the doping level of boron in the diamond films leads to variations in device behavior. Our latest results will be discussed.

1:15PM S33.00011: Thermal transport in two-dimensional disordered electron systems at intermediate temperatures*  
WOO-RAM LEE (Presenter), University of Alabama, ALEXANDER FINKELSTEIN, Texas A&M University, KAREN MICHAELI, Weizmann Institute of Science, GEORG SCHWIETE, University of Alabama — Theoretical studies of transport properties of two-dimensional electron gases often focus on two limiting cases: (i) The diffusive regime that occurs at low temperatures where inelastic electron-electron scattering is substantially weaker than scattering by disorder. (ii) The hydrodynamic limit characterized by strong electron-electron scattering which requires relatively high temperatures. The latter has been widely studied in the context of strongly correlated electron systems and graphene. Here, we report a study of electron transport in an intermediate regime where both electron-electron scattering and scattering on impurities are equally important. To address this regime, we first analyzed a simplified kinetic equation which we supplemented by a more detailed analysis of the elastic and inelastic scattering terms. In particular, we derived the thermal conductivity of a degenerate electron system at intermediate temperatures.

*This work is supported by DOE, ISF, NSF, and the College of Arts and Sciences at the University of Alabama.

1:27PM S33.00012: Comprehensive Characterization of Alkaline Earth Metal Halides using First Principles Calculations*  
LU WANG (Presenter), SARIT DHAR, MARCELO KURODA, Auburn University — Alkaline earth metal halides are among the scarce insulators with dielectric constants and band gaps larger than those of SiO₂. Here, we present a study of this class of high K/large band gap materials using first principles calculations with different levels of sophistication. In particular we focus on changes in their electronic and thermal properties as a function of composition and structure. Our results show that the most stable phases of these materials are those with larger band gaps. Determination of their band gaps requires hybrid approaches to overcome well-known limitations of density functional theory. Phonon properties and dielectric response are compared using different exchange-correlation functionals: (i) Localized Density Approximation (LDA), (ii) Generalized Gradient Approximation (GGA) and (iii) Generalized Gradient Approximation including van der Waals forces (GGA+vdW). We find that the dispersive forces correct the mode softening observed in low-frequency phonon modes in the GGA functionals yielding results similar to LDA. The different trends found in these materials class relative to their composition and structure are discussed.

*This work is supported by the Grant ARMY-W911NF-18-2-0160.
1:39PM S33.00013: In-plane field dependence of spin resolved magnetic focusing in 2D hole systems  MATTHEW RENDELL (Presenter), SCOTT LILES, ASHWIN SRINIVASAN, OLEH KLOCHAN, Univ of New South Wales, IAN FARRER, University of Sheffield, DAVID A RITCHIE, University of Cambridge, ALEX R HAMILTON, Univ of New South Wales — The spin orbit interaction allows for all-electrical control of spin. Transverse magnetic focusing provides a method for spatially separating spins so that spin dynamics can be studied. We perform transverse magnetic focusing experiments of heavy holes in highly symmetric (100) GaAs/AlGaAs heterostructures, and observe two clear spin resolved focusing peaks. It is tempting to use the area of the focusing peaks as a measure of the spin polarisation, however we find that the peak area is extremely sensitive to in-plane magnetic fields - as small as 0.1T. Additionally, we find that the peak area is asymmetric when the in-plane field direction is reversed, and this asymmetry is conserved under Onsager time reversal. This suggests that there is an additional non-spin polarisation effect at play, and that care must be taken when using focussing techniques to measure spin.

1:51PM S33.00014: Epitaxial growth of large grain size polycrystalline silicon on SiO2 by reduced pressure chemical vapor deposition  KAIGUI ZHU (Presenter), FANGFANG CHEN, Beihang University, HUICAI ZHONG, Institute of Microelectronics of Chinese Academy of Sciences — Epitaxial growth of polycrystalline silicon (poly-Si) on SiO2 was successfully carried out by reduced pressure chemical vapor deposition (RP-CVD) using SiH4/H2 mixtures. The growth rate and grain size of ploy-Si were significantly improved by increasing the epitaxial temperature. The film deposition rate was 3.1nm/s with the epitaxial temperature at 820°C. The grain size of the poly-Si film could reach as large as 700nm on annealed seed layer. Good quality poly-Si film with large and uniform grain was obtained by direct deposition on SiO2 substrate. The electrical properties of the doped poly-Si film were tested by Hall Effect and four-probe method.

2:03PM S33.00015: Chemistry Perspective to Design Novel Magnetic Semiconductors/Semimetals*  WEIWEI XIE (Presenter), XIN GUI, Chemistry, Louisiana State University, RONGYING JIN, Physics, Louisiana State University — Magnetic semiconductors combine the complementary functions of magnetic and semiconducting materials, providing tremendous potential for the development of new devices for today's information technology. If employed in devices, these materials could lead to a new pathway to control information: by charging carriers not only in traditional electronics but also in spin dimensions. The Zener model was modified by Dietl et al. to explain the origin of ferromagnetism in Mn-doped GaAs and predicted the room-temperature ferromagnetism in other semiconductors and oxides. This remarkable work opened up the era of searching for room-temperature ferromagnetism in semiconductors. It still remains a lot of work to identify plausible targets for new magnetic materials. Previous studies mainly focused on hybrid structures consisting of ferromagnetic and semiconducting multilayers and Mn-doped binary semiconductors. However, only a small handful of intrinsic magnetic semiconductors have thus far been reported. Thus, the design of specifically targeted by synthetic scientists is highly demanded. In this talk, I will describe some empirical design rules and examples that have yielded new magnetic semiconductors/semimetals.

*The research is supported through Beckman Young Investigator (BYI) award.

11:15AM S35.00001: Multilayer coaxial superconducting circuits with integrated 3D wiring* [Invited] PETER LEEK (Presenter), University of Oxford — Superconducting circuits are one of the leading candidates for the realization of quantum computers, in particular for near-term applications which may already be reached with circuits consisting of a few hundred qubits, provided they are operated at high fidelity. Until recently, the topology of superconducting circuits has typically been constrained to two dimensions, which becomes increasingly difficult as the number of qubits is scaled up and control and measurement wiring is needed for qubits in the middle of large arrays. It is natural to explore new circuit topologies that incorporate wiring in the third dimension to solve this problem. In this talk I will present an overview of an approach that builds on a coaxially-symmetric circuit QED unit cell with out-of-plane wiring [1] that provides a simple route to scaling to grids of many qubits. In this approach, arrays of qubits and resonators can be fabricated on opposing sides of a substrate and capacitively coupled, while control and readout are achieved via off-chip coaxial wires which run perpendicular to the chip plane and are built into a precision micromachined enclosure that provides a high-quality microwave environment for the circuit.

*We acknowledge financial support from the EPSRC and Oxford Quantum Circuits Ltd.

11:51AM S35.00002: Flux Tunable Superconducting Qubits With 3D Wiring* JEREMY BEJANIN (Presenter), CAROLYN EARNEST, Physics & IQC, University of Waterloo, THOMAS G MCCONKEY, Electrical And Computer Engineering & IQC, University of Waterloo, EVAN PETERS, MATTEO MARIANTONI, Physics & IQC, University of Waterloo — Superconducting qubits have the potential to lead to large-scale quantum computers, where 10^5 or more qubits are arranged in two-dimensional arrays forming quantum processing units (QPUs) on silicon chips. Operating such an array necessarily requires control signals to come from wires in the third dimension, so as to avoid overlapping control lines on the device itself. While various implementations of 3D wiring have been realized in the last few years, none has been used with flux-tunable superconducting qubits, which require a current line to inductively bias the superconducting loop of a SQUID. In this talk, we show and characterize the performance of tunable superconducting Xmon transmon qubits using the quantum socket, for which the control wiring is fully 3D, including the fast flux bias lines used for frequency tuning. We demonstrate one-qubit gates and perform quantum gate tomography to quantify gate fidelity as a function of flux bias for two Xmon transmon qubits.

*This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund (CFREF) and the Discovery and Research Tools and Instruments Grant Programs of the Natural Sciences and Engineering Research Council of Canada (NSERC).

12:03PM S35.00003: Increasing reliability for 3D integrated high-coherence superconducting qubits* BETHANY M NIEDZIELSKI (Presenter), DAVID K KIM, JONILYN L YODER, DANNA ROSENBERG, MOLLIE E. SCHWARTZ, RABINDRA DAS, ALEXANDER MELVILLE, DONNA-RUTH YOST, JUSTIN MALLEK, ALEXANDRA L DAY, STEVEN WEBER, CYRUS F. HIRJIBEHEDIN, WILLIAM D OLIVER, MIT Lincoln Laboratory — As designs for superconducting qubits become more complex, 3D integration of two or more vertically bonded chips can enable increased density and connectivity. Precise control of the spacing between these chips is required to give designers accurate parameters to plan and predict circuit performance. In this talk, we will describe our process for using silicon hard-stop mesas to control chip spacing and tilt, and our integration of these features with our high-coherence superconducting qubit fabrication process.

*This research was funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) and by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract No. FA8721-05-C-0002. 12:15PM S35.00004: 3D-wired coaxial circuit QED I: Extension to multi-qubit devices* SALHA JEBARI (Presenter), JOSEPH RAHAMIM, ANDREW D PATTERSON, PETER A SPRING, TAKAHIRO TSUNODA, SOPHIA SOSNINA, MARTINA ESPOSITO, KITTI RATTER, GIOVANNA TANCREDI, BRIAN VLASTAKIS, PETER LEEK, Condensed Matter Physics, University of Oxford — In order to realise superconducting circuits at a sufficient scale for useful near-term applications, an architecture is required which implements good connectivity between qubits, and allows for selective readout and control of the qubits without introducing detrimental crosstalk or decoherence. Since the number of readout and control lines increases linearly with the number of qubits, scaling up a circuit which is constrained to a 2D surface becomes increasingly difficult. Here we present the extension of our recently demonstrated 3D-wired coaxial circuit QED architecture [1] to 2D arrays of qubits. Qubits and readout LC resonators are fabricated on opposing sides of a substrate and entirely off-chip coaxial wiring is built into the chip enclosure and runs perpendicular to the chip plane. Scaling is simply achieved by the repetition of the unit cell across a 2D plane. We present the performance of multi-qubit circuits based on this architecture, including coherence times and two-qubit gate fidelities.

*We acknowledge financial support from the EPSRC, Oxford Instruments Nanoscience, Oxford Quantum Circuits Ltd, the Oxford Centre for Applied Superconductivity, the Nakajima Foundation and the Masason Foundation.

12:27PM S35.00005: 3D-wired coaxial circuit QED II: Evaluation of crosstalk* JOSEPH RAHAMIM (Presenter), SALHA JEBARI, ANDREW D PATTERSON, PETER A SPRING, TAKAHIRO TSUNODA, SOPHIA SOSNINA, MARTINA ESPOSITO, KITTI RATTER, GIOVANNA TANCREDI, BRIAN VLASTAKIS, PETER LEEK, Condensed Matter Physics, University of Oxford — Evaluating crosstalk in multi-qubit superconducting circuits is becoming increasingly important. Control-wiring crosstalk can cause coherent control errors that become increasingly impractical to correct in larger scale circuits, and measurement crosstalk can induce dephasing. Selective control and coupling is intrinsic to our architecture [1] due to the use of coaxial circuit elements on two planes, mode-matched to out-of-plane 3D wiring. However, in any multi-qubit circuit the electromagnetic fields associated with individual circuit elements and control signals will never be perfectly confined. We present a careful characterisation of resonator and qubit control-line crosstalk, as well as measurement crosstalk due to coupling between neighboring qubits and resonators. We incorporate a detailed understanding of the two-qubit Hamiltonian in order to extract the qubit control-line crosstalk, and utilise measurement-induced dephasing to directly characterize resonator control-line, as well as measurement crosstalk.

*We acknowledge financial support from the EPSRC, Oxford Instruments Nanoscience, Oxford Quantum Circuits Ltd, the Oxford Centre for Applied Superconductivity, the Nakajima Foundation and the Masason Foundation.

12:39PM S35.00006: Superconducting Qubits Integrated with Superconducting Through-Substrate Vias (TSVs): Fabrication* DONNA-RUTH YOST (Presenter), MOLLIE E. SCHWARTZ, DANNA ROSENBERG, JUSTIN MALLEK, RABINDRA DAS, ALEXANDRA L DAY, DAVID K KIM, BETHANY M. NIEDZIELSKI, ALEXANDER MELVILLE, WAYNE WOODS, JONILYN L YODER, ANDREW JAMES KERMAN, WILLIAM D OLIVER, Massachusetts Institute of Technology — Three-dimensional integration (3DI) is a promising approach to provide increased connectivity for complex arrays of superconducting qubits while maintaining qubit performance. In this talk we describe our process flow for fabricating wafers of superconducting through-substrate vias (TSVs) which may be integrated directly into superconducting qubit chips and/or bump bond integrated with high-coherence qubits to carry signals to and from the qubit layer.

*This research was funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) and by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract No. FA8721-05-C-0002. Superconducting qubits integrated with superconducting through-substrate vias: Measurement

MOLLIE E. SCHWARTZ (Presenter), DONNA-RUTH YOST, DANNA ROSENBERG, JUSTIN MALLEK, RABINDRA DAS, ALEXANDRA L DAY, DAVID K KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, JONILYN L YODER, ANDREW JAMES KERMAN, WILLIAM D OLIVER, MIT Lincoln Laboratory — Three-dimensional integration (3DI) is an enabling technology for superconducting qubits as circuits become larger, more complex, and more highly-connected. One promising approach to 3DI is the vertical routing of signals through superconducting through-substrate vias (TSVs), which may be integrated directly into a superconducting qubit chip or may carry signals to and from a high-coherence qubit layer via an interposer chip. We discuss recent results demonstrating superconducting qubit control, readout, and integration with high-aspect ratio superconducting TSVs.

This research was funded by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) and by the Assistant Secretary of Defense for Research & Engineering under Air Force Contract No. FA8721-05-C-0002. Multilayer Microwave Integrated Quantum Circuits: Part 1

CHAN U LEI (Presenter), LEV KRAYZMAN, SUHAS GANJAM, Yale University, TERESA L BRECHT, Yale University & HRL, CHRISTOPHER J AXLINE, Yale University & ETH, YIWEN CHU, LUKE BURKHART, LUIGI FRUNZIO, ROBERT J Schoelkopf, Yale University — Recently, superconducting quantum circuits have advanced from circuits containing few qubits to larger-scale ones with several tens of qubits. In order to increase the computational power of these circuits, many more circuit elements need to be integrated without degrading coherence of the individual components. Although the number of lithographic-precision elements in fully-planar (2D) circuits can be scaled up, it is very challenging to maintain interconnects and suppress decoherence induced by crosstalk as the circuits grow. On the other hand, three dimensional (3D) circuits which use conventionally-machined cavities to engineer the electromagnetic environment offer superior coherence but are challenging to scale up. In this talk, we discuss the multilayer microwave integrated quantum circuit (MMIQC), a platform which combines planar circuits with 3D superconducting enclosures to gain scalability while maintaining coherence.

High-quality superconducting bonds are a critical element in constructing multilayer microwave integrated quantum circuits (MMIQCs). In order to provide lithographic precision for 3D enclosures made in wafers, it is necessary to create cavities with a high aspect ratio which places the seam in a region of high current density. In this talk, we describe a model for quantifying the loss associated with the seam, present our progress on indium bonding in microwave circuits, and discuss its application in scalable 3D superconducting quantum circuits.

Development of superconducting connection by flip-chip bonding for a multilayer superconducting quantum annealing machine

KAZUMASA MAKISE (Presenter), MASAHIK MAEZAWA, MITSUO HIDAKA, HIROSHI NAKAGAWA, KATSUYA KIKUCHI, SHIHO KAWABATA, National Institute of Advanced Industrial Science and Technology (AIST) — To realize practical-scale quantum annealing machines, a large number of qubits are required for the quantum processor. However, implementation of high-density qubits-array on a chip is a difficult problem because the size of qubits is limited by the size of wiring layer, Josephson junction and SQUID. To solve this problem, we have proposed an “QUIP” (Qubit-chip, Interposer and Package-substrate) 2.5-dimensional (2.5 D) packaging structure. Therefore, development of the packaging technology of qubits is one of the most important issue for QUIP. In this presentation, we focus on flip-chip bonding (FCB) connection as a 2.5 D mounting method. We design and fabricate circular lead/indium alloy solder bumps with a 10 um diameter and 5 um height on the top chip and Nb/Ti/Au-opposing-contact pads on the base chip to form a daisy chain of over 10000 chip-to-chip interconnects. The electrical transport measurements are performed in a cryocooler using a standard dc four-probe technique. We observe a critical current for the daisy chain devices with 15000 bump array, $I_c \sim 4 \text{ mA}$.

This presentation is based on results obtained from a project commissioned by the New Energy and Industrial Technology Development Organization (NEDO), Japan.
1:39PM S35.00011: Intel Superconducting Qubits, Part 1: Performance improvements towards enabling quantum applications  ROMAN CAUDILLO (Presenter), DAVID MICHALAK, LESTER LAMPERT, ADEL A ELSHERBINI, Components Research, Intel, JAVIER A FALCON, YE SEUL ASHLEY NAM, PRESTON T MYERS, DATD, Intel, SONIKA JOHRI, XIANG CHRIS ZOU, Intel Labs, Intel, JEANETTE MARIE ROBERTS, Components Research, Intel, ALESSANDRO BRUNO, NANDINI MUTHUSUBRAMANIAN, CORNELIS CHRISTIAAN BULTINK, FILIP MALINOWSKI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, NADIA HAIDER, QuTech and TNO, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, JIM CLARKE, Components Research, Intel — Quantum processors based on superconducting materials with flux-tunable transmon qubits present many challenges, including minimizing flux and microwave crosstalk, improving qubit frequency targeting, extending coherence times, and ultimately maximizing gate fidelities. Here we present our fabrication capabilities addressing some of these challenges on die sizes ranging from small laterally wirebonded 2-qubit chips to larger flip-chip, ball-grid-array-bonded 7- and 17-qubit chips. Through improved die processing, including better-controlled materials interfaces, integration of air bridges, and Josephson Junction fabrication optimization, we demonstrate low flux and microwave crosstalk and qubit performance improvements resulting in one- and two-qubit gate fidelities that enable algorithm exploration and execution.

1:51PM S35.00012: Intel Superconducting Qubits, Part 2: Integration on through-silicon-via (TSV) substrates.  DAVID MICHALAK (Presenter), ROMAN CAUDILLO, LESTER LAMPERT, ADEL A ELSHERBINI, Components Research, Intel, JAVIER A FALCON, YE SEUL ASHLEY NAM, PRESTON T MYERS, DATD, Intel, JEANETTE MARIE ROBERTS, Components Research, Intel, ALESSANDRO BRUNO, NANDINI MUTHUSUBRAMANIAN, CORNELIS CHRISTIAAN BULTINK, FILIP MALINOWSKI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, NADIA HAIDER, QuTech and TNO, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, JIM CLARKE, Components Research, Intel — Quantum computing holds the potential for significantly improving computing speed relative to classical computing for selected algorithms and applications. Many researchers using transmons in a circuit QED quantum hardware architecture are producing chips with ever-increasing numbers of qubits. The corresponding increase in chip size shifts the cavity/drum resonant modes into a frequency range where qubits could be adversely affected. One solution is to implement through-silicon-vias (TSVs) and chip/cavity contact pins to supply more ground connections. We present recent microwave modeling and fabrication results on qubit chips containing membrane-covered TSVs. These flip chips are assembled using a ball-grid-array die-package interface for signal I/O.

2:03PM S35.00013: 3D Integration of Superconducting Qubits in a Three-Tiered Quantum Processor*  JUSTIN MALLEK (Presenter), DONNA-RUTH YOST, RABINDRA DAS, DANNA ROSENBERG, VLADIMIR BOLKHOVSKY, GREG CALUSINE, MATTHEW COOK, EVAN GOLDEN, DAVID K KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, MOLLIE E. SCHWARTZ, COREY STULL, SERGEY TOLPYGO, WAYNE WOODS, JONILYN L YODER, WILLIAM D OLIVER, MIT Lincoln Laboratory — Heterogeneous 3D integration is an enabling technology for the construction of a quantum processor with a large number of superconducting qubits and a high degree of qubit interconnectivity. Our approach entails the construction of a three-tiered quantum processor where the high-coherence superconducting qubits are controlled and read-out through superconducting through silicon vias (TSVs) in an interposer which is bump bonded to a superconducting multichip module using indium microbumps. We will discuss our work on the fabrication and integration of the interposer with superconducting TSVs as well as the superconducting multichip module and the electrical data measured from test structures.

11:15AM S36.00001: Forbidden Transitions in Molecular Nanomagnets* [Invited] JONATHAN FRIEDMAN (Presenter), Department of Physics and Astronomy, Amherst College — Selection rules typically arise from the constraints imposed by conservation laws. In electron-spin resonance spectroscopy, the standard single-photon-transition selection rule $\Delta m = 0, \pm 1$ arises from angular momentum conservation. Such selection rules can be lifted when the magnetic quantum number of the spin system under study is not a good quantum number. In molecular nanomagnets (MNMs), magnetic anisotropy can lead to a preferred (easy) axis of orientation for the molecule's spin, giving rise to an anisotropy barrier between “up” and “down” states. In addition, transverse anisotropy breaks the system's symmetry, leading to state mixing and tunneling between spin states. Thus, tunneling can lead to the observation of forbidden transitions that strongly violate selection rules. I will report studies by my group of two MNMs that exhibit such highly forbidden transitions. In the Ni$_4$ MNM, a spin-4 system, we observe single-photon transitions in which the magnetic moment changes by as much as $\sim 7 \hbar$, nearly reversing the molecule's spin [1]. In addition, we observe direct transitions between tunnel-split states in this MNM, allowing us to precisely determine its transverse anisotropy [2]. In the Cr$_7$Mn MNM, a spin-1 system, there is a large tunnel splitting lifting the zero-field ground-state degeneracy. The two lowest states then have the structure of an atomic-clock transition in which the transition frequency is to first order independent of magnetic field, making the system largely immune to the decohering effects of external-field fluctuations. We find that the decoherence time $T_2$ is enhanced by a factor of three in the vicinity of this clock transition in Cr$_7$Mn.

11:51AM S36.00002: Coherent manipulation of three spin qubits in a GdW$_{30}$ single-ion magnet* [Invited] FERNANDO LUIS (Presenter), Instituto de Ciencia de Materiales de Aragón (ICMA), Consejo Superior de Investigaciones Científicas (CSIC), MARK D JENKINS, Kavli Institute of Nanoscience, Delft University of Technology, YAN DUAN, Instituto de Ciencia Molecular (ICMol), Universidad de Valencia, JUAN JOSE GARCÍA-RIPOLL, Instituto de Física Fundamental, Consejo Superior de Investigaciones Científicas (CSIC), ALEJANDRO GAITÁ-ARIÑO, CARLOS GIMÉNEZ-SAIZ, Instituto de Ciencia Molecular (ICMol), Universidad de Valencia, PABLO J ALONSO, Instituto de Ciencia de Materiales de Aragón (ICMA), Consejo Superior de Investigaciones Científicas (CSIC), ALBERTO CASTRO, Instituto de Biofísica y Física de Sistemas Complejos (BIFI), Universidad de Zaragoza, DAVID ZUECO, Instituto de Ciencia de Materiales de Aragón (ICMA), Consejo Superior de Investigaciones Científicas (CSIC), EUGENIO CORONADO, Instituto de Ciencia Molecular (ICMol), Universidad de Valencia — Implementing quantum computation with spins faces the challenge of increasing the number of qubits while keeping errors under control. Even the simplest algorithm implies coupling two or more qubits in a controlled manner. However, dipolar interactions are also an important source of decoherence [1]. Here, we explore a way to scale up quantum resources, without introducing additional decoherence, by integrating several electron spin qubits in a single magnetic ion with spin $S > \frac{1}{2}$. This approach is illustrated with a [Gd(H$_2$O)$_5$W$_{30}$O$_{110}$]$^{12-}$ polyyxometalate single-ion magnet [2]. Electron paramagnetic resonance experiments have been performed on molecules diluted in a crystal of the diamagnetic isostructural derivative [Y(H$_2$O)$_5$W$_{30}$O$_{110}$]$^{12-}$. The seven allowed transitions between the $2S+1=8$ spin states have been separately addressed and its spin coherence $T_2$ and spin-lattice relaxation $T_1$ rates measured. Rabi oscillations have been observed for all transitions. The spin states of each Gd$^{3+}$ ion can then be mapped onto the states of three addressable qubits (or, alternatively, of a $d = 8$-level molecular “qudit”), for which the seven allowed transitions form a universal set of operations. Within this scheme, one of the coherent oscillations observed experimentally provides an implementation of a controlled-controlled-NOT (or Toffoli) three-qubit gate. We also propose a way to implement a simple quantum error correction code using this single-ion “processor”. Our findings [3] open prospects for developing more complex and robust quantum computation schemes based on molecular spin qubits.

**12:27PM S36.00003: Multifrequency and Chemical Tuning Studies of V(IV) Quantum Spins**

[Invited] JOSPEH ZADROZNY (Presenter), CHUN-YI LIN, CASSIDY JACKSON, Chemistry, Colorado State Univ. JOHAN VAN TOL, National High Magnetic Field Laboratory — Complexes of the magnetic ion vanadium(IV) are at the frontier of molecular qubit research. Indeed, several recent investigations demonstrate that these ions are capable of spin relaxation times comparable to diamond's nitrogen vacancy centers. In light of these exciting results, significant fundamental knowledge is still needed to further design these ions as qubits. For example, understanding the frequency dependence of V(IV) electron paramagnetic resonance properties underlies many applications, yet EPR studies are largely focused at only one frequency, X-band. Separately, understanding how ligand chemical composition affects spin relaxation times would enable the further improvement of relaxation times. Yet, the majority of research in this area is focused on vanadium ions surrounded by ligands that are composed entirely of carbon, oxygen, and sulfur. In this presentation, results from multi-frequency EPR analyses on families of vanadium(IV) complexes will be presented, with an eye toward the foregoing fundamental insight.

**1:03PM S36.00004: Operating quantum states in single magnetic molecules**

[Invited] WOLFGANG WERNSDORFER (Presenter), PHI-INT, KIT, CLEMENT GODFRIN, FRANCK BALESTRO, Neel, CNRS — The endeavour of quantum electronics is driven by one of the most ambitious technological goals of today’s scientists: the realization of an operational quantum computer. We have started to address this goal by the new research field of molecular quantum spintronics, which combines the concepts of spintronics, molecular electronics and quantum computing. The building blocks are magnetic molecules, i.e. well-defined spin qubits. Various research groups are currently developing low-temperature scanning tunnelling microscopes to manipulate spins in single molecules, while others are working on molecular devices (such as molecular spin-transistors) to read and manipulate the spin state and perform basic quantum operations. We will present our recent measurements of geometric phases, the iSWAP quantum gate, the coherence time of a multi-state superposition, and the application to Grover’s algorithm [1-5].

*WW aknowledges the Humboldt foundation and the ERC Advanced Grant: MoQuOS

**1:39PM S36.00005: Magnetic relaxation dynamics in dysprosium complexes**

[Invited] NICHOLAS CHILTON (Presenter), DANIEL RETA, JON KRAGSKOW, DAVID MILLS, University of Manchester, YANZHEN ZHENG, Xi'an Jiaotong University, RICHARD WINPENNY, University of Manchester — Following our discovery of the first dysprosium metallocenium cation, (Dy(Cp3)2)[B(C6F5)4], which is the vanguard of the new generation of high-temperature single-molecule magnets, we have been investigating the magnetic relaxation dynamics of various dysprosium-based single-molecule magnets (SMMs) by experimental and theoretical techniques. Here we present our recent results in unravelling the competing magnetic relaxation processes, and offer some insights into the origin of the previously pervasive quantum tunneling of the magnetization in high-barrier dysprosium(III) SMMs.

Session S37 GMAG DCMP DMP: Spin Glasses, Spinels and Other Frustrated Systems BCEC

206A - Adam Aczel, Oak Ridge National Laboratory - Tag(s): Focus

2597 of 3305
11:15AM S37.00001: Role of Anisotropy in Spin Glass 1/f Noise Measurements* DAVID HARRISON (Presenter), E. DAN DALHBERG, University of Minnesota - Twin Cities, RAYMOND ORBACH, University of Texas at Austin — We have measured the 1/f noise in the resistance of the spin glass state of Cu$_{1-x-y}$Mn$_x$Au$_y$ and Ag$_{1-x-y}$Mn$_x$Au$_y$ thin films. The magnitude of 1/f noise shows a relatively abrupt increase as the system is cooled below its spin glass transition temperature. Doping of both the Ag and Cu based alloys with Au, allows us to systematically change the strength of the Dzyaloshinskii-Moriya interaction (DMI), a unidirectional anisotropy believed to give metallic spin glasses a more Ising-like characteristic. Witness films fabricated with the noise samples allow us to make a direct comparison of the temperature dependence of our noise measurements and conventional SQUID magnetometry measurements. We also compare our data with previously published results.

*Work supported by DOE Award Number DE-SC0013599.

11:27AM S37.00002: A statistical approach to rejuvenation and memory in spin glasses* RAYMOND ORBACH (Presenter), University of Texas at Austin — Rejuvenation and memory in spin glasses are approached from a statistical perspective. The analysis is based on temperature chaos being a "rare-event-driven phenomenon." Three regions are identified with increasing magnitudes of negative temperature shifts $\delta T$ ($\delta T > 0$). The first region exhibits reversible dynamics for $\delta T$ sufficiently small. The second is the chaotic regime for larger $\delta T$ where the dynamics re-start, termed "rejuvenation." Only a few spatial regions of size of the order of the spin glass correlaton length go chaotic. The large number of separated correlated regions for correlation lengths much less than the sample thickness or crystalline size (e.g. thin films or bulk samples) suggests that, as the temperature is lowered further, the probability that those regions that went chaotic in the rejuvenation regime would go chaotic again is statistically small. The growth of free energy barriers in these "rare" regions as the temperature is lowered further ($\delta T$ increasing) "freezes" their dynamics. As the temperature is raised back to the rejuvenation regime, their dynamics are "revived" and return to those initially measured. This is the origin of "memory."

*Supported by the U.S. Department of Energy, Office of Science, award DE-SC0013599

11:39AM S37.00003: Heisenberg domain state in thin-film ferromagnet/antiferromagnet bilayers is a magnetic glass* WEIJIE LI (Presenter), SERGEI URAZHDIN, Emory University — Random exchange interaction at the interface between ferromagnetic (F) and antiferromagnetic (AF) films results in the formation of a multidomain state. It was predicted by Malozemoff that for sufficiently thin films, domains become smaller than the domain wall width, forming a "Heisenberg domain state" (HDS) [1]. The nature and properties of HDS remain unexplored. We utilize magnetoelectronic and magneto-optical measurements of relaxation and dynamical characteristics in F/AF bilayers with AF=CoO, NiO, and FeMn to show that HDS is a magnetic glass. Our observations include nearly temperature-independent universal magnetic aging below a certain temperature $T_G$, transitioning to a strong temperature dependence at $T>T_G$. The transition is associated with a qualitative change in the dependence on the magnetic history. Transverse ac susceptibility measurements indicate that the magnetic viscosity varies by 4 orders of magnitude when $T>T_G$ is varied by 20 K, indicative of magnetic freezing consistent with the glass transition. Our results demonstrate that thin-film F/AF bilayers are a readily realizable and experimentally accessible quasi-2d magnetic glass system with controllable characteristics.

*Supported by NSF DMR-1504449
11:51AM S37.00004: Investigation of the Magnetic Ground State of Ni-Mn-Sn-based Shape Memory Alloy: a combined muSR and Powder Neutron Diffraction Study*  SUBHAM MAJUMDAR (Presenter), Indian Association for the Cultivation of Science, JHUMA SANNIGRAHI, D. T. ADROJA, J LORD, DMITRY KHALYAVIN, ADRIAN HILLIER, ISIS Neutron and Muon Source Science and Technology Facilities Council — We performed muon spin relaxation (muSR) and neutron powder diffraction (NPD) measurements as a function of temperature (T) on a metamagnetic shape memory alloy of nominal composition Ni51Mn35Sn14. The initial asymmetry (A0) of the muSR data shows some unusual T variation. A0 falls rapidly below the ferromagnetic (FM) transition at TCA = 320 K, indicating the onset of bulk magnetic order. A0 regains its full asymmetry value below the structural transition at TMS = 290 K suggesting the collapse of the FM order into a fully disordered paramagnetic state. A0 again falls below the second magnetic transition at TCM = 240 K. Interestingly, A0 increases sluggishly below the exchange bias blocking temperature TB = 120 K. This indicates that the system attains a disordered/glassy magnetic phase below TB, which is responsible for the exchange bias and anomaly in the ac susceptibility data. The NPD does not show any magnetic superlattice reflection ruling out the possibility of a long range antiferromagnetic state at low temperatures. The ground state is likely to be comprising of a spin-glass phase in the backdrop of an FM state.

*The work is supported by the India-RAL collaborative project (SR/NM/Z-07/2015).

12:03PM S37.00005: Low-temperature and dynamic magnetism of highly frustrated 5d2 Li4MgOsO6 in comparison with 5d3 Li3Mg2OsO6*  JEREMY CARLO (Presenter), Department of Physics, Villanova University, SHAHAB DERAKHSAN, Department of Chemistry and Biochemistry, California State University - Long Beach, THOMAS GREDIG, Department of Physics, California State University - Long Beach, GRAEME LUKE, Department of Physics, McMaster University, JOHN GREEDAN, Department of Chemistry and Chemical Biology, McMaster University — Geometric magnetic frustration (GMF) has attracted substantial interest due to the exotic physics and rich phase diagrams revealed by the cancellation of normally-dominant magnetic interactions, giving impetus for the search for novel frustrated systems, most often based on antiferromagnetic correlations between magnetic ions decorating triangular or tetrahedral lattices. We report low-temperature magnetic susceptibility and muon spin relaxation results on Li4MgOsO6 and Li3Mg2OsO6, members of the A5BO6 “rock salt ordered” family of frustrated materials. In Li3Mg2OsO6 we find spin freezing below 12K. In Li4MgOsO6, which can crystallize into either orthorhombic Fddd or monoclinic C2/m crystal symmetries depending on synthesis conditions, we find magnetism consistent with glassy-like behavior dominating below 2K, with partial ordering and evidence for dynamics at somewhat higher temperatures.

*JPC acknowledges support from the Research Corporation for Science Advancement (Cottrell College Science Award #23314). SD is grateful for financial support from NSF-DMR-RUI Award #1601811 and the W. M. Keck Foundation for establishment of the Keck Energy Materials Program at CSULB. We thank the TRIUMF CMMS for assistance with muSR experiments.

12:15PM S37.00006: Spin Glass Behavior in Spinel Ni0.8Fe2.2O4*  ROSHAN NEPAL (Presenter), MOHAMMAD SAGHAYEZHIAN, JIANDI ZHANG, RONGYING JIN, Louisiana State University — Spinel oxides (AB2O4) with magnetic A and B ions are known to exhibit complex magnetic behavior that emerge from the competing AA, AB, and BB magnetic interactions. Here, we report the magnetic and thermal properties of single-crystalline Ni0.8Fe2.2O4, which orders ferrimagnetically (Fi) below TF ∼ 860 K, followed by another magnetic transition at TSG ∼ 14 K. The dc magnetization shows a dramatic downturn upon cooling below TSG, whereas both real and imaginary parts of ac susceptibility show frequency dependence. Further quantitative analysis reveals the presence of de Almeida-Thouless (A-T) line, dynamic magnetization behavior, memory effect, and the critical power law dependence of transition temperature to ac frequency, all indicative of a spin glass ground state. The origin of the spin glass state and its implication to other physical properties will be discussed.

*This work is supported by DoE through DE-SC0016315.
Recent experiments have demonstrated a lack of long-range magnetic order in spin-1 diamond lattice compounds such as NiRh$_2$O$_4$ [1]. These compounds can potentially provide a rich playground for exotic quantum states such as a proposed quantum spiral spin liquid [2]. We study the phase diagram of the Heisenberg model with bilinear and biquadratic interactions between nearest and next-nearest neighbors on the diamond lattice to search for ordered and quantum spin liquid states. The phase diagram for this frustrated spin-1 model reveals ground states that lack long-range spin order, including quadrupolar states and valence-bond solids. We use variational Monte Carlo with projected fermionic states to compare energies for different candidate states within a plausible region of the phase diagram corresponding to NiRh$_2$O$_4$.

*Robert A. Welch Foundation Grant C-1818, NSF Grant DMR-1350237

Coexisting zero-field and field induced relaxation channels in spinel spin ice

EDWARD RIORDAN (Presenter), Cardiff University, TOM FENNELL, paul scherrer institute, ELSA LHOTEL, Neel Institute, OKSANA ZAHARKO, paul scherrer institute, VLADIMIR TSURKAN, university of ausburg, SEAN GIBLIN, Cardiff University — Spin ice materials exhibit novel magnetic behaviour because of their atomic interactions and geometric constraints of the crystal lattice. This novel behaviour takes the form of emergent quasi-particles that behave as magnetic monopoles. We have studied the spin ice materials CdEr$_2$Se$_4$ and CdEr$_2$S$_4$ using a bespoke high frequency ac susceptometer capable of measuring at low temperatures (>2K). These ac susceptibility measurements have uncovered novel behaviour when in the presence of applied DC fields, in the form of two coexisting relaxation channels with differing time scales and temperature dependence. Such behaviour has not been so directly observed before. We have further investigated the relaxations by use of DC magnetisation and muon spin rotation techniques.

Spin Jahn-Teller effect in the antiferromagnet CoTi$_2$O$_5$

FRANZ LANG (Presenter), FRANZISKA KIRSCHNER, STEPHEN BLUNDELL, ROGER JOHNSON, DHARMALINGAM PRABHAKARAN, University of Oxford — We have used a combination of neutron powder diffraction and muon spin rotation experiments, complemented with DFT calculations, to solve the magnetic structure of orthorhombic CoTi$_2$O$_5$, which we find adapts a long-range ordered, antiferromagnetic state below 26 K with a moment of 2.72(1)μB per Co$^{2+}$ ion and propagation vector $k=(±1/2,1/2,0)$ [1]. Interestingly, in the experimentally determined crystal structure all the magnetic exchange couplings are completely frustrated by the underlying symmetry. Therefore, we conclude that the magnetic transition must driven by a Spin Jahn-Teller effect, in which the large spin degeneracy is relieved by a distortion of the crystal structure and an associated lowering of the structural symmetry. We investigate this distortion using high resolution x-ray experiments and DFT calculations. Furthermore, we discuss recent experimental studies of FeTi$_2$O$_5$ and the observed similarities to CoTi$_2$O$_5$, which leads us to conlcude that spin-phonon coupling can induce magnetic order in lower symmetry systems than previously reported.

*This work is supported by EPSRC (UK) grant EP/N023803/1. It made use of the STFC ISIS Facility (RAL, UK), the Swiss Muon Source (PSI, Switzerland), and the Univ. of Oxford Advanced Research Computing facility.

Single-Crystal Neutron Scattering Studies of Breathing Pyrochlore Ba$_3$Yb$_2$Zn$_5$O$_{11}$

SACHITH DISSANAYAKE (Presenter), WILLIAM STEINHARDT, ZHENZHONG SHI, STEPHEN J KUHN, Department of Physics, Duke University, NICHOLAS BUTCH, Center for Neutron Research, National Institute of Standards and Technology, MATTHIAS D FRONTZEK, Neutron Scattering Division, Oak Ridge National Laboratory, YIMING QIU, Center for Neutron Research, National Institute of Standards and Technology, DAVID E GRAF, National High Magnetic Field Laboratory and Department of Physics, Florida State University, HONGCHENG LU, CASEY MARJERRISON, SARA HARAVIFARD, Department of Physics, Duke University — Recently a new class of materials called Breathing pyrochlore compounds have attracted much attention. These systems consist of two alternating, opposing tetrahedra expanded and contracted, leading to differing intra- and inter-tetrahedra exchange interactions and the emergence of the Dzyaloshinskii-Moriya interaction due to loss of inversion symmetry. They are predicted to host exotic physics, including quantum spin ice state and the field-tunable Weyl magnon. In this talk we will present our recent magneto-transport and field-dependent diffuse and inelastic neutron scattering results measured on single crystal of the breathing pyrochlore compound Ba$_3$Yb$_2$Zn$_5$O$_{11}$.
1:15PM S37.00011: Powder inelastic neutron scattering of a spin-liquid candidate $\text{Ba}_3\text{ZnRu}_2\text{O}_9^*$

DANIEL PAJEROWSKI (Presenter), LIURUKARA SANJEEWA, MATTHEW BRANDON STONE, ZHENG GAI, Oak Ridge National Laboratory, JOSEPH KOLIS, Clemson University — $\text{Ba}_3\text{ZnRu}_2\text{O}_9$ (BZRO) is a 6-H perovskite compound that contains triangular lattice layers of $\text{Ru}^{5+}$ dimers, and was recently reported to have no signatures of long-range-magnetic-order down to 37 mK and therefore put forward as a spin-liquid candidate.[1] We present inelastic neutron scattering measurements on BZRO powder that show a magnetic feature with a momentum dependence that is similar to the Ru-magnetic-form-factor, a peak energy intensity at 25 meV, and no obvious dispersive character. This magnetic mode is then considered in the context of density functional theory calculations and magnetization measurements. Comparisons are then made to the historical work on the analogous $\text{Ba}_3\text{CaRu}_2\text{O}_9$.[2]

*This research used resources at the Spallation Neutron Source and High Flux Isotope Reactor, a DOE Office of Science User Facility operated by the Oak Ridge National Laboratory.

1:27PM S37.00012: Magnetic excitations of the classical spin-liquid $\text{MgCr}_2\text{O}_4^*$

MARTIN MOURIGAL, XIAOJIAN BAI, Georgia Institute of Technology, JOSEPH PADISON, Cambridge, ELIOT KAPIT, Mines, SEYED KOOPHAYEH, Johns Hopkins, JIAJIA WEN, SLAC, SIAN E DUTTON, Cambridge, COLLIN BROHOLM, Johns Hopkins, JOHN CHALKER, Oxford, ANDREI T SAVICI (Presenter), GARRETT E GRANROTH, ALEXANDER I KOLESNIKOV, ORNL — We report a comprehensive inelastic neutron-scattering study of the frustrated pyrochlore antiferromagnet $\text{MgCr}_2\text{O}_4$ in its cooperative paramagnetic regime. Theoretical modeling yields a microscopic Heisenberg model with exchange interactions up to third-nearest neighbors, which quantitatively explains all the details of the dynamic magnetic response. Our work demonstrates that the magnetic excitations in $\text{MgCr}_2\text{O}_4$ are faithfully represented in the entire Brillouin zone by a theory of magnon excitations propagating in a highly-correlated paramagnetic background. Our results also suggest that $\text{MgCr}_2\text{O}_4$ is proximate to a spiral spin-liquid phase distinct from the Coulomb phase, what has implications for the magneto-structural phase transition observed at low temperature in this material.

1:39PM S37.00013: Possible Random Singlet phase in the $S = 1/2$ magnet $\text{Y}_2\text{CuTiO}_6^*$

AVINASH MAHAJAN (Presenter), SUSANTA KUNDU, Department of Physics, Indian Institute of Technology Bombay, Powai Mumbai 400076, India, JEAN-CHRISTOPHE ORAIN, muSR group, Paul Scherrer Institute, 5232 Villigen, Switzerland, MICHAEL BAENITZ, Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany — $\text{Y}_2\text{CuTiO}_6$ contains edge-shared triangular planes where the vertices are occupied by magnetic Cu and nonmagnetic Ti atoms in equal proportion. In spite of the large dilution of the triangular magnetic lattice, the magnetic susceptibility shows a large, AF $\theta_{\text{CW}}$ of about 240 K without any sign of ordering down to 1.8 K. No bifurcation is observed in the ZFC/FC magnetisation data in a low field of 50 Oe, down to 0.5 K. Likewise, the heat capacity shows no anomalies and the magnetic contribution has a power law behaviour at low-temperatures. Our muSR measurements down to 50 mK also do not show any signs of ordering. These observations are typical of potential quantum spin liquid systems. In the present case, however, the magnetic heat capacity $C_m$ depends on the magnetic field $H$. We observed that the data could be scaled such that $H^\gamma C_m/T$ vs $T/H$ follows a universal curve with $\gamma = 0.6$. Such a scaling behaviour has been suggested in systems with random singlet formation. The randomness of exchange coupling in $\text{Y}_2\text{CuTiO}_6$ might be due to the random occupation of Cu and Ti on the vertices of triangles. It is nevertheless surprising that in spite of the large (50%) depletion of the lattice, no spin freezing is observed.

Session S38 GMAG DCMP DMP: Frustrated Square Lattice and Other Low-Dimensional Structures BCEC 206B - Oleg Tchernyshyov, Johns Hopkins University - Tag(s): Focus
Quantum Spin Liquid with Broken Unidirectional Symmetry in a Square Lattice Spin-1 Model

WENJUN HU, Department of Physics and Astronomy, Rice University, SHOUHSHU GONG, Department of Physics and International Research Institute of Multidisciplinary Science, Beihang University, Beijing, HSIN-HUA LAI, HAOYU HU, QIMIAO SI, ANDRIY NEVIDOMSKYY (Presenter), Department of Physics and Astronomy, Rice University — Quantum spin liquids (QSL) are known to arise in strongly frustrated spin systems as a result of competing interactions. Here we consider a spin-1 model on a square lattice, where despite the absence of geometric frustration, competition between the nearest neighbor Heisenberg ($J_1$) and biquadratic ($K_1$) interactions results in a QSL around the $J_1 = K_1$ point, as evidenced by our density matrix renormalization group (DMRG) studies. At that point, the model has an emergent SU(3) symmetry and calculations based on $N=3$ flavor-wave theory indicate the presence of large quantum fluctuations that destabilize the nearby antiferromagnetic and quadrupolar orders. What emerges is a QSL with no long-range order in spin or quadrupolar channels, which nevertheless has fluctuations peaked at the wavevector $(\pi, 2\pi/3)$ and spontaneously breaks the $C_4$ rotational symmetry of the square lattice [1]. We demonstrate, by studying an anisotropic model, that this lattice-nematic spin liquid is distinct from the limit of weakly coupled Haldane chains. Instead, analysis of the spectral gaps and entanglement entropy is consistent with the QSL being either gapless or having a very small gap.

Characterization of quantum spin liquids and their spinon band structures via functional renormalization

JOHANNES REUTHER (Presenter), MAX HERING, JONAS SONNENSchein, Physics Department, Freie Universitaet Berlin, YASIR IQBAL, Department of Physics, Indian Institute of Technology Madras — We combine the pseudofermion functional renormalization group (PFFRG) method with a self-consistent Fock-like mean-field scheme to calculate low-energy effective theories for emergent spinon excitations in spin-1/2 quantum spin liquids. Using effective spin interactions from PFFRG as an input for the Fock equation and allowing for the most general types of free spinon ansatze as classified by the projective symmetry group (PSG) method, we are able to systematically determine spinon band structures for spin-liquid candidate systems beyond mean-field theory. We apply this approach to the antiferromagnetic J1-J2 Heisenberg model on the square lattice and to the antiferromagnetic nearest-neighbor Heisenberg model on the kagome lattice. For the J1-J2 model, we find that in the regime of maximal frustration a SU(2) pi-flux state with Dirac spinons yields the largest mean-field amplitudes. For the kagome model, we identify a gapless Z2 spin liquid with a small circular spinon Fermi surface and approximate Dirac-cones at low but finite energies.

Critical Level Crossings and Gapless Spin Liquid in the Square-Lattice Spin-1/2 J1-J2 Heisenberg Antiferromagnet

LING WANG (Presenter), Beijing Computational Science Research Center, ANDERS W SANDVIK, Physics Department, Boston University — We use the density matrix renormalization group method to calculate several energy eigenvalues of the frustrated $S=1/2$ square-lattice J1-J2 Heisenberg model on $2L \times L$ cylinders with $L \leq 10$. We identify excited-level crossings versus the coupling ratio $g=J2/J1$ and study their drifts with the system size $L$. The lowest singlet-triplet and singlet-quintuplet crossings converge rapidly (with corrections $\propto L^{-2}$) to different $g$ values, and we argue that these correspond to ground-state transitions between the Neel antiferromagnet and a gapless spin liquid, at $gc1=0.46$, and between the spin liquid and a valence-bond solid at $gc2=0.52$. Previous studies of order parameters were not able to positively discriminate between an extended spin liquid phase and a critical point. We expect level-crossing analysis to be a generically powerful tool in density matrix renormalization group studies of quantum phase transitions.

11:51AM S38.00004: Observation of topological phenomena induced by frustration and quantum fluctuations in a programmable lattice of 1,800 qubits  [Invited] ISIL OZFIDAN (Presenter), ANDREW KING, D-Wave Systems, JUAN CARRASQUILLA, Vector Institute, JACK RAYMOND, MOHAMMAD AMIN, D-Wave Systems — The celebrated work of Berezinskii, Kosterlitz and Thouless in the 1970s [1] revealed exotic phases of matter governed by topological properties of low-dimensional materials such as thin films of superfluids and superconductors. Key to this phenomenon is the appearance and interaction of vortices and antivortices in an angular degree of freedom—typified by the classical XY model—due to thermal fluctuations. In the 2D Ising model this angular degree of freedom is absent in the classical case, but with the addition of a transverse field it can emerge from the interplay between frustration and quantum fluctuations. Consequently a Kosterlitz-Thouless (KT) phase transition has been predicted in the quantum system by theory and simulation [2]. Here we demonstrate a large-scale quantum simulation of this phenomenon in a network of 1,800 in situ programmable superconducting flux qubits arranged in a fully-frustrated square-octagonal lattice [3]. Essential to the critical behavior, we observe the emergence of a complex order parameter with continuous rotational symmetry, and the onset of quasi-long-range order as the system approaches a critical temperature. We use a simple but previously undemonstrated approach to statistical estimation with an annealing-based quantum processor, performing Monte Carlo sampling in a chain of reverse quantum annealing protocols. Observations are consistent with classical simulations across a range of Hamiltonian parameters. We anticipate that our approach of using a quantum processor as a programmable magnetic lattice will find widespread use in the simulation and development of exotic materials.

12:27PM S38.00005: Thermodynamics of a frustrated quantum magnet on a square lattice* VIVEK BHARTIYA (Presenter), KIRILL POVAROV, ZEWU YAN, ANDREY ZHELUDEV, Department of Physics, ETH Zurich — We report the magnetic and calorimetric measurements in single crystal samples of the square lattice $J_1 - J_2$ quantum antiferromagnet BaCdVO(PO4)2 [1]. An investigation of the scaling of magnetization reveals a “dimensionality reduction” indicative of a strong degree of geometric frustration. Below a characteristic temperature less than 150 mK we observe the emergence of a new strongly fluctuating quantum phase close to full magnetic saturation. It is separated from the magnetically ordered state by 1-st and 2-nd order phase transitions, depending on the orientation of the applied magnetic field. We suggest that the new phase may indeed be the theoretically predicted spin nematic state.

12:39PM S38.00006: Improving the full update and probing frustrated J1-J2 spin-1/2 model on a square lattice JURAJ HASIK (Presenter), FEDERICO BECCA, International School for Advanced Studies — The optimization of infinite projected entangled-pair state (iPEPS) ansatz represents the main challenge in obtaining accurate ground states of lattice models. In this work, we propose a simple modification of the full-update algorithm [1] and benchmark it on a frustrated $J_1-J_2$ spin-1/2 Heisenberg model on a square lattice. Using an improved full-update, we obtain extremely accurate ground-state energies but, most importantly, also values of the magnetization that are comparable with previous results from more complex variational optimization [2,3]. Moreover, we show that the recent scaling technique based on the correlation length [4,5] leads to a considerable improvement in analysis of the phase diagram.

12:51PM S38.00007: Accuracy of Restricted Boltzmann Machine wavefunctions for frustrated spin systems
FRANCESCO FERRARI (Presenter), SISSA-ISAS, International School for Advanced Studies, Trieste (Italy), JUAN CARRASQUILLA, Vector Institute for Artificial Intelligence, Toronto (Canada), FEDERICO BECCA, SISSA-ISAS, International School for Advanced Studies, Trieste (Italy) — Artificial neural networks (ANNs) constitute a powerful tool to approximate multi-variable functions in a plethora of different contexts. In the quest for an efficient representation of the ground state wavefunction of many-body quantum systems, ANNs have recently emerged as a flexible framework to construct variational ansätze [1]. We investigate the accuracy of Restricted Boltzmann Machine (RBM) networks as many-body Jastrow factors for the study of spin systems. In particular, we apply the RBM factor on top of a Gutzwiller-projected fermionic wavefunction [2], in order to construct a variational ansatz for the ground state of the spin-1/2 J1-J2 Heisenberg model in two dimensions. In the magnetically ordered phase (J2=0), Monte Carlo results show that the RBM correlator yields a significant improvement of the variational energy [2]. On the other hand, when competing interactions are turned on and the system becomes highly frustrated, the energy gain due to the RBM becomes remarkably less pronounced.

1:03PM S38.00008: Magnetic superstructures inside the ⅓ and ½ magnetization plateaux in Ba2CoTeO6 revealed by magnetostriction and magnetocaloric effect measurements* DAGMA WEICKERT (Presenter), National High Magnetic Field Laboratory, Florida State University, CAROLINA CORVALAN-MOYA, CONICET, NCNEA-UNTREF, MYRON B SALAMON, University of Texas at Dallas, CHAO DONG, KOICHI KINDO, YOSHIMITSU KOHAMA, ISSP, Tokyo University, NOBUYUKI KURITA, HIDEKAZU TANAKA, Tokyo Tech — Ba2CoTeO6 is composed of two nearly decoupled magnetic spin-systems stacked as alternating 2D layers along the crystallographic c-direction in the trigonal crystal structure. Subsystem A is a S = ½ triangular Heisenberg antiferromagnet that orders at TA = 3K. System B is a J1-J2 honeycomb Ising antiferromagnet with ordering temperature TB = 12K. Both underlying spin-models are interesting due to geometrical frustration (A) and bond frustration (B) causing magnetic plateaux upon the application of magnetic fields H. We present a combination of magnetostriction and magnetocaloric effect (MCE) measurements in high pulsed and static magnetic fields to map out the phase diagram for H ll and perp. to the A and B layers. We observe distinct anomalies in the sample length ΔL/L as a function of field and temperature indicating phase transitions as well as signatures in the MCE measurement indicating a change of entropy. These anomalies are accompanied by significant hysteresis in decreasing compared to increasing magnetic fields.

1:15PM S38.00009: Spin structure and dynamics of Pb2VO(PO4)2* SIMON BETTLER (Presenter), FLORIAN LANDOLT, ÖMER M. AKSOY, ZEWU YAN, Laboratorium für Festkörperphysik, ETH Zurich, CH-8093 Zurich, ERIC RESSOUCHE, Univ. Grenoble Alpes, CEA, INAC-MEM, F-38000 Grenoble, SERGEI ZYVAGIN, ALEXEY PONOMARYOV, Dresden High Magnet Field Lab HLD, Helmholtz Zentrum Dresden Rossendorf, KETTY BEAUVOIS, Univ. Grenoble Alpes, CEA, INAC-MEM, F-38000 Grenoble, YIMING QIU, NIST Centre for Neutron Research, National Institute of Standards and Technology, STEPHANE RAYMOND, Univ. Grenoble Alpes, CEA, INAC-MEM, F-38000 Grenoble, SEVERIAN GVASALIYA, ANDREY ZHELUDEV, Laboratorium für Festkörperphysik, ETH Zurich, CH-8093 Zurich — Pb2VO(PO4)2 is one of few quantum magnets proposed to realize the frustrated spin-1/2 square lattice with ferromagnetic nearest-neighbor exchange. We have determined the magnetic structure and excitation spectrum of Pb2VO(PO4)2 by means of single crystal neutron diffraction and neutron spectroscopy going beyond previous limited powder sample studies. The spin dynamics show qualitative differences – which were independently confirmed by ESR – from what is expected for an ideal square lattice. These are attributed to having as many as three nearest neighbor and two next-nearest neighbor. We discuss the implications for closely related materials proposed to realize a frustrated square lattice.

1:27PM S38.00010: Magnetisation process in the rare earth tetraborides, NdB₄ and HoB₄
OLEG PETRENKO (Presenter), University of Warwick, DANIEL BRUNT, National Physics Laboratory, UK, NAVID QURESHI, Institut Laue-Langevin, France, GEETHA BALAKRISHNAN, DANIEL MAYOH, MARTIN LEES, University of Warwick — We report a study into the field-induced magnetisation of the two frustrated rare earth tetraborides, HoB₄ and NdB₄. NdB₄ shows a fractional magnetisation plateau occurring at $M/M_{\text{sat}} \approx 1/5$ before saturating in a field of 33 kOe. On cooling down to 0.5 K the temperature dependent susceptibility of NdB₄ shows an unconventional transition where the system returns to the zero field antiferromagnetic state from a higher-temperature ferrimagnetic state. We are able to reconstruct the magnetic phase diagram of NdB₄ from the magnetisation, susceptibility and resistivity measurements for both $H//c$ and $H\perp c$. For HoB₄, the most interesting behaviour is found at the lowest temperature of 0.5 K, where the field dependent magnetisation demonstrates a new fractional 1/2-magnetisation plateau. Further insight into the relations between the exchange interactions and single ion effects is gained through high-field magnetisation measurements in both HoB₄ and NdB₄.

1:39PM S38.00011: Evolution of the spin-flop antiferromagnetic transition and the emergence of frustration in saw-tooth lattice Mn₂SiS₄₋ₓSex (x = 0 - 4) chalcogenides
HARIHARAN NHALIL, Department of Chemistry and Biochemistry, University of Oklahoma, RAJU BARAL, ADRIAN COSIO, BETHUEL O KHAMALA, SRINIVASA RAO SINGAMANENI, University of Texas, El Paso, MAGDALENA FITTA, Department of Magnetic Materials and Nanostructures, 3The Henryk Niewodniczanski Institute of Nuclear Physics -PAN, RAJENDRA ZOPE, TUNNA BARUAH, University of Texas, El Paso, DANIEL ANTONIO, KRZYSZTOF GOFRYK, Idaho National Laboratory, BAYRAMMURAD SAPAROV, Department of Chemistry and Biochemistry, University of Oklahoma, HARIKRISHNAN NAIR (Presenter), University of Texas, El Paso — The olivine $A_2BX_4$ structure takes $Pnma$ symmetry where the $A$ site forms the triangle-based one dimensional saw-tooth chain structure and are known for optoelectronics, thermoelectric and magnetic applications. We studied the olivines, Mn₂SiS₄₋ₓSex (0 < x < 4), using magnetization, specific heat, thermal conductivity and ab initio density functional theory (DFT) calculations and tracked the evolution of spin-flop transition and frustration. It is seen that the antiferromagnetic transition temperature $T_N$ shows a linear decrease from 86 K for Mn₂SiS₄ towards 66 K for Mn₂SiSe₄ as $x$ varied; whereas the critical field for spin-flop varied non-linearly. The magnetic phase transitions characterized using specific heat reveal very low magnetic entropy evolved at the $T_N$, suggesting the underlying frustrated nature of the Mn²⁺ ions in the saw-tooth like triangular arrangement. A semiconducting-like thermal conductivity is revealed by the olivines where the DFT calculations show a small energy gap (~0.5 eV) between the valence and conduction bands. Our results are explained based on the emergence of frustration in the triangular units of the saw-tooth Mn lattice.

*UTEP is acknowledged for the faculty start-up grant.

1:51PM S38.00012: Quantum disordered state in the $J_{\text{eff}}=1/2$ triangular lattice antiferromagnet NaYbO₂
MITCHELL BORDELON (Presenter), Materials, University of California Santa Barbara, ERIC KENNEY, Physics, Boston College, LORENZO POSTHUMA, Chemistry, University of California Santa Barbara, MARZIEH KAVAND, YUANQI LYU, MARK STEPHEN SHERWIN, Physics, University of California Santa Barbara, CRAIG BROWN, NIST Center for Neutron Research, MICHAEL JOHN GRAF, Physics, Boston College, LEON BALENTS, Physics, University of California Santa Barbara, STEPHEN WILSON, Materials, University of California Santa Barbara — There has been a great deal of interest in realizing unconventional quantum disordered magnetic ground states in frustrated antiferromagnets driven by strong fluctuations in the small spin limit. Experimentally, real materials often preclude this limit due to symmetry-breaking structural or magnetic processes or innate chemical disorder that lifts ground state degeneracies. NaYbO₂ ($R-3m$) contains geometrically-frustrated triangular layers of $J_{\text{eff}}=1/2$ Yb³⁺ ions with ideal chemical order, a robust lattice geometry to 330 mK and lacks conventional signs of magnetic ordering under zero-field conditions to 50 mK. Under a moderate applied field, NaYbO₂ enters an antiferromagnetic phase below 1 K. This material stands as an appealing candidate to realize a dynamically-disordered quantum ground state driven by highly-anisotropic, spin-orbit entangled Yb ions whose transition into a nearby field-driven magnetically-ordered phase can be probed experimentally and theoretically.

*DOE, Office of Science, Basic Energy Sciences under Award DE-SC0017752
Competing paramagnetic phases and itinerant magnetic frustration in SrCo$_2$As$_2$*  

BING LI (Presenter), BENJAMIN UELAND, WAGEESHA T JAYASEKARA, Ames Laboratory, Iowa State University, DOUGLAS L ABERNATHY, Oak Ridge National Laboratory, SANGEETHA N. S., DAVID C JOHNSTON, QING-PING DING, YUJI FURUKAWA, PETER P. ORTH, ANDREAS KREYSSIG, ALAN IRA GOLDMAN, ROBERT MCQUEENEY, Ames Laboratory, Iowa State University — Cobalt arsenides with a layered square lattice tend to be itinerant ferromagnets. However, using inelastic neutron scattering we find in SrCo$_2$As$_2$ stripe-type antiferromagnetic (AF) spin fluctuations, though no long-range AF order is observed down to 50 mK. The stripe phase competes with the itinerant ferromagnetism and wins below 115 K, resulting in the development of AF spin fluctuations concomitant with a suppression of the uniform magnetic susceptibility. Comparison of our experimental data to exact diagonalization and classical Monte Carlo simulations of a frustrated local-moment J$_1$-$J_2$ model suggests that itinerancy enhances frustration. We conclude that SrCo$_2$As$_2$ is a candidate for frustrated itinerant magnetism and harbors unique frustrated magnetism on the boundary between itinerant ferromagnetic and stripe AF instabilities.

11:15AM S39.00001: Ultrafast p-bits using synthetic antiferromagnets*  

JAN KAISER (Presenter), KEREM Y CAMSARI, SUPRIYO DATTA, PRAMEY UPADHYAYA, Purdue University — Various applications ranging from cryptography to stochastic computing need random number generators (RNGs) which can be implemented in hardware using magnetic tunnel junctions (MTJs) with low barrier unstable ferromagnets (LBMs). It has been shown that with proper design such ferromagnets can show random fluctuations at GHz speeds. In this talk using stochastic LLG simulations, we will show that synthetic antiferromagnets (SAFs) built out of LBMs can fluctuate with even higher speeds. Using full SPICE simulations, we show that MTJs using SAFs can be combined with standard transistors to provide a fast tunable RNG or p-bit which can speed up numerous applications.

*This work was supported in part by the Center for Probabilistic Spin Logic for Low-Energy Boolean and Non-Boolean Computing (CAPSL), one of the Nanoelectronic Computing Research (nCORE) Centers as task 2759.005, a Semiconductor Research Corporation (SRC) program sponsored by the NSF through ECCS 1739635.

11:27AM S39.00002: Physical meaning of the full width half maximum of switching time distribution in ferromagnetic nano-structure  

JUNG-HWAN MOON, Advanced Technology Development Team, Semiconductor R&D Center, Samsung Electronics Co. Ltd., TAE YOUNG LEE, New Memory Device and Process Integration Group, SK Hynix, CHUN-YEOL YOU (Presenter), Department of Emerging Materials Science, DGIST — Generally, line width or full width half maximum of physically measurable quantity. For example, the line with of RLC is related with quality factor of the circuit, and one of ferromagnetic resonance is related with damping constant of the ferromagnetic materials. The switching time of the ferromagnetic nano-structure has been actively studied because of its importance in the physics and device applications. And the switching behavior itself is well described by Fokker Planck Equation (FPE) [1]. Recently, we found that the full width of half maximum (FWHM) of switching time distribution is closely related with the damping constant [2]. We solved FPE with high barrier approximation, we obtained the FWHM is inversely proportional to the external applied field, and the damping constant can be obtained from the slope. Surprisingly enough, the obtained relation is quite similar to the equation for the damping constant and line width of the ferromagnetic resonance, while its underlying physics are totally different.

MD ALI AZAM (Presenter), DHIRITIMAN BHATTACHARYA, Department of Mechanical and Nuclear Engineering, Virginia Commonwealth University, CAROLINE ANNE ROSS, Department of Materials Science and Engineering, Massachusetts Institute of Technology, DAMIEN QUERLIOZ, Centre de Nanosciences et de Nanotechnologies, University of Paris-Sud, JAYASIMHA ATULASIMHA, Department of Mechanical and Nuclear Engineering, Virginia Commonwealth University — We present micromagnetic simulation of voltage-controlled spintronic neuron and synapse by utilizing domain wall (DW) motion in the free layer of a Magnetic Tunnel Junction (MTJ). The free layer is a soft ferromagnet (CoFeB) exchange coupled to a magnetostrictive Rare Earth Iron Garnet (REIG) racetrack with perpendicular magnetic anisotropy (PMA) deposited on a heavy metal layer. The whole stack is fabricated on a piezoelectric substrate. Chiral domain walls can be introduced in the free layer due to PMA and Dzyaloshinskii-Moriya Interaction (DMI) [1, 2], translated with spin orbit torque by applying a current pulse to the heavy metal layer and arrested at specific location along the racetrack domain by tuning the bulk PMA of the magnetic layer using a highly localized voltage-generated strain from the piezoelectric layer. Micromagnetic simulations with realistic defects and thermal noise will be presented for an energy efficient neuron and non-volatile programmable synapse using this device.

PANAGIOTIS CH. FILIPPOU, IBM Almaden Research Center, JAЕWOO JEONG, New Memory Technology Lab, Samsung Electronics, YARI FERRANTE (Presenter), SEE-HUN YANG, TEYA TOPURIA, MAHESH G. SAMANT, IBM Almaden Research Center, STUART S P PARKIN, Max Plank Institute for Microstructure Physics — The task of improving the performances of next-generation spin-transfer torque magnetoresistive random access memory (STT-MRAM) requires the use of new magnetic materials with high perpendicular magnetic anisotropy (PMA) and low magnetic moment within the magnetic tunnel junction, i.e. MRAM storage element. Heusler alloys are a large family of compounds with tunable magnetic properties. Some of these have a tetragonal structure with its elongated axis perpendicular to the film plane and thus they may display PMA due to their structure broken symmetry. However, so far, PMA has been observed only for 50Å-thick films, i.e. too thick for technological applications. In this talk we demonstrate that X3Z (X=Mn; Z=Ge,Sn,Sb) tetragonal Heusler films, as thin as only 1 unit cell, can be developed by using a novel chemical templating technique. We show this can be achieved by growing the Heusler films, even at room temperature, onto atomically-ordered X’Z’ (X’=Co; Z’=Al,Ga,Ge,Sn) underlayers that promote chemical ordering within the Heusler films. Excellent PMA with square hysteresis is found in Mn3Z layers that are only 1-2 unit cells thick. The possibility of preparing ultrathin Heusler films with PMA makes possible their technological application for a wide range of spintronic devices.

JAMES VOORHEIS (Presenter), VASYL S TYBERKEVYCH, Oakland University — Neuromorphic signal processing is one of the most promising post-Von Neumann computational paradigms [1]. Recently, it was proposed that antiferromagnetic (AFM) spin Hall oscillators, operating in a sub-critical regime, can function as ultra-fast artificial neurons [2, 3]. One of the characteristic features of AFM neurons is the inertial nature of their dynamics: a sufficiently large input spike may induce not one, but several output spikes. Here, we show that this feature can be used for effective encoding and decoding of information from conventional binary to neuromorphic format. The neuromorphic encoder has several inputs, which represent information in parallel binary format, and one output neuron, which produces a train of several spikes. The number of spikes produced by the output neuron equals the input binary code. The decoder reverses this operation, splitting one multi-train input into several binary outputs. The proposed neuromorphic encoder/decoder can be used as an interface between neuromorphic and conventional circuits.

12:15PM S39.00006: Voltage controlled memory device based on fixed magnetic skyrmions*  DHRITIMAN BHATTACHARYA (Presenter), Virginia Commonwealth University, SEYED ARMIN RAZAVI, HAO WU, KANG L. WANG, University of California, Los Angeles, JAYASIMHA ATULASIMHA, Virginia Commonwealth University — Manipulating static magnetic skyrmions with voltage control of magnetic anisotropy (VCMA) can be utilized to design energy efficient memory devices with reduced device footprint. Using micromagnetic simulation, we demonstrate such devices. With application of a sequential positive and negative voltage pulse, two skyrmionic (core-up and core-down) and two ferromagnetic (up and down) states can be achieved [1]. Further, starting from a ferromagnetic state, a voltage pulse that reduces PMA can induce reversal via skyrmion breathing [2]. As a proof of concept experiment, we demonstrate such VCMA induced manipulation of magnetic skyrmions in an antiferromagnet/ferromagnet/oxide heterostructure film. We observed annihilation of skyrmions while increasing PMA and formation of more skyrmions by reducing PMA. This reversible creation and annihilation of skyrmions could potentially lead to novel skyrmion based memory devices.

*D.B and J.A acknowledge NSF CAREER grant CCF-1253370, VCU Quest Commercialization Grant and Virginia Microelectronics Seed Grant. S. A. R., H. W., and K. W. acknowledge NSF (ECCS 1611570) and NSF-TANMS.

12:27PM S39.00007: YIG-based microwave magnonic circuits at millikelvin temperatures*  ALEXY KARENOWSKA (Presenter), SANDOKO KOSEN, ARJAN F. VAN LOO, University of Oxford — The experimental exploration of microwave magnonic systems at millikelvin temperatures has attracted significant recent interest. Work in this area is motivated both by the desire to better understand the behaviour and physics of these systems at very low temperatures, and their potential application in solid-state quantum information processing. In this talk, we explore recent experimental results from a range of investigations into the low-temperature properties of yttrium iron garnet (YIG) -based magnonic systems [1-4]. We discuss related technical and materials considerations relevant to successful quantum magnonic experiments, and offer a perspective on future work in this area

*The authors acknowledge EPSRC grant EP/K032690/1 and SK is grateful for the support of LPDP Indonesia.

12:39PM S39.00008: Broadband communication and information processing with edge spin waves*  FARKHAD ALIEV (Presenter), ANTONIO LARA, DIEGO CASO, CESAR GONZALEZ-RUANO, Autonomous University of Madrid, KONSTANTIN GUSLIENKO, , Universidad del País Vasco and Ikerbasque, the Basque Foundation for Science, JOSE LUIS PRIETO, Universidad Politecnica de Madrid — Spin waves, being usually reflected by domain walls, could also be channeled along them. Here we discuss quasi one-dimensional spin waves in Permalloy dots of different geometries and in different magnetic states. Recent studies allowed observation of spin waves along domain walls in rectangular, circular [1] and triangular dos in the ground or metastable states. Triangular dots could also present edge pinned inhomogeneous magnetic states, depending on the direction of the external magnetic field. These edge domain walls yield the interesting, and potentially applicable to real devices property of broadband spin waves confinement to the edges of the structure [2,3] with capabilities to be redirected at angles exceeding 100 degrees. We also show how these waves could be generalized for arbitrary shapes and propose few devices (such as edge spin wave interferometers, controllers or splitters) where edge spin waves could be implemented. Aliev, Scientific Reports, 7: 5597 (2017).

the drive frequency matches with $f_0$. These novel phenomena can be used to realize coupled oscillatory nanomagnets faster, analogous to temperature annealing. We further demonstrate the phenomenon of stochastic resonance in our underlayer. Depending on the polarity and strength of the feedback, the magnetization fluctuation becomes slower or unstable nanomagnets with weak perpendicular anisotropy made from Ta/CoFeB/MgO stack. The magnetization of such nanomagnets shows random telegraphic fluctuation with a mean that is tunable by the giant spin Hall effect (GSHE) current generated in the Ta underlayer. These nanomagnets form stochastic oscillators with a natural frequency $f_0$, given by $f_0 = (t_{up} + t_{dn})^{-1}$, where $t_{up}$ and $t_{dn}$ are the average dwell time of the magnetization in the “up” and “down” state. We demonstrate tuning of $f_0$ of individual nanomagnets by electrical feedback of the magnetization state to the GSHE underlayer. Depending on the polarity of the feedback, the magnetization fluctuation becomes slower or faster, analogous to temperature annealing. We further demonstrate the phenomenon of stochastic resonance in our nanomagnets, where the magnetization follows a weak external periodic drive through the GSHE underlayer only when the drive frequency matches with $f_0$. These novel phenomena can be used to realize coupled oscillatory nanomagnet networks with dynamic connectivity, which alleviates the full connectivity requirement in a network of $N$ oscillators from $N^2$ weighted connections to $N$ homogenous connections.

1:15PM S39.00011: Electrical annealing and stochastic resonance in superparamagnets for oscillatory networks with dynamic connectivity PUNYASHLOKA DEBASHIS (Presenter), PRAMEY UPADHYAYA, ZHIHONG CHEN, Electrical and Computer Engineering, Purdue University — In this work, we report electrical annealing and stochastic resonance in thermally unstable nanomagnets with weak perpendicular anisotropy made from Ta/CoFeB/MgO stack. The magnetization of such nanomagnets shows random telegraphic fluctuation with a mean that is tunable by the giant spin Hall effect (GSHE) current generated in the Ta underlayer. These nanomagnets form stochastic oscillators with a natural frequency $f_0$, given by $f_0 = (t_{up} + t_{dn})^{-1}$, where $t_{up}$ and $t_{dn}$ are the average dwell time of the magnetization in the “up” and “down” state. We demonstrate tuning of $f_0$ of individual nanomagnets by electrical feedback of the magnetization state to the GSHE underlayer. Depending on the polarity and strength of the feedback, the magnetization fluctuation becomes slower or faster, analogous to temperature annealing. We further demonstrate the phenomenon of stochastic resonance in our nanomagnets, where the magnetization follows a weak external periodic drive through the GSHE underlayer only when the drive frequency matches with $f_0$. These novel phenomena can be used to realize coupled oscillatory nanomagnet networks with dynamic connectivity, which alleviates the full connectivity requirement in a network of $N$ oscillators from $N^2$ weighted connections to $N$ homogenous connections.

1:27PM S39.00012: Fabrication and programming of nanomagnet arrays for nanoscale magnetic field synthesis Tzu-Ming Lu (Presenter), Ezra Bußmann, Sandia National Laboratories — Nanoscale magnetic field synthesis finds applications in band structure engineering, nano-particle manipulation, and local spin resonance. In the presence of a 1D spatially rotating magnetic field, the band structure of a 1D electron system without spin-orbit coupling can be engineered such that an effective spin-orbit (SO) gap appears in the energy dispersion. Inside the effective SO gap the spin degeneracy is removed. We present our results on fabricating nanomagnet arrays using two magnetic materials with distinct coercivities, programming the nanomagnet arrays using a global external magnetic field, and characterizing the magnetization configuration using magnetic force microscopy.

*This work was supported by the Laboratory Directed Research and Development Program at Sandia National Laboratories, and was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE, Office of Basic Energy Sciences user facility. 1:39PM S39.00013: Magnetic tunnel junction synapses for neuromorphic computing  
BENJAMIN MADON (Presenter), M A MUEED, NOEL ARELLANO, BRIAN HUGHES, IBM Research, Almaden, San Jose, California 95120, United States, MATTHIEU GRELIER, ANGELO COUTO, ESPCI, Paris, 75005, France, ERIC BILLAUD, Ecole polytechnique, Palaiseau, 91128, France, SPENCER MATONIS, University of Connecticut, Storrs, Connecticut, 06269, United States, AAKASH PUSHP, IBM Research, Almaden, San Jose, California 95120, United States — Deep learning algorithms are now widely used. However, the amount of computation power they require to run on conventional CMOS electronics remains high. Consequently, there is an important need for specialized fast and energy-efficient processors tailored for deep learning. We believe that magnetic tunnel junctions in a crossbar array potentially have all the required characteristics of an ideal synapse: high resistance (kOhms), gigahertz speed and symmetric and bi-directional partial switching behavior.

Following up on the pioneering work of Lequeux et al. [1], we have studied different device geometries and material sets. Here we demonstrate nanodevices with resistances on the order of several kiloohms in which several intermediate resistance steps were obtained and their controlled partial switching behavior were achieved using nanosecond pulses.

1:51PM S39.00014: Magnetoelectric device read-out schemes based on electric resistivity measurements in heavy metal Hall bar structures*

ATHER MAHMOOD (Presenter), WILL ECHTENKAMP, JUNLEI WANG, CHRISTIAN BINEK, University of Nebraska - Lincoln — Controlling magnetism by electrical means is a key challenge in the field of spintronics and essential for energy efficient devices in computing. Previously suggested magnetoelectric MRAMs suffer from detrimental effects associated with the magnetization reversal of a ferromagnetic layer. Eliminating a ferromagnet reduces the energy-delay product by eliminating the need to reverse a ferromagnet and us the intrinsically high switching speed of antiferromagnets (AFM). We study the electrically-controlled boundary magnetization of the AFM magnetoelectric (ME) chromia in thin films using Pt as a sensing layer. We provide evidence that the main contribution to the anomalous Hall effect (AHE)-signal in chromia/heavy metal (HM) devices originates from spin Hall magnetoresistance and not from the proximity induced magnetization in the HM. To accomplish this, we investigate the temperature, magnetic field, and Pt-thickness dependence of the transverse and longitudinal resistivity. Our results promise a pathway to optimize AHE readout, overcoming energy-delay constraints accompanying magnetization reversal in ferromagnets.

2:03PM S39.00015: Anderson localization in transition metal oxides and its application in neuromorphic circuitry*

CHRISTOPHER SINGH (Presenter), Binghamton University, KEITH T BUTLER, ISIS Neutron and Muon Source, Rutherford Appleton Laboratory, WEI-CHENG LEE, Binghamton University — It has become increasingly clear that the performance of modern computing architectures is reaching a quantum mechanical road-block, and that neuromorphic computing, a brain inspired computing model, is a very promising paradigm in going beyond the von Neumann computing architecture. At the very core of this technology, is the ability to induce fast, reversible metal-insulator transitions. We propose that Anderson localization in select transition metal oxides can be exploited to design a new generation of memristors. Utilizing toy models as well as first principles descriptions of niobium and vanadium oxide structures, we show that disordering the system can be leveraged to engineer the metal insulator switching, a key physical mechanism in the construction of modern day neuromorphic circuits. Furthermore, we demonstrate that a simple metric of eigenstate localization, the Gini vector, can be an efficient way to capture the localization properties in a first-principles tight binding model.

11:15AM S40.00001: Emergent electronic phases in Ruddlesden-Popper chromium oxide perovskites*
RICCARDO COMIN (Presenter), ZHIHAI ZHU, JONATHAN PELLICIARI, JIARUI LI, Massachusetts Institute of Technology, CHRISTIE NELSON, Brookhaven National Laboratory — Chromium-based compounds realize a multitude of electronic and magnetic phases: half-metals (CrO$_2$), ferromagnetic insulators (CrI$_3$, YCrO$_3$), antiferromagnetic insulators (Cr$_2$Se$_3$, CrSe$_2$, Cr$_2$O$_3$ and LaCrO$_3$), or antiferromagnetic metals (Cr and SrCrO$_3$). These compounds, whose magnetic transitions are often near room temperature, represent a far less charted platform for emergent quantum matter compared to their other 3$d$ transition metal siblings.

Low-dimensional perovskites of tetravalent chromium deserve particular attention as they uniquely realize a strongly-correlated electron system with $d^2$ electronic configuration and active spin and orbital degrees of freedom. Antiferromagnetism is ubiquitous in these systems, but recent theoretical studies indicate the presence of proximate electronic phases, including orbital order and superconductivity. These materials cannot be easily stabilized in bulk form and in the Cr$^{4+}$ oxidation state (with spin $S=1$) but could host interesting new phenomena enabled by the strong interplay of spin, charge, and orbital degrees of freedom.

To explore these scientific opportunities, we have grown thin films of various members of the Ruddlesden-Popper series of chromium oxide perovskites: SrCrO$_3$, Sr$_2$CrO$_4$, and Sr$_4$Cr$_3$O$_{10}$. In this talk, I will report on the synthesis and characterization of their transport and magnetic properties, including recent investigations of spin and orbital ordering in the ground state of these materials.

*This work was supported primarily by the MRSEC Program of the National Science Foundation under award number DMR - 1419807.

11:51AM S40.00002: Rh-based Double Perovskites with Unusual Properties: A computer prediction*
TANUSRI SAHA-DASGUPTA (Presenter), Indian Association for the Cultivation of Science, ANITA HALDER, S.N. Bose National Centre for Basic Sciences, PRABUDDHA SANYAL, Indian Institute of Technology, Roorkee — Using a combination of computational tools involving genetic algorithm, denisty functional theory and finite temperature Monte Carlo simulation, we make prediction on yet-to-be synthesized Rh-based double perovskites with novel properties. Interestingly while some of the predicted compounds show half-metallic ferromagnetic behavior, the rest show rare antiferromagnetic metallic properties. This makes this series of compounds a promising class of magnetic materials which need to be synthesized and investigated further.

*The authors acknowledge the computational resources created through funding of Nano-mission of Department of Science and Technology, India.

12:03PM S40.00003: Transition between two metallic ferroelectric orders in multiferroic Ca$_3$Ru$_2$O$_7$, induced by magnetism-mediated orbital re-polarization
ZHETING JIN (Presenter), WEI KU, Tsung-Dao Lee Institute & School of Physics and Astronomy, Shanghai jiao Tong University — For the past decades, the low-temperature phase of Ca$_3$Ru$_2$O$_7$ below the 48K first-order phase transition remains a puzzle with controversial suggestions involving metallic ferroelectric, orbital or magnetic ordering.

Through analysis of experimental lattice structure, density functional theory calculation, and effective model analysis, we propose that the 48K phase transition is a bond formation transition promoted by the magnetism mediated orbital re-polarization. Most interestingly, this transition is accompanied by a switch of two metallic ferroelectric orders from a $xy+y$ symmetry to $xz+z$.

Our study not only resolves a long-standing puzzle of this phase transition in this material, but also demonstrates perhaps the first example of transition between multiple emergent ferroelectric orders in bad metals, resulting from interplay between multiferroic orders.
12:15PM S40.00004: Electronic correlations in early transition metal oxides with oxygen vacancies*  JAIME SOUTO
CASARES (Presenter), NICOLA SPALDIN, CLAUDE EDERER, ETH Zurich — Oxygen vacancies are known to affect profoundly the
properties of the host system, coupling to the already coupled degrees of freedom. Electronically, in early transition metal
oxides, the presence of oxygen vacancies locates electronic states in the gap between the transition metal t_{2g} band and
the oxygen p-band, with occasional occurrences of crossings with the t_{2g}-band. The closeness and influence of the vacancy
band on the correlated electronic bands calls for a beyond-DFT analysis. Constructing an extended t_{2g} correlated subspace
where the oxygen vacancy state is explicitly consider, we have performed dynamical mean-field theory (DMFT) and
constrained random phase approximation (cRPA) calculations for three different lanthanum transition metal oxides with
different t_{2g}-occupations (LaBO_{3}, with B={Ti(d^{1}), V(d^{2}), Cr(d^{3})}) in order to investigate what is the effect of the vacancy on
the Mott insulating phase, and to monitor how the ab-initio effective Coulomb interaction parameters change.

*Work supported by the Swiss National Science Foundation, NCCR MARVEL.

12:27PM S40.00005: An ab-initio DFT+DMFT study of the effect of oxygen vacancies on structural, electronic and
magnetic properties of rare-earth nickelate perovskites (RNIo_{3})*  UTHPALA HERATH (Presenter), West Virginia University,
HYOWON PARK, Physics, University of Illinois at Chicago, ALDO H ROMERO, West Virginia University — The electronic correlations
in materials are responsible for a variety of fascinating phenomena including magnetism, superconductivity, colossal
magneto-resistance and metal-insulator transitions. As shown in previous studies, the ability to manipulate the oxygen
vacancies within these strongly correlated materials gives rise to new degrees of freedom in tuning their properties. We
employ ab-initio density functional theory (DFT) coupled to dynamical mean field theory (DMFT) calculations to
systematically study the influence of oxygen vacancies on structural, electronic and magnetic properties of strongly
correlated rare-earth nickelates, RNIo_{3} (R=rare earth element). The DFT Kohn-Sham orbitals are projected onto maximally
localized Wannier Functions within a hybridization window to provide the correlated subspace for the DMFT problem
which is solved using a continuous time quantum Monte-Carlo (CTQMC) algorithm. Based on our calculated results we
elucidate the role of oxygen vacancies on the material properties also focusing their effects on individual orbitals, which
thus far has not been studied extensively in the case of strongly correlated rare earth nickelate perovskites.

Columbia, and the Quantum Materials Fund.

12:39PM S40.00006: The Electronic Structure and Properties of Negative Charge Transfer Compounds*  ROBERT
GREEN (Presenter), University of British Columbia; University of Saskatchewan, GEORGE ALBERT SAWATZKY, University of British
Columbia — In high oxidation state oxides like the trivalent nickel oxides, tetravalent cobalt and iron oxides as well as the
parent superconductors BaBiO3 and SrBiO3, the cation electron affinity for the formal valence taking oxygen to be 2- can
result be larger than the oxygen ionization potential. This leads to a so-called negative charge transfer energy, where the
cations are more accurately described with reduced valences and the oxygen states are self-doped with holes. As a
consequence, one can have very different electronic structures and x-ray spectra than expected from the formal oxidation
state picture. We demonstrate that with this in mind we can very well explain many of the properties and phases of the
trivalent nickelates and tetravalent ferrates. Utilizing the negative charge transfer approach in cluster exact diagonalization
calculations resolves a 25 year old puzzle concerning core level spectra of nickelates, and reveals interesting orbital
polarization phenomena in strained nickelate and ferrate films.

*This research was supported by NSERC and the Max-Planck-UBC-UTokyo Center for Quantum Materials.

12:51PM S40.00007: Evolution of Antiferromagnetism with Hole Doping in HgBa_{2}Ca_{2}Cu_{3}O_{6}: A Parameter Free
Perspective  CHRISTOPHER LANE (Presenter), Northeastern University, YUBO ZHANG, Tulane University, MATTHEW MATZELLE,
Northeastern University, JOHANNES NOKELAINEN, LUT, JAMES FURNESS, Tulane University, ROBERT MARKIEWICZ, Northeastern
University, BERNARDO BARBIELLINI, LUT / Northeastern Univ, JIANWEI SUN, Tulane University, ARUN BANSIL, Northeastern
University — Since the discovery of the cuprates 33 years ago, connecting their physical properties to their electronic
structure has proven extremely challenging to capture within a uniform theoretical picture. Here, by utilizing the recently
constructed SCAN metaGGA, we show how the charge, spin and lattice degrees of freedom of HgBa_{2}Ca_{2}Cu_{3}O_{6+δ} evolve
with oxygen hole doping. Both the layer and doping dependence of our theoretically predicted antiferromagnetic order
are in good agreement with NMR observations. In particular, a local maximum in the number of holes in the CuO_{2} plane is
found in agreement with near optimal δ=0.16 doping for high-T_{c} superconductivity. Additionally, we find the doped
interstitial oxygens play a consequential role at the Fermi level throughout the phase diagram, indicating the importance
of inter-layer coupling between the CuO_{2} planes and the charge reservoir layer.
1:03PM S40.00008: Antiferromagnetism in a rocksalt high entropy oxide*  JUNJIE ZHANG (Presenter), JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, STUART CALDER, Neutron Scattering Division, Oak Ridge National Laboratory, QIANG ZHENG, ERICH T. VON GEIS, Materials Science and Technology Division, Oak Ridge National Laboratory, DOUGLAS L ABERNATHY, Neutron Scattering Division, Oak Ridge National Laboratory, YANG REN, SAUL H. LAPIDUS, Advanced Photon Source, Argonne National Laboratory, KATHARINE L. PAGE, Neutron Scattering Division, Oak Ridge National Laboratory, HONG ZHENG, Materials Science Division, Argonne National Laboratory, JOHN WILLIAM FREELAND, Advanced Photon Source, Argonne National Laboratory, JOHN D BUDAI, RAPHAEL HERMANN, Materials Science and Technology Division, Oak Ridge National Laboratory — High entropy oxides have attracted much attention because they not only significantly broaden the phases beyond the conventional phase diagram of doping, but also have the potential to exhibit multifunctional physical properties and emergent phenomena including superconductivity and quantum criticality [1-3]. The existence of extreme chemical disorder in these materials is expected to suppress the long range magnetic order. Here, by combining magnetometry, synchrotron x-ray and neutron powder diffraction, we report for the first time that a rocksalt high entropy oxide exhibits long range antiferromagnetic order at ~120 K with q=(½, ½, ½). Inelastic neutron scattering reveals strong magnetic excitations at 100 K that survive up to room temperature. The shear modulus obtained from resonant ultrasound spectroscopy shows an anomaly around the magnetic transition, and surprisingly it hardens with decreasing of temperature without saturation down to 3 K. 1:15PM S40.00009: The effect of the Co-O covalency on the spin-state ordering in LaCoO3: A DFT+DMFT study  HYOWON PARK (Presenter), University of Illinois at Chicago, RAVINDRA R NANGUNERI, Brown University — We investigated the effect of the Co-O covalency on the spin-state transition in LaCoO3 using the charge-self-consistent density functional theory plus dynamical mean field theory (DFT+DMFT) method implemented using the maximally localized Wannier functions as basis sets. The strong covalent bonding between Co and O produces the occupancy of the Co d orbital as d7 with one hole in the O ion when computed using DFT+DMFT with the fully localized form of the double counting potential. The effect of the Co-O covalency is studied by changing the double counting potential within DFT+DMFT for both homogeneous and the mixed high/low spin states. The total energy calculation of DFT+DMFT shows that the low-spin state is the lowest in energy for the d occupancy close to 7 while the spin-state ordering (high and low spins) between two Co ions occurs when the d occupancy is below 6.7 as the Co-O covalency is reduced. The valence histogram in DFT+DMFT shows that the charge ordering also occurs for the spin-state ordered LaCoO3 as the higher spin state Co ion has a higher d6 configuration than the low-spin state Co ion does. Both the charge and the energy differences between the homogeneous and the spin-state ordered phases are smaller in DFT+DMFT compared to DFT+U results.

1:27PM S40.00010: Spontaneous non-stoichiometry and ordering of metal vacancies in degenerate transparent conductive oxides*  OLEKSANDR MALYI (Presenter), University of Oslo, MICHAEL T. YEUNG, KENNETH POEPPELMEIER, Northwestern University, CLAS PERSSON, University of Oslo, ALEX ZUNGER, University of Colorado Boulder — The existence of non-stoichiometry in oxides is often thought to be a growth effect rather than a specific electronic instability. We show via DFT calculations that the presence of electrons in the conduction band of insulators can destabilize materials with respect to the spontaneous formation of cation vacancy acceptors. These tendencies result ultimately in the formation of ordered vacancy compounds (OVCS). For Ca-Al-O and Ba-Nb-O, we find that OVCS with different stoichiometries I:m:n are stable under different ranges of elemental chemical potentials, controllable during synthesis. Since each I:m:n OVC depletes the conduction band of electrons by a different amount, the formation of OVCS can be used to reduce plasma absorption, modify interband absorption, and enhance materials stability. This clarifies how non-stoichiometry often seen in oxides is an electronic effect — a high Fermi energy induces the formation of electron-killer acceptors such as cation vacancies. This also provides insights into the stability of the transparent conductive states while pointing out that controllable formation of non-stoichiometric degenerate insulators can be used to design next-generation transparent conductive oxides.

1:39PM S40.00011: Magnetic percolation transition in diluted hexaferrites* CAMERON LERCH (Presenter), THOMAS VOJTA, Missouri University of Science and Technology — The hexagonal ferrites BaFe₁₂O₁₉, SrFe₁₂O₁₉ and PbFe₁₂O₁₉ are ferrimagnets with Neel temperatures of approximately 720K that also show interesting ferroelectric properties. By randomly substituting Ga ions for the Fe ions, the Neel temperature can be suppressed to zero. Recent experiments [1] have found the phase boundary to vary as \( T_N \sim (1 - x/x_c)^{2/3} \) over a wide x range, with \( x_c \) very close to the percolation threshold of the iron spins. The shape of the phase boundary in the neighborhood of \( x_c \) does not agree with current theoretical predictions for a classical percolation transition. We investigate the shape of the low-temperature phase boundary close to the percolation threshold using large-scale Monte Carlo simulations of a three-dimensional site-diluted Heisenberg model.

*This work was supported in part by the NSF under Grants Nos. DMR-1506152 and DMR-1828489.

1:51PM S40.00012: Variations in the Magneto-optical Properties of CuAl₁₋ₓFeₓO₂ with Fe Concentration MINA AZIZIHA (Presenter), JAMES PATRICK LEWIS, Department of Physics and Astronomy, West Virginia University, SETH A BYARD, Department of Physics, Grove City College, MOHINDAR S SEEHRA, MATTHEW BRUCE JOHNSON, Department of Physics and Astronomy, West Virginia University — CuAlO₂ is among several ternary delafossites in which the electronic bandgap (2.68 eV) is less than the optical bandgap (3.5 eV). Because alloying is expected to allow band engineering in delafossites, we are investigating magneto-optical properties of CuAl₁₋ₓFeₓO₂ for \( x = 0 \) to1. The samples were prepared by solid-state reaction in air. X-ray diffraction of the powder samples shows an expansion of the rhombohedral unit cell with increasing \( x \), in accordance with Vegard’s Law. X-ray photoelectron spectroscopy, and SEM-based energy dispersive (x-ray) spectroscopy were also used to confirm the Fe concentrations. Analysis of the magnetization (\( M \)) vs. temperature data (\( T = 2 \) to 300 K) and magnetic field (up to \( H = 90 \) kOe) verifies Fe³⁺ as the electronic state of Fe and Fe³⁺-Fe³⁺ exchange coupling signifies anti-ferromagnetism for CuAl₁₋ₓFeₓO₂ for \( x = 0 \) to 0.1. The high-resolution M vs. H hysteresis loop measurements done at 300 K and 10 K shows some hysteresis, particularly for the \( x = 0.1 \) sample. However, it is concluded that this hysteresis is due to hematite impurity which is not detectable in the XRD analysis of the samples. In this talk, we will specifically report on magnetic measurements of CuAl₁₋ₓFeₓO₂ for \( x > 0.1 \) and optical absorption studies in the CuAl₁₋ₓFeₓO₂ samples.

2:03PM S40.00013: Anti-doping in Insulators and Semiconductors* QIHANG LIU (Presenter), Department of Physics, Southern University of Science and Technology, Shenzhen, China, GUSTAVO DALPIAN, ALEX ZUNGER, RASEI, University of Colorado, Boulder, US — Ordinary doping by electrons (holes) generally means that the Fermi level shifts towards the conduction band (valence band) and that the conductivity of free electrons (holes) increases. Recently, however, some peculiar doping characteristics were sporadically recorded in different materials without noting the mechanism: electron doping was observed to increase the band gap and thus lead to a decrease in conductivity. This behavior we dub as “anti-doping” was seen in rare-earth nickel oxides SmNiO₃, cobalt oxides SrCoO₂₋₅, Li-ion battery materials and even MgO with metal vacancies. Given the apparent generality of this phenomenon and that it may offer an unconventional way of controlling conductivity, we demystify the physical origin of anti-doping as well as its inverse problem – the “design principles” that would enable intelligent search of materials. We find that electron anti-doping is expected in materials having pre-existing trapped holes and is caused by annihilation of such “hole polarons” via doping.

Thursday, March 7, 2019 11:15 AM - 2:15 PM

Session S41 GMAG DMP: Spin-Transfer and Spin-Orbit Torques

BCEC 209 - Luqiao Liu, Massachusetts Institute of Technology - Tag(s): Focus
First-principles calculation of spin-orbit torques in ferromagnet/heavy-metal bilayers

KIRILL BELASHCHENKO (Presenter), ALEXEY KOVALEV, University of Nebraska - Lincoln, MARK VAN SCHILFGAARDE, King's College London — The spin-orbit torque in Co/Pt, Co/Pd, and Co/Au bilayers is calculated using a first-principles non-equilibrium Green's function formalism with an explicit treatment of disorder. The torque is formally split in the Fermi-sea and Fermi-surface contributions. The Fermi-sea term is important at low temperatures, but the Fermi-surface term dominates at room temperature. In addition to the usual damping-like and field-like terms, the odd torque contains a sizeable planar Hall-like term \( mE \times (z \times m) \), which contributes to damping and has been observed experimentally. While the torques that contribute to damping are largely due to spin-orbit coupling on the heavy-metal atoms, the field-like torque does not require it. The dependence of the torque on the thicknesses of the layers is also examined.

Deterministic spin-orbit torque switching via structural engineering

TIANYUE CHEN, HSIN-I CHAN, WEI-BANG LIAO, CHI-FENG PAI (Presenter), National Taiwan University — Current-induced spin-orbit torque (SOT) can be employed to control magnetization in magnetic random-access memory (MRAM) with perpendicular magnetic anisotropy (PMA), but typically requires an applied in-plane magnetic field. To eliminate the need of this applied field and achieve better on-chip memory designs, we deposit 4d transition metal Mo in a canted way as the SOT source. Although the spin-orbit interaction in Mo is weaker than in 5d metals such as Pt, W, or Ta, deterministic switching can still be achieved. This result suggests that growth configuration can play a more important role than material selection in some cases, which could really impact the engineering of next-generation field-free SOT-MRAM.

*This work was partly supported by the Ministry of Science and Technology of Taiwan under grant No. MOST 105-2112-M-002-007-MY3 and by the Center of Atomic Initiative for New Materials (AI-Mat), National Taiwan University, from the Featured Areas Research Center Program within the framework of the Higher Education Sprout Project by the Ministry of Education (MOE) in Taiwan under grant No. NTU-107L9008.

Spin-Orbit Torque Switching in Asymmetric Structures with Double Non-Magnetic Metal Layers

SEYED ARMIN RAZAVI (Presenter), Electrical and Computer Engineering, University of California, Los Angeles, GUOQIANG YU, Chinese Academy of Sciences, HAO WU, QIMING SHAO, KIN WONG, KANG-LUNG WANG, Electrical and Computer Engineering, University of California, Los Angeles — Spin-orbit torque (SOT) switching of magnetization is a promising emerging technology for non-volatile memory and logic applications. However, deterministic switching with SOTs requires breaking of inversion symmetry, usually provided by an external magnetic field, which is not suitable for applications. It has been shown that structures with lateral asymmetry can eliminate the need for external field and realize field-free SOT switching [1]. In this work we study field-free SOT switching in asymmetric structures with double non-magnetic metal layers, where current-induced out-of-plane effective fields are created. We break the structural symmetry by inserting a wedge-shaped second metallic layer between the ferromagnet and the first heavy metal. We investigate the creation and origin of current-induced out-of-plane effective fields, \( H_{\text{eff}} \), in various material systems (W/IrMn, W/Ta, Pt/IrMn, W/Ti), and we show the realization of field-free SOT switching in these structures. Our work provides a route for practical application of SOT devices and challenges the current understanding of the origins of SOTs in structures with lateral asymmetry.

11:51AM S41.00004: Strong Spin-Orbit Torques, Tunable DMI, and Variable Interfacial Spin-Orbit Coupling in Pt-based Spin Hall Metal/Ferromagnet Systems [Invited] LIJUN ZHU (Presenter), Cornell University, KEMAL SOBOTKIEWICH, XIN MA, XIAOQIN (ELAINE) LI, The University of Texas at Austin, DAN RALPH, ROBERT BUHRMAN, Cornell University — Recent work finds that the spin Hall effect in Pt is dominated by the intrinsic Berry phase effect. The internal spin Hall ratio $\theta_{SH}$ should be enhanced by alloying Pt with a component that raises the resistivity $\rho$ but does not materially reduce the spin Hall conductivity $\sigma_{SH}$. This talk will report on an extensive study of two fcc Pt alloys which establishes that for Au$_{1-x}$Pt$_x$(Pd$_{1-x}$Pt$_x$), at the optimal concentration $x \approx 0.25$, anti-damping spin-orbit torque efficiency $\xi_{DL} \approx 0.30$ (0.26) for $\rho = 83$ (57.5) μΩ cm at 4 nm thickness [1,2]. This indicates $\theta_{SH} \geq 0.58$ (0.47) and $\sigma_{SH} \approx 0.7(1) \times 10^6 \, \Omega^{-1} \text{m}^{-1}$; considerably larger than predicted by recent first principles-calculations. Moreover, the DMI at the Pt alloy/FM interface is both strong and tunable by composition over a wide range. These results establish Au$_{1-x}$Pt$_x$ and Pd$_{1-x}$Pt$_x$ as the most energy-efficient spin current generators for spin-torque manipulation of metallic FM systems and for chiral spintronics applications. The effect of interfacial spin-orbit coupling (ISOC) on the spin transparency of the Pt(alloy)/FM interface has also been examined through controlled variation of its strength through thermal annealing, revealing that ISOC at HM/FM interfaces should be minimized via interfacial passivation to maximize $\xi_{DL}$ [3,4].

12:27PM S41.00005: First Principles Study of Spin-Orbit Torque in Pt/Co and Pd/Co Bilayers* FARZAD MAHFOUZI (Presenter), NICHOLAS KIOUSSIS, Physics and Astronomy, California State University, Northridge — Spin-orbit torque (SOT) induced by spin Hall and interfacial effects in heavy metal(HM)/ferromagnetic(FM) bilayers has recently been employed to switch the magnetization direction using in-plane current injection. In this work, using the Keldysh Green’s function approach and first principles electronic structure calculations we determine the Field-Like (FL) and Damping-Like (DL) components of the SOT for the HM/Co (HM = Pt, Pd) bilayers. We investigate the effects of HM and FM thicknesses, strain, oxidation as well as rigid shift of the chemical potential on the SOTs. We compare the HM thickness dependence and also effect of oxigen in the FM with the experimental results where we see an overall good agreement. The dependence of the SOT on the position of the Fermi level suggests that the DL-SOT dominated by the Spin Hall effect of the bulk HM.

12:39PM S41.00006: Excitation and Amplification of Propagating Spin Waves by Spin-Orbit Torque* BORIS DIVINSKIY, VLADISLAV DEMIDOV, SERGEY DEMOKRITOV, Physics, University of Muenster, SERGEI URAZHDIN (Presenter), RYAN FREEMAN, Emory University — Spin-orbit torque (SOT) produced by electric current is among the cornerstones of modern nanomagnetism. However, until now SOT could not be utilized for the generation of propagating spin waves for magnonic (spin wave-based) applications.

We experimentally demonstrate a SOT oscillator directly incorporated into a SOT-enhanced magnonic nano-waveguide. The studied nanostructure is based on a Permalloy(Py)/Pt bilayer patterned into a nanowire forming a spin-wave waveguide, with Py thickness reduced in a narrow notched region of the nanowire. SOT produced by dc electrical current in Pt induces coherent magnetization oscillations in the nano-notch region, emitting spin waves into the nanowire. We utilize spectrally- and spatially-resolved microfocus Brillouin Light Scattering (BLS) measurements to demonstrate unidirectional emission of coherent spin waves, controlled by the direction of the static magnetic field, and simultaneous enhancement of their decay length by SOT. The demonstrated system combines all the advantages provided by the SOT, and can be used as a building block for novel integrated spin-orbit magnonic nano-circuits.

work we compute the spin-mixing conductance for Co/Bi\textsubscript{2}Se\textsubscript{3}, Co/Pt and Co/W junctions.

Functional theory combined with Floquet-nonequilibrium-Green function formalism [Phys. Rev. B] as the pre-factor of spin current vs. precession cone angle dependence, where we compute spin current using density

well-defined when spin-orbit coupling is present directly at the interface. Nevertheless, an effective one can be extracted

phenomena have been observed recently in heavy metals and topological insulators, where the spin-orbit coupling plays

axial in-plane. We show that magnetic thin films interfaced with CdWO\textsubscript{4} have strong magnetic anisotropy induced by the

substrate with strong spin-orbit coupling whose symmetries can be restricted to a single mirror plane if cleaved with the b-

axis in-plane. We show that magnetic thin films interfaced with CdWO\textsubscript{4} have strong magnetic anisotropy induced by the

low-symmetry crystal structure. This anisotropy is strongly temperature-dependent, exceeding 200 Oe at low

temperatures. In addition, measurements of spin-orbit torque in such bilayers exhibit torque components that are

commensurate with the symmetry of CdWO\textsubscript{4}. This suggests an interfacial torque mechanism in which spin-polarized

electrons flowing within the magnetic layer and scattering from the insulating CdWO\textsubscript{4} can produce a spin-orbit torque

acting back on the magnetic layer.

Demonstration of a micron-scale spin-orbit-torque emitter for coherent magnonics

MICHAEL EVELT, Institute for Applied Physics and Center for Nonlinear Science, University of Muenster, 48149 Muenster, Germany, LUCILE SOUMAH, Unite Mixte de Physique, CNRS, Thales, Univ. Paris-Sud, Université Paris-Saclay, Palaiseau, France, ANATOLII BRONISLAVOVICH RINKEVICH, Institute of Metal Physics, Ural Division of RAS, Ekaterinburg 620108, Russia, SERGEJ DEMOKRITOV, Institute for Applied Physics and Center for Nonlinear Science, University of Muenster, 48149 Muenster, Germany, JAMAL BEN YOUSSEF, LABSTICC, UMR 6285 CNRS, Universite de Bretagne Occidentale, 29238 Brest, France, GREGOIRE DE LOUBENS, SPEC, CEA-Saclay, CNRS, Université Paris-Saclay, 91191 Gif-sur-Yvette, France, OLIVIER KLEIN, SPINTEC, CEA-Grenoble, CNRS and Université Grenoble Alpes, 38054 Grenoble, France, PAOLO BORTOLOTTI, VINCENT CROS, ABDELMADJID ANANE (Presenter), Unite Mixte de Physique, CNRS, Thales, Univ. Paris-Sud, Université Paris-Saclay, Palaiseau, France, VLADISLAV DEMIDOV, Institute for Applied Physics and Center for Nonlinear Science, University of Muenster, 48149 Muenster, Germany — Using micro-focus Brillouin light scattering (BLS), we experimentally demonstrate generation of coherent propagating magnons in ultra-thin magnetic-insulator films by spin-orbit torque induced by dc electric current [1]. We show that this challenging task can be accomplished by utilizing magnetic-insulator films with large perpendicular magnetic anisotropy (PMA) possessing ultra-low Gilbert damping ($\gamma = 8 \times 10^{-4}$ for 20 nm thick Bismuth substituted YIG [2]). Fine tuning of the PMA allows to exactly cancel the dipolar field (the effective magnetization $\mathbf{M}_{\text{eff}} = 0$). As a result, the usually observed non-linear shift of the auto-oscillation frequency is suppressed. Hence, the dominant mechanism for self-localization of the auto-oscillations is inhibited. We demonstrate simple and versatile spin-orbit torque devices, which can be used as highly efficient nanoscale sources of coherent propagating magnons for insulator-based spintronic applications.

1:15PM S41.00009: Spin mixing conductance of ferromagnet/topological-insulator and ferromagnet/heavy-metal bilayers with strong interfacial spin-orbit coupling: A first-principles time-dependent quantum transport approach

KAPILDEB DOLUI (Presenter), UTKARSH BAJPAI, BRANISLAV NIKOLIC, University of Delaware — Spin pumping and related phenomena have been observed recently in heavy metals and topological insulators, where the spin-orbit coupling plays an essential role. Conventional spin mixing conductance, which governs the magnitude of pumped spin current, is not well-defined when spin-orbit coupling is present directly at the interface. Nevertheless, an effective one can be extracted as the pre-factor of spin current vs. precession cone angle dependence, where we compute spin current using density functional theory combined with Frouquet-nonequilibrium-Green function formalism [Phys. Rev. B 85, 05446 (2012)]. In this work we compute the spin-mixing conductance for Co/Bi$_2$Se$_3$, Co/Pt and Co/W junctions.

1:27PM S41.00010: Correlation between resonance mode crossing and spin torque switching probability in magnetic tunnel junctions

CHRIS SAFRANSKI (Presenter), JONATHAN SUN, IBM T. J. Watson Research Center — We report on the effect of coupled free- and reference-layer dynamics on switching errors in a spin-torque switched magnetic tunnel junction. Perpendicularly magnetized magnetic tunnel junctions (MTJ) [1-3] are used for this study. The free layer switching speed and probability is related to magnetization dynamics as revealed by spin-torque driven, and thermal fluctuation-driven ferromagnetic resonance (STT- and Thermal-FMR) spectra. We investigate the probability in spin torque driven switching as a function of applied magnetic field, and compare with the STT- and thermal-FMR spectrum in the same field range. A nonmonotonic dependence of the switching probability on field and on bias-voltage is seen, correlating to STT-FMR mode-crossings between the free- and reference-layer spectra-lines. At field values corresponding to the intersections of free- and reference-layer spin wave modes, an increase of errors is observed in switching. Our results show that excitation of the reference layer’s dynamics can affect the MTJ’s net STT-switching probability.

**1:39PM S41.00011: Zero-Threshold Rectification Using Low-Barrier Magnets**

SHEHRIN SAYED (Presenter), EECS, University of California, Berkeley, KEREM Y CAMSARI, RAFATUL FARIA, SUPRIYO DATTA, ECE, Purdue University — Stable magnets with energy barriers (~40-60 kT) have been the center of focus for spintronics. Recently, low energy barrier magnets have attracted growing interest in the community for novel applications e.g. random number generation, stochastic oscillators, probabilistic computers, etc. Using experimentally benchmarked models [1,2], we show that the charge current induced spin voltage measurements, well-established for diverse materials with spin-orbit coupling, could be used for zero-threshold rectification when the stable magnet is replaced with a low barrier magnet either with an in-plane or perpendicular anisotropy. These experiments can be used to characterize such stochastic magnets and extract parameters that determine (i) spin-orbit torque induced magnetization pinning and (ii) the frequency band of rectification. We analytically determine this frequency band from angular momentum conservation principles. The proposed structure could find application as highly sensitive passive rf detectors and as energy harvesters from weak ambient sources where standard technologies may not operate.

**1:51PM S41.00012: Fermi surface of CrNb$_3$S$_6$: giant spin-orbit effect**

TATSUYA SHISHIDOU (Presenter), MICHAEL WEINERT, University of Wisconsin - Milwaukee — Chiral magnets are of particular interest because of their exotic magnetic and transport properties. In the case of CrNb$_3$S$_6$, the ground-state magnetic configuration is a planar flat spiral with a periodicity of 48nm along the hexagonal c axis. Moderate external fields ($H$) alter the spin texture into the chiral soliton lattice ($H \perp c$) or the chiral conical phase ($H \parallel c$). With increasing $H$, these phases continuously transform into forced ferromagnetic (FM) configurations that appear at $H \sim 0.2$ ($H \perp c$) and 2 Tesla ($H \parallel c$). Using a density functional theory approach, we investigate the FM state of CrNb$_3$S$_6$, paying particular attention to the spin-orbit coupling (SOC) and its effect on the electronic band structure and Fermi surface. Importantly, for some bands near the Fermi level, SOC introduces giant and peculiar first-order changes of the band energies when the magnetization is parallel to the c axis: the band dispersion appears to be shifted in k space. Consequently, the deformed Fermi surface has a highly asymmetric shape that could lead to nonreciprocal transport. Symmetry arguments and detailed analysis of SOC effects will be given.

**2:03PM S41.00013: Observations of large spin mixing conductance in poly(3-methylthiophene) polymer brushes/NiFe heterostructures**

ERIC VETTER (Presenter), North Carolina State University, IAN VONWALD, chemistry, university of north carolina at chapel hill, DALI SUN, North Carolina State University, WEI YOU, chemistry, university of north carolina at chapel hill — Observations of large inverse spin Hall effect (ISHE) in a fullerene (C$_{60}$) thin film – usually only appearing in metals and semiconductors with heavy elements - indicate that spin-orbit coupling in terms of spin Hall angles would be significantly influenced by chemical structure parameters, such as stacking and curvatures. Here, we report studies on the effective spin mixing conductance in ‘spun cast’ poly(3-hexylthiophene) (P3HT) and ‘polymer brush’ poly(3-methylthiophene) (P3MT) thin films using ferromagnetic resonance (FMR) and spin pumping techniques. P3HT and P3MT films were spun cast and self-assembly grown, respectively, onto ITO/glass substrates followed by NiFe. Frequency-dependent FMR and ISHE measurements were carried out on both films as a function of film thickness, from which the effective spin mixing conductances were obtained. We find that the P3MT films exhibit a large increase in the effective spin mixing conductance, in contrast to that in P3HT films. The large spin mixing conductance in the ‘polymer brush’ P3MT thin films is attributed to morphological differences as compared with the spun cast films.

**Session S42 DMP: Millie Dresselhaus’ Legacy in Nanoscience** BCEC 210A - Daniel Dessau, University of Colorado, Boulder - Tag(s): Invited

**11:15AM S42.00001: Nanoelectronic Tools for Brain Science** [Invited] CHARLES LIEBER (Presenter), Harvard University — TBD

**11:51AM S42.00002: Quantum Transport in 2D Materials and Heterostructures** [Invited] CHUN NING LAU (Presenter), Ohio State University — TBD
10:30AM S42.00003: Millie Dresselhaus and 2D Materials [Invited] ANTONIO HELIO CASTRO NETO (Presenter), National University of Singapore — TBD

1:03PM S42.00004: Millie Dresselhaus the Queen of Carbon: A Role Model, an Inspiration of Young Generations, a Mentor and Colleague [Invited] MAURICIO TERRONES (Presenter), Department of Physics, Pennsylvania State University — I will review the scientific impact Mildred S. Dresselhaus (Millie) had in the Physics of Carbon since her pioneering work on the magneto-optic response of graphite crystals to establish a proper identification of electrons and holes in the Brillouin zone. Undoubtedly, Millie was a major pillar in Carbon Science, and was widely recognized as the “Queen of Carbon”. She contributed to a variety of topics that include: 1) the physical properties of graphite, 2) the electronic structure of graphene and rolled graphene (known as carbon nanotubes), 3) physico-chemical properties of graphite intercalated compounds, 4) fullerenes and derivatives, 5) Li-ion batteries, 6) the fundamentals of Raman spectroscopy in different nano-carbons, 7) enhanced Raman effects caused by two dimensional (2D) materials, etc. Sadly, Millie departed in February 2017, but she left us with an incredible amount of Physics knowledge. She was and will always be an inspiration for women, young and well-established scientists. This talk will summarize her major scientific achievements, as well as some personal experiences with her close collaborators. Millie really enjoyed science and she had a clear admiration for carbon nanomaterials. Working on carbon for more than fifty years, Millie always got engaged in the scientific understanding of novel forms of carbon and provided a forward vision. She is a great loss for Science, but fortunately, she has left us with an incredible amount of scientific knowledge and lessons to learn.

1:39PM S42.00005: Millie Dresselhaus’ Legacy and Recent Advances in Thermoelectrics [Invited] GANG CHEN (Presenter), Massachusetts Institute of Technology — Thermoelectric phenomena such as the Seebeck and the Peltier effects have been exploited for solid-state power generation and cooling, but the efficiency values of thermoelectric devices are limited by the low thermoelectric figure of merit of available materials, which is proportional to the electrical conductivity and the square of the Seebeck coefficient but inversely proportional to the thermal conductivity. These properties of a material in most cases are strongly contradictory to each other, limiting advances in the field. In 1993, Millie Dresselhaus published two pioneering papers on exploiting quantum size effects in 2D and 1D quantum structures to improve thermoelectric figure of merit (PRB, 47, 12727; 47, 16631, 2013). These papers played a significant role in reinvigorating the field of thermoelectrics, stimulating worldwide research in improving existing thermoelectric materials and searching for new ones. Since then, the field has evolved significantly, and new ideas and concepts have emerged and the materials figure of merit has seen significant improvements. This presentation will start with a summary of Millie’s contributions to the field, followed by a critical review of other successful ideas that have emerged, together with some discussion of novel electron and phonon transport physics emerged in advancing materials.

Thursday, March 7, 2019 11:15 AM - 2:15 PM

Spin-wave excitations, confinement, and coupling in high-quality organic-based magnetic structures* [Invited] MICHAEL CHILCOTE (Presenter), Ohio State University — The study of coherent magnonic interactions relies implicitly on the ability to excite and exploit long lived spin wave excitations in a magnetic material. Surprisingly, the organic-based ferrimagnet vanadium tetracyanoethylene (V[TCNE]x; x ≈ 2) has recently emerged as a low-loss material and offers a compelling alternative to yttrium iron garnet (YIG). Here, we present the synthesis of a new class of organic-based magnetic nanostructures consisting of nanowires of V[TCNE]x that assemble along the ridges of a grooved substrate. These nanowires exhibit uniaxial magnetic anisotropy with an in-plane easy axis perpendicular to the nanowires, which is in direct contrast to the isotropic in-plane response of typical thin-films. These nanostructures support the excitation of multiple modes, and when these different magnon modes are brought into resonance by varying the orientation of an in-plane magnetic field, we observe anticrossing behavior, indicating strong coherent coupling between the excitations. Furthermore, micromagnetic simulations using real nanowire profiles extracted from cross-sectional scanning electron microscopy faithfully reproduce the experimentally measured spectra without any free parameters, including spin-wave and other higher-order modes. Additionally, we use this data to explore the origin of the induced anisotropy in this materials system and note that these results offer insight into a whole class of organic-based magnetic materials of the form M[Acceptor]x (M = transition metal; x ≈ 2). These results also introduce a new degree of freedom for organic-based magnetism and spintronics, and together with recent demonstration of encapsulation technologies and demonstrated functional microwave devices that exhibit high quality factors across a frequency range, suggest future promising applications in microwave electronics and quantum magnonics.

Signatures of quantum dipole liquid in an organic Mott insulator κ-(BEDT-TTF)Hg(SCN)2Br* [Invited] NATALIA DRICHKO (Presenter), Johns Hopkins University — Mott insulators are commonly pictured with electrons localized on lattice sites. Their low-energy physics involves spins only. Recent theoretical work suggests that in molecular systems a new on-site charge degree of freedom can emerge. On a frustrated lattice with charge-spin coupling it would result in a new quantum spin liquid state. We experimentally demonstrate [1] a presence of this fluctuating charge degree of freedom in a molecule-based Mott insulator κ-(BEDT-TTF)2Hg(SCN)2Br. When electrons localize on a triangular lattice of molecular dimers of this compound at temperatures below 100 K, they form electric dipoles which do not order at low temperatures and fluctuate, resulting in a so-called quantum dipole liquid state. A frequency of dipole fluctuations of 40 cm\(^{-1}\) is detected experimentally in our Raman spectroscopy experiments through an observation of a related collective mode. We show that this spectroscopic response of a quantum dipole liquid is qualitatively different from a response of molecular Mott insulators with no on-site charge degree of freedom. The Raman spectra of the latter show two-magnon excitations at frequencies below 500 cm\(^{-1}\) expected for a S=1/2 antiferromagnet on a triangular lattice with J=250 K. Our results can be a key to understanding of organic triangular lattice spin liquid candidates.

1:03PM S43.00004: Superconductivity in potassium-doped organic materials

HAI-QING LIN (Presenter), Beijing Computational Science Research Center — Abstract: Recent discoveries demonstrated that organic materials could be candidates for high temperature superconductors. In aromatic hydrocarbons, superconducting transition temperatures were observed up to 33 K, while in potassium-doped p-terphenyl and p-quaterphenyl, there were signatures indicating Tc of 120K. These results clearly indicate that organic materials are potential high temperature superconductors. However, the accurate amount of doped electrons and their positions have not been established experimentally, nor has any consensus reached for its superconducting mechanism. Here, we report the systematic studies of the crystal structures, charge transfer, electronic structures, electron-phonon interactions, magnetism, electronic correlations, and pressure effects in potassium-doped organic materials. Our calculations show that there exists a unified superconducting phase in the same 5-7 K range for all molecules containing benzene rings. Doping two electrons in the near constant density of states at the Fermi level accounts for this unified phase. The materials exhibit multiple superconducting phases and the high density of states at Fermi level upon 2+x-electron doping is responsible. The roles of doping content, electronic correlations, and pressure effect on superconductivity are emphasized.

Giant Rashba-splitting in 2D organic-inorganic halide perovskites measured by optical modulation spectroscopies* [invited] ZEEV VARDENY (Presenter), University of Utah — Two-dimensional (2D) layered hybrid organic-inorganic halide perovskite semiconductors form natural ‘multiple quantum wells’ that possess strong spin-orbit coupling due to the heavy elements in their building blocks. This may lead to ‘Rashba-splitting’ (RS) close to the extrema in the electron bands. We have employed a plethora of ultrafast transient, electro-absorption magneto-optical spectroscopies, and theoretical calculations for studying the primary (excitons) and long-lived (free-carriers) photoexcitations in thin films of 2D perovskite, namely (C$_6$H$_5$C$_2$H$_4$NH$_3$)$_2$PbI$_4$ [1]. The density functional theory calculation shows the occurrence of RS in the plane perpendicular to the growth direction. From the electroabsorption spectrum [2] and photoinduced absorption spectra from excitons and free-carriers we indeed obtain a giant RS in this compound, with energy splitting of ~40 meV and Rashba parameter of ~1.6 eV Angstrom; which are among the highest RS size parameters reported so far. The influence of the RS on the magneto-optical properties of this compound has been measured by field induced circular dichroism and polarization at high magnetic field up to 25T. We found that the exciton absorption and photoluminescence emission spectra split due to the RS, and show g-values that are considerable shifted from that of the free electron.

*The work was supported by the Department of Energy Office of Science, grant DE-SC0014579. The film growth facility was supported by the Center for Hybrid Organic Inorganic Semiconductors for Energy (CHOISE) an Energy Frontier Research Center funded by the Office of Basic Energy Sciences, Office of Science within the US Department of Energy program at the University of Utah.

Session S44 DCMP GMAG: Quantised Transport and Disorder in Kitaev Magnets BCEC 210C -

Tag(s): Invited

11:15AM S44.00001: Vison crystals in an extended Kitaev honeycomb model [invited] GABOR HALASZ (Presenter), Oak Ridge National Laboratory — We introduce an extension of the Kitaev honeycomb model by including four-spin interactions that preserve the local gauge structure and hence the integrability of the original model. The extended model has a rich phase diagram containing five distinct vison crystals, as well as a symmetric π-flux spin liquid with an approximate Fermi surface of Majorana fermions and a sequence of topological Lifshitz transitions. We discuss possible experimental signatures and, in particular, present finite-temperature Monte Carlo calculations of the specific heat and the static vison structure factor. We argue that our extended model emerges naturally from generic perturbations to the Kitaev honeycomb model.

11:51AM S44.00002: Field dependent magnetic excitations and possible topological transitions in α-RuCl₃* [invited] CHRISTIAN BALZ (Presenter), Oak Ridge National Laboratory — It is now well-known that when a magnetic field of approximately 7.5 T is applied in the honeycomb plane, the quantum magnet α-RuCl₃ displays a transition from zigzag magnetic order to a disordered state, believed to be a quantum spin liquid. This is reflected in the magnetic excitation spectrum as a disappearance of spin waves and a strengthening of a scattering continuum centered on the 2D Γ point that is interpreted as a signature of fractionalized excitations. Published measurements by Y. Kasahara et al (Nature 559, 227 (2018)) of the thermal Hall effect suggest a possible topological transition at an even higher field. Here I will discuss new high-resolution measurements of the excitations at fields spanning these two transitions. At the highest fields the broad scattering continuum is altered, and the response is seen to be dominated by a sharp peak at the lower bound, providing a strong indication that a new phase has been entered. The implications of these observations will be discussed in detail.

*The work at ORNL's Spallation Neutron Source and the High Flux Isotope Reactor was supported by the United States Department of Energy (US-DOE), Office of Science - Basic Energy Sciences (BES), Scientific User Facilities Division, managed by UT-Battelle LLC under contract number DEAC05-00OR22725.
12:27PM S44.00003: A spin-orbital-entangled quantum liquid on a honeycomb lattice* [Invited] Hidenori Takagi (Presenter), Max Planck Institute for Solid State Research — In 5d Ir$^{4+}$ oxides, the spin-orbit coupling for 5d electrons is as large as ~0.5 eV and not small as compared with on-site Coulomb $U$. This often gives rise to a spin-orbital Mott state with $J_{\text{eff}}=1/2$ isospins [1]. In the family of insulating 5d Ir$^{4+}$ oxides with a honeycomb-based structure, such as a-, b-, g-Li$_2$IrO$_3$ and Na$_2$IrO$_3$ (and also their 4d analogue a-RuCl$_3$), Ir$^{4+}$ ions are connected by the three orthogonal Ir-O$_2$-Ir plane bonds, which gives rise to a bond-dependent Ising interactions among $J_{\text{eff}}=1/2$ isospins. These compounds were pointed out theoretically to be a materialization of Kitaev model with a topological spin liquid as the ground state [2, 3]. However, a long range magnetic ordering rather than a liquid state was observed in these compounds, likely due to the presence of magnetic interactions other than the Kitaev interactions. We recently visited a new generation of honeycomb iridates H$_3$LiIr$_2$O$_6$, where all the interlayer Li$^+$ ions in a-Li$_2$IrO$_3$ are replaced with H$^+$, and discovered that a quantum spin liquid state is realized in H$_3$LiIr$_2$O$_6$ [4]. H$_3$LiIr$_2$O$_6$ does not show any trace of magnetic ordering down to 0.05 K, despite that an energy scale of magnetic interaction is ~ 100 K. We found at low temperatures below ~5K that the magnetization $M$, the NMR $1/T_1$ and the specific heat $C$ are dominated by the contributions from spin defects and follows a scaling with $B/T$. After subtracting the scaled contribution from the defects, we find only $T^3$-contribution in $C(T)$ within the given resolution, which can be ascribed to the lattice contribution. This suggests the presence of a gap in the magnetic excitations.

1:03PM S44.00004: The scale-invariant magnetic anisotropy of RuCl$_3$ [Invited] Kimberly Modic (Presenter), Max Planck Institute for Chemical Physics of Solids, Arkady Shekhter, National High Magnetic Field Laboratory, Brad Ramshaw, Cornell University, Ross McDonald, Los Alamos National Laboratory, Philip Moll, Ecole polytechnique federale de Lausanne — We present a detailed study of the magnetic anisotropy of RuCl$_3$ – a layered honeycomb structure of effective spin-1/2 moments. The strong spin-orbit coupling of ruthenium enhances magnetic frustration, which leads to a zigzag antiferromagnetic (AFM) ground state at 7K – a temperature much lower than the exchange interaction energy scale. With magnetic fields of roughly 10 T, AFM order is suppressed and an unconventional spin state emerges. This state, characterized by an unsaturated magnetization, persists up to magnetic fields of order 100 T. We use a newly-developed technique – resonant torsion magnetometry – to explore the temperature evolution of the magnetic anisotropy in the high-field state of RuCl$_3$. The high sensitivity of this technique allows us to measure a single crystallographic, and hence magnetic, domain. With increasing magnetic field, we observe a single transition associated with the suppression of AFM order. Above this transition, the magnetic anisotropy saturates (unlike the isotropic component of the magnetization), with a saturation field that scales linearly with temperature. Our data shows that the energy scale that determines the magnetic anisotropy is set only by field and temperature. This suggests that the intrinsic energy scale is driven to zero by strong correlations – a signature of a fluid-like spin state that is decoupled from the underlying exchange interactions.

1:39PM S44.00005: Quantization of the thermal Hall conductivity at small Hall angles* [Invited] Mengxing Ye (Presenter), University of Minnesota — Recent experiments have described the measurement of a near-quantized thermal Hall conductance in α-RuCl$_3$ as direct evidence for the propagation of a chiral Majorana mode in this system and consequently as smoking gun evidence for an intermediate chiral spin liquid phase in this system. However, the large experimental longitudinal thermal conductivity, attributed to bulk phonons, begs for an investigation of the spin-lattice coupling, and its role on the quantization of the thermal Hall conductivity. We show that due to the bulk and edge mixing of energy propagation, the temperature gradient of the bulk phonons develops a transverse component which may contribute to a quantized effective thermal Hall conductance. We also discuss the situations where the quantization breaks down and predict notable experiments that test it.

11:15AM S45.00001: Low loss amorphous Ta2O5 coatings grown by reactive sputtering for dielectric mirrors used for gravitational wave detection* KEERTI SHUKLA (Presenter), Materials Science and Engineering, UC Berkeley, MANEL MOLINA-RUIZ, Physics, UC Berkeley, MATT ABERNATHY, United States Naval Research Laboratory, ALENA ANANYEVA, LIGO Laboratory, California Institute of Technology, RICCARDO BASSIRI, MARTIN FEJER, Applied Physics, Stanford University, ERIC KEITH GUSTAFSON, LIGO Laboratory, California Institute of Technology, XIAO LIU, United States Naval Research Laboratory, ASHOT MARKOSYAN, Edward L. Ginzton Laboratory, Stanford University, THOMAS METCALF, United States Naval Research Laboratory, GABRIELE VAJENTE, LIGO Laboratory, California Institute of Technology, FRANCES HELLMAN, Physics and Materials Science and Engineering, UC Berkeley — The ability of LIGO and others in the gravitational wave community to detect astronomical events relies on the quality of optical mirrors used in interferometers. A lot of effort is devoted to reduce optical absorption and mechanical loss in the layers that make up the mirror coatings. Amorphous tantala is of interest as the high index of refraction layer but contributes the most to overall mechanical loss. The mechanisms that lead to mechanical loss must be understood in order to minimize the losses.

Amorphous tantala 500nm films are deposited using reactive sputtering of a tantalum target where growth temperatures are varied from room temperature to 600C. Thermally activated and tunneling mechanisms both contribute to the overall mechanical loss which can be measured through internal friction techniques. The thermally activated are measured at room temperature using Gentle Nodal Suspension and the tunneling are measured at temperatures below 10K using Double Paddle Oscillators. These results provide a deeper understanding of the energy dissipation in amorphous tantala due to both tunneling and thermally activated loss mechanisms.

11:27AM S45.00002: WITHDRAWN ABSTRACT —

11:39AM S45.00003: Understanding the role of carbon in active trap centre formation in porous alumina for ion beam dosimetry SANGITA BHOWMICK (Presenter), SAPTARSHI PAL, DIP DAS, Shiv Nadar University, VIPIN KUMAR SINGH, devi ahilya university, SAIF KHAN, inter university accelarator center, RENE HUEBNER, Electron Microscopy Laboratory, Helmholtz-Zentrum Dresden - Rossendorf (HZDR) Institute of Ion Beam Physics and Materials Research, SUDIPTO ROYBARMAN, devi ahilya university, DINAKAR KANJILAL, inter university accelarator center, ALOKE KANJILAL, Shiv Nadar University — In recent days, due to increased use of hadron therapy for cancer and tumor treatment, precise online dose monitoring is an important issue for safety purpose. Regarding hadron therapy, recently carbon ion beam with high Linear Energy Transfer (LET) is found to be more effective than the photon beams. Among several known TL/OSL oxides phosphors, C-doped alumina (Al2O3) is favorable for radiation dosimetry, especially in medical field due to its tissue equivalent in terms of radiation absorption, simple glow curve, and high sensitivity. A facile approach to improve thermoluminescence sensitivity of electrochemically anodized porous Al2O3 (AAO) is presented by introducing carbon ions for ion beam dosimetry. Initially, ion implantation technique has been carried out for Carbon doping in AAO in controlled manner. HAADF-STEM, EDS mapping, SEM studies reveal the evolution of a porous structure followed by the carbon distribution upto 200nm. However, the evolution of optically active F+ centres with increasing ion fluence has been examined by photoluminescence investigation at room temperature and thermoluminescence (TL) measurement while the chemical nature of such defect centres has been extracted by depth dependent XPS analysis.
11:51AM S45.00004: Interface-engineered hole doping in Sr2IrO4/LaNiO3 heterostructure* FANGDI WEN (Presenter), XIAORAN LIU, Rutgers University, New Brunswick, QINGHUA ZHANG, Beijing National Laboratory for Condensed-Matter Physics and Institute of Physics, Chinese Academy of Sciences, MIKHAIL S KAREEV, BANABIR PAL, Rutgers University, New Brunswick, YANWEI CAO, Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences, JOHN WILLIAM FREELAND, Advanced Photon Source, Argonne National Laboratory, ALPHA N'DIAYE, PADRAIC SHAFER, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, LIN GU, Beijing National Laboratory for Condensed-Matter Physics and Institute of Physics, Chinese Academy of Sciences, JAK CHAKHALIAN, Rutgers University, New Brunswick — The relativistic Mott insulator Sr2IrO4 is known for the Jeff = 1/2 Mott insulating state which closely resembles the electronic structure of parent compounds of superconducting cuprates. Here, by means of interface engineering of the Sr2IrO4/LaNiO3 heterostructure, the hole-doped phase of Sr2IrO4 has been realized with a markedly higher doping level close to 10%. X-ray absorption studies at Ni L2 edge confirmed that 5d electrons from Ir sites are transferred onto Ni sites leading to the formation of a high spin Ni2+ state. Despite the large amount of doping, Sr2IrO4/LaNiO3 heterostructure shows a non-metallic behavior but a narrower band gap compared to the bulk Sr2IrO4. This implies strong electronic reconstruction at the interfaces. These findings highlight a powerful utility of interfaces to realize emerging electronic states of the Ruddlesden-Popper phases of Ir-based oxides.

12:03PM S45.00005: Over 100-THz Bandwidth Selective-Difference-Frequency Generation at LaAlO3/SrTiO3 Nanojunctions* LU CHEN (Presenter), ERIN SUTTON, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNGWOO LEE, Department of Materials Science and Engineering, University of Wisconsin-Madison, JIANAN LI, Department of Physics and Astronomy, University of Pittsburgh, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — The ability to combine continuously-tunable narrow-band terahertz (THz) generation that can access both far-infrared and mid-infrared regimes, holds great potential for uncovering the underlying light-matter interactions as well as realizing selective control of rotational or vibrational resonances in nanoscale objects. Here, we report selective difference frequency generation with over 100 THz bandwidth through femtosecond optical pulse shaping. The THz emission is generated at nanoscale junctions at the interface of LaAlO3/SrTiO3 defined by conductive atomic force microscope lithography, with the potential to perform THz spectroscopy on individual nanoparticles or molecules. Numerical simulation of the time-domain signal helps to identify different contributing components for the THz generation. These results transform the LaAlO3/SrTiO3 interface into a promising platform for integrated lab-on-chip devices.

12:15PM S45.00006: Morphological anisotropy and mosaicity in epitaxially grown VO2 films* ANATOLY SHABALIN (Presenter), University of California, San Diego, ELIHU ANOUCHI, Department of Physics, Bar-Ilan University, MARTIN HOLT, Center for Nanoscale Materials, Argonne National Laboratory, AMOS SHARONI, Department of Physics, Bar-Ilan University, OLEG SHPYRKO, University of California, San Diego — Epitaxially grown films of VO2 are one of the most promising materials for oxide electronics due to a very convenient temperature and remarkable controllability of the insulator-metal phase transition (IMT) by doping, strain, photo excitations or applying an electric field. Scaling the IMT-based devices down to submicron size is a technological challenge because of the high variability of the resulted functional characteristics from device to device. Our work focuses on the structural and morphological origins of such variations.

We used X-ray nano diffraction mapping to study the evolution of mosaicity, strain and phase coexistence in 70 nm thick VO2 film (r-cut Al2O3) during thermal cycling and annealing. We found high anisotropy in the grain and crack network structure which remarkably resonates with anisotropy of transport properties. We were able to distinguish a persistent morphological pattern due to the film manufacturing from transient features introduced by thermal cycling. Our results manifest the important role of nanomorphology in the performance of VO2-based nanodevices. We suggest that it can also be considered as a new degree of freedom to control functional properties in oxide electronics.

Preparation and X-Ray Diffraction Study of Strongly Oriented Thin Films with Potential Magnetoelectric Effect

RADOMIR KUZEL (Presenter), Faculty of Mathematics and Physics, Charles University, JOSEF BURSIK, ROBERT UHRECKY, MIROSLAV SOROKA, Institute of Inorganic Chemistry, Czech Academy of Sciences, JAN PROKLESKA, Faculty of Mathematics and Physics, Charles University — Thin films of M, Y and Z hexagonal ferrites with a potential of magnetoelectric (ME) effect were prepared by chemical solution deposition method and processing parameters were tested and optimized. Several substrates were used, and different substrate/seeding layer/ferrite layer architectures were proposed to get strong preferred grain orientation. The films were studied by X-ray diffraction (XRD), AFM and EBSD. Lattice parameters, out-of-plane and in-plane grain orientations, crystal sizes, microstrains and residual stresses were obtained by different XRD symmetric and asymmetric scans and their combinations.

New Y-ferrite phases were prepared with the composition BaSrZnCoFe_{11}(Me)O_{22} (Me = Al, Ga, In, Sc). For Me = Al, Ga the magnetic structure is of non-collinear ferrimagnetic type with unspecified helical magnetic structure. ME Z-type ferrite Sr_{3}Co_{2}Fe_{24}O_{41} and Ba_{x}Sr_{3-x}Co_{2}Fe_{24}O_{41} thin films were prepared and characterized for the first time. Three present M, S and Z phases showed well out-of-plane and in-plane mutual orientations.

1:03PM S45.00010: High Temperature Oxidation of Amorphous Zr-B-C-N Thin Films Grown by Electron Beam Evaporation*  
MORTON GREENSLIT (Presenter), MORGEN BENNINGHOFF, ROBERT J LAD, University of Maine — Boron carbonitride films have been shown to yield enhanced hardness and oxidation resistance, making them potentially attractive as protective coatings for high temperature applications. Most previous work has focused on thick films (>1μm) grown by magnetron sputtering. In this study, 200 nm thick ZrBCN films with a range of stoichiometries were grown on r-sapphire substrates at 850°C using e-beam evaporation of ZrC and B sources in a nitrogen plasma. As-deposited films were found to be amorphous by XRD, and the nitrogen content was relatively constant independent of ZrC or B evaporation rates. XPS analysis of the films after air annealing over the range 500-800°C showed that B and N were entirely depleted at the surface, while ZrO2 grains nucleated within the amorphous film matrix. XRD showed the formation of a tetragonal-ZrO2 phase at 600°C that became replaced by a monoclinic-ZrO2 phase at 800°C as the ZrO2 grains grew in size. SEM analysis showed film delamination and cracking during high temperature oxidation to relieve film stress. The oxidation resistance of the 200 nm ZrBCN films is much less than reported for thicker sputtered films, indicating that the oxidation resistance mechanism is strongly dependent on film thickness.

1:15PM S45.00011: Reduction of Stress in Dual Ion Beam Sputtered Ta2O5 and SiO2 Optical Interference Coatings*  
EMMETT RANDEL (Presenter), AARON DAVENPORT, CARMEN SUSANA MENONI, Colorado State Univ — We studied the mechanical and optical properties of tantalum pentoxide (Ta2O5) and silicon dioxide (SiO2) films prepared by dual ion beam sputtering with the goal to realize thin films with a stress below 0.3 GPa. It is shown that the use of a low energy assist beam consisting of oxygen and argon species results in a Ta2O5 film with a stress below 100 MPa and a SiO2 film with a stress below 250 MPa. Using photothermal common path interferometry (PCI), spectrophotometry, and ellipsometry, it is shown that these films are suitable for use in interference coatings.

1:27PM S45.00012: Properties of CCTO, a High Dielectric Constant Material*  
PARVEEN KUMAR (Presenter), University of California Merced 95343 USA, D. C. AGRAWAL, IIT Kanpur UP 208016 India — CaCu3Ti4O12 (CCTO) shows an extremely high dielectric constant, which, in contrast to ferroelectrics like BaTiO3, is nearly constant in a broad temperature range. Thus, this material has attracted tremendous attention due to its possible applications, e.g., for enhancing the performance of capacitive electronic elements. We used a simple Sol-Gel technique and established a novel composition of CCTO with high dielectric constant, and fabricated stable and reliable thin films. We have successfully incorporated silver nanoparticle in CCTO thin films. The conducting metal particles dispersed in a dielectric matrix are known to increase the effective dielectric constant of the medium. Based on these novel materials, we developed tunable multilayer capacitor with high dielectric constant.

*This work is done at IIT Kanpur.

1:39PM S45.00013: Influence of Assist Ion Bombardment on Mechanical Loss of Amorphous Tantala Thin Films for Gravitational Wave Interferometers*  
LE YANG (Presenter), EMMETT RANDEL, Colorado State Univ, GABRIELE VAJENTE, ALENA ANANYEVA, ERIC KEITH GUSTAFSON, California Institute of Technology, ASHOT MARKOSYAN, MARTIN FEJER, Stanford University, CARMEN SUSANA MENONI, Colorado State Univ — Thermal noise in high-reflectivity coatings is critical for improving the sensitivity of future gravitational wave detectors. Amorphous tantala (Ta2O5) thin film, used as high-index material, with lower mechanical loss is expected as one solution to further reduce the coating thermal noise. The material is also regarded as promising candidate for use in resistance random access memory as well as optical applications. In this work, amorphous tantala thin films have been deposited by reactive ion beam sputtering with assist Ar⁺ and Xe⁺ ion bombardment to investigate the effect of ion-induced surface diffusion on coating's mechanical and structural properties. The results show that the atomic structure of ion bombarded tantala thin films remain amorphous and their composition is mostly stoichiometric. The mechanical loss of ion-bombardeed tantala coatings shows no significant improvement compared to non-bombardeed samples. The coating loss angle of tantala is insensitive to ion dose or ion mass. An analysis based on surface diffusivity suggests that the ion-assisted surface diffusivity may be insignificantly modified under the current typical deposition conditions.

*This work is supported by the National Science Foundation LIGO program through grant No. 1708010
1:51PM S45.00014: TiO$_2$ doped Ta$_2$O$_5$ coatings grown by biased target ion beam deposition for gravitational wave detectors*  
MARIANA FAZIO (Presenter), Department of Electrical and Computer Engineering and NSF ERC for Extreme Ultraviolet Science and Technology, Colorado State University, Fort Collins, CO, USA, GABRIELE VAJENTE, ALENA ANANYEVA, ERIC KEITH GUSTAFSON, LIGO Laboratory, California Institute of Technology, Pasadena, CA, USA, CARL LÉVESQUE, FRANÇOIS SCHIETTEKATTE, Université de Montréal, Montréal, Quebec, Canada, ASHOT MARKOSYAN, RICCARDO BASSIRI, MARTIN FEJER, Department of Applied Physics, Ginzton Laboratory, Stanford University, Stanford, CA, USA, CARMEN SUSANA MENONI, Department of Electrical and Computer Engineering and NSF ERC for Extreme Ultraviolet Science and Technology, Colorado State University, Fort Collins, CO, USA — Advanced LIGO employs as end masses high reflectance mirrors of alternating layers of SiO$_2$ and Ta$_2$O$_5$ doped with 25% of TiO$_2$. Doping Ta$_2$O$_5$ with 25% TiO$_2$ decreased the mechanical loss which increased the sensitivity of the detector, but the physical reasons of this are still unknown. In this work we studied thin films of Ta$_2$O$_5$ doped with different TiO$_2$ concentrations grown by biased target ion beam deposition to evaluate the effect of doping in the mechanical loss and to search for high index materials with improved performance for the upcoming upgrade of LIGO and future detectors. The deposition system consists of a low energy ion source and metallic targets individually pulsed biased. Control of each target bias allows for mixing Ta$_2$O$_5$ and TiO$_2$, with estimates of the doping obtained by x-ray photoelectron spectroscopy. Extensive characterization shows the films are nearly stoichiometric and dense, with an absorption loss at 1064 nm lower than 20 ppm. Mechanical loss was measured in as deposited coatings and after annealing. For all TiO$_2$ concentrations the mechanical loss is reduced after annealing, reaching a minimum for around 20% TiO$_2$ after annealing at 600 C comparable to state-of-the-art TiO$_2$ doped Ta$_2$O$_5$.

Session S46 DMP: Complex Oxide Interfaces & Heterostructures -- Electronic and transport properties  
BCEC 212 - Ryan Comes, Auburn University - Tag(s): Focus

11:15AM S46.00001: Strain-engineered SrSnO$_3$ films with high room-temperature electron mobility*  
TIANQI WANG, ABHINAV PRAKASH (Presenter), Chemical Engineering and Materials Science, University of Minnesota - Twin Cities, YONGQI DONG, University of Science and Technology of China, TRISTAN TRUTTMANN, Chemical Engineering and Materials Science, University of Minnesota - Twin Cities, ASHLEY BUCSEK, RICHARD D JAMES, Aerospace Engineering and Mechanics, University of Minnesota - Twin Cities, DILLON D FONG, Materials Science Division, Argonne National Laboratory, JONG-WOO KIM, PHILIP RYAN, HUA ZHOU, Advanced Photon Source, Argonne National Laboratory, TURAN BIROL, BHARAT JALAN, Chemical Engineering and Materials Science, University of Minnesota - Twin Cities — Bulk SrSnO$_3$ (SSO) exhibits four crystalline polymorphs as a function of temperature. Through comprehensive thin film growth using novel radical-based MBE approach, synchrotron x-ray scattering, electronic transport, and first-principles calculations, we report on the stabilization of different polymorphs of SSO at room temperature (RT), in thin film form. Compressive strain stabilized the high-symmetry tetragonal phase of SSO at RT, which, in bulk, exists only at temperatures between 1062 K and 1295 K. A mobility enhancement of over 300% in the doped tetragonal phase of SSO films compared with the low-temperature orthorhombic polymorph was achieved. We will discuss these results in the context of the role of strain, doping, and disorder on structure and electronic transport of doped SSO films.

11:27AM S46.00002: Electrostatic gating of MBE-grown SrSnO$_3$ films using ion-gel*  
LAXMAN RAJU THOUTAM  
( Presenter), JIN YUE, ABHINAV PRAKASH, TIANQI WANG, BHARAT JALAN, University of Minnesota — Electrostatic gating using ion-gel is an effective way to dynamically tune electronic phase transitions in solid materials. We report the first experimental findings of reversible electrostatic control of insulator-to-metal transition in La-doped SrSnO$_3$ films grown by the hybrid molecular beam epitaxy method. The low temperature sheet resistance ($R_s$) of the films were modulated over four orders of magnitude at an applied gate voltage of $+4$V. The careful analysis of the temperature dependent transport properties reveal a smooth crossover from strong-localization to weak-localization behavior at 2 K with increased positive gate voltages. We further discuss the nature of quantum corrections that are responsible for the upturn in $R_s$ at low temperatures and its effect on the induced carrier density, on the metallic side of insulator-to-metal transition. The excellent overlap of the measured $R_s$ (at zero gate bias) before and after multiple sequence of $R_s$ vs T measurements at different applied gate biases indicate the true reversible and electrostatic control of the gating process in stannate systems.

*Work supported by UMN NSF MRSEC and AFOSR YIP

11:39AM S46.00003: Wide Range Reversible Transport Modulation and Electron Density Dependence of Mobility in Ion-Gel-Gated BaSnO$_3$ Films*  
HELIN WANG (Presenter), JEFFERY J WALTER, KOUSTAV GANGULY, ABHINAV PRAKASH, BIIQIONG YU, GUICHUAN YU, HAN FU, MARTIN GREVEN, CHRIS LEIGHTON, University of Minnesota — Rapid progress has been made with BSO films since the report of room temperature mobility $>300$ cm$^2$V$^{-1}$s$^{-1}$ in bulk crystals. Questions remain over mobility-limiting mechanisms, however. Here we report doping-dependent electronic transport in epitaxial-BSO-based electric double layer transistors using ion gel electrolytes. Over an exceptional gate voltage window of -3 to $+4$V, at 300 K, electrostatic gating mechanisms dominate, supported by reversible transport response and operando synchrotron X-ray diffraction experiments. This is in stark contrast with many complex oxides and, vitally, is attributed here to the exceptionally small diffusivity of oxygen vacancies in BSO. Wide-range voltage control of resistance is demonstrated in a series of undoped and initially chemically $n$-doped BSO films, including a strong to weak localization crossover. Interfacial electron density ($n$) and mobility ($\mu$) are extracted from two-channel conduction modelling and the $\mu$-n relation is probed from $\sim10^{18}$ cm$^{-3}$ to $>10^{20}$ cm$^{-3}$. Universally, $\mu$ increases rapidly with $n$ before decreasing above $\sim10^{20}$ cm$^{-3}$, potentially due to surface scattering. The highest $\mu$ achieved is 140 cm$^2$V$^{-1}$s$^{-1}$ in La-doped BSO films by increasing $\mu$ with gating by up to 55%.

*Work supported by NSF MRSEC under DMR-1420013.

11:51AM S46.00004: Weak (anti)localization in NdTiO$_3$/SrTiO$_3$ Heterointerfaces*  
XINXIN CAI (Presenter), YILIKAL AYINO, School of Physics and Astronomy, University of Minnesota, JIN YUE, PENG XU, BHARAT JALAN, Department of Chemical Engineering and Materials Science, University of Minnesota, VLAD S PRIBIAG, School of Physics and Astronomy, University of Minnesota — The quasi-two-dimensional interfacial electron gas formed at complex oxide interfaces exhibits a wide range of interesting physical properties including spin-orbit coupling and magnetism. We report magneto-transport studies on NdTiO$_3$/SrTiO$_3$ heterostructures grown by hybrid molecular beam epitaxy. The magneto-transport behavior exhibits a systematic crossover between weak antilocalization and weak localization with changing temperature. The weak-antilocalization analysis of the magnetoresistance provides information about the spin and phase relaxation mechanisms and may indicate the interplay between the interfacial magnetism and spin-orbit coupling.

*This work is supported by the Office of Naval Research and DOE Center for Quantum Materials.
12:03PM S46.00005: Quantised conductance of one-dimensional strongly-correlated electrons in a ZnO heterostructure*  
HANGTIAN HOU, University of Cambridge, YUSUKE KOZUKA, Research Center for Magnetic and Spintronic Materials, National Institute for Materials Science (NIMS), 1-2-1 Sengen, Tsukuba 305-0047, Japan, JUN-WEI LIAO, LUKE W SMITH, DEAN KOS, JONATHAN GRIFFITHS, University of Cambridge, JOSEPH FALSON, Max Planck Institute for Solid State Research, D-70569 Stuttgart, Germany, ATSUSHI TSUKAZAKI, Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, MASASHI KAWASAKI, Department of Applied Physics and Quantum-Phase Electronics Center (QPEC), The University of Tokyo, Tokyo 113-8656, Japan, CHRISTOPHER J FORD (Presenter), University of Cambridge — Oxide heterostructures are versatile platforms with which to research and create novel functional nanostructures. We have developed one-dimensional (1D) quantum-wire devices using quantum point contacts on MgZnO/ZnO heterostructures and observe ballistic electron transport with conductance quantised in units of $2e^2/h$. Using DC-bias and in-plane-field measurements, we find that the $g$-factor is enhanced to around 6.8, more than three times the value in bulk ZnO. We show that the effective mass $m^*$ increases as the electron density decreases, resulting from the strong electron-electron interactions. In this strongly interacting 1D system we study features matching the '0.7' conductance anomalies up to the fifth subband. We demonstrate that high-mobility oxide heterostructures such as this can provide good alternatives to conventional III-V semiconductors in spintronics and quantum computing as they do not have their unavoidable dephasing from nuclear spins. This paves a way for the development of qubits benefiting from the low defects of an undoped heterostructure together with the long spin lifetimes achievable in silicon.

12:15PM S46.00006: The formation of small polaron at the conducting LaAlO$_3$/SrTiO$_3$ interface  
WEILONG KONG (Presenter), JUN ZHOU, Department of Physics, National University of Singapore, MING YANG, Institute of Materials Research and Engineering (IMRE), A*STAR (Agency for Science, Technology and Research), YUAN PING FENG, Department of Physics, National University of Singapore — The interplays among various degrees of freedom such as charge, spin, orbital and lattice generate striking physical properties in oxide heterostructures that are not observed in their parent bulk materials. In this study, via first-principles calculations, we show that the excess electrons at the conducting LaAlO$_3$/SrTiO$_3$ (LAO/STO) interface favor the formation of polaron states. These electrons interact strongly with the lowest $d_{xy}$ orbital of the interfacial Ti lattices, forming localized splitting states. Compared with SrTiO$_3$ bulk, the formation of the polaron states is more favorable at LAO/STO interface, which is ascribed to the reduced dimensionality and lattice symmetry. These results suggest that some of the excess electrons are localized and do not contribute to the transport effectively, and also shed light on a new direction to understand various novel properties of the conducting LAO/STO interface.

12:27PM S46.00007: Systematic Study of Superconductivity in Hybrid MBE-grown Sr$_{1-x}$Nd$_x$TiO$_3$ Films*  
JIN YUE (Presenter), Department of Chemical Engineering and Materials Science, University of Minnesota, YILIKAL AYINO, School of Physics and Astronomy, University of Minnesota, LAXMAN RAJU THOUTAM, Department of Chemical Engineering and Materials Science, University of Minnesota, VLAD PRIBIAG, School of Physics and Astronomy, University of Minnesota, BHARAT JALAN, Department of Chemical Engineering and Materials Science, University of Minnesota — Ever since the discovery of superconductivity in n-doped SrTiO$_3$ (STO) ($10^{18}$ – $10^{21}$ cm$^{-3}$), STO has received significant attention. More recently, it has been shown that superconductivity can be stabilized at much lower concentrations ($5.5 \times 10^{17}$ cm$^{-3}$) using oxygen-vacancy doped STO raising many questions on the role of dopants and disorder on superconductivity in STO. To-date, these works have been limited to the bulk STO single crystals. In this talk, we will present the first systematic study of superconductivity in epitaxial n-doped Sr$_{1-x}$Nd$_x$TiO$_3$ films grown using hybrid molecular beam epitaxy. We will also discuss the role of dopants, point disorder, and epitaxial strain on the superconductivity and normal state transport in doped STO films.

*This work is supported by DOE center for quantum materials. Yilikal Ayino and Vlad Pribiag acknowledge UMN MRSEC for millikelvin measurements.
12:39PM S46.00008: Electrical control of phase transitions through ion transfer in oxide superlattices  DI YI (Presenter), Stanford University, YUJIA WANG, Tsinghua University, HONGTAO YUAN, Nanjing University, OLAF M VAN T ERVE, US Naval Research Laboratory, MICHAEL VEIT, PURNIMA BALAKRISHNAN, Stanford University, YONGSEONG CHOI, Argonne National Laboratory, ALPHA N'DIAYE, PADRAIC SHAFER, ELKE ARENHOLZ, Lawrence Berkeley National Laboratory, BEREND JONKER, US Naval Research Laboratory, PU YU, Tsinghua University, YURI SUZUKI, Stanford University — Electrical control of phase transitions through ion transfer has been of great interest recently. Ion transfer can have a dramatic influence on a material’s electronic, magnetic and optical properties, and thereby provides a powerful tool for fundamental research and enables many practical applications. However only a few materials have been found to exhibit significant tunability and good reversibility of electrically controlled ion transfer. In this talk, we show that superlattices comprised of the 5d oxide SrIrO3 and 3d oxide La1-xSr2MnO3 exhibit a reversible phase change under ionic liquid gating. Ionic liquid gating modulates the lattice constant by seven percent and modifies the valence of both Mn and Ir cations. The gate voltage induces a reversible transition between a ferromagnetic metallic state and a nonmagnetic insulating state, along with a large modulation of optical transmittance. Secondary ion mass spectrometry indicates that these reversible transitions are mediated by the transfer of hydrogen and oxygen ions in the superlattices. Single layer films of the constituent materials do not exhibit such significant changes in properties. Our study shows that the electrically controlled ion transfer can be engineered by designing materials at the atomic scale.

12:51PM S46.00009: Emergent Phenomena at Mott Insulator/ Band Insulator Interfaces* [Invited] YURI SUZUKI (Presenter), Stanford University — Complex oxide interfaces have been explored extensively in recent years as emergent phenomena, ranging from magnetism, metallicity, superconductivity to spin-orbit coupling, have been generated at these interfaces due to electronic, magnetic, orbital reconstruction etc. Electronic reconstruction at a Mott insulator/ band insulator interface has been predicted to exhibit a wide range of emergent electronic and magnetic behavior. A particularly interesting model system is the LaTiO3/ SrTiO3 interface where electronic reconstruction gives rise to low dimensional metallic behavior accompanied by giant Rashba spin-orbit coupling. We studied ultrathin films of LaTiO3 on SrTiO3 substrates where interface reconstruction dominates the transport behavior. We found evidence for giant Rashba spin splitting in two sets of Shubnikov-de Haas oscillations associated with an inner and outer Fermi surface, Berry phase of π, substantial anisotropic magnetoresistance and a weak anti-localization correction to the magnetoconductivity. Together these results indicate a large Rashba coupling coefficient of 2.0 x 10^{-11} eV-m which is an order of magnitude larger than other complex oxide interfaces. Such a large Rashba coupling suggests that such a Mott/band insulator interface may be an excellent candidate for spin current-based electronics.

*†This work was done in collaboration with Michael Veit, Remi Arras, Brad Ramshaw, Mun Chan and Rossitza Pentcheva and funded by the Vannevar Bush Faculty Fellowship of the Department of Defense under Contract No. N00014-15-1-0045.

1:27PM S46.00010: Controlled epitaxial growth and oxygen excess doping of the Mott insulator LaTiO3* RALPH CLAESSEN, PHILIPP SCHEIDERER, MATTHIAS SCHMITT, JUDITH GABEL, MICHAEL ZAPF, MARTIN STÜBINGER, PHILIPP SCHÜTZ, LENART DUDY, Universität Würzburg, Germany, CHRISTOPH SCHLUETER, TIEN-LIN LEE, Diamond Light Source, UK, MICHAEL SING (Presenter), Universität Würzburg, Germany — Here we demonstrate that thin films of the prototypical Mott insulator LaTiO3 grown by pulsed laser deposition under oxygen atmosphere are readily tuned by excess oxygen doping across the line of the band-filling controlled Mott transition in the electronic phase diagram [1]. The detected insulator to metal transition is characterized by a strong change in resistivity of several orders of magnitude. The use of suitable substrates and capping layers to inhibit oxygen diffusion facilitates full control of the oxygen content and renders the films stable against exposure to ambient conditions. These achievements represent a significant advancement in control and tuning of the electronic properties of LaTiO3+x thin films making it a promising channel material in future Mottronic devices.

1:39PM S46.00012: Charge Transfer and Built-in Electric Fields Between the Crystalline Oxide SrNbxTi1-xO3-δ and Silicon
ZHENG HUI LIM (Presenter), Department of Physics, University of Texas-Arlington, NICHOLAS F QUACKENBUSCH, Materials Measurement Science Division, National Institute of Standards and Technology, JOSEPH NGAI, Department of Physics, University of Texas-Arlington — Heterojunctions between semiconductors and oxides are fundamental to field-effect devices that have revolutionized information technology. However, their principal functionality remains as capacitors within the metal-insulator-semiconductor (MIS) paradigm. Here we report charge transfer and the formation of built-in electric fields across heterojunctions between single-crystalline SrNbxTi1-xO3-δ and Si(001). A non-monotonic anomaly in the sheet resistance is observed, accompanied by a crossover in sign of the Hall resistance which indicates the formation of a hole gas in the Si and the presence of strong built-in fields. Hard X-ray photoelectron spectroscopy measurements reveal pronounced asymmetric features in both the SrNbxTi1-xO3-δ and Si core-level spectra that we show arise from built-in fields. Analysis of these unprecedent asymmetries enables band-bending to be spatially mapped across the heterojunction. Control of charge transfer and built-in fields opens a pathway to realize hybrid pn-junctions, isotype junctions etc., that elevate the functionality of semiconductor-oxide heterojunctions beyond the MIS paradigm.

2:03PM S46.00013: Direct Measurement of Band Edge Profiles at Epitaxial Oxide/Semiconductor Heterojunctions*
SCOTT CHAMBERS (Presenter), PETR SUSHKO, Physical and Computational Sciences Directorate, Pacific Northwest National Laboratory, NICHOLAS F QUACKENBUSCH, JOSEPH WOICIK, Materials Measurement Science Division, National Institute of Standards, ZHENG HUI LIM, MATTHEW CHRYSLER, JOSEPH NGAI, Department of Physics, University of Texas at Arlington, TIEN-LIN LEE, Diamond Light Source, JAMES LEBEAU, Department of Materials Science & Engineering, North Carolina State University — Band edge profiles for semiconductor heterojunctions can be approximated using transport data and/or calculated from first principles, assuming an atomistic materials structure. However, direct and accurate experimental measurement has not been possible by traditional means. We have used hard x-ray photoelectron spectroscopy (HAXPES) to extract band edge profiles from core-level spectra by developing an effective algorithm that fits experimental heterostructure spectra to sums of flat-band spectra, measured for pure reference materials, in which the binding energies are exhaustively varied to sample the phase space of physically reasonable potential profiles over all layers within the HAXPES probe depth. We apply this method to heterojunctions of n-SrNb_xTi_1-xO_3 and intrinsic Si(001), prepared by molecular beam epitaxy. Heterojunction formation results in a Si hole gas and a surface depleted dead layer in the SrNb_xTi_1-xO_3. The band edge profiles resulting from the HAXPES fitting reveal both of these features, and match what is expected based on Hall data remarkably well. In this talk, we present highlights of this analysis.

TAKAHIRO CHIBA (Presenter), Fukushima National Institute of Technology, SABURO TAKAHASHI, Advanced Institute for Materials Research (AIMR), Tohoku University — Thermoelectric (TE) conversion from thermal energy into electric energy has been attracting attention as a renewable energy harvesting. The conversion efficiency is evaluated by the dimensionless figure of merit $ZT$ and for practical use $ZT \geq 1$ (conversion efficiency is 10%) is required. Bismuth chalcogenide is not only known as a representative material with high $ZT$ but also has received attention as a topological insulator (TI) phase in recent years. Here we theoretically study the thermoelectric effect on the surface of TIs that are ionically disordered as the consequence of hypothetical doping for systematic control of the Fermi levels. Coulomb type long range potential is introduced as the ionic disorders. Based on Boltzmann transport theory at finite temperature, we calculate the TE coefficient and $ZT$. As a result, we find that $ZT$ can achieve substantially high values even for the thermal phonon. Our theory may help us understand recent TE transport measurements in TI thin films and could make an ionically disordered TI a promising material for TE conversion technology.

SUNGJIN PARK (Presenter), Korea Electrotechnology Research Institute, MIN HO LEE, Institute for Metallic Materials, Leibniz Institute for Solid State and Materials Research, Dresden, BYUNGKI RYU, Korea Electrotechnology Research Institute — PbTe is very noteworthy thermoelectric material working at intermediate temperatures. Most investigations of PbTe were focused on PbTe-based alloys to control band convergence, formation of resonant level, and nanostructuring. However, the intrinsic-defect nature of PbTe is still not well understood yet. The semiconductor type of PbTe-related alloys is known to be determined by Pb concentration with respect to Te concentration. In binary, Pb-rich or Te-rich PbTe typically exhibits n-type or p-type behavior, respectively. Our experiments showed that 10% excess-Pb doping merely changes the lattice parameter (+0.3%). To understand such atomic and electrical behaviors in off-stoichiometric PbTe, we theoretically investigated the formation of intrinsic defects in PbTe by performing first-principle density functional theory calculations. We used PAW method and GGA-PBE, which are implemented in VASP code. The defect formation energies of various charged states were computed on the 128-atom FCC supercell and a 3x3x3 k-point mesh. We suggest that the formation of Pb interstitial or Te vacancy might be responsible for the off-stoichiometry in Pb-rich PbTe, while the formation of Pb vacancy or Te vacancy might be responsible in Te-rich PbTe.

JAVIER FERNANDEZ TRONCOSO (Presenter), PABLO AGUADO-PUENTE, Queen's University Belfast — Lead telluride (PbTe) is a reference high-performance thermoelectric which can exhibit low values of thermal conductivity in the presence of intrinsic defects. Here, we present an optimized Buckingham potential that provides an improved description of this material, especially for the lattice thermal conductivity. The latter is computed using two different methods: Green-Kubo method and direct thermostatting. Comparison with other classical force fields proposed in the literature shows substantial improvement.

Using this potential we studied how intrinsic defects influence the thermal conductivity, paying special attention to vacancies, interstitials and grain boundaries. Our results show that intrinsic point defects and grain boundaries can reduce the lattice conductivity of PbTe by a factor of 4, and converge towards the value of pristine PbTe under typical experimental concentrations of defects in samples. We also determine the thermal resistance of grain boundaries.

Desirable dopants for thermoelectrics

JIAWEI ZHOU (Presenter), QICHEN SONG, TE-HUAN LIU, Massachusetts Institute of Technology, JUN MAO, HANGTIAN ZHU, University of Houston, RAN HE, Institut für Metallische Werkstoffe, WUYANG REN, ZIHANG LIU, ZHIFENG REN, University of Houston, GANG CHEN, Massachusetts Institute of Technology — Doping is a common technique to achieve good electrical conduction in semiconductors, and is often used to optimize the performance of thermoelectric materials. While its effect on the electron mobility has been widely appreciated, the understandings still mostly rely on simplified models, which often neglect the chemical details of the dopants. On the other hand, experimental evidence has suggested that dopants with different chemical nature can behave quite differently. The lack of theory to explain such observations, however, has impeded our understanding for controlling dopants, and defects in general, for thermoelectric materials. Recently we have developed a first principles approach to quantitatively evaluate the the effects of dopants on the electron transport. We will discuss how the bonding environment of the atoms - a previously overlooked aspect - can significantly affect the electron transport. The study potentially provides guidelines for finding efficient dopants for thermoelectric materials.

*This work is supported partially by DOE EFRC (Grant No. DE-SC0001299, for fundamental studies on thermoelectrics), and partially by DARPA MATRIX program (Grant No. HR0011-162-0041 for supporting its thermoelectrics programs).

Dopability on Complex Diamond-Like Semiconductors: new candidates for thermoelectric applications

LIDIA GOMES (Presenter), JIAXING QU, University of Illinois at Urbana-Champaign, BRENDEN ORTIZ, ERIC TOBERER, Colorado School of Mines, ELIF ERTEKIN, University of Illinois at Urbana-Champaign — The diamond-like semiconductors (DLS) have recently garnered interest for the potential use as thermoelectric materials. DLS share the diamond structure, forming a chemically rich family of binary, ternary and quaternary compounds. To be a good thermoelectric, however, a material must be sufficiently dopable and the defect chemistry of this group is currently not well characterized.

In this work, we show our recent efforts to investigate the defect physics of these complex materials using first-principles calculations. We focus on a subset within the DLS, formed by ternary and quaternary tellurides. We show that there is a large diversity in the stability phase diagrams in this group and how this impact defect formation energies and the range of achievable carrier concentrations. Most of the ternaries show dopability windows ranging from highly p-type to intrinsic or slightly n-type. In addition, a control of carrier concentrations can be achieved by growth under different thermodynamic environments. We also highlight the importance of the computational approach to an accurate prediction of these quantities, that can be used to guide experimental works.

*We acknowledge the support of the National Center for Supercomputing Applications and the NSF via grants 1729594 and 1729149.

Hierarchical design of nanomaterials for improving the power factor

NEOPHYTOS NEOHYTOS (Presenter), LAURA DE SOUSA OLIVEIRA, VASSILIOS VARGIAMIDIS, University of Warwick — Hierarchically nanostructured thermoelectric materials, where nanoinsertions are inserted at various length scales (grain boundaries, embedded quantum dots, atomistic defects), have shown the potential to provide much larger thermoelectric performance compared to pristine materials. This is to-date being attributed to drastic reductions in the thermal conductivity, but less on power factor improvements. In this work we combine Molecular Dynamics simulations for the thermal conductivity and Non-Equilibrium Green's Function simulations for electronic transport to study thermoelectric transport through materials with hierarchically embedded nanoinsertions, namely superlattice-type barriers with quantum dots and voids in between them. We show that beyond the drastic reductions in thermal conductivity, the nanomaterials can be designed such that the power factor: i) is resilient to the presence of nanoinsertions, and ii) is even improved compared to pristine materials, independently of the density of the distorting nanoinsertions.

*This work has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 Research and Innovation Programme (Grant Agreement No. 678763).
Utilizing Magnetism and Nanostructures to Enhance Performance of Thermoelectric Materials

[Invited] TAKAO MORI (Presenter), International Center for Materials Nanoarchitectonics (WPI-MANA) and Center for Functional Sensor & Actuator (CFSN), National Institute for Materials Science (NIMS) — New principles and strategies are desired to overcome the traditional tradeoff between thermoelectric (TE) properties, i.e. electrical conductivity \( \sigma \) and thermal conductivity \( \kappa \), and Seebeck coefficient \( \alpha \). We have been trying to develop TE enhancement principles which can be relatively easily implemented and applied to a wide range of materials [1]. Porosity had been considered detrimental for TE materials, with the penalty for \( \sigma \) usually being similar or larger than the \( \kappa \) reduction. Introducing a moderate volume of nano-micropores with size distribution by simple evaporation of a secondary phase, has led to effective phonon selective scattering, and 100% enhancement to figure of merit \( \sigma\alpha^2/\kappa = ZT \approx 1.6 \) in rare earth-free (“empty”) skutterudites [2]. This strategy has also led to ZT enhancement in other materials which will be presented. We have proposed to utilize magnetic interactions between carriers and magnetic moments to enhance the power factor \( \sigma\alpha^2 \) [3]. Unlike magnon drag, TE enhancement via magnetic interaction is not solely dependent on ordering, and is effective at higher temperatures also. Magnetic ion doping for example, has led to TE enhancement for a variety of cases, CuGaTe\(_2\), BiCuSeO, Bi\(_2\)Te\(_3\), SnTe, etc., if effective coupling is created. We have also demonstrated significant enhancement of the Seebeck coefficient via spin fluctuation. CREST project members are acknowledged.

Enhanced Seebeck effect in ion-gated FeSe

SUNAO SHIMIZU (Presenter), RIKEN, SHIOGAI JUNICHI, Tohoku University, NAYUTA TAKEMORI, SHIRO SAKAI, RIKEN, HIROAKI IKEDA, Ritsumeikan University, RYOTARO ARITA, RIKEN, TSUTOMU NOJIMA, ATSUISHI TSUKAZAKI, Tohoku University, YOSHIHIRO IWASA, University of Tokyo — The reduction of the dimensionality leads to the manifestation of quantum phenomena and the development of electronic correlation. Such low dimensional effects often become even more pronounced in nano-scale materials including exfoliated atomic layers and their hetero structures, triggering the emergence of the novel electronic, optical, and magnetic properties. Here we report the thermoelectric effect of FeSe ultrathin films with an electric double layer configuration, which allows us to control not only the carrier density but also the film thickness down to monolayer [J. Shiogai et al., Nature Phys. 12, 42 (2016)]. By utilizing a chemical etching induced by applying a large gate bias, the thickness of thin films is reduced in a layer-by-layer manner. Accompanying the emergence of the high-\( T_c \) superconductivity, the ionic liquid gating on FeSe thin films induces the anomalous enhancement of the Seebeck effect. We will discuss the thickness and the temperature dependence of the thermoelectric properties in FeSe thin films in detail.

Performance Analysis of nanostructured Peltier coolers

ANIKET SINGHA (Presenter), Electronics and Electrical Communication Engineering, Indian Institute of Technology Kharagpur, BHASKARAN MURALIDHARAN, Electrical Engineering, Indian Institute of Technology Bombay — Employing non-equilibrium quantum transport models [1], we investigate the details and operating conditions of nano-structured Peltier coolers embedded with an energy filtering barrier. Our investigations point out non-trivial aspects of Peltier cooling which include an inevitable trade-off between the cooling power and the coefficient of performance, the coefficient of performance being high at a low voltage bias and subsequently deteriorating with increasing voltage bias. We point out that there is an optimum energy barrier height for nanowire Peltier coolers at which the cooling performance is optimized. However, for bulk Peltier coolers, the cooling performance is enhanced with the height of the energy filtering barrier. Exploring further, we point out that a degradation in cooling performance with respect to bulk is inevitable as a single moded nanowire transitions to a multi-moded one. The results discussed here can provide theoretical insights into optimal design of nano Peltier coolers.

Doping effects and magnetic instabilities in full-Heusler Fe$_2$YZ$_{1-x}$A$_x$ thermoelectric compounds*  
SÉBASTIEN LEMAL (Presenter), FABIO RICCI, MATTHIEU VERSTRAete, PHILIPPE GHOZEz, University of Liége — Giant thermoelectric power factors have been theoretically predicted on n-doped Fe-based full-Heusler compounds, however, when dealing explicitly with dopants, they may undergo to a magnetic phase transition with a consequent power factor reduction. Using computer experiments, we demonstrate that such transitions is purely related to electronic effects. Exploiting the broader nature of 4$d$ and 5$d$ transition metal orbitals, the appearance of the magnetic instability can be shifted to higher doping regimes, recovering high power factors. The unveiled very large power factors and magnetic fluctuations are fascinatingly very promising respectively for standard thermoelectric and spin-caloritronic device applications.

NMR Study of Doped Tetrahedrite Thermoelectric Materials.*  
NADER GHASSEMI (Presenter), Department of Physics and Astronomy, Texas A&M University, XU LU, XIAOYUAN ZHOU, YANCI YAN, Department of Applied Physics, Chongqing University, YEFAN TIAN, JOSEPH HANSBRO ROSS, Department of Physics and Astronomy, Texas A&M University — Tetrahedrite thermoelectric materials with compositions between Cu$_{12}$Sb$_4$S$_{13}$ and Cu$_{10}$Zn$_2$Sb$_4$S$_{13}$ were analyzed from room temperature to 4.2 K by $^{63}$Cu and $^{65}$Cu NMR. Cu$_{12}$Sb$_4$S$_{13}$ is known to have a metal-insulator phase transition at T = 88 K, however, structural details of the transformation are not very well known, particularly in the substituted materials of interest for thermoelectric devices. Cu NMR is very sensitive to changes in local structure, and we found the metal-insulator transition still present for Cu$_{11}$ZnSb$_4$S$_{13}$, but absent in the Zn$_2$ material. However, differences in high-temperature NMR spectra reveal a distinct local structure for Zn$_2$ vs the undoped material. Also, we found NMR evidence for Cu-ion hopping, which disappears in the Zn$_2$ material. Spin-lattice relaxation rates (1/T$_1$) furthermore provide a measure of local anharmonic vibrational motions, through an electric quadrupolar process. Results indicate that the rattling behavior is little changed by Zn substitution up to Zn$_2$, despite the structural differences.

Influence of the Mobility Ratio and Density of States Width on the Thermoelectric Properties of Polymer Blends*  
ASHKAN ABTAHI (Presenter), Physics ans Astronomy, University of Kentucky, YADONG ZHANG, Chemistry, Georgia Institute of Technology, XUYI LUO, JIANGUO MEI, Chemistry, Purdue University, SETH R. MARDer, Chemistry, Georgia Institute of Technology, KENNETH GRAHAM, Chemistry, University of Kentucky — Conjugated polymers can be used in mechanically flexible and low cost thermoelectric (TE) devices, but their thermoelectric performance must be improved to make them commercially viable. The performance of thermoelectric materials depends on the electrical conductivity, Seebeck coefficient and thermal conductivity. The higher the doping concentration, the more electrically conductive the material becomes, but generally at the cost of a decrease in the Seebeck coefficient. Blending of n-conjugated polymers has been proposed as a method to minimize the tradeoff between electrical conductivity and the Seebeck coefficient. By blending two polymers, the total density of states (D.O.S.) will be manipulated, which may be used to alter the charge transport in the TE material. The major parameters that we expect to impact the power factor in polymer blends are the mobility ratios between the two polymers and the shape of D.O.S. Here, we use a model introduced by Bässler and Arkhipov to theoretically probe how these two parameters impact the thermoelectric performance. We find that a narrower D.O.S. and lower mobility of the added polymer with respect to host polymer can lead to an enhancement in the Power factor of the TE material.

*American Chemical Society Petroleum Research Fund
Porous Structure  SEOUNG-HUN KANG (Presenter), KISUNG CHAE, SEON-MYEONG CHOI, Korea Institute for Advanced Study, DUCK YOUNG KIM, Center for High Pressure Science & Technology Advanced Research, YOUNG-WOO SON, Korea Institute for Advanced Study — Thermoelectric device is a promising next-generation energy solution owing to its capability to transform waste heat into useful electric energy, which can be realized in materials with high electric conductivities and low thermal conductivities. A recently synthesized silicon allotrope of Si24 features highly anisotropic crystal structure with nanometer-sized regular pores. Here, based on first-principles study without any empirical parameter we show that the slightly doped Si24 can provide an order-of-magnitude enhanced thermoelectric figure of merit at room temperature, compared with the cubic diamond phase of silicon. We ascribe the enhancement to the intrinsic nanostructure formed by the nanopore array, which effectively hinders heat conduction while electric conductivity is maintained. This can be a viable option to enhance the thermoelectric figure of merit without further forming an extrinsic nanostructure. In addition, we propose a practical strategy to further diminish the thermal conductivity without affecting electric conductivity by confining rattling guest atoms in the pores.

Session S48 DFD GSOFT GSNP: Drops II BCEC 251 - Irmgard Bischofberger, Massachusetts Institute of Technology - Tag(s):

Focus

11:15AM S48.00001: Drying of colloidal droplets on hydrophobic surfaces  PAUL LILIN (Presenter), PHILIPPE BOURRIANNE, GUILLAUME SINTES, IRMGARD BISCHOFBERGER, Massachusetts Institute of Technology — The evaporation of drops of colloidal suspensions on hydrophilic substrates leads to a variety of patterns, from the well-known coffee stain effect to radial crack formation. Here, we investigate the drying of aqueous solutions of silica nanoparticles on hydrophobic substrates for a large range of particle volume fractions. As the water evaporates, the particle volume fraction increases leading to a transition from a moving to a pinned contact line. This pinned contact line induces a large stress buildup within the material during the further evaporation process, which eventually gets released through the formation of fractures that shatter the dried drop into a multitude of pieces.

11:27AM S48.00002: Analyzing the Effect of Collision of Droplets on Evaporation Rate  SIAVASH ZAMANI (Presenter), AARON B MORRIS, Mechanical Engineering, Purdue University — Spray drying is a process used by many industries such as food, agricultural and pharmaceutical to convert a liquid feed into powder. Many studies have used CFD to model fluid and powder flow. However, continuum approaches track bulk powder properties resulting in loss of data for individual particles. To improve the accuracy of these models, fundamental research on drying behavior is critical. This work focuses on simulating the initial phase of the process where an atomized droplet behaves as a liquid due to excess moisture content. At this stage, the droplets collide frequently, and particle size distribution changes rapidly. Accurate calculation of the moisture content of the droplet is essential for further analysis on drying kinetics and morphology of particulate form. A computational framework has been developed where the gas phase is modeled as a continuum and individual droplets are tracked in the Lagrangian frame. Using this approach, individual droplets and their characteristic properties are captured, while evaporation effects are accurately accounted for. This works provides high-fidelity data for particle size distribution and moisture content which paves the path toward modeling of the second phase of drying, when liquid droplet has transformed into a wet-particle.

11:39AM S48.00003: Evaporation and Dynamics of Transcritical Dodecane Droplets: A Theoretical Investigation Using a Sharp Interface Method  YUVAL DAGAN (Presenter), Massachusetts Institute of Technology, PING HE, Lamar University, AHMED F GHONIEM, Massachusetts Institute of Technology — Evaporation of droplets injected into a supercritical environment plays an important role in many physical, chemical and high-pressure propulsion applications. In such processes, complex interactions due to coupling of the multiphase flow, heat transfer and multicomponent mass transfer, as well as diffusion processes across the phase interface essentially impact the droplet evaporation and surface tension. This, in turn, may drastically change the droplet's dynamic response as its interface and surface tension diminish. In this study, we use a sharp interface method to investigate the structure and the dynamic response of cold n-Dodecane droplets that are introduced into high-pressure and high temperature (supercritical) environments. The phase-change of single droplets undergoing transcritical evaporation at different conditions are explored, as well as droplet trajectories in a simplified one-dimensional flow model. A non-ideal equation of state is used to compute the fluid properties such as density, fugacity and enthalpy, and to predict phase equilibrium composition. The sharp-interface method provides a new realization for an effective radius of transcritical droplets, and a new phase diagram reveals the complex evolution of droplet during transcritical evaporation.
11:51AM S48.00004: Dynamics and structure in the deposition profile of the coffee-ring effect* NICHOLAS SCHADE (Presenter), University of Chicago, JEROME SEEBECK, Caltech, SIDNEY ROBERT NAGEL, University of Chicago — We investigate the growth dynamics and three dimensional structure of ring stains in evaporating drops of solutions and colloidal suspensions. Drying solutions generally leave behind ring stains. While this “coffee-ring effect” has been widely studied, the microscopic details of how the deposition patterns form have not been completely characterized experimentally. Using fluorescence and laser-confocal microscopy, we measure the growth rate and height profile of the deposit as functions of time, initial particle concentration, and particle size. Starting at the contact line, the particle deposition grows into the interior of the drop. The deposition front accelerates as the drop dries and the front steadily becomes sharper until the thickest part of the deposit has formed. Our experiments with fluorescent microspheres reveal the growth of a film of particles over the entire fluid-air interface. This film contracts and detaches from the contact line during the later stages of evaporation. The final deposits often contain patterns of particles in the interior of the rings resembling fractals. Prior theoretical work does not adequately describe many of the phenomena that we observe.

*NSF MRSEC

12:03PM S48.00005: The underside of a Leidenfrost drop on a bath LAURENT MAQUET, GRASP Lab, University of Liège, BENJAMIN SOBAC (Presenter), TIPs Lab, Université libre de Bruxelles, ALEXIS DUCHESNE, Department of Physics, Technical University of Denmark, HATIM MACRAFI, Thermodynamics of Irreversible Processes, University of Liège, ALEXEY REDNIKOV, TIPs Lab, Université libre de Bruxelles, PIERRE DAUBY, Thermodynamics of Irreversible Processes, University of Liège, PIERRE COLINET, TIPs Lab, Université libre de Bruxelles, STEPHANE DORBOLO, GRASP Lab, University of Liège — The Leidenfrost effect can also be observed on a liquid substrate, i.e., volatile drops may levitate on their own vapor when placed on a hot bath of non-volatile liquid. Compared to the classical Leidenfrost effect on solid substrates, the liquid bath presents three major differences: the substrate is atomically smooth, deformable, and fluid. As a consequence of such fluidity, heat transfer through the bath to the drops is most certainly dominated by convection and not by just conduction as in the solids. Here, we examine experimentally and numerically the flow motion in the bath of silicone oil V20 under the action of a Leidenfrost drop. We highlight the development of a toroidal vortex under the drop. Interestingly, the sense of circulation in this vortex is found to depend on the nature of the liquid that makes the drop. We show that this is due to a shift in a complex and delicate interplay between three mechanisms pulling in different directions: the local cooling of the bath by the drop gives rise to both (i) a buoyancy action and (ii) Marangoni stresses, whereas the vapor escaping from the gap between the drop and the bath exerts (iii) a shear action on the bath surface.

12:15PM S48.00006: Droplet moving on frosted glass* STEPHANE DORBOLO (Presenter), University of Liège — The surface of the frosted glass is very rough. This roughness offers numerous pinning sites for any sessile droplet. In the present case, the angle of contact of a water droplet is about 50°. The advancing angle is rather large (about 70°) and contrasts with the receding angle that is quite zero. This strong hysteresis has a direct consequence on the motion of a droplet when the plate is inclined. The droplet leaves a trace after its passage. The dynamic of the droplet going down the plane is studied and the microflows in the trace are described. Finally, the behavior of oil droplets is compared. As the oil wets the glass, the motion of the sliding droplet superposes to the diffusion process of the oil in the crevices of the frosted surface.

*SD is a FNRS senior research associate. Part of this work has been financially supported by the Interuniversity Attraction Pole Programme (IAP 7/38 MicroMAST) initiated by the Belgian Science Policy Office, by the PDR Wolflow (T.0021.18) and by University of Liège.

12:27PM S48.00007: Experimental and analytical studies on colliding merging of two immiscible drops* CHU-PO HUANG, KUO-LONG PAN (Presenter), Department of Mechanical Engineering, National Taiwan University — Two types of merging between two immiscible drops have been found in their collisions. Depending on the interfacial tensions among the three media of different components, including air and immiscible liquids, at an equilibrium state with negligible impact energy, partial engulfing and complete engulfing between the drops can be identified. With sufficient inertia of relative motion between the drops, it would yield adhesive merging, whereby two drops adhere to each other, or encapsulation, whereby the softer drop totally encapsulates the harder one which has higher surface tension. Based on two dimensionless numbers, a Weber number and an impact parameter, we have identified a regime diagram that indicates the parametric conditions of different regimes, including other types of consequences specifically those show separation following temporary coalescence. While the outcome of interaction between two drops at rest can be analyzed by an approach of free energy, those with significant relative motions need to account for the impact inertia. Via an analysis based on conservation of energy, a model has been established to predict the critical Weber number of transition between two different regimes of merging.

*We thank the support of NTU projects (NTU-CDP-106R7822 & NTU-107L7822).
12:39PM S48.00008: Oscillations of a hydrodynamic crystal lattice  
STUART THOMSON (Presenter), MILES COUCHMAN, JOHN WM BUSH, Massachusetts Institute of Technology — When brought into close proximity, two or more droplets bouncing on a vertically vibrating fluid bath exhibit a rich spectrum of dynamical behaviour. In particular, pairs of droplets have been shown to destabilize into oscillatory, orbiting, and promenading modes, while a collection of multiple droplets can form crystal-like lattices with highly regular structure. In this talk, we present the results of a combined experimental and theoretical study in which we characterize and rationalize the behaviour of a circular chain of bouncing drops, reminiscent of a one-dimensional crystal lattice. As the vibrational forcing is increased, the stationary chain first destabilizes into an oscillatory mode and then into a striking soliton-like disturbance, before “melting” at sufficiently high acceleration of the bath. Similarities with models such as the Toda lattice, used to model crystal vibrations in solid-state physics, are discussed.

12:51PM S48.00009: A hydrodynamic analog of the quantum potential*  
JOHN BUSH (Presenter), MATTHEW DUREY, Massachusetts Institute of Technology, PAUL MILEWSKI, Mathematics, University of Bath — A droplet may walk on a vibrating fluid bath through a resonant interaction with its own wave field. This walking droplet system has become the subject of research in the nascent field of hydrodynamic quantum analogs. We here consider the motion of droplets walking in closed systems, and demonstrate the relation between the histogram of the particle and its mean pilot-wave field. Furthermore, we demonstrate that as the Faraday threshold is approached, the instantaneous wave field converges to its mean. The resulting mean pilot-wave potential thus plays the role of the quantum potential in Bohmian mechanics. Our study highlights the differences between Bohmian mechanics and de Broglie's relatively rich double-solution theory of quantum dynamics.

*JB gratefully acknowledges the support of the NSF through award CMMI-1727565.

Thursday, March 7, 2019 11:15 AM - 2:15 PM

Session S49 DPOLY: Polymers in Reactive Conditions BCEC 252A - Nir Goldman, Lawrence Livermore Natl Lab - Tag(s): Focus

11:15AM S49.00001: Capturing shock-driven dissociation of polymers and foams* [Invited]  
DANA DATTELBAUM (Presenter), JOSHUA COE, Los Alamos National Laboratory — Polymers, and polymer-based composites and foams are used extensively in engineering and defense applications in a range of components including structural bodies and supports, insulating layers, and vibration and shock mitigation parts. In several applications, they may be subjected to impact and shockwave compression. Under these loading conditions, polymers have several features that differ from those of metals, including compression of network volume at low pressures, viscoelastic behaviors, and shock-driven dissociation. A novel equation of state methodology has been developed for describing the shock-driven decomposition of solid and porous polymers at moderate shock input conditions. Examples of the shockwave response of several polymers, and a comparison of historical metals-based equation of state approaches to the new methodology will be presented. Furthermore, this modeling approach has been extended to porous polymer foams, and revealed, through a large series of plate impact experiments, a phenomena we have termed “reactive anomalous compression.” A striking feature of our results is the shift from densification to expansion of shock-driven reaction products as a function of initial porosity. Expansion with increasing shock pressure is most commonly associated either with shock heating due to pore collapse in chemically inert materials such as metals or exothermic decomposition (detonation) of energetic materials. We describe an unexpected admixture of these two effects: shock heating due to pore collapse, but expansion in conjunction with chemical reaction. Lastly, efforts to measure reactive wave structures in shock-dissociated polymers, and new x-ray based diagnostic techniques will be described.

*This work was funded by the U.S. Department of Energy, National Nuclear Security Administration to Los Alamos National Laboratory. The authors acknowledge funding from the Dynamic Materials Properties Campaign and Advanced Simulation and Computing program.
Polymer degradation kinetics and reaction mechanisms are of a great interest for many applications. Reports about chemistry related aging effects found in the literature are, however, rarely correlated to the performance of these materials under dynamic compression conditions. One longstanding question is how much degradation must occur before a polymer-based component is significantly affected? Answering this question requires high-throughput testing under a broad spectrum of aging conditions. In this talk, we describe a path forward using an ultrafast laser compression platform. First, we demonstrate validation results from PDMS-based polymers, reproducing available gas-gun shock Hugoniot data and further, show Hugoniot slope changes with polymer filler and radiation-induced damage. Lastly, we present shock results from a set of CVD deposited Kapton and Parylene films cured at different thermal/humidity aging conditions. Discussion of our main findings and future development plans are presented.

*This work was performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Security, LLC under Contract DE-AC52-07NA27344. LLNL-ABS-760541

12:03PM S49.00003: Predicted pathways for chemical degradation in siloxane polymers*  MATTHEW KROONBLAWD (Presenter), NIR GOLDMAN, JAMES LEWICKI, Lawrence Livermore National Laboratory — Chemical degradation can result in undesirable changes in the performance of functional materials over the service lifetime, but the underlying atomic-scale processes are often subtle to probe with experiments. We use ensembles of quantum molecular dynamics (QMD) simulations to predict the chemical reactions that follow radiation-induced excitations of phenyl groups in a model copolymer of polydimethylsiloxane and polydiphenylsiloxane. Initial benzene-forming proton transfer reactions are predicted to induce subsequent reactions including intrachain cyclization and chain scission reactions. Water is found to play a crucial role in chain scission reactions, which indicates a possible synergistic effect between environmental humidity and radiation that could promote alterations of a larger polymer network. An approach for obtaining probability distributions of reaction intermediates and products by coupling high throughput semiempirical QMD simulations with automated graph-based structure recognition tools is discussed.

12:15PM S49.00004: Perturbing effects on the structure and properties of physically and chemically crosslinked phenolic resins  WEIWEI ZHAO, SHAW HSU (Presenter), University of Massachusetts Amherst — Crosslinked polymers may consist of physical crosslinks such as hydrogen bonds, or covalent bonds or both. The network of crosslinked phenolic resins involves the both. The formation of each type of crosslinking has not been studied in detail. Their contributions to the physical properties are also unclear. Utilizing a combination of infrared spectroscopy, thermal analysis, low field NMR and a cantilever deflection technique, the relative contributions of two types of crosslinks have been characterized as a function of temperature and moisture. The results show that the increased chemical crosslinks reduced the formation of hydrogen bonds. As expected, the covalent bonds dominate at elevated temperatures. However, the contribution of hydrogen bonds is unexpectedly important at low temperatures. As expected, the hydrogen bonding contribution of crosslinked structures is significantly decreased by the moisture absorbed. However, segmental relaxation behavior measured under different humidity levels depends on not only the two types of crosslinks achieved but also the morphological features affecting the moisture absorption process.

12:27PM S49.00005: Photothermally-driven oxidative degradation of LDPE nanocomposites containing plasmonic nanoparticles*  GABRIEL FIRESTONE (Presenter), Department of Physics, North Carolina State University, HONGLU HUANG, RUSSELL E GORGA, Fiber and Polymer Science, North Carolina State University, LAURA CLARKE, JASON R BOCHINSKI, Department of Physics, North Carolina State University — Novel approaches to control and drive polymer degradation are interesting because of the multiple challenges to remediating plastic waste including minimizing its effect when unconfined in the environment and potentially recovering value from discarded material. Photothermal heating from metal nanoparticles, where light is focused and converted into heat at the nanoscale, can be used to drive chemical reactions, such as oxidative degradation within low density polyethylene (LDPE), and results in a high temperature, high electric field environment in the particles' immediate vicinity within which reactions could be manipulated. It also provides a mechanism to convert sunlight to internal heat. We present an LDPE nanocomposite system incorporating silver nanoparticles and cobalt ions where the cobalt-mediated oxidative process is driven by heat resulting from illumination with blue light. In this configuration, the observed degradation (characterized by FTIR, absorption spectroscopy, electron microscopy and mechanical testing) under photothermal heating is almost identical to that due to heating conventionally, as expected due to the non-local oxidative process. We discuss these results and next steps.

12:39PM S49.00006: Phase field model for reactive blending of a symmetric binary polymer blend* MUKUL TIKEKAR (Presenter), KRIS T DELANEY, DOUGLAS R. TREE, GLENN FREDRICKSON, University of California, Santa Barbara — Reactive blending is a process for forming polymer alloys where mutually reactive homopolymers are mixed together to form compatibilizers in-situ. The dynamics of the problem is replete with rich nonequilibrium physics stemming from reactions between the polymers, spatiotemporal transport, thermodynamics of mixing, and externally imposed processing conditions, and has hence been poorly understood. To study this process, we develop a coarse-grained phase-field model designed to capture all of the above physical effects. We then implement the model using pseudospectral collocation and semi-implicit time stepping to solve for temporal evolution of concentration distributions. In the case of reaction-diffusion dynamics, we find that the reaction typically progresses with the formation of an interfacial, diblock-rich layer. Eventually, the diblock diffuses out of the interface and the homopolymers diffuse in, as the reaction proceeds toward completion. The reaction rates in each stage depend on the incompatibility of the species, the Damkohler number and the initial distribution.

12:51PM S49.00007: Integrating Particle and Field-Theoretic Simulations: A Multiscale Approach to Complex Polymeric Solutions NICK SHERCK (Presenter), KRIS T DELANEY, M. SCOTT SHELL, GLENN FREDRICKSON, University of California, Santa Barbara — Our work investigates the phase-behavior of complex polymeric solutions leveraging the strengths of both particle and polymer field-theoretic simulations. Mesostructured polymeric solutions are difficult to simulate using traditional particle-explicit approaches due to the disparate time and length scales, while the predictive capability of field-theoretic simulations is hampered by the need to specify emergent parameters (e.g., chi parameters) with nonobvious connections to molecular architecture. To overcome the weaknesses of both, we discuss an original way to use small-scale, atomistic simulations to parameterize statistical field theory models. Subsequently, field-theoretic simulations can probe behavior at larger length scales in polymeric solutions efficiently while maintaining a connection to the underlying polymer chemistry. This synergistic approach to polymer simulations opens the door to explore-de-novo-a wide variety of polymeric solution phase behavior. In particular, we will show how the above machinery can predict complex inter-colloidal potentials-of-mean force as modulated by the surrounding polymeric solution.

1:03PM S49.00008: Hydration of the polymer block in globular protein-polymer bioconjugates* HELEN YAO (Presenter), BRADLEY DAVID OLSEN, Massachusetts Institute of Technology — Protein-polymer bioconjugates are a type of AB block copolymer where one block is a globular protein. The self-assembly of these systems in solution differ significantly from that of synthetic coil block copolymers. The chemistry of the polymer block and the resulting interactions with the solvent (water) can tune the phase behavior of bioconjugates. Previously, our group has observed that changing the hydrogen bonding of the polymer can shift phase boundaries, create new phases, and change order-disorder transitions. Using small angle neutron scattering (SANS), we have devised a contrast matching method to quantify the hydration number, the number of water molecules associated with a repeat unit, of polymers that can be conjugated to globular proteins. This generalizable method can be applied to polymer solutions above the overlap concentration and does not require any underlying assumptions. The SANS data show that there are differences in the hydration of zwitterionic polymers, hydrogen bond donors, and hydrogen bond acceptors. Moreover, the hydration number correlates with a polymer's tendency to order and the homopolymers diffuse in, as the reaction proceeds toward completion. The reaction rates in each stage depend on the incompatibility of the species, the Damkohler number and the initial distribution.

1:15PM S49.00009: Controlled Crystallization of Small Organic Molecules using Polymers: the Role of Hidden Liquid-Liquid Phase Domain* GAGAN KANGOVI (Presenter), SUNGMIN PARK, SANGWOO LEE, Rensselaer Polytechnic Institute — We investigated the crystallization behaviors of model organic compound pyrene mixed with polystyrene using differential scanning calorimetry. The thermal characterization of the pyrene and polystyrene mixtures provided extensive thermodynamic information regarding the phase states and transition temperatures. Using the glass transition temperatures, the chemical compositions of phase-separated phases are elucidated. Remarkably, the crystallization temperature curve of pyrene of the mixtures shows a clear signature of upper critical solution temperature (UCST) with the composition. We attribute the UCST signature to the hidden liquid-liquid phase domain of pyrene and polystyrene in which the nucleation barrier of crystallization is significantly depressed by the spinodal decomposition of liquid phases. This result suggests that polymer additives can be effectively utilized to control the crystallization behaviors.

1:27PM S49.00010: Dynamics of photoresponsive molecules in glassy solids  KENNETH SALERNO (Presenter), TIMOTHY SIRK, US Army Research Laboratory, JUAN DE PABLO, Institute for Molecular Engineering, University of Chicago — The photoresponse of azobenzene and azobenzene-like molecules undergoing the trans → cis photoisomerization transition has been primarily explored through simulation and experiment in solution or vacuum. The response and behavior of these photoactive molecules in solids, where barriers to rearrangement are significantly higher, is less well characterized. Here we use molecular dynamics simulations to study the behavior of azobenzene and disperse red one during and after photoactivation in glassy samples. Data show that the dynamics of photoactivated molecules and the surrounding solid depends little on the sample temperature or measures of local stability such as density and energy. On the other hand, the height of transition barriers, which depends strongly on intermolecular interactions, cooling rate and temperature, is reflected in the waiting time between photoactivation and a local transition. The timescale for flipping is compared with the timescale for rotational and diffusive motion. The rotation of azobenzene or disperse red one around the long axis of the molecule is correlated with the wait time or barrier to flipping while the translational motion and the rotation of the long-axis itself is less correlated with the flipping wait time.

1:39PM S49.00011: Why do Silicones do that? A Perspective on the Stability and Dynamics Polysiloxane based Polymers*  JAMES LEWICKI (Presenter), Materials Science Division, Lawrence Livermore National Laboratory — Polysiloxane polymers (silicones) are a uniquely widespread class of inorganic polymeric material, which find application in some of the most challenging environments on, or indeed off the planet. Despite their comparative ubiquity, even the most basic aspects of their structure remain something of a mystery to many involved in their use and study at a scientific and technical level. This veil of uncertainty is in part due to the unusual path polysiloxanes took from the laboratory to the commercial sector; initially as a WW2 ace of the aided forces and later a jealously guarded jewel of the giants of the chemical industry. This spy story-esque beginning for silicones meant that silicones popped unexpectedly into public light of day in the mid 1970's and were something of a surprise for both the writers of textbooks and the materials scientists of the time. Polysiloxanes are a physically and chemically unique class of polymeric material. With significantly different electronic configuration to a carbon backboned polymer, the lowest glass transition of any stable polymer, no energy barrier to rotation of the main chain segment, their dynamics stand out over a range of size scales as 'odd'. In the rubbery state, they are best described as statistically pinned liquids rather than solids and exhibit such poor mechanical properties that they must be compounded with a range of additives to even be useable. With all this in mind then, why do silicones end up as the material of choice so many in extreme applications and just how do they behave at the extremes of temperatures, pressure and irradiation? In this paper we aim to discuss some aspects of the response of polysiloxanes under such extremes and attempt to relate their behavior in these regimes to their underlying chemical and network structure.

11:15AM S50.00001: Y-shape DNA guided Ni ion chain based nanowire transistor development and characterization*  CHIA-CHING CHANG (Presenter), WEN-HUNG WANG, Biological Science and Technology, National Chiao Tung University, WEN-BIN JIAN, YU-CHANG CHEN, Electrophysics, National Chiao Tung University, Hsinchu, Taiwan — Recently studies indicate that DNA template guided Ni ion chain (Ni-DNA) is a conducting nanowire and it possesses multi-states memory effect owing to the Ni ions redox state transition by external bias. By designing the sequences of DNA, Y-shape Ni-DNA molecules have been synthesized and characterized. Furthermore, these unique Ni-DNA molecules were linked with three-terminal nanodevice via self-assembly process. The negative differential resistance behavior of I-V curves can be observed between each two terminals of device. By assigning these three terminals as source, drain and gate terminal and the source-drain currents can be regulated by different gate voltage. This is the first Ni-DNA nanowire based transistor has be developed in the world.

Impact of self-assembled monolayers on electronic properties of poly(3-hexylthiophene) at the polymer/substrate interface

JILL WENDEROTT (Presenter), University of Michigan, PETER GREEN, National Renewable Energy Laboratory — The impact of self-assembled monolayers (SAMs) on electronic properties of poly(3-hexylthiophene) (P3HT) thin films, of different morphologies, at P3HT/substrate interfaces is reported. The SAMs, trichloro(1H,1H,2H,2H-perfluorooctyl)silane (FTS) and octadecyltrichlorosilane (OTS), modified the surface energy and work function (WF) of indium tin oxide substrates, which influenced charge transfer and band bending behavior of P3HT films at the polymer/substrate interface. This band bending behavior could not be explained solely in terms of substrate WF modification. Investigations of P3HT films fabricated via matrix-assisted pulsed laser evaporation (MAPLE) and spin-casting revealed that the degrees of band bending and breadths of densities of states were associated with changes to electronic structure, strongly affected by the morphological structures of films. The morphological structures of films were influenced by film fabrication method and surface energies of the substrates. The implications of our findings are that the electronic properties of the system are influenced by the WFs and surface energies of SAM-modified substrates and the morphologies of thin P3HT films.1

Enhanced Charge Injection Properties of Organic Field Effect Transistor via Molecular Implantation Doping

YOUNGROK KIM (Presenter), Physics and Astronomy, Seoul National University, SEUNGJUN CHUNG, Korea Institute of Science and Technology, KYUNGJUNE CHO, Physics and Astronomy, Seoul National University, DAVID HARKIN, University of Cambridge, WANG-TAEK HWANG, DAEKYOUNG YOO, JAE-KEUN KIM, WOOCHEOL LEE, Physics and Astronomy, Seoul National University, YOUNGGUL SONG, Electrical and Computer Engineering, Seoul National University, HEEBEOM AHN, Physics and Astronomy, Seoul National University, YONGTAEK HONG, Electrical and Computer Engineering, Seoul National University, HENNING SIRRINGHAUS, University of Cambridge, KEEOON KANG, TAKHEE LEE, Physics and Astronomy, Seoul National University — Organic semiconductors (OSCs) have been widely studied due to their merits such as mechanical flexibility, solution processability, and large-area fabrication. However, because of the Schottky contact at the metal/OSC interfaces, a non-ideal transfer curve feature often appears in the low drain voltage region. Here, we demonstrated a selective contact doping of 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F4-TCNQ) by solid-state diffusion in poly 2,5-bis(3-hexadecylthiophen-2-yl) thiophene (PBTTT) to enhance carrier injection in bottom-gate PBTTT organic field effect transistors (OFETs). This doping exhibited a high conductivity with favorable charge transport properties [1]. Furthermore, we investigated the effect of post-doping treatment on diffusion of F4-TCNQ molecules in order to improve the device stability. In addition, the application of the doping technique to the low-voltage operation of PBTTT OFETs with high-k gate dielectrics demonstrated a potential for designing scalable and low-power organic electronic devices by utilizing doping of conjugated polymers.

11:51AM S50.00004: Contacts in Organic Field-Effect Transistors [Invited] OANA JURCHESCU (Presenter), Department of Physics and Center for Functional Materials, Wake Forest University — Organic semiconductors are versatile materials for emerging low-cost, lightweight, flexible devices, but their incorporation in consumer applications is delayed by inadequate performance. Inefficient charge injection at the electrode/semiconductor interface represents a significant hurdle in the pursuit of the promised potential of organic semiconductors. Moreover, with increasing the effective mobility of organic semiconductor layer and reducing the channel dimensions, this problem becomes even more prevalent. In this talk, I will focus on describing the origin and characterization of contact effects in organic field-effect transistors and their impact on device performance and accuracy in extraction of charge carrier mobility. Several types of manifestations of contact effects will be presented, as well as their impact on the device characterization. I will discuss methods for reducing contact resistance and will emphasize on a simple strategy consisting of developing high workfunction surface domains at the surface of the injecting electrodes to promote channels of enhanced injection [1]. This led to contact resistances of 200 Ωcm and device charge carrier mobilities of 20 cm²/Vs independent of the applied gate voltage. The proposed approach is efficient for both small molecule and polymeric thin-film transistor devices, and can be generally applied in all common processes and device architectures. In addition to allowing the demonstration of high-mobility transistors with near ideal current-voltage characteristics, the use of this method leads to accurate measurement of the charge carrier mobility, a critical step in a rational material design.

12:27PM S50.00005: Limits to Charge Carrier Motion in High-Performance Organic Semiconductors: Role of Energy Barriers at Grain Boundaries and Interface Traps ILJA VLADIMIROV, MICHAEL KÜHN, THOMAS GESSNER, FALK MAY, BASF SE, RALF WEITZ (Presenter), Ludwig Maximilian University of Munich — Using our recently developed surface-crystallization method [1], we have realized 3 – 10 nm thin, highly-crystalline thin films of a novel perylene diimide and investigated temperature-dependent charge transport. Via a combination of as-measured density-of-states with Kinetic Monte Carlo simulations [2], we present strong hints that it is rather the energetic barriers at grain boundaries than the usually identified energetic traps that limit charge carrier motion below room temperature. We furthermore have observed that above room temperature the charge carrier mobility decreases upon increasing the charge carrier density in the semiconducting film [3]. While the true cause for this suppression is currently unclear, we present evidence that the squeezing of charges closer to the semiconductor/dielectric by the gate dielectric field a subsequent scattering at this interface might cause the drop in mobility. We believe that our combined observations will help to understand the still debated nature of charge transport in high-quality organic semiconductors.
