Saturday, March 2, 2019 1:00 PM - 6:00 PM

Session 1A DPOLY: DPOLY Short Course: X-ray and Neutron Scattering for Polymer Science I BCEC 150

1:00PM 1A.00001: DPOLY Short Course: X-ray and Neutron Scattering for Polymer Science — The DPOLY short course will introduce the principles of X-ray and Neutron Scattering from polymeric materials. The first part of the course will focus on techniques that probe polymer structure, including transmission scattering, reflectivity and grazing incidence, with emphasis on hard x-ray, soft x-ray and neutron sources. The second part of the course will cover techniques that probe polymer dynamics, including x-ray photon correlation spectroscopy, quasielastic neutron scattering, and neutron spin echo. The course will conclude with an introduction to new challenges and opportunities, such as integration of scattering with other experimental methods, machine learning, and big data.

Sunday, March 3, 2019 8:00 AM - 5:30 PM

Session 1B GSOFT: GSOFT Short Course: Structures and Order in Soft Matter Physics BCEC 153B

8:00AM 1B.00001: GSOFT Short Course: Structures and Order in Soft Matter Physics — The emergence of order is ubiquitous in soft-matter systems. Researchers observe a variety of different order phenomena, ranging from ordered crystalline structures, liquid crystals, and partially ordered systems, to glassy structures. At times it can be challenging to understand the arising structures, from a lack of either suitable experimental procedures or access to structure analysis methods.

The course will start with an overview of the increasingly diverse structures arising in soft matter systems, and introduce how these structures can be described. More intricate structural aspects will be highlighted in reviews of different kinds of simulation studies. The course will then review techniques of determining structures in experimental systems, such as optical microscopy, transmission or scanning electron microscopy, and scattering methods.

Who Should Attend?
Anyone who needs or wants to describe the structure of the soft-matter systems they study, on the colloidal or nano-scale, both in experiments and simulations. Designed to give an introduction into a wide range of experimental and simulation methods for structure determination.

Organizers
Chrisy Xiyu Du and Julia Dshemuchadse, University of Michigan

Sunday, March 3, 2019 8:00 AM - 5:00 PM

Session 1C GERA: Energy Research Workshop BCEC 154

8:00AM 1C.00001: Energy Research Workshop — This annual workshop, held on the Sunday before March Meeting begins, is intended to familiarize graduate students and early career scientists with the opportunities, challenges, and basic landscape of current energy research. Talks, panels, and informal discussions during lunch and coffee breaks will allow for interaction between the students and leading researchers from academia, government, and industry in a variety of energy fields.

Those interested in attending will need to submit a short statement of interest, their March Meeting abstract, and their current academic or research information. The workshop is sponsored by GERA and co-sponsored by FECS.

Sunday, March 3, 2019 8:15 AM - 5:30 PM
Session 1D DPOLY: DPOLY Short Course: X-ray and Neutron Scattering for Polymer Science II BCEC 150

8:15AM 1D.00001: DPOLY Short Course: X-ray and Neutron Scattering for Polymer Science — The DPOLY short course will introduce the principles of X-ray and Neutron Scattering from polymeric materials. The first part of the course will focus on techniques that probe polymer structure, including transmission scattering, reflectivity and grazing incidence, with emphasis on hard x-ray, soft x-ray and neutron sources. The second part of the course will cover techniques that probe polymer dynamics, including x-ray photon correlation spectroscopy, quasielastic neutron scattering, and neutron spin echo. The course will conclude with an introduction to new challenges and opportunities, such as integration of scattering with other experimental methods, machine learning, and big data.

Sunday, March 3, 2019 8:30 AM - 12:30 PM

Session 1E DQI: Tutorial 1: Hybrid Quantum Systems BCEC 151A

8:30AM 1E.00001: Tutorial 1: Hybrid Quantum Systems — There have been intense efforts to harness mesoscopic quantum systems such as ultracold gases, superconducting qubits, nanomechanical systems and solid-state defect centers for a suite of applications including sensing, quantum information and communication. However, no single system has been shown to be optimal for the entire range of envisioned applications. Atomic gases are extremely coherent, but they are highly isolated and fragile. Nano-resonators are highly sensitive to small forces and well suited to sensing applications, yet they suffer from dissipation and loss. While photons are robust carriers of information, they typically exhibit very weak nonlinearities. These considerations motivate the ‘hybridization’ of distinct physical systems with complementary functionalities to access new phenomena and applications. In addition, these hybrid systems can also exhibit new forms of quantum behavior to probe macroscopic quantum phenomena and the quantum-to-classical boundary. The lectures will provide a basic introduction to hybrid quantum systems, their realizations, applications to new regimes of quantum metrology and information processing, with a discussion of open questions and challenges.

Sunday, March 3, 2019 8:30 AM - 12:30 PM

Session 1F GMED: Tutorial 2: Medical Imaging: Physics, Technology and Algorithms BCEC 151B

8:30AM 1F.00001: Tutorial 2: Medical Imaging: Physics, Technology and Algorithms — Medical imaging modalities use a wide range of physical phenomena to gather diagnostic information about living tissues. Development and performance assessment of new imaging technologies is a fertile ground for significant and lasting contributions from physicists. This tutorial is intended to facilitate exchange of ideas between researchers trained in fundamental and applied physics and the medical imaging community by introducing the audience to the fundamentals of medical imaging technologies.

Sunday, March 3, 2019 8:30 AM - 12:30 PM

Session 1G DMP: Tutorial 3: Materials by Design: Computational Materials Approach BCEC 152
8:30AM 1G.00001: Tutorial 3: Materials by Design: Computational Materials Approach — With the advent of density functional theory and the growing power of computer speed and parallel algorithms, a new paradigm in the method used to design materials has emerged. Various properties are calculated for a vast amount of materials through effective workflows. The results allow scientists to populate databases. These are then queried to predict and design novel materials or processes. Using these databases, populating them, and interfacing with them requires a specific training which needs to be fulfilled by the developers or experienced research groups.

This tutorial will provide an introduction to materials databases focusing mostly on the Materials Project. Our presentation will begin by introducing the Materials Project and other existing pre-calculated property databases (OQMD, AFlow, NOMAD, Materials Cloud). We will then discuss how we can improve the existing databases by creating property workflows by using Abipy (the Python interface with Abinit) and Atomate (the interface with VASP). Examples will be offered on how these packages can be used to create databases and to query information from the Materials Project. Finally, we will survey some other methods that exist to perform structural searches and how they can complement with these methodologies.

Sunday, March 3, 2019 8:30 AM - 12:30 PM

Session 1H DMP: Tutorial 4: Layered Materials BCEC 153A

8:30AM 1H.00001: Tutorial 4: Layered Materials — Following the isolation of graphene fifteen years ago, the field of atomically thin, layered materials has flourished to incorporate an essentially comprehensive range of condensed matter properties. At the same time, graphene has proven to be an extraordinarily protean material with new surprises arriving continually, such as topological currents, fractal bands, and intrinsic superconductivity to name only a few. The aim of this tutorial is to be both broad, providing an overview of what has been achieved and what may await discovery, and deep, providing specific and detailed examples of the kinds of new questions that increasingly draw researchers to this field. Spurred by the availability of high-quality single crystals of diverse layered materials, a general theme of the past and future of this field is the ability to create van der Waals heterostructures. These combinations of similar or dissimilar layers enable the preservation of delicate materials, new probes of constituent layers, and the radical alteration of band structures, for example through the formation of Moiré bands. Potential applications will be mentioned but are too numerous to be described in any detail; instead the focus will be on the fundamental physics of atomically thin layered materials.

Sunday, March 3, 2019 9:00 AM - 5:00 PM

Session 1J DBIO: DBIO Short Course: Advanced Microscopy BCEC 153C

9:00AM 1J.00001: DBIO Short Course: Advanced Microscopy — Physics, and physicists, have enabled new views of biological systems for centuries. Recent advances on several fronts have broken the “diffraction limit,” producing nanometer-resolution images of living samples. In this short course, we will go through the physics behind recent developments in super-resolution microscopy. The course will also have a hands-on component where students will get to build their own microscope from 3D printed parts.

Who Should Attend
Students and faculty interested in recent advances in high-resolution microscopy

Sunday, March 3, 2019 1:30 PM - 5:30 PM

Session 1K DQI: Tutorial 5: Superconducting Quantum Hybrid Systems BCEC 151AB
Monday, March 4, 2019 10:00 AM - 11:30 AM

Session 1A APS: Hybrid Quasiparticles in Quantum Heterostructures
Westin Marina Ballroom I-II - Tag(s): Education

10:00AM 1A.00001: Hybrid Quasiparticles in Quantum Heterostructures
— The use of hybrid quantum systems has enabled the development of new quasiparticle states with tunable properties. This tutorial will introduce the concept of hybrid quasiparticles and discuss their applications in quantum computing, sensing, and metrology.

Session 1B APS: Strongly Coupled Quasiparticles in Quantum Heterostructures
Westin Marina Ballroom I-II - Tag(s): Education

11:00AM 1B.00001: Strongly Coupled Quasiparticles in Quantum Heterostructures
— Strong coupling between quasiparticles in quantum heterostructures has led to the development of new quantum states with unique properties. This tutorial will provide an overview of the current state of the field and discuss potential applications.

Session 1C APS: Topological Quasiparticles in Quantum Heterostructures
Westin Marina Ballroom I-II - Tag(s): Education

12:00PM 1C.00001: Topological Quasiparticles in Quantum Heterostructures
— The discovery of topological quasiparticles in quantum heterostructures has opened up new possibilities for quantum computing and sensing. This tutorial will provide an introduction to the concept of topological quasiparticles and discuss their potential applications.

Session 1D APS: Quantum Many-Body Systems with Hybridization
Westin Marina Ballroom I-II - Tag(s): Education

1:00PM 1D.00001: Quantum Many-Body Systems with Hybridization
— The development of hybrid quantum systems has enabled the study of complex quantum many-body systems. This tutorial will provide an introduction to the concept of quantum many-body systems and discuss their potential applications.
Sunday, March 3, 2019 5:00 PM - 6:00 PM

**Session 1P APS: First-Time Attendee Orientation** Westin Commonwealth A/B

**5:00PM 1P.00001: First-Time Attendee Orientation** — Join APS staff and leadership to learn how to easily navigate the APS March Meeting. You'll get a crash course on how to use the meeting program to locate sessions you want to see, find out how to use the mobile app to access the meeting program and schedule your events, and find out about interesting and fun events happening throughout the week. You'll also learn about the services APS provides at meetings and about APS programs. Refreshments will be served.

Sunday, March 3, 2019 6:00 PM - 9:00 PM

**Session 1Q APS: Wikipedia Edit-a-thon** Westin Stone - Tag(s): Diversity, Outreach

**6:00PM 1Q.00001: Wikipedia Edit-a-thon** — APS is hosting a Wikipedia Edit-a-thon which will aim to create Wikipedia pages about inspiring women and minority physicists. The event will begin with a talk by Jess Wade, a postdoctoral researcher from Imperial College, who over the last year has created and written more than 270 Wikipedia pages about women scientists. Refreshments will be provided.

Sunday, March 3, 2019 6:30 PM - 7:30 PM

**Session 1R APS/SPS: Undergraduate Student Get-Together** Westin Commonwealth A/B

**6:30PM 1R.00001: Undergraduate Student Get-Together** — Undergraduate Student Get-Together

Monday, March 4, 2019 8:00 AM - 10:48 AM

**Session A01 DCMP: Correlations and Topological States** BCEC 106 - Efstratios Manousakis, Florida State Univ - Tag(s): Focus

**8:00AM A01.00001: Study of the Dirac/Weyl candidates (Ce,Nd)Sb(Se,Te)*** KUAN-WEN CHEN (Presenter), YOU LAI, Florida State University, KAYA WEI, NHMFL, MAREIN RAHN, LANL, YU-CHE CHIU, Florida State University, DAVID E GRAF, NHMFL, MARC JANOSCHEK, LANL, LUIS BALICAS, RYAN BAUMBACH, NHMFL — The nonsymmorphic compound CeSbTe [1] was recently shown to have coexisting complex magnetism and Weyl/Dirac states, where an applied magnetic field transforms the magnetic order and potentially provides a switch between different electronic states. Here we present results for other members of this family compounds, including CeSbSe [2], NdSbSe, and NdSbTe. CeSbSe exhibits complex magnetic ordering at $T_M = 3$ K and the application of a magnetic field results in a cascade of magnetically ordered states for $H < 1.8$ T which are characterized by fractional integer size steps: i.e., a possible devil's staircase is observed. NdSbSe and NdSbTe show a low $T$ buildup of magnetic entropy in the heat capacity, also suggesting complex magnetism. These compounds offer an opportunity to study the connection between the complex magnetic orders, Kondo lattices and topological properties.

8:12AM A01.00002: Importance of electron correlations in understanding the photo-electron spectroscopy and the Weyl character of MoTe$_2$*  
EFSTRATIOS MANOUSAKIS (Presenter), NIRAJ ARYAL, Physics, Florida State University and National High Magnetic Field Laboratory — We study the role of electron correlations in the type II Weyl semimetallic candidate γ-MoTe$_2$ by using density functional theory (DFT) where the on-site Coulomb repulsion (Hubbard U) for the Mo 4d states is included within the DFT+U scheme. We find that inclusion of Hubbard U is important to describe both the light-polarization dependence of the ARPES and the angular dependence of the Fermi surface as measured by quantum oscillation experiments. We also show that though the number and position of Weyl points change non-linearly with U, the Weyl physics remains robust for a wide range of U values. Our calculations also indicate that γ-MoTe$_2$ is in the vicinity of a correlations-induced Lifshitz transition which can be probed experimentally by small amount of doping and its interplay with the Weyl physics might be intriguing.

*This work was supported in part by the U.S. National High Magnetic Field Laboratory, which is funded by NSF DMR-1157490 and the State of Florida.

8:24AM A01.00003: Abelian Topological Phases with Background Electromagnetic Field on Lattice, and Deligne-Beilinson Double Cohomology in Continuum*  
JING-YUAN CHEN (Presenter), Stanford University — Constructing exactly soluble lattice model is an important approach towards understanding topological phases of matter. The coupling of exactly soluble lattice topological models to continuous background gauge field is less well-studied compared to discrete background gauge fields. The former is however responsible for important topological phenomena such as the Hall conductivity and the spin-charge relation. In this talk, I introduce a systematic approach to this problem for abelian topological phases, which is to exactly retrieve the spacetime lattice model from the corresponding Chern-Simons theory in the continuum, via the latter's formal structure known as Deligne-Beilinson double cohomology.

*I am supported by the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF4302.

8:36AM A01.00004: Majorana zero mode on the edge of an interacting quantum wire subject to spin-orbit interaction and transverse magnetic field*  
AKIRA FURUSAKI (Presenter), RIKEN, OLEG STARYKH, University of Utah — We revisit the problem of an interacting quantum wire subject to spin-orbit interaction and transverse magnetic field. Previous studies showed that the spin sector of the model is equivalent to that of a spin chain with uniform DM interaction (D) in a transverse magnetic field (h), the ground state of which contains two ordered Ising phases and a critical Tomonaga-Luttinger liquid phase, depending on the ratio D/h. Importantly, the charge sector of the wire is a gapless Tomonaga-Luttinger liquid. We show that a quantum wire with an open boundary supports a zero-energy bound state localized at the edge, provided that the spin sector of the problem is massive. We argue that as long as the charge sector is gapless, the wire is in a topological phase and that the bound state is a Majorana zero mode, and discuss physical implications of this finding.

*This work was in part supported by Invitational Fellowship for Research in Japan from the Japan Society for the Promotion of Science and by NSF DMR-1507054.

8:48AM A01.00005: Topological exciton insulator phase in two-dimensional semiconductor systems*  
WEN-KAI LOU (Presenter), State Key Laboratory for Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, WEN YANG, Simulation of Physical Systems, Beijing Computational Science Research Center, KAI CHANG, State Key Laboratory for Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences — Exciton insulator was firstly proposed by Prof. Mott in 1961. This concept has been widely studied theoretically and confirmed experimentally in recent years. Here, We demonstrate theoretically the existence of topological exciton insulating phases in two-dimensional (2D) semiconductor systems. We consider two kinds of systems: InAs/GaSb quantum wells [1] and 2D Van der Waals heterostructures[2]. In InAs/GaSb quantum wells, i.e., a 2D topological insulator, we demonstrate theoretically that the ground state of the system is a topological exciton insulator when the Coulomb interaction between electrons and holes is included. For a 2D VdH system, we find that a perpendicular electric field can decrease the bandgap, which even becomes smaller than the exciton binding energy, leading to the formation of exciton insulator phase. Due to large exciton binding energy, the exciton insulator phase in the 2D VdH system could be observed at room temperature.

*This work was supported by the NSFC (Grants No.11574303, 11434010 and 61674145), the CAS (Grant No. 2015093) and the MOST of China (Grants No. 2015CB921503, 2016YFE0110000 ).
9:00AM A01.00006: Full Commuting Projector Hamiltonians of Interacting Symmetry-Protected Topological Phases of Fermions*  
NATHANAN TANTIVASADAKARN (Presenter), ASHVIN VISHWANATH, Harvard University — Using the decorated domain wall procedure, we construct Finite Depth Local Unitaries (FDLUs) that realize Fermionic Symmetry-Protected Topological (SPT) phases. This results in explicit ‘full’ commuting projector Hamiltonians, where ‘full’ implies the fact that the ground state, as well as all excited states, of these Hamiltonians realizes the nontrivial SPT phase. We begin by constructing explicit examples of 1+1D phases protected by symmetry groups $G = \mathbb{Z}_2 T \times \mathbb{Z}_2 F$, which also has a free fermion realization in class BDI, and $G = \mathbb{Z}_4 \times \mathbb{Z}_4 F$, which does not. We then turn to 2+1D, and construct the square roots of the Levin-Gu bosonic SPT phase, protected by $\mathbb{Z}_2 \times \mathbb{Z}_2 F$ symmetry, in a concrete model of fermions and spins on the triangular lattice. Edge states and the anomalous symmetry action on them are explicitly derived. Although this phase has a free fermion representation as two copies of $p+i p$ superconductors combined with their $p- i p$ counterparts with a different symmetry charge, the full set of commuting projectors is only realized in the strongly interacting version, which also implies that it admits a many-body localized realization.

*N.T. is supported by the Purcell fellowship. A.V. is supported by a Simons Investigator grant.

9:12AM A01.00007: Origin of Mott insulating behavior and superconductivity in twisted bilayer graphene*  
LIUJUN ZOU (Presenter), Harvard University, HOI CHUN PO, Physics, Massachusetts Institute of Technology, ASHVIN VISHWANATH, Harvard University, SENTHIL TODADRI, Physics, Massachusetts Institute of Technology — A remarkable recent experiment has observed Mott insulator and proximate superconductor phases in twisted bilayer graphene when electrons partly fill a nearly flat mini-band that arises a magic twist angle. However, the nature of the Mott insulator, origin of superconductivity and an effective low energy model remain to be determined. We will present a phenomenological picture of the Mott insulator with intervalley coherence that spontaneously breaks $U(1)$ valley symmetry, and describe a mechanism that selects this order over the competing magnetically ordered states favored by the Hunds coupling. We will discuss consequences of this picture for superconducting states obtained on doping the valley ordered Mott insulator. We show how important features of the experimental phenomenology may be explained and suggest a number of further experiments for the future.

*T. Senthil is supported by a US Department of Energy grant DE-SC0008739, and in part by a Simons Investigator award from the Simons Foundation. Ashvin Vishwanath was supported by a Simons Investigator award and by NSF-DMR 1411343.

9:24AM A01.00008: Coupled wire models on compact manifolds and the entanglement entropy for Abelian and non-Abelian topological orders  
BO HAN (Presenter), University of Illinois at Urbana-Champaign, CHI YAN JEFFREY TEO, Physics, University of Virginia — We construct coupled wire models for topologically ordered systems on the 2d torus and study the ground state degeneracy, with explicit ground states. Both Abelian and non-Abelian topological orders will be studied. With the ground states written down, we can study the entanglement entropy for the corresponding systems. Generalizations to 2d closed manifolds with higher genus and 3d closed manifolds will also be discussed.

9:36AM A01.00009: Classification of fermionic symmetry-protected topological phases  
QING-RUI WANG (Presenter), ZHENGCHENG GU, The Chinese University of Hong Kong — We give a systematic construction and classification of fermionic symmetry-protected topological states for generic fermionic symmetry group $G_f$, which is a central extension of bosonic symmetry group $G_b$ (may contain time reversal symmetry) by the fermion parity symmetry group $Z_{2f}$. For each class in the classification (except those with 2D $p+i p$ chiral superconductor decorations), we construct a fixed-point wave function which admits exactly solvable commuting-projector Hamiltonian. The classification is based on the notion of equivalence class of fermionic symmetric local unitary transformations.
necessary to recover a valid semiclassical formula for the Hall effect from the Kubo formula in the DC limit. 
We solve the model non-perturbatively by means of an inhomogeneous Dynamical Mean-Field Theory. 
We tune the strength of the harmonic trap to confine the fermions in artificial structures which are reminiscent of 
graphene nanoflakes in solid state. Starting from a non-magnetic state and increasing the strength of the harmonic 
potential, we are able to induce different magnetic states such as a Néel like antiferromagnetic state, ferromagnetic or 
ferrimagnetic states, as well as mixtures of these basic states, which can be used to design spin-filters and transistors. 
The realization of different magnetic patterns is associated with the terminations of the artificial structures induced in a 
controlled way by the confining potential. We suggest that our cold-atom-based implementation for synthesizing edges in 
order to create magnetism is also applicable in real materials and switchable spintronic devices.

Ferroelectricity and Magnetism in bad metals” (Prot. 232/2015).

10:00AM A01.00011: Fracton fusion and statistics* SHRIYA RAMACHANDRAN PAI (Presenter), MICHAEL A HERMELE,
University of Colorado, Boulder — In this work, we describe fusion and statistical processes in Abelian fracton phases in terms 
of their gapped excitations. The restricted mobility of fractonic excitations implies that statistical processes do not take the 
form of familiar braiding processes. Also, the number of distinct excitation types in fracton phases is infinite, in contrast to 
conventional phases with intrinsic topological order. Moreover, if one considers excitations supported in a region with 
linear size $L$, the number of excitation types supported in the region grows exponentially with $L$. To build a manageable 
theory that incorporates these features, we consider lattice translation symmetry. Without translation symmetry, the 
fusion of excitations in an Abelian fracton phase is described by an infinite Abelian group, whose elements correspond to 
distinct excitation types. Translation symmetry acts on this Abelian group, giving it more structure and making it a more 
manageable object to work with. Moreover, this action allows us to describe the mobility of excitations at the level of the 
fusion theory, which then forms the basis for a description of statistical processes.

DE-SC0014415.

10:12AM A01.00012: Hall and Faraday effects in interacting multiband systems* REZA NOURA FKAN (Presenter), 
ANDRE-MARIE TREMBLAY, Institut quantique, RQMP, Université de Sherbrooke — The Hall conductivity is widely used as a 
probe of Fermi surface evolution. However, in the case of interacting multi-band systems, calculations of the Hall 
conductivity are challenging because the application of the semi-classical single-band formula to many bands is 
ambiguous. Here, we derive a formula for the Hall response of interacting multi-band systems with arbitrary band 
topology and spin-orbit coupling. The formula is valid beyond the semiclassical approximation and at finite frequency, 
which is relevant for Faraday rotation, and it takes into account vertex corrections. In addition to the triangular diagrams, 
the formula includes rectangular diagrams that are absent in the single-band case. We show that these diagrams are 
necessary to recover a valid semiclassical formula for the Hall effect from the Kubo formula in the DC limit.

10:24AM A01.00013: Interacting Spin-3/2 Fermions in three-dimensional Luttinger Metal: Phases, Phase Transitions 
and Global Phase Diagram ANDRAS SZABO (Presenter), BITAN ROY, Max Planck Institute for the Physics of Complex System — 
The notion of quasiparticles constitutes the foundation of condensed matter physics. Recently it became evident that 
Dirac or Weyl materials support linearly dispersing quasi-relativistic nodal quasiparticles around few isolated points in the 
Brillouin zone. In this talk, I will focus on a collection of spin-3/2 excitations, which in three dimensions display a bi-
quadratic touching of the valence and conduction bands at the $\Gamma$ point. Such peculiar band touching can be realized in the 
normal state of 227 pyrochlore iridates, half-Heuslers, HgTe and gray tin, for example. Once electron-electron interactions 
are accounted for, this system can display a rich confluence of a plethora of exotic broken symmetry phases, among which 
nematic, magnetic, and superconducting (s-wave and topological d-waves) orders are the most prominent ones. Using a 
controlled renormalization group analysis at finite temperature and chemical doping, I will demonstrate the competition 
among these phases, as well as the associated quantum critical phenomena. In addition, I will also present various cuts of 
the global phase diagram of interacting spin-3/2 fermions, and argue that nematic and magnetic interactions are 
conducive for s-wave and d-wave pairings of Luttinger fermions, respectively.
Aspects of Three-body Interactions in Generic Fractional Quantum Hall Systems and Impact of Galilean Invariance Breaking

BO YANG (Presenter), Physics and Applied Physics, Nanyang Technological University — We derive full analytic expressions of three-body interactions from Landau level (LL) mixing in fractional quantum Hall (FQH) systems with Schrieffer-Wolff transformation. The formalism can be applied to any LL, and to very general systems without rotational or Galilean invariance. We illustrate how three-body pseudopotentials (PPs) can be readily computed from the analytical expressions for a wide variety of different systems, and show that for realistic systems, softening the bare Coulomb interactions (e.g. finite thickness or screening) can significantly suppress three-body interactions. More interestingly, for experimental systems without Galilean invariance (which is common for real materials), there is strong evidence that higher orders in band dispersion can drive the Moore-Read state from anti-Pfaffian to Pfaffian phase. Our analysis points to the importance of the realistic band structure details to the non-Abelian topological phases, and the analytical expressions we derived can also be very useful for high fidelity numerical computations. We also discuss about the importance of edge potentials in realistic experiments for determining the topological phases at half-filling, as well as the nature of such phases for systems with and without particle-hole symmetry.

Monday, March 4, 2019 8:00 AM - 10:48 AM

Session A02 DMP DCOMP: Dielectric & Ferroic Oxides -- Emergent Interfacial Phenomena

BCEC 107A - Lane Martin, University of Illinois at Urbana-Champaign - Tag(s): Focus

8:00AM A02.00001: Complex polarization textures and exotic properties in PbTiO₃/SrTiO₃ superlattices * [Invited]
JAVIER JUNQUERA (Presenter), University of Cantabria — When ultrathin ferroelectric layers of PbTiO₃ are embedded in superlattices with a paraelectric material, such as SrTiO₃, the interplay between elastic, electrostatic, and gradient energies produces complex patterns of the electrical polarization. In particular, nanometer scale of vortex-antivortex arrays have been recently detected [1], and exotic properties such as the emergence of a negative capacitance have been measured [2]. Performing predictive simulations in these systems is difficult due to the long spatial scales involved, the strong competition between a large number of phases and the sensitivity of the results to external perturbations like strain, periodicity, temperature or electric fields. In order to overcome these problems we employ a recently developed second-principles method [3] that can cope with all the degrees of freedom associated to a large number of atoms retaining high accuracy. Depending on the boundary conditions, our simulations predict the existence of several quasi-degenerate phases at low energies each displaying different properties including net polarization, negative capacitance [4], non-null topological constants [5] and chirality [5,6]. The later prediction supports the findings of optical activity in x-ray circular dichroism experiments [5,6]. Moreover, depending on the periodicity of the superlattice these chiral vortex phases coexist with ferroelectric phases and reversible phase transitions can be induced by external electric fields [7].

8:36AM A02.00002: A theoretical design of inter-correlated in-plane and out-of-plane electric polarization in conventional perovskite ferroelectric thin films
WENGUANG ZHU (Presenter), TIANPING GU, University of Science and Technology of China — Ferroelectric materials may have multiaxial electric polarization, in particular, in-plane and out-of-plane orientations for ferroelectric thin films, but the reversal of their electric polarization along different axes is normally independent. In this talk, I will present a theoretical design to make conventional perovskite ferroelectric thin films have inter-correlated in-plane and out-of-plane electric polarization, based on first-principles calculations. This work may lead to new device paradigms and applications based on conventional perovskite ferroelectric thin films.
**8:48AM A02.00003: Charge Density imaging of a ferroelectric-insulator interface with sub-Å resolution**

CHRISTOPHER ADDIEGO (Presenter), Department of Physics and Astronomy, University of California, Irvine, WENPEI GAO, Department of Materials Science and Engineering, University of California, Irvine, HUI WANG, Department of Physics and Astronomy, University of California, Irvine, YUSHENG HOU, Department of Physics of Astronomy, University of California, Irvine, DIANXIANG JI, National Laboratory of Solid State Microstructures, College of Engineering and Applied Sciences, and Collaborative Innovation Center of Advanced Microstructures, Nanjing Univ, COLIN HEIKES, Department of Materials Science and Engineering, Cornell University, YI ZHANG, LINZE LI, HUAIXUN HU, Department of Materials Science and Engineering, University of California, Irvine, THOMAS F BLUM, Department of Physics and Astronomy, University of California, Irvine, TOSHIHIRO AOKI, Irvine Materials Research Institute, University of California, Irvine, YUEFENG NIE, National Laboratory of Solid State Microstructures, College of Engineering and Applied Sciences, and Collaborative Innovation Center of Advanced Microstructures, Nanjing Univ, DARRELL G. SCHLOM, Department of Materials Science and Engineering, Kavli Institute at Cornell for Nanoscale Science, Cornell University, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, XIAOQING PAN, Department of Materials Science and Engineering, Department of Physics and Astronomy, University of California, Irvine — In complex oxide heterostructures, charge redistribution determines the characteristics of the material and can have significant influence on the behavior of the material. For example, the 2-dimensional electron gas at an LaAlO3-SrTiO3 interface is linked with superconductivity and ferromagnetism at the interface [1]. Although first principles calculations can provide highly detailed charge density maps that illustrate these phenomena, experimental methods often cannot resolve the same features at interfaces or nanostructures with high spatial resolution. Here we demonstrate the imaging of electron charge at interfaces in heterogeneous perovskite structures at atomic resolution using aberration corrected scanning transmission electron microscopy. The charge density mapping is determined using the 2D diffraction pattern acquired with a high-speed pixelated detector [2]. At a BiFeO3-SrTiO3 interface, we found evidence of charge separation caused by the penetration of the electric field from the polarized BiFeO3 into the insulating SrTiO3.

**9:00AM A02.00004: Probing ferroelectric switching of BaTiO3 thin films integrated on Silicon**

MARC REYNAUD (Presenter), Department of Physics, University of Texas at Austin, JOHANNA NORDLANDER, Department of Materials, ETH Zürich, FELIX ELTES, Neuromorphic Photonics, IBM Research-Zürich, GABRIELE DE LUCA, JACOB NÜRNBERG, Department of Materials, ETH Zürich, STEFAN ABEL, JEAN FOMPEYRINE, Neuromorphic Photonics, IBM Research-Zürich, MANFRED FIEBIG, Department of Materials, ETH Zürich, ALEXANDER DEMKOV, Department of Physics, University of Texas at Austin, MORGAN TRASSIN, Department of Materials, ETH Zürich — The integration of ferroelectric materials on Si plays an important role in the design of new photonic devices, such as optical switches and modulators. Ferroelectric materials exhibit nonlinear optical properties and in particular their refractive index can be tuned by the application of an E-field via the Pockels effect. Ferroelectric barium titanate (BTO) thin films can be epitaxially grown on silicon, using molecular beam epitaxy (MBE). Controlling the polarization of thin these films in absence of metallic buffer remains non-trivial. Orienting the polar axis beyond the limitation of epitaxy using voltage induced ferroelastic switching events to generate out-of-plane (c-domains) to in-plane polarization (a-domains) rotation would open up new pathways for fabricating photonic devices. In this study, we use transmission optical second harmonic generation (SHG) to study the ferroelastic switching dynamics in our BTO films grown on Si for varying thicknesses. The orientation of the BTO films polar axis and the a/c-domain ratio before and after the application of an external in plane E-field are mapped.

9:12 AM A02.00005: Making and manipulating ferroelectric vortices, a TEM perspective of nanoscale flux closure in dielectrically confined PbTiO₃ films* [Invited] CHRISTOPHER NELSON (Presenter), Oak Ridge National Laboratory — A prominent disparity between the two ferroic siblings of ferromagnetism and ferroelectricity is the exciting complex topologies appearing in the spin distributions of former while the electric dipole textures of the latter flag behind. By engineering the scale and field energy minimization pressures driving flux closure formation we realize in SrTiO₃ encapsulated ferroelectric PbTiO₃ thin films the formation of nanoscale ferroelectric vortices. With (S)TEM we characterize the structure of these ~5nm vortices down to atomic scales and study the transition from long-range vortex arrays to in-plane α-domains with decreasing superlattice period, including a mixed structure regime and extrinsic formation of vortices in thicknesses below the vortex-stability limit. Using in-situ applied electric bias we observe the dynamic field-response including the creation, deformation, motion, and erasure of these ferroelectric vortices.

*This work was conducted in collaboration with Zijian Hong, Ajay K. Yadav, Sujit Das, Anoop R. Damodaran, Shang-Lin Hsu, Long-Qing Chen, Lane W. Martin and Ramamoorthy Ramesh, and supported by the U.S Department of Energy, Office of Science, Basic Energy Sciences.

9:48 AM A02.00006: Ionic Gating Driven Polarization Control in Ultra-Thin and Leaky Ferroelectrics* YOGESH SHARMA (Presenter), NINA BALKE, HO NYUNG LEE, THOMAS WARD, Oak Ridge National Laboratory — Ionic liquid (IL) gating allows large electric fields to be achieved at the interface— providing an ability to control, manipulate, and elevate unique phenomena that can arise in the interfaced solid materials. Here, Ionic gating is used to induce reversible polarization switching in ultrathin and highly defective ferroelectric films. Long range electrostatic charge control is induced by modifying the electric double layer at an IL-PbZr₀.₂Ti₀.₈O₃ interface which drives electrostatic and electrochemical control of polarization orientation in the ferroelectric layer. The localized nature of the ionic gating mechanism forbids the leakage current which has historically limited the switching of ultra-thin and/or electrically leaky ferroelectric films in solid metal-gated capacitor devices. This is demonstrated on ultrathin films and in intentionally grown massively defective films with > 30% coverage of direct conducting channels running from surface to ground. We will close by discussing how the transient switching and the ability to manipulate static analog phase transitions might impact future technologies.

10:00 AM A02.00007: Possible Flexoelectric Origin of the Lifshitz Transition in LaAlO₃/SrTiO₃ Interfaces* AMANY RASLAN, BILL ATKINSON (Presenter), Trent University — Multiple experiments have observed a sharp transition in the band structure of LaAlO₃/SrTiO₃ (001) interfaces as a function of applied gate voltage. This Lifshitz transition, between a single occupied band at low electron density and multiple occupied bands at high density, is remarkable for its abruptness. We propose a mechanism by which such a transition might happen. We show via numerical modeling that the simultaneous coupling of the dielectric polarization to the interfacial strain (‘ electrostrictive coupling’) and strain gradient (‘ flexoelectric coupling’) generates a thin polarized layer whose direction reverses at a critical density. The Lifshitz transition occurs concomitantly with the polarization reversal and is first-order at T=0. A secondary Lifshitz transition, in which electrons spread out into semiclassical tails, occurs at a higher density.

Labyrinthine degeneracy and inverse transition in ferroelectric ultrathin films

YOUSRA NAHAS (Presenter), SERGEI PROKHORENKO, Physics Department and Institute for Nanoscience and Engineering, University of Arkansas, JOHANNA FISCHER, CECILE CARRETERO, STEPHANE FUSIL, Unite Mixte de Physique, CNRS-Thales, BRAHIM DKHIL, Laboratory of Structures, Properties and Modeling of Solids, Ecole Centrale Paris, VINCENT GARCIA, Unite Mixte de Physique, CNRS-Thales, LAURENT BELLAICHE, Physics Department and Institute for Nanoscience and Engineering, University of Arkansas — Already hypothesized a century ago, inverse transitions have been found experimentally in very disparate materials, ranging from polymeric and colloidal compounds to high-Tc superconductors, proteins, ultra-thin magnetic films, liquid crystals and metallic alloys, with the notable exception of ferroelectric oxides, despite the widespread theoretical and experimental work on the latter. Here we theoretically demonstrate, that subsequently to a subcritical quench, the non-equilibrium self-assembly of ferroelectric domains in ultrathin ferroelectric films results in the labyrinthine pattern featuring meandering stripe domains. Upon increasing temperature, this labyrinthine phase undergoes an inverse transition whereby it transforms into the less-symmetric parallel stripe domain structure, before the onset of paraelectricity at even higher temperatures. Furthermore, our experimental findings corroborate the universality of the phenomenon within ferroelectric oxides.

First Principle Study of the Si-EuO Interface

WENTE LI (Presenter), ALEXANDER DEMKOV, University of Texas at Austin — As scaling in the conventional semiconductor industry continues, including the electronic spin degree offers new ways of information processing. The choice of materials in semiconductor spintronics needs to provide efficient spin injection and detection along with the long coherent length and relaxation time in the semiconductor. Silicon offers a long spin relaxation time. And EuO is a promising ferromagnetic semiconductor, at least at low temperature. Due to its high spin polarization and thermodynamic stability on Si, epitaxial EuO may be a good candidate for application of spintronics. We use first principle calculations to study the atomic and electronic structure of the Si-EuO interface. We construct Si-EuO interface models and analyze the band alignment at the interface, our results suggest that Si-EuO heterostructure is a feasible option for spin injector in Si-based spintronic devices.

Electrical transport properties of two-dimensional materials on ferroelectrics toward nonvolatile memory devices

NAHEE PARK (Presenter), Department of Energy Science, Sungkyunkwan University, HAEYONG KANG, Department of Physics, Pusan National University, DONGSEOK SUH, Department of Energy Science, Sungkyunkwan University — When ferroelectric material is employed as a gate dielectric for the field effect transistor (FET) of a two-dimensional (2D) material such as graphene, MoS2, and MoTe2, it is possible to induce a giant amount of carriers in the channel by polarization field of the ferroelectric and also to show a nonvolatile memory operation. In many cases, however, the electrical coupling between 2D material and ferroelectric-oxide had shown abnormal behavior like anti-hysteresis different from 2D material/ferroelectric-polymer cases showing normal hysteresis. In our work, we also observed systematically those phenomena related to the interface by combining ferroelectric oxide material, PMN-PT (i.e. (1-x)Pb(Mg1/3Nb2/3)O3-PbTiO3) single-crystal with several 2D materials. Through the electrical transport measurement, it is found out that the ferroelectric polarization and trapped charges strongly interacts each other, which is reflected in the conductance of 2D channel. To develop the 2D electronic system in ferroelectric memory device, we should study those properties in detail.

Session A03 DCMP: Interactions and Dynamics in Topological Systems BCEC 107B - Madhab Neupane, University of Central Florida

*IBS Center for Integrated Nanostructure Physics, Institute for Basic Science, Department of Energy Science, Sungkyunkwan University, Suwon 16419, Korea.
Electronic structure of Dirac materials can be manipulated by impurity doping. One example of such manipulation is the quantum anomalous Hall effect (QAHE), observed in a three-dimensional (3D) topological insulator (TI) doped with magnetic impurities. It is known that impurities give rise to low-energy resonant states near Dirac nodes [1]. For a magnetically-doped 3D TI, an energy gap opens up at the node and is filled with impurity resonant states. Impurity effects have significant implications for QAHE [2,3]. In this work, we show how doping can be used to engineer Dirac nodes in a 3D TI. Using a microscopic tight-binding model for a typical 3D TI with impurities on the surface, we demonstrate the splitting of the surface node and the appearance of new nodes at high-symmetry points of the Brillouin zone. This opens a possibility for impurity engineering of topology and nodal structure in Dirac materials.

**8:36AM A03.00004: Observation of Two Magnetically Inequivalent Regions in SmB$_6$ at Low Temperatures**

JEFF SONIER (Presenter), KOLAWOLE AKINTOLA, SHAYAN GHEIDI, Simon Fraser University, SARAH R DUNSIGER, TRIUMF, ANDRE COTE, Kwantlen Polytechnic University, SHANTA SAHA, JOHNPIERRE PAGLIONE, University of Maryland - College Park, WESLEY T FUHRMAN, COLLIN BROHOLM, Johns Hopkins University — The temperature dependence of the μSR relaxation rate in SmB$_6$ exposed to a high transverse magnetic field (TF) was recently shown to exhibit thermally-activated behavior for 4 K < $T$ < 20 K, consistent with the freezing out of a bulk low-energy (~ 1 meV) spin exciton [K. Akintola et al., npj Quantum Materials 3:36 (2018)]. However, a 1 meV magnetic excitation has never been observed in neutron scattering measurements, all of which have been performed on the same floating-zone grown double-isotope $^{154}$Sm$^{11}$B$_6$ single crystal. In an attempt to understand why, we have performed zero-field (ZF) and longitudinal-field (LF) μSR measurements on the $^{154}$Sm$^{11}$B$_6$ and Al-flux grown SmB$_6$ single crystals. The μSR signals show greater relaxation in the $^{154}$Sm$^{11}$B$_6$ single crystal, and reveal the development of slow and fast relaxing components below $T$ ~ 20 K. The volume fraction of the slower relaxing component grows to ~ 70 % at $T$ = 2 K. While the relaxation rates are smaller, the volume fractions of the two components are similar in the Al-flux grown SmB$_6$ crystals. This suggests that the source of the two components is intrinsic and originates from spatially distinguishable regions in the sample.

**8:48AM A03.00005: Band structure engineering in short period Bi$_2$Se$_3$/Sb$_2$Te$_3$ superlattices grown by molecular beam epitaxy**

IDO LEVY (Presenter), THOR A. GARCIA, HAIMING DENG, STEVEN J. ALSHEIMER, LIA KRUSIN-ELBAUM, MARIA TAMARGO, City College of New York — When grown by molecular beam epitaxy (MBE) Bi$_2$Se$_3$ is n-type and Sb$_2$Te$_3$ is p-type due to selenium vacancies and anti-site defects, respectively. To capitalize on the unique topological surface properties of these materials it is essential to reduce the bulk carriers. Compensation doping is a way to do that, but that method requires accurate dopant incorporation levels that are difficult to achieve. In this work we explore the use of p-n-p-n short-period superlattices (SLs) to accomplish this goal. A series of Bi$_2$Se$_3$/Sb$_2$Te$_3$ short-period SLs with varying period thicknesses and Bi$_2$Se$_3$ to Sb$_2$Te$_3$ thickness ratios were grown by MBE. The samples were characterized by high resolution x-ray diffraction (HR-XRD) and transport measurements. Using HR-XRD we determine the change in effective composition and SL period for the samples. We observed a dependence of bulk background doping on the SL period thickness: lower carrier density for thinner SL period. We interpret this as the formation of a gap due to quantum confinement effects. A preservation of a weak anti-localization (WAL) cusp, typical of topological surface features, was observed by magnetoconductance.

**9:00AM A03.00006: Effects of Nitrogen Exposure on the Bismuth Selenide Density of States**

MICHAEL GOTTSCHALK (Presenter), Michigan State Univ, MAL-SOON LEE, Pacific Northwest National Laboratory, CAMILLE MIKOLAS, ERIC GOODWIN, Michigan State Univ, THOMAS CHASAPIS, MERCOURI KANATZIDIS, Northwestern University, S MAHANTI, STUART HOLDEN TESSMER, Michigan State Univ — Bi$_2$Se$_3$ is a topological insulator widely used for scientific studies due in part to the ease with which it can be cleaved, exposing a clean surface for study. Typically the materials exhibit n-type doping attributed to selenium vacancies which results in a shift of the Dirac point to more than 100 meV below the Fermi level. Using cryogenic scanning tunneling microscopy (STM), we observed a shift in the expected density of states spectra when the crystals were cleaved in a pure nitrogen gas environment. The shift tends to restore the Dirac point to the Fermi level. These results are compared against crystals cleaved in a pure helium gas environment which reproduces the expected pristine spectra. We will present density functional theory calculations supporting the picture that nitrogen can bind to the selenium vacancies and shift the density of states. Furthermore, we will present data showing an upper-bound on the level of gas exposure necessary for saturated adsorption.

9:12AM A03.00007: Topology of the Valley-Chern Effect*  
KAI QIAN (Presenter), DAVID J. APIGO, CAMELIA PRODAN, New Jersey Institute of Technology, YAFIS BARLAS, EMIL PRODAN, Yeshiva University — In this talk, we investigate the quantum valley-Hall effect (QVHE) using a versatile experimental platform based on magnetically coupled spinners. We demonstrate that this regime is not suitable for metamaterial applications due to the delocalization of the interface modes. The enlargement of the bulk gap needs to be accompanied by a Berry curvature engineering that keeps it localized near the valleys. This is a new effect which we call the valley-Chern effect (VCE). By establishing an exact relation between VCE and QVHE, we demonstrate a robust bulk-boundary principle, which could be the foundation of a new wave of applications of topological metamaterials.

9:24AM A03.00008: Observation of topological edge modes in a quasi-periodic acoustic waveguide*  
WENTING CHENG (Presenter), DAVID J. APIGO, KYLE DOBISZEWSKI, New Jersey Institute of Technology, EMIL PRODAN, Yeshiva University, CAMELIA PRODAN, New Jersey Institute of Technology — We present a system of acoustic waveguide generated by a simple quasi-periodic patterning without any additional fine-tuning. The system presents topological edge modes. The waveguides are characterized experimentally by standard acoustic measurements, and via a finite element approach utilizing COMSOL Multiphysics. The experimental results and simulations confirm the existence of topological edge modes in these gaps.

*All authors acknowledge the support from W.M. Keck Foundation.

9:36AM A03.00009: A Proposal to Detect Dark Matter Using Axionic Topological Antiferromagnets*  
DAVID JAMES EDWARD MARSH, University of Gottingen, Institute for Astrophysics, KIN CHUNG FONG, Quantum Engineering and Computing, Raytheon BBN Technologies, ERIK LENTZ, University of Gottingen, Institute for Astrophysics, LIBOR SMEJKAL, Johannes Gutenberg University Mainz, Institute for Physics, MAZHAR ALI (Presenter), Max Planck Institute for Microstructure Physics — Astrophysical and cosmological observations of the last 40 years provide strong evidence for the existence of non-baryonic dark matter. Among possible candidates are dark axions, hypothetical particles suggested to solve the CP problem in quantum chromodynamics. It is known that magnetically doped topological insulators can become "axionic insulators" and host axionic excitations. In particular, antiferromagnetically doped topological insulators (A-TI) are among the candidates to host dynamical axion fields and axion-polaritons. Here we demonstrate that using the axion quasiparticle and antiferromagnetic fluctuations in A-TI's in conjunction with low-noise methods of detecting THz photons presents a viable route to detect axion dark matter with mass 0.7 to 3.5 meV, a range currently inaccessible to all other dark matter detection experiments and proposals.

9:48AM A03.00010: Dzyaloshinskii-Moriya Interaction on Surfaces of Topological Insulator*  
DOMENICO ANDREOLI (Presenter), Physics, University of New Hampshire, CHAO-XING LIU, Physics, The Pennsylvania State University, JIADONG ZANG, Physics, University of New Hampshire — The Topological Hall Effect (THE) is a hallmark of nontrivial spin texture. In this work we theoretically study the THE is realizable in centrosymmetric materials. The only requirement being that local inversion symmetry is broken. To show that the THE can occur we start with the model of surface states of a Topological Insulator (TI) and include magnetization on the top and bottom surfaces of the TI. From here the Spin Susceptibility (SS) tensor is determined numerically and it is shown to have off-diagonal components. These components are then related to the Dzyaloshinskii-Moriya (DM) vector. Demonstration of nonzero DM interaction on the surfaces of the TI reveals nontrivial topology in the real space, along with the nontrivial electronic band structure of the TI in momentum space allows for the possibility of the THE in centrosymmetric materials.

*This work was supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES) under Award No. de-sc0016424.
10:00AM A03.00011: Valley-Chern Effect with LC-Resonators: A Modular Platform* YISHAI EISENBERG (Presenter), YAFIS BARLAS, EMIL PRODAN, Yeshiva University — The valley Chern-effect is theoretically demonstrated with a novel alternating current circuitry, where closed-loop LC-resonators sitting at the nodes of a honeycomb lattice are inductively coupled along the bonds. This enables us to generate a dynamical matrix which copies identically the Hamiltonian driving the electrons in graphene. The valley-Chern effect is generated by splitting the inversion symmetry of the lattice. After a detailed study of the Berry curvature landscape and of the localization of the interface modes, we derive an optimal configuration of the circuit. Furthermore, we show that Q-factors as high as $10^5$ can be achieved with reasonable materials and configurations.

*W.M. Keck Foundation

10:12AM A03.00012: LONG RANGE DYNAMICAL COUPLING BETWEEN MAGNETIC ADATOMS MEDIATED BY EDGE STATES IN A 2D TOPOLOGICAL INSULATOR* MARCIO COSTA (Presenter), LNNANO-CNPEM, MARCO BUONGIORNO NARDELLI, Univ. North Texas, ADALBERTO FAZZIO, LNNANO-CNPEM, ANTÔNIO COSTA, Univ. Federal Fluminense — We study the spin excitation spectra and the dynamical exchange coupling between iron adatoms on a bismuthene nanoribbon. We show that the topological character of the edge states is preserved in the presence of the magnetic adatoms. Nevertheless, they couple significantly to the edge spin currents, as witnessed by the large and long-range dynamical coupling we obtain in our calculations. The large effective magnetocrystalline anisotropy of the magnetic adatoms combined with the transport properties of the topologically protected edge states make this system a strong candidate for implementation of spintronics devices. We use a multi-orbital tight-binding Hamiltonian to describe the electronic structure of the decorated nanoribbon. The full Hamiltonian can be written as the sum of band energy $H_0$, effective intra-atomic Coulomb repulsion $H_{\text{I}}$ and the atomic spin-orbit coupling $H_{\text{SOC}}$. The hopping matrix is obtained directly from a DFT calculation using the pseudo-atomic orbital projection method[1].

M.B.N. - DOD-ONR (N00014-13-1-0635, N00014-11-1-0136, and N00014-15-1-2863)

10:24AM A03.00013: Topological Logical Gates with Meta-Materials* EMIL PRODAN (Presenter), YAFIS BARLAS, Yeshiva University — Recently, the classification table of strong topological condensed matter systems has been implemented with classical passive metamaterials. This includes the topological superconductors, which opens up the possibility of stabilizing and braiding Majorana-like modes in topological metamaterials. This talk puts forward several platforms for topological computations with these systems. The discussion will be aided by numerical simulations.

*W. M. Keck Foundation

10:36AM A03.00014: Interacting Topological Insulators with Synthetic Dimensions* CHAO-MING JIAN (Presenter), CENKE XU, University of California, Santa Barbara — Recent developments of experimental techniques have given us unprecedented opportunities of studying topological insulators in high dimensions, while some of the dimensions are "synthetic", in the sense that the effective lattice momenta along these synthetic dimensions are controllable periodic tuning parameters. In this work, we study interaction effects on topological insulators with synthetic dimensions. We show that although the free fermion band structure of high dimensional topological insulators can be precisely simulated with the "synthetic techniques", generic interactions in these effective synthetic topological insulators are qualitatively different from the local interactions in ordinary condensed matter systems. And we show that these special but generic interactions have unexpected effects on topological insulators, namely they would change (or reduce) the classification of topological insulators differently from the previously extensively studied local interactions.

10:48AM A03.00015: Anomalous Josephson supercurrent in bulk-insulating topological insulator BiSbTeSe₂

SUBHAMOY GHATAK (Presenter), Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, OLIVER BREUNIG, University of Cologne, II. Physics Institute, FAN YANG, Center for Joint Quantum Studies, Tianjin University, ZHIWEI WANG, ALEXEY A TASKIN, YOICHI ANDO, University of Cologne, II. Physics Institute — Three dimensional topological insulators (3D-TIs) have recently drawn a considerable interest due to their spin-helical surface band structure. The Josephson junctions made of these 3D-TIs, by proximitizing with s-wave superconductors, are predicted to harbour 1D- Majorana modes. While observations of supercurrent in 3D-TI-based Josephson junctions are recently reported, the Fraunhofer patterns observed in such topological Josephson junctions, which sometimes present anomalous features, are still not well understood. In this talk, I will discuss about our study on highly gate-tunable topological Josephson junctions made of bulk-insulating TI materials, BiSbTeSe₂. The Fermi level can be tuned by gating across the Dirac point, and the high transparency of the Al/BiSbTeSe₂ interface is evinced by high multiple Andreev reflections peak indices reaching \( n = 12 \). Anomalous Fraunhofer patterns with missing lobes were observed in the entire range of gate voltage. We find that, by employing an fitting procedure to use the maximum entropy method in a Monte Carlo algorithm, the anomalous Fraunhofer patterns can be explained as a result of inhomogeneous supercurrent distributions on the TI surface in the junction.

*We acknowledge ERC and DFG-CRC for funding this project.

Session A04 DMP: Dirac/Weyl Semimetals -- Thin Films and Nanostructures BCEC 107C - Hugh Churchill, Univ of Arkansas-Fayetteville - Tag(s): Focus

8:00AM A04.00001: Weyl orbit quantum Hall states observed in Dirac semimetal Cd₃As₂ thin films

SHINICHI NISHIHAYA (Presenter), MASAKI UCHIDA, YUSUKE NAKAZAWA, Department of Applied Physics and Quantum-Phase Electronics Center (QPEC), Univ. of Tokyo, Tokyo, Japan., RYOSUKE KURIHARA, KAZUTO AKIBA, Institute of Solid State Physics (ISSP), Univ. of Tokyo, Kashiwa, Japan., MARKUS KRIENER, RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan., ATSUSHI MIYAKE, Institute of Solid State Physics (ISSP), Univ. of Tokyo, Kashiwa, Japan., YASUJIRO TAGUCHI, RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan., MASASHI KAWASAKI, Department of Applied Physics and Quantum-Phase Electronics Center (QPEC), Univ. of Tokyo, Tokyo, Japan.— Topologically protected surface states in topological materials provide access to various unconventional transport phenomena. One example in gapless topological semimetals is the unique interplay between bulk and surface Fermi-arc states resulting in an exotic magnetic orbit (Weyl orbit). The Weyl orbit weaves together two spatially-separated Fermi-arc states across the bulk state under the field, allowing the appearance of two-dimensional (2D) quantized conduction even in a 3D system. Here, we report the observation of quantum Hall (QH) states in Dirac semimetal Cd₃As₂ thin films. By controlling Fermi level and band topology of the 3D bulk state with electrostatic gating and chemical-doping-induced topological phase transition, we clarify that the quantized conduction emerges originating from the Weyl orbit. In particular, the successive scan from bulk-dominant conduction to Weyl orbit QH effect, reveals that the emergence of the QH states depends on the bulk Landau level occupation and the induced asymmetry between the film surfaces.

8:12AM A04.00002: Confinement Effects in Cd₃As₂ (001) Grown by Molecular Beam Epitaxy

DAVID KEALHOFER (Presenter), LUCA GALLETTI, MANIK GOYAL, HONGGYU KIM, TIMO SCHUMANN, SUSANNE STEMMER, University of California, Santa Barbara — Cadmium arsenide (Cd₃As₂) is a 3D Dirac semimetal in which two Dirac nodes along the \( k_x \) axis are stabilized by a symmetry of the crystal lattice. In a thin film, the fate of the Dirac nodes and associated surface states depends on the orientation of the confinement potential, which is effected by the growth direction. Here we report on improvements to the epitaxial growth of (001)-oriented cadmium arsenide thin films on a III–V compound semiconductor substrate. We show that smooth films can be achieved by altering the surface chemistry at the epilayer–buffer layer interface. We discuss the nature of the resulting clean, two-dimensional transport on the (001)-like surfaces with reference to previous work on the more widely studied (112)-like surfaces.
8:24AM A04.00003: Transport study in Coherently Strained Thin Films of a 3D Dirac Semimetal  MANIK GOYAL  
(Presenter), TIMO SCHUMANN, DAVID KEALHOFER, SALVA SALMANI-REZAIE, LUCA GALLETTI, SUSANNE STEMMER, University of California, Santa Barbara — Cd$_3$As$_2$ is a 3D Dirac semimetal with doubly degenerate band crossings at isolated points in Brillouin zone. Here, we present a study of epitaxially strained thin films of Cd$_3$As$_2$, grown by molecular beam epitaxy on (111) GaAs with In$_x$Ga$_{1-x}$Sb buffer. The composition (x) was varied to obtain layers that are lattice matched with the Cd$_3$As$_2$, as well as to obtain tensile and compressively strained Cd$_3$As$_2$. Films grow coherently strained between 0.44% (tensile) and -0.46% (compressive) strain up to 85 nm thickness. Magneto transport measurements for the thin films (below 50 nm) reveal 2D quantum oscillations under tensile strain, whereas in compressive direction the quantum oscillations are from 3D Fermi surface. We discuss how strain engineering can be used to control the electronic states in thin films of Dirac Semimetals.

8:36AM A04.00004: Non-local Signatures of the Chiral Magnetic Effect in Dirac Semimetal Bi$_{0.97}$Sb$_{0.03}$  
DAAN WIELENS (Presenter), JORRIT C. DE BOER, JORIS A. VOERMAN, BOB DE RONDE, University of Twente, YINGKAI HUANG, MARK GOLDEN, Zeeman Institute, University of Amsterdam, CHUAN LI, ALEXANDER BRINKMAN, University of Twente — Recently there has been a lot of interest in 3D Dirac semimetals (DSM), which exhibit robust Dirac phases in the bulk of the material. The chiral magnetic effect (CME), which originates from the Weyl cones, causes an E.B-dependent chiral charge polarization, which manifests itself as negative magnetoresistance.

We exploit the extended lifetime of this chirally polarized charge and study the CME in both local and non-local measurements on structured devices of mechanically exfoliated single crystalline flakes of DSM Bi$_{1-x}$Sbx with x ≈ 0.03. From the transport measurements on the non-local devices we find that the chiral charge relaxation time is over an order of magnitude larger than the transport lifetime.

*The authors acknowledge financial support from the European Research Council through a Consolidator Grant and from the Netherlands Organization for Scientific Research through a VICI Grant.

8:48AM A04.00005: Quantum transport properties of Cd$_3$As$_2$ films with low carrier density  
YUSUKE NAKAZAWA  
(Presenter), MASAKI UCHIDA, SHINICHI NISHIHAYA, SHIN SATO, MASASHI KAWASAKI, Department of Applied Physics and Quantum-Phase Electronics Center (QPEC), the University of Tokyo — Cd$_3$As$_2$ is a typical three-dimensional topological Dirac semimetal, characterized by a pair of Dirac points protected by rotational symmetry. While high-crystallinity and high-flatness Cd$_3$As$_2$ films have been obtained by the combination of pulsed laser deposition and subsequent high-temperature annealing [1,2], the carrier density is rather high compared to ones prepared by molecular beam epitaxy [3,4]. In this talk, we report quantum transport properties of Cd$_3$As$_2$ thin films epitaxially grown by molecular beam epitaxy. A typical film thicker than 100 nm shows a carrier density of 5×10$^{16}$ cm$^{-3}$ and an electron mobility exceeding 3×10$^4$ cm$^2$/Vs. In this thickness regime corresponding to the three-dimensional electronic structure, the film shows plateau-like structures in the Hall resistance, indicating the emergence of a two-dimensional conduction state. This can be understood to originate from the Weyl orbit surface state of the topological Dirac semimetal.

9:00AM A04.00006: Negative longitudinal magnetoresistance in GaAs quantum wells* JING XU (Presenter), Argonne National Lab, MENG MA, Princeton University, ZHILI XIAO, Argonne National Lab, YONGLEI WANG, Nanjing University, DAFEI JIN, Argonne National Lab, YANGYANG LYU, Nanjing University, WEI ZHANG, Oakland University, LOREN PFEIFFER, KENNETH WEST, K. W. BALDWIN, MANSOUR SHAYEGAN, Princeton University, WAI-KWONG KWOK, Argonne National Lab, MAKSIM SULTANOV, Northern Illinois University —

Negative longitudinal magnetoresistances (NLMRs) have been observed in a variety of materials and often considered to be associated with Weyl fermions that have a defined chirality. We conducted magnetotransport measurements and observed NLMRs in non-Weyl GaAs quantum wells. We observed pronounced NLMRs up to 9 Tesla at temperatures above the transition temperature and also weak NLMRs at low magnetic fields at temperatures close to the transition and at very low temperatures. The observed NLMRs show various types of magnetic field behavior, the origin of which we attribute to microscopic disorder and we use a phenomenological model to account for the various features. Our results showcase a new contribution of microscopic disorder to the occurrence of novel phenomena. They may stimulate further work on tuning electronic properties via disorder/defect nano-engineering.

X. also acknowledge support by the NSF under Grant No. DMR-1407175.

9:12AM A04.00007: Topological phase transitions by interface engineering DONG ZHANG (Presenter), SKLSM, Institute of semiconductors, Chinese Academy of Sciences — Novel phase transitions, especially topological phase transitions, have attracted intense interests in condensed matter physics in recent years. However, the reported materials possess novel phases are majorly composed of heavy elements with relatively low abundances. We switched investigate objectives into commonly-used semiconductors, and demonstrated that, utilizing giant electric fields generated by charge accumulation at GaAs/Ge/GaAs opposite semiconductor interfaces and band folding, the interface engineering can reduce the sizable gap in Ge, induce large spin-orbit interaction, and drive Ge into a topological insulating phase [1]. Natural topological semimetals hosting multiple topological states will be demonstrated through simple symmetry considerations [2,3], and the possibilities to realize “ideal” topological semimetals utilizing interface design[4] will also be disscussed.

9:24AM A04.00008: Charge transfer in a transition metal dichalcogenide semiconductor/Weyl semimetal van der Waals junctions KYUSUP LEE (Presenter), Department of Electrical and Computer Engineering, National University of Singapore, JIE LI, School of Materials Science and Engineering, Huazhong University of Science and Technology, LIANG CHENG, School of Physical and Mathematical Sciences, Nanyang Technological University, JUNYONG WANG, Department of Physics, National University of Singapore, DUSHYANT KUMAR, QISHENG WANG, MENGJI CHEN, YANG WU, Department of Electrical and Computer Engineering, National University of Singapore, GOKI EDA, Department of Physics, National University of Singapore, EE MIN CHIA, School of Physical and Mathematical Sciences, Nanyang Technological University, HAIXIN CHANG, School of Materials Science and Engineering, Huazhong University of Science and Technology, HYUNSOO YANG, Department of Electrical and Computer Engineering, National University of Singapore — Transient metal dichalcogenides (TMDs) heterostructures have recently made a meteoric rise in quantum device engineering due to its van der Waals (vdW) layered nature. A Weyl semimetal WTe$_2$, also a TMD compound, displays a wide range of exotic electronic and spintronic properties. A central approach in heterostructures is driving charge transfer across the interface mainly governing the carrier dynamics, which determines fundamental optoelectronic properties. Here, we report a new type of CVD grown TMD vdW junctions with a semiconductor 2H-MoTe$_2$ and its sister compound of semimetallic Td-WTe$_2$. Time-resolved terahertz spectroscopy reveals the ultrafast relaxation of the photo-excited carriers in the junctions, which attributes to the charge transfer and the interlayer exciton decay serving as a fast relaxation channel with a characteristic time of ~0.6 ps, faster than that of the each layer (~1.5 ps from Td-WTe$_2$ and ~5.9 ps from 2H-MoTe$_2$). Moreover, we observe the negligible band-filling and hot-phonon effects according to the optical fluence (< 10 mJ/cm$^2$) due to such an ultrafast interfacial relaxation channel. This ultrafast photoresponse in sister-compound large-area TMDs vdW junctions provide a platform for high-speed optoelectronic devices.
9:36 AM A04.00009: Exploring Transport Properties in the 2D–3D Dirac Semimetal Heterostructures* YANFEI WU (Presenter), Massachusetts Institute of Technology, LIANG ZHANG, LI CAIZHEN, ZHI-MIN LIAO, Peking University, DAPENG YU, SONG LIU, ZHEN-SHENG ZHANG, Southern University of Science and Technology — Dirac semimetal is an emerging class of quantum matters, ranging from two-dimensional (2D) category, such as graphene and surface states of topological insulator to three-dimensional (3D) category, for instance, Cd$_3$As$_2$ and Na$_3$Bi. Exotic surface states in 3D Dirac semimetals is attractive for the interface engineering and the research on 2D–3D Dirac van der Waals heterostructures. Here we fabricated graphene–Cd$_3$As$_2$ heterostructure through direct layer-by-layer stacking and investigated their electron transport properties. The electronic coupling results in a notable interlayer charge transfer, which modulates the Fermi level of graphene through Cd$_3$As$_2$. This heterostructure enable us to naturally fabricate graphene p–n–p junctions, showing the quantized conductance plateaus. Moreover, the nonlocal transport studies show large nonlocal signals near Dirac point in graphene–Cd$_3$As$_2$ device, due to the charge transfer from the spin-polarized surface states in Cd$_3$As$_2$. Our results enrich the family of van der Waals heterostructures and can inspire more studies on the application of Dirac/Weyl semimetals in spintronics.

9:48 AM A04.00010: Manipulating the Topological Surface States of Cd$_3$As$_2$ by N* Plasma Exposure TIMO SCHUMANN (Presenter), LUCA GALLETTI, THOMAS E MATES, SUSANNE STEMMER, University of California, Santa Barbara — Cd$_3$As$_2$ belongs to the family of three-dimensional Dirac semimetals, which are characterized by a linear dispersion of their bulk bands at the Fermi energy. For thin films, the electronic transport properties of Cd$_3$As$_2$ are dominated by surface states, which, as we show in this presentation, are highly sensitive to the chemistry of the surface. Temperature-dependent magneto-transport measurements show that exposure of the surface to a low-energy nitrogen plasma improves carrier mobility and facilitates the observation of the quantum Hall effect in confined thin films. X-ray photoemission spectroscopy reveals changes in the surface chemistry of air-exposed and nitrogen-plasma surfaces, respectively. The results provide insights into the role of surface band bending and the relative contributions of surface and bulk states to the measured transport properties.

10:00 AM A04.00011: Realization of an Elemental Topological Dirac Semimetal: α-Sn on InSb(111) [Invited] TAI-CHANG CHIANG (Presenter), University of Illinois at Urbana-Champaign — Three-dimensional (3D) topological Dirac semimetals (TDSs) are rare but important as a versatile platform for exploring exotic electronic properties and topological phase transitions. A quintessential feature of TDSs is 3D Dirac fermions associated with bulk electronic states near the Fermi level. Using angle-resolved photoemission spectroscopy, we have observed such bulk Dirac cones in epitaxially grown α-Sn films on InSb(111), the first such TDS system realized in an elemental form. First-principles calculations confirm that epitaxial strain caused by the in-plane lattice mismatch of 0.14% is key to the formation of the TDS phase. A phase diagram as a function of epitaxial strain is established that connects the 3D TDS phase through a singular point of a zero-gap semimetal phase to a topological insulator phase. The nature of the Dirac cone crosses over from 3D to 2D as the film thickness is reduced to a few layers.

In collaboration with Cai-Zhi Xu, Yang-Hao Chan, Yige Chen, Peng Chen, Xiaoxiong Wang, Catherine Dejoie, Man-Hong Wong, Joseph Andrew Hlevyack, Hyejin Ryu, Hae-Young Kee, Nobumichi Tamura, Mei-Yin Chou, Zahid Hussain, and Sung-Kwan Mo

10:36 AM A04.00012: First principles study of WTe$_2$ with Wannier model* AMARTYAJYOTI SAHA (Presenter), School of Physics and Astronomy, University of Minnesota, TURAN BIROL, Department of Chemical Engineering and Materials Science, UNIVERSITY OF MINNESOTA — Two-dimensional transition metal dichalcogenides are a class of atomically thin materials which can host a wide range of physical properties such as strong spin-orbit coupling and nontrivial topological phases. Both monolayer and bulk tungsten ditelluride (WTe$_2$) has been studied in great detail over the past years for their electronic properties. Here we present the results of our first principles study of the behaviour of finite thickness WTe$_2$. To connect between the bulk and the monolayer material, we employ Wannier functions to build tight binding models for different numbers of WTe$_2$ layers. This study provides insight into the effect of van der Waals interactions and spin-orbit coupling on the symmetry, crystal and band structures, and topology of WTe$_2$.

*This work was supported primarily by the National Science Foundation through the University of Minnesota MRSEC under Award Number DMR-1420013 and the iSuperseed program.
Using linear response theory, we evaluate the optical conductivity of 2D semi-Dirac materials for light polarized along two mutually orthogonal directions and predict a strong anisotropy of the optical response as a consequence of their unique dispersion spectrum. Our results also predict a large degree of sensitivity for inter-band optical conductivity to the polarization direction. While it reveals an abruptly large value for certain frequency for light along a particular polarization direction, it is significantly suppressed along the direction orthogonal to the former. The frequency corresponding to the predicted giant optical conductivity is found to be independent of the chemical potential, for a lightly doped system. This direction-dependency of the giant inter-band optical conductivity may, in turn, be used to uniquely predict the dispersive nature of the 2D \textit{semi}-Dirac materials, in addition to possible applications that arise from this direction dependent optical transparency.

Monday, March 4, 2019 8:00 AM - 11:00 AM

Session A05 DMP: Topological Superconductivity: Majorana

8:00AM A05.00001: Majorana in Chains and Hinges\textsuperscript{*}  [Invited] ALI YAZDANI (Presenter), Princeton University — In recent years, following pioneering theoretical work of Kitaev and others, we have learned how to engineer materials that harbor quasiparticles that behave similar to fermions that Majorana had first envisioned. In particular, there has been a focus on one-dimensional topological superconductor that harbor Majorana zero modes (MZM) that can potentially be used to make fault-tolerant topological quantum computation possible. We have proposed and implemented a platform for realization of topological superconductivity and MZM in chains of magnetic atoms on the surface of a superconductor. In this talk, I will describe the series of experiments on this platform that we have performed to establish the presence of these exotic quasi-particle using spectroscopic mapping with the scanning tunneling microscope (STM). These include the most recent study of the unique spin signature of MZM. I will also describe work on a new platform where we use the one-dimensional helical hinge states of a higher order topological insulators. In paritcular, I will show experiment demonstrating how combination of magnetism and superconductivity on such one-dimensional states can also give rise to MZM that can be detected with an STM. Overall these experiments, illustrate how the power of spectroscopic imaging with the STM can be used to characterize novel quantum states of matter and visualize their exotic quasi-particles.

\textsuperscript{*}We acknowledge funding from ONR, Moore foundation, NSF-DMR, and NSF-MRSEC through Princeton Center for Complex Materials.

8:36AM A05.00002: Experimental signatures of Majorana bound states in S-TI-S lateral Josephson junctions\textsuperscript{*}
GUANG YUE (Presenter), CAN ZHANG, ERIK HUEMILLER, University of Illinois at Urbana-Champaign, MARYAM SALEHI, NIKESH KOIRALA, SEONGSHIK OH, Rutgers University - New Brunswick, ALEXEY BEZRYADIN, DALE J VAN HARLINGEN, University of Illinois at Urbana-Champaign — We present experiments designed to search for features of Majorana bound states (MBS) in lateral Josephson junctions formed by depositing s-wave superconductors onto the surface of topological insulator thin films. In a vertical magnetic field that induces a phase gradient across the junction, the localized MBS are expected to be stable at the cores of Josephson vortices where the phase difference across the junction is an odd multiple of $\pi$. To test this picture, we have fabricated Nb-Bi$_2$Se$_3$-Nb Josephson junctions with different geometries and carried out extensive measurements of their Josephson supercurrent vs. magnetic field diffraction patterns and the statistical critical current switching distribution in hysteretic junctions. Our results show a number of expected features of MBS, including: (1) finite critical current at the location of odd-numbered nodes of the diffraction pattern, (2) anomalous critical current distributions characterized by either a double peak in the switching distribution or an increase in the standard deviation of the distribution changes at values of magnetic field at which MBS are expected to be present in the junction. We will present a compilation of our data and analysis of these experiments.

\textsuperscript{*}NSF DMR 16-10114
ANDREY ANTIPOV (Presenter), Microsoft, ARNO BARGERBOS, TU Delft, GEORG W. WINKLER, BELA BAUER, ENRICO ROSSI, ROMAN LUCHYN, Microsoft — We study the effect of gate-induced electric fields on the properties of semiconductor-superconductor hybrid nanowires which represent a promising platform for realizing topological superconductivity and Majorana zero modes. Using a self-consistent Schrödinger-Poisson approach that describes the semiconductor and the superconductor on equal footing, we are able to access the strong tunneling regime and identify the impact of an applied gate voltage on the coupling between semiconductor and superconductor. We discuss how physical parameters such as the induced superconducting gap and Landé g-factor in the semiconductor are modified by redistributing the density of states across the interface upon application of an external gate voltage. Finally, we map out the topological phase diagram as a function of magnetic field and gate voltage for InAs/Al nanowires.

MARTIN CLAASSEN (Presenter), Center for Computational Quantum Physics, Simons Foundation Flatiron Institute, DANTE KENNES, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, MANUEL ZINGL, Center for Computational Quantum Physics, Simons Foundation Flatiron Institute, MICHAEL SENTEF, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter — Chiral superconductors are a novel class of unconventional superconductors that host topologically protected chiral Majorana fermions at interfaces and domain walls, with great potential for topological quantum computing. Here we show that the out-of-equilibrium superconducting state in such materials is itself described by a Bloch vector in analogy to a qubit, which can be controlled all-optically on ultrafast time scales [1]. The mechanism is universal and permits a dynamical change of handedness of the condensate, relying on transient dynamical breaking of lattice rotation, mirror or time-reversal symmetries via choice of pump pulse polarization to enable arbitrary rotations of the Bloch vector. The underlying physics can be intuitively understood in terms of transient Floquet dynamics, however the mechanism extends to ultrafast time scales, and importantly the engineered state persists after the pump is switched off. We demonstrate that these novel phenomena should appear in graphene and magic-angle twisted bilayer graphene (TBG), as well as Sr$_2$RuO$_4$, as candidate chiral $d+id$ and $p+ip$ superconductors, and show that chiral superconductivity can be detected in time-resolved pump-probe measurements.

QIYUE WANG (Presenter), Department of Physics, University of Texas at Dallas, CHENG-CHENG LIU, School of Physics, Beijing Institute of Technology, YUAN-MING LU, Deparment of Physics, Ohio State University, FAN ZHANG, Department of Physics, University of Texas at Dallas — Majorana bound states often occur at the end of a 1D topological superconductor. Validated by a new bulk invariant and an intuitive edge argument, we show the emergence of one Majorana Kramers pair at each corner of a square-shaped 2D topological insulator proximitized by an extended s-wave (e.g., Fe-based) superconductor. We obtain a phase diagram that addresses the relaxation of crystal symmetry and edge orientation. We propose two experimental realizations in candidate materials. Our scheme offers a higher-order and higher-temperature route for exploring non-Abelian quasiparticles.

9:24AM A05.00006: Majorana modes as electrical switches: computing the conductance of a junction between a
Topological superconductor and a multi-channel Luttinger liquid ALBERTO NOCERA (Presenter), Stewart Blusson
Quantum Matter Institute, University of British Columbia, ARMIN RAHMANI, Physics, Western Washington University, ADRIAN
FEIGUIN, Physics, Northeastern University, MARCEL FRANZ, IAN AFFLECK, Stewart Blusson Quantum Matter Institute, University of
British Columbia — Motivated by the experimental confirmation of topological superconductivity in semiconducting
nanowires, I study the transport properties of a junction of three wires (T-junction), which provides the simplest nontrivial
example of wire network, as well as an important building block for topological quantum computing architectures. I show
how to compute the electrical conductance of a T-junction between a Topological superconductor and two normal
interacting nanowires using the Density Matrix Renormalization Group (DMRG) method [1] that allows one to extract the
conductance in the thermodynamic limit from static ground-state DMRG computations in closed finite systems [2]. As
main result, I numerically demonstrate that the T-junction can act as an electrical switch in the presence of a localized
Majorana mode in agreement with field theory predictions [3]. I finally focus on the regime where the tunnel couplings
between the superconductor and the nanowires is fine tuned to the same value, and compare the numerical results to the
field theory calculations that predict a non-trivial critical point with an unusual conductance tensor.

9:36AM A05.00007: Chiral Majorana modes on electrically gated high Tc Topological Superconductors*
NIMA DJAVID (Presenter), ROGER LAKE, ECE, University of California, Riverside — Majorana edge modes were detected by observation
of half-integer conductivity in a magnetic topological insulator/superconductor (MTI/SC) heterostructure [1]. Recently
proposed systems which are compatible with standard semiconductor processing are the most promising schemes for
braiding Majorana modes. However, identifying Majorana zero modes experimentally has been challenging mostly
because of the small pairing gap of s-wave SCs. A heterostructure between an anomalous quantum Hall insulator and a
high Tc d-wave superconductor with a large pairing gap may offer a more feasible approach for implementing Majorana
zero modes.

In this work, we study topological properties of a gated d-wave (MTI/SC) heterostructure. The phase diagram of the system
is obtained by employing the Kubo formula. The existence of Majorana edge modes in the presence of electrical gating has
been shown in d-wave topological superconductors. A Green’s function formalism has been employed for the detection of
Majorana edge modes and their localization properties have been investigated.

9:48AM A05.00008: Majorana Zero Modes and Braiding in Realistic Nanowire Y-Junctions* FENNER HARPER
(Presenter), University of California, Los Angeles, M A MUEED, BENJAMIN MADON, IBM Almaden Research Center, FABRIZIO
NICHELE, MARKUS RITTER, IBM Zurich Research Laboratory, NOEL ARELLANO, IBM Almaden Research Center, HEINZ SCHMID,
SIEGFRIED KARG, HEIKE RIEL, IBM Zurich Research Laboratory, AAKASH PUSHP, IBM Almaden Research Center, RAHUL ROY,
University of California, Los Angeles — Under the right conditions, semiconductor nanowires are believed to host zero-energy
Majorana fermions, particles with non-abelian properties suitable for topological quantum computation. While recent
experiments have demonstrated encouraging local signatures of Majorana fermions, evidence for their non-abelian
nature remains elusive. Motivated by ongoing experimental work at IBM, we build a realistic model of a nanowire Y-
junction and study the properties of the resulting Majorana fermions numerically. We make quantitative predictions about
the device parameters and geometry that are conducive to realising Majorana zero modes, and study the corresponding
experimental signatures that would be expected. We go on to simulate braiding operations between multiple Majorana
fermions, and suggest experimental gating protocols that may lead to signatures of their non-abelian nature.

Majorana double nanowires in the presence of magnetic field, interactions, and disorder

MANISHA THAKURATHI (Presenter), Department of Physics, University of Basel, PASCAL SIMON, Laboratoire de Physique des Solides (CNRS/ U-PSUD), Université Paris Sud, JELENA KLINOVJA, DANIEL LOSS, Department of Physics, University of Basel — We study double Rashba nanowires (NWs) coupled to an s-wave superconductor, which has been recently proposed as a versatile platform to generate Kramers pairs of Majorana bound states in the absence of magnetic field [1]. We also analyze the effects of electron-electron interactions and disorder on the system and find that the interactions drive the system into the topological phase [2]. We further consider an external magnetic field along the NWs and demonstrate that the setup exhibits a new previously overlooked Majorana phase that emerges at low magnetic field [3]. Also we demonstrate the charge and spin signatures of topological superconductivity in the double NWs setup.

Multi-band Physics in Inhomogeneous Majorana Nanowires

BENJAMIN WOODS (Presenter), TUDOR DAN STANESCU, West Virginia University — Semiconductor nanowires proximity coupled to superconductors are a promising platform to detect and manipulate Majorana zero energy modes. Single band models are used ubiquitously throughout the literature to describe these systems. In practice, however, it is quite likely that multiple confinement bands determine the properties of these devices, which can lead to new features not predicted by the single band models. We consider different types of inhomogeneity, such as a quantum dot defined by a region of the nanowire not covered by the superconductor. As previously shown, the dot region can give rise to Andreev bound states that mimic some of the signatures of Majorana zero modes. We find an increased pinning of Andreev bound states to zero energy within the multi-band model due to strong inter-band coupling induced by an inhomogeneous electrostatic potential. Understanding in detail the multi-band effects are important for the practical realization of Majorana zero modes in semiconductor-superconductor nanowire devices.

Non-hermitian topology: a unifying framework for the Andreev versus Majorana states controversy

RAMON AGUADO (Presenter), PABLO SAN-JOSE, Materials Science Institute of Madrid (ICMM), Spanish Research Council (CSIC), ELSA PRADA, FERNANDO PEÑARANDA, Condensed Matter Physics Center (IFIMAC), Universidad Autonoma de Madrid (UAM), JESUS AVILA, Materials Science Institute of Madrid (ICMM), Spanish Research Council (CSIC) — Andreev bound states (ABSs) in hybrid semiconductor-superconductor nanowires can have near-zero energy in parameter regions where band topology predicts trivial phases. This surprising fact has been used to challenge the interpretation of a number of transport experiments in terms of non-trivial topology with Majorana zero modes (MZMs). We show that this ongoing ABS versus MZM controversy is fully clarified when framed in the language of non-Hermitian topology, the natural description for open quantum systems. This change of paradigm allows us to understand topological transitions and the emergence of pairs of zero modes more broadly, in terms of exceptional point (EP) bifurcations of system eigenvalue pairs in the complex plane. Within this framework, we show that some zero energy ABSs are actually non-trivial, and share all the properties of conventional MZMs, such as the recently observed 2e^2/h conductance quantization. From this point of view, any distinction between such ABS zero modes and conventional MZMs becomes artificial. The key feature that underlies their common non-trivial properties is an asymmetric coupling of Majorana components to the reservoir, which triggers the EP bifurcation [1].

10:36AM A05.00012: Metamorphosis of Andreev bound states into Majorana bound states in pristine nanowires*  
YINGYI HUANG, HAINING PAN (Presenter), Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, CHUN-XIAO LIU, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, JAY SAU, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, TUDOR DAN STANESCU, Department of Physics and Astronomy, West Virginia University — We show theoretically that a clean superconducting spin-orbit-coupled nanowire with finite chemical potential has two distinct non-topological regimes as a function of Zeeman splitting: one is characterized by finite-energy in-gap Andreev bound states (ABS), while the other has only extended bulk states. The Andreev bound state regime is characterized by strong features in the tunneling spectra creating a “gap closure” signature. However, no “gap reopening” signature should be apparent above the topological quantum phase transition (TQPT), in agreement with the most recent experimental observations. The gap closure feature is not a signature of the trivial gap of extended bulk states closing at the transition, but rather reflects the coming together of the ABS in systems with high chemical potential. Our theoretical finding establishes the generic intrinsic ABS on the trivial side of the topological quantum phase transition as the main contributors to the tunneling conductance spectra, providing a generic interpretation of existing experiments in clean Majorana nanowires. Our work also explains why experimental tunnel conductance spectra generically have gap closing features below the TQPT, but no gap opening features above it.

*This work is supported by LPS and Microsoft.

10:48AM A05.00013: Phonon-Assisted Andreev Reection at Majorana Zero Mode  
NING DAI (Presenter), QING-FENG SUN, International Center for Quantum Materials, Peking University — One of the typical features of Majorana zero mode (MZM) at the edge of topological superconductor is a zero-bias peak in the tunneling spectroscopy of the normal-superconductor (NS) junction. We study on a model with one phonon mode coupling to the superconductor lead of the NS junction, which can be viewed as an electron-lead/phonon-coupled-MZM/hole-lead structure. The phonon-coupled MZM acts as a series of channels in which electron can turn into hole by transmitting phonons to itself. These channels present in the local density of states(LDOS) as a series of stripes, generating the corresponding peaks in the tunneling spectroscopy. In LDOS, the electron-phonon interaction narrows and redistributes the weight among stripes. In the tunneling spectroscopy, the heights of peaks present a feature of the multi-phonon process. With these investigations, our work illuminates the mechanism of phonon-assisted Andreev reflection at a Majorana zero mode.

Monday, March 4, 2019 8:00 AM - 10:48 AM

Session A06 DCMP: Beyond Fermi Liquid Theory  
BCEC 109A - Peter Riseborough, Temple University - Tag(s): Focus

8:00AM A06.00001: Superdiffusive transport of energy in generic Luttinger liquids  
JOEL MOORE (Presenter), University of California, Berkeley, and Lawrence Berkeley National Laboratory, VIR BULCHANDANI, University of California, Berkeley, CHRISTOPH KARRASCH, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin — Metals in one spatial dimension are described at the lowest energy scales by the Luttinger liquid theory. It is well understood that this free theory, and even interacting integrable models, can support ballistic transport of conserved quantities including energy. Realistic Luttinger liquids, even in pure systems without disorder, contain integrability-breaking interactions, which are expected to lead to thermalization and conventional diffusive linear response. We show that the expansion of energy when such a non-integrable Luttinger liquid is locally heated above its ground state shows superdiffusive behavior (i.e., spreading of energy that is intermediate between diffusion and ballistic propagation), by combining an analytical anomalous diffusion model with numerical matrix product state calculations. The main ingredient in the analytical model is the power-law in linear-response transport that originates in the scaling dimension of integrability-breaking corrections to the Luttinger liquid. Some other one-dimensional systems that also remain far from the linear-response regime for long times are discussed.
Lorentz ratio of a compensated metal

SONGCI LI (Presenter), National High Magnetic Field Laboratory/University of Florida, DMITRII MASLOV, University of Florida — A violation of the Wiedemann-Franz law in a metal can be quantified by comparing the Lorentz ratio, \( L = \kappa / \rho / T \), where \( \kappa \) is the thermal conductivity and \( \rho \) is the electrical resistivity, with the universal Sommerfeld constant, \( L_0 = \pi^2/3 \) \( (k_B/e)^2 \).

We obtain the Lorentz ratio of a clean compensated metal with intercarrier interaction as the dominant scattering mechanism by solving exactly the system of coupled integral Boltzmann equations. The Lorentz ratio is shown to assume a particular simple form in the forward-scattering limit: \( L/L_0 = \Theta^2 / 2 \), where \( \Theta \) is the scattering angle. In this limit, \( L/L_0 \) can be arbitrarily small. We also show how the same result can be obtained without the benefit of an exact solution. We discuss how a strong downward violation of the Wiedemann-Franz law in a type-II Weyl semimetal WP_2 can be explained within our model.

Uncovering non-Fermi-liquid behavior in Hund metals: critical behavior of a three-orbital Kondo model

ELIAS WALTER (Presenter), KATHARINA M STADLER, SEUNG-SUP B. LEE, Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-University of Munich, Germany, YILIN WANG, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, NY, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University, NJ, ANDREAS WEICHSELBAUM, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, NY, JAN VON DELFT, Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-University of Munich, Germany — When using dynamical mean field theory (DMFT) to study Hund metals, one arrives at self-consistent impurity models in which bath and impurity both have spin and orbital degrees of freedom. If these are screened at different energy scales, \( T_K^{\text{sp}} < T_K^{\text{orb}} \), the intermediate energy window is governed by a novel non-Fermi-liquid (NFL) fixed point, involving screened orbital degrees of freedom weakly coupled to an unscreened local spin. Here we characterize the corresponding NFL behavior in detail for a 3-orbital Kondo model, tuned such that the NFL energy window is very wide. We find excellent agreement between conformal field theory (CFT) predictions and numerical renormalization group (NRG) results.

Transport properties of a disordered two-dimensional metal in the vicinity of SDW order: A memory matrix calculation

HERMANN FREIRE (Presenter), Instituto de Física, Universidade Federal de Goiás, Goiânia-GO, Brazil — We perform the calculation of many transport coefficients as a function of temperature in the “strange-metal” phase that emerges in the vicinity of a SDW phase transition in the presence of weak disorder. This scenario is relevant to the phenomenology of many important correlated materials, such as, e.g., the cuprates and the iron-based superconductors. We implement the memory-matrix approach that allows the calculation of all transport coefficients for the corresponding field-theory model beyond the quasiparticle paradigm. As a result, we are able to obtain here the temperature dependence of the dc resistivity, the Hall angle, the thermal conductivity, the Seebeck coefficient and the Nernst response for a disordered two-dimensional SDW quantum critical theory with an effective composite operator that couples the order-parameter fluctuations to the entire Fermi surface of the system. We argue that our present theory provides a good basis in order to unify the experimental transport data, e.g., of the cuprates, within a wide range of doping regimes.

8:48AM A06.00005: Transconducting Transition for a Dynamic Boundary Coupled to Several Tomonaga-Luttinger Liquids*  BARUCH HOROVITZ, Department of Physics, Ben Gurion University, THIERRY GIAMARCHI (Presenter), DQMP, University of Geneva, PIERRE LE DOUSSAL, LPTENS, Ecole Normale Superieure — The question on how a quantum bath can affect the dynamical properties of a quantum degree of freedom is a long standing and important one. Here we study a dynamic boundary, e.g., a mobile impurity, coupled to N independent Tomonaga-Luttinger liquids (TLLs) each with interaction parameter K. We demonstrate [1] that for N ≥ 2 there is a quantum phase transition at a critical value of K ≥ 1/2, where the TLL phases lock together at the particle position, resulting in a nonzero transconductance equal to e²/(Nh). We analyze this transition line and compare it with large N predictions. We discuss experimental applications both for cold atomic or condensed matter realizations.

9:00AM A06.00006: T-linear resistivity in models with local self-energy*  EUN-AH KIM (Presenter), PETER CHA, Cornell University, AAVISHKAR PATEL, Harvard University, EMANUEL C GULL, University of Michigan — Bad metallic transport is commonly observed in strongly correlated systems. In particular, T-linear resistivity is of special theoretical interest in its connection to quantum criticality and superconductivity. Recently, T-linear resistivity have been explicitly found in several models with local self-energy yet relation between different mechanisms remain unclear. In this work, we discuss two models that demonstrate T-linearity: lattice-Sachdev-Ye-Kitaev model and the Hubbard model within the dynamical mean-field theory (DMFT). In the former, we find that T-scaling depends crucially on the details of both the infra-red- and ultraviolet-limits. In the latter, we study the Hubbard model within single-site DMFT, and show that transport quantities and compressibility are driven by atomic interactions down to the temperatures of the order of the bandwidth. We also study the temperature dependence of the Lorentz ratio and Diffusivity and contrast different mechanisms of T-linear resistivity.

9:12AM A06.00007: Theory of Strange Metals from Hot Fermions*  CONNIE MOUSATOV (Presenter), Department of Physics, Stanford University, EREZ BERG, Department of Condensed Matter Physics, Weizmann Institute of Science, SEAN HARTNOLL, Department of Physics, Stanford University — We study a metal where a large Fermi surface coexists with a set of `hot spots' with a high density of states. The hot electrons occupy a small fraction of the Brillouin zone, yet qualitatively modify the properties of the entire system. We emphasize the importance of scattering processes in which two electrons from the large, `cold' Fermi surface scatter into one hot and one cold electron. These lead to a `strange metallic' state with anomalous, non-Fermi liquid thermodynamic and transport properties. Scattering into hot electrons that are effectively classical (non-degenerate) in a finite portion of the Brillouin zone leads to a marginal Fermi liquid. This explains, in detail, the phenomenology of Sr3Ru2O7 in field, including T-linear resistivity and a T log(1/T) electronic specific heat. Hot electrons that are instead localized near a point in the Brillouin zone, such as a two-dimensional van Hove singularity, lead to different power laws. We show that the transport behavior of strained Sr2RuO4 is recovered from this picture.

9:24AM A06.00008: Emergent Anisotropic Non-Fermi Liquid  SANGEUN HAN (Presenter), Department of Physics, KAIST, CHANGHEE LEE, Department of Physics and Astronomy, SNU, EUN-GOOK MOON, Department of Physics, KAIST, HONGKI MIN, Department of Physics and Astronomy, SNU — Understanding correlation effects in topological phases and their transitions is a cutting-edge area of research in recent condensed matter physics. We study topological quantum phase transitions (TQPTs) between double-Weyl semimetals (DWSMs) and insulators, and argue that a novel class of quantum criticality appears at the TQPT characterized by emergent anisotropic non-Fermi liquid behaviors, in which the interplay between the Coulomb interaction and electronic critical modes induces not only anisotropic renormalization of the Coulomb interaction but also strongly correlated electronic excitation. Using the standard renormalization group methods, large $N_f$ theory and the $\varepsilon=4-d$ method with fermion flavor number $N_f$ and spatial dimension $d$, we obtain the anomalous dimensions of electrons ($\eta_f=0.366/N_f$) in large $N_f$ theory and the associated anisotropic scaling relations of various physical observables. Our results may be observed in candidate materials for DWSMs such as HgCr2Se4 or SrSi2 when the system undergoes a TQPT.
temperatures down to a low coherence scale, $T_{coh}$. The intermediate NFL regime displays anomalous transport properties, such as the ruthenates and cobaltates, display metallic non-Fermi liquid (NFL) properties over a broad range of temperatures $T$ and at low bias voltages $eV$. We also apply the formulas to the SU(N) symmetric case and calculate order $T^2$ and $(eV)^2$ contributions of the differential conductance $dI/dV$, by using the numerical renormalization group (NRG) approach and also the $1/(N-1)$ expansion [3]. Our results, obtained in a wide range of electron fillings, show that contributions of three-body fluctuations that enter through nonlinear susceptibilities play an important role as a gate voltage varies away from the particle-hole symmetric point where the impurity levels are half-filled. Furthermore, the contributions of three body fluctuations show an oscillatory behavior as gate voltage $\varepsilon_d$ varies and, the three body fluctuations decrease as the number of the orbital $N$ increases.

9:48AM A06.00010: Out-of-equilibrium dynamics and thermalization across a solvable non-Fermi liquid to Fermi liquid transition*  
ARJIT HALDAR (Presenter), PROSENJIT HALDAR, SUMILAN BANERJEE, Center for Condensed Matter Theory, Dept. of Physics, Indian Institute of Science, Indian Institute of Science — We study the non-equilibrium dynamics of an interacting model [1] having a quantum phase transition from a Sachdev-Ye-Kitaev (SYK) non-Fermi liquid (NFL) to a Fermi liquid (FL). The model has SYK fermions on $N$ sites quadratically coupled to non-interacting peripheral fermions on $M$ sites. The transition from the NFL ($p < 1$) to FL ($p > 1$) is obtained at $p=1$ by tuning the ratio $p=M/N$. We study the dynamics as a function of $p$, (a) after a quench where the coupling between initially disconnected SYK and peripheral fermions is suddenly switched on, and (b) during a slow quench when the coupling is slowly ramped over a duration $\tau$. In the sudden quench, we find that a thermal state is reached in the NFL ($p < 1$) through collapse-revival oscillations of the quasiparticle residue of the peripheral fermions. In the FL phase, the system fails to thermalize within the accessible time and shows multiple pre-thermal regimes. In the slow quench, the excitation energy generated has a power-law dependence $\sim \tau^{-\eta}$ for intermediate $\tau$, with a strong $p$-dependent $\eta$ having a minimum at the transition. At larger $\tau$ the power-law breaks down, along with adiabaticity, due to the initial residual entropy of the SYK fermions. [1] S. Banerjee and E. Altman, PRB 95, 134302 (2017).

10:00AM A06.00011: Solvable lattice models for intermediate scale non-Fermi liquid metals  
DEBANJAN CHOWDHURY (Presenter), SENTHIL TODADRI, Massachusetts Institute of Technology — A number of strongly correlated materials, such as the ruthenates and cobaltates, display metallic non-Fermi liquid (NFL) properties over a broad range of temperatures down to a low coherence scale, $T_{coh}$. The intermediate NFL regime displays anomalous transport properties, broad electronic spectral functions indicating the absence of sharp quasiparticles and is often accompanied by a finite extrapolated zero temperature entropy. Theoretically, examples of similar NFL metals can be obtained using higher dimensional generalizations of the solvable SYK model and have also been shown to arise in dynamical mean-field theory solutions of more realistic microscopic models. Going beyond these approaches, I will propose other models and setups where a broad incoherent metallic regime arises in the presence of a finite configurational entropy.

10:12AM A06.00012: Conductivity of a compensated metal near a Pomeranchuk quantum critical point: the absence of mass renormalization*  
DMITRI MASLOV (Presenter), University of Florida, SONGCI LI, National High Magnetic Field Laboratory/University of Florida — The role of mass renormalization, $m^*/m_B$, in electron transport near a quantum critical point (QCP) is a nontrivial issue. According to a naive interpretation of the Drude formula, as electrons get heavier near a QCP, their electrical and thermal conductivities decrease. However, this picture has never been supported by an actual calculation. In this work, we employ a model case of a compensated metal near a Pomeranchuk-type criticality. The advantage of this model is that it allows one to treat electrical and thermal conductivities on the same footing, without invoking umklapp scattering or any other channels of momentum relaxation which are extraneous to the electron system. By solving exactly the kinetic equation, we obtain explicit results for the electrical and thermal conductivities, and also for the viscosity of a two-band compensated metal. We show that mass renormalization factors cancel out with the $Z$ factors, which renormalize the scattering probability, such that all the transport quantities contain the bare rather than renormalized electron masses. We also demonstrate how the same cancelation happens diagrammatically, on an example of the optical conductivity of a compensated metal.

10:24AM A06.00013: Entanglement signatures of quantum-to-classical crossover of a Fermi surface

HASSAN SHAPOURIAN (Presenter), SHINSEI RYU, University of Chicago — The entanglement entropy of free fermions with a Fermi surface is known to obey a logarithmic scaling and violate the area law in all dimensions. Here, we would like to see how thermal fluctuations affect the logarithmic scaling behavior. To this end, we analytically compute the bipartite entanglement negativity of a finite-temperature state and show that the coherent Fermi surface is gradually destroyed as a function of temperature and eventually turns into an incoherent classical system, where the entanglement is completely lost. We check that our analytical results agree with the numerical simulation of free fermions on a lattice.

10:36AM A06.00014: Strong-Coupling Study of Interlayer Pairing in Bilayer Composite Fermion Metals

LUIS MENDOZA (Presenter), NICHOLAS EVANS BONESTEEL, Florida State University — We study the T=0 Eliashberg equations for interlayer pairing in the composite fermion description of the ν=1/2+1/2 quantum Hall bilayer system. In this description, composite fermions are coupled to two bosonic gauge fields which, in addition to leading to a breakdown of Fermi liquid theory, mediate a singular attractive interaction and a less singular repulsive interaction in the interlayer Cooper channel. Our solution of the T=0 Eliashberg equations includes both these pairing and pair-breaking effects, along with self-energy effects. We compare our results with previous Eliashberg results which do not take self-energy effects into account [1], and results obtained using the RG [2,3]. The connection between the RG and Eliashberg frameworks is also studied through the local approximation introduced in [4]. In particular we carry out the local approximation explicitly and compare with our results obtained from the full Eliashberg equations.

8:00AM A07.00001: Honeycomb Lattice-Type CDW associated with Interlayer Cu Ions Ordering in 1T-CuxTiSe2

SHUNSUKE KITOU (Presenter), Nagoya University, and Institute for Molecular Science, SHINTARO KOBAYASHI, Nagoya University, TATSUYA KANEKO, RIKEN, NAOYUKI KATAYAMA, Nagoya University, SEIJI YUNOKI, RIKEN, TOSHIKAZU NAKAMURA, Institute for Molecular Science, Japan, HIROSHI SAWA, Nagoya University — The electronic state in 1T-TiSe2, which has attracted attention as an excitonic insulator, can be changed by electronic doping through Cu+ intercalation. Indeed, the superconductivity was reported in Cu_xTiSe2 on 0.04 ≤ x ≤ 0.10 [1]. We succeeded in synthesis of single crystal samples of Cu_xTiSe2 (x = 0 ~ 0.35) and performed physical property measurements, synchrotron x-ray diffraction experiments, and density-functional-theory calculations. It was found that x = 1/4 and 1/3 were magical numbers in this system and disorder-order transitions were caused by the interaction among Cu atoms. Furthermore, in x = 1/3, a hybrid-type phase transition caused by the commensurate connection between Cu-ordering and a new honeycomb lattice-type charge-density-wave in TiSe2 layers was realized.

8:12AM A07.00002: Charge disproportionation, mixed valence, and Janus effect in multiorbital systems: A tale of two insulators* ALDO ISIDORI (Presenter), MAJA BEROVIC, LAURA FANFARILLO, International School for Advanced Studies (SISSA, Trieste, Italy), LUCE DE MEDICI, Laboratoire de Physique et d’Etude des Materiaux, Paris, France, MICHELE FABRIZIO, MASSIMO CAPONE, International School for Advanced Studies (SISSA, Trieste, Italy) — Multiorbital Hubbard models host strongly correlated 'Hund's metals' even for interactions much stronger than the bandwidth. We characterize this interaction-resilient metal as a mixed-valence state. In particular it can be pictured as a bridge between two strongly correlated insulators: a high-spin Mott insulator and a charge-disproportionated insulator which is stabilized by a very large Hund's coupling. This picture is confirmed comparing models with negative and positive Hund's coupling for different fillings. Our results provide a characterization of the Hund's metal state and connect its presence with charge disproportionation, which has indeed been observed in chromates and proposed to play a role in iron-based superconductors.

8:24AM A07.00003: Unraveling spin and charge dynamics in two-leg spin ladders using resonant inelastic x-ray scattering UMESH KUMAR (Presenter), Department of Physics and Astronomy, University of Tennessee, Knoxville, ALBERTO NOCERA, Stewart Blusson Quantum Matter Institute, University of British Columbia, ELBIO R DAGOTTO, STEVEN JOHNSTON, Department of Physics and Astronomy, University of Tennessee, Knoxville — Resonant inelastic x-ray scattering (RIXS) has become an important tool to study the spin and charge excitations in materials. We investigate the RIXS spectra of undoped and doped antiferromagnetic spin-ladder cuprate in both the non-spin conserving (NSC) and spin-conserving (SC) channels at the Cu $L_3$-edge. The spectra are rich and host many exotic excitations. In the undoped NSC-channel, we identify one-triplon, triplet two-triplon excitations in the strong rung coupling limit and confined spinons in the weak rung coupling limit. In the doped NSC-channel, we identify new dispersive quasiparticle-like spectral features composed of bound 'charge and spin-1/2' in strong rung coupling limit in addition to the excitations branches already present in the undoped case. The NSC-channel can be well described by $S(q, \omega)$. On the other hand, SC-channel is unique to RIXS and reveals new features. In the undoped SC channel, we identify singlet two-triplon for the strong rung coupling and confined spinons for the weak rung coupling. In the doped SC-channel, RIXS probes the charge excitations instead of spin-excitations, and we identify gapless and gapped charge excitations in the spectra.

8:36AM A07.00004: Stripes and Nematicity in a Hole-Doped Three-Orbital Spin-Fermion Model for Superconducting Cuprates* ADRIANA MOREO (Presenter), Physics, University of Tennessee and ORNL — Numerical studies of a spin-fermion model that captures the charge-transfer properties of Cu-based high critical temperature superconductors[1] reveal the spin and charge order in the parent compound and under hole doping. In clusters of dimension 16X4, that break the rotational symmetry, half-filled stripes are observed upon hole doping, i.e., $n$ stripes of length 4 develop when $2n$ holes are introduced in the system. The antiferromagnetic order observed in the parent compound develops a pi-shift across each stripe and the magnetic structure factor peaks at momentum $k=(\pi,\pi)$ with $\delta=2\pi N_h/L$ where $L=16$ and $N_h$ is the number of doped holes.

The electronic charge is also modulated and the charge structure factor peaks at $k=(2\delta,0)$. In addition, orbital nematicity with $\langle n_{px}\rangle-\langle n_{py}\rangle\neq 0$ develops as electrons are removed from the system. These results indicate that the spin and charge distribution experimentally observed in hole-doped cuprates is captured by unbiased Monte Carlo studies of a doped charge-transfer insulator.

the upshifted T\textsubscript{SHABALIN}, University of California, San Diego, DILING ZHU, SLAC- Natl Accelerator Lab, ERIC FULLERTON, OLEG SHPYRKO, NUH GEDIK, Massachusetts Institute of Technology — The phase diagram of cuprate superconductors exhibits a plethora of

9:24AM A07.00008: Ultrafast probing of collective mode of the charge order in La\textsubscript{1.87}Ba\textsubscript{0.125}CuO\textsubscript{4}

Electrons react very quickly, and moreover generally are the smallest component of the total heat capacity. This allows us to uncover a new long-lived metastable state in the charge density wave material 17-TaSe\textsubscript{2}, that is distinct from all of the known equilibrium phases: it is characterized by a significantly reduced effective heat capacity that is only 30% of the normal value, due to selective electron-phonon coupling to a subset of phonon modes. As a result, significantly less energy is required to melt the charge order and transform the state of the material than under thermal equilibrium conditions.

9:00AM A07.00006: Observation of M2 phase coming from the charge density wave for the insulator-to-metal transition in VO\textsubscript{2}.

Due to the strain, the intermediate monoclinic phase, known as the M2 phase, was clearly seen through the Raman phonon mode near 650 cm\textsuperscript{-1} [2]. The M2 phase has two substructures of both the charge density wave (CDW) responsible for the Peierls insulator and zig-zag chain for the Mott insulator [3]. However, the mechanism of the upshifted T\textsubscript{IMT} does not yet revealed.

In this talk, through simultaneous measurements of temperature dependence of micro-Raman spectra and resistance, as well as in-situ XRD and resistance, we observed that T\textsubscript{IMT} is prior to temperature of structural phase transition, and that M2 Raman peak still remains from screening effect despite high temperature of 370 K. Therefore, we suggest that the observed M2 Raman peak is caused by the remained CDW structure. Moreover, this can be a reason of upshifted T\textsubscript{IMT}.

9:36AM A07.00009: The role of non-local correlations in the valence band spectra in NiO*  BYUNGKYUN KANG (Presenter), SANGKOOK CHOI, PATRICK SEMON, ANDREY KUTEPOV, VAN DAM HUBERTUS, GABRIEL KOTLIAR, Brookhaven National Laboratory — As an archetypical strongly-correlated material, late-transition metal NiO has been attracted for number of decades. The interesting electronic properties of charge transfer insulator and low energy Zhang-Rice bound state are attributed to Ni 3d and O 2p hybridization along with strong Coulomb interactions of Ni 3d. However, the rich physics may still raise unclear physical properties in NiO. One example is the second peak from the Fermi level in X-ray photoemission spectra which is enhanced below Neel temperature. By Using recently developed LQSGW + DMFT along with charge self-consistent LDA+DMFT, we will discuss the role of non-local correlation in the formation of the second peak and their temperature dependence.

9:48AM A07.00010: Magnetotransport in $H||c$ of La$_{1.875}$Ba$_{0.125}$CuO$_4$ near the charge order (CO) transition* LILY STANLEY (Presenter), PAUL G. BAITY, DRAGANA POPOVIC, Dept. of Phys. Natl. High Magnetic Field Lab., JOHN TRANQUADA, GENDA GU, Brookhaven Natl Lab — The nature of the dynamics of charge-ordered states in underdoped cuprates has been of great recent interest. Our work on La$_{2-x}$Ba$_x$CuO$_4$ with $x=0.125$ (LBCO) in zero magnetic field ($H$) reveals the presence of dynamic behavior within the charge-ordered state in the form of avalanches, similar to that in La$_{1.48}$Nd$_{0.4}$Sr$_{0.12}$CuO$_4$ (LNSCO). In LNSCO, avalanches were also observed to be asymmetrically driven by $H$ around the concurrent CO and structural transition with an additional onset of negative magnetoresistance (MR), which was attributed to the emergence of CO [1]. In La$_{1.7}$Eu$_{0.2}$Sr$_{0.12}$CuO$_4$ (LESCO) negative MR, albeit with no avalanches, was observed at the onset of CO but not at the higher temperatures around the structural transition [1]. The presence of avalanches and overlap of the CO and structural transitions in LBCO present the opportunity to clarify the role of the LNSCO Nd$^{3+}$ moments and the origin of the negative MR. Therefore, we report the $H = 0$ findings and the study of $H||c$ magneto resistance of LBCO near the CO transition.

10:00AM A07.00011: Precision measurement of charge-order formation by coherent Resonant X-ray Scattering LI YUE (Presenter), School of Physics, Peking University, JIARUI LI, Department of Physics, Massachusetts Institute of Technology, CLAUDIO MAZZOLI, Brookhaven National Lab, RICCARDO COMIN, Department of Physics, Massachusetts Institute of Technology, YUAN LI, School of Physics, Peking University — We report experimental research on the spontaneous formation of charge order and its relationship with disorder pinning effects. By studying a prototypical charge-density-wave material, ZrTe$_3$, with high-precision resonant elastic X-ray scattering (REXS), we observe a clear temperature evolution of the ordering wave vector, along with a drastic increase in the correlation length, upon the development of the long-range charge order below $T \approx 63$ K. These results are attributed to band-structure changes near the Fermi level due to the opening of the charge-ordering gap. By further utilizing a coherent X-ray beam, we are able to reveal unprecedented details in the mesoscopic dynamics of the charge order by X-ray photon correlation spectroscopy (XPCS), the results of which can be most naturally explained by the combined effects of thermal activation and disorder pinning. Our results provide empirical insights for understanding charge-order phenomena in correlated-electron systems such as the high-Tc cuprates.

10:12AM A07.00012: Charge Density Waves in a Doped Kondo Chain* YIXUAN HUANG (Presenter), University of Houston, DONNA SHENG, California State University, Northridge, CHIN-SEN TING, University of Houston — We show that charge density waves (CDWs) exist in the ground state of the one-dimensional Kondo lattice model at the filling of $n=0.75$ with a finite charge gap, while most of the doped phase is metallic. Based on our numerical results using the density matrix renormalization group method, we separate the CDW phase from the paramagnetic phase previously known as the Tomonaga-Luttinger liquid. The emergence of this phase serves as an example of CDW induced without repulsive interaction between electrons, and enriches the phase diagram of the 1D Kondo Lattice model.

Femtosecond electron imaging of a transformation between different symmetry broken ground states of 2D charge density wave near a nonthermal critical point

FARAN ZHOU (Presenter), JOSEPH WILLIAMS, Michigan State Univ, CHRISTOS MALLIAKAS, MERCOURI KANATZIDIS, Northwestern University, CHONG-YU RUAN, Michigan State Univ — We study the atomic scale dynamics of a CDW phase transition from a stripe phase into a new topological phase in rare-earth tritelluride compound. Such a new state is a hidden ground state not allowed thermodynamically, but is driven to form after an interaction quench by an intense infrared laser pulse. With femtosecond electron-based scattering, we capture the entire course of this transformation and show an emergent self-organization that defines a nonthermal critical point substantially different from a thermal critical point. The dynamical stabilization after the quench is achieved through the inherent underpinning symmetry that allows the development of the long-range coherence simultaneously for different broken symmetry states at far from equilibrium.

*We thank the funding support by NSF MRI facility grant: DMR1625181 and DOE grant: DE-FG02-06ER46309

Charge Density Wave Order in the Half-Filled Three Dimensional Holstein Model

BENJAMIN COHEN-STEAD (Presenter), University of California, Davis, CHUANG CHEN, ZI YANG MENG, Institute of Physics, Chinese Academy of Science, RICHARD THEODORE SCALETTAR, University of California, Davis — The Holstein Model (HM) is a tight-binding Hamiltonian describing electrons coupled to local phonon degrees of freedom. The electron phonon interaction gives rise to charge density wave (CDW) order at half-filling and superconducting (SC) order away from half-filling. The HM has been a recent focus for Determinant Quantum Monte Carlo (DQMC) simulation studies. However, the cubic scaling with system size, and long autocorrelation times, have restricted simulations to one and two dimensional systems. Here we demonstrate that the recent development of Self-Learning Monte Carlo (SLMC)[1,2] has made it possible to significantly reduce autocorrelation times, thereby allowing for simulation studies of the Holstein model on a fully three-dimensional cubic lattice at half-filling. SLMC is able to control autocorrelation times by learning an effective model that is used to propose more effective monte carlo moves, while still satisfying detailed-balance. SLMC allows us to not only access larger system sizes, but also slower phonon modes where the phonon frequency \( \omega \) is less than the inter-site hopping parameter \( t \).

Session A08 DCMP DMP: Low Carrier Density Superconductors

Electron-phonon coupling and superconductivity in SrTiO3

DIRK VAN DER MAREL (Presenter), University of Geneva — Doped STO is a superconductor with a maximal Tc rising from zero at zero doping to 400 mK around 0.005 electrons per Ti atom, and dropping to zero above 0.02 electrons per Ti atom. Substituting the heavier O-18 isotope for the natural O-16 in the samples results in a strong increase of Tc with an isotope coefficient some 20 times larger and of opposite sign as predicted by the BCS model. This effect was theoretically anticipated based on a model where the superconducting pairing in STO is mediated by the optical phonons which are associated to the para- to ferro-electric phase transition in in the undoped insulating compound, the so-called TO1 mode. Here we demonstrate from experimental data that the spectral weight of the TO1 mode is anomalously large, providing a strong indication for the so-called “charged phonon” effect predicted by MJ Rice. The experimentally observed spectral weight of mode TO1 is used to determine the nature and strength of its’ coupling to the conduction electrons, and implications of these numbers are presented for the corresponding channel of superconducting pairing.

8:12AM A08.00002: Low density superconductivity of SrTiO₃ bounded by the adiabatic condition

HYEOK YOON (Presenter), ADRIAN G SWARTZ, HISASHI INOUE, Geballe Laboratory for Advanced Materials, Department of Applied Physics, Stanford University, YASUYUKI HIKITA, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, HAROLD HWANG, Geballe Laboratory for Advanced Materials, Department of Applied Physics, Stanford University — The dilute oxide semiconductor SrTiO₃ exhibits superconductivity over a wide range of carrier densities (10¹⁷⁻¹⁰²¹ cm⁻³) lying outside of the Bardeen-Cooper-Schrieffer (BCS) and Migdal-Eliashberg theories for conventional superconductors. Across this range, the Fermi level traverses a variety of vibrational modes in the system and therefore spans the widest range of adiabatic parameter (ω/EF) of any superconductor, making it an ideal choice to study the physics of dilute superconductivity. Recently, we have developed an approach using atomically controlled oxide heterostructures to spectroscopically probe the electronic structure of SrTiO₃ using planar tunneling junctions [1, 2]. Using this technique, we have examined the superconductivity of bulk doped SrTiO₃ across the superconducting dome and found that superconducting state is bounded by the adiabatic condition, maintaining the thermodynamic relationship of BCS weak-coupling theory (2Δ/k_B T_c = 3.53).

8:24AM A08.00003: Plasmon-Polaron Superconductivity in Strontium Titanate

ALEXANDER EDELMAN (Presenter), PETER B LITTLEWOOD, University of Chicago — Strontium titanate (STO) is a bulk insulator that becomes a semiconducting superconductor at remarkably low carrier densities - below 10¹⁷ cm⁻³ - with a characteristic superconducting dome as a function of doping which peaks at T_c~300mK, all in very close proximity to a ferroelectric quantum critical point. Photoemission[1] and tunneling[2] have revealed multiple phonon replica bands, and the challenge to theory is to reconcile these observations of a very strongly coupled normal state with the apparently conventional weakly-coupled BCS superconducting state[3]. We propose a simple model that extends an Engelsberg-Schrieffer theory of electrons coupled to a single longitudinal optic (LO) phonon mode to self-consistently include the effects of electronic interactions. For the carrier densities of interest, we find that the plasmon hybridizes strongly with LO mode with one of the resulting coupled modes inheriting the low energy scales of the softening ferroelectric mode. We calculate spectral signatures of our model and the superconducting phase diagram, including vertex corrections crucial in this strongly-coupled regime, and compare to experiment.

8:36AM A08.00004: Gate voltage tunable superconductivity in low-carrier-density SrTiO₃

TERENCE BRETZ-SULLIVAN (Presenter), J SAMUEL JIANG, Argonne National Laboratory, ALEXEY SUSLOV, National High Magnetic Field Laboratory, JOHN E. PEARSON, ALEX MARTINSON, ANAND BHATTACHARYA, Argonne National Laboratory — We demonstrate gate voltage control of the critical current of a surface channel of the low-carrier-density, bulk-superconducting oxide system SrTiO₃. The devices are in a conventional field effect transistor geometry with a solid gate dielectric and superconducting leads. We can modulate the critical current by a factor of 2-3 in our devices as a function of gate voltage. Additionally, we study the magnetic field dependence of the differential resistance of these devices to understand the role the superconducting leads play on the channel properties. A device such as this could serve as a new qubit architecture when integrated into a microwave resonator circuit.

We acknowledge support of the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES), Materials Sciences and Engineering Division. The use of facilities at the Center for Nanoscale Materials was supported by the U.S. DOE, BES under Contract No. DE-AC02-06CH11357. 8:48AM A08.00005: Enhancement of the superconducting $T_c$ upon isotopic substitution in Strontium Titanate

Willem Schau (Presenter), Dorota Pulmanova, Gernot Scheerer, Enrico Giannini, Dirk Van Der Marel, University of Geneva — SrTiO$_3$, a quantum paraelectric, becomes a metal with a superconducting instability after removal of an extremely small number of oxygen atoms. It turns into a ferroelectric upon isotopic $^{18}$O substitution exceeding a quantum critical point (QCP) located at a substitution level of around 33 at% $^{18}$O. The exceptionally dilute superconducting and the ferroelectric order may be accidental neighbors or intimately connected, as in the picture of quantum critical ferroelectricity.

We developed an $^{18}$O substitution process to control substitution levels in SrTi(O$_{1-x}$O$_x$)$_3$ beyond the critical point. Dielectric measurements evidence a ferroelectric order below the Curie temperature. In metallic SrTi(O$_{1-x}$O$_x$)$_3$-$\delta$ with $^{18}$O-substitution levels above the QCP, we find that the superconducting critical temperature seen in resistivity measurements is enhanced by more than a factor two and reaches values of up to 700 mK. This enhancement strongly supports the role played by the vicinity to the ferroelectric order in the precocious emergence of superconductivity, restricting possible theoretical scenarios for pairing.

9:00AM A08.00006: Quantum ferroelectric instabilities in superconducting SrTiO$_3$*

José Rafael Arce-Gamboa, Gian G. Guzmán-Verrí (Presenter), Materials Research Science and Engineering Center (CICIMA), University of Costa Rica — We examine the effects of strain and cation substitution on the superconducting (SC) phase of polar semiconductors near a ferroelectric (FE) quantum phase transition with a model that combines a strong coupling theory of superconductors with a standard microscopic framework for displacive polar modes coupled to strain. Our calculations reveal that the SC transition temperature $T_c$ is enhanced by proximity to the FE instability from the disordered side, while it is generally suppressed in the ordered phase due to its increase in dielectric stiffness and a reduction of critical fluctuations from dipolar induced anisotropies. The condensation of the pairing phonon excitations generates a kink in $T_c$ at a charge density that is generally lower than that of the quantum critical point (QCP) and where both SC and FE orders set-in. We apply our model to SrTiO$_3$ and find that the anti-adiabatic limit places the kink nearly at its QCP. As the QCP is pushed to higher charge densities, the dome narrows and sharpens. We compare to recent experiments and theory.

9:12AM A08.00007: Pairbreaking Induced by Magnetic Impurity Doping Shrinks the Giant Magnetoresistance Peak of the Cooper Pair Insulator*

James Valles (Presenter), Xue Zhang, James C Joy, Chunshu Wu, Physics, Brown University, Jimmy Xu, Physics and School of Engineering, Brown University — Films near the critical point of a boson fluctuation dominated superconductor to insulator transition exhibit a giant magnetoresistance peak that grows exponentially with decreasing temperature. Experiments indicate that Cooper pair transport dominates the low magnetic field side of the MR peak so that the resistance rise indicates increasing Cooper pair localization. To probe whether the peak arises from magnetic field induced orbital dephasing of the Cooper pair states or Cooper pair breaking, our group investigated its response to a pure pairbreaking perturbation: magnetic impurity doping. We quench deposited a-Bi films onto nanoporous anodized aluminum oxide substrates and tuned their thickness to produce an insulating state of Cooper pairs. Gd impurity doping 1) reduces the size of the MR peak while pushing it to lower magnetic fields and 2) causes changes in the zero magnetic field resistance that are much smaller than the MR peak. How this behavior suggests that orbital dephasing effects are primarily responsible for the MR peak will be discussed.

**We are grateful for the support of NSF Grant No. DMR-1307290.
Reports of superconductivity in systems with very low carrier densities are becoming increasingly prevalent. Examples include strontium titanate, bismuth, and twisted bilayer graphene. Here, we investigate this general issue by studying superconductivity in the Bardeen-Pines model of an electron gas interacting with an optical phonon with frequency $\omega_L$, as function of carrier concentration. The pairing interaction in the model is a combination of screened Coulomb repulsion and an attraction due to phonons, dressed by electron polarizability. We first focus on the attractive part of the interaction and argue that processes away from the Fermi surface cannot be neglected at low electron density. Contrary to expectations from BCS theory, we obtain a large increase of the critical temperature $T_c$ as the system enters the dilute region, with a power-law dependence of $T_c$ on $\omega_L$. Next, we explore how the superconducting instability and the frequency dependence of the pairing function get modified once we add the Coulomb repulsion.

*This work is supported by the Department of Energy through the University of Minnesota Center for Quantum Materials, under DE-SC-0016371.

---

We present results for the onset pairing instability temperature for superconductivity mediated by an Einstein phonon in a 2D electron gas with a parabolic dispersion, in the regime of low carrier density. We go beyond the leading order in the electron-phonon coupling and include contributions to the pairing kernel from fermionic self-energy and from Kohn-Luttinger processes. We then compute the phase stiffness and obtain the actual critical temperature $T_c$. We analyze thermodynamic properties of our system, such as the specific heat jump across $T_c$.

*This work was supported by the U.S. Department of Energy through the University of Minnesota Center for Quantum Materials, under award DE-SC-0016371.

---

We investigate the superconductivity of compounds with a small carrier density, such as SrTiO3, bismuth and YPtBi. In these materials, the pairing instability is often described as a consequence of charge fluctuations either due to longitudinal phonons or through the dynamic screening of the Coulomb repulsion. Since the Fermi energy is small, the influence of interband transitions cannot be neglected in the the dynamic pairing potential. We will discuss how this alters the superconducting critical temperature in the various channels.

**10:12AM A08.00012: A sign of anticorrelation between the orbital related order and the superconductivity in LiTi$_2$O$_{4.5}$ system**

WEI HU (Presenter), Chinese Academy of Sciences, Institute of Physics — Previously studies show that for the Li$_{1+x}$Ti$_{2-x}$O$_{4.5}$(x<1/3) samples grown below a certain oxygen pressure, $T_{c0}$ remains the same whereas the orbital related order become weaker as the oxygen pressure increasing. It seems that the superconductivity of those samples isn't obviously related to the orbital related order. However, it is recently founded that, for those samples, there is a small linear region exists in temperature dependent resistance curve (R-T curve) above the superconducting state, and the temperature that the R-T curve begin to deviate from this linear region at the low temperature side enhances with the increase of the oxygen pressure. The suppressive effect of current on superconductivity shows that this temperature is the beginning of the superconductivity. Therefore, it indicates that the superconductivity is actually strengthened as the oxygen pressure increasing, contrary to the effect of the oxygen pressure on the orbital related order. Moreover, a new superconducting film similar to LiTi$_2$O$_{4.5}$ has been synthesized by PLD, which shows more directly that the superconductivity can be weakened by the orbital order.

**10:24AM A08.00013: Unconventional full-gap superconductivity in Kondo lattice with semi-metallic conduction bands**

SHOMA IIMURA (Presenter), Saitama University, MOTOAKI HIRAYAMA, RIKEN, SHINTARO HOSHINO, Saitama University — Non-local and anisotropic Cooper pairings are favored in heavy-electron materials with nearly localized f-electrons. On the other hand, the full-gap nature of the superconducting states in CeCu2Si2 and UBe13 have been revealed by the specific heat measurements in a rotating magnetic-field. Therefore, it is desirable to propose a new mechanism of superconductivity that is specific to heavy-electron materials. Here we theoretically study the Kondo lattice with semi-metallic conduction bands, and propose the mechanism for full-gap superconductivity in f-electron systems. Based on the mean-field approach, we reveal that the superposition between electron conduction band and hole conduction band is realized through the formation of the Kondo-singlet states. The resultant ground state spontaneously breaks the gauge symmetry to make the system superconducting. This superconducting state is characterized by the composite pairing amplitude, which has been proposed in the context of two-channel Kondo lattice. We have demonstrated here that the semi-metallic conduction bands with electron and hole Fermi surfaces are closely related to the composite pairing.

**10:36AM A08.00014: Dynamical effects on BCS-BEC crossover in the Holstein model**

TAE-HO PARK (Presenter), HANYONG CHOI, Sungkyunkwan University — We present a study of the half-filled Holstein model with superconducting order employing the dynamical mean-field theory in combination with the numerical renormalization group. Here, we investigate the dynamical effects on the crossover from the BCS to Bose-Einstein condensation (BEC) regimes as the on-site electron-phonon coupling $g$ is varied for both adiabatic ($t/\omega_0 >>1$) and antiadiabatic ($t/\omega_0 <1$) phonons, where $t$ is the hopping amplitude and $\omega_0$ is the phonon frequency. It turns out that the maximum superconducting transition temperature $T_c$ universally coincides with the critical electron-phonon coupling $g_c$ where the bipolaron instability takes place in the normal state. However, in the case of the adiabatic phonon, the pairing amplitude $\Delta_P$ is suppressed with increasing the electron-phonon coupling in the BEC regime, while it increases with increasing $g$ for the antiadiabatic phonon. Further, the calculated superfluid stiffness $D_f$ for the adiabatic phonon decreases rapidly as increasing $g$ together with the suppression of the coherence peak in the BEC regime. We also calculated the spectral intensities to identify BCS and BEC regimes and those results are comparable to the angle resolved photoemission spectroscopy (ARPES) experiment.

**10:48AM A08.00015: Intermolecular Coupling and Superconductivity in Chevrel Phase Compounds**

JIA CHEN (Presenter), ANDREW MILLIS, DAVID REICHMAN, Columbia University — To understand superconductivity in Chevrel phase compounds and guide the search for interesting properties in materials created with Chevrel phase molecules as building blocks, we use ab-initio methods to study the properties of single Mo6X8 molecules with X=S, Se, Te as well as the bulk solid PbMo6S8. In bulk PbMo6S8, the different energy scales from strong to weak are: the band kinetic energy, the intra-molecular Coulomb interaction, the on-molecule Jahn-Teller energy and the Hund’s exchange coupling. The metallic state is stable with respect to Mott and polaronic insulating states. The bulk compound is characterized by a strong electron-phonon interaction with the largest coupling involving phonon modes with energies about 12 meV and with a strong inter-molecule (Peierls) character. A two-band Eliashberg equation analysis shows that the superconductivity has different gaps on the two Fermi surface sheets. A Bergman-Rainer analysis reveals that the Peierls modes provide the most important contribution to the superconductivity. This work illustrates the importance of inter-molecular coupling for collective phenomena in molecular solids.

8:00AM A09.00001: Multiple solutions for superconductivity at T=0 in a quantum-critical metal*  
ANDREY CHUBUKOV (Presenter), University of Minnesota, ARTEM G ABANOV, Physics, Texas A&M — We discuss the interplay between non-Fermi liquid behaviour and superconductivity at a quantum-critical point (QCP) in a metal. It is widely thought that the tendency towards superconductivity and towards non-Fermi liquid behaviour compete with each other, and if the pairing interaction is reduced below a certain threshold, the system displays a naked non-Fermi liquid QC behaviour. We show that at T=0 there is indeed a threshold below which the system remains in the normal state. We argue that above the threshold the system develops a discrete, but infinite set of solutions for the pairing gap. In particular, for ant value of the pairing interaction above the threshold there exists a solution of the linearized gap equation. This is very different from a conventional superconductivity, when the solution of the linearized gap equation exists only at a critical strength of the pairing interaction. We present some exact results set the results of the QC models with frequency-dependent effective interaction and discuss the consequences of the existence of multiple solutions for superconductivity at a QCP.

8:12AM A09.00002: The special role of the first Matsubara frequency for superconductivity near a quantum critical point: the non linear gap equation below Tc and spectral properties in real frequency axis.*  
YI-MING WU (Presenter), University of Minnesota, ARTEM G ABANOV, Physics, Texas A&M U, YUXUAN WANG, Physics, University of Florida, ANDREY CHUBUKOV, University of Minnesota — We consider a model of itinerant fermions near a quantum critical point, where the effective interaction is mediated by order parameter fluctuations. This interaction makes fermions ncoherent and, at the same time, gives rise to attraction in at least one pairing channel. These two tendencies compete with each other. We argue that the situation is more tricky because the self-energy without thermal fluctuation piece, which one needs for the calculation of $T_c$, vanishes at the first two Matsubara frequencies($\pm \pi T$), while the pairing interacion between fermions with these two frequencies remains strong. We investigate how this affects the system behavior below $T_c$, in particular the density of states and the spectral function. We argue that there is a crossover at some $T_{cross} < T_c$ between conventional behavior at low T, when frequency variation occurs at a scale of the gap Delta, and a new behavior at higher T, when frequency variation occurs at a scale set by T.

We argue that our theory naturally explains the crossover from "gap closing" to "gap filling", observed in cuprate and other superconductors.

*We thank D. Dessau, S. Raghu, G. Torroba, and A. Yazdani for useful discussions. This work by Y. Wu and AVC was supported by the NSF DMR-1523036.

8:24AM A09.00003: Strange metal crossover in the doped holographic superconductor*  
GASTON GIORDANO, NICOLAS GRANDI, ADRIAN LUGO, Departamento de Física, Universidad Nacional de la Plata, RODRIGO SOTO GARRIDO (Presenter), Facultad de Ingeniería y Tecnología, Universidad San Sebastián — In this talk, we study the "normal" phase of a holographic superconductor. The specific model used was originally introduced by Kiritsis and Li (JHEP01(2016)147) to incorporate the different orders phases similar to the ones observed in High Temperature Superconductors. These phases include the normal phase, the SC phase, the antiferromagnetic phase and a striped phase as a function of both, temperature and doping. Within this model we study the fermionic spectral functions in the normal phase at zero and finite temperatures. Using analytic and numerical methods, we found a crossover in the normal phase from a strange metal with short lived excitations at small doping, into a Fermi liquid with well defined quasiparticles at large doping. The critical doping at which excitations becomes long lived increases with temperature. The emerging phase diagram is qualitatively similar to that of High Temperature Superconductors.

The results of this work have been published in JHEP10(2018)068

Non-Fermi liquid scattering against emergent Bose liquid: manifestations in the kink and other exotic quasiparticle behaviors in the normal-state cuprate superconductors

SHENGTAO JIANG (Presenter), LONG ZOU, WEI KU, Tsung-Dao Lee Institute & School of Physics and Astronomy, Shanghai Jiao Tong University — The normal state of cuprate superconductors exhibits many exotic behaviors qualitatively different from the Fermi liquid, the foundation of condensed matter physics. Here we demonstrate that non-Fermi liquid behaviors emerge naturally from scattering against an emergent Bose liquid. Particularly, we find a finite zero-energy scattering rate at low-temperature limit that grows linearly with respect to temperature, against clean fermions' generic non-dissipative characteristics. Surprisingly, three other seemingly unrelated experimental observations are also produced, including the well-studied "kink" in the quasi-particle dispersion, as well as the puzzling correspondences between the normal and superconducting state. Our findings provide a general route for fermionic systems to generate non-Fermi liquid behavior, and suggest that by room temperature large number of the doped holes in the cuprates have already formed an emergent Bose liquid of tightly bound pairs, whose low-temperature condensation gives unconventional superconductivity.

Renormalization group study of superconductivity in Nickelates

MICHAEL KLETT (Presenter), TILMAN SCHWEMMER, XIANXIN WU, DAVID RIEGLER, RONNY THOMALE, Institute for Theoretical Physics, University of Wuerzburg — Since the discovery of high Tc superconductivity in the cuprates by Bednorz and Mueller, materials bearing similarities to copper oxide compounds have emerged as a contemporary research topic of high interest. Although LaNiO3/LaAlO3 shares many similarities with the cuprates, it exhibits no superconducting phase down to lowest temperatures.

In this talk we sketch a simple two-band model of a d7 Nickelate-compound and argue why, based on renormalization group calculations competing superconducting ordering propensities make these systems belong to the class of low-Tc materials.

Pairing Mechanism in Hunds Metal Superconductors and the Universality of the Superconducting Gap to Critical Temperature Ratio

TSUNG-HAN LEE (Presenter), Physics and Astronomy Department, Rutgers University, ANDREY CHUBUKOV, School of Physics and Astronomy, University of Minnesota, HU MIAO, Brookhaven National Laboratory, GABRIEL KOTLIAR, Physics and Astronomy Department, Rutgers University — We propose a simple spin-fluctuation Eliashberg model that contains the physical ingredients of a Hund's metal, the local spin-fluctuations with super-linear correlators, (Ω0/|Ω|)γ with γ>1, interacting with electrons. Our model yields a universal superconducting gap to critical temperature ratio 2Δmax/Tc≈7.2 that coincides with the experimental observation in a series of iron-based superconductors. We also discuss the implications of our model in the other classes of superconductors, e.g., cuprates and heavy fermion superconductors.

A Simple Model for Quantum Tunneling of Cooper Pairs

EDGAR PATINO (Presenter), School of Physical Sciences and Nanotechnology, Yachay Tech University, DANIEL LOZANO, University of the Andes, DENIS CHEVALLIER, University of Basel — We propose a simple phenomenological model for quantum tunneling of Cooper pairs based on their boson like nature. Thus applies to the low energy regime i.e. in the absence of quasiparticle excitations. Around zero bias voltage our model reveals a rapid increase in tunneling current which rapidly saturates. This manifests as a zero bias conductance peak that strongly depends on the superconductors transition temperature. This low energy tunneling of Cooper pairs could serve as an alternative explanation for a number of tunneling experiments where zero bias conductance peak has been observed.

*This work was funded by Vicerrectoria de Investigaciones of Universidad de los Andes and School of Physical Sciences and Nanotechnology of Yachay Tech University.
9:24AM A09.00008: Gap anisotropy in nematic quantum critical superconductors* AVRAHAM KLEIN (Presenter), YI-MING WU, ANDREY CHUBUKOV, University of Minnesota — When pairing is driven by nematic quantum fluctuations, it results in a unique form of superconductivity. Nematic fluctuations, while anisotropic, couple to the entire Fermi surface, in contrast to, e.g. spin fluctuations that typically couple to so-called ‘hotspots’. The result is an entire series of possible anisotropic pairing states, with closely spaced condensation temperatures, all with s-wave symmetry. The existence of these states drives a strong temperature evolution of the anisotropy of the superconducting gap. This evolution is a direct consequence of critical fluctuations, and provides a clear signature of quantum criticality inside the superconducting state.

*This work was supported by NSF DMR-1523036.

9:36AM A09.00009: Collective modes in 2 dimensional fermionic superfluid near Pomeranchuk instability WEIHAN HSIAO (Presenter), University of Chicago — In this work we investigate order parameter collective modes in 2 dimensional fermionic superfluids in finite angular momentum pairing channels. We discover subgap bosonic excitations with finite mass analogous to order parameter collective modes in 3 dimensional superfluid 3He. We further investigate the effect of fermion vacuum on these modes and it is shown that some of these modes in the spectrum soften as the underlying Fermi liquid approaches Pomeranchuk instability, or the nematic critical point when considering a p-wave chiral superfluid.

9:48AM A09.00010: Fragile superconductivity in the presence of weakly disordered charge density waves YUE YU (Presenter), STEVEN KIVELSON, Stanford University — When superconducting (SC) and charge-density wave (CDW) orders compete, novel low temperature behaviors can result. From an analysis of the Landau-Ginzburg-Wilson theory of competing orders, we demonstrate the generic occurrence of a “fragile” SC phase at low temperatures and high fields in the presence of weak disorder. Here, the SC order is largely concentrated in the vicinity of dilute dislocations in the CDW order, leading to transition temperatures and critical currents that are parametrically smaller than those characterizing the zero field SC phase. This may provide the outline of an explanation of the recently discovered “resilient” superconducting phase at high fields in underdoped YBa2Cu3O6+δ.

10:00AM A09.00011: Study of the superconducting $T_c$ dome in the phase diagram of the two-dimensional Holstein model YAN WANG (Presenter), Departement de Physique, Universite de Sherbrooke, PHILLIP DEE, KEN NAKATSUKASA, STEVEN JOHNSTON, Department of Physics and Astronomy, University of Tennessee — $T_c$ dome, i.e., the nonmonotonic superconducting $T_c$ dependence as a function of parameters such as doping or pressure, is ubiquitous in the phase diagrams of unconventional superconductors, where the pairing interaction has a magnetic and electronic origin. By contrast, $T_c$ dome is rarely seen in conventional electron-phonon superconductors. We report the $T_c$ dome in the phase diagram of the two-dimensional Holstein model, where electrons and phonons interact through a local coupling. By solving the model using strong coupling Migdal-Eliashberg formalism and self-consistently renormalizing both the electrons and phonons, a $T_c$ dome as function of filling $n$ arises in the phase diagram, alongside a charge-density-wave phase around the half-filling. The dome is tied to the competition of three renormalized quantities as the filling increases: the increasing coupling constant $\lambda$, the decreasing $\omega_{\text{log}}$, and the nonmonotonically varying density of states at the Fermi-level. Interestingly, we also find the effective electron-electron interaction becomes nonlocal in $\mathbf{r}$-space and even repulsive at neighboring lattice sites. Our discovery could shed light on the high $T_c$ of the strongly electron-phonon coupled system such as the dense hydrogen-rich compounds and the monolayer FeSe on SrTiO3.

10:12AM A09.00012: Polaron, bipolaron and few-polaron states in the Peierls model of electron-phonon coupling* JOHN SOUS (Presenter), ALBERTO NOCERA, MONA INESA BERCIU, University of British Columbia — We consider the one-dimensional Peierls model of electron-phonon coupling describing the modulation of the electron hopping by phonons. We review recent results on single polarons and bipolarons, and extend our discussion to few-polaron states in the regime of competing phononic and electronic excitations. Single polarons experience a transition from weak coupling to strong coupling, while the Peierls coupling stabilizes strongly bound yet very light bipolarons. Few polarons, however, experience higher order interactions that result in the formation of multipolaron bound states. In the anti-adiabatic limit of large phonon frequencies, we find that bipolarons are stable against phase separation. We discuss the relevance of these ideas to superconductivity in higher dimensions.

*NSERC
Emergence of a Macroscopic Phase in an Isolated Electron-Phonon Superconductor*

WATARU KOHNO (Presenter), TAKAFUMI KITA, Hokkaido University — Within the number-conserving formalism introduced by Ambegaokar, we constructed a variational wave function of electron-phonon superconductors. The many-body correlations originated from electron-phonon coupling are incorporated in our variational wave function. Moreover, this wave function gives rise to a superposition over the number of condensed particles and the Cooper-pair wave function with a macroscopic phase can be defined naturally. Therefore, we conclude dynamical exchanges of phonons induce a well-defined macroscopic phase with emergence of superconductivity in an electron-phonon superconductor.

*Wataru Kohno is a JSPS Research Fellow, and this work was supported in part by JSPS KAKENHI Grant Number 18J13241.

Generalization of Anderson’s Theorem for Disordered Superconductors*

JOHN DODARO (Presenter), STEVEN KIVELSON, Stanford University, CATHERINE KALLIN, McMaster University — We show that at the level of BCS mean-field theory, the superconducting Tc is always increased in the presence of disorder, regardless of order parameter symmetry, disorder strength, and spatial dimension. This result reflects the physics of rare events - formally analogous to the problem of Lifshitz tails in disordered semiconductors - and arises from considerations of spatially inhomogeneous solutions of the gap equation. We discuss the relevance of these effects for short coherence length superconductors and compare them with an exact treatment of disorder within dirty d-wave BCS theory to describe superfluid stiffness results on the overdoped cuprates.

Monday, March 4, 2019 8:00 AM - 10:36 AM

Session A10 DMP: Fe-based Superconductors I

8:00AM A10.00001: Orbital-selectivity in iron chalcogenide superconductors [Invited] MING YI (Presenter), Rice University — The electron correlation strength has a systematic spread across the material-base of iron-based superconductors. Near the most correlated end of the spectrum are the iron chalcogenides, where strong orbital-selective correlations are observed. In particular, the dxy orbital exhibits much stronger local behavior than the dxz and dyz orbitals, putting the material in close proximity to an orbital-selective Mott phase (OSMP). In this talk, I will first demonstrate the universality of orbital-selectivity amongst all iron chalcogenide superconductors including both Fe(Se,Te) and heavily electron-doped FeSe systems. For the second part of the talk, I will use the phase diagram of Fe(Se,Te) to illustrate that both Te-substitution and temperature increase act as effective pathways towards the OSMP. In the process, a dramatic increase of the dxy effective mass together with a redistribution of spectral weight on the Fermi surface strongly modify the low energy electronic states of this material family.

8:36AM A10.00002: A Neutron Total Scattering Study of the Nanoscale Structure of KxFe2−ySe2−zS

PANAGIOTIS MANGELIS, Institute of Electronic Structure and Laser, Foundation for Research and Technology—Hellas, HECHANG LEI, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, MARSHALL MCDONNELL, MIKHAIL FEYGENSON, Neutron Scattering Division, Oak Ridge National Laboratory, CEDOMIR PETROVIC, EMIL BOZIN, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, ALEXANDROS LAPPAS, Institute of Electronic Structure and Laser, Foundation for Research and Technology—Hellas, ROBERT KOCH (Presenter), Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — A Neutron Total Scattering Study of the Nanoscale Structure of KxFe2−ySe2−zS

Isovalent substitutions in alkali iron chalcogenides allow for selective tuning of electronic properties. For example, KxFe2−ySe2 is a superconductor (Tc = 32 K), while the sulfide analogue KxFe2−yS2 displays a spin glass semiconducting behavior. This change in behavior is accompanied by structural fluctuations both in the chalcogen and Fe sublattices. Motivated by such observations, the local atomic structure of the KxFe2−ySe2−zS compositional series was studied using neutron total scattering-based atomic pair distribution function (PDF) analysis at 5K. Aspects of the local structure are discussed in the context of electronic properties.

8:48AM A10.00003: Intertwined spin-orbit coupled orders in the iron-based superconductors  MORTEN HOLM
CHRISTENSEN (Presenter), University of Minnesota, JIAN KANG, National High Magnetic Field Laboratory, Florida State University, WILLIAM MEIER, ANDREAS KREYSSIG, Ames Laboratory & Department of Physics, Iowa State University, RAFAEL M FERNANDES, University of Minnesota — The phase diagram of the underdoped iron-based superconductors exhibits two electronically ordered phases, nematicity and stripe magnetism. Nematic order breaks the rotational symmetry of the lattice and can be seen as a vestigial phase of stripe magnetism. Here we discuss a similar phenomenon occurring for the tetragonal magnetic orders, the spin-vortex crystal and the charge-spin-density-wave phases. These vestigial phases break the glide-plane symmetry and render respectively the As/Se or Fe sites inequivalent. In materials with staggered FeAs/Se layers (e.g. 122), these have ordering vector \( Q = (0, 0, \pi) \) while in compounds with no staggering (e.g. 111) these are \( Q = 0 \) orders. We discuss how these vestigial phases couple to the lattice. Moreover, Kramers degeneracy is broken and Rashba- and Dresselhaus-like spin-orbit couplings are induced. Finally, we discuss the behavior under electromagnetic fields, including magneto-electric effects.

9:00AM A10.00004: Discovery of a strain-stabilized charge density wave in LiFeAs  CHI MING YIM (Presenter), CHRISTOPHER TRAINER, RAMA K P ALURU, University of St Andrews, SHUN CHI, WALTER N HARDY, RUIXING LIANG, DOUGLAS ANDREW BONN, Univ of British Columbia, PETER WAHL, University of St Andrews — In a number of high \( T_c \) superconductors, small orthorhombic distortions of the lattice structure result in surprisingly large symmetry breaking of the electronic states and macroscopic properties, an effect often referred to as nematicity. This nematicity has been studied extensively on materials with an orthorhombic crystal structure, where the lattice symmetry is already reduced from four-fold (\( C_4 \)) to two-fold (\( C_2 \)). To directly study the impact of symmetry breaking lattice distortions on the electronic states, we image at the atomic scale the influence of strain-tuned lattice distortions on the correlated electronic states in the iron-based superconductor LiFeAs, a material which in its ground state is tetragonal, with \( C_4 \) symmetry. Our experiments uncover a new strain-stabilized nematic phase that exhibits a unidirectional charge density wave (CDW) in LiFeAs, an electronic state which not only breaks rotational symmetry but also reduces translational symmetry. We follow the evolution of the superconducting gap from the unstrained material with \( C_4 \) symmetry through the new nematic phase with \( C_2 \) symmetry and CDW order to a state where superconductivity is completely suppressed.

9:12AM A10.00005: Evidence for multi-gap nodal superconductivity in FeS by penetration depth measurements.  SUJITH KUNNININYIL SUDHEESH (Presenter), Division of Physics and Applied Physics, School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore, TIANPING YING, State Key Laboratory of Surface Physics, Department of Physics and Laboratory of Advanced Materials, Fudan University, Shanghai, China, XIAOFANG LAI, School of Physics and Optoelectronic Engineering, Guangdong University of Technology, Guangdong, China, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory, SHIYAN LI, State Key Laboratory of Surface Physics, Department of Physics and Laboratory of Advanced Materials, Fudan University, Shanghai, China, EE MIN CHIA, Division of Physics and Applied Physics, School of Physical and Mathematical Sciences, Nanyang Technological University, Singapore — We report measurements of London penetration depth and magnetization on single crystals of FeS superconductor with a transition temperature of 4 K. From magnetization measurements, FeS was confirmed to be a type-II superconductor with \( H_{c1}(0) = 58 \pm 4 \) Oe, \( \lambda_{ab}(0) = 900 \pm 90 \) nm, and \( \xi(0) = 90 \pm 12 \) nm. The low temperature (\( T < 0.3T_c \)) behavior of penetration depth deviates from a conventional exponential predicted by BCS theory and fits well to a power law with an exponent \( n = 2.2 \pm 0.1 \) which suggests the presence of nodes in the system. The superfluid density was calculated and was found to fit best to a multi-gap s+d wave model with the d-wave gap having slightly larger weight (\( p = 0.6 \)). \( \Delta(0)/k_BT_c \) for the d-wave gap is higher than that of the BCS weak coupling model, implying superfluid density was calculated and was found to fit best to a multi-gap s+d wave model with the d-wave gap having a slightly larger weight (\( p = 0.6 \)). \( \Delta(0)/k_BT_c \) for the d-wave gap is higher than that of the BCS weak coupling model, implying superfluid density was calculated and was found to fit best to a multi-gap s+d wave model with the d-wave gap having a slightly larger weight (\( p = 0.6 \)). \( \Delta(0)/k_BT_c \) for the d-wave gap is higher than that of the BCS weak coupling model, implying superfluid density was calculated and was found to fit best to a multi-gap s+d wave model with the d-wave gap having a slightly larger weight (\( p = 0.6 \)).

9:24AM A10.00006: Influence of Spin-Orbit Coupling in the Iron-Based Superconductors  RYAN DAY (Presenter), GIORGIO LEVY, MATTEO MICHARDI, BEREND ZWARTSENBERG, MARTA ZONNO, SHUN CHI, Quantum Matter Institute, University of British Columbia, IVANA VOBORNIK, Elettra Synchrotron, WALTER HARDY, DOUGLAS BONN, ILYA ELFIMOV, ANDREA DAMASCHELLI, Quantum Matter Institute, University of British Columbia — In addition to the remarkable resilience of unconventional superconductivity, the iron-based superconductors (FeSCs) are characterized by a broad phenomenology across their phase diagram. This diversity has compounded the challenge of defining a minimal model for these complex materials. We explore the essential role of spin-orbit coupling (SOC) in the FeSCs via circularly-polarized spin- and angle-resolved photoemission spectroscopy (CPS-ARPES), a technique which provides direct access to both spin and orbital degrees of freedom [1]. Applying this technique to both LiFeAs and FeSe, we establish a strong momentum dependence of the spin-orbital entanglement near the Fermi surface imbedded by SOC. Influenced strongly by the details of the crystal field, the relevance of SOC to the states near the Fermi level, and consequently to superconductivity and magnetism is found to be strongly material-dependent. Furthermore, in the case of hole-like carriers in FeSe, SOC is observed to be of comparable strength to orbital order, allowing spin-orbit mixing to persist to the nematic phase.

9:36AM A10.00007: Infrared Spectroscopic Studies of the Phonon Dynamics in Iron-based Superconductors*  
XIANGGANG QIU (Presenter), RUN YANG, BING XU, ZIYANG QIU, Chinese Academy of Sciences, YAOMIN DAI, Nanjing University — The temperature dependent optical reflectivity has been measurement on iron-based superconductors of different families. The optical conductivity has been obtained by using the two-Drude components model. It has been found that the phonons show red- or blue-shift in different samples. Interestingly, the phonon conductivity exhibits a Fano lineshape, suggesting possible coupling between phonon and electrons. Based on the temperature evolution of the lineshape and peak shift, we discuss the possible role played by electron-phonon coupling and spin fluctuation in the occurrence of superconductivity in iron-based superconductors.

9:48AM A10.00008: Spin anisotropy in the stoichiometric iron-based superconductor CaKFe$_4$As$_4$*  
TAO XIE (Presenter), HUIQIAN LUO, SHILIANG LI, National Lab for superconductivity, Institute of Physics, Chinese Academy of Sciences, Beijing, China — In the stoichiometric iron pnictide superconductor CaKFe$_4$As$_4$, we have discovered triple spin resonance modes with strong L-modulation by unpolarized neutron scattering experiments. The two odd modes appear around 9.5 meV and 13 meV, and the even mode locates around 18.3 meV. [1] To study the spin anisotropy of the three modes, we performed polarized inelastic neutron scattering experiments on the same CaKFe$_4$As$_4$ sample. Here, I will present our recent results. These results will give better understanding on the spin-orbit coupling in iron-based superconductors, which can also enlighten us about the nature of magnetism and its relation with unconventional superconductivity.

*We thank the funding supports from MOST of China, NSFC and CAS.

10:00AM A10.00009: Study of CaK(Fe$_{1-x}A_x$)$_4$As$_4$ ($A$ = Mn and Cr) single crystals*  
MINGYU XU (Presenter), WILLIAM MEIER, LI XIANG, SERGEY BUDKO, PAUL CANFIELD, Iowa State University and Ames Laboratory — Stoichiometric CaKFe$_4$As$_4$ is a Fe-based superconductor which has a critical temperature at 35 K. Substituting Fe with Ni or Co suppresses superconductivity and stabilizes an unusual hedgehog spin-vortex crystal magnetic structure [1]. There is a range of concentrations where superconductivity and magnetism coexist [2,3,4]. Having in mind different effect of [Fe, Co] and [Mn, Cr] substitutions in BaFe$_2$As$_2$, we grew single crystals of CaK(Fe$_{1-x}A_x$)$_4$As$_4$ ($A$ = Cr and Mn) and characterized them by magnetic and transport measurements. Phase diagrams of CaK(Fe$_{1-x}A_x$)$_4$As$_4$ ($A$ = Fe, Co, Mn, Cr) will be compared and the observed trends will be discussed in the context of Fe-based superconductors.

*We thank A. Kreyssig for insightful discussions. This work is supported by the US DOE, Basic Energy Sciences, Materials Science and Engineering Division under contract No.DE-AC02-07CH11358. W.R.M. was supported by the Gordon and Betty Moore Foundation’s EPiQS Initiative through Grant No. GBMF4411. L. X. was supported, in part, by the W. M. Keck Foundation.

10:12AM A10.00010: The FFLO State in Unconventional Superconductors  
CHARLES AGOSTA (Presenter), RAJU GHIMIRE, CAMILLE E BALES, Clark University, MAKARIY A TANATAR, Ames Laboratory — Recent experiments suggest that inhomogeneous superconductivity (the FFLO state) exists in organic$^1$, pnictide$^2$, and heavy Fermion$^3$ superconductors. The FFLO state is a type of superconducting pair density wave, although unlike the proposed pair density wave in cuprates, the FFLO state is accompanied by a magnetized charge density wave (CDW) of the left over (un-condensed) quasiparticles. We will review the data from each of the families of superconductors above and present new data for the Ba$_4$K$_{1-x}$Fe$_2$As$_2$ family of pnictide superconductors via measurements of the rf penetration depth using a tunnel diode oscillator, down to 40 mK. We will also discuss early results of experiments to measure the q-vector of a CDW in organic conductors with x-rays. This CDW is known to compete with the superconducting state rather than coexist with the FFLO state referred to above. Additionally, this technique may be a way to measure the q-vector of the FFLO state directly. Understanding these competing and intertwined orders in unconventional superconductors will further our knowledge of quantum mechanical ground states in electronic materials.

Enhancement of $J_c$ at around $1/3B_\Phi$ in Iron-based Superconductors with Splayed Columnar Defects

TSUYOSHI TAMEGAI (Presenter), AYUMU TAKAHASHI, NOZOMU ITO, SUNSENG PYON, Department of Applied Physics, The University of Tokyo, ATSUSHI YOSHIDA, TADASHI KAMBARA, Nishina Center, RIKEN, SATORU OKAYASU, Japan Atomic Energy Agency, ATARU ICHINOSE, Electric Power Engineering Research Laboratory, Central Research Institute of Electric Power Industry — Columnar defects (CDs) are known to trap vortices very effectively, leading to a significant increase in the critical current density ($J_c$). In contrast to the case of parallel CDs along the c-axis, splaying the direction of columnar defects enhances $J_c$ even further due to the suppression of kink motions. In (Ba,K)Fe$_2$As$_2$ with splayed CDs introduced by irradiating 2.6 GeV U ions, we found a novel enhancement of $J_c$ at around $1/3B_\Phi$ ($B_\Phi$: matching field) for a range of splay angle of CDs. In the present study, we compare the enhancement of $J_c$ in (Ba,K)Fe$_2$As$_2$ with splayed CDs created by 2.6 GeV U ions with those created by 320 MeV Au ions. We find that the enhancement of $J_c$ always occurs at $\sim 1/3B_\Phi$, while the degree of enhancement and optimum splay angle depends on the morphology of splayed CDs. We also investigate the effect of the symmetry breaking of the two sets of splayed CDs, namely for the case where the average direction of two sets of CDs is different from the c-axis and another case where doses of two sets of splayed CDs are different.

Session A11 DMP DCOMP FIAP: Defects in Semiconductors -- 1D, 2D, and Layered Materials

8:00AM A11.00001: Nanoscale Conductivity Measurements of Biased Silicon Nanowires with Infrared Near-Field Optical Microscopy

CLAYTON CASPER (Presenter), EARL T RITCHIE, DAVID J HILL, TAYLOR S TEITSWORTH, Chemistry, University of North Carolina at Chapel Hill, SAMUEL BERWEGER, National Institute of Standards and Technology, JAMES F CAHOON, JOANNA M ATKIN, Chemistry, University of North Carolina at Chapel Hill — Vapor-liquid-solid (VLS) growth of Si nanowires (SiNWs) allows for precise control of dopant density and type. These encoded dopant superlattices have enabled microscopic diodes for a wide range of optoelectronic applications. However, performance of these diodes depends critically on the behavior of carriers at junctions, which is influenced by dopant activation, geometry, and defect states. Furthermore, junctions in SiNWs are abrupt (<100 nm), making it difficult to apply traditional characterization methods. Here we use mid-infrared scattering-scanning near-field optical microscopy (s-SNOM) to image the carrier distribution in axial p-i-n junction SiNWs in operando. The high spatial resolution (< 20 nm) allows us to directly measure the free-carrier concentration arising from not only the native doping, but also from band bending. Combined with finite element modeling, we can semi-quantitatively determine the local carrier concentration and mobility, and examine the effect of bias on junction lengths and space-charge regions. These measurements will demonstrate that s-SNOM can be used to study the I-V characteristics of SiNWs with unprecedented spatial resolution.

8:12AM A11.00002: Real space pseudopotential calculations for the Raman spectra of doped Si and C nanostructures

JOSHUA C NEITZEL (Presenter), JAMES CHELIKOWSKY, University of Texas at Austin — We use a real-space pseudopotential method implemented within density functional theory to calculate Raman spectra for doped Si and C nanostructures. We examine the role of dopant location, local structure, and quantum confinement on the Raman spectra. We contrast these nanoscale spectra with those of bulk crystals.

*Our work is supported by the U.S. Department of Energy under grant No. DE-FG02-06ER46286. Computational resources were provided by NERSC.
A comprehensive advanced solid-state NMR analysis reveals that approximately a third of carbon atoms reside in the partially saturated structures, the degree-4 nanotreads, with isolated double bonds retained in the recovered sample. Some enumerated degree-4 structures, like IV-12 and IV-18, have much smaller distances between the double bonds than that in normal materials due to the rigid sp³ backbone, which leads to very dispersive bands near the Fermi level and may make these threads feasible to be doped. We investigated such doping computationally, using jellium models, alkali intercalation, and nitrogen substitution on the carbon backbone in both pristine and partially fluorinated IV-12 and IV-18 threads. Under doping, the IV-12 thread collapses to fully saturated structures, probably due to the strongly overlapping of the double bonds. There is no clear evidence for charge transfer in the pristine IV-18 thread, but the partially fluorinated IV-18 thread can be doped; this system may constitute a new type of conductive polymer.

9:00AM A11.00006: Integrating quantum emitters in low-dimensional materials with nanocavities* [Invited] STEFAN STRAUF (Presenter), Stevens Institute of Technology — It was recently shown that low-dimensional materials such as 1D single-walled carbon nanotubes (SWCNTs) as well as 2D materials such as transition-metal dichalcogenides (TMDCs) and hexagonal boron nitride (hBN) can host 0D-confined quantum emitters. These quantum emitters hold great promise for future quantum technologies, particularly through covalent sidewall functionalization of SWCNTs resulting in quantum light emission at room temperature into telecom bands, through local strain-engineering in monolayer TMDCs providing spatial scalability, and via color centers in hBN that survive up to 800 K. Here we review our recent work integrating these quantum emitters into optical cavities. We will first focus on coupling to metallo-dielectric antennas and demonstrate near-unity light collection efficiency for SWCNTs [1,2] and hBN emitters. The second part of the talk focuses on reversible and deterministic coupling schemes of excitons with respect to nanoplasmonic gap-mode cavities in SWCNTs [3] and strain-induced excitons in TMDCs [4]. We will further discuss methods to increase the quantum emitter yield to near unity, ways to increase thermal stability for excitons in TMDCs, as well as discuss our latest work on indistinguishable single photon generation.

9:36AM A11.00007: Deterministic Quantum Emitter Formation in Hexagonal Boron Nitride via Controlled Edge Creation* JOSHUA ZIEGLER (Presenter), RACHAEL KLAISS, ANDREW BLAIKIE, DAVID MILLER, University of Oregon, VIVA HOROWITZ, Hamilton College, BENJAMIN J ALEMAN, University of Oregon — Quantum emitters (QEs) in 2D hexagonal boron nitride (hBN) are extremely bright, stable under harsh conditions, and have the potential for strong coupling to hybrid devices due to their 2D host crystal. However, due to the difficulty of precisely creating these QEs, this potential for coupling into hybrid devices has been difficult to utilize. Motivated by recent studies showing that QEs in hBN tend to form at edges, we use a focused ion beam (FIB) to mill patterns in hBN. We optically characterize these milled hBN sheets and find that optimal FIB parameters create single QEs with a nearly Poisson-limited yield of 35%, and a 94% chance of creating at least one QE. We use atomic force microscopy to understand why these parameters are optimal and find that single QE yield is highest with a smooth milling profile on smooth hBN. This technique dramatically broadens the usefulness and convenience of hBN QEs – enabling facile integration into optoelectronic devices to fully take advantage of the appealing hBN QEs.

*We would like to acknowledge the use of the University of Oregon’s Rapid Materials Prototyping facility, funded by the Murdock Charitable Trust, and funding from University of Oregon and the National Science Foundation (NSF) under grant No. DMR-1532225.

9:48AM A11.00008: Quantifying the Effects of Sample Treatments on Quantum Emitters in Hexagonal Boron Nitride* STANLEY BREITWEISER (Presenter), Quantum Engineering Laboratory, Department of Electrical and Systems Engineering, University of Pennsylvania, ANNEMARIE L EXARHOS, Department of Physics, Lafayette College, RAJ PATEL, JENNIFER SAOUAF, BENJAMIN PORAT, LEE BASSETT, Quantum Engineering Laboratory, Department of Electrical and Systems Engineering, University of Pennsylvania — Hexagonal boron nitride (hBN) has emerged as a leading two-dimensional van der Waals material for next-generation quantum technologies. In particular, recent studies have identified spin-dependent quantum emission from defect states within the bandgap of hBN, making it a promising platform for quantum information processing and sensing applications. These optical-frequency emitters are among the brightest known, but they display heterogeneous properties and are poorly understood at the microscopic level. Confounding this, samples have undergone a variety of treatments in reported experiments - the two most common treatments being low-energy (keV) electron-beam irradiation and high-temperature (850°C) annealing in inert gas - with only a qualitative understanding of their effects. Here we systematically and quantitatively study the effect of these treatments using an analytical model which relates pixel intensity distributions from large-area confocal photoluminescence images to the density and brightness distributions of emitter ensembles. The results inform future efforts to control the formation and stabilization of quantum emitters in hBN.

*This work was supported by the Army Research Office (W911NF-15-1-0589).
10:00AM A11.00009: Stark shifts observed in single-photon emitters in hexagonal boron nitride  

GICHAN GOH (Presenter), DAEBOK CHOI, Physics and Energy Systems Research, Ajou University, JIN-HUN KIM, DONG-GIL IM, YOON-HO KIM, Physics, Pohang University of Science and Technology, HOSUNG SEO, JIEUN LEE, Physics and Energy Systems Research, Ajou University — Atomic defects, such as diamond NV-centers and SiC divacancies, have been widely studied as single-photon emitters, which are key ingredients of quantum information technology. Recently, two-dimensional (2D) materials are also found to host atomic defects that generate single-photons. Of particular interest is hexagonal boron nitride (h-BN) which possess single-photon emitters operating at room temperature. In this talk, we show the Stark-shift induced energy control of single-photon emitters in h-BN. By fabricating van der Waals heterostructures of h-BN with graphene gates, we observe linear Stark shifts as large as 7 meV induced by an out-of-plane electric field. We propose possible defect structures with out-of-plane dipoles, which are supported by theoretical calculations. We will also present other types of Stark shifts which have quadratic components. These Stark shifts are measured not only at low temperatures around 10 K, but also at room temperature. Our results demonstrating the on-demand energy control of atomic defects in h-BN show the potential of 2D-based single photon emitters for quantum information applications.

TAO JIANG (Presenter), VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, University of Central Florida — By employing density functional theory (DFT) and time-dependent DFT (TDDFT), we study the electronic and optical properties of monolayers of pure (h-BN) and defect-laden hexagonal Boron Nitride dh-BN (with boron vacancy (VB), nitrogen vacancy (VN), boron substitution for nitrogen (BN), nitrogen substitution for boron (NB), carbon substitution for boron (CB) and carbon substitution for nitrogen (CN)). The DFT analysis traces the defect-induced changes to the orbital- and spin-projected density of states of h-BN and their implications for the optical properties of the system. The TDDFT results show that the long-range nature of the exchange-correlation kernel significantly affects the excitation energy, and hence the absorption and emission properties of the systems. We demonstrate that experimental data on the emission in dh-BN can be explained by the VN defects only. Namely, the conduction band-to-VN electron transitions give the dominant contribution to the photoluminescence spectrum, observed experimentally [1]. We discuss possible applications of the results in optoelectronic single-photon emitting devices.

*Work is supported in part by DOE grant DE-FG02-07ER46354

10:24AM A11.00011: Dielectric environment effects on charged defects in 2D materials  

DAN WANG (Presenter), RAVISHANKAR SUNDARARAMAN, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute — Two-dimensional (2D) materials are the subject of significant ongoing research for technological applications in electronics, optoelectronics and quantum computing. These applications critically depend on the properties of charged defects, which has necessitated the development of computational methods to evaluate energies of charged defects in 2D materials. Such methods overcome the energy divergence from the Coulomb interaction of a charged defect with its periodic images and the compensating background charges. However, these methods do not easily account for the effects of substrates on charged defect properties, which is vital for realistic treatment of 2D materials that cannot be free-standing for most applications. We present a general technique for predicting properties of charged defects in 2D materials with substrates, bringing together accurate prediction techniques for free-standing charged defects with continuum solvation theories. Application of this method to defects in molybdenum disulfide (MoS2) on various substrates reveals how charge transition levels of these defects evolve with environmental screening effects and will guide the design of defects for 2D devices.
10:36AM A11.00012: Electrically tunable quantum emitters in an ultrathin graphene - hexagonal boron nitride van der Waals heterostructure  
ALESSIO SCAVUZZO (Presenter), SHAI MANGEL, Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany, JI-HOON PARK, SANGHYUP LEE, DINH LOC DUONG, CIFAP, IBS, DOES, SSKU, Suwon 16419, Korea, CHRISTIAN STRELOW, ALF MEWS, Institute of Physical Chemistry, University of Hamburg, 20146 Hamburg, Germany, MARKO BURGHARD, KLAUS KERN, Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany — The recent discovery of solid-state single-photon emitters in two-dimensional host systems has unveiled a huge potential for quantum information processing and integrated nanophotonics.

In this context, hexagonal boron nitride (h-BN), owing to its unique optical properties, has emerged as a highly promising candidate for exploring atomic defect-related quantum emission. However, the presence of inhomogeneous energy distribution and spectral diffusion of the zero-phonon line (ZPL) makes it difficult to achieve the emission of indistinguishable photons as required for many applications. Stark effect-induced spectral tuning of the ZPL is able to compensate intrinsic local strain and electrostatic fields, which constitute the main sources of inhomogeneity and instability in the emission from individual h-BN defects.

Here, we investigate the Stark tuning of quantum emitters in few-layer h-BN sheets by means of low-temperature confocal photoluminescence spectroscopy. The required vertical electric field is implemented using a graphene top contact. The emitters can be effectively and reproducibly tuned, revealing a high robustness under repeated gate voltage sweep cycles. Moreover, we demonstrate an electric field-induced modulation of the emission intensity and fluorescence lifetime.

Session A12 DMP: Devices from 2D Materials -- Microscopy and Spectroscopy BCEC 153A - Kyle Seyler, Univ of Washington - Tag(s): Focus

8:00AM A12.00001: Band structure engineering of monochalcogenides and van der Waals heterostructures [Invited]  
SHUYUN ZHOU (Presenter), Tsinghua University — Two-dimensional (2D) materials provide an important playground for exploring fundamental physics and potential applications. In this talk, I will present our recent process on the band structure structure of 2D materials and heterostructures. In particular, I will present our recent work on the electronic structure of a few transition metal monochalcogenides - thermoelectric SnSe [1] and a charge density wave material CuTe [2]. I will also present our recent progress on the band structure engineering of two prototypical examples of van der Waals heterostructures, a commensurate graphene/BN heterostructure with Moiré pattern [3], and an incommensurate 30° twisted bilayer graphene which shows symmetries similar to a quasicrystal [4].

8:36AM A12.00002: Visualizing and Controlling Coupled Graphene Quantum Dots  
FERESHTE GHAHARI (Presenter), DANIEL WALKUP, National Institute of Standards and Technology (NIST), KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, NIKOLAI BORISOVICH ZHITENEV, JOSEPH A STROSCIO, National Institute of Standards and Technology (NIST) — Recent progress in creating graphene quantum dots (QDs) with fixed build-in potentials has enabled visualizing the confined electronic states employing local probe measurements. In these nanometer-sized circular QDs, the Dirac quasiparticles are confined by Klein scattering from p-n junction boundaries. In this talk, I will present the scanning tunneling measurements (STM) of such double graphene QDs where the size and coupling between QDs can be tuned by varying the back-gate voltage. At high magnetic fields, Landau levels (LLs) inside each QD form a series of metallic rings separated by highly insulating incompressible rings where each LL shows its own charging characteristics. We used Coulomb blockade spectroscopy to probe and visualize the transition from the double dot system to a single large dot. The transition is reflected in distinct anticrossing patterns between charging lines corresponding to LL's electrons in different quantum dots.
Layered ferroelectric materials such as CuInP$_2$S$_6$ (CIPS) offer a huge potential for adding functionality in van der Waals heterostructures and domain dynamics. In graphene devices supported by hexagonal boron nitride (hBN), local charge pockets can be written by pulsing the bias voltage of a scanning tunneling microscope (STM) tip. In a strong magnetic field, discrete Landau levels (LLs) replace the continuous graphene density of states, and the charge pocket is characterized by a concentric series of compressible and incompressible rings, as successive LLs cross the Fermi energy. Here, Coulomb blockade peaks appear in the scanning tunneling di/dV spectra, revealing the addition of single electrons to the confined Landau island, and encoding the capacitances between it and the tip and back-gate electrodes. When two highly-gapped LLs cross the Fermi energy, two series of peaks appear, experiencing avoided crossings within the dot. The observed avoidance pattern of these anti-crossings is unusual and defies conventional explanation. We present a new phenomenological electrostatic model, taking into account the self-contained geometry of this double-quantum dot system, and are able to reproduce the most striking features of the experimental data.

Visualization and transport properties of complex graphene moiré superlattices. Graphene/hBN superlattices formed by a dual-alignment of graphene with respect to two hBN slabs. The atomic-scale phonon emitters that establish the dominant dissipation mechanism in graphene exhibit sharp peaks when the Fermi level comes into resonance with electronic quasi-bound states at such defects, a hitherto uncharted process. The atomic defects are very rare in the bulk but abundant at the edges, acting as switchable energy dissipation centers.

Energy dissipation is a fundamental process governing the dynamics of classical and quantum systems, even though direct imaging of dissipation in quantum systems remained out-of-reach experimentally until recently. We developed a scanning nanoSQUID with sub 50 nm diameter that resides at the apex of a sharp pipette acting simultaneously as nanomagnetometer with single spin sensitivity and as nano-thermometer providing cryogenic thermal imaging with four orders of magnitude improved thermal sensitivity of below 1 µK/Hz$^{1/2}$. Using this scanning nano-thermometry we visualize and control phonon emission due to inelastic electron scattering off individual atomic defects in graphene. The inferred electron-phonon “cooling power spectrum” exhibits sharp peaks when the Fermi level comes into resonance with electronic quasi-bound states at such defects, a hitherto uncharted process. The atomic defects are very rare in the bulk but abundant at the edges, acting as switchable atomic-scale phonon emitters that establish the dominant dissipation mechanism in graphene.

Two-dimensional ferroelectric van der Waals heterostructures and domain dynamics*. Layered ferroelectric materials such as CuInP$_2$S$_6$ (CIPS) offer a huge potential for adding functionality in van der Waals (vdW) heterostructures and furthermore the opportunity to investigate some fundamental physics related to confinement in two dimensions plus the effect of electrostatic doping through ferroelectric polarization modulation. In this study we investigate, through piezoresponse force microscopy (PFM), pure-phase CIPS flakes exfoliated by standard Scotch tape methods and incorporated into vdW stacks through a dry-transfer technique. We show that the vdW interface electrostatic environment has significant effects on the local domain structure. Local switching dynamics determined by PFM were also observed to depend on the exact device geometry.

9:36AM A12.00007: Sub-Micron Imaging of Encapsulated 2D layers of Graphene and Transition Metal Dichalcogenides by Conductive Scanning Probe Microscopy*  

MICHAEL ALTVATER (Presenter), TIANHUI ZHU, JUNXI DUAN, GUOHONG LI, EVA ANDREI, Rutgers University, New Brunswick — Encapsulation of 2D materials protects them from environmental disturbances and significantly improves their quality. However, these benefits are lost if impurities or structural defects become trapped within the encapsulating layers. It is therefore crucial to detect these prior to embarking on time-consuming device processing. While encapsulated flakes can be detected via post-processing of optical images or by confocal Raman microscopy, these techniques lack the sub-micrometer resolution to identify structural defects and charged impurities within the encapsulated layer. We demonstrate a facile technique to visualize charged contaminants within the heterostructure by measuring surface potential fluctuations using Kelvin probe force microscopy (KPFM). By applying a fixed tip bias larger than the surface potential fluctuations, the encapsulated flakes and their sub-micron structural defects, cracks, and bubbles can be detected through electrostatic force microscopy (EFM). We show that these methods, which are standard extensions of atomic force microscopy (AFM), are perfectly suited for imaging encapsulated conductors and their local charge environments.

9:48AM A12.00008: Graphene-based Hall sensors for scanning magnetic microscopy*  

BRIAN SCHAEFER (Presenter), LEI WANG, ALEXANDER B JARJOUR, Cornell University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, PAUL L MCEUEN, KATJA NOWACK, Cornell University — Incorporating few-layer graphite gate electrodes and hexagonal boron nitride gate dielectrics into graphene devices provides an accessible route to create two-dimensional electron systems with extremely low charge inhomogeneity. Here, we fabricate micrometer-scale graphene Hall sensors that can be tuned to a carrier density of $\sim 2 \times 10^9$ cm$^{-2}$ at cryogenic temperatures. This translates to a Hall coefficient exceeding 300,000 $\Omega$/T, two orders of magnitude larger than previously reported in any other Hall sensor. The magnetic resolution of our devices is ultimately limited by low-frequency flicker (1/$f$) and random telegraph noise, and we reach a minimum magnetic field noise spectral density of 60 nT/$\sqrt{\text{Hz}}$ at 1 kHz. Together, our results suggest that these devices have the potential to outperform semiconductor-based Hall sensors. We will also discuss our progress towards fabricating submicron-scale graphene-based scanning Hall probes that function over a wide range of temperatures and magnetic fields.

10:00AM A12.00009: Inelastic Electron Tunneling Spectroscopy of Graphene/hexagonal Boron Nitride heterostructures  

ZHEHAO GE (Presenter), JOHN L DAVENPORT, FREDERIC JOUCKEN, EBERTH QUEZADA, JUNYAN LIU, Physics, University of California, Santa Cruz, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, DAVID LEDERMAN, JAIRO VELASCO JR., Physics, University of California, Santa Cruz — Inelastic Electron Tunneling Spectroscopy (IETS) has been used for several decades as an experimental probe to access the vibrational properties of low dimensional materials. Notably, the ability to investigate these properties could be leveraged to gain further insight into the recently reported unconventional superconductivity in twisted bilayer graphene. Currently, there exists several IETS measurements on heterostructures of graphene and hexagonal Boron Nitride (hBN). These studies employed different experimental approaches such as tunneling from an atomically sharp asperity with scanning tunneling spectroscopy (STS) and planar tunneling via tunneling field effect transistors (TFETs). Importantly, the IETS results from these different experimental approaches lack agreement. To address this disparity we provide a direct comparison between IETS measurements acquired from STS and TFETs on graphene/hBN heterostructures that underwent the same fabrication processes. Our work contributes towards benchmarking IETS of two-dimensional material heterostructures and will enable future application of this technique to the study of unconventional superconductivity in twisted bilayer graphene.
10:12AM A12.00010: Complete Strain Mapping of Nanosheets of Transition Metal Chalcogenides  YUE CAO
(Presenter), Argonne National Laboratory, TADESSE ASSEFA, Brookhaven National Laboratory, SOHAM BANERJEE, SIMON J L BILLINGE, JEDRZEJ WIETESKA, DENNIS WANG, ABHAY PASUPATHY, Columbia University, XIAO TONG, Brookhaven National Laboratory, YU LIU, WENJIAN LU, YUPING SUN, Institute of Solid State Physics, Chinese Academy of Sciences, YAN HE, Shanghai Synchrotron Radiation Facility (SSRF), Shanghai Institute of Applied Physics, Chinese Academy of Sciences, XIAOQING HUANG, HANFEI YAN, YONG S. CHU, IAN KEITH ROBINSON, Brookhaven National Laboratory — Holding promise for future electronics because of their unique band structures, quasi-two-dimensional (quasi-2D) materials host electronic and mechanical properties sensitive to crystal strains in all three dimensions. Quantifying the crystal strain is a prerequisite to correlating it with the performance of the relevant device, and calls for fast characterization methods compatible with the potential devices and applications. Here we bridge this knowledge gap using fly-scan nano X-ray diffraction with strain sensitivity below 0.001 over sub 100 µm length scales. Coherent diffraction patterns were collected from a thin sheet of 1T-TaS2 using an area detector by scanning across and rotating the sample. Reconstructing from the resulting five-dimensional datasets yields information on the morphology of and the strain distribution around micron and sub-micron ‘bubbles’ which form spontaneously in the quasi-2D plane. Our studies thus open way to experimentally quantify local strains in these quasi-2D materials and will allow better understanding of strains in tuning material properties.

10:24AM A12.00011: Reversible Nanoscale Control of the Charge Neutrality Point in Graphene Using LaAlO3/SrTiO3 Heterostructures* JIANAN LI (Presenter), QING GUO, JEN-FENG HSU, SHAN HAO, YANG HU, University of Pittsburgh, HYUNGWOO LEE, JUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin-Madison, BRIAN R D’URSO, Montana State University, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — The properties of graphene depend sensitively on doping with respect to the charge-neutrality point (CNP). Tuning the CNP usually involves electrical gating or chemical doping. Here, we describe a technique to reversibly control the CNP in graphene with extreme nanoscale precision, using LaAlO3/SrTiO3 (LAO/STO) heterostructures and conductive atomic force microscope (c-AFM) lithography. The conductivity of the LAO/STO interface can be tuned using a conductive AFM tip, even through graphene transferred on, affecting the LAO/STO interface conductive while shifting the position of graphene CNP. Here we demonstrate that edge state engineering can be achieved from this method using the quantum Hall effect. Clear quantized resistance at plateaus h/e2 and h/3e2 are observed in a split Hall device, demonstrating edge transport along the c-AFM written edge. This technique can be extended to many other device geometries.

10:36AM A12.00012: Probing band structure renormalization in 2D semiconductors induced by external dielectric screening through angle-resolved photoemission spectroscopy  LUTZ WALDECKER (Presenter), Stanford University and SLAC National Laboratory, ARCHANA RAJA, University of California, Berkeley, MALTE ROESNER, University of Southern California and CCQ, Flatiron Institute, CHRISTINA STEINKE, University of Bremen, ROLAND KOCH, AARON BOSTWICK, CHRIS JOZWIAK, Advanced Light Source, E. O. Lawrence Berkeley National Laboratory, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Tsukuba, ELI ROTENBERG, Advanced Light Source, E. O. Lawrence Berkeley National Laboratory, TIM WEHLING, University of Bremen, TONY F HEINZ, Stanford University and SLAC National Laboratory — We investigate the effect of dielectric screening by the external environment on the electronic states in the two-dimensional (2D) semiconductor WS2 using angle-resolved photoemission spectroscopy (ARPES). As has been previously reported from optical spectroscopy of monolayer WS2 [1], an increase in environmental screening from the presence of graphene can lead to a ~100 meV reduction of the bandgap. Our ARPES study of monolayer WS2 partially placed on h-BN and graphene, however, reveals that the dispersion of the valence band is essentially unchanged (< 10 meV shifts) when screening by graphene is present. Thus the screening-induced band renormalization appears to lead only to a rigid shift, rather than a restructuring of the valence band. We compare this experimental finding with theory based on GΔW calculations, including material-realistic frequency and momentum dependent screening due to the substrate. In agreement with experiment, theory predicts the primary effect of bandgap renormalization along with a scissor-like shift of all electronic states. We discuss the physical origin of this result and its implication for the use of controlled changes in the environment to tune the band structure of 2D semiconductors.

10:48AM A12.00013: Gating and superlattice effects in monolayer WSe2 devices in micro-ARPES* PAUL NGUYEN (Presenter), University of Washington, NATALIE TEUTSCH, ABIGAIL J GRAHAM, Physics, University of Warwick, MINHAO HE, University of Washington, VIKTOR KANDYBA, ALEXEI VICTOROVICH BARINOV, Elettra - Sincrotrone Trieste S.C.p.A, NEIL R WILSON, Physics, University of Warwick, XIAODONG XU, DAVID HENRY COBDEN, University of Washington — We investigate the effects of electrostatic doping and moiré superlattice potentials on monolayer WSe2 using micro-angle-resolved photoemission spectroscopy (micro-ARPES). By employing a local back gate of thin graphite under a hexagonal boron nitride dielectric support, we electrostatically populate the WSe2 conduction band during the photoemission measurements. We find the conduction band edge to be at the zone corner, or K point, confirming the direct gap nature of this material and yielding a measurement of the single-particle gap. As the electron doping is increased to a maximum of ~1.4E13 cm−2 the valence band shifts upwards towards the conduction band, corresponding to substantial band gap renormalization. At the highest doping levels, the conduction band minimum at the lower symmetry Q point is also populated, showing that it is within ~30 meV of the minimum at K. In some devices we also observe folded copies of the hBN and WSe2 bands with intensities often comparable to the original bands, yielding information about moiré superlattice effects.

Session A13 DMP: 2D Materials (General) -- Transport BCEC 153B - Daniel Ralph, Cornell University - Tag(s): Focus

8:00AM A13.00001: First-principles studies of the electronic structure and photophysics of monolayer WS2 with point defects* JUN-HO LEE (Presenter), Lawrence Berkeley National Laboratory, University of California - Berkeley, SIVAN REFAELY-ABRAMSON, Weizmann Institute of Science, Lawrence Berkeley National Laboratory, University of California - Berkeley, DIANA QIU, University of California - Berkeley, Lawrence Berkeley National Laboratory, BRUNO SCHULER, KATHERINE COCHRANE, ALEXANDER WEBER-BARGIONI, Molecular Foundry, Lawrence Berkeley National Laboratory, STEVEN G. LOUIE, University of California - Berkeley, Lawrence Berkeley National Laboratory, JEFFREY B NEATON, Lawrence Berkeley National Laboratory, University of California - Berkeley, Kavli Energy NanoSciences Institute at Berkeley — Point defects in single-layer transition-metal dichalcogenides (TMDs) are common, and point defects in layered TMDs – including vacancies and chemical substitutions – have been reported to affect their electronic structure and photophysics. Here, we use first-principles density functional theory and the GW and GW-BSE calculations to explore the structure and the tunneling and optical properties of substitutional points defects in monolayer tungsten disulfide. Using a large supercell, we compute the atomic structure, quasiparticle band structure, defect states, and low-lying excitons for dilute defect concentrations. We compare our structure and quasiparticle excitation spectrum with state-of-the-art non-contact atomic force microscope and scanning tunneling spectroscopy measurements.

8:12AM A13.00002: Dopant induced electronic inhomogeneity of epitaxial bilayer graphene in SiC* SHUAI ZHANG (Presenter), DI HUANG, LEHUA GU, YUAN WANG, SHIWEI WU, Department of Physics, Fudan University — Graphene has been a promising candidate for next-generation electronics due to its intriguing properties, particularly the high carrier mobility. Currently, wafer-scale single crystal graphene could be readily produced on silicon carbide (SiC) substrate by high-temperature annealing. But the mobility of epitaxial graphene is relatively lower than that by mechanical exfoliation. The underlying mechanism has not yet been resolved. Here we study the topography and electronic state of epitaxial graphene grown on 6H-SiC by scanning tunneling microscopy (STM) and spectroscopy (STS). We show that the nitrogen dopants inside SiC substrate result in the electronic inhomogeneity of epitaxial graphene, and give rise to electron-lack puddles. Our results provide the plausible microscopic mechanism for the low mobility in epitaxial graphene.

*The work at Fudan University was supported by the National Basic Research Program of China (Grant Nos. 2014CB921601, 2016YFA0301002), National Natural Science Foundation of China (Grant No. 11427902), and the Science and Technology Commission of Shanghai Municipality (Grant No. 16jC1400401).
8:24AM A13.00003: The Intrinsic Carrier Mobility in Two-Dimensional Semiconductors [Invited] YUANYUE LIU (Presenter), University of Texas at Austin — Two-dimensional (2D) semiconductors have attracted great interest for next-generation electronics and optoelectronics. However, they typically have a low mobility of electrons/holes, compared with Si/III-V semiconductors. Here I will discuss our recent theoretical understandings of the mobility-limiting factors in 2D semiconductors [1], and strategies of increasing the mobility. These results are based on the calculation of electron-phonon coupling matrix using density functional perturbation theory and the Wannier interpolation, as well as the Boltzmann transport theory. Moreover, I will also present a new approach for decoupling the entangled phonons to standard phonon modes [2], to analyze the electron-phonon coupling.

9:00AM A13.00004: Effect of current annealing to the transport properties of CVD graphene cooled with a biased gate voltage* U. KUSHAN WIJEWARDENA (Presenter), THARANGA NANAYAKKARA, RASANGA SAMARAWEERA, BINUKA GUNAWARDANA, C. RASADI MUNASINGHE, SAJITH WITHANAGE, ANNIKA KRIISA, RAMESH MANI, Georgia State University — Chemical vapor deposition of graphene is an excellent method for obtaining large area single-layer graphene. A topic of interest in this area is to characterize and reduce the impurity level in this material. In this experimental work, we investigate impurity effects on electron /hole transport in a graphene specimen by cooling down a graphene Hall bar device under different gate bias voltages. Further, we examine the impact of current annealing on the transport characteristics. Here we present results from the measurements carried out in a closed cycle refrigerator out over a broad temperature range (295K–15K), focusing on the charge neutrality point.

9:12AM A13.00005: Gateless and reversible carrier density tunability in epitaxial graphene devices functionalized with chromium tricarbonyl* ALBERT RIGOSI (Presenter), MATTIAS KRUSKOPF, HEATHER M. HILL, HANBYUL JIN, BI-YI WU, PHILIP E JOHNSON, SIYUAN ZHANG, MICHAEL BERILLA, ANGELA HIGHT WALKER, CHRISTINA HACKER, DAVID B NEWELL, RANDOLPH E ELMQUIST, National Institute of Standards and Technology — Monolayer epitaxial graphene (EG) has been shown to have clearly superior properties for the development of quantized Hall resistance (QHR) standards. One major difficulty with QHR devices based on EG is that their electrical properties drift slowly over time if the device is stored in air due to adsorption of atmospheric molecular dopants. The crucial parameter for device stability is the charge carrier density, which determines the energy spacing of the Landau levels and thus the magnetic flux density required for precise QHR measurements. This work presents one solution to this problem of instability in air by functionalizing the surface of EG devices with chromium tricarbonyl - Cr(CO)3. Observations of carrier density stability in air over the course of one year are reported, as well as the ability to tune the carrier density by annealing the devices. For low temperature annealing, the presence of Cr(CO)3 stabilizes the electrical properties and allows for the reversible tuning of the carrier density in millimeter-scale graphene devices close to the Dirac point. Precision measurements in the quantum Hall regime show no detrimental effect on the carrier mobility.

9:24AM A13.00006: Electronic properties of armchair transition metal dichalcogenides nanoribbons deposited with atomic chains.* CHI-HSUAN LEE (Presenter), CHIH-KAI YANG, National Chengchi University — Electronic properties of armchair transition metal dichalcogenides (TMD) nanoribbons bonded with atomic chains are studied using density-functional calculations. The pure armchair TMD nanoribbon with 15 dimer lines possesses non-magnetic band structures with a moderate energy gap. Their edge states near the Fermi level exhibit different kinds of behavior in accordance to the different elements. Energy bands of the deposited atomic chains hybridize with the edge states of the ribbon and induce various magnetic properties, with different locations of deposition taken into account. The results are useful for fabricating novel nanoelectronic devices.

9:36AM A13.00007: ABSTRACT WITHDRAWN
Tuning Charge Transport in Voltage-Reduced Graphene Oxide through Defect Control and Quantum Confinement* KEVIN SILVERSTEIN (Presenter), Department of Physics, Applied Physics, and Astronomy, Binghamton University, CHRISTIAN E HALBIG, Institute of Chemistry and Biochemistry, Freie Universität Berlin, AUSTIN C FAUCETT, JEREMY MEHTA, Department of Physics, Applied Physics, and Astronomy, Binghamton University, ANJU SHARMA, Small Scale Systems Integration and Packaging Center, Binghamton University, SIEGFRIED EIGLER, Institute of Chemistry and Biochemistry, Freie Universität Berlin, JEFFREY M. MATIVETSKY, Department of Physics, Applied Physics, and Astronomy, Binghamton University — Graphene oxide (GO) is a versatile two-dimensional nanomaterial that is being explored for its tunable electrical, optical, and chemical properties. This tunability is afforded by reduction which removes oxygen-containing functional groups, restores the sp² carbon lattice, and converts the electrically insulating material to one that is conducting. Here, we use voltage reduction, a simple and environmentally benign procedure, to manipulate the electrical properties of GO from insulating to conducting, and potentially semiconducting. A low-defect form of GO, oxo-G, was synthesized and voltage-reduced to produce a highly conductive graphene derivative. Variable temperature electrical resistance measurements reveal a transition from hopping transport to a temperature-stable resistance over a broad temperature range, making this material promising for use in sensors and other applications that require temperature-stable performance. Nanopatterning was also employed, by using a conductive atomic force microscope probe to initiate voltage reduction. Preliminary data suggests possible transport gap opening due to quantum confinement.

The role of defects in the performance of graphene hot-electron devices.* A EL FATIMY, PEIZE HAN, LUKE ST. MARIE, Physics, Georgetown University, NICHOLAS QUIRK, Physics, Princeton University, MATTHEW T DEJARLD, RACHAEL MYERS-WARD, US Naval Research Laboratory, KEVIN DANIELS, Electrical and Computer Engineering, University of Maryland, SHOJAN PAVUNNY, DAVID KURT GASKILL, US Naval Research Laboratory, YIGIT AYTAC, THOMAS E MURPHY, Electrical and Computer Engineering, University of Maryland, PAOLA BARBARA (Presenter), Physics, Georgetown University — Defect-mediated electron-phonon collisions (supercollisions) play an important role in the cooling dynamics of hot electrons in graphene, but their impact on the performance of optoelectronic devices is still largely unexplored. Here we study supercollisions in hot-electron bolometers based on quantum dots of epitaxial graphene grown on SiC. We find that the fabrication process substantially affects the defect density and that a higher defect density greatly enhances the device performance, yielding faster response time and lower thermal conductance in a wide range of power and temperature.

Incorporation of metallocene as n-dopant in vertical stacked van der Waals homostructure of atomically thin HfS₂* CHINEDU EKUMA (Presenter), SINA NAJMAEI, MADAN DUBEY, Sensors and Electron Devices Directorate, U.S. Army Research Laboratory, ALC, MD — Chemical or electrical doping is an efficient means of improving and controlling carrier transport and charge injection in materials. Using a combination of first-principles calculations and experiment, we tailor the properties of vertically stacked two-dimensional HfS₂ by intercalation of cobaltocene and chromocene (MC₅₂). Our data show that MC₅₂ behaves as pseudo-alkali metals, transferring electrons to the homostructure characterized by a shift of the Fermi level towards the empty states and an increase of the current density. The process of MC₅₂ evolving in the homostructure which led to the doping is due to charge transfer from the intercalant to the host material that induced ion pairing between the host and the dopant.

*This work has been supported by the U.S. Army Research Laboratory (ARL) and was accomplished under the Cooperative Agreement Number W911NF-11-2-0030 as an ARL Research [George F. Adams] Fellow.
Charge transfer in few-layer InSe/gas Interface*  
HANSIKA SIRIKUMARA (Presenter), MILINDA WASALA, ANANTH PANCHAMUKHI, PRASANNA DNYANESHWAR PATIL, ARON C WALBER, Department of Physics, Southern Illinois University Carbondale, SIDONG LEI, ROBERT VAJTAI, PULICHEL M AJAYAN, Department of Materials Science and Nano Engineering, Rice University, SAIKAT TALAPATRA, THUSHARI JAYASEKERA, Department of Physics, Southern Illinois University Carbondale — Few-layer InSe shows a strong potential for gas sensing applications primarily due to high sensitivity of electron lone pairs on Se to external gas molecules. Based on the results from first principles Density Functional Theory calculations, we carefully analyzed electronic band structures of few-layer InSe/Gas configurations. Our calculations show that charge transfer across few-layer InSe/gas system depends on the orientation and the type of the gas molecules. Therefore, it was seen that for certain gas molecules such as ethanol, the InSe layers are p-doped, while for other molecules such as methanol the InSe layers are n-doped. These results were verified through gas sensing experiments using few layer InSe FET devices. Further we show, while majority charge transfer happens through InSe/Gas interface, the polarity of external molecule can tune interlayer spacing through an induced dipole moment between the layers. The change in interlayer spacing is not monotonic, which results in pinning of impurity band with respect to valence band maximum. Fundamental understanding of charge transfer in few-layer InSe/gas interfaces at the atomic level is expected to pave the path for designing gas sensing devices based on few-layer InSe.

*U.S.Army Research Office MURI grant #W911NF-11-1-0362

Redox-Governed Charge Doping in WS2 and Graphene  
SUNMIN RYU (Presenter), KWANGHEE PARK, HA NEUL KANG, Pohang University of Science and Technology — Low dimensional materials often undergo spontaneous hole doping in the ambient conditions, the detailed mechanism of which has yet to be revealed. In this work, we propose a mechanism based on a redox couple of O2/H2O and verified it for two model systems: photoluminescence (PL) modulation in single-layer WS2 and thermally-activated phonon hardening in graphene with both supported on silica substrates. The PL modulation was directly correlated with the concentration of oxygen both in gaseous and aqueous states. Wide-field PL imaging, however, showed distinctively different spatial propagations of the modulation for the two states, revealing the microscopic picture of the charge doping in WS2. The mechanistic details and thermodynamic driving force for the charge doping will also be discussed in conjunction with the activated hole doping in graphene probed by Raman spectroscopy.

Monday, March 4, 2019 8:00 AM - 10:36 AM

Session A14 DMP: 2D Materials (Metals, Superconductors, and Correlated Materials) -- CDWs

Orbital- and k_z-selective hybridisation of Se 4p and Ti 3d states at the CDW transition of TiSe2*  
MATTHEW WATSON (Presenter), OLIVER J CLARK, FEDERICO MAZZOLA, IGOR MARKOVIĆ, VERONIKA SUNKO, School of Physics and Astronomy, University of St Andrews, St. Andrews KY16 9SS, United Kingdom, TIMUR KIM, Diamond Light Source, Harwell Campus, Didcot, OX11 0DE, United Kingdom, KAI ROSSNAGEL, Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24098 Kiel, Germany, PHILIP KING, School of Physics and Astronomy, University of St Andrews, St. Andrews KY16 9SS, United Kingdom — We revisit the enduring problem of the 2×2×2 charge density wave (CDW) order in TiSe2, utilising photon energy-dependent angle-resolved photoemission spectroscopy (ARPES) to probe the full three-dimensional high- and low-temperature electronic structure. Our measurements demonstrate how a mismatch of dimensionality between the 3D conduction bands and the quasi-2D valence bands in this system leads to a hybridisation that is strongly k_z-dependent. This 3D momentum-selective coupling shifts the strongly hybridized states well away from the Fermi level, providing the energy gain required to form the CDW. However, we show how additional `passenger" states remain, and dominate the low energy physics in the ordered state. In particular we find that a branch of the conduction band with 3dz² character remains essentially unhybridised in the ordered phase, forming a coherent and ungepapped electron-like Fermi surface. We conclude by making a comparison to the 2x2 CDW of monolayer TiSe2, where k_z-selective effects are absent, but orbital-selective hybridisation persists. [1] Watson et al., arXiv:1808.07141 (2018).

Pairing induced by CDW fluctuations: the case of superconductivity in TiSe$_2$*  

CHUAN CHEN (Presenter), ANTONIO HELIO CASTRO NETO, VITOR PEREIRA, National University of Singapore — We theoretically studied the modes and spectrum of fluctuations of the CDW in TiSe$_2$ using a model that describes its CDW state as a result of the intrinsic excitonic instability in TiSe$_2$. The charge carriers are electrons within the CDW-renormalized conduction band (CDW quasiparticles). A calculation of the effective action for the CDW fluctuations shows the presence of gapless phase modes and gapped amplitude modes. Upon integrating out these fluctuations, we find that the amplitude fluctuations induce attractive pairing between the CDW quasiparticles resulting in s-wave superconductivity. A subsequent mean-field phase diagram of both CDW and superconducting critical temperatures as a function of doping reveals a dome-shaped superconducting phase coexisting with CDW in the near-commensurate regime, in agreement with the experimental phase diagram.

Electronic properties and charge density wave transition in single-layer VSe$_2$  

KIEN NGUYEN-CONG (Presenter), PAULA COELHO NETO, MATTHIAS BATZILL, IVAN OLEYNIK, University of South Florida — Single-layer VSe$_2$ has been recently attracted attention due to experimental observations of ferromagnetism and charge density wave (CDW) transition. There are controversies from both theory and experiment concerning ferromagnetism in both bulk and single layer VSe$_2$. In addition, CDW transition in VSe$_2$ is not well understood. In this work, structural, electronic, magnetic and CDW properties of this system are investigated using first-principle calculations. The calculated electronic structure is compared with recent APPRES measurements and conclusions concerning its magnetic state are made. The calculated phonon spectra are used in investigation of CDW transition mechanism. Crystal structure of the CDW state is determined using the evolutionary crystal structure prediction combined with lattice dynamics.

Unique gap structure and symmetry of the charge density wave in single-layer VSe$_2$  

PENG CHEN (Presenter), Physics, University of Illinois Urbana-Champaign, WOEI WU PAI, National Taiwan University, YANG-HAO CHAN, Academia Sinica, VIDYA MADHAVAN, Physics, University of Illinois Urbana-Champaign, MEI-YIN CHOU, National Taiwan University, SUNG-KWAN MO, ALEXEI V. FEDOROV, Lawrence Berkeley National Laboratory, TAI-CHANG CHIANG, Physics, University of Illinois Urbana-Champaign — Single layers of transition metal dichalcogenides (TMDCs) are excellent candidates for electronic applications beyond the graphene platform; many of them exhibit novel properties including charge density waves (CDWs) and magnetic ordering. CDWs in these single layers are generally a planar projection of the corresponding bulk CDWs because of the quasi-two-dimensional nature of TMDCs; a different CDW symmetry is unexpected. We report herein the successful creation of pristine single-layer VSe$_2$, which shows a (sqrt(7) x sqrt(3)) CDW in contrast to the (4 x 4) CDW for the layers in bulk VSe$_2$. Angle-resolved photoemission spectroscopy (ARPES) from the single layer shows a sizable (sqrt(7) x sqrt(3)) CDW gap of ~100 meV at the zone boundary, a 220 K CDW transition temperature twice the bulk value, and no ferromagnetic exchange splitting as predicated by theory. This robust CDW with an exotic broken symmetry as the ground state is explained via a first-principles analysis. The results illustrate a unique CDW phenomenon in the two-dimensional limit.
extendable to a broad set of two-dimensional materials with CDW order, including cuprates. Information includes orbital selectivity and electron-phonon coupling can explain both general and specific features and might be

CHOI, Physics, University of Seoul, Korea, CHRIS JOZWIAK, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source (ALS), E. O. Lawrence Berkeley National Laboratory, USA, JE-GUEN PARK, Center for Correlated Electron Systems, Institute for Basic Science (IBS), Korea, RAMAN SANKAR, Physics, Academia Sinica, Taiwan, KI-SEOK KIM, Physics, POSTECH, Korea, JUNGDae KIM, Physics, Ulsan University, Korea, YOUNG JUN CHANG (Presenter), Physics, University of Seoul, Korea — Although emergent phenomena driven by electronic reconstructions in oxide heterostructures have been intensively discussed, such interface-driven phenomena in shaping the electronic properties has not been well established in van der Waals heterointerfaces. By diminishing the material thickness and forming a heterointerface, we observed two types of charge-ordering transitions in monolayer VSe$_2$ on graphene substrates. Comprehensive combination of ARPES, STM, and renormalization group analysis enable us to reveal the low-dimensionality and the heterointerface play important roles in enhancing charge density wave temperature to 350 K contrasted to the 105 K in bulk VSe$_2$ and in driving the unexpected metal-insulator transition at 135 K in the family of monolayer transition metal dichalcogenides. We will discuss implications of our observations in comparison with the similar results reported by two other groups.

9:00AM A14.00006: General and specific features of the charge density waves in transition metal dichalcogenides*

KAPILA WIJAYARATNE (Presenter), JUNJING ZHAO, Department of Physics, University of Virginia, CHRISTOS MALLIAKAS, Department of Chemistry, Northwestern University, DUCK YOUNG CHUNG, Materials Science Division, Argonne National Lab, GENDA GU, Condensed Matter Physics & Materials Science, Brookhaven National Lab, MERCOURI KANATZIDIS, Department of Chemistry, Northwestern University, JASPER VAN WEZEL, Institute of Theoretical Physics, University of Amsterdam, UTPAL CHATTERJEE, Department of Physics, University of Virginia — We report a series of elaborate Angle-Resolved Photoemission Spectroscopy (ARPES) studies on the charge density wave (CDW) phase in transition metal dichalcogenides (TMD) 2H-TaS$_2$, TaSe$_2$ and NbSe$_2$, analyzed above/ below the CDW transition temperature ($T_{\text{CDW}}$). Generally; i) On Fermi surface, CDW energy gap appears only in the vicinity of some symmetry points, while other momentum points are ungapped. ii) Gap is asymmetric in particles and holes. iii) Gap existed above $T_{\text{CDW}}$ beyond the CDW phase, (pseudogap). iv) Conventional Fermi surface nesting model is incapable of describing the CDWs in TMDs. v) phonon related band renormalizations were observed in 2H-TaS$_2$. Compound-specific features, due to different orbital orientations were; i) Size variation of some Fermi pockets are related to $T_{\text{CDW}}$ while other pockets were similar among compounds. ii) About a given symmetry point, in 2H-NbSe$_2$ the gap size varied upon momentum in contrast to 2H-TaS$_2$, where this variation was insignificant. A tight binding model that includes orbital selectivity and electron-phonon coupling can explain both general and specific features and might be extendable to a broad set of two-dimensional materials with CDW order, including cuprates.

9:12AM A14.00007: Ion intercalation tuned quantum transport, charge density waves, and superconductivity in atomically thin crystals of 2H-TaSe$_2$

YUESHEN WU (Presenter), Physics, Shanghai Jiao Tong University, CHAO-SHENG LIAN, Physics, Zhengzhou University, HUI XING, CHAO YAO, Physics, Shanghai Jiao Tong University, DUAN WENHUI, Physics, Tsinghua University, JINYU LIU, Physics, Shanghai Jiao Tong University, ZHIQIANG MAO, YING LIU, Physics, Pennsylvania State Univ — Quantum transport in an electronic system dealing with the quantum interference of diffusive electrons is influenced strongly by spin-orbital and electron-phonon interactions. Two-dimensional (2D) crystals of transition metal chalcogenides (TMCs) were found recently to show interesting behavior in quantum transport, which can be tuned, for example, by electric field effects. However, ion intercalation has not been used to tune quantum transport involving weak localization or weak antilocalization in 2D TMCs. We carried out magneto electrical transport measurements on atomically thin crystals of 2H-TaSe$_2$ intercalated by Li ions controlled by ionic gating. Gate voltage and temperature tuned crossovers from weak antilocalization to weak localization were observed. Meanwhile, ion intercalation was found to suppress charge density waves and enhance superconductivity at the same time. Band structure and phonon spectrum calculations show that the electronic density of states and the number of acoustic phonons available for scattering are reduced. Our observations suggest that the ion intercalation leads to an enhancement of the electron-phonon interaction and a simultaneous reduction in spin-orbital scattering.
Atomic-scale visualization of the low temperature charge density wave phase in 1T'-TaTe$_2$

Ismail El Baggari (Presenter), Nikhil Sivadas, Gregory Steihl, Daniel Ralph, Craig J Fennie, Lena F Kourkoutis, Cornell University — Many transition-metal dichalcogenides, such as TaS$_2$ and NbSe$_2$, exhibit charge density wave (CDW) instabilities which, by coupling to the lattice, induce complex periodic lattice displacement patterns. Tellurium-based TMDs further exhibit large electronic and structural anisotropy and significant interlayer correlations. Here, we use cryogenic scanning transmission electron microscopy (STEM) to probe in real space the high temperature (HT) and low temperature (LT) CDW phases in metallic 1T'-TaTe$_2$. We visualize Ta trimer states at room temperature and observe below the CDW transition temperature ($T_c \sim 170$ K) the formation of a superstructure arising from complex, periodic intensity modulations in STEM data. The modulations reflect longitudinal periodic lattice displacements that stack in a staggered fashion between the layers. Cross-sectional imaging, density functional theory calculations, and multislice image simulations further elucidate the nature of the HT and LT states. These atomically-resolved measurements reveal the complex role of lattice degrees of freedom in CDW transitions.

First principles description of Charge Density Waves in single-layer TiSe$_2$ and TiTe$_2$.

Bogdan Guster (Presenter), Roberto Robles, Miguel Pruneda, Catalan Institute of Nanoscience and Nanotechnology, Enric Canadell, ICMAB-CSIC, Pablo Ordejón, Catalan Institute of Nanoscience and Nanotechnology — We present some of our recent work on the understanding of the appearance of Charge Density Waves (CDW) in single-layer 2D transition metal dichalcogenides by means of first principles electronic structure calculations. This is done in connection with recent experimental studies that have been able to demonstrate the presence of CDS in several 2D single-layer materials like TiSe$_2$ and TiTe$_2$. The evolution of the CDW with external electrostatic doping, which has been achieved experimentally using field effect transistor setups, will be analyzed for the case of TiSe$_2$ [1]. For TiTe$_2$, we focus on the recently observed CDW in the single layer, which is not present in the bulk material [2].

Spectroscopic signatures of many-body renormalizations in 1T-TiSe$_2$.

Utpal Chatterjee (Presenter), Physics, University of Virginia, Nandini Trivedi, Kyungmin Lee, Physics, Ohio State University, Goran Karapetrov, Physics, Drexel University, Junjing Zhao, Physics, University of Virginia — We have investigated the many-body renormalization of the single-particle excitations in 1T-TiSe$_2$ by employing high resolution angle resolved photoemission spectroscopy (ARPES) measurements. The energy distribution curves of the ARPES data reveal an intrinsic peak-dip-hump feature. The electronic dispersion extracted from the momentum distribution curves highlights, for the first time, multiple kink structures. These are canonical signatures of coupling between the electronic degrees of freedom and bosonic modes in the system. Theoretical modeling of electrons coupled to an Einstein mode provides insight into the peak-dip-hump features observed in the data. From a self-energy analysis of our ARPES data, we find a bosonic mode at 26 meV that correlates with ab-initio phonon-dispersion calculations and observation of Raman active shear (E$_g$) mode in Raman scattering experiments. The direct observation of band-renormalization due to such electron-boson coupling suggests that such modes could be important for driving charge density wave (CDW) and superconductivity in 1T-TiSe$_2$ like in many other transition metal dichalcogenides.

10:00AM A14.00011: Charge density wave order in a transition metal dichalcogenide probed by second harmonic generation*  
BRYAN FICHERA (Presenter), ANSHUL KOGAR, LINDA YE, JOSEPH CHECKELSKY, NUH GEDIK, Massachusetts Institute of Technology — Rotational anisotropy second harmonic generation (RA-SHG) is a nonlinear optical probe which has been used to study electronic order in solid state materials. Because the leading-order contribution to the second harmonic signal is zero in the bulk of centrosymmetric crystals, RA-SHG can be used to study the surface properties of ordered materials. We use RA-SHG to study electronic order on the surface of a transition metal dichalcogenide (TMD). We find that the symmetry-breaking character of ordered charge density wave (CDW) states in the TMD can be identified using RA-SHG, and that our technique can be used to differentiate surface CDW domains. We also posit a new framework for understanding RA-SHG data from crystal structures with incommensurate charge order.

10:12AM A14.00012: Dynamical slowing down in an ultrafast photo-induced phase transition* 
ALFRED ZONG (Presenter), ANSHUL KOGAR, Massachusetts Institute of Technology, PAVEL E DOLGIREV, Skolkovo Institute of Science and Technology, EMRE ERGECEN, MEHMET B YILMAZ, YA-QING BIE, TIMM ROHWER, Massachusetts Institute of Technology, I-CHENG TUNG, Argonne National Laboratory, JOSHUA STRAQUADINE, PHILIP WALMSLEY, Stanford University, XIAOZHE SHEN, JIE YANG, RENKAI LI, SUJI PARK, MATTHIAS C HOFFMANN, BENJAMIN K OFORI-OKAI, MICHAEL E KOZINA, SLAC National Accelerator Laboratory, HAIDAN WEN, Argonne National Laboratory, XJIE WANG, SLAC National Accelerator Laboratory, IAN R FISHER, Stanford University, PABLO JARILLO-HERRERO, NUH GEDIK, Massachusetts Institute of Technology — Complex systems, which consist of a large number of interacting constituents, often exhibit universal behavior near a phase transition. A slowdown of certain dynamical observables is one such recurring feature found in a vast array of contexts. This phenomenon, known as critical slowing down, is well studied mostly in thermodynamic phase transitions. However, it is less understood in highly nonequilibrium settings, where the time it takes to traverse the phase boundary becomes comparable to the timescale of dynamical fluctuations. Using transient optical spectroscopy and femtosecond electron diffraction, we studied a photo-induced transition of a model charge-density-wave (CDW) compound, LaTe3. We observed that it takes the longest time to suppress the order parameter at the threshold photoexcitation density, where the CDW transiently vanishes. This finding can be quantitatively captured by generalizing the time-dependent Landau theory to a system far from equilibrium. The experimental observation and theoretical understanding of dynamical slowing down may offer insight into other general principles behind nonequilibrium phase transitions in many-body systems.

10:24AM A14.00013: Superconductivity in Weyl semimetal Mo$_x$W$_{1-x}$Te$_2$ driven by high pressure  
RABIN DAHAL (Presenter), LIANGZI DENG, NARAYAN POUDEL, MELISSA GOOCH, ZHENG WU, CHING-WU CHU, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, TX 77204, USA — Tungsten ditelluride and molybdenum ditelluride have attracted tremendous attention due to recent discoveries of the Weyl semimetal state, large unsaturated magnetoresistance, and superconductivity in these materials. Mo$_x$W$_{1-x}$Te$_2$ is reported to be a Weyl semimetal with x = 0.25 and Weyl semimetal states are also predicted to exist in other doping. We carried out systematic high pressure measurements on Mo$_x$W$_{1-x}$Te$_2$ single crystals with doping via homemade BeCu clamp cells. High-quality single crystals of Mo$_x$W$_{1-x}$Te$_2$, with x = 0.25, 0.60, 0.90, were grown by chemical vapor transport method which were then characterized by X-ray diffraction and energy dispersive X-ray spectroscopy. In Mo$_{0.25}$W$_{0.75}$Te$_2$, a structural transition was observed under pressure 12.3 kbar with no signature of superconductivity at temperature down to 1.3 K and under pressure up to 17 kbar. In Mo$_{0.60}$W$_{0.40}$Te$_2$ and Mo$_{0.90}$W$_{0.10}$Te$_2$, structural transitions were observed at ambient pressure. Superconductivity appears in Mo$_{0.60}$W$_{0.40}$Te$_2$ with an onset T$_c$ of 1.7 K under 8.4 kbar and in Mo$_{0.90}$W$_{0.10}$Te$_2$ with an onset T$_c$ of 1.4 K under 3.9 kbar. T$_c$ continuously increases as pressure increases up to 17 kbar, the highest pressure we applied. Measurements under higher pressure range using diamond anvil cells are in progress.

Session A15 DMP: 2D Materials (Semiconductors) -- Monolayers BCEC 154 - Vinod Sangwan, Northwestern University
8:00AM A15.00001: Shortwave Coulomb excitations and local-field effects in monolayer transition-metal dichalcogenides.*  
HANAN DERY (Presenter), DINH VAN TUAN, University of Rochester, BENEDIKT SCHARF, Physics, university of Wuerzburg, IGOR ZUTIC, Physics, State University of New York at Buffalo — Many-body interactions in monolayer transition-metal dichalcogenides are strongly affected by local-field effects and their spin-split band structure. The former is caused by a strong contribution of umklapp processes to Coulomb excitations between the time-reversed valleys, where the effect is stronger for conduction-band electrons because of the nature of their atomic orbital. As a result, the blueshift of the neutral exciton, $X_0$, in electron-doped samples can be larger than 10 meV when the electron density increases from 0 to $5 \times 10^{12}$ cm$^{-2}$, while the blueshift in hole-doped samples is nearly absent. We develop an analytical theoretical model that elucidates the important role played by intervalley plasmons and local-field effects. We compute the energy shift of $X_0$ as a function of charge density and show that similar to experiment, the blueshift is evident only in electron-doped conditions, and that it is stronger in MoSe$_2$ than in WSe$_2$ due to differences in their band ordering and direct vs indirect exciton energies. In addition, the theory elucidates the observed emergence of exciton-plasmon peak in electron-doped WSe$_2$.

8:12AM A15.00002: Impact of dielectric environment on exciton binding energy in monolayer WS$_2$ and WSe$_2$*  
WEI-TING HSU (Presenter), JIAMIN QUAN, CHUN YUAN WANG, Department of Physics, The University of Texas at Austin, USA, LI-SHUAN LU, WEN-HAO CHANG, Department of Electrophysics, National Chiao Tung University, Taiwan, XIAOQIN (ELAINE) LI, CHIH-KANG SHIH, Department of Physics, The University of Texas at Austin, USA — The large exciton binding energy in monolayer transition metal dichalcogenides (TMDs) was determined recently. The robust excitons open a venue to explore the exciton physics such as Bose-Einstein condensation at room temperature. Recent reports further demonstrated the Coulomb engineering via dielectric environment based on a few-layer graphene. However, due to the conducting nature, quenching of optical transitions is often unavoidable. Thus, it is desirable to show the tunability using insulating dielectrics. Here we investigate the impact of dielectric environment on exciton binding energy and quasiparticle bandgap in monolayer WS$_2$ and WSe$_2$ by exciton Rydberg spectroscopy. The dielectric constant is systematically varied from $\kappa = 1.49$ to 3.82. We found that, with increasing $\kappa$, the exciton binding energy and quasiparticle bandgap exhibit significant reductions. We found the model using nonlocally-screened Keldysh potential captures the results very well. Our work validates the applicability of Keldysh model which can be used to design TMD-based optoelectronic devices in different dielectric media.

8:24AM A15.00003: Band Symmetries in Two-Dimensional Materials*  
EDWARD ARIS FAJARDO (Presenter), ROLAND WINKLER, Northern Illinois University — The symmetries of the energy bands are of fundamental importance for understanding many properties of a material. Here we develop a general scheme to determine the irreducible representations of Bloch functions for a given wave vector. Using a tight-binding picture and exploiting the fact that the atomic orbitals are localized in the vicinity of the atomic sites, we demonstrate that this problem can be factorized into one characterizing the atomic orbitals times one characterizing the crystal-periodic plane waves. Each of these subproblems permits a universal classification, independent of the details of a particular crystal structure. We apply this general scheme to two-dimensional materials including transition metal dichalcogenides (such as MoS$_2$, WS$_2$, MoSe$_2$, and WSe$_2$) and few-layer graphene. We demonstrate that the irreducible representations characterizing the energy bands are not always uniquely determined by the symmetry of a crystal structure. However, we also show that this ambiguity does not affect observable physics such as selection rules or the effective Hamiltonians for Bloch states that can be derived by means of the theory of invariants.

8:36AM A15.00004: Direct observation and gate manipulation of dark trions in monolayer WSe$_2$  

CHUN HUNG LUI (Presenter), JEREMIAH VAN BAREN, University of California, Riverside, ZHENGGUANG LU, National High Magnetic Field Laboratory, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, DMITRY SMIRNOV, National High Magnetic Field Laboratory, CHUN HUNG LUI, University of California, Riverside — Dark trions, the bound states between a dark exciton and an electron (hole), are intriguing entities with novel applications, because their long lifetime and finite net charge allow us to efficiently control the excitonic dynamics by electric field. Detection of dark trions is, however, exceedingly challenging due to their optical inactivity. Prior research required indirect detection techniques, such as altering their spins with in-plane magnetic field and coupling to surface plasmons. Here we report the direct observation and gate manipulation of intrinsic dark trions in monolayer WSe$_2$. By using ultraclean WSe$_2$ devices encapsulated by boron nitride, we can directly resolve the weak photoluminescence of spin-forbidden dark trions and continuously tune between negative and positive charged dark trions with electrostatic gating. We also reveal their spin triplet configuration and distinct valley emission by their characteristic Zeeman splitting under magnetic field. The dark trions exhibit large binding energy (14-16 meV) and narrow line width (2.5 meV), signifying their high stability and long lifetime. Such robust and directly detectable dark trions provide a crucial component to realize electrically controllable trion transport in two-dimensional materials.

8:48AM A15.00005: Observation of trion Rydberg states in monolayer MoSe$_2$  

CHUN HUNG LUI (Presenter), ERFU LIU, JEREMIAH VAN BAREN, University of California, Riverside, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, HONGYI YU, WANG YAO, Department of Physics and Center of Theoretical and Computational Physics, University of Hong Kong, ZHENGGUANG LU, DMITRY SMIRNOV, National High Magnetic Field Laboratory — Trions in monolayer transition metal dichalcogenides (TMDs) attract much attention due to their large binding energy (20 ~ 50 meV). The high stability of trions makes them possible to form excited states. Here we report the observation of trion Rydberg states in monolayer TMD. By measuring the photoluminescence of ultraclean boron-nitride-encapsulated MoSe$_2$, we reveal the first and second excited states of trions. The excited-state trions exhibit much stronger interaction with the Fermi sea as well as higher valley polarization and coherence than the ground-state trions. The results reveal rich physics of few-body quantum states in two-dimensional systems.

9:00AM A15.00006: The Born-Oppenheimer approximation in graphene: A time-dependent perspective*  

VAIBHAV MOHANTY (Presenter), ERIC JOHNSON HELLER, Harvard University — In graphene, electron-phonon interactions are known to play an important role in the loss of electronic wavefunction character and relaxation processes following photoexcitation. We model electronic interactions with nuclear vibrations from a microscopic, time-dependent perspective. Utilizing a time-dependent tight-binding Hamiltonian for the electronic degrees of freedom, we numerically determine the time-evolved electronic wavefunction in the presence of classical nuclei vibrating along normal modes. We examine the solutions by comparing them to those predicted within the adiabatic Born-Oppenheimer (ABO) approximation. We find that, for electronic states on energetically isolated potential energy surfaces, the adiabatic Born-Oppenheimer (ABO) approximation offers an accurate picture of time-evolution. But, in the presence of avoided crossings, the ABO approximation quickly breaks down as the electronic wavefunction becomes a superposition of ABO basis states. Moreover, electronic character is preserved over several vibrational periods for a finite lifetime, indicating highly diabatic time-evolution.

*Research supported in part by the Harvard Program for Research in Science and Engineering and the Herchel Smith-Harvard Undergraduate Science Research Program.

9:12AM A15.00007: Transport and photoluminescent characterization of high-quality single layer WSe$_2$ devices  

KATERYNA PISTUNOVA (Presenter), LUIS JAUREGUI, ANDREW Y JOE, KRISTIAAN DE GREVE, ANDREY SUSHKO, Harvard University, DANIEL A RHODES, JAMES HONE, Columbia University, HONGKUN PARK, MIKHAIL LUKIN, PHILIP KIM, Harvard University — Single layer semiconducting transition metal dichalcogenides (TMD) are direct band gap semiconductors that exhibit a variety of novel phenomena, ranging from valley hall effect to highly correlated electron physic. However, the transport studies of many of these phenomena have been hindered by low mobility, defective TMD materials. While the defect density of commercially grown TMD can be higher than 0.1%, in this work we use flux grown TMD samples with defect density significantly reduced to 0.01%. We report unprecedentedly high hole mobility values of up to 30,000 cm$^2$/V.s in single layer (1L) WSe$_2$ encapsulated in between hBN single crystals. Unlike that of conventional semiconductors, mobility of flux grown WSe$_2$ devices increases with reduced carrier density, indicating that mobility is not dominated by charged impurities. We find the quantum scattering time, $\tau_q$, to be ~400 ps, similar to $\tau_q$ in graphene devices. Moreover, by preforming photoluminescence spectroscopy, we find extremely sharp exciton linewidth (>1 meV) and other optical features such as dark excitons and biexcitons.
The stable trion states in 2D WSe$_2$ monolayer

SHALVA TSIKLAURI (Presenter), Science, The City University of New York-BMCC, ROMAN KEZERASHVILI, Physics, City Tech and Graduate Center The City University of New York — We study the binding energies of negatively (two electron and one hole) and positively (one electron and two holes) charged trions in suspended two-dimensional monolayer of WSe$_2$ in the framework of effective-mass model by employing the method of hyperspherical harmonics in configuration space [1,2]. The binding energies of trions are calculated using the Ritova-Keldysh potential. Trion fine structure based on formation of intravalley trions in spin singlet (S=1/2) state and intervalley trions in triplet (S=3/2) state is addressed. Our calculations show that those state are stables. To understand the importance of dielectric screening on the formation of trions, we perform calculations of the binding energy for WSe$_2$ placed in three different dielectric environments: supported on an SiO$_2$ substrate, supported on an h-BN substrate, and encapsulated by h-BN, and compare these results with the case of suspended WSe$_2$ binding energy. The analysis and comparison of our results for the binding energies of trions with those calculated via different theoretical methods and experimental data are presented.

Revealing the Unusual Excitonic Complexes in BN Encapsulated Monolayer WSe$_2$

ZHIPENG LI (Presenter), TIANMENG WANG, Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute, ZHENGUANG LU, Department of Physics, Florida State University, CHENHAO JIN, Physics Department, University of California, Berkeley, YANWEN CHEN, YUZE MENG, ZHEN LIAN, Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute, TING CAO, Geballe Laboratory for Advanced Materials, Stanford University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, SHENGBAI ZHANG, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, DMITRY SMIRNOV, National High Magnetic Field Lab, SUFEI SHI, Department of Chemical and Biological Engineering, Rensselaer Polytechnic Institute — Strong Coulomb interactions in single-layer transition metal dichalcogenides (TMDs) result in the emergence of strongly bound excitons, trions and biexcitons. These excitonic complexes possess the valley degree of freedom, which can be exploited for quantum optoelectronics. However, in contrast to the good understanding of the exciton and trion properties, the binding energy of the biexciton remains elusive, with theoretical calculations and experimental studies reporting discrepant results. In this work, we present the high-quality low-temperature photoluminescence (PL) spectra of BN encapsulated monolayer WSe$_2$, which directly reveals the biexciton state only exists in charge neutral WSe$_2$ and one free electron binds to a biexciton and forms the trion-exciton complex, the binding energy is $\sim$17 meV and $\sim$49 meV for biexciton and trion-exciton complex, respectively. The magneto-PL also reveals unambiguous evidence of the dark exciton. The improved understanding of the biexciton, trion-exciton complexes and other excitonic complexes improve our understanding of the many-body interaction in TMDs, promising novel application in low-dimensional quantum optoelectronics.

Edge states of two-dimensional materials

GEORGIOS KOPIDAKIS (Presenter), GEORGIOS VAILAKIS, DAPHNE DAVELOU, IOANNIS N. REMEDIAKIS, Materials Science and Technology, University of Crete — Single layers of atomic thickness such as graphene, molybdenum disulfide and other transition metal dichalcogenides (TMDs) display unique electronic properties which depend on composition, dimensionality, strain, defects, chemical modification and nanostructurering, so that they may be engineered for specific applications. Intensive efforts to use two-dimensional (2D) materials in a wide range of technologies highlight the importance of edges in nanoribbons and nanoflakes. We will present theoretical results based on density functional theory calculations combined with simple models which clarify the effect of strain on TMD electronic and dielectric properties [1], the role of the metallic edge states in these otherwise semiconducting materials, especially in quasi-1D and 0D systems, and nanostructure stability [2]. The common origin of the edge states in TMD and graphene nanoribbons, as well as their main differences, will also be discussed.

*Financial support from the Research Committee of the University of Crete (KA 10120) is gratefully acknowledged.
10:00 AM A15.00011: Quasiparticle and optical properties of hexagonal boron nitride: from monolayer to bulk *
WEIYI XIA (Presenter), University at Buffalo, The State University of New York, WEIWEI GAO, Center for Computational Materials, University of Texas at Austin, PEIHONG ZHANG, University at Buffalo, The State University of New York — Hexagonal boron nitride (h-BN), an emerging building block for van der Waals heterostructures, has become a research focus in recent years. Interesting, some of the most fundamental aspects of this material are still not fully understood. For example, there are still debates on whether the fundamental band gap of bulk h-BN is direct or indirect, and, to the best of our knowledge, the quasiparticle band gap of monolayer h-BN has not been accurately determined. In this talk, we will present fully converged GW+BSE results for monolayer, bilayer and bulk h-BN, aiming to resolve some of the controversies and illustrate the effects of dielectric screening and interlayer interaction on the quasiparticle and optical properties of this material.

*This work is supported in part by the NSF (Grant No. DMR-1506669 and DMR-1626967) and NSFC (Grant No. 11328401 and 11628407).

10:12 AM A15.00012: Origins of spectral doublets from 2D semiconductors embedded in optical microcavities *
TREVOR LAMOUNTAIN (Presenter), Applied Physics Program, Northwestern University, Evanston, IL, United States, HONGFEI ZENG, Physics and Astronomy, Northwestern University, Evanston, IL, United States, PUFAN LIU, Materials Science and Engineering, Northwestern University, Evanston, IL, United States, NATHANIEL STERN, Physics and Astronomy, Northwestern University, Evanston, IL, United States — Recent progress embedding atomically-thin materials such as monolayer transition metal dichalcogenides (TMDs) in microcavities has enabled applications such as nanolaser devices as well as novel regimes of polarization-sensitive exciton-polaritons [1]. Compared to the highly optimized III-V semiconductors typically used in microcavities, TMDs exhibit significantly more spatial inhomogeneity as well as additional tears, strains, and chemical contaminants introduced by the mechanical layer transfer process. We show how the spatial inhomogeneity of WS2 and MoS2 can produce spectral doublets that mimic the upper and lower polariton branches. We identify common pitfalls for misidentifying these doublets, as well as more robust measurements that can be used to distinguish the anti-crossing feature of exciton-polaritons.

*Work supported by the U.S. Department of Energy (BES DE-SC0012130) and the NSF MRSEC program (DMR-1720139).

10:24 AM A15.00013: Quantum yield engineering of quantum emitters in WSe2 by deterministically coupling to plasmonic nanocavities
YUE LUO (Presenter), GABRIELLA D. SHEPARD, Stevens Institute of Technology, JENNY V. ARDELEAN, DANIEL A RHODES, BUMHO KIM, KATAYUN BARMAK, JAMES HONE, Mechanical Engineering, Columbia University, STEFAN STRAUF, Stevens Institute of Technology — Solid-state single-quantum emitters are important resources for on-chip photonic quantum technologies. Efficient cavity-emitter coupling is required to realize quantum networks application. Recent studies explored the scalability aspect via spatially defined stressors to create quantum emitters from monolayer transition metal dichalcogenide semiconductor. Yet the low quantum yield of those quantum emitters is a crucial challenge to any real applications. Here we present a deterministic approach to achieve Purcell-enhancement at lithographically defined locations using the sharp corners of a Au nanocube for both electric field enhancement and to deform a two-dimensional material. This nanoplasmatic platform allows for studying the same quantum emitter before and after coupling. We reached record high quantum yield to near-unity in combination with flux grown high quality material that has naturally low non-radiative defect centers1.

10:36AM A15.00014: Electronic Dipole Spin Resonance of 2D Semiconductor Spin Qubits  MATTHEW BROOKS
(Presenter), GUIDO BURKARD, University of Konstanz — Monolayer transition metal dichalcogenides (TMDs) offer a novel two-
dimensional platform for semiconductor devices. One such application, whereby the added low dimensional crystal
physics (i.e. optical spin selection rules) may prove TMDs a competitive candidate, is quantum dots as qubits. The band
structure of TMD monolayers offers a number of different degrees of freedom and combinations thereof as potential
qubit basis, primarily electron spin, valley isospin and the combination of the two due to the strong spin orbit coulping
known as a Kramers qubit. Pure spin qubits in monolayer MoX$_2$ (where $X = S$ or Se) have been shown to be achievable by
energetically isolating a single valley and tuning to a spin degenerate regime within that valley by a combination of a
sufficiently small quantum dot radius and large perpendicular magnetic field. Within such a TMD spin qubit, we
theoretically induce and analyse single qubit rotations with an electric dipole spin resonance. We employ a rotating wave
approximation within a time dependant Schrieffer-Wolf approximation to derive analytic expressions for the Rabi
frequency of single qubit oscilations, and compare this result to more exact numerics, as to find optimal operational
regimes.

10:48AM A15.00015: Magneto-spectroscopy probe of exciton-electron interactions in monolayer MoSe$_2$
ZHENGGUANG LU (Presenter), National High Magnetic Field Laboratory, ZHIPENG LI, TIANMENG WANG, YUZE MENG, Rensselaer
Polytechnic Institute, YUXUAN JIANG, National High Magnetic Field Laboratory, SUFEI SHI, Rensselaer Polytechnic Institute, DMITRY
SMIRNOV, National High Magnetic Field Laboratory — Coulomb interaction driven many-body effects are expected to modify
significantly the quasiparticles properties in monolayer transition metal dichalcogenides at high carrier densities. Here we
report on low temperature magneto-photoluminescence and broadband reflection contrast measurements on high
quality monolayer MoSe$_2$ over a wide doping range. A valley g-factor around 4 is measured in the low-density regime,
which is consistent with the value deduced from the single particle picture. As the carrier density increases, one can access
the strongly interacting regime and observe a pronounced change of the valley magnetic response. The observed strong
modification of the valley g-factor in highly doped MoSe$_2$ will be discussed and compared to the previously reported
results on WSe$_2$ [1].

Monday, March 4, 2019 8:00 AM - 11:00 AM

Session A16 DMP: Transport in Nanostructures -- Thin Films, Heterostructures and
Nanodevices  BCEC 155 - Jean Heremans, Virginia Tech - Tag(s): Focus

8:00AM A16.00001: Pascal-liquid phases in ballistic one-dimensional LaAlO$_3$/SrTiO$_3$ channels* [Invited]  JEREMY LEVY
(Presenter), MEGAN BRIGGEMAN, MICHELLE TOMCZYK, BINBIN TIAN, University of Pittsburgh, HYUNGWOO LEE, JUNG-WOO
LEE, University of Wisconsin-Madison, YUCHI HE, Carnegie Mellon University, ANTHONY TYLAN-TYLER, MENGCHEN HUANG,
University of Pittsburgh, CHANG-BEOM EOM, University of Wisconsin-Madison, DAVID PEKKER, ROGER MONG, PATRICK IRVIN,
University of Pittsburgh — The challenge of understanding strongly interacting composite fermionic phases of matter spans
many fields in physics, ranging from neutron stars to solid-state materials to quark-gluon plasmas. We report
experimental evidence of a new family of degenerate quantum liquids formed from bound states of $n = 2, 3, 4, ...$
 electrons, which are stabilized within quasi-one-dimensional electron waveguides formed at the LaAlO$_3$/SrTiO$_3$ interface.
The key signature of this phase is the existence of quantized conduction that follows a characteristic sequence within
Pascal's triangle: (1, 3, 6, 10, 15,...), where is the electron charge and is the Planck constant. The ability to create and
investigate composite fermionic phases opens new avenues for the investigation of strongly correlated quantum matter.

YANG HU (Presenter), YUHE TANG, DENGYU YANG, YUN-YI PAI, JIANAN LI, University of Pittsburgh, HYUNGWOO LEE, JUNG-WOO LEE, CHANG-BEOM EOM, University of Wisconsin–Madison, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — The 2D electron gas at the LaAlO$_3$/SrTiO$_3$ interface can be patterned using conductive atomic force microscope (c-AFM) lithography [1], which has been used to create quantum dots and single electron transistors [2]. We aim to use this technique to create an on-demand single-electron source by sketching a linear array of quantum dots and applying out-of-phase excitation across the dot array. We will discuss both double-dot and triple-dot devices and their associated electron tunneling phenomenon and issues related to the individual tunabilities of the dots.

*JL acknowledges a Vannevar Bush Faculty Fellowship, funded by ONR (N00014-15-1-2847). C-BE acknowledges support from NSF DMREF (DMR-1629270), AFOSR (FA9550-15-1-0334), and AOARD (FA2386-15-1-4046).
9:24AM A16.00006: Stark Control of Electrons Across Interfaces*  ANTONIO GARZÓN-RAMÍREZ (Presenter), IGNACIO FRANCO, University of Rochester — We introduce a laser control scenario to transiently transform an insulating heterojunction into a conducting one on a femtosecond timescale. The scenario is based on opening Landau-Zener quantum tunneling channels for electron transfer between two adjacent semiconductors via Stark shifts induced by non-resonant lasers of intermediate intensity (non-perturbative but non-ionizing). Through quantum dynamics simulations we demonstrate the robustness of the approach and its utility for controlling electron dynamics at interfaces.

*This material is based on the work supported by the National Science Foundation under No. CHE-1553939.

9:36AM A16.00007: Photothermoelectric effects at and near individual grain boundaries in gold*  CHARLOTTE EVANS (Presenter), Physics and Astronomy, Rice University, RUI YANG, RACHEL TRAYLOR, Electrical Engineering, Stanford University, MAHDIYEH ABBASI, Electrical and Computer Engineering, Rice University, XIFAN WANG, Materials Science, Rice University, STEPHANIE BOHAICHUK, JONATHAN FAN, Electrical Engineering, Stanford University, DOUGLAS NATELSON, Physics and Astronomy, Rice University — Thermoelectricity is best known for thermocouples, where a voltage is generated when heating the interface of two materials with different Seebeck coefficients. In metals, the electronic Seebeck coefficient depends on the electrical conductivity which can be manipulated at the nanoscale to create single metal thermocouples. We will present scanning photothermoelectric measurements of the simplest single metal thermocouple: a single grain boundary between two single-crystal gold nanowires. Unlike a traditional thermocouple, where heating the grain boundary results in the largest voltage, the photovoltage as a function of laser position changes polarity at the grain boundary, varying on length scales much larger than the laser size. Modeling suggests that these results are consistent with long-scale Seebeck coefficient gradients within the crystals. Electron back-scatter diffraction relates the voltages to the relative crystallographic orientation across the boundary and x-ray probes provide insight of strain within the device. We propose how thermovoltages can probe areas of impurities, strain, and other intrinsic irregularities that may not otherwise be detected using traditional electronic transport measurements.

*Robert A. Welch Foundation award C-1636, and NSF ECCS-1704625

9:48AM A16.00008: Hierarchical Kinetics in 1/f Noise in Amorphous and Nanocrystalline Semiconductor Thin Films*  BRENDA KNAUBER (Presenter), School of Physics and Astronomy, University of Minnesota, MOHAMMAD ALI ESLAMISARAY, Department of Mechanical Engineering, University of Minnesota, JAMES KAKALIOS, School of Physics and Astronomy, University of Minnesota — We report studies of conductance fluctuations in hydrogenated amorphous germanium (a-Ge:H) that have an inverse frequency (1/f) spectral density with non-Gaussian statistics, as reflected in (1) histograms of the noise power per octave that are not described by Gaussian distributions, (2) strong correlations of the noise power in frequency-space and (3) power-law second spectra. In particular, histograms of the 1/f noise power per octave for a-Ge:H are well described by a log-normal distribution. The correlation coefficients across frequencies are non-zero and larger than expected for independently modulated fluctuators, and grow with averaging time with a logarithmic time-dependence. In contrast, the 1/f noise for polycrystalline Ge, and free-standing nanocrystalline thin films display Gaussian statistics. These results are discussed in terms of a model of filamentary conduction, where the conductance is modulated by hydrogen motion governed by hierarchical kinetics.

*This work was partially supported by NSF grants DMR-1608937 and PHYS-1344251, the NINN Characterization Facility, the Minnesota Nano Center and the University of Minnesota.
10:00AM A16.00009: Quantum dynamics of single-photon detection using functionalized quantum transport
electronic channels*  CATALIN SPATARU (Presenter), FRANCOIS LEONARD, Sandia National Laboratories California — Single photon detectors have historically consisted of macroscopic-sized materials, but recent experimental and theoretical progress opens new approaches based on nanoscale and molecular electronics. Here we present a theoretical study of photodetection in a system composed of a quantum electronic transport channel functionalized by a photon absorber. Notably, the photon field, absorption process, transduction mechanism, and measurement process are all treated as part of one fully-coupled quantum system, with explicit interactions. Using non-equilibrium, time-dependent quantum transport simulations, we reveal the unique temporal signatures of the single photon detection process, and show that the system can be described using optical Bloch equations, with a new non-linearity as a consequence of time-dependent detuning caused by the back-action from the transport channel. We compute the photodetector signal-to-noise ratio and demonstrate that single photon detection is possible for realistic parameters.

*This research was developed with funding from the Defense Advanced Research Projects Agency. Sandia National Laboratories is a multimission laboratory managed by NTI, a wholly owned subsidiary of Honeywell International, Inc., for the US DOE’s NNSA under contract DE-NA-0003525.

10:12AM A16.00010: Cross-plane thermal conductance of Au/graphene/Au heterojunction*  XIAOHUI QIU (Presenter), Chinese Academy of Sciences — Thermal management has become a critical issue for microelectronics, as the characteristic sizes of these devices shrink into the nanometer region. Interesting phenomena were observed for heat conduction through ultrathin interfacial layers, such as thickness dependent thermal boundary conductivity. Here, we use the Frequency Domain Thermoreflectance technique to investigate the heat conduction across the heterojunction composed of few-layer graphene as the interfacial layer between gold. By varying the graphene layer number to control the thickness of the interfacial layer, we measure the thickness dependent thermal conductance across this sandwiched structure. We found that electron transmission dominates the thermal conductance for monolayer graphene, and a two-orders of magnitude decrease in thermal conductance through bilayer graphene. For more layers graphene, phonon thermal conductivity is suggested to be the major contributor.

*This work was supported by the National Natural Science Foundation of China (Project No. 21425310) and CAS-PKU Pioneer Cooperation Team.

10:24AM A16.00011: Quantum oscillations under photoexcitation involve direct and indirect excitons and quantum photocapacitance in GaAs/AlAs/InAs p-i-n diode*  AMIT BHUNIA ( Presenter), Department of Physics, Indian Institute of Science Education and Research, Pune, India, MOHAMED HENINI, School of Physics and Astronomy, University of Nottingham, SHOUVIK DATTA, Department of Physics, Indian Institute of Science Education and Research, Pune, India — We explore the quantum dynamics at the interface of a single barrier GaAs/AlAs p-i-n device having InAs quantum dots embedded inside AlAs layer. We observe systematic quantum oscillations in photocapacitance measurements when the sample is optically excited at 10 K. Two sharp peaks in the photocapacitance spectra imply the presence of direct and indirect excitons formed inside the InAs quantum dot and at the interface of quantum dot and the triangular GaAs quantum well, respectively. Spectral peak shifts with increasing applied bias complies with the change of energy levels of triangular quantum well due to effective electric field. Presence of two-dimensional electron and hole gases near the GaAs/AlAs interface certainly point towards the involvement of quantum capacitance. In addition, we also discuss how the formation of excitonic dipoles affects such quantum capacitance. Moreover, periodic variation of negative differential resistance in photocurrent oscillations also correlate with photoconductance oscillations. Understanding the quantum dynamics of carriers involving quantum capacitance and negative differential resistance will help us to explain the many-body physics of these interfacial excitons and its applications.

*AB thankful to DST, India for Inspire PhD Fellowship.
non-classical noise and light emission of an ac-driven tunnel junction  HONGXIN ZHAN (Presenter), GIANLUCA RASTELLI, WOLFGANG BELZIG, Fachbereich Physik, Universitaet Konstanz — The non-symmetrized noise is crucial for the analysis of light emission in nanojunctions. The latter represent non-classical photon emitters whose description requires a full quantum approach [1]. It was found experimentally that light emission can occur with a photon energy exceeding the applied dc voltage [2], which intuitively should be forbidden due to Pauli principle. This overbias light emission cannot be described by the single-electron physics, but can be explained by 2-electron or even 3-electron process, correlated by a local antenna mode in analogy to the well-known dynamical Coulomb blockade (DCB) [3]. Here, we obtain the non-symmetrized noise for junctions driven by an arbitrarily shaped periodic voltage. We find that when the junction is driven, overbias light emission occurs and exhibits intriguing different features compared to the dc case. For example, multiple peaks appear at integers of the ac driving frequency. Our work generalizes the DCB theory to light emission in driven tunnel junctions and opens the avenue to engineered quantum light sources, which can be tuned purely by applied voltages.

Long-Range Frictional Drag in Coupled LaAlO3/SrTiO3 Nanowires*  YUHE TANG (Presenter), ANTHONY TYLAN-TYLER, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, JUNG-WOO LEE, Department of Materials Science and Engineering, University of Wisconsin-Madison, MICHELLE TOMCZYK, MENGCHEN HUANG, Department of Physics and Astronomy, University of Pittsburgh, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — Frictional drag, where current in one nanowire induces a voltage across a nearby nanowire, is a powerful tool to study electron interactions. Here we investigate long-range electron interactions in coupled nanowires at the LaAlO3/SrTiO3 interface via frictional drag. In the normal state (B > 0.3T) regime, the antisymmetric drag resistance of double-wire devices is independent of their separation, ruling out the Coulomb interaction as the dominant coupling mechanism. In triple-wire devices this separation independence is corroborated. In the superconducting (B < 0.3T, T < 300mK) regime, a symmetric component is identified in the drag resistance and its separation independence also shows the coupling is predominantly non-Coulombic. These results provide strong evidence for a new long-range non-Coulombic electron interaction that must be accounted for in description of electron transport at oxide interfaces.

Session A17 DCOMP: Matter in Extreme Environments: Energetic Materials  BICEC 156A - Maosheng Miao, California State University, Northridge - Tag(s): Focus

Scalable Atomistic Simulations of Energetic Materials*  [Invited] AIICHIRO NAKANO (Presenter), RAJIV KALIA, PRIYA VASHISHTA, University of Southern California — We have developed an extension of the divide-and-conquer algorithmic framework called divide-conquer-recombine to make quantum molecular dynamics (QMD) and reactive molecular dynamics (RMD) simulations scalable on emerging exascale supercomputers and beyond. On today's supercomputing platform, for instance, the framework has achieved over 98% of the perfect speedup on 786,432 IBM Blue Gene/Q processors for 40 trillion electronic degrees-of-freedom QMD in the framework of density functional theory and 68 billion-atom RMD. Production simulations on energetic materials include: (1) dynamic phase transition, crossover in anisotropic mechanochemistry and multistage reaction pathways in energetic crystals; and (2) reaction dynamics and enhanced energetic performance of metallic-nanoparticle/graphene composites.

*Part of the work was supported by the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award Number DE-SC0014607.
Detonation on a tabletop in nitromethane: effects of sensitizers and desensitizers

MITHUN BHOWMICK (Presenter), ERIN J NISSEN, DANA DLOTT, University of Illinois at Urbana-Champaign — We have developed a method to study shock to detonation process on a tabletop with high temporal and spatial resolution. Here we present effects of additives on nitromethane (NM) detonation studied with optical pyrometry, photon doppler velocimetry, and high-speed video photography. Addition of ethylenediamine (EDA, 1% by wt.) reduces the detonation threshold from 20 GPa to 14 GPa of input pressures, while addition of acetone (up to 30% by wt.) inhibits the reaction and detonation is not at all observed for up to 20 GPa input pressure. With the help of optical pyrometry and high-speed videos, thermal properties of emission from the above mixtures were probed. Detonation experiments often measure the detonation shock wave using an optical window contacted to the explosive. We measured NM detonation in 9 different window materials and found that polycrystalline materials such as LiF are somewhat better than glasses, and both are much better than polymers, reported in earlier works.

Sub-nanosecond carbon condensation under ultrafast shock compression of cryogenic liquid carbon monoxide

MICHAEL ARMSTRONG (Presenter), REBECCA LINDSEY, NIR GOLDMAN, I-FENG W. KUO, TIAN LI, ELISSAIOS STAVROUL, JOSEPH MICHAEL ZAUG, SORIN BASTEA, Lawrence Livermore National Laboratory — The detonation of negative oxygen-balance explosives typically results in the formation of carbon condensates, including nano-onions and nano-diamonds. Although the production of carbon nano-condensates can occur via detonation, the carbon chemistry required to form such products does not require detonation chemistry per se: a negative oxygen-balance organic reactant and high pressure and temperature conditions are likely sufficient to condense nanocarbon. Furthermore, although carbon chemistry during detonation is thought to require 10-100s nanosecond time scales, simulations suggest that condensation of carbon can occur on nanosecond or sub-nanosecond time scales. To explore these fundamental issues, here we present the results of experiments and simulations of ultrafast shock compression of a simple negative oxygen-balance reactant, cryogenic liquid carbon monoxide.

Chemical behavior of strontium and magnesium oxalates at high-pressure

ISKANDER G BATYREV (Presenter), JENNIFER A CIEZAK-JENKINS, US Army Research Lab., Aberdeen Proving Ground, MD 21005, MICHAEL GOJKO PRAVICA, Department of Physicis, Univ. of Nevada Las Vegas, NV 89154 — We report theoretical and experimental investigations on the structure of strontium and magnesium oxalates at high-pressure. Both systems have shown progress in the generation of CO2 and in the synthesis of high-energy polymeric carbon monoxide after X-ray irradiation. It has been previously proposed that X-ray irradiation may facilitate photochemical reactions such as: SrC2O4 +hv -> SrCO3 +CO2 + poly-CO (MgC2O4 +hv -> MgO + CO2 + poly-CO) [1]. Density functional perturbation theory was used to calculate the zone center optical phonons and to identify the vibration modes in term of atomic displacements. The simulations were compared to previous EXAFS and IR spectroscopic studies [1] in an effort to elucidate the chemical structure. Additional calculations of the phonon dispersion and density of states, as well as the electronic band structure were performed to gain better insight into the phase behavior in strontium and magnesium oxalates.

Temperature evolution in plastic bonded explosives during impacts

NISHA MOHAN (Presenter), DARBY J LUSCHER, MARC CAWKWELL, KYLE J RAMOS, Los Alamos National Laboratory — The heterogeneous, polycrystalline structure of plastic-bonded explosives (PBX) leads to temperature localization under impacts. The thermo-mechanical responses of PBXs span processes from dislocation-mediated plasticity at small-scales to interfacial stress wave reflection and diffusion at higher scales. The thermal and deformation localization response under impact of a RDX/estane PBX have been studied using finite element simulations with ABAQUS. The modeling framework combines a dislocation-based, anisotropic, single crystal plasticity model with a visco-elastic constitutive model for estane. We systematically studied how heating arising from wave interactions and localized plasticity in the PBX depends on the impact velocity, slip resistance, grain orientation, position, and proximity to stress concentrators. The broadening of the shock front with increasing run distance by the microstructure of the PBX was found to play an important role in the evolution of temperature in the PBX. Grains with certain orientations produced higher temperatures and larger localized zones. Higher intrinsic resistance to slip restricts the dislocation density growth and thermal localization.
9:24AM A17.00006: Anisotropic Thermal Expansion of CL-20 Polymorphs from Ab initio Molecular Dynamics Simulations* IGOR SCHWEIGERT (Presenter), United States Naval Research Laboratory — Hexanitrohexaazaizowurtizane (CL-20) is a high-density nitramine compound with several known polymorphs. Anisotropic thermal expansion coefficients for different polymorphs are needed to model effects of polymorphic impurities during thermal cycling. In this presentation, I will describe density functional theory (DFT) based molecular dynamics simulations of temperature-dependent lattice constants of the epsilon and gamma polymorphs and compare the results to available experimental data as well as predictions from density functional tight binding and ReaxFF-based molecular dynamics simulations.

*This work was supported by the Office of Naval Research (ONR), both directly (project N0001416WX0003) and through the U.S. Naval Research Laboratory (NRL).

9:36AM A17.00007: High pressure structural study of TATB: Evidence of a structural phase transition.* ELISSAIOS STAVROU (Presenter), BRAD A STEELE, SAMANTHA CLARKE, JOSEPH MICHAEL ZAUG, MATTHEW KROONBLAWD, I-FENG W. KUO,SORIN BASTEA, LAURENCE FRIED, Lawrence Livermore Natl Lab, JESSE SMITH, HPCAT, X-ray Science Division, Argonne National Laboratory, VITALI PRAKAPENKA, ERAN GREENBERG, Advanced Photon Source - Sector-13, Argonne National Laboratory, OLIVER TSCHAUNER, Department of Geoscience, University of Nevada, Las Vegas — High pressure unreacted isothermal equations of state (EOS) for energetic materials are needed for accurate modeling of detonation and shock initiation. EOS determination through conventional powder X-ray diffraction (XRD) experiments is often problematic due to the low-Z of constituent elements (typically CHNO) and the low symmetry of the corresponding crystal structure. To overcome this barrier for TATB, we performed a concomitant powder and single crystal (SC) XRD study. Our SC XRD results reveal a structural phase transition, reported for the first time, towards a monoclinic C-centered structure above 4-5GPa. Experimental results are supported by calculations using the USPEX evolutionary crystal structure prediction algorithm. The phase transition involves a pressure-induced alteration of the stacking of the layers of the TATB molecules. This results to a higher crystal symmetry, from triclinic to monoclinic, without an abrupt change of the volume per formula unit.

*This work was performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Security, LLC under Contract DE-AC52-07NA27344. We thank the high explosives science campaign II research program at LLNL for supporting this study.

9:48AM A17.00008: WITHDRAWN ABSTRACT —

10:00AM A17.00009: Computational design of new fused heterocyclic energetic materials* MAIJA M KUKLA (Presenter), ROMAN TYSHEVSKIY, University of Maryland College Park, ALEKSANDR S. SMIRNOV, Bakhirev Scientific Research Institute of Mechanical Engineering — Linear oxadiazole-based energetic materials exhibit attractive performance and sensitivity characteristics compared to known conventional high energy density materials and are considered as appealing potential candidates to be used as explosives, propellants, and cast-melt ingredients in composite explosives. Despite all advantages of the oxadiazole-based compounds the improvements of their physical and chemical properties are bound by certain limits. It is impossible to create new material with significantly improved parameters by variation of oxadiazole rings within the linear molecule. A further step in enhancing explosive characteristics, i.e. higher performance and lower sensitivity, in heterocycles would be to probe a fused energetic molecules in which a stable (rigid) molecular core is functionalized with appropriate rings (or even combinations of rings). Here we report a systematic study that helps to reveal and optimize structure-property-function relationships in fused heterocyclic energetic materials. We show that arrangement of heterocyclic rings in fused molecules opens new opportunities for design new insensitive energetic materials with high performance.

*This work is funded by ONR (Grant N00014-16-1-2069). We used XSEDE, NERSC, MARCC and UMD supercomputing resources
Probing Equations of State and Novel Phases of Energetic Crystals via First Principles Simulations*  
BRAD A STEELE (Presenter), I-FENG W. KUO, Lawrence Livermore Natl Lab — Energetic crystals are widely used in military and industrial applications. Modeling the shock propagation and initiation of energetic materials rely on the unreacted equation of state which can vary greatly if there is a phase transition. Many current models do not include phase transitions which can be difficult to detect in experiment. Furthermore, most first-principles based models use density functional theory that gives a poor description of dispersion. In this work, pressure-induced phase transitions and equations of state of energetic crystals are investigated using first-principles based approaches ranging from density functional theory to post-Hartree-Fock perturbative methods that give a better description of dispersion. Novel high-pressure phases are probed using crystal structure prediction method USPEX. The feasibility of using perturbative and hybrid methods to predict phase transition pressures is investigated.

*This work was performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Security, LLC under Contract DE-AC52-07NA27344. Thanks to the Laboratory Directed Research and Development Program at LLNL for supporting this study under 18-SI-004.

Monday, March 4, 2019 8:00 AM - 10:24 AM

Session A18 DCOMP DCMP DAMOP: Machine Learning Material and Experimental Data I

8:00AM A18.0001: Unsupervised machine learning of single crystal x-ray diffraction data [Invited]  
JORDAN VENDERLEY (Presenter), MICHAEL MATTY, EUN-AH KIM, Cornell University — Data analysis has become a critical bottleneck in reciprocal spaces studies of single crystal x-ray diffraction. This is because while dramatic leaps in detector technology have enabled the collection of large amounts of data in short amounts of time, a parallel development in data analysis has been lacking. Current approaches for investigating this data often require highly devoted researchers to manually comb through it looking for evidence of new physics. This is time-intensive and increasingly infeasible as datasets continue to grow in size. Here we discuss an unsupervised machine learning approach to studying phase transitions in single crystal x-ray diffraction data. Our method leverages novel techniques for approximate Bayesian inference to identify contributions to the scattering intensity with distinct physical origins. It is highly scalable and employs recent developments in numerical linear algebra for memory efficiency and high speed on parallel computing hardware, such as graphical processing units.

8:36AM A18.0002: X-ray hyperspectral classification of the metal-insulator transition in NdNiO3  
WILLIAM ZHENG (Presenter), ALEXANDER SWINTON MCLEOD, Columbia University, KIRK W POST, University of California San Diego, MATTHIAS HEPTING, MARTIN BLUSCHKE, MATTEO MINOLA, ALEXANDER BORIS, EVA BENCKISER, Max Planck Institute Stuttgart, RAJESH V CHOPDEKAR, ANDREAS SCHOLL, LBNL Advanced Light Source, BERNHARD KEIMER, Max Planck Institute Stuttgart, DIMITRI BASOV, Columbia University — Rare-earth nickelates, such as NdNiO3, belong to a family of strongly correlated electron systems in which the electronic and magnetic properties are strongly coupled: NdNiO3 undergoes a temperature driven first-order Metal to Insulator phase transition (MIT) accompanied by charge-order and spin density wave-order phase transition. During the phase transition, the underlying evolution of the insulating domains are averaged out by the limited spatial resolution of conventional bulk probes but, soft X-ray photoemission electron microscopy (X-PEEM) can be applied in order to elucidate nanoscale heterogeneity. In this work we apply X-PEEM to image cooling and heating MITs and develop machine learning based analysis techniques, mainly Principle Component Analysis (PCA) and Independent Component Analysis (ICA) with k-means classification, to classify thermally evolving metallic and insulating domains. The performance of our suite of classifiers is evaluated in this novel application and we discuss their physical interpretation on the basis of charge ordering through the MIT. This class of tools can be applied to other experimental hyperspectral data to extract the characteristics of coexisting phases from otherwise intractably large datasets.
8:48AM A18.00003: Classifying Grazing Incidence X-ray Scattering Patterns via Convolutional Neural Networks*  
CHARLES MELTON (Presenter), Advanced Light Source, Lawrence Berkeley National Laboratory, SHUAI LIU, University of California Berkeley, ALEXANDER HEXEMER, Advanced Light Source, Lawrence Berkeley National Laboratory, DANIELA USHIZIMA, Lawrence Berkeley National Laboratory — Nano-structured thin films have a variety of applications, such as antireflecting coatings for solar cells, waveguides, gaseous sensors, and piezoelectric devices. Grazing-incidence small-angle X-ray scattering (GISAXS) has become a key technique to determine the morphologies of such thin films. One of the main challenges is to determine the structure information encoded in the data based on scattering patterns alone. We propose a computational scheme that learns the structure of well-defined layers of nanoparticles from GISAXS patterns. We explore this class of thin-film materials in terms of physics-based simulation models and experimental data and apply convolutional neural networks to the simulated data to obtain the encoded information of the morphology. Our classification models categorize millions of simulated scattering patterns with success rates over 94%. In addition, we show how these data-driven models have the potential to decrease analysis time of real scattering patterns from experiment.

*Supported by the Center of Advanced Mathematics for Energy Research Applications (CAMERA) through the Office of Science, DOE, No. DE-AC02-05CH11231, and the National Energy Research Scientific Computing Center (NERSC), No. DE-AC02-05CH11231.

9:00AM A18.00004: Deep learning X-ray Absorption Near Edge Spectra  
LIANG LI (Presenter), MARIA CHAN, Center for Nanoscale Materials, Argonne National Laboratory — The interpretation of core-level spectroscopy data, such as x-ray absorption, has long been a challenging problem. In this talk, we will discuss the use of deep learning for the interpretation of x-ray absorption near edge spectra (XANES). In this work, computed spectra using a Bethe-Salpeter Equation-based approach, of transition metal oxides, are used as the training set. Corresponding experimental data of the system will be interpreted using the trained neural networks. We will discuss, in addition, the hyperparameter tuning and optimization for bias-variance tradeoff.

9:12AM A18.00005: Using machine learning to predict local chemical environments from X-ray absorption spectra*  
DEYU LU (Presenter), Brookhaven National Laboratory, MATTHEW CARBONE, MEHMET TOPSAKAL, Columbia university, SHINJAE YOO, Brookhaven National Laboratory — X-ray absorption spectroscopy is an element-specific technique for materials characterization. Specifically, X-ray absorption near edge structure (XANES) encodes important information of the local chemical environment (LCE, e.g. coordination number, symmetry and oxidation state) of the absorber atom that is key to the understanding of the electronic and chemical properties of materials. As such, unraveling the LCE from XANES spectra is akin to solving a challenging inverse problem. Existing methods rely on empirical fingerprints, which are often qualitative or semi-quantitative and not transferable. In this study, we present a machine learning-based approach to classify the LCE's of eight 3d transition metal families from the simulated K-edge XANES of a large number of compounds. The machine learning classifier can learn important spectral features in a broad energy range without human bias and once trained, can make predictions on the fly. We found that the machine learning classifier can achieve about 85% accuracy across the wide chemical space.

*This research used resources of the Center for Functional Nanomaterials, which is a U.S. DOE Office of Science Facility, at Brookhaven National Laboratory under Contract No. DE-SC0012704.

LUDWIG HOLLEIS, BELLAVE SHIVARAM, PRASANNA BALACHANDRAN (Presenter), University of Virginia — Single molecule magnets (SMM) are candidate materials for magnetocaloric applications, high-density information storage, magnetic qubits, and spintronic devices. These molecules are made of several lanthanide and/or transition metal ions coordinated by organic ligands. Despite the progress made in experimental and traditional first-principles modeling efforts, lack of predictive design guidelines hinder rapid design of SMM for targeted applications. Here, we develop a machine learning approach for predicting novel SMM for magnetocaloric applications. We construct a database from surveying the published literature on magnetocaloric effect in SMM and develop a representation scheme that include aspects related to dimensionality, structure, local coordination environment, ideal number of spins of magnetic ions, ligands, and linking chemistry. We train machine learning models to predict the entropy change. The models capture successfully the observed trends and identify key variables that contribute to the entropy. We also predict new SMMs and await experimental validation.
A Classifier for Metal-Insulator Transitions*  

NICHOLAS WAGNER (Presenter), JAMES M RONDINELLI, Materials Science and Engineering, Northwestern University — We have assembled the largest dataset of resistivity-temperature measurements on temperature-activated metal-insulator transitions (MITs) to date (45 unique compounds). We supplemented this dataset with additional entries on metals and insulators with known transport behavior, i.e., do not undergo temperature-driven MITs, for comparison. We then use the 147 compounds to formulate a machine-learning model using features we collected, which describe chemical composition (e.g. mean electronegativity, atomic radii, and elemental heat of fusion); overall and local atomic structure; and estimates of the on-site electron repulsion, charge transfer energy, and compound polarizability. From this data, we constructed a machine-learning classifier to predict whether a material would undergo a MIT or not. Our model achieves a cross-validation AUC score of 88.24 +/- 11.63 and a mean accuracy of 79.23 +/- 9.23%. We also conducted a survey of 51 graduate students, faculty, and staff scientists to estimate the ability of scientists to perform this classification. The mean accuracy for humans was 59.8%.

Machine-learning model to predict adsorption energies in thiolated bimetallic nanoclusters  

GIHAN PANAPITIYA (Presenter), GUILLERMO AVENDANO FRANO, JAMES PATRICK LEWIS, West Virginia University — We developed a random forest based machine learning model to predict adsorption energies in Ag-alloyed thiolated gold nanoclusters. The features of this model are based only on the geometric properties of non-relaxed and adsorbate-free nanocluster. The features have been defined so that they can be applied to any nanocluster. Using Au_{25} system as a test case, we obtained prediction accuracies of 0.173 (RMSE) and 0.779 (R2). To show the applicability of our model to nanoclusters with different sizes and shapes, we also predicted adsorption energies in Au_{36} and Au_{133} nanoclusters. Our model can be used as a filtering tool to downselect nanoclusters with desired adsorption energies for further calculations.

Model Selection Based on Bayesian Inference that Uncovers Fundamental Dynamics of Desiccation Crack Patterns*  

SHIN-ICHI ITO (Presenter), The University of Tokyo, AKIO NAKAHARA, Nihon University, SATOSHI YUKAWA, Osaka University — We investigate dynamic properties of fragment size distribution in surface crack patterns observed on a thin layer of drying dense colloidal suspension experimentally and theoretically. The model selection analysis based on Bayesian inference reveals that the time-varying fragment size distribution observed in experiments exhibits a dynamic transition in its functional form from a lognormal distribution to a generalized gamma distribution. In order to explain this dynamic transition theoretically, we construct a statistical model based on an elastic theory that describes the dynamics of the shrinkage of the colloidal suspension owing to the desiccation. The statistical model predicts the existence of a characteristic length scale that determines the crossover of the dynamic transition, and reproduces the functional forms of fragment size distributions observed in experiments quantitatively.

A machine-learning approach to magnetic neutron scattering  

ROBERT TWYMAN, STUART J. GIBSON, University of Kent, JAMES MOLONY, University of Durham, JORGE QUINTANILLA (Presenter), University of Kent — One of the benefits of magnetic neutron scattering (NS) is that it can constrain the parameters of a pre-existing model Hamiltonian. Here we propose an unbiased approach that can be used before a model has been formulated. It combines Principal Component Analysis (PCA) with an artificial neural network (ANN). The PCA algorithm extracts the essential variables describing a set of NS cross-sections in an unsupervised way. The ANN then uses that information to learn to predict the cross-sections under different conditions, with supervision. To test our method, we apply it to simulated diffuse NS cross-sections obtained by exact diagonalisation of a previously-studied model of molecular magnets [H. R. Irons et al., PRB 96, 224408 (2017)]. Our main result is that the PCA can efficiently "discover" the number of fundamental parameters in the problem. The principal component scores capture key elements of the Physics including entanglement transitions. The ANN can then accurately predict NS cross-sections, confirming the validity of the PCA-based description. We conclude that PCA of NS data from real materials can be a powerful tool, specifically one capable of placing severe constraints on possible model Hamiltonians.

Session A19 DCOMP DAMOP: Precision Many Body Physics | BCEC 156C - Tag(s): Focus
8:00AM A19.00001: Enhanced metrology using quantum-correlated matter* [Invited] ANA MARIA REY (Presenter), JILA, NIST and University of Colorado at Boulder — The best clock in the world has no hands, no pendulum, no digital display. It is made of ultra-cold atoms trapped in a crystal of light.

To date, this clock is the most precise table-top instrument built by humankind; had it begun ticking when the Earth first formed billions of years ago, it would not have gained or lost a second. Even so, current atomic clocks still use collections of independent atoms, and are fundamentally limited in precision by these atoms' intrinsic quantum noise. Here, I will discuss a simple protocol to break through this limit by entangling fermionic atoms in an optical lattice clock. The basic idea is to use atomic interactions to prolong inter-particle spin coherence, transforming the dephasing effect of spin-orbit coupling into a collective entangling process that generates spin squeezing. I will show squeezing can be further enhanced by driving the clock, and how even with realistic experimental imperfections our scheme can generate ~12-15 dB of spin squeezing with 10^2-10^3 atoms. I will also discuss how a generalization of this protocol can be used to generate high dimensional cluster states useful for one quantum computing. In addition to advancing the achievable precision of atomic clocks, our protocol showcases a new paradigm of employing driven, non-equilibrium systems to overcome current limitations in quantum metrology and for the development of the foundations necessary for the construction of a universal quantum computer.

8:36AM A19.00002: Algebraic Time Crystallization in a Two-dimensional Superfluid NIKOLAI PROKOF'EV, BORIS SVISTUNOV (Presenter), University of Massachusetts Amherst — Time crystallization is a hallmark of superfluidity, indicative of the fundamental fact that along with breaking the global U(1) symmetry, superfluids also break time-translation symmetry. While the standard discussion of the time crystallization phenomenon is based on the notion of the global phase and genuine condensate, for the superfluidity to take place in two dimensions an algebraic (topological) order is sufficient. We find that the absence of long-range order in a finite-temperature two-dimensional superfluid translates into an algebraic time crystallization caused by the temporal phase correlations. The exponent controlling the algebraic decay is a universal function of the superfluid-stiffness-to-temperature ratio; this exponent can be also seen in the power-law singularity of the Fourier spectrum of the AC Josephson current. We elaborate on subtleties involved in defining the phenomenon of time crystallization in both classical-filed and all-quantum cases and propose an experimental protocol in which the broken time translation symmetry--more precisely, temporal correlations of the relative phase, with all possible finite-size, dimensional, and quantum effects included--can be observed without permanently keeping two superfluids in a contact.

8:48AM A19.00003: Density dependence of the superfluid properties of superclimbing dislocation in solid 4He* ANATOLY KUKLOV (Presenter), Department of Physics and Astronomy, CSI of CUNY, NIKOLAI PROKOF'EV, BORIS SVISTUNOV, Department of Physics, UMASS — Dislocations with superfluid core [1,2] are the main candidates for the mechanism behind the observation of superflow through solid and the syringe effect [3]. The same features have been confirmed in Refs.[4,5], respectively. One of the unusual features observed in the experiment [4] is the exponentially strong suppression of the flow versus pressure (or crystal density). Our grand canonical ab initio simulations of the superclimbing dislocation by the Worm Algorithm [6] on samples containing about 1430 particles at T=0.25K find that Luttinger parameter K obeys the dependence K=exp (3.4 - 39 n), where n>0 stands for the fractional deviation of the density from the melting value, within the accuracy of 10-15%. Thus, by increasing the density by only about 10% the K-value drops by about two orders of magnitude. This qualitatively agrees with the observation [4].

9:00AM A19.00004: Numerical solutions of three-dimensional helium like atoms from the linear combination of their analogue one-dimensional wave functions*  
FAIZ UR RAHMAN, YANOAR PRIBADI SARWONO, RUIQIN ZHANG  
(Presenter), City University of Hong Kong — The solutions of Schrödinger wave equations for the ground state of three-dimensional helium atom and its isoelectronic series were obtained from the linear combination of one-dimensional helium-like wave functions. The result shows that the one-dimensional bases along the axes are good choices which facilitate easy numerical integration. The three-dimensional wave function was constructed from the linear combination of the bases and the result was further refined to converge to the exact value using the iteration technique. The resultant ground state energy for the helium atom is with deviation of from the exact value. The method developed is thus demonstrated to be an effective numerical approach to the many-body problem and could be extended to other atomic and molecular systems.

9:12AM A19.00005: An integrable multi-channel sine-Gordon model with Josephson circuits*  
ANANDA ROY  
(Presenter), HUBERT SALEUR, Institut de Physique Theorique, CEA Saclay — Integrable field theories have always fascinated physicists. In particular, those which describe quantum impurity problems have been of much interest to both theorists and experimentalists. A prominent example is the boundary sine-Gordon (bSG) field theory. The latter describes a Luttinger liquid in the presence of an impurity. In this work, we propose an experimentally realizable, multi-channel generalization of the bSG model. We establish the classical and quantum integrability of the model by constructing a corresponding integrable bulk theory. We provide the first nontrivial conserved current of the bulk theory. Subsequently, we postulate the factorized scattering matrix describing the bulk theory and verify it using Bethe Ansatz computation of the ground state energy. Subsequently, we provide the factorized scattering matrix of the boundary field theory. Thermodynamic properties of both the bulk and boundary model are computed using the Thermodynamic Bethe Ansatz. Finally, we propose an experimental realization of the model with superconducting circuits, making use of the robust, tunable and dispersive Josephson nonlinearity. Our proposal can be realized with state-of-the-art system parameters.

9:24AM A19.00006: Non-Equilibrium Transport in the Kondo Model: Strong and Weak Coupling*  
ADRIAN CULVER  
(Presenter), NATAN ANDREI, Center for Materials Theory, Rutgers University — We present an exact method of calculating the non-equilibrium current driven by a voltage drop across a quantum impurity. The system is described by the two lead Kondo model with non-interacting Fermi-liquid leads. We prepare the system in an initial state consisting of a free Fermi sea in each lead with the voltage drop given as the difference between the two Fermi levels. We quench the system by coupling the impurity to the leads at t=0 and following the time evolution of the wavefunction. In the long time limit, a steady state emerges provided that the size of the system is large compared to the time of evolution (the open system limit). We determine the wavefunction explicitly at any time and show, in particular, that the long time limit satisfies the Lippmann-Schwinger equation with the two Fermi seas serving as the boundary conditions. Using this wavefunction, we obtain an infinite series expression for the current as a function of voltage, either in powers of the antiferromagnetic Kondo coupling constant J or in powers of 1/J. Evaluating the first few terms, we find that a quench to small J reproduces known results while a quench to large J leads to a pre-thermalized regime of maximal conductance with ferromagnetic corrections.

9:36AM A19.00007: Strong and Weak Field Criticality of Liquid Gas Transition in 2D*  MAX YARMOLINSKY (Presenter), ANATOLY KUKLOV, Physics, College of Staten Island & the Graduate Center — Finite size scaling (FSS) analysis of the liquid gas criticality is complicated by the absence of any broken symmetry. This, does not allow a straightforward finding of the coexistence line and the critical point -- especially in 2D. The numerical flowgram (NF) method[1] is adapted for a controlled determination of the boundary between weak and strong field critical regions by applying classical Monte Carlo to the square well model. This boundary coincides with the coexistence line of the liquid-gas transition with respect to the leading scaling behavior. The NF method allows measuring the critical indices μ, ν within 1-2% of the total error. Furthermore, the NF allows testing the so called complete scaling theory of the critical point[2] without tuning the system into the coexistence line. This theory predicts linear mixing between the primary scaling operators and pressure. We show that the NF analysis should see corrections to scaling which are stronger than the standard ones of the 2D Ising model. It can also resolve the non analytical correction to the diameter.

9:48AM A19.00008: Emergent Symmetry U(1) and Tricriticality in a 2D Quantum Clock Model*  PRANAY PATIL (Presenter), Boston University, HUI SHAO, WENAN GUO, Physics, Beijing Normal University, ANDERS W SANDVIK, Boston University — We propose a quantum clock model on the square lattice built out of a q-state classical clock model with a quantum fluctuation (a generalization of a transverse field) added to it. We see evidence that this model is closely related to the 3D classical clock model through the standard quantum to classical mapping. For q=5, we see a continuous phase transition and for q=5,6 we show that, at the phase transition, an emergent U(1) symmetry appears, similar to the 3D classical clock models. We address the connection that this emergent symmetry has to a second length scale within the scenario of dangerously irrelevant perturbations of the XY model. We also demonstrate the existence of a tricritical point in the case of q=4, which can be tuned by changing the form of the quantum fluctuation operator.

10:00AM A19.00009: Symmetry enhanced first-order phase transition in a two-dimensional quantum magnet*  BOWEN ZHAO (Presenter), ANDERS W SANDVIK, PHILLIP E WEINBERG, Boston University — Theoretical descriptions of quantum phase transitions have indicated the existence of critical points with higher symmetries than those of the underlying Hamiltonian. Here we present an example of such an emergent symmetry at a first-order transition, where coexistence of two ordered phases takes the form of higher rotational symmetry in the space of the two order parameters. Using quantum Monte Carlo simulations, we study a two-dimensional (2D) S = 1/2 quantum magnet hosting the antiferromagnetic (AFM) and plaquette-singlet solid (PSS) states recently detected in SrCu2(BO3)2. We observe that the O(3) symmetric AFM order and the Z2 symmetric PSS order form an O(4) vector at the transition. The control parameter (a coupling ratio) rotates the vector from the AFM sector to the PSS sector, with the length of the combined order parameter vector always remaining non-zero. This phenomenon should be observable in SrCu2(BO3)2.

10:12AM A19.00010: Even-Odd effect of an Spin-S impurity coupled to a quantum critical system  KUN CHEN, YASHAR KOMIJANI, Department of Physics, Rutgers University, YUAN HUANG (Presenter), University of Massachusetts Amherst — We discuss an even-odd effect for an impurity with N degenerate internal states immersed in a two-dimensional superfluid--Mott-insulator quantum critical bath, which is described by a spin-S XY Bose Kondo impurity model with N = 2S + 1. Using a dimensionally and momentum-cut-off regularized renormalization group and an unbiased large-scale Monte Carlo numerical simulations, we establish the phase diagram of an S = 1 impurity with relevant terms included. We show that the impurity with N = 3-fold degeneracy is fully screened by the critical bath, which is qualitatively different from the N = 2 case where the impurity is only partially screened. We then argue that all even-N impurities share the same universal physics as the N = 2 case, and all odd-N impurities are as the N = 3 case. We validate our conjecture with unbiased Monte Carlo simulations up to N = 5.
10:24 AM A19.00011: Trapping Collapse: Generic weak traps localize an infinite number of repulsive bosons*  
NIKOLAI PROKOF’EV (Presenter), University of Massachusetts Amherst, KUN CHEN, Physics, Rutgers University, BORIS SVISTUNOV, University of Massachusetts Amherst — Weak potential wells (or traps) in one and two dimensions, and the potential wells slightly deeper than the critical ones in three dimensions, feature shallow bound states with localization length much larger than the well radii. We address a simple fundamental question of how many repulsively interacting bosons can be localized by such traps. We find that under rather generic conditions, for both weakly and strongly repulsive particles, in two and three dimensions—but not in one dimension!—the potential well will trap infinitely many bosons. For example, even hard-core repulsive interactions do not prevent this ``trapping collapse'' phenomenon from taking place. A quantum system acquires the phenomenon along with the universal (asymptotically exact) classical-field behavior at large distances, allowing generic description by the Gross-Pitaevskii equation. We also discuss the possibility of having a transition between the infinite and finite number of trapped particles when strong repulsive inter-particle correlations are increased.

10:36 AM A19.00012: Two Temperature Scales in the Triangular Lattice Heisenberg Antiferromagnet*  
WEI LI (Presenter), BIN-BIN CHEN, LEI CHEN, HAN LI, DAI-WEI QU, Beihang University, JAN VON DELFT, University of Munich, ANDREAS WEICHSELBAUM, Brookhaven National Lab — The anomalous thermodynamic properties of the paradigmatic frustrated spin-1/2 triangular lattice Heisenberg antiferromagnet (TLH), has remained an open topic of research over decades, both experimentally and theoretically. Here we further the theoretical understanding using the recently developed, powerful exponential tensor renormalization group (XTRG) method on cylinders and stripes in a quasi one-dimensional (1D) setup, as well as a tensor product operator approach directly in 2D. The observed thermal properties of the TLH are in excellent agreement with two recent experimental measurements on the virtually ideal TLH material Ba8CoNb6O24. Remarkably, our numerical simulations reveal two cross-over temperature scales, at T₁/J ~ 0.2 and T₂/J ∼ 0.55, with J the Heisenberg exchange coupling, which are also confirmed by a more careful inspection of the experimental data. We propose that in the intermediate temperature range, the gapped roton-like excitations are activated with a strong chiral component and a large contribution to thermal entropies, which thus suppresses the incipient 120° order that emerges for temperatures below T₁.

10:48 AM A19.00013: Some Novel Applications and Interpretations of the Path Integral Formalism*  
JARETH BACA (Presenter), AJIT HIRA, JOSE PACHECO, Math and Physics, Northern New Mexico College, TOMMY CATHEY, Chemical Physics, Lockheed Information Systems, MATILDA FERNANDEZ, Math and Physics, Northern New Mexico College — Two important considerations which will be addressed in this presentation pertain to extending applications of the Feynman Path Integral Formalism (FPIF) to some important physical problems, and also to the role of this formalism in providing a generally acceptable view of the interpretation of Quantum Mechanics (QM). Of particular interest for our research is the extension of path integral quantization geometries other than spherical: namely parabolic, elliptic and hyperbolic geometries. We calculate perturbative expansions of various path integrals of interest, with a view to obtaining Conformal Field Theories (CFTs). We used a Python programming language interface, and Monte Carlo (MC) integrations in our computer codes. Our main results are in the field of plasma Physics, with some applications in fusion and Astrophysics.

Session A20 DCOMP DMP: First-principles Modeling of Excited-state Phenomena in Materials I: Many-body Perturbation Theory (Techniques and Applications)  
BCEC 157A - Andre Schleife, University of Illinois at Urbana-Champaign - Tag(s): Focus
8:00AM A20.00001: Accurate Core-Level Spectra from GW* [Invited] DOROTHEA GOLZE (Presenter), PATRICK RINKE, Aalto University — We present an accurate method for computing X-ray photoelectron spectra based on the GW approximation that overcomes the limitations of density functional theory (DFT) approaches. The GW method is routinely used to predict charged valence excitations in molecules and solids. However, GW core-level spectroscopy has thus far been poorly explored. This in parts related to the fact that numerically very efficient techniques such as the analytic continuation, which treat the frequency dependence on the imaginary axis, break down for inner-shell excitations. We implemented a full-frequency approach on the real axis in the all-electron code FHI-aims [1] using a localized basis to enable the treatment of core levels in GW[2]. Our scheme is based on the contour deformation technique and facilitates precise and efficient calculations of the self-energy, which has a complicated pole structure for core states. We present benchmark studies for 1s excitations of small- and medium-sized molecules and discuss the optimization of the starting point as well as self-consistent approaches. We find that the absolute core-level binding energies deviate on average by less than 0.5 eV from experiment outperforming the DFT-based Delta Self-Consistent Field approach. Relative core excitations are also well reproduced with average deviations of less 0.2 eV from the experimental reference. Furthermore, our calculations reveal that the GW excitation spectrum exhibits satellite features in addition to the photoelectric peak, which might provide access to interesting many-body physics.

*The research is supported by Academy of Finland grant no. 316168.

8:36AM A20.00002: Time-dependent GW: Progress in Solving Kadanoff-Baym Equations with Dynamic GW Self Energy* DIANA QIU (Presenter), YANG-HAO CHAN, FELIPE DA JORNADA, STEVEN G. LOUIE, Lawrence Berkeley National Lab and University of California, Berkeley — The ab initio GW plus Bethe-Salpeter equation (GW-BSE) approach has achieved great success in describing the linear absorption spectra of materials in equilibrium. However, many important photo-processes and experiments of interest that involve ultrafast and high-intensity pulses of light fall well outside the regime of equilibrium and linear responses. One can generalize the Green's function formalism in many-body perturbation theory to nonequilibrium situations by solving the Kadanoff-Baym equations (KBE), but the presence of two time variables that need to be simultaneously evolved presents a significant computational challenge. In recent years, progress has been made in solving the KBE from ab initio in the static limit of the GW self energy, which greatly simplifies the time evolution. Here, we present progress on solving the KBE including dynamical effects in the self energy. We discuss time-evolution algorithms, memory effects, approximations to the dynamics, and convergence behavior.

8:48AM A20.00003: Excitonic effects in shift currents of low dimensional materials from time-dependent GW approach* YANG-HAO CHAN (Presenter), Lawrence Berkeley National Lab, DIANA QIU, Physics, University of California, Berkeley, FELIPE DA JORNADA, Lawrence Berkeley National Lab, STEVEN G. LOUIE, Physics, University of California, Berkeley — We present first-principles studies on shift currents with excitonic effects in 2D materials using an adiabatic time-dependent GW approach. Shift current in a noncentrosymmetric semiconductor is a DC current generated by optical excitations from a nonlinear response processes. Using a newly developed real-time simulation method, we are able to include excitonic effects in the nonlinear responses from first principles, treating the complicated electron-hole interaction at the GW plus Bethe-Salpeter equation level for the first time. We applied this method to study shift currents in monolayer GeS and found strongly enhanced responses due to excitonic effects. Most interestingly, the dominant contributions to the shift currents here are generated at in-gap frequencies, which peaked at energies below the quasi-particle band gap by the exciton binding energies.

*This work was supported by the Center for Computational Study of Excited State Phenomena in Energy Materials (C2SEPEM), which is funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-05CH11231.
Correlation satellites in optical and loss spectra

PIER LUIGI CUDAZZO (Presenter), Faculté des Sciences, de la Technologie et de la Communication, Université du Luxembourg, LUCIA REINING, Ecole Polytechnique — The coupling of excitations leads to intriguing effects in the spectra of materials. Current approximations to calculate spectra most often describe this coupling insufficiently. We propose a cumulant formulation for neutral electronic excitations which opens the way to describe effects such as double plasmon satellites or exciton-exciton coupling. Our approach starts from the widely used GW plus Bethe-Salpeter approximation to many-body perturbation theory which is based on a quasiparticle picture, and it adds coupling to other excitations through a consistent inclusion of dynamically screened interactions. We show that this requires to consider scattering contributions that are usually neglected. The result is formulated in a way that highlights essential physics, that can be implemented as a post-processing tool in widely used first principles codes, and that suggests which kind of materials and measurements should exhibit strong effects. This is illustrated using a model.

Faster and more accurate stochastic GW*

VOJTECH VLCEK (Presenter), Chemistry and Biochemistry, UC Santa Barbara, ERAN RABANI, College of Chemistry, UC Berkeley, ROI BAER, Chemistry, Hebrew University (Israel), DANIEL NEUHAUSER, Chemistry and Biochemistry, UC Los Angeles — I will present recent developments in stochastic approach to the GW approximation, which further accelerate the calculation of quasiparticle energies and increase their accuracy. A new concept of sparse stochastic compression is used to speed up stochastic approaches and leads to an overall decrease of statistical errors in large finite and periodic systems. Computation of quasiparticle energies and gaps for systems with up to $N_e > 10,000$ electrons is thus feasible with only small statistical fluctuation ($\pm 0.05$ eV) and consuming < 2000 core CPU hours. Further, I will present an efficient scissors-like GW self-consistency approach that can be implemented at zero additional cost. This result is a simple modification of the time-dependent G0W0 and enables an a posteriori self-consistency cycle applicable to large systems.

*This work was supported by the Center for Computational Study of Excited-State Phenomena in Energy Materials at the Lawrence Berkeley National Laboratory, which is funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DEAC02-05CH11231 as part of the Computational materials Sciences Program.

Calculations of Multiplet Splittings in Open Shell Systems within the GW approximation*

MEISAM REZAEI (Presenter), SERDAR OGUT, University of Illinois at Chicago — In open shell systems, the coupling of the orbital and spin angular momenta of electrons can result in multiple energy eigenstates of the electronically excited system leading to the characteristic multiplet structures observed in photoemission experiments. While DFT is not capable of determining the resulting multiplet splittings accurately, recent studies have shown that the GW approximation can describe the multiplet structure with reasonable accuracy. In this work, we investigate the multiplet splittings for open shell molecules such as NO$_2$, NF$_2$, O$_2$, ClO$_2$, and single atoms by applying the one-shot GW approximation. We compare predictions obtained with $G$ and $W$ computed with the same hybrid functional starting points containing varying amounts of Fock exchange with those where $G$ is still computed with a hybrid functional starting point but $W$ is computed within PBE. We show that it is possible to achieve excellent agreement with experimental results for molecular systems using both types of approaches, but the amount of exact exchange needed for quantitative accuracy depends on the molecule as well as the choice of the GW method employed.

*Work supported by DOE Grant No. DE-SC0017824.
9:36AM A20.00007: Electronic structure of 3d-transition-metal oxide clusters with partially filled d shells from GW calculations*  
YOUNG-MOO BYUN (Presenter), SERDAR OGUT, Department of Physics, University of Illinois at Chicago — The GW approximation using atom-centered localized basis sets is an emerging method for studying the excited properties of confined systems. However, G0W0@PBE, which is typically used for simple extended systems, fails to accurately describe the electronic excitations in 3d-transition-metal oxide clusters due to dimensionality and correlation effects, and suffers from exhibiting multiple solutions of the quasiparticle equation due to complex self-energy poles. G0W0 on top of exact exchange (EXX) is one way to overcome these problems, but the predictions depend on the amount of EXX and the method suffers from convergence errors in open-shell systems (e.g. due to spin contamination). In our previous work on early and late 3d transition metal oxide clusters, we showed that G0W0@PBE addresses all the above issues, and thus is an accurate and efficient GW method for these systems. In this work, we investigate various flavors of the GW method (one-shot, partially self-consistent, quasiparticle self-consistent) with different starting points for 3d transition metal oxide clusters, VO-, CrO-, MnO-, FeO-, CoO-, and NiO-, which display a number of high multiplicity states and exhibit moderate electronic correlation.

*This work was supported by DOE Grant No. DE-SC-0017824.

9:48AM A20.00008: Spin wave spectrum of 3d ferromagnet based on QSGW calculations  
OKUMURA HARUKI (Presenter), KAZUNORI SATO, Graduate School of Engineering, Osaka University, TAKAO KOTANI, Department of applied mathematics and physics, Tottori University — We have developed spin wave (SW) spectrum calculation code, combining quasi-particle self-consistent GW(QSGW) and maximum localized Wannier function (MLWF). With MLWF, we can overcome time-consuming calculations for large q-point SW spectrum. Since we adopt the linear response method for dynamical susceptibility,[1] our SW spectrum includes Stoner excitation, which causes the damping of spin SW. Stoner excitation is important in weak ferromagnet such as Fe, while not important in strong ferromagnet such as Ni. In the local density approximation (LDA), our SW energy in Fe is smaller than experimental result or other frozen SW calculation. In the QSGW calculations, due to the corrections of exchange splitting, the calculated SW stiffness constant of Ni (481 meV·Å in average) is in good agreement with inelastic neutron scattering experiment (483 meV·Å), while the LDA result (834 meV·Å) is almost twice as large as experimental one. In the fcc Co, our LDA result corresponds to frozen SW calculation because of weak Stoner excitation coupling in this strong ferromagnet. In the case of cubic FeCo in ordered state, we found acoustic and optical mode in the SW spectrum. [1] C. Friedrich, et al., First Principles Approaches to Spectroscopic Properties of Complex Materials pp 259-301 (2014).

10:00AM A20.00009: Tunable Low Temperature Phonon-induced Electronic Bi-stability in Vanadium Dioxide*  
MARK SCHILFGAARDE (Presenter), CEDRIC WEBER, SWAGATA ACHARYA, King's College London, MOSTAFA SHALABY, Beijing Normal University, Science Park, Beijing — We use a joint theory and experimental approach to clarify the nature of the Metal-insulator transition in VO₂, by QSGW calculations in the frozen phonon approach, and pump-probe ultra-fast spectroscopy with THz radiation. We first show that the insulating state is induced by a Peierls instability, that is responsible for the orbital selection that drives the material to its insulating state, and is associated with a degenerate two-orbital electronic valence band. At the same time, Peierls excitations driven by the lattice dynamics. A 5.7 THz phonon modes split the degeneracy, in a particular, which in turn induces a rapid metallization. This mode is observed in THz pump measurements, far below the critical temperature in the M₁ phase. Our combined approach sheds light in the nature of the transition, which is in our view mediated by a combination of the lattice dynamics and electronic excitations. Finally, we report a possibility in the theory for a novel mechanism to induce an electronic metal-insulator hysteresis via the electron-phonon coupling to the 6.5 THz phonon mode.

**Alternative approaches for calculations of exchange and correlation contributions to thermodynamic properties**

JOSHUA KAS (Presenter), JOHN REHR, University of Washington — The cumulant expansion of the one-electron Green's function has been found to be an improved method for calculations of excited states and spectra for a wide variety of systems [1]. Additionally, an extension of the cumulant Green's function approach to finite temperatures has yielded total energies and exchange correlation potentials in good agreement with quantum Monte-Carlo results [2]. Here we present an investigation of alternative thermodynamic pathways for properties such as the free energy, entropy, and heat capacity of the homogeneous electron gas. In addition we discuss approximate methods based on quasiparticle properties alone. These approximate methods improve the efficiency of the approach, and could be applied to real systems for which calculations of GW quasiparticle effects are computationally reasonable.

*Supported by DOE Office of Science BES Grant DE-FG02-97ER45623

**Electron Hydrodynamics of Graphene from a First-Principles GW Approach: Electronic Compressibility, Backflows and Transport Coefficients**

ANDREA CEPELLOTTI (Presenter), STEVEN G. LOUIE, Physics and Materials Sciences, University of California at Berkeley and Lawrence Berkeley National Laboratory — Doped graphene at low temperatures has experimental signatures of hydrodynamic behavior originating from the electron-electron interaction. Here, we use the GW approximation to study the electronic and thermal properties of graphene from first-principles within a Fermi liquid framework. We show how the electronic compressibility is modified by many-body contributions at finite temperature. Next, we solve the kinetic equation using an exact expression of the scattering matrix. We show how the commonly-used relaxation time approximation causes a severe underestimation of transport coefficients, and how a correct treatment of momentum dissipation is critical to the description of transport properties. We will present results for transport coefficients, including electrical conductivity, the electronic contribution to thermal conductivity and the viscosity coefficients, discussing corrections due to the interaction of carriers with the environment and the behavior of the electron liquid as a non-Newtonian fluid.

*Work supported by the Center for Computational Study of Excited-State Phenomena in Energy Materials at LBNL, as part of the Computational Materials Sciences Program, funded by the U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources provided by NERSC.

**Cumulant Green's function approach for phonon satellites in resonant inelastic X-ray scattering**

KEITH GILMORE (Presenter), Brookhaven National Laboratory, ANDREY GEONDZHIAN, European Synchrotron Radiation Facility — Resonant inelastic X-ray scattering (RIXS) probes various excitations in materials, including plasmons, magnons and phonons. Calculating RIXS spectra is challenging since it is a second-order process involving the coupling of core-excited states to bosonic collective modes, and requires summation over virtual intermediate states. Using a cumulant expansion [1], we develop a tractable excitonic Green's function formulation of the RIXS cross section. We demonstrate our methodology by reproducing the phonon contribution to the RIXS spectrum of acetone [2]. The relative intensities of multiple phonon satellites are used to quantify the electron-phonon coupling strength. First, we show that RIXS actually probes exciton-phonon coupling, which can differ significantly from electron-phonon coupling. Second, we extend our numerical demonstration on acetone to the more challenging cases of quasi-1D Li$_2$CuO$_2$ and 3D SrTiO$_3$. This requires generalizing concepts of density functional perturbation theory to generate exciton-phonon coupling constants throughout the Brillouin zone. Comparison to experiment is made, resolving apparent anomalies in the spectra of Li$_2$CuO$_2$.

10:48AM A20.00013: Reexamining a local, real-space approach to screening  JOHN VINSON (Presenter), ERIC SHIRLEY, National Institute of Standards and Technology — Various many-body perturbation theory techniques for calculating electron behavior rely on $W$, i.e., the screened Coulomb interaction. The exact screening requires complete knowledge of the dielectric response of the electronic system. As a simplification, calculations often begin with the RPA or random phase approximation. However, even at the RPA level the calculations are costly and scale poorly with system size. A local approach has been shown to be efficient while maintaining accuracy [1]. We present improvements to this scheme, including reconstruction of the all-electron character of the pseudopotential-based wave functions, improved scaling with system size, and a parallelized implementation. We discuss applications to Bethe-Salpeter calculations of core and valence spectroscopies.

Session A21 DCOMP: Big Data in Physics 8CEC 157B - Hans Herrmann, Universidade Federal do Ceará - Tag(s): Careers, Focus, Undergraduate

8:00AM A21.00001: Big data in physics, biology and social science [Invited]  FLAVIANO MORONE (Presenter), City College of New York — In the digital age, we are creating 2.5 billion gigabytes of data every single day of our lives, and the 75% is unstructured, coming from texts, videos and opinions spread through online social networks. These data sets are so voluminous and complex that traditional data analytics methods are often inadequate to extract value from them. Here, I show how to extract summarized data by identifying an optimal set of network nodes, called influencers, with high predictive power in anticipating opinion trends and tracking the effectiveness of messages in massive social networks. I illustrate the theoretical framework to identify influencers using the concept of optimal percolation (OP). Big data analyses in social networks reveal that the set of influencers identified by OP theory is much smaller than the one predicted by heuristic centralities. Remarkably, a large number of previously neglected weakly connected nodes emerges among the optimal influencers.

I show that OP theory is also a powerful indicator of personal economic status. Said in very simple terms, we discovered that people located in positions of high influence have high financial levels. This result comes from the combined analysis of two large-scale datasets including telecommunication and financial data of 110 million people in Mexico. Finally, I also discuss applications of OP theory to brain networks. In particular, I show how OP theory identifies the essential nodes for integration of the memory network in a rat brain.

8:36AM A21.00002: AI Astrophysics [Invited]  KEVIN SCHAWINSKI (Presenter), Modulos AG — I present how some recent advances in artificial intelligence can help us explore astrophysical problems. Astrophysics faces a particular challenge from the fact that experiments with controlled variables are impossible. New approaches such as generative models can help us better constrain and understand the underlying processes governing the formation and evolution of galaxies and other objects. While cutting edge research from computer science can be helpful in many case, new tools abstracting AI/ML to a more user-friendly level also have a significant potential for advancing research in astrophysics, and other areas of the physical sciences.
9:12AM A21.00003: Insights into the world connectivity from aviation and tourism data* [Invited] NUNO ARAUJO (Presenter), University of Lisbon — The World Airline Network (WAN) is an infrastructure that reduces the geographical gap between societies, both small and large, and bring forth economic gains. With the extensive use of a publicly maintained data set that contains information about airports and alternative connections between these airports, we empirically reveal that WAN is a redundant and resilient network for long distance air travel, but otherwise breaks down completely due to removal of short and apparently insignificant connections [1]. These short-range connections with moderate number of passengers are the connections that keep remote parts of the world accessible. It is surprising, insofar as there exists a highly resilient and strongly connected core consisting of a small fraction of airports (around 2.3%) together with an extremely fragile star-like periphery. The core-periphery structure is also observed for a number of important transport networks. With a dynamic model for the evolution of transport networks, we show that core-periphery structures are (very likely) a product of a tug of war between connectivity and economic profit [2]. Finally, we will discuss how the mobility pattern of tourists around the world correlates with the underlying Airline Network [3].

9:48AM A21.00004: Dynamics of Traffic Congestions from Large-Scale Data in the Taiwan Highway System* T. S. CHOI, YEE MAN TAI, YULIN XU, KWONG TAI SIU, Physics, Hong Kong University of Science and Technology, KI WING TO, Institute of Physics, Academia Sinica, K.Y. MICHAEL WONG (Presenter), Physics, Hong Kong University of Science and Technology — The Taiwan Highway System has the longest electronic toll collection (ETC) freeway mileage in the world. There are 300 sensors installed on the two North-South spanning highways. The collected data consists of the time information of individual vehicles passing through ETC sensors along their highway journeys. Highway segments are demarcated by successive sensors, enabling us to extract a tremendous volume of dynamical segment-wise data. We trace the evolution of the system on the so-called fundamental diagram with vehicle flux versus vehicle density during traffic congestions in segments, and show that congestions are characterized by loopy trajectories in the diagram. By considering the area enclosed by a loop, we find that there are two types of congestion dynamics -- moderate flow and serious congestion. They behave differently in terms of the area enclosed. Data extracted from the time delays of individual vehicles show that the area enclosed is a measure of the economic loss due to congestion.

10:00AM A21.00005: How the brain transitions from conscious to subliminal perception FRANCESCA ARESE LUCINI (Presenter), City College of New York — We study the transition in the functional network that characterize the human brains’ conscious state to an unconscious subliminal state of perception by using k-core percolation. We find that the most inner core (ie, the most connected kernel) of the functional network in the state of consciousness (the visual cortex and the left middle frontal gyrus) is represented by the areas that remain active when the brain transitions to the subliminal unconscious state. That is, the inner core of the conscious network coincides with the unconscious state. Based on data analysis and mathematical modeling we interpret these results as a transition driven by k-core percolation, where the conscious state is inactivated by the disappearance of the peripheral shells in the k-shell decomposition structure. Thus, the inner core and most robust component of the brain seems to be the unconscious subliminal state. If this result were to be found valid for other states of the brain, it could set interesting constraints to models of consciousness and brain structure, in that the location of the core of the functional brain network is in the unconscious part of the brain rather than in the conscious state as previously thought.
10:12AM A21.00006: Super Resolution Convolutional Neural Network for Feature Extraction in Spectroscopic Data*

HAN PENG (Presenter), Department of Engineering, University of Oxford, XIANG GAO, Department of Chemistry, University of Florida, YU HE, Department of Applied Physics, Stanford University, YIWEI LI, Department of Physics, University of Oxford, YUCHEN JI, CHUHANG LIU, School of Physical Science and Technology, ShanghaiTech University, SANDY ADHITIA EKAHANA, DING PEI, Department of Physics, University of Oxford, ZHONGKAI LIU, School of Physical Science and Technology, ShanghaiTech University, ZHIXUN SHEN, Department of Applied Physics, Stanford University, YULIN CHEN, Department of Physics, University of Oxford — Two dimensional (2D) peak finding is a common practice in data analysis for physics experiments, which is typically achieved by computing the local derivatives. However, this method is inherently unstable when the local landscape is complicated, or the signal-to-noise ratio of the data is low. In this work, we propose a new method in which the peak tracking task is formalized as an inverse problem, thus can be solved with a convolutional neural network (CNN). In addition, we show that the underlying physics principle of the experiments can be used to generate the training data. By generalizing the trained neural network on real experimental data, we show that the CNN method can achieve comparable or better results than traditional derivative based methods. This approach can be further generalized in different physics experiments when the physical process is known.

10:24AM A21.00007: A Library for Real Time Interactive High Performance Computing of 2D and 3D Physics Problems through GPU*

FLAVIO FENTON (Presenter), ABOUZAR KABOUDIAN, Georgia Institute of Technology — Many interesting and complex physics problems such as those that use large scale reaction-diffusion equations to study animal skin patterns, brain activity and cardiac arrhythmias require the use of supercomputers. Likewise is the case for systems displaying turbulent fluid dynamics, surface growth, and systems using heat and wave equations. We have developed a library using WebGL, which allows to code and run physics problems, that generally require supercomputers to run, in the GPU of a local PC and even a cellphone, which can run up to 7 billion differential equations per second. We have used this library not only for research but also with undergraduates in Computational Physics Courses at Georgia Tech and in workshops at RIT. In this talk we present the library and show interactive simulations of interesting problems in real time. 2D and 3D examples including Turing patterns, turbulent fluid flow, coral growth and fibrillation in the heart among others.

10:36AM A21.00008: A Robust Approach to Compressive Sensing by Shortest-Solution Decimation

MUTIAN SHEN (Presenter), University of Science and Technology of China, PAN ZHANG, HAIJUN ZHOU, Institute of Theoretical Physics, Chinese Academy of Sciences — Compressed sensing is an important problem in many fields of science and engineering, including computational physics. It reconstructs signals by finding sparse solutions to underdetermined linear equations. We propose a deterministic and non-parametric algorithm, shortest-solution guided decimation (SSD), to construct support of the sparse solution under the guidance of the dense least-squares solution of the recursively decimated linear equation. The most significant feature of SSD is its insensitivity to correlations in the sampling matrix. Using extensive numerical experiments, we show that SSD greatly outperforms $L_1$ -norm based methods, orthogonal least squares, orthogonal matching pursuit, and approximate message passing when the sampling matrix contains strong correlations. This nice property of correlation tolerance makes SSD a versatile and robust tool for different types of real-world signal acquisition tasks.
TBTK aims to solve this problem by providing general purpose data structures tailored for quantum mechanics. These data structures are intended to act as a layer between application developers that are interested in quickly developing code that answers specific physical questions and method developers that need high degree of low level control of the data representation in the most critical parts of their algorithms.

For further information, see the preprint (https://arxiv.org/abs/1808.02409), code (https://github.com/dafer45/TBTK), and documentation (http://www.second-quantization.com/).

Session A22 DCOMP DMP DCMP DCP: Building the Bridge to Exascale: Applications and Opportunities for Materials, Chemistry, and Biology I

8:00AM A22.00001: Performance of Open-Source Real-Space Multigrid DFT Code on Pre-Exascale Architecture

EMIL BRIGGS (Presenter), WENCHANG LU, JERRY BERNHOLC, North Carolina State University — RMG (www.rmgdft.org) is an open-source suite of codes for performing large-scale, high-throughput electronic structure calculations. Designed for scalability, it discretizes the DFT equations on real-space grids that are distributed over the nodes of a massively parallel system via domain decomposition. The Kohn-Sham and Poisson equations are solved using multigrid techniques that dramatically accelerate convergence while only requiring nearest neighbor communications. In addition to the multigrid algorithms, the main parts of the calculations consist of dense matrix multiplications and iterative solutions of a partitioned eigenvalue problem that are particularly well suited for GPU accelerators. RMG makes very efficient use of GPUs, including multiple GPUs per node, if they are available. On the IBM/NVIDIA Summit supercomputer at ORNL, RMG utilizes all 6 GPUs per node and Cuda-managed memory to reach 83x performance improvement over the previous generation Cray XK7 Titan supercomputer at ORNL, which contains 1 prior-generation GPU per node. We will also discuss algorithmic improvements enabled by large-memory, high memory bandwidth nodes in view of future exascale architectures.

8:12AM A22.00002: Full-potential LSMS method for \textit{ab initio} electronic structure calculations at large scale

YANG WANG (Presenter), Pittsburgh Supercomputing Center, Carnegie Mellon University, XIANGLIN LIU, MARKUS EISENBACH, GEORGE MALCOLM STOCKS, Oak Ridge National Laboratory — The locally self-consistent multiple scattering (LSMS) method is a linear scaling \textit{ab initio} electronic structure calculation method in the framework of density functional theory with local density approximation. It is based on multiple scattering theory, which allows to use Green function and contour integration techniques for the calculation of electron density and density of states. With muffin-tin approximation, the LSMS method has demonstrated linear scaling and petascale performance at the scale of tens of thousands of atoms and has been applied to the study of nanostructures and random alloys. Recently, we have implemented full-potential capability in the LSMS method that enables the calculation of the Hellmann-Feynman force and also allows \textit{ab initio} investigation of materials with dislocations, interstitial defects, etc. In this presentation, we will show the scalability of the full-potential LSMS method on supercomputers, and discuss its applications in the study of mechanical properties of transition metal alloys.

*This work is supported by DOE, Office of Science, BES, MSE Division. This research used resources of the Oak Ridge Leadership Computing Facility, which is supported by the Office of Science of DOE under Contract No. DE-AC05-00OR22725.
8:24AM A22.00003: Application of full-potential LSMS method in high entropy alloys*  XIANGLIN LIU (Presenter), Oak Ridge National Laboratory, YANG WANG, Pittsburgh Supercomputing Center, CARNegie MELLon UNIVERSITY, MARKUS EISENBACH, GEORGE MALcolm STOCKS, Oak Ridge National Laboratory — The ability to treat large number of atoms from first principles is highly desired for the investigation of alloy systems. Here we demonstrate our latest implementation of the full potential LSMS method (FP-LSMS) that can accurately calculate systems with thousands of atoms. The acceleration is achieved by a parallelization of the FFT part of the Poisson solver for the electrostatic potential. We employed the code to investigate the elastic properties of high entropy alloys, which are a class of interesting new structural materials. Moreover, to demonstrate the power of the FP scheme, we used FP-LSMS to calculate the Hellman-Feynman forces.

*This work is supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Science and Engineering Division. This research used resources of the Oak Ridge Leadership Computing Facility, which is supported by the Office of Science of the U.S. Department of Energy under Contract No. DE-AC05-00OR22725.

8:36AM A22.00004: Opportunities for exascale in the characterization of uranium materials*  ASHLEY SHIELDS (Presenter), ANDREW MISKOWIEC, JENNIFER NIEDZIELA, MARIE C KIRKEGAARD, ROGER KAPSIMALIS, BRIAN ANDERSON, Oak Ridge National Laboratory — Characterizing new materials or unknown polycrystalline solids is a long-standing challenge for chemists. This problem has new resonance with the nuclear forensics community, where polycrystalline and amorphous materials are regularly encountered. Further, prediction of crystal structures and the calculation of vibrational properties for actinide materials is computationally intensive, limiting the unit cell size and number of structures which can be calculated. By analyzing basic geometric configurations, we hope to isolate spectroscopic characterization of low-symmetry systems to fundamental units. We have performed an analysis of coordination geometries of over 4000 uranium oxide and uranium fluoride structures, generated by combining genetic algorithm searches for stable phases with density functional theory. Here we present progress toward correlating vibrational properties with the fundamental coordination environments, aiming to facilitate interpretation of experimental analytical data from spectroscopy to characterize complex uranium phases. We discuss the opportunities and challenges for exascale computing and actinide materials, with an emphasis on the impacts and importance to the field of nuclear forensics.

*A.E.S. is funded by a US DHS Postdoctoral Fellowship

8:48AM A22.00005: Moving the Effective Fragment Molecular Orbital method towards exascale*  ANASTASIA GUNINA (Presenter), Ames Laboratory, MARK S GORDON, Chemistry, Iowa State University — Steep computational scaling and significant memory requirements of conventional electronic structure methods both limit the size of systems that can be described and hinder transitioning towards exascale computing. One of the ways to overcome these problems is to use fragmentation approaches. Our approach of choice is the Effective Fragment Molecular Orbitals (EFMO) method, which combines advantages of the Fragment Molecular Orbital (FMO) and the Effective Fragment Potential (EFP) methods. The current implementation in the GAMESS program package, however, is not optimized nor fully parallelized.

In this study, a major effort is related to optimizing the bottleneck step of generating EFP parameters, called MAKEFP, which needs to be repeated for every new fragment geometry in the EFMO method. In addition, improvements implemented in other parts of the EFMO code include increasing accessible system sizes. The resulting performance is demonstrated using a ~1700-atoms piece of a mesoporous silica nanoparticle (MSN), which was inaccessible in the original implementation.

*Department of Energy Exascale Computing Project (ECP) grant

9:00AM A22.00006: Recent Advances in PARSEC for Performing Large-scale Electronic Structure Calculations in Real Space*  KAI-HSIN LIOU (Presenter), JAMES CHELIKOWSKY, University of Texas at Austin, CHAO YANG, Lawrence Berkeley National Laboratory — The electronic structure of various types of materials, including complex biomolecules, nanostructures, and interfacial systems can be obtained by solving the Kohn–Sham (KS) equations. PARSEC, a real-space pseudopotential density functional theory KS equation solver, can routinely tackle systems with thousands of atoms using a Chebyshev-filtered subspace iteration (CheFSI) method. We will present a number of recent advances made in PARSEC that allow users to tackle larger systems that contain tens of thousands of atoms. These new advances include new parallelization strategies that significantly improve the scalability of orthogonalization and the Rayleigh–Ritz steps in the CheFSI framework and a more efficient way to perform the previously proposed spectrum slicing method. We will demonstrate the scalability of both the CheFSI and spectrum slicing methods on modern high performance computers and discuss the remaining challenges.

*Our work is supported by an award from the U.S.Department of Energy under Contract No. DE-AC02-05CH11231
Towards Paradigm Shifts in Electronic Structure Calculation for Large Systems: Wavelets, Fragments and Advanced Treatments of Excited States* [Invited] LAURA RATCLIFF (Presenter), Department of Materials, Imperial College London, STEPHAN MOHR, Barcelona Supercomputing Center, THIERRY DEUTSCH, LUIGI GENOVESE, CEA Grenoble — The increasing power of massively parallel machines offers new opportunities for first principles materials simulations, providing software can be developed to effectively exploit new hardware. Density functional theory (DFT) has enjoyed widespread success for systems of up to a few hundred atoms, but is limited by the cubic scaling with the number of atoms of standard approaches. However, in recent years various linear scaling (LS) approaches have been developed, enabling simulations on tens of thousands of atoms. Since the parallel scalability is related to the number of atoms, such methods are also well suited to exploit supercomputers. One key factor influencing the accuracy and cost of DFT is the choice of basis set, where minimal, localized basis sets compete with extended, systematic basis sets. However, wavelets offer both locality and systematicity and are thus ideal for representing an adaptive local orbital basis which may be exploited for LS-DFT [1]. One may also make further approximations, e.g. dividing a system into fragments or exploiting underlying repetition of local chemical environments [2,3], where each approximation may be controlled and quantified. This ability to treat large systems with controlled precision offers the possibility of new types of materials simulations [4].

We will demonstrate the advantages of wavelets as a basis for large scale DFT calculations, as implemented in BigDFT. We will focus on the example of materials for organic LEDs, showing how our approach may be used to account for environmental and statistical effects on excited state calculations of disordered supramolecular materials [5].

*LER acknowledges an EPSRC Early Career Research Fellowship

Affordable and accurate large-scale hybrid-functional calculations on GPU-accelerated supercomputers* THIERRY DEUTSCH (Presenter), LUIGI GENOVESE, CEA Grenoble, LAURA RATCLIFF, Imperial College London — Since 2008, the BigDFT project consortium has developed an ab initio DFT code based on Daubechies wavelets. Performing high accuracy hybrid functional calculations for condensed matter systems containing a large number of atoms is at present computationally very demanding or even out of reach if high quality basis sets are used. We present a highly optimized multiple graphics processing unit implementation of the exact exchange operator which allows one to perform fast hybrid functional density-functional theory (DFT) calculations with systematic basis sets without additional approximations for up to a thousand atoms. With this method hybrid DFT calculations of high quality become accessible on state-of-the-art supercomputers within a time-to-solution that is of the same order of magnitude as traditional semilocal-GGA functionals. The method is implemented in a portable open-source library.

At 10:00 AM A22.00009: Attacking the Strong and Weak Scaling Limits in Linear Scaling Hybrid Density Functional Theory

ROBERT DISTASIO (Presenter), Chemistry and Chemical Biology, Cornell University, HSIN-YU KO, Chemistry, Princeton University, JUNTENG JIA, Chemistry and Chemical Biology, Cornell University, BISWAJIT SANTRA, Physics, Temple University, ZACHARY SPARROW, Chemistry and Chemical Biology, Cornell University, ALVARO VAZQUEZ-MAYAGOITIA, Argonne National Labs, XIFAN WU, Physics, Temple University, ROBERTO CAR, Chemistry, Princeton University — Hybrid density functional theory (DFT) represents a quite favorable balance between accuracy and cost, and has therefore become the de facto standard in quantum chemistry. However, the steep computational cost associated with a cubic-scaling reciprocal-space evaluation of the exact-exchange energy has largely hindered the widespread use of hybrid DFT in the condensed phase. By utilizing a local representation of the occupied space, we have developed a formally exact and linear-scaling algorithm that exploits the real-space sparsity in the exact-exchange interaction by rigorously treating all overlapping orbital pairs. In this work, we present a series of theoretical developments and algorithmic improvements which drastically reduce the time to solution and take us one step closer to routine hybrid DFT-based ab initio molecular dynamics simulations of large-scale condensed-phase systems. In particular, we will focus on: (i) novel preconditioning techniques to speed up the computation, (ii) game and graph theoretical methods to improve the workload imbalance, (iii) sparse and asynchronous data transfer to mitigate the communication cost, and (iv) extensive code optimization/vectorization to efficiently utilize current- and next-generation architectures.

At 10:12 AM A22.00010: Large-Scale Benchmark of Electronic Structure Solvers with the ELSI Infrastructure*

VICTOR YU (Presenter), Department of Mechanical Engineering and Materials Science, Duke University, WILLIAM DAWSON, Center for Computational Science, RIKEN, Japan, ALBERTO GARCIA, Laboratorio de Estructura Electronica de Materiales, Institut de Ciencia de Materials de Barcelona, Spain, VILLE HAVU, Department of Applied Physics, Aalto University, Finland, BEN HOURAHINE, Department of Physics, University of Strathclyde, Scotland, WILLIAM P HUHN, Department of Mechanical Engineering and Materials Science, Duke University, MATHIAS JACQUELIN, Computational Research Division, Lawrence Berkeley National Laboratory, WEILE JIA, Department of Mathematics, University of California, Berkeley, MURAT KECELI, Argonne Leadership Computing Facility, Argonne National Laboratory, RAUL LAASNER, Department of Mechanical Engineering and Materials Science, Duke University, YINGZHOU LI, Department of Mathematics, Duke University, LIN LIN, Department of Mathematics, University of California, Berkeley, JIANFENG LU, Department of Mathematics, Duke University, JOSE ROMAN, Departament de Sistemes Informatics i Computacio, Universitat Politècnica de València, Spain, ALVARO VAZQUEZ-MAYAGOITIA, Argonne Leadership Computing Facility, Argonne National Laboratory, CHAO YANG, Computational Research Division, Lawrence Berkeley National Laboratory, VOLKER BLUM, Department of Mechanical Engineering and Materials Science, Duke University — Routine application of electronic structure theory to systems consisting of thousands of atoms is often hindered by the solution of an eigenproblem. We here present an update to the ELectronic Structure Infrastructure (ELSI), an open-source software interface to facilitate the implementation and optimal use of high-performance solver libraries covering cubic scaling eigensolvers, linear scaling density-matrix-based algorithms, and other reduced scaling methods in between. The ELSI interface has been integrated into four electronic structure code projects (DFTB+, DGDFT, FHI-aims, SIESTA), forming the foundation of our effort to rigorously benchmark the performance of the solvers on equal footing. This presentation will particularly focus on a systematic set of large-scale benchmarks for multiple solvers performed with Kohn-Sham density-functional theory and density-functional tight-binding theory. Factors that strongly affect the efficiency of the solvers are identified and analyzed, including system size and dimensionality, matrix sparsity, eigenspectrum width, number of MPI processes, etc. Based on these benchmarks, we discuss our strategy to automatically select a solver for an arbitrary problem.

*This work is supported by NSF under grant number 1450280.
Enabling Large-Scale Isobaric-Isothermal Hybrid Density Functional Theory Simulations in the Condensed Phase

HSIN-YU KO (Presenter), Chemistry, Princeton University, ROBERT DISTASIO, Chemistry and Chemical Biology, Cornell University, BISWAJIT SANTRA, Physics, Temple University, ROBERTO CAR, Chemistry, Princeton University — The combination of ab initio molecular dynamics (AIMD) and high-performance computing (HPC) has the potential to furnish an atomistic-level understanding of complex condensed-phase systems such as molecular liquids and crystals. Such a detailed understanding requires an accurate treatment of both the quantum mechanical interactions and statistical mechanical sampling under realistic experimental conditions (e.g., in the isobaric-isothermal (NpT) ensemble). However, the routine use of sophisticated quantum mechanical methods like dispersion-inclusive hybrid density functional theory (DFT) is hindered by the cubic-scaling cost of conventional reciprocal-space based approaches. With the use of localized occupied orbitals, we have developed a formally exact and linear-scaling algorithm that directly addresses this prohibitive cost. In this work, we derive and implement the exact-exchange contributions to the stress tensor, thereby enabling hybrid DFT-based AIMD simulations of arbitrary cell sizes and shapes in the NpT ensemble. As an application of this method, we will discuss the pyridine molecular crystal.

NWChemEx: Tackling Chemical, Materials, and Biochemical Challenges in the Exascale Era

WIBE A DE JONG (Presenter), Lawrence Berkeley National Laboratory, KRISTOPHER W. KEIPERT, RAYMOND A. BAIR, Computational Science Division, Argonne National Laboratory, RYAN RICHARD, JEFFREY S. BOSCHEN, THERESA L. WINDUS, Ames Laboratory, Iowa State University, ROBERT J HARRISON, Institute for Advanced Computational Science, Stony Brook University, THOMAS DUNNING, Northwest Institute for Advanced Computing, Pacific Northwest National Laboratory — Historically, the NWChem computational chemistry package has been adapted and optimized for supercomputer architectures as they emerged. While this strategy has been successful over the past two decades, adapting NWChem to the major changes in hardware and programming models anticipated at the exascale is infeasible without a revolutionary redesign of the code. The NWChemEx project is redesigning and re-implementing NWChem for exascale computers using C++ with the goal of dramatically improving upon the scalability, performance, extensibility, and portability of the original application. In the first portion of this talk, the limitations of NWChem will be described. Next, we will illustrate how the scalability limitations are addressed in the NWChemEx design via the implementation of novel reduced-scaling methods with a new high-performance tensor library. Finally, we will show how lossy compression and differenced checkpointing techniques are utilized in NWChemEx to address more general exascale challenges related to data volume and system resilience.

Fast Heat-Bath Configuration Interaction

JUNHAO LI (Presenter), MATTHEW OTTEN, ADAM HOLMES, Cornell University, SANDEEP SHARMA, Department of Chemistry and Biochemistry, University of Colorado Boulder, CYRUS JEHANGIR UMRIGAR, Cornell University — For many quantum mechanical systems the entire Hilbert space is enormous, but the important part is many orders of magnitude smaller. We have recently developed the semistochastic heat-bath configuration interaction (SHCI) method for efficiently calculating such systems. It is a systematically improvable selected configuration interaction plus perturbation theory method that is capable of giving essentially exact energies for larger systems than is possible with other such methods. I present recent advances we have made to the method that allow us to use 2 billion variational determinants and trillions of perturbative determinants. Details about the key data structures and the parallelization are presented. We use the algorithm to compute the potential energy surface of the very challenging chromium dimer in the cc-pVDZ-DK basis, correlating 28 valence and the semicore electrons. The Hilbert space has 5*10^29 determinants. At equilibrium our energy agrees with the recent p-DMRG energy, but is more precise. We also present results for the homogeneous electron gas.

8:36AM A23.00002: Automation of Atom-Scale Device Patterning using Machine Learning
JEREMIAH CROSHAW (Presenter), MOHAMMAD RASHIDI, KIERAN MASTEL, MARCUS TAMURA, Physics, University of Alberta — In recent years, research involving dangling bonds (DBs) patterned on hydrogen-terminated silicon (H-Si) has reached several significant benchmarks, including their applications as logic gates, binary wires¹ and rewritable memory². These newly developed devices show promise for the implementation of atom scale DB circuitry. As device applications become realizable, automation of device fabrication is necessary to facilitate the transition to commercial applications. We show that by incorporating a deep neural network in our patterning process, we can greatly reduce the amount of active user time needed for device fabrication. Semantic segmentation is used with a convolution-deconvolution network to properly map and label surface defects. By combining this neural network with libraries from a commercial scanning probe microscope controller and a previously implemented probe tip conditioning suite³, complete automation of the patterning process is realized.

8:48AM A23.00003: Reduced Damage Electron Microscopy with Conditional Sample Re-illumination*
AKSHAY AGARWAL (Presenter), Electrical Engineering and Computer Science, Massachusetts Institute of Technology, YURI VAN STAADEN, Technische Universiteit Delft, VIVEK GOYAL, Electrical and Computer Engineering, Boston University, KARL K BERGGREN, Electrical Engineering and Computer Science, Massachusetts Institute of Technology — We propose and theoretically analyze an electron microscopy scheme based on multiple sample illuminations with a very low current beam, in combination with Elitzur and Vaidman's interaction-free measurement scheme. Our analysis starts with a prior guess for the characteristic transparency of each pixel on the sample. We update these priors after each round of illumination based on the statistics at the imaging detectors. The re-illumination for a pixel ceases once a stopping criterion is met. This criterion could be based on either a minimum required signal-to-noise-ratio, or a maximum imaging time. We show that this scheme reduces the damage suffered by the sample during imaging, compared to a conventional imaging scheme without conditional re-illumination. We calculated the maximum resolution at a given sample damage and signal-to-noise ratio that could be obtained with this scheme. This resolution shows an improvement over that from conventional imaging. We are working towards implementing this scheme on a scanning electron microscope, modified to include bright- and dark-field transmission electron detectors, and a fast beam blanker to obtain extremely low-dose electron pulses.

9:00AM A23.00004: In situ observation of Sb₂S₃ single crystal formation in glass by micro x-ray diffraction *
COURTNEY AU-YEUNG (Presenter), Physics, Lehigh University, CAMELIA STAN, NOBUMICHI TAMURA, Lawrence Berkeley National Laboratory, HIMANSHU JAIN, Materials Science and Engineering, Lehigh University, VOLKMAR R G DIEROLF, Physics, Lehigh University — Single crystal architectures in glass can be formed by a solid-solid transformation via localized heating by a laser or x-ray beam. As a result of the confined environment and the asymmetry of the boundary conditions close to the surface new phenomena such as a rotating crystal lattice are observed. This novel form of a crystals can offer new functionalities in micro/nano-opto-electro-mechanical systems. To understand the process of lattice formation that proceeds via crystal growth, we have observed in situ Sb₂S₃ crystal formation under x-ray irradiation. In these experiments, an x-ray beam is used as the heating source to fabricate the crystal structures while Laue diffraction patterns are collected at the same time. We explore the earliest stages of crystallization in this model system wherein glass transforms into single crystal without any change in local composition or long-range diffusion. The implications of these observations for the origin of the lattice rotation and crystal growth in a confined medium will be discussed.

*This work is supported by the National Science Foundation Graduate Research Fellowship under Grant #DGE-1452783 and the U.S. Department of Energy, Basic Energy Science Division Award #DE-SC0005010
Characterization of stress induced by Si$_{1-x}$Ge$_x$ in the active epitaxial film on a SOI substrate via Scanning Surface PhotoVoltage Microscopy. JAMES SLINKMAN (Presenter), RF Technology Development, IBM Microelectronics (retired), DAMINDA DAHANAYAKA, PHILIP KASZUBA, LEON MOSZKOWICZ, RANDALL WELLS, SPM Laboratory, Globalfoundries, LLOYD BUMM, Dept. of Physics & Astronomy, University of Oklahoma — The mobility and breakdown voltage of field-effect transistors fabricated on a Silicon-on-Insulator substrate can be improved by embedding a Si$_{1-x}$Ge$_x$ layer in the active epitaxial silicon layer\textsuperscript{1}. The choice of the Ge fraction, $x$, dictates the mobility improvement due to band-bending proportionate to misfit strain. The thickness of the embedded Si$_{1-x}$Ge$_x$ layer, modulates associated stress relaxation, the density of extended defects, and degree of amorphization of the epitaxy. Techniques such as TEM and Raman spectroscopy are traditionally used to characterize the film stress state in such heterostructures. We present here a systematic study of the evolution of the stress state and relaxation as a function of the Si$_{1-x}$Ge$_x$ layer thickness in the active epitaxy on production SOI wafers using a novel technique, Scanning Surface PhotoVoltage Microscopy (SSPVM). These results are correlated with those obtained by Raman spectroscopy. Some advantages of the use of SSPVM are noted, as well other uses of it for semiconductor characterization.

Artificial Neural Networks for Analysis of Coherent X-Ray Diffraction Images* DANIEL ABARBANEL (Presenter), MARK SUTTON, HONG GUO, Physics, McGill University — We present an application of neural networks to the analysis of diffraction images produced via X-ray photon correlation spectroscopy (XPCS) experiments. The detection apparatus for these experiments is an array of charge-coupled devices (CCDs). Determining the incident location of each photon allows for estimation of the image contrast, which elucidates structural and dynamical properties of a measured system such as diffusion constant and particle radius. Photons incident on the detector in the same vicinity result in additive interference that obscures their individual locations. A neural network classifier was designed and trained on data from an artificial model to scan an image and determine a discrete probability distribution for the number of photons that have been incident within the area of each CCD. These distributions were fit to the contrast and were found to be in agreement with the true underlying value. We have thus demonstrated a promising method for accurately determining the contrast from experimental XPCS images.

*Supported by the Natural Sciences and Engineering Research Council (NSERC) and McGill University.

2-beam action spectroscopy for probing multiphoton absorption processes in semiconductors* NIKOLAOS LIAROS (Presenter), DANIEL JOVINELLI, JOHN T FOURKAS, University of Maryland, College Park — We recently introduced a new class of methods, called two-beam action (2-BA) spectroscopies for determining the order of effective absorptive nonlinearity in different materials. The 2-BA spectroscopy approach offers significant advantages over traditional logarithmic plots of an observable as a function of average excitation power, particularly when multiple orders of absorption are involved. In this work, we extend the 2-BA concept in a technique that we call 2-beam constant-amplitude photocurrent spectroscopy (2-BCAmP). We use this technique to study multiphoton absorption in wide-bandgap semiconductors. 2-BCAmP allows us for the measurement of the effective order of the absorption process at any desired value of the photocurrent or photovoltage, as opposed to traditional approaches that require data that span several orders of magnitude of average excitation power. Furthermore, the relative contributions of two different absorption orders can be extracted from non-integral 2-BCAmP exponents, and these data to validate the model of the absorption orders that are involved in photocurrent generation.

High-Resolution Localization with Arbitrary Point Spread Functions ROHAN PARAB, Texas Tech University, CRAIG SNOEYINK (Presenter), Mechanical and Aerospace Engineering, University at Buffalo — We present a method of three dimensional localization of particles which is agnostic to point spread functions and which achieves high localization resolution. By learning the spatial variation of the imaging system’s point spread function using computationally efficient spline surfaces it is possible to utilize convex expectation-maximization localization methods with any imaging system. Perhaps more importantly, this methodology allows for the use of common localization point spread functions (Astigmatism, Double-Helix, Bessel Beam among others) but where strong aberrations might have precluded measurements. In addition to the method we will present experimental results comparing the resolution of this technique to localization where the point spread function is well known.
10:00AM A23.00009: Development of in-situ RF-enabled high-brightness femtosecond electron microscopy for complex material research*  
SHUAISHUAI SUN (Presenter), XIAOYI SUN, DANIEL BARTLES, ELLIOT D WOZNIAK, JOSEPH WILLIAMS, FARAN ZHOU, Department of Physics and Astronomy, Michigan State University, NELSON SEPULVEDA, Department of Electrical and Computer Engineering, Michigan State University, CHONG-YU RUAN, Department of Physics and Astronomy, Michigan State University — Correlated structural and electronic degrees of freedom in electronic materials help engineer macroscopic functional responses to external control parameters. Increasingly, new functionalities have been explored through integrating different electronic materials to form hybrid interfaces. Spatially and temporally resolved imaging and spectroscopy probe could provide a new perspective to study functionalities in ever increasing complexity in these new material platforms. However, significant challenges exist in reaching adequate sensitivities at the ultrafast timescale and nanometer spatial scale. Here we report a new development of ultrafast in-situ electron microscopy to address this limitation through active control of high-intensity femtosecond electron pulses, targeting the respective probe space using adaptive optics. An integrated system with compact DC gun, RF compression optics, and commercial TEM electron optics is established with the aim of nanometer-scale selected area imaging and core-level spectroscopy with combined ~100 femtosecond and ~1 eV resolution. We demonstrate our first application in studying the inhomogeneous phase transitions in VO₂ microelectronic devices.

Monday, March 4, 2019 8:00 AM - 10:48 AM

Session A24 DAMOP: Strongly Interacting Quantum Fermi and Bose Gases BCEC 159 - Bo Zhen, University of Pennsylvania

8:00AM A24.00001: Probing the many-body physics via measurement of the closed-channel fraction in a ⁶Li superfluid*  
QIJIN CHEN, Zhejiang University, XING-CAN YAO (Presenter), XIANG-PEI LIU, HAO-ZE CHEN, XIAO-QIONG WANG, YU-XUAN WANG, YU-AO CHEN, Department of Modern Physics, University of Science and Technology of China, KATHRYN LEVIN, University of Chicago, JIAN-WEI PAN, Department of Modern Physics, University of Science and Technology of China — Atomic Fermi gases provide an ideal platform for studying the pairing and superfluid physics, utilizing a Feshbach resonance between closed channel molecular states and open channel scattering states. The closed-channel fraction \( Z \) contains important many-body interacting effects. Here we probe the many-body physics of interacting Fermi gases of \( ^6\text{Li} \) by measuring \( Z \) in the entire system. We have observed a significant departure from two-body physics. Away from the deep BEC regime, the fraction \( Z \) is sensitive to the Fermi temperature \( T_F \). In particular, our data show \( Z \sim \sqrt{T_F} \) at unitarity, in good agreement with theory. Further more, we have found a progressive departure of our measured \( Z \) value from theory as the system enters the BCS regime, calling for further investigation in both theory and experiment.

8:12AM A24.00002: Comparative Study of One-Dimensional Bose and Fermi Gases with Contact Interactions*  
YUTA SEKINO (Presenter), Department of Physics, Tokyo Institute of Technology, SHINA TAN, School of Physics, Georgia Institute of Technology, YUSUKE NISHIDA, Department of Physics, Tokyo Institute of Technology — One-dimensional spinless Bose and Fermi gases with contact interactions have the close relationship via Girardeau’s Bose-Fermi mapping, leading to the correspondences in their energy spectra and thermodynamics. However, correlation functions are in general not identical between these systems. We derive in both systems the universal relations for correlation functions, which hold for any energy eigenstate and any statistical ensemble of the eigenstates[1]. These relations include the large-momentum tails of static structure factors and of momentum distributions as well as energy relations, which connect the sums of kinetic and interaction energies to the momentum distributions. The relations involve two- and three-body contacts, which measure local two- and three-body correlations, respectively. We clarify how the relations for bosons and fermions differ and are connected with each other. In particular, we find that the three-body contact makes no contribution to the bosonic energy relation, but it plays a crucial role in fermionic one.

8:24AM A24.00003: Ultracold Gas of NaLi Molecules in the Triplet Ground State  JULIANA PARK (Presenter), Massachusetts Institute of Technology — Ultracold gases of molecules allow us to study short-range chemical reactions, novel quantum phases, and quantum information processing. The NaLi molecule, the lightest bi-alkali molecule, in the triplet ground state has permanent electric and magnetic dipole moments and is predicted to have a small universal loss rate leading to long collisional lifetime. This enables us to investigate the complexity of chemical reactions by finding links to scattering theory. Also, with the aid of tunable long-range interactions between the molecules, we can explore the possibility of quantum simulation of many-body physics. We have previously achieved the long-lived triplet ground state molecules in an optical dipole trap through a two-step process: formation of Feshbach molecules and stimulated rapid adiabatic passage. We report results of recent studies with our triplet state molecules including the observation of long lifetime of the molecules in a longer wavelength optical dipole trap.

8:36AM A24.00004: An improved Lieb-Robinson bound for many-body Hamiltonians with power-law interactions  FRANCISCO MACHADO (Presenter), University of California, Berkeley, DOMINIC ELSE, Massachusetts Institute of Technology and University of California, Santa Barbara, CHETAN NAYAK, University of California, Santa Barbara and Microsoft Research, Station Q, NORMAN YAO, University of California, Berkeley and Lawrence Berkeley National Laboratory, Materials Sciences Division — The Lieb-Robinson bound limits the velocity of the spread of information in non-relativistic short-range interacting quantum systems, inducing a notion of speed of light. More specifically, it proves that, under time evolution, any local operator remains confined (up to exponentially decaying tails) to a region whose radius grows linearly with time. Motivated by experimental platforms such as ion traps, Rydberg atoms and spin defects in solids, recent work has investigated such bounds in long-range interacting systems, where the interaction strength decays as a power-law of the distance. In these results, the extent of the time evolved local operator is characterized by power-law tails and one obtains a power-law light-cone. In this talk, we introduce a new notion of light-cone for power-law interacting systems that induces a more stringent definition of locality. We prove new Lieb-Robinson bounds for multi-body interacting systems which improve the spatial decay profile of the time evolved local operator and thus lead to a better light-cone. These improvements enable the proof of the existence of a long-lived prethermal regime in long-range interacting systems.

8:48AM A24.00005: Quantum phases of many-body dipolar system in one dimension*  NIRAJ GHIMIRE (Presenter), SUSANNE F YELIN, Department of Physics, University of Connecticut — We study the zero temperature quantum phases of dipoles in a quasi-one-dimensional zigzag chain. Since the dipole-dipole interaction is long-range, a dipolar many-body system is predicted to feature intriguing phases. We investigate the many-body effects in this model using the Density Matrix Renormalization Group (DMRG) method.

*This research project is supported by National Science Foundation.

9:00AM A24.00006: Efimov Enhanced Kondo Effect in Alkaline and Alkaline-Earth Atomic Gas Mixture  JUAN YAO (Presenter), HUI ZHAI, Tsinghua University, REN ZHANG, Xi'an Jiaotong University — Recent experiment has observed Feshbach resonances between alkaline and alkaline-earth atoms. These Feshbach resonances are insensitive to the nuclear spin of alkaline-earth atoms. Utilizing this feature, we propose to take this system as a candidate to perform quantum simulation of the Kondo effect. An alkaline atom can form a molecule with an alkaline-earth atom with different nuclear spins, which plays the role of spin-exchange scattering responsible for the Kondo effect. Furthermore, we point out that the existence of three-body bound state and atom-molecule resonance due to the Efimov effect can enhance this spin-exchange scattering, and therefore enhance the Kondo effect. We discuss this mechanism first with a three-body problem in free space, and then demonstrate that the same mechanism still holds when the alkaline atom is localized by an external trap and becomes an impurity embedded in the alkaline-earth atomic gases.

9:12AM A24.00007: Asymmetric Conductivity as a Manifestation of Kondo Effect in Cold Atom  YANTING CHENG (Presenter), XIN CHEN, Tsinghua University, ZHIGANG WU, Southern University of Science and Technology, REN ZHANG, Department of Applied Physics, School of Science, Xi'an Jiaotong University — Motivated by recent theoretical and experimental advances in the quantum simulation of alkaline earth(AE) atoms, we raise a proposal to detect the Kondo physics in cold atom system. It has been demonstrated that the intrinsic spin-exchange interaction in AE atoms can be significantly enhanced near a confinement-induced resonance(CIR), which facilitates the simulation of Kondo physics. Since the Kondo effect appears only for antiferromagnetic coupling, we find that the conductivity of such a system exhibits an asymmetry across a resonance of spin-exchange interaction. The asymmetric conductivity can serve as the smoking gun for Kondo physics in the cold-atom context. When an extra magnetic field ramps up, the spin-exchange process near Fermi surface is suppressed by Zeeman energy and hence the conductivity becomes more and more symmetric. Our results can be verified in the current experimental setup.
Variational methods are extensively used in quantum many-body problems to overcome the exponential growth of the Hilbert space with the system size. By focusing on a suitable submanifold of states, we can study properties of ground states and low excited states. Here, we will introduce a novel framework to approximate the low lying energy spectrum by studying the linearized Hamiltonian flow on the tangent plane to this manifold at the ground state.

Part I: After explaining our method, I will compare it with other tangent plane approaches and discuss key advantages in the context of the paradigmatic Bose-Hubbard model.

Variational methods are extensively used in quantum many-body problems to overcome the exponential growth of the Hilbert space with the system size. By focusing on a suitable submanifold of states, we can study properties of ground states and low excited states. Here, we will introduce a novel framework to approximate the low lying energy spectrum by studying the linearized Hamiltonian flow on the tangent plane to this manifold at the ground state.

Part II: I will focus on the underlying geometry and explain how the approximate ground state and the low energy spectra arise from invariant geometric structures of the variational manifold.

I will present an experimental test of the new theory of Generalized HydroDynamics (GHD), introduced in 2016 to describe long wave-length dynamics of one-dimensional (1d) quantum integrable systems [1]. Integrable systems possess an infinite number of conserved quantities and GHD takes into account the conservation of all of them. We monitor the time evolution of the in situ density profiles of a single 1d cloud of bosonic atoms trapped on an atom chip after a quench of the longitudinal trapping potential. The weakly interacting atomic clouds lie at the crossover between the quasicondensate and the ideal Bose gas regimes. Predictions of GHD are in very good agreement with the experiment. Previously existing theories such as the "conventional" hydrodynamic approach, which relies on the assumption of local thermal equilibrium, described by a Gibbs ensemble, are unable to reproduce the experimental data. These results can be found in [3].

10:12AM A24.00012: Hydrodynamics of operator spreading and quasiparticle diffusion in interacting integrable systems (part I)* SARANG GOPALAKRISHNAN, Physics, The Graduate Center, CUNY, DAVID HUSE, Physics, Princeton University, VEDIKA KHEMANI, Physics, Harvard University, ROMAIN VASSEUR (Presenter), University of Massachusetts Amherst — We address the hydrodynamics of operator spreading in interacting integrable lattice models. In these models, operators spread through the ballistic propagation of quasiparticles, with an operator front whose velocity is locally set by the fastest quasiparticle velocity. In interacting integrable systems, this velocity depends on the density of the other quasiparticles, so equilibrium density fluctuations cause the front to follow a biased random walk, and therefore to broaden diffusively. Ballistic front propagation and diffusive front broadening are also generically present in non-integrable systems in one dimension; thus, although the mechanisms for operator spreading are distinct in the two cases, these coarse grained measures of the operator front do not distinguish between the two cases. Our results elucidate the microscopic mechanism for diffusive corrections to ballistic transport in interacting integrable models.

10:36AM A24.00014: Hydrodynamics with Spacetime-dependent Scattering Length* KEISUKE FUJII (Presenter), YUSUKE NISHIDA, Department of Physics, Tokyo Institute of Technology — Hydrodynamics provides concise but powerful description of long-time and long-distance physics of correlated systems out of thermodynamic equilibrium. Here we construct hydrodynamic equations for nonrelativistic particles with the spacetime-dependent scattering length and show that it enters constitutive relations uniquely so as to represent the fluid expansion and contraction in both normal and superfluid phases. As a consequence, we find that a leading dissipative correction to the contact density due to the spacetime-dependent scattering length is proportional to the bulk viscosity. Also, when the scattering length is slowly varied over time in a uniform system, the entropy density is found to be produced even without fluid flows in proportion to the bulk viscosity, which may be useful as a novel probe to measure the bulk viscosity in ultracold atom experiments.

Session A25 DPOLY: Deformation, Flow and Relaxation of Melt and Glassy Polymers BCEC

160A - Robert Riggleman, University of Pennsylvania
8:00AM A25.00001: Dynamic Mechanical Spectrum of an Epoxy Polymer  JAMES M CARUTHERS (Presenter), YELIN NI, GRIGORI MEDVEDEV, Purdue University — Dynamic mechanical experiments were performed on an epoxy thermoset with a $T_g=101^\circ$C over a wide temperature range from -150$^\circ$C to 260$^\circ$C. Time-temperature superposition (TTS) is only observed at temperatures above $T_g+100^\circ$C where the network relaxation is the dominant relaxation process. At lower temperatures, both above and below $T_g$, TTS is clearly violated. The traditional representation of the relaxation spectrum as a sum of several broad empirical functions each with its own independent temperature dependence that are often designated as $\alpha$-, $\beta$-, etc. processes cannot describe the set of isotherms. Using a procedure that includes Tikhonov regularization with adaptive meshing, a relaxation spectrum consisting of discrete processes emerges. It is shown that determination of the spectrum is robust, resulting in a continuous spectrum at high temperatures and discrete peaks at lower temperatures. Each relaxation process has its own temperature dependence, which becomes stronger as $T_g$ is approached. Below $T_g$ the relaxation time of each process is affected differently by aging. The implications of a discrete spectrum of relaxation times vs. the more commonly assumed continuous distribution of relaxation processes for a theory of the amorphous state will be discussed.

8:12AM A25.00002: Different temperature dependence of nonlinear rheological responses in melt stretching*  JIANNING LIU, SHIQING WANG (Presenter), Department of Polymer Science, University of Akron — Decades of research in nonlinear polymer rheology [1] have not fully cleared all the confusion in the literature including one concerning the alleged difference in the rheological responses of entangled solutions and melts to fast extensional deformation. The idea of nematic interaction modification of chain friction has caused Huang et al. [2] to find support from the examination of three polystyrene solutions where the solvent is polystyrene of respective molecular weight equal 1 kg/mol (that has $T_g = 20^\circ$C), 2 kg/mol and 4 kg/mol with $T_g \sim 75^\circ$C. We refute this idea by investigating similar PS solutions to indicate a different interpretation by showing how a breakdown of the time-temperature superposition occurs in nonlinear responses of these solutions, causing the 1K solution to respond more strongly than a 5K solution where the 1K solution is examined at a lower temperature.

*This work is supported, in part, by NSF-DMR 1609977.

8:24AM A25.00003: Brittle-Ductile Transition of a polymer glass in the presence of a crack*  YEXIN ZHENG (Presenter), MESFIN TSIGE, SHIQING WANG, The University of Akron — Fracture behavior of polymer glasses under deformation has been widely studied in the experiment. However, molecular-level understanding of crack propagation in polymer glasses is still lacking. In this work, the standard bead-spring model based molecular dynamic simulation was modified to gain microscopic insights into the crack propagation in glassy polymers. In the presence of a pre-existing crack, the transition from brittle failure to shear yielding in extension was investigated by varying the temperature, the length of the pre-crack length and deformation rate. The results from the simulation are consistent with experiment. Our simulation results also show that the brittle-ductile transition temperature is strongly dependent on the strength of the pair potential.

*This work is supported, in part, by NSF-DMR 1609977.

8:36AM A25.00004: The relationship between unstable localized vibrational modes and dynamical heterogeneity in glass formers  WENGANG ZHANG (Presenter), JACK DOUGLAS, National Institute of Standards and Technology, FRANCIS STARR, Wesleyan University — The heterogenous dynamics of glass-forming materials is commonly characterized by the spatially correlated particles (clusters) with high and low mobilities, and are helpful for explaining the temperature dependence of the non-Arrhenius behavior of relaxation time. Due to the inherent difficulty to experimentally observe heterogeneous dynamical clusters, we consider the possibility that the localized unstable modes of the vibrational spectrum may be related to dynamical clusters. Specifically, we analyze the instantaneous normal modes (INMs) associated with the Hessian matrix of glass-forming liquids. We find that the particles that contribute most to the unstable, localized modes form spatially correlated clusters. We quantify the degree to which these clusters correlate to string-like cooperative motions and mobile clusters, and how polymer topology affects these clusters.
MASOUD RAZAVI (Presenter), SHIQING WANG, Department of Polymer Science, University of Akron — We borrow the insights that explain the molecular mechanism for the brittle-to-ductile transition in polymeric glasses [1] to study the mechanics of semicrystalline polymers. Polyesters such as poly(lactic acid) (PLA) and poly(ethylene terephthalate) (PET) are known to be brittle in their fully crystalline form. PLA is brittle in its amorphous state because of the rapid physical aging that cannot be avoided. Such poor mechanical properties are the bottleneck preventing the wider application of PLA to replace the petroleum-based polymers including PET. We demonstrate a strategy to make PLA tough and heat resistant with zero shrinkage at 100 °C along with a molecular picture detailing the structure-property relationship.

*This work is supported, in part, by NSF-DMR 1609977.

TREVOR BENNIN (Presenter), JOSHUA V RICCI, MARK EDIGER, University of Wisconsin - Madison — Polymer glasses are ubiquitous engineering materials, but their deformation is not well understood at a fundamental level. Here, the segmental dynamics of glassy poly(lactic acid) (PLA) were measured with a probe reorientation technique during constant strain rate tensile deformation at temperatures between T_g – 25 K and T_g – 15 K and local strain rates between 10^{-5} s^{-1} and 10^{-4} s^{-1}. The relaxation time of the undeformed PLA is about 10^4 s and decreases by up to a factor of 30 during deformation. The relaxation time in the plastic flow regime shows a temperature dependence of about 30 K/decade and is related to the local strain rate through a power-law relationship with an exponent near -1 for all investigated temperatures. We also find that the KWW β parameter for PLA increases during deformation from 0.42 to 0.60, indicating a narrowing of the distribution of relaxation times. These results are very similar to those previously reported on lightly crosslinked poly(methyl methacrylate) (PMMA) glasses, suggesting that these are universal effects of constant strain rate deformation on the segmental dynamics of polymer glasses.

*We thank the National Science Foundation (DMR-1708248) for support of this work

VALERIY GINZBURG (Presenter), Dow Chemical Company — The low-temperature behavior of glass-forming liquids is still poorly understood. Here, we propose a simple model with no divergence of relaxation time at any finite temperature. We hypothesize a “key degree of freedom” (KDF) associated with the Arrhenius-Andrade-Eyring transition state mechanism of the liquid flow. We then assume that the KDF energy levels are quantized in increments of ε (where ε can be an energy of a gauche-trans-gauche kink1 or another low-energy excitation). In that case, the “fictive temperature”, T_f, is proportional to the KDF internal energy, determined by the Planck-Bose-Einstein statistics, T_f = <u>/k_B = (ε/k_B)(exp(βε) – 1)^{-1}, where β = (k_B T)^{-1}. The temperature-dependent viscosity (or the shift factor) is then estimated in the standard fashion, ln(η) = const + (E_a/ε)(exp(βε) - 1) (where E_a is the Arrhenius activation energy). This expression is similar to the Mauro2 equation and is shown to agree very well with multiple experimental data sets for both polymers and organic liquids. The theory can be further extended to describe the behavior of random copolymers and miscible blends.

BRET SAVOIE (Presenter), GRIGORI MEDVEDEV, JAMES M CARUTHERS, Purdue University — Glass forming materials exhibit dramatic mobility decreases of up to ten orders of magnitude as their temperature approaches T_g. This slow-down exhibits a super-Arrhenian temperature dependence that is diagnostic for testing competing theories of glass formation. Using experimental data, it was recently shown that for 21 molecular glass formers a simple one-parameter model based on the excess enthalpy accurately predicts the super-Arrhenian behavior, whereas the traditional configurational entropy model of Adam-Gibbs shows significant deviations. Extending this analysis to polymeric materials is challenging since the requisite experimental data is limited. Here we present simulations on several common small molecules and polymers to explore the temperature dependence of the polymer dynamics in the supercooled regime, making comparisons with the new configurational enthalpy model and experimental data where available. We show that the configurational enthalpy model accurately describes the temperature and pressure dependence of the mobility slowdown in the studied polymers. Moving forward this provides justification for using simulations to investigate the molecular mechanisms responsible for the accurate predictions of the configurational enthalpy model.
9:36AM A25.00009: Chain-length dependent relaxation dynamics in glass-forming polymers*  DANIEL BAKER, Physics & Astronomy, University of Leeds, ROBIN MASUREL, University of Paris, Diderot, MATTHEW REYNOLDS, Physics & Astronomy, University of Leeds, PETER OLMSTED (Presenter), Georgetown University, JOHAN MATTSSON, Physics & Astronomy, University of Leeds — We present experimental and computational results on the effects of molecular size, monomer chemistry, and flexibility on the relaxation behaviour of glass-forming polymers. We show experimental data from broadband dielectric spectroscopy, calorimetry, and oscillatory rheology together with RIS computer simulation calculations. We discuss the length-dependence of molecular relaxation dynamics, chain conformation and shape; and relate these features to the glass transition temperature. We discuss the links between glass-formation in small molecules and oligomeric/polymeric glass-formers and the dependences on polymer chemistry and flexibility.

*Funding provided from Georgetown University, JS Ives Endowment, the UK Engineering and Physical Sciences Research Council.

9:48AM A25.00010: Dynamics of Viscoelastic Filaments based on Onsager Principle*  JIAJIA ZHOU (Presenter), MASAO DOI, Beihang University — When a polymer solution is uniaxially stretched and held fixed at both ends, the solution quickly separates into droplets connected by strings and takes the beads-on-string structure. The string then becomes thinner by capillary forces. Here we develop a theoretical framework on viscoelastic fluids based on Onsager principle, and apply it to the dynamics of viscoelastic filaments. We show that the beads-on-string structure is a thermodynamic quasi-equilibrium state, and derive an equation for the coexistence condition in the pseudo-equilibrium state. Using the condition, we solve the evolution equation analytically and show that the string radius and the tensile stress vary exponentially as predicted by the classical theory of Entov and Hinch [J. Non-Newtonian Fluid Mech. 72, 31 (1997)], but the prefactor for the tensile stress is different from their theory and agrees with the numerical solutions of Clasen et al. [J. Fluid Mech. 556, 283 (2006)].

10:00AM A25.00011: Visco-Elastic Property Reconstitution in Chain-Like Polymers*  MANON HEILI, JOHN KIEFFER (Presenter), University of Michigan — We investigate the elastic deformation and structural reorganization process in a chain-like polymer, e.g., polyvinylidene fluoride (PVDF) during straining and stress relaxation. Using a unique experimental setup in which a miniature tensile tester is placed into the optical path of a Brillouin light scattering (BLS) system, we simultaneously measure the adiabatic and isothermal elastic moduli of the polymer as a function of the strain history. Upon straining, elastic moduli of the polymer drop instantaneously, while during stress relaxation at constant strain both the static and adiabatic moduli reconstitute, tending towards the unstrained values. While such behavior is expected for the former, it is not for the latter. Although a detailed analysis allows us to identify a spectrum of relaxation rates, general visco-elastic theory (e.g., Maxwell-Wiechert model) is not adequate to describe the observed behavior, not even that of the static moduli. An improved description of material's visco-elastic response requires taking the structural rearrangements during straining and relaxation into account, and that the relaxation mechanisms, as well as the inherent elastic properties of the strained and unstrained polymer are indeed different.

Tube models are not compatible with the slip-link model for entangled star polymers*  

JAY SCHIEBER (Presenter), KONSTANTIN TALETSKIY, Illinois Institute of Technology — The dynamics of entangled linear and star polymers have been described reasonably successfully by both the slip-link model and various tube models. Theory suggests that constraint dynamics plays a much larger role for star polymers than for linear chains, and has been essential in describing data even qualitatively. Experimentally, the role of constraint dynamics can be examined by blending star and linear chains. However, recent work has shown that the tube models are incapable of explaining these blends, whereas the slip-link model agrees well without any parameter adjustment.

These observations raise the question of whether slip-link models are capable of repairing the discrepancy of tube models with data. We have attempted to coarse grain the slip-link model to a tube level of description of stars. We find that the two models predict very different molecular weight dependence on the relaxation time of star arms without constraint dynamics. Moreover, we find that the tube level of description is incapable of capturing the physics in the slip-link model. We conclude that the two theories are incompatible, and at least one of them should be eliminated by comparison with data.

Thermal and viscoelastic properties of selectively hydrogenated poly(1,1-diphenylethylene-alt-butadiene)  

SUNGMIN PARK (Presenter), GAGAN KANGOVI, SANGWOO LEE, Rensselaer Polytechnic Institute — The synthetic utility of 1,1-diphenylethylene (DPE) to produce nearly perfectly alternating copolymers of DPE and vinyl monomers is well-established, but the physical properties of the alternating DPE copolymers have not been well documented. We characterized the thermal and viscoelastic properties of nearly perfectly alternating copolymer of 1,1-diphenylethylene (DPE) and butadiene and its selectively hydrogenated polymers. The entanglement molecular weights of the DPE-butadiene alternating copolymer and hydrogenated copolymers are measured 20 – 22 kg/mol. Interestingly, the glass transition temperatures of the DPE-butadiene copolymers decrease from 120 °C to 100 °C as the copolymer is selectively hydrogenated, and this behavior is opposite to the earlier report on the increasing glass transition temperature of hydrogenated DPE and styrene copolymers.

The Density Fluctuations of Polycarbonate under Deformation by Time-resolved small angle X-ray Scattering  

SHOTARO NISHITSUJI (Presenter), HIROSHI ITO, MASARU ISHIKAWA, TAKASHI INOUE, Yamagata University, MIKIHIITO TAKENAKA, Kyoto University — Polycarbonate(PC) in an excellent thermoplastic with high impact strength, good transparency and so on. However, PC becomes brittle by annealing below the glass transition temperature. The mechanism of this phenomenon, which is so-called physical aging, is not clarified. To understand this phenomenon, we focus on density fluctuations of PC. By using a strong X-ray source of synchrotron, this density fluctuations can be detected under deformation. In this study, the change with density fluctuations of PC under deformation is investigated by using time-resolved small angle X-ray scattering. PC sample used in this study is a commercial polymer (viscosity average molecular weight Mv=19,500). Time-resolved small angle X-ray scattering is carried out under a constant load at BL05XU, SPring-8, Japan. At steady state, the isotropic scattering pattern is detected. After applying a load, the scattering pattern become anisotropic and the scattering intensity is enhanced in the parallel direction of load. This means the density fluctuations are enhanced by deformation. After necking, the density fluctuations are enhanced at an accelerating rate. We will discuss the detailed change of density fluctuations in this presentation.

Accelerated and depressed aging of PS blocks under 3D nanoconfinement in diblock copolymers  

MINGCHAO MA (Presenter), YUNLONG GUO, Shanghai jiao Tong University — In this work, physical aging of polystyrene (PS) blocks in two representative diblock copolymers were investigated by a differential scanning calorimeter. Aging of PS blocks was remarkably accelerated in polystyrene-\textit{block}-poly(methyl methacrylate) (PS-b-PMMA), compared to the homo-PS. In addition, the enthalpy results demonstrate that the aging rate of PS blocks in PS-b-PMMA increases with larger PMMA/PS mole ratio. On the other hand, the aging rate of PS blocks in polystyrene-\textit{block}-poly(n-butyl methacrylate) (PS-b-PnBMA) is lower than the relaxation rate of corresponding neat PS. Together with morphology in these copolymers, the aging results imply that the hard three-dimensional confinement induced by the PMMA blocks accelerates the aging rate of relatively soft PS blocks in copolymer, while the sluggish aging of PS blocks in PS-b-PnBMA is attributed to the extremely soft confinement formed by PnBMA blocks, which was liquid in the aging process due to its low glass transition temperature.
8:00AM A26.00001: Measurement of GHZ and cluster state entanglement monotones in transmon qubits

AMARA KATABARWA (Presenter), MICHAEL GELLER, University of Georgia — Experimental detection of entanglement in superconducting qubits has been mostly limited, for more than two qubits, to witness-based and related approaches that can certify the presence of some entanglement, but not rigorously quantify how much. Here we measure the entanglement of three- and four-qubit GHZ and linear cluster states prepared on the 16-qubit IBM Rueschlikon (ibmqx5) chip, by estimating their entanglement monotones. We measure the decay of the monotones with time, and find in the GHZ case that they actually oscillate, which we interpret as a drift in the relative phase between the all zero and all one components, but not an oscillation in the actual entanglement. After experimentally correcting for this drift with virtual Z rotations we find that the GHZ states appear to be considerably more robust than cluster states, exhibiting higher fidelity and entanglement at later times. Our results contribute to the quantification and understanding of the strength and robustness of multi-qubit entanglement in the noisy environment of a superconducting quantum computer.

8:12AM A26.00002: Scalable generation of genuine multiparticle entanglement with superconducting qubits

MING GONG (Presenter), MING-CHENG CHEN, YARUI ZHENG, SHIYU WANG, CHEN ZHA, HUI DENG, ZHIGUANG YAN, HAO RONG, YULIN WU, SHAOWEI LI, FUSHENG CHEN, YOUWEI ZHAO, FUTIAN LIANG, JIN LIN, YU XU, CHENG GUO, LIHUA SUN, ANTHONY D CASTELLANO, Hefei National Laboratory for Physical Sciences at Microscale and Department of Modern Physics, University of Science and Technology of China, Hefei, HAOHUA WANG, Department of Physics, Zhejiang University, CHENGZHI PENG, CHAO-YANG LU, XIAOBO ZHU, JIAN-WEI PAN, Hefei National Laboratory for Physical Sciences at Microscale and Department of Modern Physics, University of Science and Technology of China, Hefei — Solid state qubits by their nature are a scalable technology, but the number of entangled qubits still trails the size of state-of-the-art systems considerably. Producing large entangled states requires many different measures of processor quality to be high simultaneously: coherence times and tunability must be high; crosstalk and state leakage must be minimized. In addition, gate operations need to be specifically calibrated to create entanglement. In this work, based only on single-qubit gates and controlled-phase gates, we generated and verified the genuine multiparticle entanglement for more than 10 superconducting qubits. This gate-based approach to entanglement generation is directly scalable to larger systems. Our result is an important step towards achieving near-term quantum supremacy.

8:24AM A26.00003: Simple preparation of Bell and GHZ states using ultrastrong-coupling circuit QED

ANTON FRISK KOCKUM (Presenter), Chalmers University of Technology, VINCENZO MACRÌ, FRANCO NORI, RIKEN — The ability to entangle quantum systems is crucial for many applications in quantum technology, including quantum communication and quantum computing. Here, we propose a new, simple, and versatile setup for deterministically creating Bell and Greenberger-Horne-Zeilinger (GHZ) states between photons of different frequencies in a two-step protocol. The setup consists of a quantum bit (qubit) coupled ultrastrongly to three photonic resonator modes. The only operations needed in our protocol are to put the qubit in a superposition state, and then tune its frequency in and out of resonance with sums of the resonator-mode frequencies. By choosing which frequency we tune the qubit to, we select which entangled state we create. We show that our protocol can be implemented with high fidelity using feasible experimental parameters in state-of-the-art circuit quantum electrodynamics. One possible application of our setup is as a node distributing entanglement in a quantum network.
8:36AM A26.00004: Proposal to Generate and Characterize Quantum Entanglement using Coupled Metamaterial Resonators* FRANCISCO ROUXINOL (Presenter), Condensed Matter Physics Department, University of Campinas, FREDERICO BRITO, Instituto de Fisica de Sao Carlos, Universidade de Sao Paulo, MATTHEW LAHAYE, B.L.T. PLOURDE, Physics Department, Syracuse University — Entanglement is an underlying principle in quantum physics. Undoubtedly, the consequences of the correlations observed between measurements in spatially separated entangled systems has had a profound effect on our view of local realism of the world (EPR, Bell etc.). Using a left-handed metamaterial coupled to a nanomechanical resonator, we propose a new procedure to couple multiple microwave resonant modes and investigate entanglement in these limits. These investigation allow for the possibility to develop new techniques for characterizing entanglement in multi-mode systems. The potential of using these circuits in QED architectures is discussed.

8:48AM A26.00005: Propagating Non-Gaussian States Generated by Degenerate 3-photon Downconversion CHUNG WAI SANDBO CHANG (Presenter), A. VADIRAJ, IBRAHIM NSANZINEZA, CHRISTOPHER WILSON, University of Waterloo — Nonclassical light sources have generated broad interest across a number of fields for their potential to enable novel quantum protocols. Spontaneous parametric downconversion (SPDC) processes have been widely adopted as an essential source of nonclassical light, generating various resource states. However, SPDC beyond second order has been an experimental challenge for decades. Here, with a superconducting parametric cavity designed for cubic interactions, we present experimental results for spontaneous three-photon downconversion when the cavity is flux pumped at three times the mode frequency. We measure propagating output states that are clearly non-Gaussian with a high degree of skewness in the quadrature amplitude distribution. Further, theory predicts that Wigner function negativity can persist for these states even after they escape from the cavity. With a linear detection scheme, we reconstruct the Wigner function of the propagating states from the directly measured moment matrix. We will present preliminary results on this reconstructed Wigner function.

9:00AM A26.00006: Multipartite entanglement mediated by shared microwave resonators* MARIE LU (Presenter), SYDNEY SCHREPPLER, University of California, Berkeley, LUKAS F BUCHMANN, FELIX MOTZOI, Physics, Aarhus University, IRFAN SIDDIQI, University of California, Berkeley — Developing highly connected networks of qubits is invaluable for implementing various quantum codes and simulations. Increased connectivity allows for entangling qubits with reduced gate depth. For example, the Mølmer-Sørensen gate generates high fidelity entanglement between multiple ions. We use shared coplanar waveguide (CPW) resonators to realize an analogous Mølmer-Sørensen gate between superconducting qubits. This talk describes how the CPW enables multipartite entanglement of all qubits coupled to the resonator as well as arbitrary subsets of qubits.

9:12AM A26.00007: Probing the Tavis-Cummings level splitting with intermediate-scale superconducting circuits* MARTIN WEIDES (Presenter), University of Glasgow, PING YANG, JAN DAVID BREHM, JUHA LEPPAEKANGAS, Institute of Physics, Karlsruhe Institute of Technology, LINGZHEN GUO, Max Planck Institute for the Science of Light, MICHAEL MARTHALER, Institute for Theoretical Condensed Matter physics, Karlsruhe Institute of Technology, ISABELLA BOVENTER, Institute of Physics, University Mainz, ALEXANDER STEHLI, TIM WOLZ, ALEXEY USTINOV, Institute of Physics, Karlsruhe Institute of Technology — We demonstrate the local control of up to eight two-level systems interacting strongly with a microwave cavity. Following calibration, the frequency of each individual two-level system (qubit) is tunable without influencing the others. Bringing the qubits one by one on resonance with the cavity, we observe the collective coupling strength of the qubit ensemble. The splitting scales up with the square root of the number of the qubits, being the hallmark of the Tavis-Cummings model. The local control circuitry causes a bypass shunting the resonator, and a Fano interference in the microwave readout, whose contribution can be calibrated away to recover the pure cavity spectrum. The simulator's attainable size of dressed states is limited by reduced signal visibility, and -if uncalibrated- by off-resonance shifts of sub-components. Our work demonstrates control and readout of quantum coherent mesoscopic multi-qubit system of intermediate scale under conditions of noise.

9:24AM A26.00008: Improving the fidelity of entangling gates via \textit{in situ} characterization of qubit control lines. ANATOLY KULIKOV (Presenter), MARKUS JERGER, ARKADY FEDOROV, ARC Centre for Engineered Quantum Systems — One of the factors limiting the fidelity of entangling gates are control signal distortions arising from non-trivial transfer functions of microwave lines. Distortions can be canceled, in principle, if the complex transfer function of the control line is known, by applying its inverse to the signal before it is transmitted. We have previously developed a method for \textit{in-situ} measurement of the system function using a qubit as a network vector analyser [1]. I will present the refinement of the method and its experimental application to improve the fidelity of CPHASE gate between two superconducting transmon qutrits. I will also show how our technique can be combined with other recently reported \textit{in-situ} methods to calibrate low-frequency response of control lines [2,3] to further enhance the fidelity of the two-qubit gates.

9:36AM A26.00009: \textbf{Fast Amplification and Rephasing of Entangled Cat States in a Qubit-Oscillator System} T. Fuse (Presenter), National Institute of Information and Communications Technology, Zhihao Xiao, Louisiana State University, Sahel Ashhab, Qatar Environment and Energy Research Institute, Fumiki Yoshihara, Kouichi Samba, Masahide Sasaki, Masahiro Takeoka, National Institute of Information and Communications Technology, Jonathan P Dowling, Louisiana State University — In this work [1], we study a qubit-oscillator system described by the quantum Rabi model with a time-dependent coupling coefficient, and present two schemes. We propose a scheme for the fast generation of entangled Schrödinger-cat states. We propose another scheme for protecting the cat states against dephasing caused by the nonlinearity in the system. We focus on the case where the qubit frequency is small compared to the oscillator frequency. We first present the exact quantum state evolution in the limit of infinitesimal qubit frequency, and then analyze the first-order effect of the nonzero qubit frequency. Our scheme works for systems with wide range of coupling strength, including the ultra-strong and deep-strong coupling regimes [2-5].

9:48AM A26.00010: \textbf{Ground-state cooling, Fock-state stabilization and photon-resolved thermalization dynamics in a hot 170 MHz resonator} M. Gely (Presenter), Marios Kounalakis, Christian Dickel, Jacob Dalle, Rémy Vatré, Mark D Jenkins, Gary Steele, Delft University of Technology — In order to observe coherent quantum effects, systems are usually cooled to their thermal ground states. Despite millikelvin temperatures being a dominant energy scale in a 170 MHz circuit QED mode, we show that quantum control of the mode can still be realized. This is achieved by coupling it to a cold mode at 5.9 GHz through the non-linearity of a Josephson junction shared between both modes. The resulting coupling leads to photon number splitting that allows reading out the state of the low frequency mode. Via four-wave mixing, we can sideband cool the low-frequency mode to its ground state, as well as stabilize one- and two-photon Fock states. In time-domain, we can then observe the photon-resolved thermalization dynamics of these stabilized states. Our platform could be used to resonantly interface quantum circuits with MHz frequency systems (e.g. mechanical elements) or enable further exploration of thermodynamical processes at the quantum scale.

**10:00AM A26.00011: Probing the influence of many-body fluctuations on Cooper pair tunneling using circuit QED**

SÉBASTIEN LÉGER (Presenter), JAVIER PUERTAS, LUCA PLANAT, REMY DASSONVILLE, VLADIMIR MILCHAKOV, KARTHIK SRIKANTH BHARADWAJ, JOVIAN DELAFORCE, FARSHAD FOROUGHI, OLIVIER BUISSON, CECILE NAUD, WIEBKE GUICHARD, Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, 38000 Grenoble, France, IZAK SNYMAN, Mandelstam Institute for Theoretical Physics, School of Physics, University of the Witwatersrand, Johannesburg, South Africa, SERGE FLORENS, NICOLAS ROCH, Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, 38000 Grenoble, France —

Because of the value of the hyperfine constant (~ 1/137) observing many body effects in light-matter interaction is challenging. Reaching this regime is now possible using the tools of circuit Quantum ElectroDynamics (cQED) [1,2]. In this work we investigate the interactions between the plasma modes propagating in arrays of more than 4000 SQUIDs (which simulate the light) and a small Josephson junction (the matter). The first effect of these modes is to broaden the energy level of the Josephson junction [1,2]. More interestingly they can also induce strong phase fluctuations across the junction, which directly affects the Cooper pair tunneling. We will present our on-going experimental efforts aimed at observing this purely quantum many-body effect.

**10:12AM A26.00012: Driving not so forbidden state transitions in a frequency-tunable transmon**

ALEXANDER OPREMCAK (Presenter), University of Wisconsin-Madison and Google, BEN CHIARO, BROOKS FOXEN, MATTHEW MCEWEN, Physics, University of California, Santa Barbara, ROBERT F MCDERMOTT, University of Wisconsin-Madison, JOHN M MARTINIS, Google — In a frequency-tunable transmon, transitions between the |0> and |2> states are nominally forbidden by selection rules, yet an experiment (Sank et al., PRL 117) observed that it is possible to drive these transitions. In this talk we explain that observation. We show that the apparent selection rule violation is a direct consequence of parametric modulation of the Josephson energy of the compound junction of the device. From a theoretical analysis of the dc SQUID, we derive a drive term that explains the violation. We validate our theory using experimentally measured Rabi oscillations and Ramsey interferometry on the |0> --> |2> transition. Surprisingly, the transition occurs for a transmon driven through a capacitor, indicating a modest degree of stray inductive coupling between the XY drive line and the compound junction of the transmon. These results identify a leakage channel and should inform efforts to integrate cryogenic control systems with arrays of frequency-tunable transmons.

*This work was supported by Google.

**10:24AM A26.00013: Perfect quantum state transfer in a superconducting qubit chain with parametrically tunable couplings**

XUEGANG LI (Presenter), Tsinghua University — Faithfully transferring quantum state is essential for quantum information processing. Here, we demonstrate a fast (in 84 ns) and high-fidelity (99.2%) transfer of arbitrary quantum states in a chain of four superconducting qubits with nearest-neighbor coupling. This transfer relies on full control of the effective couplings between neighboring qubits, which is realized only by parametrically modulating the qubits without increasing circuit complexity. Once the couplings between qubits fulfill specific ratio, a perfect quantum state transfer can be achieved in a single step, therefore robust to noise and accumulation of experimental errors. This quantum state transfer can be extended to a larger qubit chain and thus adds a desirable tool for future quantum information processing. The demonstrated flexibility of the coupling tunability is suitable for quantum simulation of many-body physics which requires different configurations of qubit couplings.

*This work was supported by the National Key R & D Program of China (Grants No. 2017YFA0304303 and No. 2016YFA0301803) and National Natural Science Foundation of China (Grants No. 11474177, No. 11874156, and No. 61771278). L. S. also thanks R. Vijay and his group for help on the parametric amplifier measurements.
Tunability and coherence are the desired properties of an ideal quantum computer. However, introducing tunability directly in the qubit often adversely affects its coherence. This tunability-coherence tradeoff can be optimized by using fixed frequency qubits coupled with a tunable coupler. This architecture has been widely used for demonstrating parametrically stimulated entangling gates. In previous theoretical studies of superconducting circuits, the coupler has always been assumed to be in the ground state and an examination of the temperature dependence of parametric gates has been lacking. Here we present the importance of thermalization of the tunable coupler, to the base temperature of a dilution refrigerator, for achieving a high-fidelity parametric gate. This talk is based on the work presented in "Suppression of Qubit Crosstalk in a Tunable Coupling Superconducting Circuit" (arXiv:1810.04182 [quant-ph]).

Quantum entanglement dynamics due to dynamical Lamb effect

Mirko Amico (Presenter), Oleg Berman, Roman Kezerashvili, CUNY Graduate Center — We investigate the dynamics of a system of \( N \) qubits coupled to a common resonator with time-dependent coupling. The instantaneous switching on and off of the qubit/cavity coupling gives rise to the dynamical Lamb effect. The dynamical Lamb effect is the parametric excitation of the qubits, and the creation of cavity photons, due to the sudden change in Lamb shift of the qubit. In the absence of dissipation, the Schrodinger equation which describes the dynamics of the \( N \) qubits is solved within a perturbative approach. When dissipation is taken into account, the Lindblad equation for the system of \( N \) qubits is solved numerically. Different measures of entanglement compatible with pure and mixed states are adopted. The concurrence and the negativity are obtained in the two-qubit case; the three-\( \pi \) and the negativity are obtained in the three-qubit case. It is demonstrated that the different measures show different level of details of the entanglement between the qubits. We find that the dynamical Lamb effect can be used to create Greenberger-Horne-Zeilinger states even in presence of dissipation. Furthermore, the dynamical Lamb effect can be used as a fast entangling gate between two qubits.

Monday, March 4, 2019 8:00 AM - 10:48 AM

Session A27 DQI: Quantum Simulation of Many-Body Physics

8:00AM A27.00001: WITHDRAWN ABSTRACT

8:12AM A27.00002: Hybrid quantum-classical algorithm for variational coupled cluster method

Sathyawageeswar Subramanian (Presenter), DAMTP, Cambridge University, Yudong Cao, Zapata Computing, Inc. — We present a hybrid quantum algorithm for the variational coupled cluster (vCC) method in quantum chemistry. We show that for a problem instance of \( n \) electrons described by \( m \) spin orbitals and a constant level \( \ell' \) of excitations, the energy expectation value of the vCC trial wavefunction can be estimated to precision \( \varepsilon \) in time proportional to \( \widetilde{O}(n^{3/2}m^{3/2}/\epsilon^2) \) on a quantum computer. Classically, computing the same expectation generally incurs a cost exponential in \( n \) and \( m \), implying that our quantum algorithm can yield a significant speedup over known classical methods. We envision that such capability combined with the framework of the variational quantum eigensolver (VQE) will add to recent quantum algorithms for unitary coupled cluster methods, enriching the toolset of quantum chemistry calculations beyond what is feasible on classical computers. We also illustrate a method for calculating analytical gradients for the vCC method, which can be used with gradient-free direct-search optimisation methods (such as the Nelder-Mead and COBYLA algorithms).

8:24AM A27.00003: Optical manipulation of entanglement in plasmonically coupled quantum dot qubits

Matthew Otten, Stephen K Gray, CNM, Argonne National Lab, German Kolmakov (Presenter), Physics, New York City College of Technology — We consider a system composed of two quantum dot qubits coupled with a common, damped surface plasmon mode; each quantum dot is also coupled to a separate photonic cavity mode. Cavity quantum electrodynamics calculations show that upon optical excitation by a femtosecond laser pulse, entanglement of the quantum dot excitons occurs, and the time evolution of the \( g(2) \) pair correlation function of the cavity photons is an indicator of the entanglement. We also show that the degree of entanglement is conserved during the time evolution of the system. Furthermore, if coupling of the photonic cavity and quantum dot modes is large enough, the quantum dot entanglement can be transferred to the cavity modes to increase the overall entanglement lifetime. This latter phenomenon can be viewed as a signature of entangled, long-lived quantum dot exciton-polariton formation. The preservation of total entanglement in the strong coupling limit of the cavity/quantum dot interactions suggests a novel means of entanglement storage and manipulation in high-quality optical cavities.
**8:36AM A27.00004: Simulating the t-J Model on a Quantum Computer**
BRIAN ROST (Presenter), JAMES FREERICKS, Georgetown University — Quantum computers are expected to give an exponential speed-up over classical computers for the simulation of strongly correlated quantum systems. Efficient implementation of these simulations is of great interest for many fields in the physical sciences. We consider algorithms for simulating the t-J model, a prominent model for high temperature superconductivity, on a quantum computer. Our approach focuses the computation on the low-energy projected phase space instead of taking the large interaction limit of the Hubbard model. We investigate trade-offs in noise, complexity, time and gate count in extracting the system's Green's function and self-energy, from which a wide variety of interesting physical quantities can be computed.

In addition, BR received supplemental support from the National Science Foundation under Award DMR-1747426 and JKF received supplemental support from the McDevitt bequest at Georgetown.*

**8:48AM A27.00005: Non-linear sigma model approach to many-body quantum chaos: regularized and unregularized out-of-time-ordered correlators**
YUNXIANG LIAO (Presenter), VICTOR GALITSKI, University of Maryland, College Park — In this work, we derive an extended version of Keldysh non-linear sigma model to investigate many-body quantum chaos in a 2D interacting fermion system subject to quenched disorder. This model provides a framework in which the regularized and unregularized out-of-time-ordered correlators with different arrangements of the thermal factors can be studied. The two types of correlators grow exponentially with different growth rates which can be extracted from the mass of the “inter-world” diffuson propagator. This should be compared with its “intra-world” counterpart that gives the dephasing rate corresponding to the phase relaxation of single-particle states. Our result for regularized exponent is consistent with the previous one obtained from the diagrammatic perturbation approach. Furthermore, the regularized (unregularized) exponent obeys (violates) the chaos bound 2πT. We note that the regularized exponent is entirely due to the inelastic collisions between particles, while the unregularized exponent contains an additional contribution from elastic scattering of particles off of the Friedel oscillations of the particle density. Therefore, we believe that the unregularized exponent cannot measure many-body quantum chaos which originates from interactions.

**9:00AM A27.00006: Information spreading in many-body systems and the out-of-time-ordered correlator**
SHENGLONG XU (Presenter), BRIAN SWINGLE, University of Maryland, College Park — The information spreading in quantum many-body systems under unitary real-time evolution is related to the growth of simple Heisenberg operators, which is quantified by out-of-order correlation (OTOC) functions. Using a time-dependent disordered Hamiltonian model, I will analytically show the emergence of hydrodynamics description of the OTOC arising from the unitary real-time dynamics. Corrections of quantum fluctuation are manifested as the diffusively broadened wavefront of the OTOC. This picture is supported by large-scale (~200 spins) real-time dynamics simulation on realistic spin Hamiltonians using our newly developed tensor-network method.

**9:12AM A27.00007: Graph theory and bounds on operator growth**
ANDREW LUCAS (Presenter), Stanford University — Motivated by recent developments in many-body quantum chaos, I will present bounds on the growth of operators in k-local quantum many-body systems. These bounds can be interpreted as simple combinatorics problems in graph theory. I will give explicit examples of how these bounds can be parametrically stronger than Lieb-Robinson bounds.
Quantum codes for quantum simulation of Fermions on a square lattice of qubits*  
MARK STEUDTNER (Presenter), Lorentz Institute, STEPHANIE WEHNER, Delft University of Technology, QuTech — Quantum simulation of fermionic systems is a promising application of quantum computers, but in order to program them, we need to map fermionic states and operators to qubit states and quantum gates. While quantum processors may be built as two-dimensional qubit networks with couplings between nearest neighbors, standard Fermion-to-qubit mappings do not account for that kind of connectivity. In this work we concatenate the (one-dimensional) Jordan-Wigner transform with specific quantum codes defined under the addition of a certain number of auxiliary qubits. This yields a novel class of mappings with which any fermionic system can be embedded in a two-dimensional qubit setup, fostering scalable quantum simulation. Our technique is demonstrated on the two-dimensional Fermi-Hubbard model, that we transform into a local Hamiltonian. What is more, we adapt the Verstraete-Cirac transform and Bravyi-Kitaev Superfast simulation to the square lattice connectivity and compare them to our mappings.

Tripartite information and scrambling in quantum lattice models*  
OSKAR H. SCHNAACK, Max-Planck-Institute for Dynamics and Selforganization, SEBASTIAN PAECKEL, SALVATORE MANMANA (Presenter), STEFAN KEHREIN, University of Gottingen, MARKUS SCHMITT, UC Berkeley — For the characterization of dynamics in quantum many-body systems the question how information spreads and becomes distributed over the constituent degrees of freedom is of fundamental interest. The delocalization of information under many-body dynamics has been dubbed "scrambling" and out-of-time-order correlators were proposed to probe this behavior. In this work we investigate the time-evolution of tripartite information as a natural operator-independent measure of scrambling, which quantifies to which extent the initially localized information can only be recovered by global measurements. Studying the dynamics of quantum lattice models with tunable integrability breaking we demonstrate that in contrast to quadratic models a generic non-integrable system scrambles information irrespective of the chosen partitioning of the Hilbert space, which justifies the characterization as "scrambler."

Realizing quantum Ising models in tunable two-dimensional arrays of single Rydberg atoms  
[Invited] ANTOINE BROWAEYS (Presenter), Institut d'Optique — tbd

Phase structure of Ising models at complex temperature*  
VADIM OGANESYAN, SANKHYA BASU (Presenter), Physics and Astronomy, CSI and GC, CUNY — This work explores continuation of phases and phase transitions in statistical sums of planar Ising models to complex couplings -- temperature and field. We use a combination of analytic and numerical techniques, based on tensor network formulations of renormalization group (TRG and SRG) to access the regimes of phase space displaying novel modulated correlations and entirely out of reach of standard monte carlo methods. We also study and improve convergence and stability properties of tensor renormalization methods.

*NSF DMR Grant No. 1508538

Quantum Feedback Protocol for Calculating Single-Particle Green's Functions at Finite Temperature*  
JAMES FREERICKS (Presenter), JEFFREY COHN, Georgetown University, FOREST YANG, Computer Science and Physics, University of California, Berkeley, KHADIJEH NAJAFI, Georgetown University, BARBARA JONES, IBM — Drawing on the eigenstate thermalization hypothesis, we present a quantum feedback algorithm that approximates single-particle Green's functions at finite temperature. Measuring a single-particle Green's function from a thermal state on a quantum computer is a well known procedure, but the challenges and resources needed for full Gibbs state preparation are generally too expensive for practical simulation in the near future. We examine how sampling from more easily prepared states yields accurate approximations to single-particle Green's functions at finite temperature. We employ an additional feedback mechanism, that tests for convergence and extracts the effective temperature of the system being simulated. We also compare the trade-offs of different approaches to make these techniques applicable on near term devices.

*This work was funded by the National Science Foundation under grants numbered PHY-1620555 and DMR-1659532. In addition, JKF was funded by the McDevitt bequest at Georgetown University.
MARCINIAK (Presenter), ROBERT WOLF, MICHAEL JORDAN BIERCUK, Univ of Sydney — We will present recent achievements in ultraviolet wavelengths required to cool and control $^{88}\text{Sr}^+$ trapped ion qubits. The combination of recently developed low-loss UV photonic waveguides made from Al$_2$O$_3$ with more typical SiN waveguides for IR and visible wavelengths within multiple layers of the chip enables integration of light at all the wavelengths required for ion control. We study the interaction of these new multi-wavelength photonics with a single ion qubit towards demonstration of a two qubit gate controlled via integrated technologies, a key component of a scalable trapped ion quantum information processor.

WAKS, University of Maryland-College Park — Time-multiplexed quantum random walk provides an efficient method to realize a quantum random walk via time delays and beam-splitters. Previously, researchers have demonstrated the control of random walk evolution based on photon's polarization degree of freedom. In this presentation, we propose adding synthetic gauge fields for controlling the evolution of the random walk which is important to simulate a broad class of physical effects. In this platform, varied lengths of optical fibers create the time delays and the gauge fields are implemented through phase modulations. We show how different gauge fields provide the possibility of opening band gaps in the band structure. The presence of these bandgaps leads to the pseudo magnetic confinement of the random walk distribution. We present the theoretical predictions and experimental observations of this confinement. We also demonstrate the possibility of creating edge states by applying different gauge fields to different regions of the synthetic space. The experimental results confirm the confinement of the evolution of the random walk around the boundary.

Session A28 DQI DAMOP: AMO Quantum Information

8:00AM A28.00001: Coherent control of large ion crystals in a Penning trap quantum simulator* CHRISTIAN MARCINIAK (Presenter), ROBERT WOLF, MICHAEL JORDAN BIERCUK, Univ of Sydney — We will present recent achievements towards building a quantum simulator for transverse-field Ising-type Hamiltonians based on laser-cooled Coulomb crystals of $^{9}\text{Be}^+$ in a Penning trap. We introduce the overall system design and describe key technical elements that have permitted site-resolved imaging of rapidly rotating 2D ion crystals with $> 70$ ions, stable over tens of seconds. Novel approaches to ion imaging using a room temperature APD-array-camera coupled to a microlens array are also presented as a means to achieve high-speed state detection with spatial resolution. In addition, we demonstrate coherent control over the ions' electron spin using millimeter waves near 55 GHz via a custom high-stability source and delivery system.

8:12AM A28.00002: Integrated multi-wavelength photonic addressing of trapped ion qubits ROBERT NIFFENEGGER (Presenter), JULES STUART, COLIN BRUZEWICZ, ROBERT MCCONNELL, MIT Lincoln Laboratory, GAVIN WEST, GARRETT SIMON, Physics, Massachusetts Institute of Technology, DAVE KHARAS, CHERYL SORACE-AGASKAR, SURAJ BRAMHAVAR, JEREMY SAGE, JOHN CHIAVERINI, MIT Lincoln Laboratory — Integrating quantum and classical technologies with systems like trapped ions is critical to enable the Moore's law like scaling of qubits necessary to develop practical quantum computers. For instance, individual addressing of trapped ion qubits typically requires bulky free space optics to tightly focus multiple laser beams onto single ions within linear chains, limiting scalability. Here we have designed and fabricated an ion trap chip with integrated photonic waveguides and grating out-couplers for integrated addressing in all of the infrared, visible, and ultraviolet wavelengths required to cool and control $^{88}\text{Sr}^+$ trapped ion qubits. The combination of recently developed low loss UV photonic waveguides made from Al$_2$O$_3$ with more typical SiN waveguides for IR and visible wavelengths within multiple layers of the chip enables integration of light at all the wavelengths required for ion control. We study the interaction of these new multi-wavelength photonics with a single ion qubit towards demonstration of a two qubit gate controlled via integrated technologies, a key component of a scalable trapped ion quantum information processor.

*We acknowledge Simons Foundation, Gordon and Betty Moore Foundation, NSF Grants PHY-1125565 and PHY-1125915.

Phase-modulated entangling gates robust against static and time-varying errors

INIGO ARRAZOLA (Presenter), Department of Physical Chemistry, University of the Basque Country, Bilbao, Spain, XIAO-HANG CHENG, Department of Physics, Shanghai University, Shanghai, China, JULEN S. PEDERNALES, Institute for Theoretical Physics and IQST, Universität Ulm, Ulm, Germany, LUCAS LAMATA, Department of Physical Chemistry, University of the Basque Country, Bilbao, Spain, XI CHEN, Department of Physics, Shanghai University, Shanghai, China, ENRIQUE SOLANO, Department of Physical Chemistry, University of the Basque Country, Bilbao, Spain — We study the nonlinear dynamics of trapped-ion models far away from the Lamb-Dicke regime. This nonlinearity induces a blockade on the propagation of quantum information along the Hilbert space of the Jaynes-Cummings and quantum Rabi models. We propose to use this blockade as a resource for the dissipative generation of high-number Fock states. Also, we compare the linear and nonlinear cases of the quantum Rabi model in the ultrastrong and deep strong-coupling regimes. Moreover, we propose a scheme to simulate the nonlinear quantum Rabi model in all coupling regimes. This can be done via off-resonant nonlinear red- and blue-sideband interactions in a single trapped ion, yielding applications as a dynamical quantum filter.

Characterizing Unwanted Motional Coupling in Mølmer-Sørensen Gates

LEONARDO ANDRETA DE CASTRO (Presenter), Electrical and Computer Engineering, Duke University, PAK HONG LEUNG, Department of Physics, Duke University, PAVITHRAN S IYER, Université de Sherbrooke, KENNETH R BROWN, Electrical and Computer Engineering, Duke University — Mølmer–Sørensen gates constitute an integral hardware component of an ion trap quantum computer. These gates entangle qubits to motional modes of the ions, generating phonons that manifest in errors on future gates. As a result, the analysis of fault tolerant quantum computation schemes becomes challenging. In this work, we quantify the impact of ignoring non-Markovian features in the noise model for Mølmer–Sørensen gates by developing numerical tools to compute the fidelity of a sequence of N Mølmer–Sørensen gates. Although completely ignoring non-Markovianity results in an overestimation of this fidelity, we present Markovian models that can reproduce the same scaling of fidelity as the true noise process. These accurate Markovian models rely on a heuristic assumption that the displacements of the motional modes resemble a random walk.

Scalable Trapped Ion Architectures and Micromotion Enhancement

ALEXANDER RATCLIFFE (Presenter), JOSEPH HOPE, Department of Quantum Science, Australian National University — Quantum computing promises exciting new opportunities to answer currently intractable problems. To achieve this feat, a quantum architecture that is able to perform high fidelity operations and can be readily scaled to large numbers of qubits is required. The main obstacle to quantum computation being used as another computational tool is the limited scalability of current architectures. Trapped ions are presently one of the most promising platforms for large scale quantum computing, achieving high fidelity operations and long coherence times. Their current limitation lies in scalability. Most proposals to overcome this require coupling to many small trapped ion systems via an optical bus, or call for ions to be shuttled between segments of the system. Both of these proposals introduce new challenges and increase the complexity of the platform. Here, I demonstrate that a simple approach to scalability using microtrap arrays provides a feasible road to scalability. I show that this can be achieved without introducing any more complexity to the system than is required for trapping. Further, I show that this is realistically achievable with already demonstrated technology. Finally, I show that within this scheme, an old foe —micromotion —becomes an unlikely ally.
**9:12AM A28.00007: On-chip optical quantum memory using erbium ions**

IOANA CRAICIU (Presenter), MI LEI, JAKE ROCHMAN, JONATHAN KINDEM, JOHN BARTHOLOMEW, EVAN MIYAZONO, TIAN ZHONG, ANDREI FARAON, Caltech — Rare earth ion doped crystals provide an excellent solid state platform for optical quantum memories, which will enable long distance quantum communication and modular quantum computing. Among rare earths, erbium is appealing due to its long lived telecom wavelength resonance, allowing integration with silicon and with existing optical communication technology and infrastructure.

We present an on-chip all-optical quantum memory at telecom wavelengths using the atomic frequency comb protocol. By working at dilution fridge temperatures, we access a regime where the erbium ions have long optical coherence times and good spectral holeburning properties using only a moderate magnetic field, applied with permanent magnets. A nanobeam photonic crystal cavity etched directly in erbium-167 doped yttrium orthosilicate is used to enhance coupling to the ions. We store coherent pulses for memory times as long as 10 µs, albeit with limited efficiency. The memory has a high fidelity (>90%) and can be multiplexed in frequency and time. Ongoing work towards a higher efficiency device is discussed.

*We would like to acknowledge funding support from the Air Force Office of Scientific Research. Ioana Craiciu acknowledges support from Natural Sciences and Engineering Research Council of Canada.*

**9:24AM A28.00008: Probing amplified spontaneous emission to superradiance transition in cold Cs atoms inside a hollow-core photonic-crystal fiber**

ZHENGHAO DING (Presenter), Physics, Institute for Quantum Computing, University of Waterloo, TAE HYUN YOON, Electrical and Computer Engineering, Institute for Quantum Computing, University of Waterloo, JEREMY FLANNERY, PAUL ANDERSON, BRIAN DUONG, SHENG-XIANG LIN, FERESHTEH RAJABI, Physics, Institute for Quantum Computing, University of Waterloo, MARTIN HOUDE, Physics, University of Western Ontario, RUBAYET AL MARUF, MICHAL BAJCSY, Electrical and Computer Engineering, Institute for Quantum Computing, University of Waterloo — We investigate the critical conditions to realize the transition from amplified spontaneous emission (ASE) to superradiance (SR) with an ensemble of laser-cooled Cs atoms inside a hollow-core photonic crystal fiber (HCPCF). In our experiment, the Cs atoms, initially cooled using a magneto-optical trap (MOT), are guided and confined inside a short piece of HCPCF with a magic-wavelength dipole trap. This work constitutes the preliminary elements of our current experimental investigations towards realization of an ultra-narrow linewidth superriant laser. Additionally, we aim to study long range coherence in atomic ensembles and explore the symmetries governing atom-field couplings in the HCPCF platform.

*This works has been supported by Industry Canada, NSERC Discovery grant, Ontario’s Early Researcher Award, and by Transformative Quantum Technologies (TQT).*

**9:36AM A28.00009: Time/frequency high-dimensional entanglement via engineered parametric down conversion**

FRANCESCO GRAFFITTI (Presenter), PETER BARROW, MASSIMILIANO PROIETTI, ALEX PICKSTON, DMYTRO KUNDYS, Heriot-Watt University, AGATA M BRANCZYK, Perimeter Institute, ALESSANDRO FEDRIZZI, Heriot-Watt University — Photonic quantum technologies rely on the deterministic preparation of qubits encoded in single-photons degrees of freedom (DoF). While polarisation, orbital angular momentum and path have been routinely used since the early days of quantum information, the last few years have seen an increasing interest in the frequency-time encoding, due to the possibility of generating high-dimensional states combined with the compatibility of frequency modes with standard optical components. Here we present a new scheme for generating frequency-entangled photon pairs in parametric down-conversion (PDC) processes. By means of our novel non-linearity engineering technique, we deterministically choose the orientation of each ferroelectric domain of a poled crystal to tailor its phase-matching function as a multi-peaked function. The photons produced in such crystals emerge in a coherent superposition of an arbitrary number of orthogonal spectral Schmidt modes, allowing us to explore high-dimensional Hilbert spaces.

Our technique can easily be implemented as requires no additional components respect to a standard PDC setup, it’s highly compatible with other DoF encodings, and can be adapted to integrated waveguide sources.

*EPSRC Council (EP/N002962/1,EP/L015110/1).*
9:48AM A28.00010: Polarization-Independent Photon Storage System with Variable Time Delay* MICHELLE VICTORA (Presenter), FEDOR BERGMANN, University of Illinois at Urbana-Champaign, MICHAEL E GOGGIN, Truman State University, JIA JUN WONG, PAUL G KW IAT, University of Illinois at Urbana-Champaign — Quantum optical memories are a key component to a variety of quantum information applications, from extending quantum communication channels to building high-efficiency single-photon sources to synchronizing multiple protocols. However, most current broad bandwidth photon storage systems operate with somewhat shorter storage times (on the order of 10 ns), or require cryogenic operation. Here we develop a system with multiplexed free-space storage cavities, able to store single photons with high efficiency over variable delays [N x 12.5 ns, 1 ≤ N ≤ 999], and over several nanometers bandwidth. The system can store multiple photons simultaneously and can potentially store qubits encoded in various degrees of freedom, e.g., spatial modes, time-bin, and polarization. For the latter, we have demonstrated a memory fidelity >90% for storage times up to 500 ns. A future goal for this experiment is to achieve storage of hyperentanglement. While previous hyperentangled photon storage systems only achieved 5% efficiency, we have currently demonstrated a free-space transmission above 50% for delay times up to 5 µs.

10:00AM A28.00011: Efficient Two-Photon Interference with Pulse-Driven Quantum Emitters in Dynamic Environments HERBERT FOTSO (Presenter), Department of Physics, University at Albany, SUNY — The ability to achieve distributed entanglement across distant quantum nodes is essential for the construction of scalable quantum networks and other fundamental quantum information processing operations including quantum teleportation and Bell inequality tests[1, 2]. For solid-state spin qubits, it can be achieved through photon interference on a beam splitter. The efficiency of these interference operations rely on the indistinguishability of photons arriving from different emitters. However, for quantum emitters in dynamic environments, uncorrelated environment fluctuations lead to differences in temporal and spectral profiles of emitted photons resulting in reduced photon indistinguishability. We simulate the TPI operation in a Hong-Ou-Mandel-type experiment for two distant qubits in diffusion-inducing environments. We find that when the emitters are driven by appropriate pulse sequences, besides their emission spectra having little dependence on the environment[3, 4], photon indistinguishability can be restored to optimal values paving the way for improved efficiency in photon-mediated QIP operations.

10:12AM A28.00012: Universal Dynamics of Inhomogeneous Quantum Phase Transitions: Suppressing Defect Formation* FERNANDO GÓMEZ-RUIZ (Presenter), Physics, Universidad de Los Andes, ADOLFO DEL CAMPO, Physics, University of Massachusetts Boston — In the nonadiabatic dynamics across a quantum phase transition, the Kibble-Zurek mechanism predicts that the formation of topological defects is suppressed as a universal power law with the quench time. In inhomogeneous systems, the critical point is reached locally and causality reduces the effective system size for defect formation to regions where the velocity of the critical front is slower than the second-sound velocity, favoring adiabatic dynamics. The reduced density of excitations exhibits a much steeper dependence on the quench rate and is also described by a universal power-law, that we demonstrated in a quantum Ising chain.

10:24AM A28.00013: Controlling Quantum Spin States and Dynamics with Light [Invited] MONIKA SCHLEIER-SMITH (Invited), EMILY J DAVIS, GREGORY BENTSEN, Stanford University, LUKAS HOMEIER, LMU Munich — Coupling many atoms to a single mode of light provides an efficient means of generating quantum correlations in an extended many-body system. I will report on experiments in which we harness photons in an optical cavity to mediate “flip-flop” interactions among distant spins in a millimeter-long cloud of atoms, as we directly observe by imaging quench dynamics. In our spin-1 system, these exchange interactions enable correlated pair creation in the m = ±1 Zeeman states, a process analogous to spontaneous parametric down-conversion or to collisional spin mixing in Bose-Einstein condensates. In contrast to direct collisional interactions, non-local light-mediated interactions offer unprecedented opportunities for engineering the spatial structure of spin-spin couplings and correlations. I will describe progress and prospects in tailoring atom-light interactions to enable new directions in quantum simulation and to generate new resources for quantum-enhanced sensing.
Cross-resonance gates applied to pairs of transmons satisfy this requirement with the added advantage of being fully controlled by microwave signals. However, applying these gates to a large transmon lattice is quite challenging. This is because cross-resonance gates set stringent requirements on the frequency landscape of neighboring qubits, which are difficult to satisfy with fixed-frequency transmons due to their relatively large frequency spread. To solve this problem, we realize a new flux-tunable qubit, compatible with cross-resonance gates, which can be tuned by less than 150 MHz. Such a weakly tunable qubit is useful for avoiding frequency collisions in a large lattice while limiting its susceptibility to flux noise. In this talk, we will introduce the qubit circuit and theory.

This work is funded by the IARPA Grant No. W911NF-16-1-0114-FE

Performing fast, high-fidelity two-qubit gates is an important requirement of quantum computers. Cross-resonance gates applied to pairs of transmons satisfy this requirement with the added advantage of being fully controlled by microwave signals. However, applying these gates to a large transmon lattice is quite challenging. This is because cross-resonance gates set stringent requirements on the frequency landscape of neighboring qubits, which are difficult to satisfy with fixed-frequency transmons due to their relatively large frequency spread. To solve this problem, we realize a new flux-tunable qubit, compatible with cross-resonance gates, which can be tuned by less than 150 MHz. Such a weakly tunable qubit is useful for avoiding frequency collisions in a large lattice while limiting its susceptibility to flux noise. In this talk, we will present some preliminary measurement results of these weakly tunable qubits.

This work is funded by the IARPA Grant No. W911NF-16-1-0114-FE

The quantization of magnetic flux in superconductors lies at the heart of realizing qubits using superconducting circuits. To construct a flux qubit, one must coherently couple the flux states of a superconducting ring, which requires breaking the rotational symmetry of the ring to introduce a phase-slip center. Established implementations guarantee an inherently broken symmetry by interrupting the ring with an insulating barrier; hence, forming a Josephson junction, giving rise to the flux qubit. However, these implementations are plagued by the variability of the fabrication process of the junction. Here, we theoretically propose a junctionless flux qubit consisting of a voltage-biased superconducting ring. The in-plane electric field, arising from the bias voltage, locally suppresses the density of superconducting electrons; hence, imitating the effect of interrupting the superconductor with an insulator. Furthermore, the proposed qubit could allow for electric-tunability of the transition frequency, a desired feature for multi-qubit systems since it renders the circuit less sensitive to magnetic noise. Realizing electrically-tunable flux qubits with long coherence times paves the road towards scaling up superconducting quantum computers.

We discuss a superconducting flux qubit whose sensitivity to low frequency flux is reduced through a null flux geometry consisting of one closed wire loop twisted into a “figure eight” shape composed of two open loops, each with opposite circulation. This protects against global flux noise in a similar way as the gradiometer qubit, but with only one loop degree of freedom instead of the two DOF of the gradiometer. This important difference opens several possibilities for dealing with the local flux noise that causes decoherence in the gradiometer qubit. We further show that the null flux shape increases the sensitivity to high frequency flux, making the system potentially useful for superconducting transduction.
8:48AM A29.00005: Symmetry Protected Qubits Through Fluxon Pairing* WEN TING HSIEH (Presenter), MATTHEW BELL, Department of Electrical Engineering, University of Massachusetts, WEN-SEN LU, WENYUAN ZHANG, PLAMEN KAMENOV, KONSTANTIN KALASHNIKOV, MICHAEL GERSHENSON, Department of Physics and Astronomy, Rutgers University — We present time-domain experiments with symmetry-protected qubits whose quantum states are encoded in the parity of fluxons in a superconducting loop. The qubit is composed of a Cooper pair box and a superinductor arranged in a superconducting loop [1]. The lowest-energy states of this qubit correspond to even/odd parity of fluxons in the loop. We will discuss proof-of-concept experiments that show how the qubit can be placed into a state protected against energy relaxation where the fluxon parity is preserved through the Aharonov-Casher interference. We will show that using fast gate pulses, the fluxon-pairing qubit can be adiabatically switched between the protected and unprotected states for quantum state initialization and readout. We will also discuss preliminary results on the implementation of fluxon-pairing qubits with superinductors fabricated from meandered nanowires made of strongly disordered Aluminum [2].

9:00AM A29.00006: Breaking the trade-off between gate and relaxation times of a superconducting qubit with a Josephson quantum filter: Theory* KAZUKI KOSHINO (Presenter), College of Liberal Arts and Sciences, Tokyo Medical and Dental University, SHINGO KONO, YUTAKA TABUCHI, ATSUSHI NOGUCHI, DANY LACHANCE-QUIRION, YASUNOBU NAKAMURA, Research Center for Advanced Science and Technology, The University of Tokyo — When we couple a superconducting qubit strongly to a transmission line, the qubit completely reflects a weak resonant microwave field propagating through the line. On the other hand, the qubit becomes transparent to a stronger field due to the absorption saturation. This implies that a superconducting qubit functions as a nonlinear mirror, which we call a Josephson quantum filter (JQF). We theoretically investigate a setup in which a qubit (data qubit) to be controlled is coupled to an end of a semi-infinite control line and a JQF is placed at a distance of the order of the resonance wavelength of the qubit. An effective cavity is formed by the termination point and the JQF, and the radiative decay of the data qubit is suppressed if this effective cavity has a large detuning from the data qubit. Nearly complete suppression is achieved under the following conditions: the radiative decay rate of JQF is much larger than that of the data qubit, and the distance between the data qubit and the JQF is close to the half of the resonance wavelength.

*This work was supported in part by JST ERATO (Grant No. JPMJER1601), JSPS KAKENHI (No. 16K05497 and No. 26220601), JSPS Grant-in-Aid for JSPS Research Fellow, and ALPS, The University of Tokyo.

9:12AM A29.00007: Breaking the trade-off between gate and relaxation times of a superconducting qubit with a Josephson quantum filter: Experiment* SHINGO KONO (Presenter), The University of Tokyo, KAZUKI KOSHINO, Tokyo Medical and Dental University, YUTAKA TABUCHI, ATSUSHI NOGUCHI, DANY LACHANCE-QUIRION, YASUNOBU NAKAMURA, The University of Tokyo — The rapid development in designs and fabrication techniques of superconducting qubits is making coherence times of qubits longer and longer. In the near future, however, the radiation decay of the qubit (data qubit) into the control line will be a fundamental limitation, imposing a trade-off between the gate and relaxation times. Here, we successfully break the trade-off by strongly coupling another superconducting qubit, or a Josephson quantum filter (JQF), along the control line connected to the data qubit. The JQF prevents the data qubit from emitting a microwave photon and thus suppresses the relaxation, while transmitting faithfully large-amplitude control microwave pulses through the saturation of the quantum filter. In this talk, we will present the circuit design and demonstrate the effect of JQF on the qubit coherence.

*This work was supported in part by JST ERATO (Grant No. JPMJER1601), JSPS KAKENHI (No. 16K05497 and No. 26220601), JSPS Grant-in-Aid for JSPS Research Fellow, and ALPS, The University of Tokyo.
Theoretical analysis on the composite qubit approach to superconducting quantum computing

YUN-PIL SHIM (Presenter), Laboratory for Physical Sciences, DANIEL CAMPBELL, BHARATH KANNAN, RONI WINIK, Research Laboratory of Electronics, Massachusetts Institute of Technology, DAVID K KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, JONILYN L YODER, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, WILLIAM D OLIVER, Research Laboratory of Electronics, Massachusetts Institute of Technology, CHARLES TAHAN, Laboratory for Physical Sciences — Encoded qubit scheme [1] for superconducting qubit architecture could be a useful alternative to the conventional approach for simpler control of qubits. The composite qubit (CQB) defined in a two-dimensional subspace of a system of two physical transmon qubits can be manipulated using only base band control of each transmon qubit frequencies, allowing for microwave-free single- and two-qubit quantum gates. We present theoretical analysis of the optimal operating point (sweet spot) and the gate operations in a real device in the presence of various sources of noise and errors. The CQB computational subspace consists of excited states of the system and relaxation to the physical ground state is one of the main sources of error. We discuss the randomized benchmarking (RB) protocol in the presence of this leakage error.

Hamiltonian Quantum Computing with transmon qubits

ALESSANDRO CIANI (Presenter), RWTH Aachen University, BARBARA TERHAL, TU Delft, DAVID PETER DIVINCENZO, RWTH Aachen University — We discuss a possible implementation based on superconducting transmon qubits of the scheme for Hamiltonian Quantum Computing introduced in Ref. [1]. The scheme is completely passive and requires active control only for initialization and measurement. The scheme requires strong and negative cross-Kerr interactions and relatively weaker hopping interactions. We propose the implementation the strong of the cross-Kerr interactions with a newly designed direct coupler based on array of few Josephson junctions, which should allow to reach larger cross-Kerr coupling compared to other proposals, without causing any increase in the problem of cross-talk. The hopping interactions are responsible for the implementation of quantum gates, and can be implemented with simple capacitances or via indirect coupling mediated by resonators. In this way it is possible to obtain sufficient flexibility to achieve universality using only real gates. To this end, we also discuss explicitly how to implement a Toffoli gate. We finally discuss the main sources of errors in the model.

Low-Loss Dielectric Materials and the Merged Element Transmon

COREY RAE MCRAE (Presenter), National Institute of Standards and Technology Boulder, ANTHONY MCFADDEN, University of California Santa Barbara, MUSTAFA BAL, National Institute of Standards and Technology Boulder, XIAN WU, Lawrence Livermore National Laboratory, JUNLING LONG, National Institute of Standards and Technology Boulder, HSIANG-SHENG KU, Alibaba, JIANGUO WEN, JIE WANG, ILKE ARSLAN, Argonne National Laboratory, CHRIS PALMSTROM, University of California Santa Barbara, DAVID PAPPAS, RUSSELL LAKE, National Institute of Standards and Technology Boulder — Josephson junctions, a crucial component in quantum bits (qubits), are commonly composed of a pair of superconducting aluminum films separated by a thin layer of amorphous aluminum oxide. In order to avoid the high density of two-level states (TLS) in amorphous oxides, Josephson junctions are designed to be small, thus reducing the participation of the lossy material. However, the persistence of lossy materials in qubits leads to diminishing returns with this strategy. An alternative approach to TLS loss minimization in a transmon qubit junction is to combine the qubit’s nonlinear inductance and capacitance into a single trilayer junction with extremely low dielectric loss, i.e., a merged-element transmon. In this work, we characterize dielectric thin films within lumped-element resonators to determine microwave losses in the single-photon regime and to identify dielectric barrier materials for a merged element transmon. In addition to amorphous solid barriers, we measure microwave-frequency loss of single-crystal epitaxial superconductor-insulator-superconductor trilayers.

*Army Research Office
The design is highly hardware-efficient and eliminates the need for fast external measurement and feedback. Here, we discuss the theoretical model, highlighting features of experimental relevance. We present simulations results demonstrating coherence improvements of an order of magnitude against realistic noise models.

*This work was supported by NSERC, CMC Microsystems, and the Joint Waterloo-Technion Cooperation Program.

10:12 AM A29.00012: Engineering Sideband Interactions with the Very Small Logical Qubit (VSLQ) Device Part I*

GABRIELLE ROBERTS (Presenter), YAO LU, NELSON LEUNG, SRIVATSAN CHAKRAM, University of Chicago, ELIOT KAPIT, Physics, Colorado School of Mines, DAVID SCHUSTER, University of Chicago — Like most other architectures, superconducting quantum bits are extremely sensitive to unwanted interactions with the environment. Determining effective and hardware-efficient quantum error correction protocols is thus an urgent scientific priority. I will describe a simple circuit and protocol that autonomously implements the error correction process [1]. The circuit consists of two transmons connected to dissipative baths in the form of lossy cavities and driven by superconducting quantum interference device couplings. Autonomous error correction is achieved using resonances to coherently correct errored qubit states while leaving un-errored states unaffected. The design is highly hardware-efficient and eliminates the need for fast external measurement and feedback. Here, we discuss the theoretical model, highlighting features of experimental relevance. We present simulations results demonstrating coherence improvements of an order of magnitude against realistic noise models.

*This work was supported by NSERC, CMC Microsystems, and the Joint Waterloo-Technion Cooperation Program.

10:24 AM A29.00013: Engineering Sideband Interactions with the Very Small Logical Qubit (VSLQ) Device Part II*

YAO LU (Presenter), GABRIELLE ROBERTS, NELSON LEUNG, SRIVATSAN CHAKRAM, University of Chicago, ELIOT KAPIT, Colorado School of Mines, DAVID SCHUSTER, University of Chicago — We report our experimental progress towards implementing a VSLQ device for the autonomous quantum error correction. As a first step, we modify the original VSLQ superconducting circuit [1] and propose a new parametric modulation scheme for engineering the VSLQ Hamiltonian. The new scheme requires many fewer RF flux lines, which significantly reduces the device operational complexity and substantially mitigates cross-talks between the multiple flux loops. Next, in our experiment, we calibrate the static circuit parameters under DC flux biasing. We then further explore the dynamic behavior of the circuit under RF flux modulation, and demonstrate how to generate different types of sideband interactions from RF flux modulations with appropriately chosen frequencies and phases. These sideband interactions serve not only as critical components of the VSLQ protocol, but can also be used to realize instantaneous qubit interactions along arbitrary axes.

10:36 AM A29.00014: Efficient characterization of correlated SPAM errors

MINGYU SUN (Presenter), MICHAEL GELLER, University of Georgia — State preparation and measurement (SPAM) errors limit the performance of gate-based quantum computers, but are partly correctable after a calibration step that requires, for exact implementation on a register of n qubits, 2n additional characterization experiments. Here we introduce an approximate but efficient method for SPAM error characterization requiring 2n(n − 1) measurements. The technique assumes that multi-qubit measurement errors are dominated by pair correlations, which are estimated with n(n − 1)/2 two-qubit experiments. We demonstrate this technique on the IBM and Rigetti online quantum computers, allowing comparison of their SPAM errors in both magnitude and degree of correlation. We find that the pair-correlation model is reasonably accurate on linear arrays of qubits. However qubits with more closely spaced two-dimensional geometries exhibit significant higher order (e.g., 3-qubit) SPAM error correlations.
8:00AM A30.00001: ‘Sideways’ and stable crack propagation in a silicone elastomer [Invited] MATT PHARR (Presenter), SEUNGHYUN LEE, Texas A&M University — This talk will describe a peculiar form of fracture that we have found in a highly stretchable silicone elastomer. Namely, under certain conditions a crack will deviate from its ‘standard’ trajectory and instead propagate perpendicular to that trajectory. The crack arrests stably, allowing the material ahead of the crack front to continue to sustain load, and thereby enabling enormous stretchabilities. We call this phenomenon ‘sideways’ cracking. To explain this behavior, we first perform finite element simulations that demonstrate a propensity for sideways cracking, even in isotropic elastomers. Next, we provide a hypothesis on the origin of sideways cracking that invokes microstructural anisotropy. To substantiate this hypothesis, we transversely pre-stretch samples to various extents prior to fracture testing, as to determine the influence of microstructural arrangement (chain alignment) on fracture energy. We conclude by describing how a number of loading conditions, such as sample geometry and strain rate affect this phenomenon. Overall, this talk aims to provide fundamental mechanical insight into basic phenomena associated with fracture of elastomers.

8:36AM A30.00002: How Supertough Gels Break* ITAMAR KOLVIN (Presenter), Physics, UC Santa Barbara, JOHN KOLINSKI, Mechanical Engineering, Ecole Polytechnique Federale de Lausanne,, JIAN PING GONG, Faculty of Advanced Life Science and Soft Matter Gi-CoRE, Hokkaido University, JAY FINEBERG, Hebrew University of Jerusalem — Fracture of soft materials typically takes place at large stretches. This condition challenges our view of how things break, which is based on small-strain linear elasticity. In this talk, I will show how we directly visualized rupture of tough double-network gels at >50% strain. During fracture, crack tip shapes obey a \( x \sim y^{1.6} \) power law, in contrast to the parabolic profile observed in low-strain cracks. A new length scale emerges from the power law that scales directly with the stored elastic energy and diverges when the crack velocity approaches the shear wave speed. Our results show that double-network gels undergo brittle fracture and provide a testing ground for large-strain fracture mechanics.

8:48AM A30.00003: Quantitative Analysis of Spiropyran Mechanophore Activation in Multiple Network Elastomers* CHYI-HUEY YEH (Presenter), YINJUN CHEN, COSTANTINO CRETON, PPM, ESPCI — Multiple network elastomers (MNE) have been used as model systems to characterize the crack tip behavior in soft tough materials. These materials contain reinforcing swelled network chains that are largely responsible for the high fracture toughness of MNEs. By incorporating a spiropyran mechanophore as a chromatic force sensor in the swelled network, stress and energy density localization around a crack tip can be optically detected and quantified. Also, regions with a history of loading and unloading around a crack tip can be identified based on the reversible changes in absorbance of merocyanine isomers (spiropyran in its activated form) in the loading and unloading states. This allows for a more accurate identification of the onset of crack propagation, which occurs before reaching the peak stress. Based on the experimental results, a perspective can be constructed on how statistical molecular information, provided by the mechano-activation of spiropyran, can inform macroscopic modeling of soft tough materials.

9:00AM A30.00004: Depinning dynamics of crack fronts 
JULIEN CHOPIN (Presenter), Instituto de Fisica, UFBA, ADITYA BHASKAR, ATHARV JOG, LAURENT PONSON, Institut J. le Rond d'Alembert, UPMC/CNRS — Nacre, bones or rationally designed artificial materials are all heterogeneous solids with mechanical properties far exceeding those of their constitutive components. Understanding the role of microscale heterogeneities on the macroscale fracture behavior of solids remains a query, especially when toughness gradients are large. In this talk, I will present a combined experimental and theoretical study of the micro-instabilities of a crack front taking place in heterogeneous materials between two successive equilibrium positions. The instabilities are triggered by pinning the front by isolated tough obstacles of controlled strength and size. We show that the depinning dynamics is controlled by a nonlocal line elasticity and the rate dependency of the dissipative mechanisms taking place within the process zone. We model the behavior by an overdamped equation of motion involving a characteristic material speed and provide an analytical solution which captures quantitatively all our experimental observations. The implications of our results on the energy dissipated during fast fracture events and the fracture behavior of materials with randomly distributed obstacles will be discussed.

[Invited] WILLIAM STEINHARDT (Presenter), SHMUEL RUBINSTEIN, Harvard University — There is a disconnect between our theoretical understanding of brittle fracture, where 2D (effectively 1D) mathematical descriptions generate idealized fractures that are flat, smooth, and stable, and most brittle fractures we encounter in natural or manmade materials (rocks, bones, ceramics), which have significant 3D complexity. However, much of the basic physics that governs this complexity is not well understood. We have developed an experimental system to study 3D fracture mechanics by observing hydraulic fractures in brittle hydrogels. Heavily cross-linked hydrogels have been shown to be a good model system for brittle materials, with the benefits of highly tunable rheology, transparency, and low breakdown pressures. Studying hydraulic fractures allows us to match the refractive index of the interior of the fracture to the bulk, which combined with high speed photography and scanning laser sheet illumination, enables us to resolve the fracture dynamics in three dimensions at up to 1000 volumes per second. We observe that macro-scale roughness comes in the form of step-like perturbations of the fracture front, resulting from material heterogeneity, which leave in their wake a curved linear scar known as a step line. Our dynamic three-dimensional observations of these steps and their interactions allow us to understand the surprisingly elegant topological rules that govern their growth and interaction.

9:48AM A30.00006: Tearing path: instabilities for crack paths in thin sheets cut by blunt objects*
BENOIT ROMAN (Presenter), Physique et Mecanique des Milieux Heterogenes (PMMH), EUGENIO HAMM, Departamento de fisica, USACH, IRYNA SIVAK, Mathematics, EPFL — A thin sheet is a very soft object, which therefore undergoes very large deformation when torn. We found that a straight crack which propagates quasistatically in such a sheet when driven by a blunt object may become unstable in several configurations: oscillatory fracture when the object is displaced along a line, or spiraling when using a perforating cone. We wish to compare these two configurations and show how these instabilities compare in involving the very soft bending mode.

10:00AM A30.00007: The Virtual Frame Technique (VFT): direct imaging of fast cracks in soft elastomers*
SAMUEL DILLAVOU, SHMUEL RUBINSTEIN, SEAS, Harvard University, JOHN KOLINSKI (Presenter), IGM, Ecole polytechnique federale de Lausanne — Many phenomena of interest in nature and industry are rapid, making direct imaging both challenging and cost prohibitive. Dynamic cracks can propagate at the sound speed of a material and are ubiquitous in the earth sciences and engineering applications; thus fracture epitomizes such phenomena. In soft materials, the sound speed is of order several meters per second, and a dynamic crack will entirely rupture a cm-scale sample in about 10 msec requiring rapid imaging for direct visualization. Here we present the Virtual Frame Technique (VFT), a simple, useful, and accessible form of compressed sensing that leverages the dynamic range of the camera's sensor to increase the frame acquisition rate by up to 6 orders of magnitude. We discuss the requirements for use of the VFT and its performance when employed with several commercially available conventional and high-speed cameras. Even Modern cell phones can achieve imaging rates of over a million fps using the VFT.

*EMSI lab at EPFL
10:12AM A30.00008: Controlling fracture cascades through twisting and quenching  VISHAL PATIL (Presenter), Department of Mathematics, Massachusetts Institute of Technology, RONALD HEISSER, Sibley School of Mechanical and Aerospace Engineering, Cornell University, NORBERT STOOP, Department of Mathematics, Massachusetts Institute of Technology, EMMANUEL VILLERMAUX, IRPHE, Université Aix Marseille, JORN DUNKEL, Department of Mathematics, Massachusetts Institute of Technology — Fracture fundamentally limits the structural stability of macroscopic and microscopic matter, from beams and bones to microtubules and nanotubes. Despite substantial recent experimental and theoretical progress, fracture control continues to present profound practical and theoretical challenges. While bending-induced fracture of elongated rod-like objects has been intensely studied, the effects of twist and quench dynamics have yet to be explored systematically. Here, we show how twist and quench protocols may be used to control such fracture processes, by revisiting Feynman's observation that dry spaghetti typically break into three or more pieces when exposed to large pure bending stresses. Combining theory and experiment, we demonstrate controlled binary fracture of brittle elastic rods for two distinct protocols based on twisting and nonadiabatic quenching. Our experimental data for twist-controlled fracture agree quantitatively with a theoretically predicted phase diagram, and we establish novel asymptotic scaling relations for quenched fracture. Due to their general character, these results are expected to apply to torsional and kinetic fracture processes in a wide range of systems.

10:24AM A30.00009: Rifts in Rafts  KHA-I TO (Presenter), DANIEL HEXNER, VINCENZO VITELLI, SIDNEY ROBERT NAGEL, University of Chicago — Two-dimensional particle rafts are single-layers of aggregated sub-millimeter polydisperse particles floating at an air-fluid interface. The material failure of such rafts under an applied extensional load has a morphology that appears to be distinct from other known fracture modes. At higher extensional shear rates, numerous small-scale cracks are distributed diffusively throughout the entire system; at low strain rates, the distance between adjacent cracks increases. The characteristics of this distributed failure also depend on the surface tension and viscosity of the underlying fluid. To decrease the influence of secondary flows, we perform experiments by changing the liquid level in the tanks with inclined walls so that we are able to increase the area accessible to the rafts as the liquid height changes. This results in an expansion in quasi-1D (with and without boundaries) and isotropic 2-D expansion in the linear and cylindrical geometries respectively. We simulate this behavior with a model based on weak interparticle forces coupled to an expanding underlying metric.

10:36AM A30.00010: Cracking and self-healing in soft, shrinkable hydrogel packings  HAN-JAE JEREMY CHO (Presenter), MICHAEL P HOWARD, NANCY B LU, REBEKAH A ADAMS, SUJIT DATTA, Princeton University — We aim to better understand cracking in granular, shrinkable packings. Such packings are relevant to agriculture and CO2 sequestration; they also have potential uses in non-fouling films, biosensors, cosmetics, and drug delivery platforms. We use hydrogel particle packings as a model system and experimentally observed how these packings dry, shrink, and crack at an individual-particle level. Most remarkably, we observed a behavior where cracks can form but eventually self-heal. Furthermore, using discrete-element simulations that we developed, we found the precise range of individual-particle shrinkabilities, capillary forces, and contact forces needed to produce this self-healing behavior. Our results inform ways to control crack evolution, which could ultimately pave the way to engineering crack behavior for a wide variety of applications.

First-principles studies of spin-electric coupling in frustrated triangular single molecule magnet qubits

FHOKRUL ISLAM, CARLO CANALI (Presenter), Linnaeus University, MARK PEDERSON, Johns Hopkins University — The efficient manipulation of the quantum states of single-molecule magnets (SMMs) by an electric field is highly desirable for using SMMs in molecular spintronics and quantum information processing. Frustrated triangular SMMs with antiferromagnetic exchange, such as Cu$_3$, are characterized by a doubly degenerate $S=1/2$ ground-state with opposite chirality. It has been proposed theoretically [1] and later verified by ab-initio calculations [2] that the lack of inversion symmetry in these triangular SMMs allows an external electric field to couple these two chiral spin states, even in the absence of spin-orbit interaction. The existence of such spin-electric coupling (SEC) has been observed only very recently in an experiment with a single crystal Fe$_3$ SMM [3]. In this talk, following this recent development, we consider the Fe$_3$ molecule and compare its SEC strength with the one of other triangular SMMs (Cu$_3$, V$_3$ and V$_{15}$), discussing their advantages and disadvantages.

Spin frustration, zero-field splittings, and Jahn-Teller effects in trinuclear copper SMMs: Insights from spin-flip calculations

PAVEL POKHILKO (Presenter), ANNA KRYLOV, University of Southern California — SMMs (single-molecule magnets) are molecules with several unpaired electrons that can be prepared in high-spin states and retain their magnetization for some time. From methodological point of view, SMMs are strongly correlated systems that require specially designed ab initio methods. In our group, we use spin-flip approach (SF). Starting from the highest spin state (usually triplet or quartet), SF treats in a balanced way lower-spin configurations, which is crucial for qualitatively correct description of SMMs. I will present the SF results for copper di- and triradicals. One of the systems has a spin-frustrated trinuclear copper structural motif. Natural orbital analysis indicates that the two lowest doublets and the quartet have purely covalent character thus validating Heisenberg-Dirac-van-Vleck model Hamiltonian. PBE50, a recommended functional from previous benchmarks, matches an experimental estimate for Jahn-Teller splitting of the doublets states – 19 cm$^{-1}$. A large zero-field splitting, previously explained through Dzyaloshinskii-Moriya interaction, originating from spin-orbit coupling (SOC). Validation of this idea will be done using our new SOC code within EOM-CC framework. Additional confirmation comes from El-Sayed rules, predicting a relative magnitude of SOC.

Generalized Hartree-Fock with Non-perturbative Treatment of Strong Magnetic Field: Application to Molecular Spin Phase Transition

XIAOSONG LI (Presenter), Chemistry, University of Washington — In this work, we present a framework of ab initio variational approach to effectively explore the spin phase space in the presence of a homogenous magnetic field. Complex generalized Hartree-Fock (C-GHF) in the spinor formalism is implemented with London orbitals. Recursive algorithms for computing one- and two-electron integrals of London orbitals are also provided. A Pauli matrix representation of the C-GHF is introduced to separate spin contributions from scalar part of the Fock matrix. The spin phase transition in the several molecular systems in the presence of a strong magnetic field is investigated. Non-collinear spin configurations are observed during the phase transition. The competing driving forces of exchange coupling and spin Zeeman effect have been shown to govern the spin phase transition and transition rate. The energetic contributions of the spin Zeeman, orbital Zeeman, and diamagnetic terms to the potential energy surface are also analyzed.

Molecular Magnets for Information and Sensing Applications: Response to Fields and Nuclear Spins*

KYUNGWHA PARK (Presenter), Virginia Tech — Recent advances have allowed the experimental realizations of quantum bits and quantum gates by using molecular magnets as active elements, as well as the experimental implementation of quantum algorithms within them. In particular, lanthanide-based molecular magnets are promising for such applications because of strong spin-orbit interaction, compatible molecular geometry to devices, and tunability of coupling between electron and nuclear spins via electric field. So far, there is a lack of ab-initio studies of such coupling and tuning corresponding magnetic properties for lanthanide-based molecular magnets. Nearly degenerate f-orbitals and strongly localized f-electrons suggest importance of calculations beyond density-functional theory. Here we investigate how magnetic properties of monometallic terbium-based molecular magnets are influenced by electric field and coupling to nuclear spin, using multireference quantum chemistry methods including scalar relativistic effects and spin-orbit interaction. We present effects of chemical environment and electric field on such coupling and magnetic anisotropy.

*Funded by the Department of Energy Basic Energy Sciences grant No DE-SC0018326. Computational support by Virginia Tech ARC.

Implementing high fidelity single and entangling two-qubit gates in multi-level systems*

KHADIJEH NAJAFI (Presenter), SOPHIA ECONOMOU, EDWIN BARNES, Physics, Virginia Tech — A recent experiment introduced a novel multi-level nuclear spin (3/2) of single molecule magnet TbPc2 as qubit or qudit. Due to the strong coupling of the nuclear spin to the electric field, this system exhibits simultaneously long coherence times and fast controllability. One of the important questions to address is how well one can implement quantum gates in these systems. By using a combination of analytically solvable two level dynamics and the Suzuki-Trotter product formula, we design z-rotations of high fidelity. We also investigate the implementation of two-qubit entangling gates mediated by a superconducting transmission line resonator coupling two TbPc2 qudits.

*This work is supported by the DOE (grant number DE-SC0018326).

Multireference ab initio studies of magnetic properties of TbPc2-type single-molecule magnets in different charge states*

RYAN PEDERSON, ALEKSANDER WYSOCKI (Presenter), Department of Physics, Virginia Tech, NICHOLAS MAYHALL, Department of Chemistry, Virginia Tech, KYUNGWHA PARK, Department of Physics, Virginia Tech — Lanthanide-based single-molecule magnets (SMMs) can have exceptionally large magnetic anisotropy due to interplay between the ligand crystal field and spin-orbit interaction. Among them, TbPc2 SMM was shown to be promising for quantum information science applications. Although a variety of TbPc2-type SMMs were synthesized in neutral and charged states under different chemical environment, there are no systematic theoretical studies of magnetic properties of such SMMs yet. Almost degenerate 4f orbitals demand multireference quantum chemistry calculations for the magnetic properties. Here, we investigate electronic structure and magnetic properties of TbPc2 and TbPcNc SMMs as a function of oxidation state, ligand type and distortion of molecular geometry, using first-principles relativistic multireference methods including spin-orbit interaction. By applying effective pseudospin Hamiltonian to the lowest multiplet, we examine how these chemical factors affect several important energy scales, such as tunnel splitting, exchange coupling between the Tb magnetic moment and the ligand spin, zero-field splitting, and magnetic anisotropy barrier.

*Funded by the Department of Energy Basic Energy Sciences grant No DE-SC0018326. Computational support by Virginia Tech ARC.
Towards magnetic resonance imaging of a single molecule.*

ALEXEI BYLINSKII (Presenter), Chemistry and Chemical Biology, Harvard University, ZIWEI QIU, SEAS, Harvard University, JEREMY AMDUR, LEI SUN, Chemistry, Northwestern University, DOMINIK BUCHER, OREN BEN DOR, DAVID GLENN, NITHYA ARUNKUMAR, Smithsonian - CFA, Harvard University, ELANA URBACH, TAMARA SUMARAC, BO DWYER, Physics, Harvard University, RONALD L WALSWORTH, Smithsonian - CFA, Harvard University, DANNA FREEDMAN, Chemistry, Northwestern University, MIKHAIL LUKIN, HONGKUN PARK, Physics, Harvard University — While magnetic resonance is an established tool for applications ranging from molecular structure determination to quantum computing, it typically requires large ensembles of molecules to detect the weak magnetic signals. In order to push magnetic resonance spectroscopy and control to the single-molecule limit, we magnetically couple spin-carrying metal-organic complexes to the electron spin of an individual nitrogen-vacancy (NV) defect in diamond, which can be optically initialized and read out. The electron spin on the coordinated metal acts as a reporter of the nuclear spin positions on the complex or a target of interest attached to it, promising to extend electron paramagnetic resonance spectroscopy (EPR) to the limit of single-molecule magnetic resonance imaging (MRI). In addition, the complex can be coherently controlled via the NV center and act as a molecular qubit, which can be assembled into desired quantum spin network architectures via chemical linking.

Magnetic Anisotropy of a Tri-anionic Complex*

DER-YOU KAO (Presenter), SHAWN DOMAGAL-GOLDMAN, NASA Goddard Space Flight Center — The trivalent chromium tri-oxalate complex, \(\text{Cr}^{3+}\{(\text{C}_2\text{O}_4)^{2-}\}_3\)\(^3\) is known to exist as a tri-anion in water. Such systems are difficult to describe with standard DFT due to the fact the HOMO level of the complex solute is pushed to higher energies than the LUMO levels of the \(\text{H}_2\text{O}\) solvent. The mismatch in the solute/solvent Fermi-levels causes charge transfer from the tri-anion to the water as shown in earlier work. However, the spin of the solute complex is not affected by the unphysical charge transfer. The generalized gradient approximation gives a magnetic anisotropy for the isolated and solvated tri-anion \(\text{Cr}^{3+}\{(\text{C}_2\text{O}_4)^{2-}\}_3\)\(^3\)\(\{(\text{H}_2\text{O})_{24}\) of 0.83 and 0.82 Kelvin respectively. These values of magnetic anisotropy agree with 0.89 Kelvin (0.619 cm\(^{-1}\)), which is derived from measurement [1], and imply that the oxalates lose electrons. In this paper results on the electronic and magnetic structure of the tri-anionic complex in water are presented with and without a self-interaction corrected method as a function of cluster size.

NSF Quantum Leap Big Idea

EVELYN GOLDFIELD (Presenter), National Science Foundation — We are in the midst of the second quantum revolution which aims to exploit quantum phenomena such as superposition, entanglement, interference to enable major advances in quantum sensing, quantum communication, quantum computation and quantum simulation. These advances require a broad inter-disciplinary effort which includes physical scientists (including chemical physicists and chemists of all types), computer scientists, mathematicians and engineers. The NSF's Quantum Leap (QL) Big Idea draws from all these disciplines to engage in a transformative, high-risk-high reward enterprise to address fundamental questions such as how to prepare and manipulate complex or dynamic quantum states; how to control material-light interactions to create new quantum phenomena; how to design and engineer systems that use quantum effects to their fullest extent. In this talk, I will focus on opportunities for those engaged in chemical and molecular science to engage in NSF QL related initiatives.
8:00AM A32.00001: Catalytic CO oxidation by gas phase atomic clusters [Invited] SHENG-GUI HE (Presenter), Institute of Chemistry, Chinese Academy of Sciences — Oxidation of carbon monoxide (CO) into CO$_2$ is a major solution to removal of CO in air purification and this oxidation process also serves as a prototypical reaction in heterogeneous catalysis. Atomic clusters are ideal models of active sites in condensed phase systems and the elementary and catalytic oxidations of CO by gas phase metal clusters are being actively studied. I will report our recent research progress on catalytic CO oxidation by hetero-nuclear metal oxide clusters including M-Al-O, M-Ti-O, and M-V-O (M=Au, Pt, Cu, Ni, or others) species in the gas phase. The hetero-nuclear metal oxide clusters are generally more catalytic than their homo-nuclear counterparts. The electronic origins such as electro-negativity ladder effect have been proposed to account for the enhanced catalytic reactivity in the oxidation of CO by O$_2$.

8:36AM A32.00002: Computational studies of the properties and reactions of metal oxide clusters* [Invited] DAVID DIXON (Presenter), University of Alabama — Modern computational chemistry methods on advanced computer architectures are now capable of providing useful information, for example for catalytic reactions. Benchmarks of electronic structure methods for metal oxides will be described. Coupled cluster CCSD(T) theory has been used to provide benchmark values for the reactivity of metal oxide clusters including normalized clustering energies, Lewis acidities from fluoride affinities, and electron affinities for redox. The reactions of alcohols as models for biomass, the splitting of water, and splitting of hydrogen on transition metal oxide clusters will be described. Correlations with quantities such as Lewis and Brönsted acidities and redox properties will be described. New approaches for predicting the growth of nanoparticles of metal oxides will also be described.

9:12AM A32.00003: Spectroscopy of metal oxide clusters using high resolution anion photoelectron spectroscopy and infrared photodissociation* [Invited] DANIEL NEUMARK (Presenter), University of California, Berkeley — Metal oxide clusters are important model systems for understanding a variety of catalytic processes. Here, the vibrational spectroscopy of size selected metal clusters is investigated with two complementary techniques: slow-electron velocity-map imaging of cryogenically cooled anions (cryo-SEVI) and infrared photodissociation spectroscopy (IRPD).

*This work is supported by the Air Force Office of Scientific Research under Grant No. FA9550-16-1-0097.

9:48AM A32.00004: Nanoparticles versus bulk materials: dramatic changes of ZrO$_2$ properties by nanostructuring GIANFRANCO PACCHIONI (Presenter), University of Milano - Bicocca — Materials in form of nanoparticles or clusters exhibit rather different properties compared to their bulk counterparts. This has been widely shown in the case of metals. Much less is known in the field of oxides. Here we report the results of first principles calculations on nanoparticles of ZrO$_2$ containing from a few tens to a few hundred of atoms. Zirconia is widely used in many technological applications for its wide gap, non-reducibility, low defects concentration, non-magnetic behaviour. We demonstrate that ZrO$_2$ in form of stoichiometric nanoparticles exhibits completely different properties: it becomes easily reducible (by oxygen removal or H$_2$ treatment), highly reactive (with charge transfer to supported metal species) and it turns from a non-magnetic material to a stable ferromagnet at room temperature. These results show the importance of preparing traditional materials in form of nm size particles to obtain new and unprecedented physical properties.
10:00AM A32.00005: Recent advances in THz/far-IR vibrational spectroscopy, synergy DFT-MD simulations and experiments* [Invited] MARIE-PIERRE GAIGEOT (Presenter), Physics, LAMBE UMR8587, Universite d'Evry val d'Essonne, Universite Paris-Saclay — We will present our most recent combined experimental (with the group of Dr A.M. Rijs, FELIX laboratory, Univ Nijmegen, The Netherlands; IR-UV ion dip IR spectroscopy) and theoretical investigations (our group at Univ Evry, Univ Paris-Saclay, France) in the 100-800 cm⁻¹ far-IR/THz vibrational domain for a series of Peptides, Phenol derivatives, beta-sheet Peptides. Finite temperature DFT-MD trajectories are employed in order to calculate anharmonic vibrational spectra of gas phase molecules and clusters.

Our emphasis is on the mapping of THz/far-IR vibrational motions and how to use such mapping to unveil 3D conformational structures in a systematic way. We will especially discuss localized/delocalized vibrational motions in the far-IR, anharmonic/harmonic modes, large amplitude motions, mode couplings and H-bonds signatures in the far-IR/THz spectral domain. We will also present our most recent methods development for extracting ‘effective modes’ from the DFT-MD trajectories and hence assign the vibrational modes.

Session A33 FIAP: 2D Materials and Transition Metal Chalcogenides BCEC 204B - Akm Newaz, San Francisco State University

8:00AM A33.00001: Ultrafast nonlocal collective dynamics of Kane plasmon-polaritons in a narrow-gap semiconductor ALIAKSEI CHARNUKHA (Presenter), IFW Dresden, AARON STERNBACH, Department of Physics, Columbia University, H. TED STINSON, University of California, San Diego, CHRISTOPH BRÜNE, LAURENS W MOLENKAMP, Physikalisches Institut (EP3), University of Würzburg, DIMITRI BASOV, Department of Physics, Columbia University — The observation of ultrarelativistic Dirac, Weyl, and Kane fermions in condensed-matter systems has uncovered a cornucopia of novel phenomenology as well as a potential for effective ultrafast light engineering of novel states of matter. While the non-equilibrium properties of two- and three-dimensional (3D) hexagonal crystals have been studied extensively, our understanding of the photinduced dynamics in 3D singlevalley ultrarelativistic materials is lacking. Here, we employ ultrafast scanning near-field optical spectroscopy to access and control non-equilibrium finite-momentum plasmon-polaritons in thin films of a prototypical narrow-band-gap semiconductor Hg0.81Cd0.19Te. We demonstrate that these collective excitations exhibit distinctly non-classical scaling with electron density characteristic of the ultrarelativistic Kane regime and experience mode splitting due to the coupling of charge oscillations at the top and bottom surface of the thin film. Our observation and ultrafast control of Kane plasmon-polaritons in a semiconducting material using light sources in the standard telecommunications fiber-optics window open a new avenue towards high-bandwidth coherent information processing in next-generation plasmonic circuits.

8:12AM A33.00002: Quantum nonlinear Hall effect in two-dimensional materials with time-reversal symmetry JHIH-SHIH YOU (Presenter), Institute for Theoretical Solid State Physics, IFW Dresden, SHIANG FANG, Department of Physics, Harvard University, SUYANG XU, Department of Physics, Massachusetts Institute of Technology, EFTHIMIOS KAXIRAS, Department of Physics, Harvard University, TONY LOW, Department of Electrical and Computer Engineering, University of Minnesota — We study the quantum nonlinear Hall effect in two-dimensional (2D) materials with time-reversal symmetry. When only one mirror line exists, a transverse charge current occurs in the second-order response to an external electric field, as a result of the Berry curvature dipole in momentum space. Candidate 2D materials to observe this effect are two-dimensional transition metal dichalcogenides (TMDCs). First, we use an ab initio based tight-binding approach to demonstrate that monolayer T_d structure TMDCs exhibit a finite Berry curvature dipole. In the 1H and 1T^* phase of TMDCs, we show the emergence of a finite Berry curvature dipole with the application of an electrical displacement field, respectively.

Quasiparticle Interference on a natural mineral: Mapping the bands of argentiferous Galena

CAROLINA DE ALMEIDA MARQUES (Presenter), CHRISTOPHER TRAINER, CHI MING YIM, School of Physics and Astronomy, University of St Andrews, TIMOTHY DAVID RAUB, School of Earth and Environmental Sciences, University of St Andrews, PETER WAHL, School of Physics and Astronomy, University of St Andrews — Galena (PbS) is the main ore of lead, and in the early days of wireless technology, it played a fundamental part in crystal radios. High-quality samples, that cleave perfectly, are common natural occurrences. It belongs to the lead chalcogenides PbX (X=Te, Se, S), narrow direct bandgap semiconductors which have high thermoelectric figures of merit and unusual semiconducting properties. Their electronic band structure has been studied theoretically and experimentally, revealing a bandgap which decreases with decreasing temperature and under pressure.

Previous Scanning tunnelling microscopy (STM) studies on PbS crystals reported atomically-resolved surfaces. In this study, a natural argentiferous PbS crystal (Ag impurities, p-doped) was cleaved in situ and measured at 20K, using a home-built low-temperature STM. We observe high-quality surfaces with a large variety of defects, surrounded by clear patterns due to quasiparticle interference (QPI). We will show results from QPI to map its electronic structure in the occupied and unoccupied states.

Emphanitic anharmonicity in PbSe at high temperature and anomalous electronic properties in the PbQ (Q=S,Se,Te) system

RUNZE YU, EMIL BOZIN, MILINDA ABYEYKOON, Brookhaven National Laboratory, BORIS SANGIORGIO, NICOLA SPALDIN, ETH Zurich, CHRISTOS MALLIAKAS, Northwestern University, MERCOURI KANATZIDIS, Argonne National Laboratory, SIMON J L BILLINGE (Presenter), Brookhaven National Laboratory — The temperature dependence of the local structure of PbSe has been investigated using pair distribution function (PDF) analysis of x-ray and neutron powder diffraction data and density functional theory (DFT) calculations. Observation of non-Gaussian PDF peaks at high temperature indicates the presence of significant anharmonicity, which can be modeled as Pb off-centering along [100] directions that grows on warming similar to the behavior seen in PbTe and PbS and sometimes called emphanisis. Interestingly, the emphanitic response is smaller in PbSe than in both PbS and PbTe indicating a nonmonotonic evolution with chalcogen atomic number in the PbQ (Q = S, Se, Te) series. The DFT calculations indicate a correlation between band gap and the amplitude of [100] dipolar distortion, suggesting that emphanisis may be behind the anomalous composition and temperature dependencies of the band gaps in this series.

Nonreciprocity in Thermal and Thermoelectric Transport of Electrons in Noncentrosymmetric Crystals

RYOTA NAKAI (Presenter), RIKEN, NAOTO NAGAOSA, University of Tokyo — A system with broken inversion symmetry shows direction-dependent conduction phenomena beyond linear response regime, which is referred to as nonreciprocal transport. In a single crystalline system, noncentrosymmetric crystal structure serves as a source of the nonreciprocal transport of the electrons. In this study, the nonlinear thermal and thermoelectric conductivities of electronic systems are calculated up to the second order in an electric field and a temperature gradient by using the Boltzmann equation with the relaxation time approximation. All the second-order conductivities are described by a small number of functions including the Berry curvature dipole. The second-order conductivities are estimated for the 1H monolayer of the transition metal dichalcogenides and a polar semiconductor BiTeX(X=I,Br).

WS2 atomically thin nanodot array via self-organized templates

ARCHANA KUMARI (Presenter), Slippery Rock University of Pennsylvania — Tungsten Disulphide (WS2) atomic layer nanodot arrays were fabricated with self-organized porous alumina templates as evaporation masks. First tungsten oxide (WO3) was deposited on sapphire substrates through the alumina template to create WO3 nanodot arrays, then WS2 nanodots were formed by the reaction of sulfur with WO3 using chemical vapor deposition (CVD) technique. The sizes of the observed two-dimensional WS2 nanodots varies from 45nm to 70nm. These nanodots exhibit a layer thickness ranging from monolayers to a few atomic layers. This is confirmed by atomic force microscopy (AFM) measurements. Monolayer dots dominated region produces characteristic Raman peaks and high intensity photoluminescence (PL) due to direct band gap transition. Also it has more edge sites which can increase the PL of WS2 dots. A region dominated by multilayer dots produces WS2 Raman peaks but negligible photoluminescence due to indirect transition in multilayers. These novel atomically thin nanodots are attractive for both fundamental studies and future device applications, for e.g. ultrasensitive and ultrafast sensors. Scanning Electron Microscopy and Atomic Force Microscopy of WS2 nanodots is shown in figure.
Piezochromism in the magnetic chalcogenide MnPS$_3$  
NATHAN HARMS (Presenter), University of Tennessee, HEUNG SIK KIM, Rutgers University, New Brunswick, KENNETH R O’NEAL, AMANDA CLUNE, AMANDA HAGLUND, University of Tennessee, DAVID GEORGE MANDRUS, Oak Ridge National Lab, ZHENXIAN LIU, Brookhaven National Lab, DAVID VANDERBILT, Rutgers University, New Brunswick, JANICE LYNN MUSFELDT, University of Tennessee — We bring together diamond anvil cell techniques, optical spectroscopy, and first principles electronic structure calculations to reveal the piezochromic properties of MnPS$_3$. Color changes (green - red - black) take place with pressure as the charge gap systematically redshifts across the visible regime and into the near infrared, moving toward closure at the rate of 0.05 eV/GPa. Strikingly, this extrapolated value for potential band gap closure (55 GPa) corresponds to the theoretically-predicted crossover to the dimerized phase.

Epitaxial growth and collective electronic states of monolayer 1T-NbSe$_2$*  
LIAN LI (Presenter), HUIMIN ZHANG, LIWEI LIU, ZHUOZHI GE, CHENHUI YAN, Department of Physics and Astronomy, West Virginia University, MICHAEL WEINERT, Department of Physics, University of Wisconsin — At the single layer limit, transition metal dichalcogenides (TMDs) can adopt two different structural variants, i.e., polymorphs, depending on the anionic environment around the metal ions: the anions arrange in trigonal prismatic fashion in the 1H polymorph, whereas in 1T the arrangement is octahedral. While bulk 1T NbSe$_2$ doesn't exist in nature, here we show that single layer 1T NbSe$_2$ polymorph can be grown by molecular beam epitaxy on epitaxial graphene/SiC(0001) substrates. A (Ö13xÖ13) Star-of-David charge density waves is observed by in situ scanning tunnelling microscopy, which persists above room temperature. A gap of 0.50 eV are further observed by tunnelling spectroscopy and angle resolved photoemission spectroscopy, indicating that this monolayer 1T phase of NbSe$_2$ is also a Mott insulator, similar to that of bulk 1T TaS$_2$. Our findings indicate that the presence of epitaxial constraints can generate structural configurations that are prohibited in fully-bonded TMD crystals. These findings and their implication on the collective electronic states of single layer 1T-NbSe$_2$ will be discussed at the meeting.

*This research is supported by NSF (DMR-1734017).

Low-Pressure Chemical Vapor Deposition Growth of Iron-Doped MoS$_2$ Monolayers*  
SHICHEN FU (Presenter), KYUNGNAM KANG, XIAOTIAN WANG, SIWEI CHEN, EUI-HYEOK YANG, Mechanical Engineering, Stevens Institute of Technology — Dilute magnetic semiconductors have drawn researchers' attention over the last decade, driven by the advent of spintronics. Transition metal dichalcogenides (TMDs) have demonstrated great potential for new generation spintronics owing to their unique structural and electronic properties. Experimental and theoretical efforts have been made to understand the role of magnetic impurities in TMDs, such as Mn, Fe, Co, and Ni.¹ Theoretical studies show that Fe-substitution in Mo site leads to spin-polarized states and can achieve room temperature ferromagnetic ordering and clustering.² Here, we demonstrate direct growth of Fe-doped monolayer (ML) MoS$_2$ via the chemical vapor deposition. We obtained Fe-doped ML MoS$_2$ with an average crystal size of 40 μm. We observed a PL peak at 1.78 eV, a 70 MeV eV redshift from 1.85 eV obtained from undoped ML MoS$_2$ synthesized in our lab. Scanning transmission electron microscopy images show Fe atoms substituted Mo atoms. X-ray photoelectron spectroscopy will be performed to quantitatively analyze the doping concentration. We will then correlate the growth recipe with its doping concentration for the optimized growth of Fe-doped MoS$_2$ monolayers.

9:48 AM A33.00010: Direct observation of ultrafast free carrier dynamics in InSe  XIAOQIAN ZHANG (Presenter), University of Missouri — The optical properties of semiconductors are specified by the dynamics of free carriers and bound excitons, both originating from dynamics of electron-hole pair excitations. However, the contribution of free carrier to the optical properties is masked by the excitons-related features. We overcome this issue by assessing the free carrier dynamics in bulk InSe with TR-ARPES measurements. Snapshots of conduction band pumped by 1.55 eV photons at different time delays is explored. The peak excitation is reached at $t = 0.2$ ps. The parabolic dispersion around the conduction band edges can be extracted from the peak intensity difference at $t = 0.2$ ps, where the full parabolic dispersions of the band extrema emerge due to the increased population of carriers. This then relaxes at later time delays. During interband excitons, a non-thermal distribution of excited electron-hole pairs is generated at the earliest time delays, relaxing into a quasi-equilibrium state with a temperature higher than that of the lattice. Our measurements provide a direct observation of population inversion occurs immediately after interband excitation. By directly measuring the band occupancy at all energies and times, we have made a quantitative evaluation of the carrier dynamics.

10:00 AM A33.00011: High harmonic anti-stokes upconversion in van der Waals heterostructure p-n junction photodidodes  FATEMEH BARATI (Presenter), NATHANIEL MONROE GABOR, VIVEK M AJI, University of California, Riverside — Here, we report phonon assisted antistokes absorption near the interlayer exciton edge of a van der Waals semiconductor heterostructure composed of tungsten diselenide and molybdenum diselenide. By carefully tuning the chemical potential of a WSe$_2$/MoSe$_2$ heterojunction, we find highly rectifying I-V characteristics of the device. We use photocurrent spectroscopy to show the system is depleted of charged excitons (trions) as we reach the charge neutrality point at the interface. At low photon energies near 1eV, we observe a strong photocurrent peak with several low energy echoes spaced by 30meV below this fundamental absorption feature. We attribute these highly unusual features to sub-gap antistokes absorption involving out-of-plane optical phonons. Multiple phonons are combined with a low energy photon to generate an electron-hole pair. This highly efficient process due to the alignment of the exciton dipole moment to the atomic displacement of the out-of-plane optical phonons marks the first and most critical step toward laser cooling of atomic layer semiconductors. The antistokes absorption process observed could enhance the efficiency of next generation photovoltaics, by converting vibrational energy into electronic excitations using photons with energies lower than band gap.

10:12 AM A33.00012: ReS$_2$ double gate field-effect transistors with h-BN as dielectric layers  JUNHEE CHOI (Presenter), Department of Physics, Ewha Womans University, KOOKJIN LEE, Electrical Engineering, Korea University, DONG HOON SHIN, Department of Physics, Ewha Womans University, GYU-TAE KIM, Electrical Engineering, Korea University, SANG WOOK LEE, Department of Physics, Ewha Womans University — Transition metal dichalcogenides (TMDs) are regarded as promising 2-dimensional materials for semiconducting devices and optoelectronic applications. Unlike group VI-TMDs, the rhenium-based dichalcogenides crystallize in a distorted triclinic (1T') structure due to an extra electron in the $d$ orbital. Because of this structure, the interlayer coupling effect is weaker than other TMDs. Here, we demonstrated electrical characteristics of double gate multilayer ReS$_2$ FETs, which is passivated with h-BN as gate dielectric layers. The device were measured in double gate mode by sweeping the bottom gate voltage with fixed the top gate bias. The field effect mobilities can be modulated from 26.1 to 40.2 cm$^2$V$^{-1}$s$^{-1}$. The second peak in transconductance ($g_m$) of bottom gate sweep is appeared depending on changing top gate potential indicating that conduction path separates in a multilayer system. Also, the threshold voltage shift of the bottom gate depends on the top gate voltage with two linear relationships due to top gate screening effect.

10:24 AM A33.00013: The thermoelectric and electron transport properties on the charge density wave(CDW) transition of (PbSe)$_n$(VSe$_2$)$_{1.2.3}$ heterostructure materials as well as 1-T VSe$_2$ 2D materials  YU WANG (Presenter), Materials Science, University of Southern California — A series of (PbSe)$_n$(VSe$_2$)$_n$ with $n = 1,2,3$ turbostratic disorder heterostructure materials were synthesized through modulated elemental reactants (MER) method. The in-plane and cross-plane Seebeck coefficient, as well as electron transport properties and Hall coefficient, were measured from 80K to 300K. At the charge density wave (CDW) transition, the Seebeck coefficient decrease by approximately two-fold when the material transforms from CDW state to normal state. And the Raman shift spectra dependence on the temperature of the materials were also measured. All those properties were also compared to the 1-T VSe$_2$ 2D materials.
10:36AM A33.00014: Structure and Electronic Properties of InSe and GaSe Polytypes  
MICHAEL BADAWI (Presenter), ANDREI POSTNIKOV, University of Lorraine, JULIANA SROUR, FOUAD EL HAJ HASSAN, Lebanese University — Equilibrium crystal structures, electron band dispersions, and bandgap values of layered GaSe and InSe semiconductors, each being represented by four polytypes, have been investigated within the density functional theory [1]. Several dispersion correction methods to the DFT, from empirical Grimme corrections to many-body dispersion schemes, have been assessed in comparison with experimental cell parameters [2]. Due to the high technical accuracy achieved, nearly degenerate energy-volume curves of different polytypes are resolved, and the conclusions concerning the relative stability of competing polytypes drawn [3]. The band structures are inspected using the modified Becke-Johnson (mBJ) scheme and hybrid HSE06 functional. Both methods nicely agree with the experimental results and with state-of-the-art GW calculations. Some discrepancies are identified in cases of close competition between the direct and indirect gap (e.g., in GaSe). The placement of bands are slightly different for mBJ and HSE06.

10:48AM A33.00015: Interplay between Rashba Spin-Orbit Coupling, Magnetic Field, and Topological Superconductivity in Monolayer NbSe_2  
DANIEL SHAFFER (Presenter), FIONA BURNELL, RAFAEL M FERNANDES, University of Minnesota, JIAN KANG, Physcis, Florida State University — The persistence of superconductivity above the Pauli limit in monolayer 1H-NbSe_2 is indicative of strong Ising spin-orbit coupling (SOC). It has been suggested that the interplay between Ising SOC and strong in-plane magnetic fields can lead to a topological nodal superconducting phase protected by a time reversal-like symmetry. An important ingredient not fully considered, however, is Rashba SOC. Not only is it expected to be significant due to substrate effects, but it is also tunable by electrostatic gating. In this talk, we present a microscopic model for superconductivity of NbSe_2 driven by repulsive electronic interactions as a function of magnetic field and Rashba SOC. For large enough magnetic fields, a small Rashba SOC lifts the nodes unless the magnetic field is aligned along certain directions, in which case a residual mirror symmetry protects some of the nodes and corresponding flat band edge modes. In the opposite limit of small magnetic fields, a topological chiral phase is found to be stabilized by large Rashba SOC.

Session A35 DQI: Semiconducting Quantum Computing with Donors  
BCEC 205B - Ryan Jock, Sandia National Laboratories - Tag(s): Focus

8:00AM A35.00001: Modeling dopants in silicon: application to atomic-scale Si qubit systems.  
KEYI LIU (Presenter), Joint Quantum Institute, NIST/University of Maryland, College Park, GARNETT BRYANT, NIST, MICHAL ZIELINSKI, Nicholas Copernicus University — Dopants in silicon are strong candidates for qubits in scalable, atom-based, solid-state quantum systems due to their long decoherence times and Si nanofabrication infrastructure. In these devices, an impurity atom binds a donor electron at low temperatures and information is stored either in the electron or the dopant nuclear spin. Typically, tight-binding (TB) theory is expected to provide a good computational model with reasonable precision. However, calculations based on simple central cell potential cutoff failed to predict the well-established energy degeneracies for a variety of bulk Si tight-binding models, hinting missing corrections in the model. We present TB calculations using several new corrections including the induced nearest neighbor hopping, the varying screened potential, and the orthogonalization of the on-site wavefunctions. We also discuss the consequences of applying these atomic scale corrections on the dopant models, including effects on the hyperfine interactions and STM imaging of dopants. Finally, we discuss how these models can be potential guides for experiments in many-body physics using atom-based devices.
8:12AM A35.00002: Using multivalley effective mass theory to probe the phosphorus donor effective potential in silicon* LUKE PENDO (Presenter), XUEDONG HU, University at Buffalo, The State University of New York — Multivalley effective mass (MEM) theories combine physical intuition with an efficient use of computational resources. However, the most appropriate form of effective potential to use with MEM theory remains an open question. Here we develop an MEM theory for an electron confined to a phosphorous donor in Silicon, and explore the most useful form of effective potential that would allow us to accurately predict both spectrum and wavefunction of the electron. We employ a variational method with a freely extensible set of symmetrized Gauss- or Slater-type atomic basis states, with representatives from all five irreducible representations of the Td point-symmetry group. We employ stochastic optimization to complete both variational minimization and model parameter fitting, which allows for parameter spaces of large dimensionality. We consider an effective potential with tetrahedrally symmetric central cell corrections and a dynamic dielectric, as well as exchange-correlation effects, and we also explore effects of external perturbations such as an applied electric field. Our investigation here lays a solid foundation for studies of electronic states and interactions of multiple donors.

*We acknowledge financial support by US ARO via grant W911NF1710257.

8:24AM A35.00003: Quantum computation and simulation with dopants in silicon [Invited] SVEN ROGGE (Presenter), Univ of New South Wales — Bottom-up dopant engineering in silicon reached a level of control where devices can be reproducibly fabricated at the atomic scale with high yield. This talk focuses on the progress of single dopant atom placement in the context of quantum computation and simulation. Silicon offers a particularly interesting platform for quantum bits (qubits) because when isotopically purified it acts as a “semiconductor vacuum” for spins. This leads to extraordinary coherence that is used to realise donor atom based qubits. One and two qubit gates have been achieved with phosphorus qubits in silicon. High-bandwidth dispersive readout has been implemented and single-shot capability has been demonstrated with this technique. Spatially resolved tunnelling experiments that reveal the spectrum and quantum state image of single atoms and tunnel coupled arrangements of atoms will be discussed. This technique enabled the design and verification of a robust scheme to achieve exchange coupling of an two dimensional array of dopants that is immune to placement errors of the atoms. In addition, the fabrication of strongly coupled donor arrays that represent a hardware implementation of a Hubbard simulator will be presented. Quasi-particle tunnelling maps of spin-resolved states with atomic resolution reveal interference processes from which the entanglement entropy and Hubbard interactions are quantified. This represents a first stepping stone towards artificial quantum matter with up to 30 spins to implement complex highly correlated systems.

9:00AM A35.00004: Decoherence of donors in silicon at millikelvin temperatures* PATRICE BERTET (Presenter), VISHAL RANJAN, BARTOLO ALBANESE, SEBASTIAN PROBST, CEA-Saclay, GENGLI ZHANG, The Chinese University of HongKong, EMMANUEL FLURIN, DENIS VION, DANIEL ESTEVE, CEA-Saclay, REN-BAO LIU, The Chinese University of HongKong, JOHN MORTON, UCL London — Donors in silicon are model spin systems [1] and potential candidates for implementing solid-state quantum bits. In that perspective, a detailed understanding of their coherence properties is needed. I will present measurements of Bismuth donors spin relaxation and coherence times at millikelvin temperatures obtained with a homemade spectrometer working at the quantum limit of sensitivity based on superconducting micro-resonators and Josephson parametric amplifiers [2], and I will discuss the various mechanisms at play.

*Support of the European Research Council (grant 615767) and of the French Agence Nationale de la Recherche (projects QIPSE and NASNIQ) is acknowledged.

9:12AM A35.00005: Desorption and lithographic patterning of halogen-terminated Si(100)-(2x1) using STM K.J. DWYER (Presenter), University of Maryland, College Park, JENNIFER E. DEMELL, Laboratory for Physical Sciences, MICHAEL DREYER, University of Maryland, College Park, ROBERT E BUTERA, Laboratory for Physical Sciences — Scanning tunneling microscopy (STM)-based hydrogen depassivation lithography is a well-established technique used for fabricating atomic-scale devices in Si. Incorporation of donor atoms from PH3 into lithographic patterns in a Si surface allows for the formation of metallic wires, electrostatically defined quantum dots, and precise placement of donor atom qubits for quantum information (QI) research. However, interest in acceptor dopants and hole-based devices in QI and other fields necessitates the development of alternate precursor and/or resist chemistries for STM device fabrication. Here, we present results on the passivation and selective depassivation characteristics of halogen resists (Cl and Br) used for STM lithography on Si(100)-(2x1) at low and elevated temperatures (77 K, 300 K, 400 K). We explore STM tip-induced desorption and lithography as a function of tip bias, tunnel current, and electron dose. Through these studies, we demonstrate halogen lithography in an atomically precise mode where single Si dimer-wide features are depassivated, as well as a field emission mode for patterning larger areas of the halogen-terminated Si surface. This work moves us closer to realizing a resist and acceptor combination for fabricating atomic-scale, hole-based devices for QI.
Suppressing spectral diffusion in phosphorus-doped silicon via optical excitation in high magnetic fields* LIHUANG ZHU, Physics and Astronomy, Dartmouth College, JOHAN VAN TOL, National High Magnetic Field Laboratory, CHANDRASEKHAR RAMANATHAN (Presenter), Physics and Astronomy, Dartmouth College — The phosphorus donor impurity in silicon is a promising candidate for spin-based quantum devices. Recent experiments have shown that above-band gap optical excitation can result in strong hyperpolarization of the donor nuclear spins [1,2]. Here we show that low-power above-band-gap excitation can also extend the phase memory time of the donor electron spins in a low-concentration (\(\sim 3.3 - 3.5 \times 10^{15} \text{ cm}^{-3}\)) phosphorus-doped natural abundance silicon sample. A two-pulse Hahn echo experiment at 8.5T and 4K was used to measure the decay of the echo amplitude with time. The non-exponential decays (\(\sim \exp(-t/T_{SD})^n\)) suggest that the phase memory time is dominated by spectral diffusion due to the \(^{29}\text{Si}\) spins [3]. \(T_{SD}\) was measured to be 110 µs in the dark and with sub-bandgap excitation, rising to over 180 µs with 1050 nm laser excitation. With 980 nm excitation, \(T_{SD}\) was observed to increase with applied laser power, saturating at 200 µs.

Machine Learning approach to the inverse problem in STM imaging of dopant-based quantum devices* PIOTR T. RÀSKI (Presenter), MARTYNA PATERA, Institute of Physics, Nicolaus Copernicus University, GARNETT BRYANT, Atomic-Scale Device Group, NIST, MICHAL ZIELINSKI, Institute of Physics, Nicolaus Copernicus University — Atomic-scale solid-state qubits could be implemented using scanned-probe lithography to place two or more phosphorus dopants in silicon close to each other. Scanning tunnelling microscopy (STM) has been used to image individual dopants and to find dopant positions in the host silicon lattice based on that image. Determining the geometry of two-dopant based devices will be an essential step in device fabrication, however, double dopant-based devices will lead to a more challenging problem due to the complicated inter-valley wave-function interference patterns. Here we propose a theoretical solution to that problem. We utilize a multi-million atom tight-binding method, accounting for d-orbitals, surface passivation and surface reconstruction. Further, we use a machine learning approach to determine the positions of both dopants based on STM images generated with tight-binding simulations. From that we derive a set of rules for imaging two dopants and discuss possible generalizations for structures with a larger number of dopants.

*Support from the Polish National Science Centre based on decision No. 2015/18/E/ST3/00583 is kindly acknowledged.
10:00AM A35.00009: Investigating the impact of laser illumination upon coherence times of electron spin qubits bound to donors in silicon* DAVID WISE (Presenter), NAITIK PANJWANI, SIDDHARTH DHOMKAR, JOHN MORTON, London Centre for Nanotechnology, University College London — Donor spin qubits in silicon have long represented an attractive proposition for a qubit architecture. They have long coherence times, fast gate times and development can leverage techniques of the semiconductor industry. Another potential spin qubit, the optically active crystal defect - of which the NV centre in diamond is the most prominent example - has demonstrated exceptional single qubit properties particularly with regards to high fidelity single-shot read out.
An intriguing research question is whether these two different species of spin qubit could be employed in a hybrid architecture. To assess the potential for this an initial study is needed on the impact of laser illumination on coherence times of donor spin qubits in silicon to establish threshold wavelengths and powers at which coherence is negligibly affected. Here, we present an analysis of the impact of NIR illumination on the coherence of electrons bound to phosphorus donors in silicon.

*The authors gratefully acknowledge funding from EPSRC

10:12AM A35.00010: Electronic transport along atomically placed P ribbons in Si* BELITA KOILLER (Presenter), Universidade Federal do Rio de Janeiro, Brazil, AMINTOR DUSKO, CAIO LEWENKOPF, Universidade Federal Fluminense, Brazil — Atomically precise placement of dopants in Si permits creating P nanowires by design. High-resolution images show that these wires are few atoms wide with some positioning disorder with respect to the Si structure sites, which is expected to lead to electronic localization. Experiments, however, report good transport properties in quasi-1D P nanoribbons. We investigate their electronic properties using an effective single-particle approach based on a linear combination of donor orbitals (LCDO), keeping the ground state donor orbitals' oscillatory behavior due to interference among the states at the Si conduction band minima. Our model for the P positioning errors accounts for the presently achievable placement precision.

Transport properties are inferred from the calculated localization length $\zeta$ at the half-filling. For 1 to 3 atoms thick wires, $\zeta$ shows a rich non-monotonic behavior with respect to placement target parameters. We consider different systems widths and disorder scenarios to explore how transverse and longitudinal aimed interdonor distances can be chosen to optimize and control $\zeta$ for specific device applications.

*This work is partially supported by the Brazilian agencies CNPq and FAPERJ.

Monday, March 4, 2019 8:00 AM - 11:00 AM

Session A36 DAMOP: Hybrid Quantum Systems BCEC 205C - Mukund Vengalattore, Cornell University - Tag(s): Invited

8:00AM A36.00001: Perfect bosonic quantum state transfer using imperfect transducers and interference* [Invited] AASHISH CLERK (Presenter), IME, University of Chicago — The ability to faithfully transfer quantum states between disparate quantum systems is a crucial functionality for quantum information processing. Quantum transducers are often limited by a weak overall coupling strength, or by unwanted spurious interactions. I will discuss recent theoretical work showing that such imperfect transducers can nonetheless be used to accomplish perfect transduction by harnessing interference effects. Unlike other recent approaches for mitigating transduction errors, our approach does not require the ability to inject squeezing at both source and receiver systems, and is applicable to a wide class of imperfect transducers. Our work has direct relevance to optomechanical microwave-to-optics transduction, and also to hybrid quantum memory schemes.

*This work was supported by the AFOSR MURI FA9550-15-1-0029 on quantum transduction.
Combined feedback and sympathetic cooling of a mechanical oscillator coupled to ultracold atoms* [Invited] PHILIPP CHRISTOPH, TOBIAS WAGNER, HAI ZHONG, ALEXANDER SCHWARZ, KLAUS SENGSTOCK, ROLAND MARTIN WISENDANGER, CHRISTOPH BECKER (Presenter), University of Hamburg — A promising route to novel quantum technologies are hybrid quantum systems, which combine the advantages of several individual quantum systems. We have realized a hybrid atomic-mechanical experiment consisting of a Si3N4 membrane oscillator cryogenically precooled to 500 mK and optically coupled to a cloud of laser cooled 87Rb atoms. Here, we demonstrate active feedback cooling of the oscillator to a minimum mode occupation of \( n = 16 \) corresponding to a mode temperature of \( T \approx 200 \mu K \). Furthermore, we characterize in detail the coupling of the membrane to the atoms by means of sympathetic cooling. By simultaneously applying both cooling methods we demonstrate the possibility of preparing the oscillator near the motional ground state while it is coupled to the atoms. Realistic modifications of our setup will enable the creation of a ground state hybrid quantum system, which opens the door for coherent quantum state transfer, teleportation and entanglement as well as quantum enhanced sensing applications.

*We gratefully acknowledge financial support by the DFG (grant No. BE 4793/2-1, SCHW 780/8-1, SE 717/9-1, WI 1277/29-1).

A Topological Source of Quantum Light [Invited] MOHAMMAD HAFEZI (Presenter), University of Maryland, College Park — TBD

Phonon networks with SiV centers in diamond waveguides [Invited] PETER RABL (Presenter), Atominstitut, TU Wien — Electronic and nuclear spins associated with defects in solids comprise a promising platform for various quantum technologies. Prominent examples are NV and SiV centers in diamond, for which many techniques for coherent manipulations and local entanglement operations are already available. However, despite the impressive progress in the local control of spin qubits in diamond and other materials, the next big step of coherently integrating many spin qubits into larger networks has not been achieved yet. In this talk I will discuss a new approach to reach this goal by using quantized mechanical vibrations to mediate interactions between distant spin qubits. Specifically, I will describe the implementation of phonon quantum networks, where multiple SiV centers are coupled to propagating phonon modes in a quasi-1D diamond waveguide. In this setting, quantum states encoded in long-lived electronic spin states can be converted into travelling phonon wave packets and be reabsorbed by a distant defect center in a fully controllable way. I will show that under realistic experimental conditions, this technique enables the implementation of high-fidelity, scalable quantum communication protocols within chip-scale spin-qubit networks.

Optical and mechanical properties of superfluid helium drops levitated in vacuum* [Invited] JACK HARRIS (Presenter), Yale Univ — Many of the goals of quantum optomechanics require a combination of low optical and mechanical loss, low temperature, and high-precision measurement. As a material, superfluid helium offers a number of potential advantages in these regards: vanishing optical absorption and viscosity, high thermal conductivity, and the ability to cool itself efficiently via evaporation. Superfluid optomechanical devices have made considerable advances in recent years, but their performance is often limited by the materials used to contain the superfluid. To avoid these limits we have proposed the use of magnetic levitation to suspend a drop of liquid helium in vacuum[1] with the goal of using the drop’s optical whispering gallery modes (WGMs) and its surface waves as an optomechanical system, while relying on the drop’s evaporation to maintain low temperature. Each of these individual components (i.e., magnetic levitation, WGMs, and evaporative cooling) has been previously demonstrated by other groups, but combining them in a single device should offer several intriguing possibilities. We will describe some of these possibilities, and will also present recent measurements of mm-scale superfluid drops that are magnetically levitated in high vacuum. Specifically, we will describe the formation and trapping of the drops, and their evaporative cooling in the trap to \( \sim 330 \) mK. We will also present measurements of the drops’ mechanical resonances, and of their optical Mie resonances.

8:00 AM A37.00001: Gapless Visons and Emergent U(1) Spin Liquid in Kitaev’s Honeycomb Model* [Invited] CIARÁN HICKEY (Presenter), University of Cologne — In the field of quantum magnetism, the exactly solvable Kitaev honeycomb model serves as a paradigm for the fractionalization of spin degrees of freedom and the formation of $Z_2$ spin liquid ground states. An intense experimental search has led to the discovery of a number of spin-orbit entangled Mott insulators that realize its characteristic bond-directional spin interactions and, in the presence of strong magnetic fields, exhibit no indications of long-range magnetic order. Here, we map out the complete phase diagram of the Kitaev model in tilted magnetic fields and report the emergence of a distinct gapless quantum spin liquid at intermediate field strengths. Analyzing a number of static, dynamical, and finite temperature quantities using numerical exact diagonalization techniques, we find strong evidence that this phase exhibits gapless fermions coupled to a massless gauge field resulting in a dense continuum of low-energy states. Such a phase can be naturally understood within the framework of Abrikosov fermionic partons as a U(1) quantum spin liquid with a spinon Fermi surface, emerging via a superconductor-metal transition. Finally, we discuss its stability in the presence of perturbations, Heisenberg and off-diagonal symmetric exchange interactions, that naturally arise in spin-orbit entangled Mott insulators alongside Kitaev interactions.

8:36 AM A37.00002: Ground State of the Spin-1/2 Honeycomb Γ Model: Zigzag Magnetic Order HAI-JUN LIAO (Presenter), RUIZHEN HUANG, YI-BIN GUO, Institute of Physics, Chinese Academy of Sciences, P.O. Box 603, Beijing 100190, China, ZHI-YUAN XIE, Department of Physics, Renmin University of China, Beijing 100872, China, BRUCE NORMAND, Laboratory for Neutron Scattering and Imaging, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland, TAO XIANG, Institute of Physics, Chinese Academy of Sciences, P.O. Box 603, Beijing 100190, China — The off-diagonal symmetric interaction, $\Gamma ( S_i^\alpha S_{i+\gamma}^\beta + S_i^\beta S_{i+\gamma}^\alpha )$, has sprung to prominence as a competing term in the spin Hamiltonians of candidate Kitaev materials. We investigate the quantum ($S = 1/2$) $\Gamma$ model on the honeycomb lattice using the tensor-network method of infinite projected entangled pair states (iPEPS). We demonstrate that the ground state is a zigzag magnetically ordered state, rather than the spin liquid reported on the basis of density-matrix renormalization-group (DMRG) studies. By applying two quasi-one-dimensional numerical treatments, the infinite matrix-product-state (iMPS) and DMRG methods, we show that this contrast is a consequence of the system size considered. Thus the quantum $\Gamma$ model is quite different from its classical counterpart, which is a classical spin liquid due to its macroscopic ground-state degeneracy.

8:48 AM A37.00003: Nonlinear magnetic susceptibility in the Kitaev model YOSITOMO KAMIYA (Presenter), Department of Physics and Astronomy, Shanghai Jiao Tong University, JUNKI YOSHITAKE, YASUYUKI KATO, Department of Applied Physics, University of Tokyo, JOJI NASU, Department of Physics, Tokyo Institute of Technology, YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo — We study the nonlinear spin susceptibility in the Kitaev model [1]. The model has been serving as a paradigmatic model for studying a quantum spin liquid and extensive experimental efforts are currently undertaken. While the Jackeli-Khaliullin mechanism [2] predicts the ferromagnetic Kitaev model, recent theoretical studies suggest that the antiferromagnetic Kitaev model may stabilize distinct spin liquids in a magnetic field. Since the determination of the sign of the Kitaev coupling can be experimentally problematic, we propose a convenient complementary experimental signature to distinguish the two cases. Here, in the gapped spin liquid phase, we derive an analytical expression in perturbation theory and find that the nonlinear spin susceptibility exhibits a characteristic sign change at finite temperature in the ferromagnetic Kitaev model. We also present results based on numerical simulations (exact diagonalization and quantum Monte Carlo simulations), with which we show that the characteristic sign change also appears in the gapless spin liquid phase with a ferromagnetic coupling [3].

9:00AM A37.00004: Ground-state phase diagram of the extended Kitaev-Heisenberg model on a honeycomb lattice

9:12AM A37.00005: Dynamical and Topological Signatures of the Kitaev-Model in a [111] Magnetic Field* [Invited]

MATTHIAS GOHLKE (Presenter), RODERICH MOESSNER, Max-Planck-Institute for the Physics of Complex Systems, 01187 Dresden, Germany, FRANK POLLMANN, Technische Universität München, 85747 Garching, Germany — Quantum spin-liquids represent exotic phases of matter that host emergent fractionalized excitations. The Kitaev model [1] is a two-dimensional model system in this context and relevant for recent experiments on putative quantum spin-liquid materials. Here, we present results for the Kitaev model coupled to a magnetic field along the [111] axis. Using infinite DMRG, we confirm three phases with vastly different transition fields depending on the sign of the Kitaev exchange [2]: A topological phase hosting non-abelian anyons at low fields, an intermediate regime only existing for antiferromagnetic Kitaev exchange, and a field-polarized phase hosting topological magnons [3].

For the topological phase, we numerically observe the expected cubic scaling of the gap and extract the quantum dimension of the non-abelian anyons.

A novel time-evolution based on matrix product operators enables to obtain the dynamical spin-structure factor, which in presence of a field behaves very differently compared to what is known for the three-spin exchange [4] obtained within a perturbation theory approach [1]. The magnetic field causes the flux degrees of freedom to become mobile. As a consequence the low-energy spectrum contains more structure and the gap in the dynamical spin-structure factor is reduced. Upon approaching the intermediate regime from high fields, the magnon modes reduce in frequency and simultaneously flatten. Near the transition, a broad continuum forms, that ranges down to zero frequency and merges with the single magnon branches. The spectrum appears to be gapless in the entire reciprocal space.

9:48AM A37.00006: Field-induced neutral Fermi surface and QCD3 quantum criticalities in Kitaev materials

LIUJUN ZOU, Harvard University, YIN-CHEN HE (Presenter), Perimeter Institute — We perform both numerical and theoretical studies on the phase diagram of the Kitaev materials in the presence of a magnetic field. We find that a new quantum spin liquid state with neutral Fermi surfaces emerges at intermediate field strengths, between the regimes for the non-Abelian chiral spin liquid state and for the trivial polarized state. We discuss the exotic field-induced quantum phase transitions from this new state with neutral Fermi surfaces to its nearby phases. We also theoretically study the field-induced quantum phase transitions from the non-Abelian chiral spin liquid to the symmetry-broken zigzag phase and to the trivial polarized state. Utilizing the recently developed dualities of gauge theories, we find these transitions can be described by critical bosons or gapless fermions coupled to emergent non-Abelian gauge fields, and the critical theories are of the type of a $\text{QCD}_3$-Chern-Simons theory. We propose that all these exotic quantum phase transitions can be direct and continuous in the Kitaev materials. Therefore, besides being systems with intriguing quantum magnetism, Kitaev materials may also serve as table-top experimental platforms to study the interesting dynamics of emergent strongly interacting quarks and gluons in 2 + 1 dimensions.
10:00AM A37.00007: Formation of magnetic order in the Kitaev-Heisenberg model*
SHANG-SHUN ZHANG (Presenter), University of Tennessee, GABOR HALASZ, Oak Ridge National Laboratory, WEI ZHU, Los Alamos National Laboratory, CRISTIAN BATISTA, University of Tennessee — We compute the low-energy excitation spectrum and the dynamical magnetic spin structure factor of the Kitaev-Heisenberg model using a variational approach, that becomes exact at the exactly solvable Kitaev points. This approach reveals the physical origin of the asymmetry in the stability range of Kitaev spin liquid phases around the ferromagnetic and antiferromagnetic Kitaev points. We also show that bound states of fractionalized excitations appear in the proximity of a quantum phase transition between the ferromagnetic Kitaev spin liquid and the magnetically ordered states induced by ferro and antiferromagnetic Heisenberg interactions.

10:12AM A37.00008: Quantum phases in spin-1 honeycomb antiferromagnets: application to Ni$_2$Mo$_3$O$_8$*
SHUYI LI (Presenter), VAIDEESH LOGANATHAN, WENJUN HU, ANDRIY NEVIDOMSKYY, Department of Physics and Astronomy, Rice University — Ni$_2$Mo$_3$O$_8$ is a recently synthesized material containing spin-1 moments on a honeycomb lattice [1]. Such systems are of interest due to their potential to exhibit topological magnons. According to the recent neutron scattering experiment [1], the two sub-lattices making up the bipartite honeycomb lattice each display a zig-zag antiferromagnetic order. Moreover, the order is non-coplanar with a non-trivial angle between adjacent spins due to competing interactions. In this work, we attempt to explain this spin ordering by the means of mean-field theory and Density Matrix Renormalization Group (DMRG) calculations. We use ab initio Density Functional Theory (DFT) calculations to extract the spin-exchange coefficients in the effective low-energy model. We propose that the Dzyaloshinskii-Moriya interaction is the most natural way to explain the observed magnetic ordering.

*Robert A. Welch Foundation Grant C-1818, NSF Grant DMR-1350237

10:24AM A37.00009: Three-dimensional chiral spin liquids in the Kitaev model on a hypernonagon lattice
PETR MISHCHENKO (Presenter), YASUYUKI KATO, Department of Applied Physics, The University of Tokyo, KEVIN O’BRIEN, Institute for Theoretical Physics, University of Cologne, TROELS BOJESEN, Department of Applied Physics, The University of Tokyo, TIM ESCHMANN, Institute for Theoretical Physics, University of Cologne, MARIA HERMANNS, Department of Physics, University of Gothenburg, SIMON TREBST, Institute for Theoretical Physics, University of Cologne, YUKITOSHI MOTOME, Department of Applied Physics, The University of Tokyo — Chiral spin liquids (CSLs) are exotic quantum states without magnetic order but with broken time-reversal symmetry. Recently, the ground-state and finite-temperature ($T$) behaviors of CSLs have been studied for the Kitaev models [1] on two and three-dimensional (3D) lattice geometries [2-4]. In this talk, we will present a comprehensive study of the ground state and thermodynamic properties of the Kitaev model on the 3D hypernonagon lattice, which has previously been explored in the limit of anisotropic interactions [4]. Our numerical simulations employ quantum Monte Carlo technique, which in combination with the Chebyshev polynomial expansion [5], allows us to study systems of up to 2600 spins. We find evidence for a first-order phase transition in the isotropic interactions case similar to the anistotopic limits, but into a different type of CSL ground state. We also present the ground-state phase diagram obtained by variational calculations.

10:36AM A37.00010: Nonlocal String Order Parameter in the S=1/2 Kitaev-Heisenberg Ladder*  ERIK SORENSEN  (Presenter), Physics, McMaster University, HAE-YOUNG KEE, ANDREI CATUNEANU, Physics, University of Toronto — We study the S=1/2 Kitaev-Heisenberg (KJ) model in a two-leg ladder. Without a Heisenberg interaction, the Kitaev phase in the ladder model has Majorana fermions with local Z2 gauge fields and is usually described as a disordered phase without any order parameter. Here we prove the existence of a non-local string order parameter (SOP) in the Kitaev phase which survives with a finite Heisenberg interaction. The SOP is obtained by relating the Kitaev ladder, through a non-local unitary transformation, to a one-dimensional XY chain with an Ising coupling to a dangling spin at every site. This differentiates the Kitaev phases from other nearby phases including a rung singlet. Two phases with non-zero SOP corresponding to ferromagnetic and antiferromagnetic Kitaev interactions are identified. The full phase diagram of the KJ model is determined using exact diagonalization and density matrix renormalization group methods, which shows a striking similarity to the KJ model on a two-dimensional honeycomb lattice.

10:48AM A37.00011: Ground-state phase diagram of the Kitaev-Heisenberg model on a kagome lattice  KATSUHIRO MORITA (Presenter), MASANORI KISHIMOTO, TAKAMI TOHYAMA, Tokyo University of Science Katsushika Campus — The Kitaev-Heisenberg model on the honeycomb lattice has been studied for the purpose of finding exotic states such as quantum spin liquid and topological orders. On the kagome lattice, in spite of a spin-liquid ground state in the Heisenberg model, the stability of the spin-liquid state has hardly been studied in the presence of the Kitaev interaction. Therefore, we investigate the ground state of the classical and quantum spin systems of the kagome Kitaev-Heisenberg model. In the classical system, we obtain an exact phase diagram that has an eight-fold degenerated canted ferromagnetic phase and a subextensive degenerated Kitaev antiferromagnetic phase. In the quantum system, using the Lanczos-type exact diagonalization and cluster mean-field methods, we obtain two quantum spin-liquid phases, an eight-fold degenerated canted ferromagnetic phase similar to the classical spin system, and an eight-fold degenerated q=0, 120° ordered phase induced by quantum fluctuation.

Session A38 GMAG DMP: Magnetoelectric and Multiferroic Effects in Molecular Systems
BCEC 206B - Janice Musfeldt, Univ of Tennessee, Knoxville - Tag(s): Focus

8:00AM A38.00001: Structure-property relations in multiferroic [(CH3)2NH2]M(HCOO)3 (M=Mn,Co,Ni)  KENDALL HUGHEY (Presenter), AMANDA CLUNE, MICHAEL O YOKOSUK, University of Tennessee, JING LI, Fudan University, NANDITA ABHYANKAR, Florida State University, XIAXIN DING, Los Alamos National Laboratory, NARESH DALAL, Florida State University, HONGJUN XIANG, Fudan University, DMITRY SMIRNOV, National High Magnetic Field Laboratory, JOHN SINGLETON, Los Alamos National Laboratory, JANICE LYNN MUSFELDT, University of Tennessee — We combine magnetization and infrared spectroscopy to unveil the B-T phase diagrams and vibrational properties of the [(CH3)2NH2]M(HCOO)3 (M=Mn,Co,Ni) family of multiferroics. While the magnetically-driven transition to Bc in the Mn analog takes place at 15.3 T, much higher fields are required to saturate the Ni and Co materials. Analysis of the infrared spectrum of the Mn and Ni compounds across Tc reveals splitting of the formate bending mode which functions as an order parameter of the ferroelectric transition. By contrast, the Co complex reveals a surprising framework rigidity where the ferroelectric state is driven solely by counterion freezing. With magnetic field, the Mn (and most likely, the Ni) materials engage the formate bending mode to facilitate the transition to the fully saturated magnetic states, whereas the Co complex adopts an alternate mechanism involving formate stretching distortions. Similar structure-property relations involving substitution of transition metal centers and control of the flexible molecular architecture are likely to exist in other molecule-based multiferroics.
8:12AM A38.00002: DFT Study of the Magnetic and Structural Properties of the DTN Molecular Crystal  

MAHER YAZBACK (Presenter), SHUANGLONG LIU, NEIL SULLIVAN, HAI-PING CHENG, University of Florida — DTN or dichloro-tetrakis-thiourea-nickel (NiCl₂ – [SC(NH₂)₂]₄) is a molecular crystal whose soft lattice structure allows it to more easily deform, allowing stronger magneto-electric coupling (ME) manifestations, compared to typical ME materials. At low temperatures and in moderate magnetic fields DTN exhibits exotic behavior including a quantum phase transition into a Bose-Einstein condensate/XY antiferromagnetic state. Moreover, the presence of disorder introduced by Br doping experimentally shows evidence for the existence of a Bose glass state. This system poses a challenge when trying to accurately model structural and mechanical properties due to its weak intermolecular interactions. Our work attempts to understand the nature of DTN and Br-DTN using density functional theory (DFT). By including the effects of Van der Waals interactions using the DFT-D3 correction we show that we can get accurate lattice constants, bond lengths and bond angles, which allows us to further probe the mechanism responsible for the magneto-electric phenomena present in DTN. We also report our calculation of the exchange coupling constants and zero-field splitting constants responsible for the behavior of DTN at low temperatures.

8:24AM A38.00003: Electron-Beam Patterning of the Low-Loss (High-Q) Ferrimagnetic Coordination Compound V[TCNE]ₓ₋₂ (Vanadium Tetracyanoethylene)*  

ANDREW FRANSON (Presenter), Physics, The Ohio State University, NA ZHU, Electrical Engineering, Yale University, SETH KURFMAN, MICHAEL CHILCOTE, EZEKIEL JOHNSTON-HALPERIN, Physics, The Ohio State University, HONG X TANG, Electrical Engineering, Yale University — Integrating patterned, low-loss magnetic materials into silicon-based devices and circuits presents many difficulties, from lattice matching requirements to extreme deposition conditions for traditional ferrite materials. Here we present the deposition, patterning, and characterization of the low-loss (α = 3.94 x 10⁻⁵), room-temperature ferrimagnetic coordination compound vanadium tetracyanoethylene, (V[TCNE]ₓ₋₂). Patterning of V[TCNE]ₓ₋₂ thin films from 100 nm to 1 µm thick is performed via electron-beam lithographic patterning using a poly(methyl methacrylate), poly(methyl methacrylate-methacrylic acid 8.5%) copolymer bilayer (PMMA/P(MMA-MAA)) on sapphire and silicon, and this process can be trivially extended to most inorganic substrates. The V[TCNE]ₓ₋₂ is deposited on the patterned PMMA/P(MMA-MAA) via chemical vapor deposition (CVD) at 30 mTorr and 50°C in an argon atmosphere. V[TCNE]ₓ₋₂ patterned in this method retains its low-loss characteristics down to feature sizes of 10s of µm, below which a non-conformal deposition regime leads to a non-trivial geometry. These results establish the versatility and potential of V[TCNE]ₓ₋₂ to be incorporated in future silicon-based electronic devices.

*NSF Grant No. EFMA–1741666

8:36AM A38.00004: Electric field modulation of magnetic exchange in molecular helices detected by Electron Paramagnetic Resonance*  

[Invited] MARIA FITTIPALDI, ALBERTO CINI, Department of Physics, University of Florence, Italy, GIUSEPPE ANNINO, Istituto per i Processi Chimico-Fisici - IPCF, CNR, Italy, ALESSANDRO VINDIGNI, Physics, ETH, Zurich, Switzerland, ANDREA CANESCHI, Department of Industrial Engineering, University of Florence, Italy, ROBERTA SESSOLI (Presenter), Department of Chemistry, University of Florence, Italy — The possibility to operate on magnetic materials through the application of electric rather than magnetic fields - promising faster, more compact and energy efficient circuits - continues to spur the investigation of magneto-electric effects. Beyond symmetry requirements, large spin-orbit coupling is generally considered a necessary ingredient. On the contrary, a control of the spin-spin interaction by an electric field, not relying directly on spin-orbit coupling but rather on the overlap of the electronic clouds of interacting centers, would be quite appealing in the emerging field of quantum materials. Here, we report the detection of a magneto-electric effect that we attribute to an electric field modulation of the magnetic exchange interaction theoretically predicted for molecular magnetic helices. On a Manganese(II)-radical helix, thus comprising spin centers with negligible orbital contribution, the application of an electric field (E) introduces an energy contribution, which is different in case of parallel or antiparallel alignment of neighboring spins along the helix. The E field effect on the intra-chain exchange interaction J has been here experimentally observed by exploiting the sensitivity of Electron Paramagnetic Resonance (EPR) spectroscopy under electric field modulation. It is in fact well known that one-dimensional spin correlation can induce a significant g-shift even when only a weak anisotropy of dipolar origin is present. By replacing the usual B-field modulation with the E-field modulation an EPR signal is induced by the shift of the resonance as a result of the electric field effect on J. The symmetry of the observed phenomenon unambiguously confirms its magneto-chiral nature. Our observation opens interesting perspectives, which may be relevant also for the investigation of multiferroic materials.

*Italian MIUR (PRIN 2015 HYFSRT project), European QuantERA (SUMO project), and Fondazione CR Firenze.
Together, this opens the door to further exploration of the high field phase using powered and pulsed magnets. Multiferroic materials with a cascade of transitions up to and including the 31 T transition to the fully polarized state. The phase diagram is different to other temperature phase diagram. Density functional theory and numerical simulations of the exchange interactions was measured using pulsed magnetic fields of up to 60 T and temperatures down to 0.6 K, to reveal the magnetic field-dependent electronic structure. The result implies a potential approach to realize spin injection and detection on SCs without using any magnetic material.

The zero-field effect of chirality-induced spin selectivity has been observed in a host of nanostructures involving chiral molecule monolayers on noble metals.1 However, there has been no report of similar experiments on semiconductor (SC) surfaces. Here, we report on a study of spin-selective electron transport across chiral polyalanine molecules in vertical junctions of (Ga,Mn)As/polyalanine/Au. The bottom electrode is an epitaxially strained (Ga,Mn)As film with perpendicular magnetic anisotropy. The junctions are formed in openings in a hardened PMMA layer on the (Ga,Mn)As defined by electron beam lithography. The native oxide on the exposed (Ga,Mn)As is removed by ion milling, followed immediately by polyalanine monolayer self-assembly in a solution. The top Cr/Au electrodes are thermally evaporated under liquid nitrogen cooling. The (Ga,Mn)As acts as a spin analyzer: Sweeping the perpendicular magnetic field at low temperatures, sharp jumps in the junction resistance are observed at the coercive fields, indicating spin filtering of electrons from the Au electrode by the polyalanine monolayer. The result implies a potential approach to realize spin injection and detection on SCs without using any magnetic material.

The interplay of magnetism and chirality with valley excitons SHUOFENG LAN (Presenter), XIAOZE LIU, SIQI WANG, HANYU ZHU, University of California, Berkeley, YAWEN LIU, University of California, Riverside, CHENG GONG, University of California, Berkeley, JING SHI, University of California, Riverside, YUAN WANG, XIANG ZHANG, University of California, Berkeley — Most biological molecules are chiral and exist in one of the two mirror-image enantiomers. The so-called homochirality of life is one of the most fundamental mysteries for human beings. Theory and experiments show that the magneto-chiral (MCh) effect albeit small may play a role in the molecular enantioselectivity of prehistoric life by simultaneously breaking both the parity-inversion and time-reversal symmetry. For the first time, we observe an excitonic MCh effect in artificially arranged van der Waals (vdW) crystals with an unprecedented giant MCh anisotropy more than 30 times larger than that in natural materials. Moreover, the observed excitonic MCh effect possesses a spectral splitting that is more than 50 times larger than that induced by the Zeeman effect. Such an excitonic MCh effect creates a link among magnetism, chirality, spin, and excitons, which has long been explored ever since the discovery of the natural optical activity by Arago and magnetically induced optical activity by Faraday in the early 19th century. Furthermore, the electronic nature of spins in two-dimensional vdW semiconductors makes the manipulation of enantioselectivity in magneto-chiral systems attractive for photochemical reactions, asymmetric synthesis, and chiral quantum optics.

Multiferroic Quantum Criticality AWADHESH NARAYAN (Presenter), ETH Zurich, ANDRES CANO, Institut Neel, CNRS & Univ. Grenoble Alpes, ALEXANDER BALATSKY, NORDITA, NICOLA SPALDIN, ETH Zurich — The zero-temperature limit of a continuous phase transition is marked by a quantum critical point, which can generate exotic physics that extends to elevated temperatures. Magnetic quantum criticality is now well known, and has been widely explored [1]. Ferroelectric quantum critical behavior has also been recently established [2], motivating a flurry of research investigating its consequences. In this talk, I will present the concept of multiferroic quantum criticality -- in which both magnetic and ferroelectric quantum criticality occur in the same system -- that we have recently proposed [3]. I will describe the phenomenology of multiferroic quantum critical behavior, its emergence in complex transition metal perovskite oxides and propose candidate materials in which it should be observable.

Magnetic field-temperature phase diagram of the molecule-based multiferroic (NH4)2FeCl3H2O AMANDA CLUNE (Presenter), University of Tennessee, JISOO NAM, Ulsan Natl Inst of Sci & Tech, KENDALL HUGHEY, University of Tennessee, MINSEONG LEE, Ulsan Natl Inst of Sci & Tech, WEI TIAN, JAIME FERNANDEZ-BACA, RANDY FISHMAN, Oak Ridge National Laboratory, JOHN SINGLETON, Los Alamos Natl Lab, JUN HEE LEE, Ulsan Natl Inst of Sci & Tech, JANICE LYNN MUSFELDT, University of Tennessee — The magnetization of a molecule-based multiferroic, (NH4)2FeCl3H2O and its deuterated analog, was measured using pulsed magnetic fields of up to 60 T and temperatures down to 0.6 K, to reveal the magnetic field-temperature phase diagram. Density functional theory and numerical simulations of the exchange interactions demonstrates the origin of non-collinearity and multiferroicity within the system. The phase diagram is different to other multiferroic materials with a cascade of transitions up to and including the 31 T transition to the fully polarized state. Together, this opens the door to further exploration of the high field phase using powered and pulsed magnets.
Spin dynamics in molecular multiferroic (ND₄)₂[FeCl₅(D₂O)]*  
WEI TIAN, HUIBO CAO, GABRIELE SALA, TAO HONG, RANDY FISHMAN, JAIME FERNANDEZ-BACA (Presenter), Oak Ridge National Laboratory — (ND₄)₂[FeCl₅(D₂O)] is a molecular magnet that exhibits extraordinary coupled magnetic and ferroelectric properties. Applying modest magnetic field induces successive magnetic transitions with distinct magnetoelectric (ME) coupling and the underlying mechanism is not fully understood yet. Knowing the microscopic interactions is essential to understand the complex coupled phenomena. We performed inelastic neutron scattering experiments to measure the spin dynamics in (ND₄)₂[FeCl₅(D₂O)]. We will present here some INS data analysis results using linear spin wave theory.

*Research conducted at ORNL's Spallation Neutron Source and High Flux Isotope Reactor was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

Giant Electrically Controlled Spinterface in Organic Ferroelectric Copolymer-based Multiferroic Tunnel Junctions  
HOANG LUONG (Presenter), RUGANG GENG, MINH PHAM, THO NGUYEN, Physics and Astronomy, University of Georgia — Controlling spin of electron by purely electrical means at high temperature is challenging and a long sought device in spintronics. In this APL (110, 053302, 2018), we report electrically controlled interfacial spin polarization, or the magnetoelectric effect in multiferroic tunnel junctions (MTJs) by employing organic ferroelectric copolymers, poly(vinylidene fluoride-trifluoroethylene) (P(VDF-TrFE)), as a tunneling barrier. First, we show that the spontaneous ferroelectric polarization of the P(VDF-TrFE) films can be formed in a thin interlayer. Next, the tunneling magnetoresistance in the unpolarized TMJ quenches from 21% at 20 K to 0.7% at 296 K. Remarkably, the interfacial spin polarization of the device, dubbed spinterface, can be gradually tuned by an applied electric field. Upon the electric polarization reversal, the tunneling electroresistance reaches about 30% at 200 K and the spinterface of the device significantly changes up to 100%. The interface between P(VDF-TrFE) and Co electrode might act as an electric-field-dependent spin filter causing the large magnetoelectric effect. The resistance of the MTJs can be controlled by either electric field or magnetic field, and therefore can potentially be used as a high density information storage element with four states.

Tunnel magnetoresistance in oligophenyl based magnetic tunnel junctions  
RICHARD MATTANA (Presenter), BENOIT QUINARD, SOPHIE DELPRAT, SOPHIE COLLIN, FRÉDÉRIC PETROFF, PIERRE SENEOR, Unité Mixte de Physique CNRS/Thales — Molecular spintronics, an emerging research field at the frontier between organic chemistry and spintronics, has opened novel and exciting opportunities in terms of functionalities for spintronics devices. Among those devices, molecular magnetic tunnel junctions have attracted a growing interest over the years. Indeed, it was shown that spin dependent hybridization at the metal/molecule interface could lead to a radical tailoring of spintronics properties. To achieve this, self-assembled monolayers appear to be very promising candidates thanks to their impressive molecular scale crafting properties and easy-processing. Previous works were done with basic molecules such as linear alkanethiols. We now focus on more complex molecules integrating aromatic moieties to study how the modification of the tunnel barrier impacts the magnetic and electronic behaviour of the devices. We will present spin dependent tunneling transport underlining the main similarities and differences between alkanethiols and oligophenyls MTJs.

Spin transport through graphene/molecules-based magnetic tunnel junctions*  
CLEMENT BARRAUD (Presenter), JACKO RASTIKIAN, PASCAL MARTIN, PHILIPPE LAFARGE, MARIA LUISA DELLA ROCCA, MPQ, Université de Paris, RICHARD MATTANA, UMR 137, CNRS, PIERRE SENEOR, UMR 137, Université Paris Saclay, FRÉDÉRIC PETROFF, BRUNO DLUBAK, UMR 137, CNRS — Spin transport through organic molecules is motivated by the ability to tune at the atomic scale the spin injection/detection properties. This property is barely achievable in inorganic systems and it is due to the possibility of designing molecules atoms by atoms. With this respct, ferromagnetic metal/molecules interfaces has focused most of the attention.

A common issue remains the quality of such complex interfaces. Ferromagnetic metals like Co, Fe, Ni are transition metals and are easily oxidizable. The presence of oxygen atoms is known to completely modify the magnetic and electronic properties of magnetic surfaces. The recently proposed Ni/graphene electrodes for spintronics applications is very appealing due to their protected character. Moreover, graphene is more and more viewed as a good platform for the absorption of molecules.

In this talk, I will describe the fabrication process of magnetic tunnel junctions made of Ni/graphene/nitrobenzene molecules/Co/Au. I will especially detail the electrografting procedure to attach molecules over the graphene surface. I will then present the magnetotransport measurements performed at low temperatures. I will also discuss the bias voltage dependence of the magnetoresistance.

*"2DSPIN" from the Emergence program (City of Paris)
Electronic Phase Separation induced dramatic enhancement of large magnetoresistance in Organic Spin Valves*  

WENTING YANG (Presenter), QIAN SHI, TIAN MIAO, QIANG LI, PENG CAI, HAO LIU, HANXUAN LIN, BAI YU, YINYAN ZHU, YANG YU, LINA DENG, WENBIN WANG, LIFENG YIN, Fudan University, DALI SUN, Department of Physics, North Carolina State University, XIAOGUANG ZHANG, Department of Physics, University of Florida, JIAN SHEN, Fudan University —  

Organic spin valves (OSVs) have been studied widely with respect to the long spin relaxation time of the carriers in the organic materials and their synthetic versatility, ease of manufacturing and pliability. Recent advances focused on the spin-interface and the multi-functionalities of OSVs. Here we employ LPCMO with high spin polarization and electronic phase separation (EPS) to tune the MR of the OSV, which depends strongly on the pre-set magnetic field, voltage and temperature due to the spin-flip scattering in LPCMO and the interface. An extremely high MR of 438% and the rangeability of 5.9 times are observed. Our findings point an alternative way for multistate of OSVs and controllable room temperature OSVs by using LPCMO with high Tc and electronic phase separation.

Session A39 GMAG DQI DMP: Coherent Spins in Semiconductors  

8:00AM A39.00001: Spin–photon interface and spin-controlled photon switching in a nanobeam waveguide  
PETER LODAHL (Presenter), University of Copenhagen — Selected by FT organizers

8:36AM A39.00002: Off-Resonance Time-Resolved Kerr Rotation Spectroscopy*  
MEHMET NOYAN (Presenter), J. M. KIKKAWA, University of Pennsylvania — We show that time-resolved Kerr rotation (TRKR) is a quantitatively accurate tool to measure spin dynamics, even when conducted highly off resonance. We find that TRKR measurements have essentially identical temporal profiles when the probe energy is tuned far below, far above, and on resonance with a semiconducting band gap. We also present energy dependent TRKR spectra, and show they have an odd Lorenztian profile around the semiconducting band gap, at odds with the simplest theoretical model which predicts an even Lorenztian form. We show that this discrepancy is resolved if one accounts for a decrease in the transition linewidth as the optical energy increases above the band-edge transition.

*We gratefully acknowledge support from NSF DMR-1206270.

8:48AM A39.00003: Identification of multi-photon transitions between magnetic dipole states using electrically detected magnetic resonant excitation with variable drive-field helicities.*  
ADNAN NAHLAWI (Presenter), HANS MALISSA, Department of Physics and Astronomy, University of Utah, 115 South 1400 East, Salt Lake City, Utah 84112, USA, DANI STOLTZFUS, PAUL BURN, Centre for Organic Photonics and Electronics, School of Chemistry & Molecular Biosciences, The University of Queensland, Queensland 4072, Australia, TAMIM DARWISH, ANNA LEUNG, National Deuteration Facility, ANSTO, Lucas Heights, New South Wales 2234, Australia, JOHN LUPTON, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, D-93040 Regensburg, Germany, CHRISTOPH BOEHME, Department of Physics and Astronomy, University of Utah, 115 South 1400 East, Salt Lake City, Utah 84112, USA — For magnetic resonance conditions where the amplitude of the resonant driving field \( B_1 \) is close to the static magnetic Zeeman field \( B_0 \), quantum-optical effects linked to the two photon helicities, including the Bloch-Siegert shift [1,2] or multiple photon effects [3,4,5], emerge. In order to study the latter, we built a radio frequency domain electron spin resonance setup which allows for driving fields with arbitrary polarization. For the detection of magnetic resonance at \( B_0 \) in the mT-range where spin polarization is all but vanishing, we used spin-dependent recombination currents in a fully deuterated form of poly[2-methoxy-5-(2-ethylhexyloxy)-1,4-phenylenevinylene] (d-MEH-PPV), in which proton-induced random hyperfine fields are minimized. We report results obtained for circularly, linearly, and elliptically polarized excitation states. [1] J. J. Sakurai, Modern Quantum Mechanics, Revised Edition. *Addison-Wesley* (1994); [2] J. A charge-tunable quantum dot strongly coupled to a nanophotonic cavity

ZHOUCHEN LUO (Presenter), EDO WAKS, University of Maryland, College Park — Quantum dots (QDs) integrated with photonic structures is a promising scalable platform for the development of quantum networks and distributed quantum computing. Probabilistic charging of the QDs with electron/hole spins by adding a doping layer suffers from low charging stability due to carrier tunneling. Sandwiching the QDs into a p-n junction, which allows deterministically changing the charging state of the QDs by changing the external gate voltage can resolve this problem. Many experiments that previously have been achieved in probabilistic charged QDs sample, like cavity assisted QDs spin manipulation, have been successfully demonstrated using those charge tunable p-n junction QDs sample. However, the strong coupling between QDs spin and a microcavity, which is the basis of many QDs-based quantum information processing protocols and quantum optics experiments, hasn’t been accomplished yet. Here, we report for the first time the realization of strong coupling between charge tunable QDs spin and a micro cavity, and the demonstration of spin population transfer via optical pumping. The strong coupling combined with deterministic charging paves way for applications of QDs in quantum optics.

Theory of the circulating current of a single magnetic impurity in a semiconductor

ADONAI RODRIGUES DA CRUZ (Presenter), Department of Applied Physics, Eindhoven University of Technology, MICHAEL FLATTÉ, Department of Physics and Astronomy, University of Iowa — The localized electron spin of a single impurity in a semiconductor is a promising system to realize quantum information schemes [1]. Coherent control of this spin depends on understanding the structure of the magnetic moment that couples the system with external fields. In this work we investigate the spin-orbit induced circulating current associated with the ground state of a single magnetic impurity in zincblende III-V semiconductor. This circulating current is dissipationless and represents an electron moving in a closed trajectory producing an orbital contribution to the magnetic moment [2]. We developed a formalism employing Green's functions obtained by the Koster-Slater technique [3,4] with a sp^3d^5s^* empirical tight-binding Hamiltonian to describe the host material.

Polarization-to-spin conversion and entanglement distribution via coherent interface with semiconductor double quantum dot

CHIEN-YUAN CHANG (Presenter), KAZUYUKI KUROYAMA, MARCUS LARSSON, SADASHIGE MATSUO, Department of Applied Physics, University of Tokyo, TAKAFUMI FUJITA, Institute of Scientific and Industrial Research, Osaka University, SASCHA R VALENTIN, ARNE LUDWIG, ANDREAS D. WIECK, Ruhr-Universität, AKIRA OIWA, Institute of Scientific and Industrial Research, Osaka University, SEIGO TARUCHA, Department of Applied Physics, University of Tokyo — Interfacing photonic qubits with a gate-defined spin qubit remains critical challenges in semiconductor devices. In this talk, we discuss the key properties of a coherent interface by two separate experiments, quantum state transfer, and entanglement absorption with a double quantum dot. We report polarization-to-spin conversion implemented with single-shot readout of a single electron spin generated in a GaAs quantum dot. The optical spin blockade effect requires in-plane magnetic field and photo-excitation associate to Zeeman-split light-holes, but not heavy-holes. This effect, following the optical selection rules, determines the generation efficiency depending on the photon linear-polarization and the electron number in the dot. Secondly, we discuss the experimental progress of entanglement absorption between an entangled photon pair to a single spin and a photon. With the temporal coincidences and the conditional probabilities of the polarized photon and the electron spin correlation, we plan to detect individual entanglement transferal events.

9:36AM A39.00007: Observation of magnetoresistance effect in charge pumping measurements  MARK A ANDERS (Presenter), National Institute of Standards and Technology, PATRICK MICHAEL LENAHAN, Pennsylvania State University, JASON T RYAN, National Institute of Standards and Technology — We report on a new magnetoresistance effect based on spin dependent trapping events at MOSFET gate/substrate interfaces called near zero field spin dependent charge pumping (NZF SDCP). NZF SDCP involves the application of a trapezoidal gate voltage waveform which cycles the substrate Fermi level between the conduction and valence band edges. Interface defects are cyclically filled and emptied, generating a net substrate recombination current proportional to the number of defects. The change in current is measured as a function of magnetic field. We find that: (1) in most cases the NZF SDCP amplitude appears to saturate as a function of waveform frequency, and (2) the NZF SDCP spectrum broadens with increasing frequency. These observations may allow for experimental exploration of several magnetoresistance theories regarding interaction or exchange times between charge carriers and defect spin centers. (3) The addition of N to the 4H-SiC MOSFET interface can have a profound impact on the NZF SDCP response, and (4) we almost certainly resolve electron-nuclear hyperfine interactions from a H-complexed defect. These observations strongly suggest that NZF SDCP could be a powerful tool to obtain atomic-scale physiochemical information about MOSFET interface defects.

9:48AM A39.00008: Electrically Detected Magnetic Resonance in Silicon Nitride Thin Films of Widely Varying Stoichiometries*  RYAN WASKIEWICZ (Presenter), ELIAS B FRANTZ, PATRICK MICHAEL LENAHAN, Pennsylvania State University, SEAN KING, Intel Corporation — We utilize electrically detected magnetic resonance (EDMR) to identify defects responsible for electronic transport in thin films of silicon nitride. The EDMR response is detected via spin dependent trap assisted tunneling over a range of electric fields. The EDMR measurements are made at both high and low field/frequency combinations. These EDMR measurements are compared with near-zero field magnetoresistance (NZFMR) measurements in which no oscillating magnetic field is applied; we observe an NZFMR response related to the EDMR. A comparison between the EDMR and NZFMR allows us to draw conclusions with regard to the relative analytical power of NZFMR versus EDMR as well as aid in the development of the physical understanding of the NZFMR response.

10:00AM A39.00009: Electrically Detected Magnetic Resonance Study of 4H-SiC/SiO2 Transistors with Barium Passivation*  JAMES ASHTON (Presenter), PATRICK MICHAEL LENAHAN, Pennsylvania State University, DANIEL J LICHTENWALNER, Wolfspeed, a Cree Company, AIVARS J LELIS, United States Army Research Laboratory, MARK A ANDERS, National Institute of Standards and Technology — We report on electrically detected magnetic resonance measurements on 4H-SiC/SiO2 metal oxide semiconductor field effect transistors. 4H-SiC/SiO2 based MOSFETs show great promise for high power and high temperature applications. However, the SiC/SiO2 interface has a high concentration of interface and near-interface traps which limits effective channel mobility. Passivation decreases the interface state density and thus increases the mobility. Passivation schemes typically including post-oxidation annealing in NO. Recent work suggests promise for a barium interfacial layer (IL) before oxidation1. We probe the atomic scale defects at the SiC/SiO2 in NO and barium treated devices and compare the results with those on unpassivated devices. Both the NO anneal and the barium IL greatly reduce the density of near-interface silicon vacancies, but yield somewhat different post-passivation defect structures.

We report the tunneling current behavior in a nano-semiconductor structure of (Ga, Al) As / GaAs, which contains the Rashba spin orbital interaction in the presence of embedded InAs quantum dots of different geometries (lens, pyramid and ring) depending on the voltage, magnetic field, and different spin-orbit interaction values \( k_\text{gL} = \pi/4, \pi/2, 3\pi/4 \). These results show that the intensity of the current presents appreciable changes when the morphology of the quantum dot changes and also when the intensity of the bias voltage and magnetic field increase. For voltages less than or equal to 0.2 V and considering spin up we observed the appearance of the first peaks of current intensity according to the morphology of the following way: Pyramid, lens and ring. However, when the voltage is greater than 0.2 V a change in the current occurs due to the morphology of the quantum dots changing in its order: Ring, lens and pyramid. This phenomenon also occurs when the spin orbit coupling is changed, showing that as the value of the phase increases, a change in the domain of the morphology for similar voltages also occurs.

**10:24AM A39.00011: Zeeman-type spin splitting in non-magnetic three-dimensional compounds: Material prediction and electrical control** CARLOS MERA ACOSTA (Presenter), Center of Natural and Human Sciences, Federal University of ABC, Brazil, ADALBERTO FAZZIO, Brazilian Nanotechnology National Laboratory, Campinas, SP, Brazil, GUSTAVO DALPIAN, Center of Natural and Human Sciences, Federal University of ABC, Brazil — Besides the Rashba and Dresselhaus effects, another kind of spin discrimination phenomena in non-magnetic inversion asymmetry (IA) compounds is the so-called *Zeeman-type* spin splitting, which exhibits a spin-texture similar to the one observed in the magnetic Zeeman effect. Despite its potential for device application, this non-magnetic effect has only been predicted and observed in the two-dimensional WSe\(_2\) and MoS\(_2\) materials. Here, we demonstrate that three-dimensional compounds can also exhibit this splitting. The required conditions for this effect are: valence band maximum or conduction band minimum in a non-time-reversal-invariant \( k \)-point, inversion asymmetry, and zero magnetic moment. Using these conditions as filters, we perform a material screening and high-throughput *ab-initio* calculations to systematically search for these materials in the ICSD database. We find 20 candidates featuring this splitting. Our calculated spin splittings can be as large as 433, 510, and 491 meV for the compounds WN\(_2\) (\( P6m1 \)), WS\(_2\) (\( R3m \)), and SnTe (\( F43m \)), respectively. We also demonstrate that the spin splitting in slabs of these compounds depends on the growth direction and can be controlled by an external electric field.

*We thank FAPESP (grant 18/11856-7) and CNPq for financial support.

**10:36AM A39.00012: DETECTION OF STRONG MAGNETIC RESONANT DRIVE EFFECTS USING SPIN-DEPENDENT ELECTRONIC TRANSITION RATES IN ORGANIC SEMICONDUCTOR MATERIALS** SHIRIN JAMALI (Presenter), HANS MALISSA, Department of Physics and Astronomy, University of Utah, 115 South 1400 East, Salt Lake City, Utah 84112, USA,., DANI STOLTZFUS, PAUL BURN, Centre for Organic Photonics and Electronics, School of Chemistry & Molecular Biosciences, The University of Queensland, Queensland 4072, Australia., TAMIM DARWISH, ANNA LEUNG, The National Deuteration Facility, ANSTO, Lucas Heights, New South Wales 2234, Australia., JOHN LUPTON, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, Universitätsstrasse 31-93040 Regensburg, Germany., CHRISTOPH BOEHME, Department of Physics and Astronomy, University of Utah, 115 South 1400 East, Salt Lake City, Utah 84112, USA. — Spin-dependent recombination currents in \( \pi \)-conjugated polymers allow for the detection of charge carrier spin resonance at very weak applied static Zeeman fields \( B_0 \) [1]. We have used this effect to study magnetic resonance in the strong driving regime when the amplitude of the driving field \( B_1 \sim B_0 \). Technologically, these measurements were carried out by using monolithic thin-film device structures in which a polymer bipolar injection device [an organic light emitting diode] was fabricated directly on top of an RF microwire [2]. We used a fully deuterated form of poly [2-methoxy-5-(2-ethylhexyloxy)-1,4-phenylenevinylene] as active device layer due to its low local hyperfine fields. Under strong-drive, spin collectivity set in [1,2] and a variety of strong drive effects could be observed, including the Bloch-Siegert shift and two photon transitions. The measured dependence of the former on \( B_1 \) confirmed theoretical predictions, suggesting that the monolithic nano-layer device stack used in these experiments could serve as probe for ultra-strong light-matter coupling of paramagnetic charge carriers in polymer materials. Looking for new layered ferromagnetic semiconductor*  
TAI KONG (Presenter), KAROLINE STOLZE, Chemistry, Princeton University, JING TAO, Brookhaven National Laboratory, DANRUI NI, ROBERT CAVA, Chemistry, Princeton University — Layered magnetic semiconductors have attracted great attention recently since ferromagnetism was demonstrated to persist down to single-molecular-layer level. In this talk, we will show our recent effort in looking for new compounds under this category and report the discovery of a new layered ferromagnetic semiconductor with a van der Waals gap.

*Gordon and Betty Moore EPiQS initiative, Grant No. GBMF-4412

Session A40 GMAG: Electric Field and Strain Control of Magnetism  
Virginia Commonwealth Univ - Tag(s): Focus

8:00AM A40.00001: E-field control of RKKY interaction in FeCoB/Ru/FeCoB/PMN-PT (011) multiferroic heterostructures  
XINJUN WANG (Presenter), YUYI WEI, NIAN-XIANG SUN, Northeastern University — E-field control of antiferromagnetic orders is promising for the realization of fast, compact, and energy-efficient AFM applications. However, because of the invisibility of AFM spins, the E-field control process is mainly based on the exchange bias regulation that usually confines at a low temperature. Here we explore a new magnetoelectric (ME) coupling mechanism for the modulation of AFM orders at room temperature. Based on the FeCoB/Ru/FeCoB/PMN-PT, the external E-field generates relative magnetization switching in the two ferromagnetic layers, leading the Ruderman–Kittel–Kasuya–Yosida interaction tuning. This voltage induced switching behavior can be repeated in a stable and reversible manner for various SAFs. We further quantify the voltage induced RKKY interaction changes by analyzing the dynamic optical and acoustic modes through the ferromagnetic resonance measurement, and with first principle calculations, we find that the distortion of the Fermi surface by the lattice reconstruction is the key of the relative magnetization switching and RKKY interaction modulation. This voltage control of RKKY interaction in ME heterostructures provides an easy way for the AFM coupling control and for achieving the next generation of AFM/FM spintronic applications.

8:12AM A40.00002: Voltage control of magnetic anisotropy of a FePt/MgO(001) heterostructure  
QURAT AIN (Presenter), Department of Physics, University of Ulsan, DORJ ODKHUU, Department of Physics, Incheon National University, SUNG-HYON RHM, SOON CHEOL HONG, Department of Physics, University of Ulsan — Control of magnetic properties by an external electric field can be a potential candidate to overcome the limitation of high-power consumption for non-volatile magnetoelectric random access memory (MeRAM). We predict a huge voltage control magnetic anisotropy (VCMA) coefficient \(1.77 \times 10^{-3}\) pJ/(V.m) of the Fe(Pt)-interfaced FePt/MgO heterostructure. The Fe-interfaced FePt/MgO film exhibits strain-induced magnetization reorientation instigated through second order magnetoelastic coupling along with extremely sensitive VCMA behavior. We anticipate a significant effect of the external field on the induced electric dipole that is formed in terms of charge accumulation or depletion at the metal/dielectric interface. These results are a step forward to achieve a full potential of MeRAM with write voltage below 1 V and switching bit energy below 1 fJ.

8:24AM A40.00003: Electric Field-Modulated Propagating Spin Wave Properties in Ultrathin CoFeB Film  
SAMIRAN CHOUDHURY (Presenter), S.N. Bose National Centre for Basic Sciences, BIVAS RANA, RIKEN-CEMS, ANJAN BARMAN, S.N. Bose National Centre for Basic Sciences, YOSHICHIKA OTANI, RIKEN-CEMS — One of the most promising magneto-electric effects is the recently discovered electric field controlled magnetic anisotropy (ECMA), generally observed at the interface between 3d-ferromagnets and oxide where CoFeB/MgO interface has attracted particular attention due to high TMR ratio at room temperature and low Gilbert damping. Interestingly, ECMA can be used to modulate SW properties at ultralow power consumption. We report a systematic experimental study on the modulation of propagating SW frequency in ultrathin CoFeB films by tuning interfacial perpendicular magnetic anisotropy (iPMA) by electric field applied through a top metal gate electrode. The magnetostatic surface SWs are excited and propagate along the waveguide. The SW signals are detected by measuring inverse spin Hall effect voltage across Ta layer underneath the CoFeB films. To modulate the SW frequency a dc gate voltage is applied from a voltage source. The resonance frequency either decreases or increases under the application of negative or positive gate voltages due to the increment or decrement of iPMA with gate voltages. We have also measured SW signals from CoFeB films of lower thicknesses and observed significant modulation of SW frequency with gate voltage due to higher magneto-electric coefficient.
Oxide heterostructures provide an exciting opportunity to engineer new artificial systems with unique properties that cannot be found in naturally occurring materials. Enabling the control of electronic properties of oxides that feature a metal-insulator transition (MIT) is a key requirement for developing a new class of electronics often referred to as “Motttronics” [1]. Although doping and radiation damage are effective tools to permanently change the MIT temperature in these materials, a simple method to switch the MIT properties in real-time is needed for practical applications. In this talk I will present the discovery of giant nonvolatile resistive switching ($\Delta R/R > 1000\%$) and strong modulation of the MIT temperature ($\Delta T_c > 30$ K) in a voltage-actuated $V_2O_3/PMN$-PT heterostructure. The control of the $V_2O_3$ electronic properties is achieved using the transfer of ferroelastic strain from the PMN-PT substrate into the epitaxially-grown $V_2O_3$ film. Strain can reversibly promote/hinder the structural phase transition in $V_2O_3$, thus advancing/suppressing the associated MIT. While oxide/ferroelectric hybrids had been studied in the past using other correlated materials, such as VO$_2$ [2], Fe$_3$O$_4$ [3], LaNiO$_3$ [4], NdNiO$_3$ [5], etc., the reported nonvolatile resistive switching was rather modest: $1.5\% < \Delta R/R < 110\%$. More than an order of magnitude larger resistive switching in $V_2O_3/PMN$-PT could enable practical implementations of voltage-controlled Mott devices and provide a new platform for exploring fundamental electronic properties of $V_2O_3$.

*The research was supported by the Vannevar Bush Faculty Fellowship program, funded by the Office of Naval Research through grant N00014-15-1-2848.
9:24AM A40.00006: Ultralow Voltage Control of Magnetism* YEN-LIN HUANG (Presenter), Lawrence Berkeley National Lab, BHAGWATI PRASAD, Department of Materials Science and Engineering, University of California, Berkeley, JAMES STEFFES, Department of Materials Science & Engineering, University of Connecticut, SAHAR SAREMI, LEI ZHANG, Department of Materials Science and Engineering, University of California, Berkeley, SASIKANTH MANIPATRUNI, Intel Corporation, BRYAN HUEY, Department of Materials Science & Engineering, University of Connecticut, IAN YOUNG, Intel Corporation, RAJESH CHOPDEKAR, Lawrence Berkeley National Lab, R RAMESH, Department of Materials Science and Engineering, University of California, Berkeley — The key to integrating the concepts of spintronics into conventional nanoelectronics lies with the ability to control the magnetic order in nanoscale devices. With the continuous shrinkage of integrated circuits, the energy efficiency required to control these tiny magnets as power dissipation becomes more and more important. Over the past decades, the oxide community has been exploring the materials that can provide the opportunities to control magnetism. Among the large investigated materials, multiferroics might be one of the most promising material family. Multiferroics are the materials which possess at least two order of parameters, particularly, the coexistence of ferroelectricity(P) and magnetism(M), and exhibit coupling from one to another. In this talk, I will demonstrate an ultra-low-voltage (<500 mV) and non-volatile manipulation of ferromagnetism at room temperature via the heterostructure of spin valves on a multiferroic layer, BiFeO3(BFO). Finally, I will conclude this talk with a summary of current challenges and future direction of multiferroics, especially BFO, toward the low-power electronics.

*Acknowledgments: R.R acknowledges support from the SRC-JUMP program through the ASCENT center. Y.L.H is supported by a grant from the DOE Advanced Manufacturing Office.

9:36AM A40.00007: Electric field manipulation of exchange bias in antiferromagnetic Cr2O3 thin films* WEI YUAN (Presenter), CLIFF CHEN, JUNXUE LI, YAWEN LIU, VICTOR ORTIZ, Physics and Astronomy, UC riverside, TANG SU, School of Physics, Peking University, PENG WEI, JING SHI, Physics and Astronomy, UC riverside — Cr2O3 is an interesting insulating antiferromagnetic material, which has been widely investigated recently, including in the studies of the spin Seebeck effect and the long spacing distance spin transport. Cr2O3 is also a well-known magneto-electric material, whose sublattice spins can be switched by an electric field. In this study, we first grow a 5 nm thick Pt layer on the substrate of (0001)-oriented Al2O3 using magnetron sputtering, and then the Cr2O3 thin films using high vacuum pulsed laser deposition. 1 nm Co is grown on top of Cr2O3 by molecular beam epitaxy or magnetron sputtering, followed by a 2 nm thick Pt capping layer deposited in-situ to prevent the oxidation of the ferromagnetic Co. The Co layer shows a very strong perpendicular magnetic anisotropy with exchange bias by anisotropy magnetoresistance measurements. The exchange bias can be reversibly manipulated by the gating electric field in Cr2O3 between the bottom and top Pt layers. The magneto-electric manipulation of Cr2O3 spins offers potential to switch the magnetization in high-density memory devices incorporating antiferromagnets with low energy consumption.

*Spins and Heat in Nanoscale Electronic Systems, funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences award NO. SC0012670

9:48AM A40.00008: Control over the ISHE in a platinum film by ionic gating SERGEY DUSHENKO (Presenter), University of Maryland, College Park/National Institute of Standards and Technology, MASAYA HOKAZONO, Department of Electronic Science and Engineering, Kyoto University, KOHJI NAKAMURA, Department of Physics Engineering, Mie University, TERUYA SHINJO, YUICHIRO ANDO, MASASHI SHIRAISHI, Department of Electronic Science and Engineering, Kyoto University — We report reversible modulation of the inverse spin Hall effect (ISHE) in Pt achieved through the careful control of Pt thickness and an ionic gating technique. The ISHE converts spin current into charge current, which allows easy detection of spin current and integration of spintronics and electronics. The effect is governed by spin-orbit interaction and is particularly strong in Pt, which has been widely used as the ISHE-based spin current detector. However, the gate tuning of the spin-orbit interaction in metals was considered out of reach because of high carrier density.

We fabricated Pt films, 1.5 nm to 20 nm thick, on top of the YIG ferrimagnetic layer and used spin pumping to inject spin current in the Pt layer. Using the the ionic gel (DEME-TFSI) top gate, the resistance of the Pt film was tuned up to 280%. Such control over the resistance and carrier density in Pt allowed us to gate tune the amplitude of the ISHE over two orders of magnitude—a result that can be used in spin-torque and other spintronics devices that use spin-charge conversion [1].

10:00AM A40.00009: Voltage control of magnetism in metal oxide/metal nanoislands and nanostripes*  MARTIN NICHTERWITZ (Presenter), SHASHANK HONNALI SUDHEENDRA, JONAS ZEHNER, KENNY DUSCHEK, Leibniz Institute of Solid State and Materials Research (IFW Dresden), Helmholtzstr. 20, 01069 Dresden, Germany, KORNELIUS NIELSCH, Leibniz Institute of Solid State and Materials Research (IFW Dresden), Helmholtzstr. 20, 01069 Dresden, Germany; Institute of Materials Science, Technische Universität Dresden, KARIN LEISTNER, Leibniz Institute of Solid State and Materials Research (IFW Dresden), Helmholtzstr. 20, 01069 Dresden, Germany — Voltage control of magnetism by ionic approaches presents a promising pathway to low-power magnetic devices. Up to now, magneto-ionic manipulation has been reported mainly for ultrathin films and nanoporous structures.[1-3] Since the mechanism is based on interfacial charge transfer, the morphology may be key to the magneto-ionic efficiency.

We investigate the influence of morphology on magneto-ionic changes during electrolytic gating of FeOx/Fe nanostructures. In FeOx/Fe nanoislands [4], the magneto-ionic changes are enhanced compared to continuous films and close to ON/OFF switching of magnetization is achieved.[5] The results are explained mainly by the higher surface/volume ratio of the nanoislands. Further, we investigate the transfer of magneto-ionic effects from extended thin film to nanostripe geometry. We present initial results on voltage-controlled magnetoresistance in FeOx/Fe stripes probed via in situ magneto-transport measurements.

10:12AM A40.00010: The Effect of Material Defects on Magneto-Elastic Switching*  DAVID WINTERS (Presenter), MD AHSANUL ABEED, SUPRIYO BANDYOPADHYAY, Electrical and Computer Engineering, Virginia Commonwealth University — Past experiments have shown that magneto-elastic switching phenomenon is extremely energy-efficient but error-prone. We have studied the effect of material defects (voids, thickness variations, etc.) on the switching probability of elliptical magnetostrictive nanomagnets subjected to uniaxial strain using micromagnetic simulations in the presence of thermal noise. Defects drastically increase the switching error rate. Curiously, there is a critical value of stress that results in the minimum error rate for both defective and defect-free nanomagnets. The critical stress is much higher for defective nanomagnets. Another interesting observation was that if the nanomagnet's thickness is different in two different halves, then stable magnetization states are spawned along the nanomagnet's hard axis. Above a certain thickness variation, the magnetization tends to get pinned along the hard axis when the nanomagnet is stressed and remains stuck there even after stress removal. These unexpected observations reveal some of the complexities associated with magneto-elastic switching, with important ramifications for practical applications of straintronics.

10:24AM A40.00011: Ferroelectric control of magnetism in Pt/BaTiO3 thin films  QILONG SUN (Presenter), California State University, Northridge, JULIAN VELEV, Department of Physics, University of Puerto Rico at Rio Piedras, NICHOLAS KIOUSSIS, California State University, Northridge — The quest for artificial multiferroic heterostructures consisting of ferroelectric (FE) and ferromagnetic (FM) layers is of increasing interest. Because the optimizing interfacial magnetoelastic coupling between the magnetic and electric polarizations allows novel means of controlling magnetization or polarization in view of efficient, low-power spintronic devices. Using first principles calculations we predict the emergence of magnetism in ultrathin nonmagnetic Pt films induced by the ferroelectric polarization of BaTiO3 films, where the induced Pt magnetization depends on the polarization direction. More importantly, the calculations reveal that the Pt/BaTiO3 bilayer undergoes an in-plane to out-of-plane spin reorientation via ferroelectric polarization switching of the BTO, with a giant change of magnetic anisotropy from 1.15 to -0.49 erg/cm², indicating a huge magnetoelectric effect. These findings open interesting prospects for exploiting higher electric field efficiency of magnetic anisotropy for the next generation of magnetoelectric random access memory devices.
Strain and magnetic properties of antiferromagnetic NaNiF₃ thin films

SOPHIE MORLEY (Presenter), HUMBERTO MARQUEZ, DAVID LEDERMAN, University of California, Santa Cruz – Fluoro-perovskites have been proposed as an alternative candidate to the oxide perovskites for magneto-electric applications.¹,² It is therefore desirable to create thin film samples to integrate into devices. NaNiF₃ (NNF) is an antiferromagnet which has a distorted perovskite crystal structure that sustains weak ferromagnetism with a bulk TN = 156 K and a Pnma space group symmetry.³ We have grown NNF via molecular beam epitaxy on SrTiO₃ (100) to produce high quality epitaxial films in the thickness range of 5–50 nm. The films had the expected Pnma structure and were predominantly oriented along the [101] direction. The SQUID magnetometry displayed a temperature-dependent magnetization consistent with antiferromagnetic ordering and a weak ferromagnetic moment. We observe a thickness-dependent transition temperature, where the change is ΔTN = -7 K for decreasing thickness between 40 and 10 nm, which correlates with the increased tensile strain measured using x-ray diffraction.

Session A41 GMAG DMP: Spin Transport and Excitations in Antiferromagnets

Fengyuan Yang, Ohio State University - Tag(s): Focus

8:00AM A41.00001: Spin Torque Switching of Antiferromagnet* [Invited] CHENG SONG (Presenter), XIANZHE CHEN, Tsinghua University, RICARDO ZARZUELA, YAROSLAV TSEKOVNYAK, University of California, Los Angeles, JIA ZHANG, Huazhong University of Science and Technology, FENG PAN, Tsinghua University — Antiferromagnets with zero net magnetic moment, strong anti-interference and ultrafast switching speed have potential competitiveness in high-density data storage. Electrical switching of antiferromagnets is at the heart of their device application [1,2]. The antidamping torque-induced switching of Néel order is attained in a biaxial antiferromagnetic insulator NiO, which is manifested electrically via spin Hall magnetoresistance in NiO (100)/Pt bilayers [3]. The antiferromagnetic moments are switched towards the current direction, different from the vertical configuration in the fieldlike torque scenario (e.g., CuMnAs and Mn₂Au) [4,5]. On the other hand, electric field is used to switch the magnetic moment of Mn₂Au films grown on piezoelectric Pb(Mg₁/₃Nb₂/₃O₃₋ₓTiO₃-x) (PMN-PT) (011) substrates. When the electric field is swept, the easy axis of Mn₂Au is switched between [100] and [01-1] directions of PMN-PT (011) at room temperature, exhibiting a butterfly-like switching feature. This feature indicates that the underlying mechanism is the electric field-induced ferroelastic strain. Such a transition of the easy axis leads to the change of threshold current for the field-like torque switching of Mn₂Au [6]. Electrical switching of antiferromagnetic moments pave the way for all-electrical writing and readout in antiferromagnetic spintronics.

8:36AM A41.00002: Spin Dissipation Independent of Antiferromagnetic Order in IrMn BEHROUZ KHODADADI, YOUNGMIN LIM, DAVID A SMITH, RYAN W GREENING, Virginia Tech, YUANKAI ZHENG, ZHITAO DIAO, CHRISTIAN KAISER, Western Digital, SATORU EMORI (Presenter), Virginia Tech — We investigate the interaction of spin current with antiferromagnetic order in polycrystalline IrMn by resonant spin pumping. We use spin-valve-like multilayers (NiFe/Cu/IrMn/CoFe), in which no direct magnon coupling is present between the NiFe spin source and the exchange-biased IrMn/CoFe spin sink; the pumped pure spin current is mediated solely by electrons through the Cu spacer layer. We observe no anisotropic spin dissipation with respect to the exchange bias direction, nor do we observe any difference in spin dissipation for samples with and without pinned antiferromagnetic order. Moreover, although there is a pronounced resonance linewidth increase in NiFe that coincides with the switching of IrMn/CoFe, we show that this is not indicative of anisotropic spin dissipation in IrMn. Our results demonstrate that the dissipation of electron-mediated spin current is remarkably insensitive to the magnetization state of the antiferromagnetic IrMn spin sink.
8:48AM A41.00003: Two-Magnon Scattering Enhanced by Randomly-Distributed Antiferromagnetic Exchange Field
HIROTO SAKIMURA (Presenter), School of Materials and Chemical Technology, Tokyo Institute of Technology, AKIO ASAMI, Department of Applied Physics and Physico-Informatics, Keio University, TAKASHI HARUMOTO, YOSHIO NAKAMURA, JI SHI, School of Materials and Chemical Technology, Tokyo Institute of Technology, KAZUYA ANDO, Department of Applied Physics and Physico-Informatics, Keio University — We report a quantitative study of two-magnon scattering in Ni$_{81}$Fe$_{19}$/NiO bilayers with various NiO thicknesses. The magnetic damping of the Ni$_{81}$Fe$_{19}$/NiO bilayer was found to have strong dependence on NiO thickness. The amplitude of the two-magnon scattering is enhanced with increasing the thickness of the antiferromagnetic layer, which was evaluated from the out-of-plane-angular-dependent spectral linewidth of ferromagnetic resonance. The origin of this enhancement in the Ni$_{81}$Fe$_{19}$/NiO bilayer is the increase of randomly-distributed antiferromagnetic exchange fields. We have calculated the spin-mixing conductance by eliminating the effect of the two-magnon scattering, and found that the value is at 8.1 nm$^{-2}$ for the Ni$_{81}$Fe$_{19}$/NiO interface. Skipping this process leads to overestimation of spin-mixing conductance in ferromagnet/antiferromagnet bilayer structures. Our result gives further insight on the role of the two-magnon scattering in manipulating magnetic damping, which is crucial for generation and transmission of spin currents in widely-studied ferromagnet/antiferromagnet systems.

9:00AM A41.00004: An effective model of antiferromagnetic metal in the adiabatic region and its spin-motive forces*
JUNJI FUJIMOTO (Presenter), ICR, Kyoto University — Antiferromagnetic spintronics is one of the active research fields because of its potential advantages. Compared to ferromagnets, antiferromagnetic materials have favorable characteristics to spintronic applications; ultrafast dynamics, robustness against perturbation due to magnetic fields, and so on. Considering the connection to modern electronics, the effect of conducting electrons coupling with antiferromagnetic order parameters is a fundamental subject. However, it is hard to intuitively understand physics of the electrons even in the adiabatic region, where the antiferromagnetic texture is slowly varying, hence the conduction electrons staying bonding/antibonding states. These states are inherently different from the states of ferromagnetic metals in the adiabatic region.

Here, we derive an effective Lagrangian of electrons coupling to antiferromagnetic textures in the adiabatic region, from the tight-binding model in a general lattice with the exchange coupling to the antiferromagnetic order parameter depending on space and time. In the presentation, we show the effective model and discuss the spin-motive forces calculated using the linear response theory and the Green function method.

9:12AM A41.00005: A Dirac nodal line metal for topological antiferromagnetic spintronics*
DING-FU SHAO (Presenter), GAUTAM GURUNG, University of Nebraska - Lincoln, SHUHUI ZHANG, Beijing University of Chemical Technology, EVGENY Y TSYMBAL, University of Nebraska - Lincoln — Topological antiferromagnetic (AFM) spintronics is an emerging field of research, which exploits the Néel vector to control the topological electronic states and the associated spin-dependent transport properties. A recently discovered Néel spin-orbit torque has been proposed to electrically manipulate Dirac band crossings in antiferromagnets; however, a reliable AFM material to realize these properties in practice is missing. Here, we predict that room temperature AFM metal MnPd$_2$ allows the electrical control of the Dirac nodal line by the Néel spin-orbit torque. Based on first-principles density functional theory calculations, we show that reorientation of the Néel vector leads to switching between the symmetry-protected degenerate state and the gapped state associated with the dispersive Dirac nodal line at the Fermi energy. The calculated spin Hall conductivity strongly depends on the Néel vector orientation and can be used to experimentally detect the predicted effect using a proposed spin-orbit torque device. Our results indicate that AFM Dirac nodal line metal MnPd$_2$ represents a promising material for topological AFM spintronics.

Antiferromagnetic Mn3NiN thin films supporting giant piezomagnetism

DAVID BOLDRIN, Blackett Laboratory, Imperial College London, ANDREI MIHAI, BIN ZOU, Department of Materials, Imperial College London, JAN ZEMEN, Faculty of Electrical Engineering, Czech Technical University in Prague, LESLEY COHEN (Presenter), Blackett Laboratory, Imperial College London — Controlling magnetism with electric field directly or through strain-driven piezoelectric coupling remains a key goal of spintronics. Here we demonstrate that giant piezomagnetism, a linear magneto-mechanic coupling effect, is manifest in antiperovskite Mn3NiN, facilitated by its geometrically frustrated antiferromagnetism opening the possibility of new memory device concepts. Films of Mn3NiN with intrinsic biaxial strains of 0.25% result in Néel transition shifts up to 60K and magnetisation changes consistent with theory [1]. Films grown on BaTiO3 display a striking magnetisation jump in response to uniaxial strain from the intrinsic BaTiO3 structural transition, with an inferred 44% strain coupling efficiency and a magnetoelastic coefficient approximately a 1000-fold increase over Cr2O3 as predicted previously by theory. Overall our observations pave the way for further research into the broader family of Mn-based antiperovskites where yet larger piezomagnetic effects are predicted to occur at room temperature [2]. In this talk we will review progress towards application of thin film piezomagnetism in Mn3NiN.

Spin Hall Effects in Antiferromagnets

SVERRE GULBRANDSEN (Presenter), CAMILLA ESPEDAL, ARNE BRATAAS, QuSpin Center of Excellence, Norwegian University of Science and Technology — Recent experiments demonstrate that antiferromagnets exhibit a spin Hall effect. Calculations also indicate that the intrinsic contribution is important in determining the magnitude of the spin Hall angle. However, we do not know how the mean free path, exchange interaction, and spin-orbit coupling govern these results and how these factors might influence our understanding of experiments. To address these questions, we consider a minimal model of an antiferromagnet. We numerically compute the spin Hall conductance as a function of impurity concentration, exchange energy, and spin-orbit coupling. We find that the spin Hall conductance is considerably larger in antiferromagnetic systems compared to normal metals. This opens yet another avenue of using antiferromagnets in spintronics devices.

Spin Orbit Torque Switching Mediated by Antiferromagnetic Insulators

HAILONG WANG (Presenter), JOSEPH FINLEY, PENGXIAO ZHANG, JIAHAO HAN, JUSTIN HOU, LUQIAO LIU, Massachusetts Institute of Technology — Spin transport and magnetic dynamics in antiferromagnetic (AF) insulators have attracted wide research interests recently. In contrary to the popular belief of AF being an inactive element for spin transport, recent experiments based on spin pumping, nonlocal spin transport and spin Seebeck effect suggest efficient spin current transmission can be realized in various antiferromagnetic systems, via the mediation of antiferromagnetic magnons. In this work, we show initial experimental evidences towards this direction, where by utilizing the current induced spin orbit torque in Pt layer, we achieved magnetic switching in CoxTb1-x free layer across a thin AF insulator NiO. In the ultrathin spacer thickness regime (1~2nm), we even observed an enhancement of the spin orbital torque efficiency compared with the Pt/CoxTb1-x bilayer film. The realization of magnetic switching in Pt/NiO/CoxTb1-x heterostructures provides an existence proof on AF insulator mediated spin orbit torque, enabling promising material platform and device structures for energy favorable spin manipulation.

Nonlocal Coupling between Antiferromagnets and Ferromagnets in Cavities

ØYVIND JOHANSEN (Presenter), ARNE BRATAAS, Norwegian University of Science and Technology — Microwaves couple to magnetic moments in both ferromagnets and antiferromagnets. Although the magnons in ferromagnets and antiferromagnets radically differ, they can become hybridized via strong coupling to the same microwave mode in a cavity. The equilibrium configuration of the magnetic moments crucially governs the coupling between the different magnons, because the antiferromagnetic and ferromagnetic magnons have opposite spins when their dispersion relations cross. We derive analytical expressions for the coupling strengths and find that the coupling between antiferromagnets and ferromagnets is comparable to the coupling between two ferromagnets. Our findings reveal a robust link between cavity spintronics with ferromagnets and antiferromagnets.

This work was supported by the Research Council of Norway through its Centres of Excellence funding scheme, Project No. 262633 “QuSpin” and Grant No. 239926 “Super Insulator Spintronics,” as well as by the European Research Council via Advanced Grant No. 669442 “Insulatronics.”
10:12AM A41.00010: Gigahertz frequency antiferromagnetic resonance and strong magnon-magnon coupling in the layered crystal CrCl₃  
JUSTIN HOU (Presenter), Electrical Engineering and Computer Science, MIT, DAVID MACNEILL, DAHLIA KLEIN, Physics, MIT, PENGXUANG ZHANG, Electrical Engineering and Computer Science, MIT, PABLO JARILLO-HERRERO, Physics, MIT, LUQIAO LIU, Electrical Engineering and Computer Science, MIT — Antiferromagnetic spintronics is an emerging field with the potential to realize logic and memory devices with high speed and bit density. Compared with well-studied ferromagnetic materials, the understanding on antiferromagnetic dynamics remains very limited, partly due to the ultrahigh intrinsic frequency, which often requires specialized terahertz techniques beyond the reach of facile device integration. Here we report broadband microwave magnetic resonance spectroscopy of the layered antiferromagnet CrCl₃. We observe a rich structure of resonances arising from quasi-two-dimensional antiferromagnetic dynamics. Due to the weak interlayer magnetic coupling in this material, we are able to observe both optical and acoustic branches of antiferromagnetic resonance in GHz frequency range. By breaking the rotational symmetry of the crystal, we further show that strong magnon-magnon coupling with large tunable gaps in orders of GHz can be induced between the two resonant modes. Our results therefore provide a versatile system for microwave control of antiferromagnetic dynamics.

10:24AM A41.00011: Electrical Signal Generation at Magnetic Resonance in Insulating Antiferromagnets  
PRIYANKA VAIDYA (Presenter), University of Central Florida, SOPHIE MORLEY, University of California, Santa Cruz, ENRIQUE DEL BARCO, University of Central Florida, JOHAN VAN TOL, National High Magnetic Field Lab, DAVID LEDERMAN, University of California, Santa Cruz — Antiferromagnetic materials, particularly antiferromagnetic insulators provide an alternative to present ferromagnetic spin-transfer torque based devices which suffer from limitations in terms of density and speed owing to their magnetic anisotropy dominated spin dynamics. In antiferromagnets spin dynamics are governed by the interatomic exchange interaction energies which are orders of magnitude larger than the magnetic anisotropy energy, leading to the potential for ultrafast information processing and communication in the THz frequency range. We will present studies of spin pumping at Manganese Difluoride(MnF₂) / Platinum (Pt) interfaces at temperatures below the MnF₂ Néel temperature (Tₐ = 67.34K). In particular, measurements of the inverse spin Hall Effect (ISHE) voltage arising from the interconversion of the dynamically injected spin currents into Pt will be reported. We observe clear electrostatic potential signals coinciding with the MnF₂ magnetic resonance positions including the spin-flop transition (Hₛₐₕ = 9T). The signals reverse by switching the polarity of the magnetic field, and display a marked dependence on the power of the microwave stimuli, as expected from the ISHE.

10:36AM A41.00012: Spin Nernst Effect in the Paramagnetic Regime of An Antiferromagnetic Insulator*  
YINHAN ZHANG (Presenter), Carnegie Mellon University, SATOSHI OKAMOTO, Oak Ridge National Lab, DI XIAO, Carnegie Mellon University — We theoretically investigate a pure spin Hall current driven by a longitudinal temperature gradient, i.e., the spin Nernst effect (SNE), in a paramagnetic state of a collinear antiferromagnetic insulator with the Dzyaloshinskii-Moriya interaction. The SNE in a magnetic ordered state in such an insulator was proposed by Cheng et al. [R. Cheng, S. Okamoto, and D. Xiao, Phys. Rev. Lett. 117, 217202 (2016)]. Here we show that the Dzyaloshinskii-Moriya interaction can generate a pure spin Hall current even without magnetic ordering. By using a Schwinger boson mean-field theory, we calculate the temperature dependence of SNE in a disordered phase. We also discuss the implication of our results to experimental realizations.

10:48AM A41.00013: Spin-torque control of the anomalous Hall effect in non-collinear antiferromagnets  
GAUTAM GURUNG (Presenter), DING-FU SHAO, EVGENY Y TSYMBAL, University of Nebraska - Lincoln — Non-collinear antiferromagnets have recently aroused significant interest due to the non-vanishing Berry curvature and the associated anomalous Hall effect sensitive to the magnetic ordering. In this work, we explore series of antiperovskite compounds Ga₁₋ₓNₓMn₃ with competing Γ₄g and Γ₅g phases, where the magnetic moments of Mn atoms are aligned in the (111) plane. An electric current flowing and polarized in the [111] direction produces a spin-transfer torque rotating the magnetic moments in the (111) plane. Based on the Landau-Lifshitz-Gilbert-Slonczewski equation, we explore spin dynamics in these non-collinear antiferromagnets and obtain conditions at which a pulse of the spin-polarized current can reverse the Néel vector and thus change the sign of the anomalous Hall conductivity. We find that the strength of the applied spin-polarized current density largely depends on the magnetocrystalline anisotropy energy controlling the stability of the Γ₄g and Γ₅g phases. Using density functional theory methods, we calculate the magnetocrystalline anisotropy energy in these antiperovskite compounds and find the optimum conditions for the current-induced reversal of the Néel vector.

8:00AM A42.00001: A blueprint for demonstrating quantum supremacy with superconducting qubits [Invited]
CHARLES NEILL (Presenter), Google AI Quantum — Here, using nine superconducting qubits, we experimentally illustrate a blueprint for demonstrating quantum supremacy. We present data characterizing two basic ingredients required for any supremacy experiment: *complexity* and *fidelity*. First, we demonstrate that the qubits can uniformly explore the Hilbert-space, providing a direct measure of algorithm complexity. Next, we compare the measurement results with the expected behavior and show that the algorithm can be implemented with high fidelity. Experiments for probing complexity and fidelity provide a foundation for demonstrating quantum supremacy.

8:36AM A42.00002: Operating and Characterizing of a 72 Superconducting Qubit Processor “Bristlecone”: Part 1
JULIAN KELLY (Presenter), ZIJUN CHEN, Santa Barbara, Google, BEN CHIARO, BROOKS FOXEN, Physics, UCSB, JOHN M MARTINIS, Santa Barbara, Google — Quantum computing has recently entered a new regime where a number of quantum processors with tens of qubits are being built and operated around the world. With approximately 50 qubits and high performance, it is possible to outperform classical computers in limited cases, a feat known as “Quantum Supremacy.” However, achieving supremacy requires high-fidelity operations in all aspects of the algorithm, including single-qubit gates, two-qubit gates, and readout. While these milestones have been achieved in small scale devices, challenges in calibration, precision control, and reproducibility are amplified at scale. In this talk, we will discuss the 72 qubit “Bristlecone” processor we have been developing at Google, and our work towards calibrating, operating, and characterizing this device. Part 1 of 2.

8:48AM A42.00003: Operating and Characterizing a 72 Superconducting Qubit Processor “Bristlecone”: Part 2
ZIJUN CHEN (Presenter), JULIAN KELLY, Google Inc - Santa Barbara, BEN CHIARO, BROOKS FOXEN, Physics, University of California, Santa Barbara, JOHN M MARTINIS, Google Inc - Santa Barbara — Quantum computing has recently entered a new regime where a number of quantum processors with tens of qubits are being built and operated around the world. With approximately 50 qubits and high performance, it is possible to outperform classical computers in limited cases, a feat known as “Quantum Supremacy.” However, achieving supremacy requires high-fidelity operations in all aspects of the algorithm, including single-qubit gates, two-qubit gates, and readout. While these milestones have been achieved in small scale devices, challenges in calibration, precision control, and reproducibility are amplified at scale. In this talk, we will discuss the 72 qubit “Bristlecone” processor we have been developing at Google, and our work towards calibrating, operating, and characterizing this device. Part 2 of 2.

9:00AM A42.00004: Characterization and mitigation of noise and crosstalk in a five-qutrit transmon processor
VINAY RAMASESH (Presenter), MACHIEL BLOK, KEVIN P. O’BRIEN, DAR DAHLEN, JOHN MARK KREIKEBAUM, IRFAN SIDDIQI, University of California, Berkeley — The multi-level structure of the transmon circuit makes it an attractive choice for implementing multi-valued quantum logic, i.e. qudit-based protocols with d > 2. To date, while transmon levels outside of the qubit computational subspace have been used for control and sensing, experimental implementation of a quantum algorithm using multi-level transmons has not been demonstrated. Specifically, we address practical issues which arise when running a multi-qutrit algorithm. These include classical microwave crosstalk between the individual transmon control lines; an always-on ZZ interaction due to fixed off-resonant coupling between neighboring qutrits; conditionality of single-qutrit pulses due to the cross-resonance effect; and challenges due to the sensitivity of higher transmon levels to charge noise. For each of these issues, we present methods of characterization and mitigation, demonstrating their efficacy on our hardware and the future design choices they inform.

9:12AM A42.00005: Automatic calibration of arrays of superconducting qubits and couplers
KEVIN SATZINGER (Presenter), Google Inc - Santa Barbara, BROOKS FOXEN, BEN CHIARO, MATTHEW MCEWEN, University of California, Santa Barbara, JOHN M MARTINIS, Google Inc - Santa Barbara — High-fidelity operation of superconducting qubits requires fine-tuning numerous experimental parameters. As superconducting qubit systems scale up to large arrays, automatic calibration becomes essential, both for bringing up systems from scratch and for maintaining calibrations. These algorithms depend strongly on the qubit architecture. For example, consider arrays of qubits connected by adjustable couplers, where the coupling can be turned off to isolate qubits and turned on to facilitate fast interactions. These couplers substantially complicate automatic calibration. At the start, the coupling may inadvertently be very strong, which can disrupt qubit bringup, and we can only learn about the coupler configuration indirectly through qubit measurements. In this presentation, we describe algorithms and experiments to automatically calibrate superconducting qubits and couplers.
**9:24AM A42.00006: Coupler characterization of transmons for cross-resonance**

HANHEE PAIK (Presenter), JOSÉ CHAVEZ-GARCIA, MARTIN SANDBERG, OBLESH JINKA, JENG-BANG YAU, DONGBING SHAO, FIRAT SOLGUN, MARKUS BRINK, JERRY M. CHOW, IBM Thomas J. Watson Research Center — We characterize two-qubit cross-resonance gates and unintended residual coupling on various coupled qubit arrangements. Direct coupling versus coupling via a quantum bus are studied on the basis of cross-resonance gate rate and fall-off of non-nearest neighbor coupling. We experimentally extract coupling rates using Hamiltonian tomography methods, and compare with microwave simulations.

**9:36AM A42.00007: Deletrious Effects of Spectator Qubits in Multiqubit Circuits**

XUAN WEI (Presenter), DAVID CHRISTOPHER MCKAY, SARAH SHELDON, EASWAR M MAGESAN, JAY GAMBETTA, IBM Thomas J. Watson Research Center — For a number of quantum technologies, such as superconducting qubits, multiqubit algorithms are performed by concatenating a series of one- and two-qubit gates. However, in such an architecture there will be no true one- and two-qubit gates because of spectator qubits, i.e., qubits which are connected, but should be idle during the gate. For drive activated two-qubit gates, such as the cross-resonance gate, the role of these spectator qubits can be non-trivial. Here we will discuss our studies on these spectator qubits, for example, by measuring the entanglement dynamics of the spectator qubit with the active qubits. Understanding spectator dynamics will lead to improved designs of multiqubit gates for quantum computing technologies.

---

**9:48AM A42.00008: Measuring and quantifying classical crosstalk in multi-qubit superconducting circuits**

PETAR JURCEVIC (Presenter), ABHINAV KANDALA, ANTONIO CORCOLES, EASWAR M MAGESAN, JERRY M. CHOW, JAY GAMBETTA, IBM Thomas J. Watson Research Center — In the most general sense, crosstalk is used to describe the unwanted interactions on elements of a quantum processor due to targeted drives on non-local elements. For superconducting circuits, we use “classical crosstalk” specifically to describe crosstalk that is a result of the microwave environment of the chip, and is not a direct consequence of the qubit frequency arrangement or the drive Hamiltonians. Such crosstalk can be an important source of gate infidelity. Here, we shall present techniques to measure and quantify classical crosstalk, and use them to probe the microwave environment of our chips. These techniques could serve as a useful guide for the design and packaging of large multi-qubit devices.

*We acknowledge support from IARPA under Contract No. W911NF-16-0114.

---

**10:00AM A42.00009: Multi-qubit circuit characterization through physics-based statistical inference**

VADIM SMELYANSKIY (Presenter), SERGIO BOIXO, Google Inc., HRANT GHARIBYAN, Physics, Stanford, MURPHY YUEZHEN NIU, Physics, MIT, KOSTYANTYN KECHEDZHI, DVIR KAFRI, RAMI BAREND, ANDRE PETUKHOV, HARTMUT NEVEN, Google Inc. — We develop new physical models for realistic two-qubit gates in superconducting qubit architectures to account for specific shape of qubit control pulses and effects of noise and decoherence, including those induced by two-level defects prevalent in the fabrications of superconducting chip. We then formulate statistical inference method to efficiently estimate the physical model parameters for an ensemble of quasi-random circuits that contain non-Clifford gates. For a family of circuit ensembles, we are able to obtain analytically the circuit fidelities and their variances by averaging the log-likelihood distribution of the model parameters over Haar measure. Our inference method applies to quantum systems with arbitrary number of qubits and thus serves as valuable tools for characterizing large scale quantum circuit that will likely outperform the most powerful classical computers existing to date.
10:12AM A42.00010: Mode Hybridization Analysis of Bus Resonators for a Superconducting Multi-Qubit Chip*

NADIA HAIDER (Presenter), QuTech and Netherlands Organisation for Scientific Research (TNO), Delft, The Netherlands, JONATHAN GNANADHAS, QuTech, Netherlands Organisation for Applied Scientific Research (TNO) and Delft University of Technology, Delft, The Netherlands, MARC BEEKMAN, RENE VOLLMER, NANDINI MUTHUSUBRAMANIAN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands, ROMAN CAUDILLO, Components Research, Intel Corporation, 2501 NW 229th Avenue, Hillsboro, OR, 97124, USA, ALESSANDRO BRUNO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands, DAVID MICHALAK, Components Research, Intel Corporation, 2501 NW 229th Avenue, Hillsboro, OR, 97124, USA, FILIP MALINOWSKI, CORNELIS CHRISTIAAN BULTINK, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands, ADEL A ELSHERBINI, LESTER LAMPERT, Components Research, Intel Corporation, 2501 NW 229th Avenue, Hillsboro, OR, 97124, USA, ALEXANDER YAROVOY, Microwave Sensing, Signals and Systems, Delft University of Technology, Delft, The Netherlands, JIM CLARKE, Components Research, Intel Corporation, 2501 NW 229th Avenue, Hillsboro, OR, 97124, USA, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands.

— We present an effective numerical method to analyze the mode hybridization in a multi-transmon circuit QED chip. Surface code, a promising architecture for fault-tolerant quantum computing, requires qubits with connectivity to all nearest neighbors. This extensive interconnectivity together with strong coupling between qubits and resonators causes mode hybridization. A complete analysis of the chip is needed in these conditions to accurately predict the loaded frequency of the bus resonators and thereby also the two-qubit gate time. We present and experimentally verify a simulation method for analyzing the complete chip combining finite-element electromagnetic simulation with numerical circuit simulation for accurate and fast computation. This research is funded by Intel Corporation and IARPA (U.S. Army Research Office grant W911NF-16-1-0071).

10:24AM A42.00011: A many-body coupler for coherent 4-local interaction of superconducting flux qubits*

TIM MENKE (Presenter), Department of Physics, Harvard University; Department of Physics, MIT; Research Laboratory of Electronics, MIT, CYRUS F. HIRJIBEHDIN, STEVEN J. WEBER, MIT Lincoln Laboratory, GABRIEL O. SAMACH, Department of Electrical Engineering and Computer Science, MIT; MIT Lincoln Laboratory, SIMON GUSTAVSSON, Research Laboratory of Electronics, MIT, ALAN ASPURGUZIK, Department of Chemistry and Department of Computer Science, University of Toronto; Vector Institute for Artificial Intelligence, Toronto; Canadian Institute for Advanced Rese, WILLIAM D OLIVER, Department of Physics, MIT; Research Laboratory of Electronics, MIT; MIT Lincoln Laboratory, ANDREW JAMES KERMAN, MIT Lincoln Laboratory — Interactions of more than two bodies simultaneously rarely appear in nature. Even in dense systems, forces usually act pairwise. However, n-local terms with n>3 frequently arise when mapping physical or mathematical problems to an Ising spin Hamiltonian. Superconducting flux qubits have emerged as a promising, versatile platform to simulate such spin systems and find their ground state, but the implementation of n-local superconducting qubit couplers has so far proven elusive. Here we present a circuit that enables large 4-local interaction between four flux qubits without spurious 2-local terms and without relying on an effective low-energy description as in Hamiltonian gadgets. We demonstrate numerically how 4-local coupling of up to several hundred MHz arises from a coupler circuit with tailored spectral properties. These properties are engineered by combining known superconducting circuit physics with suggestions by an inverse design algorithm that we have developed previously. In addition, we show first experimental results probing a fabricated coupler prototype.

10:36AM A42.00012: Robust And Versatile Superconducting Coupler

CATHERINE LEROUX (Presenter), AGUSTIN DI PAOLO, ALEXANDRE BLAIS, Institut Quantique and Département de Physique, Université de Sherbrooke, Sherbrooke, QC, Canada, J1K 2R1 — Having access to a large collection of fast and high-fidelity two-qubit gates can significantly reduce the gate count of large-scale quantum computations. In this talk, we present a novel tunable superconducting dipole coupling element that enables a variety of strong two-qubit interactions by modulating external fields. The proposed device can realize both high-fidelity and fast SWAP and controlled two-qubit gates.
10:48AM A42.00013: Implementing optimized time-varying coupling and dissipation in small logical qubit architectures.* DAVID RODRIGUEZ PEREZ (Presenter), ELIOT KAPIT, Colorado Sch of Mines — Tunable couplings between high coherence quantum objects and lossy resonators is a promising approach to state stabilization. Using an additional lossy resonator to provide a mechanism for the fast reset of the first resonator, a steady state residual error scaling of about 1 / T1 can be achieved. While this technique has been demonstrated for a single qubit coupled to a single resonator, this work looks at applying the same resonator reset technique for an idealized three qubit bit flip code and the Very Small Logical Qubit (VSLQ), a promising route to passive error correction in superconducting architectures. Optimal device and signal parameters for the VSLQ are well understood for a numerically optimized, continuous coupling strength, so we explore the effects of using an optimized, time-varying coupling strength between the primary qubits and shadow resonators and report a best possible scaling logical qubit lifetime T_L that scales as T_1^2, where T_1 is the lifetime for a single primary qubit.

Monday, March 4, 2019 8:00 AM - 11:00 AM

Session A43 DCMP: 2D Materials Twistronics: Correlations and Moiré Physics BCEC 210B - Pablo Jarillo-Herrero, Massachusetts Inst of Tech-MIT - Tag(s): Invited

8:00AM A43.00001: Twisted Graphene Superlattices: Superconductivity, Electron Correlations and Beyond [Invited] YUAN CAO (Presenter), DANIEL RODAN LEGRAIN, ORIOL RUBIES-BIGORDA, VALLA FATEMI, Massachusetts Institute of Technology, SHIANG FANG, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, EFTHIMIOS KAXIRAS, Harvard University, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — The understanding of strongly-correlated quantum matter has challenged physicists for decades. Such difficulties have stimulated new research paradigms, such as ultra-cold atom lattices for simulating quantum materials. In this talk I will present a new platform to investigate strongly correlated physics, based on graphene moiré superlattices. In particular, when two graphene sheets are twisted by an angle close to the theoretically predicted ‘magic angle’, the resulting flat band structure near the Dirac point gives rise to a strongly-correlated electronic system[1]. These flat bands exhibit half-filling insulating phases at zero magnetic field, which we show to be a Mott-like insulator arising from electrons localized in the moiré superlattice[2]. Moreover, upon doping, we find electrically tunable superconductivity in this system, with many characteristics similar to high-temperature cuprates superconductivity[3]. These unique properties of magic-angle twisted bilayer graphene open up a new playground for exotic many-body quantum phases in a 2D platform made of pure carbon and without magnetic field. Since these discoveries, a large number of theoretical models have been proposed based on the magic-angle graphene superlattices and beyond. I will also discuss our data demonstrating nematic superconductivity as well as correlated states in other types of graphene superlattices. The easy accessibility of the flat bands, the electrical tunability, and the bandwidth tunability though twist angle may pave the way towards more exotic correlated systems, such as quantum spin liquids.

8:36AM A43.00002: Tuning flat bands in twisted bilayer graphene with pressure [Invited] MATTHEW YANKOWITZ (Presenter), Columbia University — Twisted bilayer graphene (tBLG) with rotational mismatch of ~1.1°, referred to as the “magic angle,” has emerged as an exciting new platform to host strongly correlated electronic states due to its very flat low-energy bands. The electronic bandwidth – and consequently the strength of the correlated states – is determined by an interplay between the separation of the Dirac cones of the two graphene layers in momentum space and the strength of the interlayer electronic coupling which hybridizes the bands. Here we demonstrate the capability to vary the bandwidth at fixed rotation angle by using hydrostatic pressure to modify the interlayer coupling [1]. For angles larger than the native magic angle, we can tune to the flat band condition with pressure, inducing correlated insulating states and superconductivity for both hole- and electron-type carriers. For a 1.27° twist angle, T_c increases above 3 K at ~1.3 GPa, and then diminishes with further pressure. This behavior is consistent with theoretical efforts to model the relationship between bandwidth and interlayer coupling strength, establishing layer compression as a viable route to engineering the energy scale of the superconductivity in this system. Improvements in device quality additionally allow us to resolve new sequences of quantum oscillations emerging from quarter-, half-, and three-quarters-filling of the moiré unit cell associated with the presence of new Fermi surfaces.

9:12 AM A43.00003: Topology and Correlations in Magic Angle Bilayer Graphene [Invited] ASHVIN VISHWANATH
(Presenter), Harvard University — The recent discovery of superconductivity and Mott insulators in twisted bilayer graphene and related materials points to the importance of correlation effects. An additional interesting and potentially crucial ingredient is band topology inherited from the Dirac fermion dispersion of graphene. We will discuss our theoretical efforts to derive faithful tight binding models that captures both the symmetry and topology of the flat bands, as well as their energetics. We then discuss aspects of the Mott and superconducting phases and find that key aspects of the physics differ from previously studied correlated superconductors.

9:48 AM A43.00004: Topologically Protected Helical States in Minimally Twisted Bilayer Graphene* [Invited] BRIAN LEROY (Presenter), University of Arizona — The ability to create arbitrary stacking configurations of layered two-dimensional materials has opened the way to the creation of designer band structures. Twisted bilayer graphene is one of the simplest examples of such a van der Waals heterostructure where the electronic properties of the composite material can be fundamentally tuned with twist angle. The angle between the two graphene layers in the heterostructure produces a moiré pattern which affects its electronic properties. Using scanning tunneling microscopy and spectroscopy, we have investigated these minimally twisted bilayer graphene heterostructures. As the twist angle between the layers decreases there are fundamental changes in the electronic properties. We have found that the degeneracy of the low energy bands increases at twist angles below about 1 degree. For even smaller twist angles, a series of domain walls form connecting the AA sites in the moiré pattern. When an electric field is applied to these very small twist angle samples, the AB and BA regions develop band gaps while topologically protected states emerge along the domain walls. In this talk, we will discuss the fabrication of these minimally twisted heterostructures as well as our latest scanning probe microscopy results.

*The work at the University of Arizona was partially supported by the U.S. Army Research Laboratory and the U.S. Army Research Office under Contract Grant No. W911NF-14-1-0653 and the National Science Foundation under Grant No. EECS-1607911.
Quantum Simulation and Many-Body Physics in Moiré Bilayers* [Invited]  FENGCHENG WU (Presenter), University of Maryland — Moiré superlattices form in van der Waals bilayers with a small lattice mismatch or misalignment. The moiré pattern produces spatial modulation and can dramatically alter electronic properties. I will present theoretical proposals of using moiré bilayers as a quantum simulation platform to realize model Hamiltonians, and discuss many-body effects that are magnified when the moiré bands are nearly flat. In semiconducting transition metal dichalcogenide (TMD) heterobilayers, isolated flat moiré bands can be used to simulate Fermi-Hubbard model on a triangular lattice [1], in which parameters such as bandwidth, interaction strength, and band filling are widely tunable. When the two layers are formed from the same TMD, holes in \( \pm K \) valleys move in a layer-pseudospin skyrmion texture in real space. The low-energy moiré bands then realize Kane-Mele model [2], providing a platform to study interplay between topology and correlation. Excitons in twisted TMD bilayers also experience moiré potential, which can be used to design topological exciton bands and to simulate Bose-Hubbard model [3]. Twisted bilayer graphene (TBLG) is a distinct example where the effective lattice theory does not simply map to any known model Hamiltonian. Motivated by the observed superconductivity, I will present a candidate theory of phonon-mediated superconductivity in TBLG [4]. Phonon fluctuations lead to both s-wave and d-wave pairings. New phenomena of the d-wave superconductivity in moiré pattern will be discussed.

Session A44 DCMP: Polariton Condensates at Room Temperature and Equilibrium BCEC 210C
- Peter Littlewood, University of Chicago - Tag(s): Invited

8:00AM A44.00001: Polaritons, a growing field of condensate studies* [Invited]  DAVID SNOKE (Presenter), University of Pittsburgh — In this talk I will review the physics of Bose condensation of polaritons, sometimes called “superfluids of light,” and review recent experimental results, such as equilibrium condensation, long-distance propagation to the global ground state of a system, phase locking of spatially separated condensates, evidence for superfluidity, measurement of correlation functions, and propagation in quasi-one-dimensional systems. I will end with a discussion of some of the challenges and promises of room-temperature condensation of polaritons.

*This work has been supported by the US Army Research Office under MURI award W911NF-17-1-0312.

8:36AM A44.00002: Room temperature polariton condensate using a biologically produced fluorescent protein [Invited]  MALTE GATHER (Presenter), School of Physics and Astronomy, University of St Andrews — Organic materials offer attractive properties for solid-state lasers, including large oscillator strength, high exciton binding energy, spectral tunability, and compatibility with low-cost fabrication processes. However, despite impressive proof-of-principle demonstrations and dramatic improvements in performance, important fundamental limitations remain. Particular challenges are concentration quenching and bi-molecular exciton recombination, which limit the available gain under practical pumping conditions. For electrical pumping, there are further restrictions, including the low charge carrier mobility of most organic materials. Recently, it has been suggested that lasers operating in the regime of strong exciton-photon coupling may address some of these challenges.

Here, we will summarize key results from two collaborations that both look at unconventional nano-scale organic materials for solid-state lasers: Biologically produced fluorescent proteins and single-walled carbon nanotubes. We found that the barrel-like molecular structure of fluorescent proteins prevents concentration-induced quenching of fluorescence and drastically reduces singlet-singlet annihilation at high exciton densities. This facilitates low-threshold lasing in various configurations and has recently enabled the realization of the first organic polariton laser that can be pumped in a quasi-continuous ns-regime.

In another collaboration, we have shown that the special photo-physical properties of polymer-sorted semiconducting single-walled carbon nanotubes render them well suited for strong light-matter coupling, possibly up to the ultra-strong coupling regime. Most recently, we found that the high charge carrier mobility and stability also enable efficient electrical generation of exciton polaritons. Using a light-emitting field-effect transistor geometry, we achieved current densities ~18,000 A/cm² while maintaining strong coupling conditions.
Zhang (KPZ) superfluid and the newly discovered rigid fluid phase, as well as the recently achieved equilibrium limit. I will discuss a few examples of novel non-equilibrium collective effects in polariton systems, such as the Kardar-Parisi-Zhang (KPZ) superfluid and the newly discovered rigid fluid phase, as well as the recently achieved equilibrium limit.

I will discuss a few examples of novel non-equilibrium collective effects in polariton systems, such as the Kardar-Parisi-Zhang (KPZ) superfluid and the newly discovered rigid fluid phase, as well as the recently achieved equilibrium limit.

10:24AM A44.00005: Room Temperature Long-Range Coherent Exciton Polariton Condensate Propagation in Lead Halide Perovskites Microwire Cavity [Invited] RUI SU, Nanyang Technological University, CAROLE DIEDERICHS, Laboratoire Pierre Aigrain, Département de physique de l'ENS, Ecole normale supérieure, PSL Research University, Université Paris Diderot, Sorbonne Paris Cité, Sorbonne Unive, TIMOTHY LIEW, QIHUA XIONG (Presenter), Nanyang Technological University — Recent progress has shown that halide perovskites are promising optical gain materials towards room-temperature strong-light matter coupling leading to robust exciton polariton, due to large exciton binding energy and strong oscillator strength. Polariton condensates, exhibiting high speed coherent propagation and spin-based behaviour, attract considerable interest for implementing the basic elements of integrated optoelectronic devices: switching, transport, and logic. However, the implementation of such coherent polariton condensate flow is typically limited to cryogenic temperatures, constrained by small exciton binding energy in most semiconductor microcavities. Here, we demonstrate the capability of long-range non-resonantly excited polariton condensate flow at room temperature in a one-dimensional all-inorganic cesium lead bromide (CsPbBr3) perovskite microwire microcavity. The polariton condensate exhibits high speed propagation over macroscopic distances of 60 µm, while still preserving the long-range off-diagonal order. Our findings pave the way for utilizing coherent polariton condensate flow for all-optical integrated logic circuits and polaritonic devices operating at room temperature.

Monday, March 4, 2019 8:00 AM - 10:36 AM

Session A45 DCMP: Photophysics and Pattern Formation in Thin Films BCEC 211 - Radwan Elzein, University of South Florida - Tag(s): Focus

8:00AM A45.00001: Photosresponsive thin film based on photochromic diarylethene blended with thermoplastic elastomer: Structural and morphological analysis MAROUA LOUATI (Presenter), SOPHIE BARRAU, JEAN-FRANÇOIS TAISON, Unité matériaux et transformations, Lille University, France, STÉPHANE ALOISE, Laboratoire de Spectrochimie Infrarouge et Raman, Lille University, France, MICHINORI TAKESHITA, Advanced Technology and Fusion, Graduate School of Science and Engineering, Saga University, Japan — An increasing attention has been paid to photo-deformable polymeric materials that can convert light energy into mechanical energy without contact or electrical wires, using photosresponsive molecules. Diarylethenes known for their thermal stability and their fatigue resistance are one of the best studied compounds that exhibit photomechanical response. Upon alternating irradiation with UV and visible light, a change in molecular volume occurs between open- and close-ring during the photochromic reaction which induces photomechanical motions. In order to develop a light-driven polymer actuator, we investigate a novel system based on the mixture of a derivative diarylethene (Ureidopyrimidinone-functionalized diarylethene denoted UPy-DTE) and a thermoplastic elastomer (Ureidopyrimidinone -functionalized poly(ethylene-co-butylene) denoted UPy-PEB). In solution, the UPy-DTE/UPy-PEB system leads to a supramolecular assembly via quadrupole hydrogen bonding. The thin films are elaborated using different techniques such as drop casting or melt molding. Under illumination, a photomechanical response of the film is observed. Our strategy is to establish a correlation between the structural and morphological properties responsible for the macroscopic deformations.
8:12AM A45.00002: Singlet fission and exciton dynamics in vapor deposited rubrene films  DREW FINTON (Presenter), ELIZABETH DEJONG, VINCENT ZOUTENBIER, IVAN BIAGGIO, Physics, Lehigh University — In rubrene single crystals, singlet excitons can efficiently transition into two independent triplet excitons through a process called singlet fission. Photoluminescence in single crystals is a result of the singlet exciton’s radiative decay and both geminate and non-geminate triplet pair recombination. This process has been well documented, although a precise description of the intermediate steps is still an active area of research. In more disordered systems, such as amorphous films of rubrene, the singlet fission process is greatly hindered and the likelihood of non-geminate triplet recombination is effectively zero. As a result, photoluminescence measurements show only the radiative decay of the singlet exciton, as no singlet fission can occur. The effect of molecular ordering and the photoluminescence dynamics of amorphous rubrene samples will be addressed.

8:24AM A45.00003: Defect Engineering for Modulating the Trap States in Two-dimensional Photoconductor  JIE JIANG (Presenter), CHONGYI LING, TAO XU, WENHUI WANG, Southeast University, XIHANGONG NIU, Nanjing University of Posts and Telecommunications, AMINA ZAFAR, ZHENZHONG YAN, Southeast University, XIAOMU WANG, Nanjing university, YUMENG YOU, LITAO SUN, JUPENG LU, JINLAN WANG, ZHENHUA NI, Southeast University — Defect induced trap states are essential in determining the performance of semiconductor photodetectors. The de-trap time of carriers from a deep trap could be prolonged by several orders of magnitude as compared to shallow trap, resulting in additional decay/response time of the device. Here, we demonstrate that the trap states in two-dimensional ReS2 could be efficiently modulated by defect engineering through molecule decoration. The deep traps that greatly prolong the response time could be mostly filled by Protoporphyrin (H2PP) molecules. At the same time, carrier recombination and shallow traps would in-turn play dominant roles in determining the decay time of the device, which can be several orders of magnitude faster than the as-prepared device. Moreover, the specific detectivity of the device is enhanced (as high as ~1.89x10^13 Jones) due to the significant reduction of dark current through charge transfer between ReS2 and molecules. Defect engineering of trap states therefore provides a solution to achieve photodetectors with both high responsivity and fast response.

8:36AM A45.00004: Photothermoelectric detection of gold oxide non-thermal decomposition and related studies*  XIFAN WANG (Presenter), CHARLOTTE EVANS, MAHDIYEH ABBASI, DOUGLAS NATELSON, Rice University — Controlling morphology and composition via nanoscale structuring gives opportunities to improve the thermoelectric properties of materials for energy conversion and photodetection. In this study, we report the detection of the decomposition of metastable gold oxide via open circuit photothermoelectric voltage detection on thin-film Au nanowire devices as a function of the position of an optical heat source. A focused laser beam is used to locally heat the metal nanostructure. The first-scan enhanced photovoltage correlates with a reduction of the electrical resistance of the nanostructure back to pre-oxygen-exposure levels. These experiments demonstrate that combined optical and electronic measurements can provide a window on surface-sensitive photochemical processes. Besides the photothermoelectric voltage detection of gold oxide, we also report preliminary data on the thermoelectric properties of Au nanowires via other surface modification methods includes self-assembled monolayer formation.

*Acknowledge support from Robert A. Welch Foundation Grant C-1636. and support from NSF award ECCS-1704625.

8:48AM A45.00005: Formation of gold nanoparticles by laser annealing and enhanced terahertz beam by plasmonics  DONG HO WU (Presenter), Materials Science and Technology Division, United States Naval Research Laboratory — The plasmonic effect increases photocurrents substantially. There are considerable efforts to exploit this phenomenon for various applications, such as a high-efficiency photovoltaic cell, photodetector, etc. In this presentation, we will report gold nanoparticles on a photoconductive antenna and substantial terahertz power enhancement by the plasmonics. A laser annealing process creates the gold nanoparticles, and the plasmonic effect occurs when the gold nanoparticles interact with the femtosecond laser beam. The photoconductive antenna contains a pair of Schottky electrodes, which are fabricated by depositing shallow titanium-gold layers on a semi-insulating GaAs substrate. After the fabrication, the photoconductive antenna is exposed to a rather intense femtosecond laser beam exceeding 130 mW while applying a 70 V AC bias voltage to the electrodes. This laser annealing process generates about 1 mW of terahertz beam, which is nearly stable until the annealing time past 60 minutes when terahertz power abruptly jumps more than 20 -30%. This sudden power enhancement is coincident with the formation of gold nanoparticles and dendrites in a tiny area around the electrodes. We found that the plasmonic effect enhances the photocurrents of more than one order of magnitude.
9:00AM A45.00006: The Influence of Fractional Surface Coverage on Core-Core Separation in Monolayers of Thiol-Ligated Gold Nanoparticles*  
MORGAN REIK (Presenter), STUART A RICE, BINHUA LIN, MELANIE S CALABRO, SEAN GRIESEMER, SOPHIE MACFARLAND, University of Chicago — The way in which thiol-ligated gold nanoparticles self-assemble into ordered monolayers when deposited on a surface is contingent on the thiol's length and concentration. The influence of ligand composition on the properties of nanoparticle films is well-reported. However, the understanding of the molecular and structural origins of these properties is incomplete, particularly when examining the number of ligands on a nanoparticle surface. It has been assumed that the concentration of ligands in solution, within typical ranges, always generates the maximum possible nanoparticle surface packing. We demonstrate through Grazing Incidence X-Ray Diffraction and Transmission Electron Microscopy that the nanoparticle separation and correlation length of these films increases linearly with thiol concentration in solution, indicating that the bulk thiol is in equilibrium with thiol on the core surface. Our findings thus challenge the assumption that the free energy of binding of an alkanethiol to a gold nanoparticle is so large that its surface is consistently saturated with ligands.

9:12AM A45.00007: Laser-induced Detuning of Quartz Crystal Microbalances in Adsorbing and Non-adsorbing Environments*  
SAMUEL KENNY (Presenter), JACQUELINE KRIM, Physics, North Carolina State University — Light induced modifications in frictional behavior of films of adsorbed molecules constitute an area of current interest in nanotribology, and are potentially observable at room temperature by means of a quartz crystal microbalance (QCM). In order for such studies to be viable, the impact of laser light on a QCM must be established. We report here an investigation of the response of a QCM to green laser light in vacuum, nitrogen, and ethanol gas. Measurements of frequency and amplitude responses of the QCMs were performed, for samples with electrodes composed of AuNi alloys with varying degrees of Ni content. For the adsorbing ethanol films, we observed that the frequency response upon green laser irradiation initially strongly decreased with pressure, but recovered slowly up to the vapor pressure. This effect was more pronounced in electrodes with higher Ni content. QCMs exposed to non-adsorbing nitrogen produced responses of similar magnitude regardless of Ni content, however, we noticed marked changes in the initial response behavior upon illumination. The effects can be explained within the context of the effects of mass uptake, desorption and laser heating [1].

*Support of NSF-DMR1310456 is gratefully acknowledged.

9:24AM A45.00008: Interferometric Measurements of High Quality Acoustic Microcavities (MCs) on Anisotropic Surfaces*  
MADELEINE MSALL (Presenter), Bowdoin College, PAULO SANTOS, Paul Drude Institute for Solid State Electronics — Applications that couple high frequency surface acoustic waves (SAW) to quasi 0-D systems require high-Q acoustic MCs. We use optical interferometry to measure the surface displacement patterns between pairs of interdigital transducers (IDTs) configured to form resonant MCs with $Q \sim 1800$. Our focusing Al/Ti IDT with 0.6 rad (34°) aperture and wavelength $\lambda=5.6\,\mu$m emits a SAW beam along the [110] direction on GaAs with focusing comparable to the predicted 1.2$\lambda$ beam waist and 8$\lambda$ Rayleigh length. Reflections from the anisotropy corrected outer edges of the IDT fingers play an important role in performance. Previous assumptions of parabolic dispersion overcorrect for anisotropy and move the device focus closer to the IDT. Our resonant MC is created by placing additional floating fingers to form a 2.5$\lambda$ cavity around the focus. Since the inner cavity fingers are in the near field of the beam focus, their positions must also be adjusted to account for the Gouy phase shift. The resulting IDT + MC system shows highly localized elastic strain at frequencies within the electrical resonance band of the driving IDT. These 514 MHz, 5.6$\mu$m devices should scale well to the submicron wavelength and GHz frequency domain appropriate to quantum dot applications.

9:36AM A45.00009: Resonant Scattering as a Rapid and Site-Specific Spatiochemical Probe of Patterned Interfaces* ISVAR CORDOVA (Presenter), GUILLAUME FREYCHET, Lawrence Berkeley National Laboratory, CHRISTOPHER CHI, UC Berkeley, WEI XU, ALEXANDER HEXEMER, CHENG WANG, Lawrence Berkeley National Laboratory — The advent of highly precise nanofabrication tools has enabled the development of a new generation of mesoscale materials with potential across a variety of applications, but concomitant progress in the characterization techniques is also required.

In this presentation, we reveal a simple, yet powerful, patterning approach for sub-nm characterization that takes advantage of the physical processes intrinsic to small angle resonant X-ray scattering in order to 1) decouple the bulk from the interface scattering signal, 2) enhance the strength of the interfacial signal, and 3) collect a site-specific x-ray absorption spectra.

We demonstrate the potential of our approach by combining it with recently-developed in-situ/operando instrumentation compatible with a variety of soft and tender x-ray techniques. In particular, we highlight how the statistically-significant shape and electronic structure of a buried Ni(OH)2 interface can be monitored as it is charged/discharged under aqueous conditions with sub-nanometer spatial resolution and sub-millisecond time resolution. Moreover, we will show how this approach may be extended to a variety of materials relevant across a variety of fields including semiconductors, polymer science, energy conversion/storage, etc.

9:48AM A45.00010: Effect of titanium adhesion layer on iridium thin film optical properties NICOLE PFIESTER, MARGARET STEVENS, THOMAS VANDERVELDE (Presenter), KEVIN GROSSKLAUS, Tufts University — The refractory metal iridium is useful for highly reflective mirrors for x-ray astronomy and high temperature plasmonic applications like selective emitters. However, the deposition conditions of the thin film can produce very different optical properties which will affect the final performance of the optical device. In this study, we report on the optical properties, crystal structures, and surface roughness of Ir thin films produced by dc magnetron sputtering. The chamber pressure was varied from 10 mTorr to 25 mTorr with a constant plasma power of 160 W. Films deposited on a titanium adhesion layer or directly on a silicon substrate will be compared.

10:00AM A45.00011: Pattern formation on a bubble: Capillary waves on surfactant-laden interfaces* LI SHEN (Presenter), Department of Mechanical Engineering, Imperial College London, FABIAN DENNER, Lehrstuhl fur Mechanische Verfahrenstechnik, Otto-von-Guericke-Universitat Magdeburg, NEAL MORGAN, Shell Global Solutions (UK), DANIELE DINI, Department of Mechanical Engineering, Imperial College London — On a surface-tension-driven liquid interface, the behaviour of the capillary wave is often a bellweather of the overall motion of the system. Consequently, understanding how capillary waves behave is crucial in various interfacial flows at the edge of instability, such as capillary-driven breakup, liquid bridges and pattern formation phenomena. Examining the dynamics of the capillary waves on a surfactant-laden interface, the role of critical wavenumber (at which the capillary wave transitions from the dispersive underdamped regime to the non-dispersive overdamped regime) is explored in the context of the onset behaviour of pattern formation instabilities observed experimentally. Moreover, we look at the effect of the convective-diffusive transport of insoluble surfactants along the interface on the critical wavenumber and the overall dynamics of the capillary waves.

*The authors acknowledge the financial support of the Shell University Technology Centre for fuels and lubricants.

10:12AM A45.00012: Active control of thin liquid film flows: beyond reduced-order models RADU CIMPEANU (Presenter), Mathematical Institute, University of Oxford, SUSANA N GOMES, Warwick Mathematics Institute, University of Warwick — A thin liquid film flowing down an inclined plane is a canonical setup in fluid mechanics and pertains to a wide range of industrial applications. In some cases it is desirable to maintain the liquid-gas interface flat (e.g. coating problems), whereas other contexts (e.g. heat transfer) benefit from increased interfacial area. Ultimately, there is a strong need to reliably manipulate the flow in this mathematically rich system. Control theory has recently been applied successfully by A.B. Thompson et al. (Physics of Fluids 28, 012107, 2016) for an extended range of long-wave models such as the Benney and weighted residual equations, forming a hierarchy of complexity in which the effect of the control is well understood. The subject of this talk relates to the transition from controls on reduced dimensional systems to full Navier-Stokes solutions of this setup. A state-of-the-art volume-of-fluid methodology is used for the direct numerical simulation of the target flow, with control techniques informed by the modelling framework. We study both distributed and localised controls and analyse the robustness of these strategies, bringing us closer to their integration into real-life engineering designs.
10:24AM A45.00013: How to control the morphology of a multiple-liquid system via direct mixing? TAO LI (Presenter), Institute of Physics, The Chinese Academy of Sciences — Arrested composites can be created via the stabilization of convoluted fluid-fluid interfaces, which applies to multiple immiscible liquid systems containing dispersed colloidal particles. Such systems can form various morphologies, including the conventional Pickering emulsions, multiple emulsions, Janus droplets and non-spherical droplets. Moreover, the jamming of interfacial particles provides a promising route to create even more elaborate arrested states. For instance, the bijels (bicontinuous interfacially jammed emulsion gels)! All these structures exhibit novel properties and can lead to numerous applications in drug delivery, food, energy conversion and functional materials. Part I of this talk will focus on the viscosity effect on the formed structures in a binary liquid system, which reveals the formation mechanism of bijels created by direct mixing, and fills an important gap between the phase behaviors in low molecular weight liquids and that in bulk polymers. When mixing three immiscible liquids, the morphology development becomes more complex. In Part II, I will introduce both the formation mechanism and the stability mechanism of Janus emulsions, which can be a combined effect of multiphase immiscibility, interfacial tensions and surface stabilization.

8:00AM A46.00001: Anisotropic spin-orbit torque generation in epitaxial SrIrO3 by symmetry design [Invited]
TIANXIANG NAN (Presenter), University of Wisconsin Madison — Selected by Focus Topic Organizer (Gang Car and Jan Musfeldt)

8:36AM A46.00002: Electric Field Tuning of the Anomalous Hall Effect at the Oxide Interfaces: SrIrO3/SrMnO3 SASHI SEKHAR SATPATHY (Presenter), SAYANTIKA BHOWAL, University of Missouri — Using density-functional studies and appropriate models, we show that the anomalous Hall effect (AHE) at the magnetic oxide interfaces can be tuned by modifying the Rashba interaction with the application of an external electric field. Explicit density-functional calculations were performed for the recently grown SrIrO3/SrMnO3 interface in presence of an electric field to demonstrate the effect. Our model calculation indicates the importance of off-diagonal inter-orbital hopping in driving a non-zero Berry curvature, the central quantity that leads to the AHE. Furthermore, with the broken inversion symmetry by an applied electric field, the Rashba interaction comes into play, which enhances the AHE, providing a mechanism to manipulate the AHE. The observed results from the model calculations are corroborated by the first-principles studies, which yield an anomalous Hall conductivity in reasonable agreement with the available experiments in absence of an electric field. Our work has potential applications in spintronics with possible use of AHE as a novel electric field sensor.

8:48AM A46.00003: Role of non-local correlations for spectral properties of Sr2IrO4* BENJAMIN LENZ (Presenter), Centre de Physique Théorique (CPHT), Ecole Polytechnique, CYRIL MARTINS, Laboratoire de Chimie et Physique Quantiques, Université Paul Sabatier Toulouse, SILKE BIERMANN, Centre de Physique Théorique (CPHT), Ecole Polytechnique — The spin-orbit Mott insulator Sr2IrO4 has raised tremendous interest recently due to striking similarities to high-Tc superconducting copper oxides both in the pure and in electron-doped compounds. Here, we study the evolution of the spectral function of this 5d transition metal system as a function of doping by means of a combined ab-initio electronic structure and many-body quantum cluster approach. Thereby, important ingredients like spin-orbit coupling and distortions of the oxygen octahedra as well as Hubbard interactions and non-local charge fluctuations are taken into account. The spectral function of pure Sr2IrO4 is analyzed both in its high-temperature paramagnetic and in its low-temperature antiferromagnetic phase and the importance of non-local fluctuations is discussed. The spectra compare well with angular-resolved photoemission measurements and allow to study emerging changes under electron- and hole-doping. Special emphasis is placed on pseudogap features of the spectral function of electron-doped Sr2IrO4, which are found to be in good agreement with experiment.

*This work was supported by a Consolidator Grant of the European Research Council (CorrelMat-617196), the French Agence Nationale de la Recherche (ANR-15-CE30-0009-01) and IDRIS/GENCI Orsay (t2017091393).
9:00AM A46.00004: Broken in-plane rotational symmetry in the hidden order phase of Sr$_2$Ir$_{1-x}$Rh$_x$O$_4$  
SHIGERU KASAHARA, RYO KURIHARA, HINAKO MURAYAMA, YUKI SATO, YUICHI KASAHARA, YUJI MATSUDA, Kyoto University, DAVID HSIEH, California Institute of Technology, GANG CAO (Presenter), University of Colorado Boulder — The layered 5d transition metal oxide Sr$_2$IrO$_4$ hosts a $J_{\text{eff}} = \frac{1}{2}$ antiferromagnetic Mott insulating state, which strikingly resembles to the parent state of high-$T_c$ cuprate superconductors. Recently, great interest has been aroused in the series of Sr$_2$Ir$_{1-x}$Rh$_x$O$_4$, especially on the proposed hidden order phase above the antiferromagnetic ordering, which has been highlighted by optical second-harmonic generation and polarized neutron diffraction experiments [1, 2]. Here, by using exceptionally precise in-plane torque magnetometry [3-5], we provide thermodynamic evidence that nematicity, a spontaneous breaking of rotational symmetry of the underlying lattice, develops well above the antiferromagnetic transition in pure and doped Sr$_2$Ir$_{1-x}$Rh$_x$O$_4$. Our highly sensitive magnetic anisotropy measurements under in-plane field rotation reveal the growth of two-fold oscillations, which onset at the hidden order temperature $T^*$. The present results demonstrate striking similarities between the hidden order phase in Sr$_2$Ir$_{1-x}$Rh$_x$O$_4$ and the pseudogap phase in high-$T_c$ cuprates.

9:12AM A46.00005: Ultrafast control of antiferromagnetism in a Mott insulator by photo-doping  
ALBERTO DE LA TORRE (Presenter), Caltech, GUFENG ZHANG, University of California, San Diego, MICHAEL BUCHHOLD, YUVAL BAUM, NICHOLAS LAURITA, Caltech, JOHN W HARTER, University of California, Santa Barbara, LIUYAN ZHAO, University of Michigan, Ann Arbor, XIANG CHEN, University of California, Santa Barbara, RICHARD DOUGLAS AVERITT, University of California, San Diego, STEPHEN WILSON, University of California, Santa Barbara, GANG CAO, University of Colorado, Boulder, GIL REFAEL, DAVID HSIEH, Caltech — Ultrafast photo-doping provides a possible route to control antiferromagnetic order in Mott-Hubbard insulators out-of-equilibrium [1]. However, AFM order is notoriously challenging to probe by optical techniques [2]. Here, we demonstrate time-resolved nonlinear optical rotational anisotropy as a method to detect ultrafast transient changes of magnetic symmetry group. We leverage this technique to uncover the mechanisms by which photo-carriers suppress long range AFM order in the Mott insulator Sr$_2$IrO$_4$ and by which the AFM order is temporally restored.

9:24AM A46.00006: A time- and wavelength-resolved optical pump-probe reflectivity study of the Mott insulator Sr$_2$IrO$_4$  
ISABELLE PHINNEY (Presenter), ALBERTO DE LA TORRE, Caltech, XIANG CHEN, STEPHEN WILSON, UC Santa Barbara, DAVID HSIEH, Caltech — Photo-induced charge excitations in the copper oxide based antiferromagnetic Mott insulators are able to decay on extremely fast timescales owing to strong spin-charge coupling effects [1]. In recent years, the photo-carrier dynamics of the antiferromagnetic Mott insulator Sr$_2$IrO$_4$ has also become a subject of intensive study [2-4] owing to its similarity to the cuprates in terms of structural, electronic and magnetic properties. Here we examine how the photo-carrier relaxation dynamics of Sr$_2$IrO$_4$ vary with different excitation densities and excitation wavelengths, which access different inter-band transitions, using time-resolved optical reflectivity measurements. We will discuss our results in comparison to the cuprates.

9:36AM A46.00007: Novel Excitonic Condensate State with Block Magnetic Order at n=3.5 in Spin-Orbit Coupled Multiorbital Hubbard Model

NITIN KAUSHAL (Presenter), ALBERTO NOCERA, University of Tennessee, GONZALO ALVAREZ, CNMS, Oak Ridge National Lab, ADRIANA MOREO, ELBIO R DAGOTTO, University of Tennessee — Recent theoretical studies have established the condensation of spin-orbit excitons at momentum \( q = \pi \) for \( t_{2g}^{4} \) spin-orbit coupled three-orbital Hubbard models [1,2], but there is no consensus on experimental finding of this excitonic condensate for \( n=4 \) [3]. In parallel, materials with fractional valence states of Ir ions [4] have also attracted theoretical attention. In this work, we show numerical evidence for the existence of an excitonic condensation at the momentum \( q = \pi/2 \) for doping \( n=3.5 \), for intermediate Hubbard (U). We use the DMRG technique to study the one-dimensional multi orbital Hubbard model. We found an excitonic condensation between \( J_{\text{eff}} = 3/2 \) and \( J_{\text{eff}} = 1/2 \) bands in the triplet channel, together with a block magnetism. This new “block excitonic phase” is present even at large values of \( \lambda \) unlike the \( n=4 \) excitonic phase[2]. Our exact study can help to understand the magnetic phases of materials with the d3.5 valence and robust spin-orbit coupling.

9:48AM A46.00008: Symmetry-based analysis on Raman spectroscopy of two-magnon excitations in a spin-orbit coupled bilayer magnet \( \text{Sr}_3\text{Ir}_2\text{O}_7 \)

SIWEN LI (Presenter), WENCAN JIN, ROBERTO D MERLIN, KAI SUN, University of Michigan, ZACH PORTER, STEPHEN WILSON, University of California, Santa Barbara, LIUYAN ZHAO, University of Michigan — Layered perovskite iridates have been shown to realize a rare \( J_{\text{eff}} = \frac{1}{2} \) Mott insulating antiferromagnetic ground state. While the magnetic excitation dispersion of the single layer perovskite iridate \( \text{Sr}_2\text{IrO}_4 \) can be well explained by a classical spin wave modelof an isotropic Heisenberg magnet, the bilayer counterpart \( \text{Sr}_3\text{Ir}_2\text{O}_7 \) exhibits a giant magnetic excitation gap, ~90 meV, in the resonant inelastic X-ray scattering (RIXS) spectra whose origin is highly debated in literature. In this talk, we present our recent polarized Raman spectroscopy studies on magnetic excitations in \( \text{Sr}_3\text{Ir}_2\text{O}_7 \). Two continuums associated with magnetic excitations are observed, one centering around 170 meV and the other around 100 meV that is close to the magnetic gap reported in RIXS spectra. Through Raman selection rule measurements, we observe that the ~100 meV feature only shows up in the symmetric A1g channel, while the ~170 meV one is present in both A1g and B2g channels. We show that both features originate from two-magnon excitations, by performing symmetry analysis on the spin waves of a bilayer magnet. Our result provides a new insight to the origin of “the giant magnetic gap” in RIXS spectra.

10:00AM A46.00009: Unusual magnetic fluctuations in the hidden order phase of \( \text{Sr}_2(\text{Ir,Rh})\text{O}_4 \)

CHENG TAN (Presenter), ZHAOFENG DING, JIAN ZHANG, LEI SHU, Fudan University — Recently, hidden order was observed by L. Zhao et al. in Rhodium doped \( \text{Sr}_2\text{IrO}_4 \) at temperature \( T_{\Omega} \). As in the pseudogap phase of high \( T_{c} \) cuprates, this order breaks rotational symmetry and time reversal symmetry, while preserving translational symmetry. Using muon spin relaxation (MuSR) measurement, we found two types of dynamic magnetic order with different fluctuation rates in the hidden order phase of \( \text{Sr}_2(\text{Ir,Rh})\text{O}_4 \). We also found that the higher fluctuating magnetic field generated by the order setting in at the higher temperature slows its fluctuation rate on exiting the hidden order at \( T_{\Omega} \). A bump appears in the relaxation rate around \( T_{\Omega} \). The \( T_{\Omega} \) obtained by the MuSR measurements are consistent with those determined by second harmonic generation and polarized neutron scattering.
10:12AM A46.00010: Pseudospin-lattice coupling in the spin-orbit Mott insulator Sr$_2$IrO$_4$  JUAN PORRAS (Presenter), JOEL BERTINSHAW, HUIMEI LIU, GINIYATH KHALIULLIN, NAKHEON SUNG, Max Planck Institute for Solid State Research, JONG-WOO KIM, Advanced Photon Source, Argonne National Laboratory, SONIA FRANCOUAL, Deutsches Elektronen-Synchrotron DESY, PAUL STEFFENS, Institut Laue-Langevin, GUOCHU DENG, Australian Nuclear Science and Technology Organization, MARCO MORETTI SALA, ANNA EFIMENKO, European Synchrotron Radiation Facility, AYMÁN SAID, DIEGO M CASA, XIAN-RONG HUANG, THOMAS GOG, JUNGHO KIM, Advanced Photon Source, Argonne National Laboratory, BERNHARD KEIMER, Max Planck Institute for Solid State Research, BUMJOON KIM, Department of Physics, Pohang University of Science and Technology — Spin-orbit entangled magnetic dipoles, often referred to as pseudospins, provide a new avenue to explore novel magnetism inconceivable in the weak spin-orbit coupling limit, but the nature of their low-energy interactions remains to be understood. We present a comprehensive study of the static magnetism and low-energy pseudospin dynamics in the archetypal spin-orbit Mott insulator Sr$_2$IrO$_4$. We find that in order to understand even basic magnetization measurements, a formerly overlooked in-plane anisotropy is fundamental. In addition to magnetometry, we use neutron diffraction, inelastic neutron scattering and resonant elastic and inelastic x-ray scattering to identify and quantify the interactions that determine the global symmetry of the system and govern the linear responses of pseudospins to external magnetic fields and their low-energy dynamics. We find that a pseudospin-only Hamiltonian is insufficient for an accurate description of the magnetism in Sr$_2$IrO$_4$, and that pseudospin-lattice coupling is essential. This finding should be generally applicable to other pseudospin systems with sizable orbital moments sensitive to anisotropic crystalline environments.

10:24AM A46.00011: Bond ordering and phase transitions in Na$_2$IrO$_3$ under high pressure*  ZHIMOU ZHOU (Presenter), Peking University, KAIGE HU, Guangdong University of Technology, YI-WEN WEI, CHAO-KAI LI, JI FENG, Peking University — The Kitaev model of spin-1/2 on a honeycomb lattice supports degenerate topological ground states and may be useful in topological quantum computation. Na$_2$IrO$_3$ with a honeycomb lattice of Ir ions has been extensively studied as a candidate for the realization of this model, due to the effective $J_{\text{eff}} = 1/2$ low-energy excitations produced by the spin-orbit and crystal-field effect. As the eventual realization of the Kitaev model has remained evasive, it is highly desirable and challenging to tune the candidate materials toward such an end. It is well known that external pressure often leads to dramatic changes in the geometric and electronic structure of materials. In this work, the high-pressure phase diagram of Na$_2$IrO$_3$ is examined by first-principles calculations. It is found that Na$_2$IrO$_3$ undergoes a sequence of structural and magnetic phase transitions, from a magnetically ordered phase with space group $C2/m$ to two bond-ordered nonmagnetic phases. The low-energy excitations in these high-pressure phases can be well described by the $J_{\text{eff}} = 1/2$ states.

10:36AM A46.00012: Breakdown of magnetic order in the pressurized 3D Kitaev iridate β-Li$_2$IrO$_3$  RUDRA SEKHAR MANNA (Presenter), Department of Physics, Indian Institute of Technology Tirupati, Renigunta Road, Settipalli post, Tirupati - 517506, AP, India, M MAJUMDER, EP VI, EKM, University of Augsburg, 86159 Augsburg, Germany, G. SIMUTIS, ORAIN JEAN CHRISTOPHE, PSI, 5232 Villigen, Switzerland, T. DEY, F. FREUND, ANTON JESCHE, EP VI, EKM, University of Augsburg, 86159 Augsburg, Germany, RUSTEM KHASANOV, PSI, 5232 Villigen, Switzerland, P. K. BISWAS, ISIS, STFC Rutherford Appleton Laboratory, Didcot, Oxfordshire OX11 0QX, UK, E. BYKOVA, NATALIA DUBROVINSKAIA, Laboratory of Crystallography, University of Bayreuth, 95440 Bayreuth, Germany, L. S. DUBROVINSKY, Bayerisches Geoinstitut, University of Bayreuth, 95440 Bayreuth, Germany, R. YADAV, L. HOZOI, S. NISHIMOTO, Institute for Theoretical Physics, IFW Dresden, 01069 Dresden, Germany, ALEXANDER TSIRLIN, PHILIPP GEGENWART, EP VI, EKM, University of Augsburg, 86159 Augsburg, Germany — Novel electronic and magnetic properties are found in honeycomb lattice iridates, having dominant Kitaev interactions, due to the presence of strong spin-orbit coupling and electronic correlations. We present the measurements of magnetization, thermal expansion, magnetostriction, muon spin resonance, single crystal x-ray diffraction under hydrostatic pressure of 3D hyperhoneycomb β-Li$_2$IrO$_3$. These measurements are complemented by the $ab initio$ calculations. The incommensurate magnetic order at 38 K initially increases as a function of hydrostatic pressure with a rate of 0.9 K/GPa, consistent with the thermodynamic Ehrenfest relation. The partial polarization at 2.5 T decreases with increasing pressure signifies the instability of the magnetic order. The ordered state breaks down upon a first-order transition at around 1.4 GPa, giving way to a new ground state marked by the coexistence of dynamically correlated and frozen spins. This partial spin freezing may indicate the classical nature of the resulting pressure-induced spin-liquid, expected for large-$\Gamma$ (nearest-neighbor off-diagonal exchange) limit [1].

Monday, March 4, 2019 8:00 AM - 11:00 AM
8:00AM A47.00001: Facet dependent cation segregation in layered lithium transition-metal oxide cathode materials  
HAKIM IDDIR (Presenter), JUAN GARCIA, Argonne National Laboratory, JAVIER BAREÑO, MIMSI Materials, GUOYING CHEN, Energy Storage and Distributed Resources Division, Lawrence Berkeley National Laboratory, JASON CROY, Argonne National Laboratory — The development of energy storage devices with enough power and energy density, long term stability, and extended cycle life that are capable of meeting environmental constraints is an important challenge for modern electrochemistry. Lithium-ion batteries are the primary energy storage devices for electric vehicles. However, there are still challenges for making this technology more competitive. Improving the understanding of the fundamental processes taking place in such materials is a prerequisite to accomplish any significant improvement. For example, the segregation of transition metals (TM) from the bulk to the surface of typical cathode-oxide particles plays a critical role in the formation and composition of surface reconstruction layers (SRL) that appear on pristine and cycled materials. Such layers have been indicated as the origin of cathode impedance rise with cycling, and hence, may significantly decrease the performance of batteries. The origin and thermodynamic driving force for such segregation processes are not clear yet. In the present work, we propose a facet dependent TM segregation/phase-change mechanism to explain observed experimental results.

8:12AM A47.00002: LiFePO4-Carbon Nanofiber Composite Cathodes for Li-ion Batteries*  
ADEWALE A. ADEPOJU (Presenter), QUINTON L WILLIAMS, Howard University — LiFePO4 offers interesting possibilities as a cathode material for Li-ion batteries because of its steady operating voltage, excellent structural stability, nontoxicity, and inexpensive source materials. However, its poor electronic conductivity is a major challenge for commercialization. Although different techniques have been developed to address this problem, we approach this challenge by incorporating carbon nanofibers (CNFs) as conductive additives in the LiFePO4 cathode material. CNFs have high electrical conductivity and high aspect ratio. The effect of adding different percentages of CNFs to LiFePO4 cathodes was investigated using scanning electron microscopy (SEM), four-point probe, and electrochemical measurements. Electrochemical testing showed the LiFePO4 with few percents CNFs added to the composite cathode exhibited excellent rate capability performance at 20C and higher cycling capacity with less fading over 200 cycles at 5C. This improved performance is attributed to the increase in electronic percolation pathways created by adding CNFs.

8:24AM A47.00003: First principles theory of unanticipated electron transfers in new organic energy-storage materials: application to phenothiazine-based polymer cathodes.*  
MARIEL TADER (Presenter), BRIAN PETERSON, HÉCTOR ABRUÑA, BRETT FORS, TOMAS ALBERTO ARIAS, Cornell University — Organic polymer cathodes have promise as low-cost, environmentally clean, lightweight alternatives to traditional inorganic battery cathodes, but are limited by their instability. To explain the observed limits to the charge capacity of PT-DMPD, a phenothiazine-based organic material, we utilize recently developed Joint Density Functional Theory (JDFT) methods to study electron transfer (redox) events. Comparing to experimental cyclic voltammetry (CV) data, we find that electron transfer from the primary PT-DMPD redox sites actually occurs at lower voltages than anticipated. As a consequence, batteries using this and related materials have been operated at voltages where some of the primary redox reactions have actually already occurred, so that, during operation, unexpected redox centers are accessed. These new centers weaken important structural bonds, perhaps explaining the observed loss of capacity of PT-DMPD cathode batteries with cycling. These findings suggest a pathway for design of more power dense, stable energy storage materials.

*This work was primarily supported by the Cornell Center for Materials Research with funding from the NSF MRSEC program (DMR-1719875).
8:36AM A47.00004: Electrogenerated Hexacyanoferrate Thin Films for Battery Applications

ELSE AMANDA RENSMO, SCOTT D JOFFRE, JENNIFER R HAMPTON (Presenter), Hope College — Prussian Blue Analogues such as transition metal hexacyanoferrates (HCFs) have gained increasing interest as materials for energy storage applications, as they provide enhanced stability due to their open framework structure and potential for reduced cost by use of earth-abundant materials. Using Ni, NiCo and NiCu substrates, a variety of alloy HCF films were electrogenerated by cyclic in the presence of hexacyanoferrate. For NiCo- and NiCu-based HCF materials, the charge storage and transport properties were measured and compared to Ni-HCF to explore the effects of the addition of alloying metals. The addition of Co or Cu in the substrate results in a small increase in the total stored charge, but no observable trend in the transport kinetics. For Ni-HCF, the total amount of Fe in the resulting material was measured both electrochemically and with x-ray spectroscopic methods. Unexpectedly, the spectroscopic measurements were smaller than the electrochemical ones, indicating there must be additional electrochemical reactions occurring in the presence of the HCF.

*This research was made possible by the National Science Foundation under NSF-RUI Grant No. DMR-1608327, NSF-MRI Grant No. CHE-0959282, and NSF-MRI/RUI Grant No. PHY-0319523.

8:48AM A47.00005: Structural, Electronic, and Magnetic Properties of Li\(_{1+x}\)Mn\(_2\)O\(_4\) Based on First-Principles Calculations

JINSEON PARK (Presenter), Department of Physics and Astronomy, University of Tennessee, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Lab — Recent studies have focused on understanding the reaction mechanisms driven by the lithiation of Li\(_{1+x}\)Mn\(_2\)O\(_4\) spinels, in an effort to enhance the energy density of lithium-ion batteries. Experiments to characterize the spinels' fundamental properties during the reaction are challenging. Thus computational/theoretical modeling is highly desirable. In this study, we identified global/local minimum structures of Li\(_{1+x}\)Mn\(_2\)O\(_4\) spinels by using a global structure optimization algorithm coupled with first-principles calculations, and further characterized their basic electronic and magnetic properties, as well as their relative structural stabilities under external perturbations. Interestingly, the local Jahn–Teller distortion was found to play a governing role in determining spinels' relative stabilities, in comparison to other key factors such as charge states of the Mn ions, positions of the Li ions, and magnetic configurations. Feasible pathways for the experimental verification of lithiation are proposed.

9:00AM A47.00006: Structural mechanisms in complex oxides enabling high-rate lithium-ion energy storage

KENT GRIFFITH (Presenter), Northwestern University, KAMILA WIADEREK, Advanced Photon Source, Argonne National Laboratory, GIANNANTONIO CIBIN, Diamond Light Source, GIANNANTONIO CIBIN, Department of Chemical Engineering, Columbia University, LAUREN MARBELLA, Department of Chemistry, University of Cambridge — The maximum power output and minimum charging time of a lithium-ion battery depend on mixed ionic–electronic conduction. We show that complex niobium tungsten oxides with frustrated polyhedral arrangements and dense μm-scale particle morphologies can rapidly and reversibly intercalate large quantities of lithium. Analysis of high-rate and multi-electron energy storage will be discussed with insights from operando X-ray diffraction, solid-state nuclear magnetic resonance spectroscopy, and multi-edge X-ray absorption spectroscopy for the recently reported crystallographic shear structure and bronze-like oxide phases[1]. Materials and mechanisms that enable lithiation of μm particles in minutes have implications for high power applications, fast charging devices, all-solid-state batteries, and general approaches to electrode design and materials discovery.

*The Winston Churchill Foundation of the United States, a Herchel Smith Scholarship, and a Science and Technology Facilities Council Futures Early Career Award (KJG). EPSRC grant EP/M009521/1 (KJG, CPG). EU Horizon 2020/Marie Sklodowska–Curie grant 750294 and a Darwin Research Fellowship (LEM).
Study of Structural Transitions, Jahn-Teller Distortion, Cyclability, and Specific Energy in P2-type Na$_x$MO$_2$ Na-ion Battery Cathodes* WILLIAM REXHAUSEN (Presenter), UMA GARG, NATHANIEL SMITH, Department of Physics, University of Wisconsin Milwaukee, Wisconsin 53211, JOSHUA HARRIS, DEYANG QU, Department of Mechanical Engineering, University of Wisconsin Milwaukee, Wisconsin 53211, PRASENJIT GUPTASARMA, Department of Physics, University of Wisconsin Milwaukee, Wisconsin 53211 — Recent years have seen an interest in exploring the viability of Na-ion based battery cathode materials. Here, we report relationships between crystal structure and properties in the Na$_x$MO$_2$ (M=transition metal) family of layered metal-oxide battery cathodes. Using detailed Rietveld fitting, we characterize structural transitions that occur as a result of cycling. We further report the effect of these transitions on battery cyclability, and the effect of transition metal substitution in crystal structure and distortion in Na$_{2/3}$MnxFe$_{1-x}$O$_2$ (NMFO). Using specially designed transfer chambers, we have studied ex situ x-ray diffraction at different potentials in the charge-discharge cycle to examine the nature of the structural transitions both in the metal oxide planes and in the layering structure. We report specific energy, capacity, and cyclability of cells when cycling over several voltage ranges for different cathodes and find that substituents for Mn perform well when charged no higher than 4.0 V (vs. Na). Conversely, charging to 4.3 V degrades crystallinity.

Modeling of 2D Materials for Sustainable Energy Storage: Opportunities and Challenges* VIDUSHI SHARMA, KAMALIKA GHATAK (Presenter), DIBAKAR DATTA, New Jersey Institute of Technology — In recent years, extensive research has been carried out on 2D materials to develop high-capacity anode materials for Li-ion batteries (LIBs). By first-principle calculations, we investigated the adsorption of Li on graphene with defects. We find that with controlled defect, we can achieve a maximum storage capacity of approximately 1675 for LIBs. However, despite enormous opportunities, we need to concern about several challenges such as adatom trapping at the defect sites, the effect of defects on adatoms diffusivity, microstructural changes, etc. In addition, our recent work shows that for the Si-based anode, we can achieve better electrochemical stability by coating the current collector surface with graphene sheets. Besides graphene, several other 2D materials such as graphene allotropes, Transition Metal Dichalcogenides (TMD), etc. have tremendous potential in energy applications. Moreover, by building heterostructures (stacking of different 2D materials), it is possible to combine the advantage and eliminate the disadvantages of the individual sheet. In this presentation, we will provide a detailed overview of opportunities and challenges of modeling of 2D materials and its heterostructures for the next-generation sustainable energy storage applications.

*XSEDE, DMR180013

Impact of Hybridization and Correlations on Transition-Metal Valence and Oxygen Redox in Li-ion Battery Cathode Materials ILKYU LEE (Presenter), CHUNJING JIA, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford University — Transition-metal oxide battery cathode compounds undergo distinct changes in their electronic distribution as one goes from a fully lithiated to a fully delithiated state. This would lead nominally to energetically unfavorable high valence states on the transition-metal, affecting overall energy capacity. Here, we analyze the influence of metal-to-ligand orbital hybridization and effective charge transfer using a configuration interaction cluster model to simulate different spectroscopic tools. We connect our observations to the framework of anionic redox, which prevents high transition-metal valency, and has been linked to increases in energy capacity of Li-ion batteries. By gaining insight into crucial features that are identified with such processes, we aim to have a greater understanding of the fundamental physics of Li-ion cathode materials, in the hopes of predicting novel, better performing Li-ion compounds.
Advanced characterization of high-capacity electrodes with x-ray Compton scattering

HASNAIN HAFIZ (Presenter), Mechanical Engineering, Carnegie Mellon University, Pittsburgh, PA, USA, BERNARDO BARBIELLINI, Physics, School of Engineering Science, Lappeenranta University of Technology, Lappeenranta, Finland, KOSUKE SUZUKI, Graduate School of Science and Technology, Gunma University, Kiryu, Gunma, Japan, GREGORY HOUCHINS, Mechanical Engineering, Carnegie Mellon University, Pittsburgh, PA, USA, HIROSHI SAKURAI, Graduate School of Science and Technology, Gunma University, Kiryu, Gunma, Japan, ARUN BANSIL, Physics, Northeastern University, Boston, MA, USA, VENKATASUBRAMANIAN VISWANATHAN, Mechanical Engineering, Carnegie Mellon University, Pittsburgh, PA, USA — Li-rich layered oxides (LRLOs) have been very promising cathode materials due to their exceptionally high capacity of ~300 mAh/g and energy density of ~1000 mWh/g. However, the reaction mechanism underlying their electrochemical operation is not fully understood. Recent work on pristine cathode materials shows that Compton scattering spectroscopy can provide a useful tool to unravel the relationship between the key battery characteristics and the nature of the electronic orbitals involved in Li intercalation reactions [1]. Here, we discuss high-energy x-ray Compton scattering spectra along with parallel first-principles computations from Li$_{1.2-x}$Ti$_{0.4}$Me$_{0.4}$O$_2$ (Me = Mn and Fe) for the purpose of developing advanced spectroscopic tools for characterizing LRLO battery materials. Our study gives insight into how we can obtain a faithful reconstruction of the redox orbitals using the Compton scattering technique. We also discuss the reversibility of the solid-state redox processes, and the related issues of lattice distortions, charge compensation, and the covalent mechanism of transition metal and oxide ions as a pathway to provide a new generation of insights into the mechanisms at play in LRLO battery materials.

Theoretical understanding of oxygen redox feature observed on RIXS map of battery cathode materials

IWNETIM ABATE (Presenter), Department of Materials Science and Engineering, Stanford University, CHUNJING JIA, BRIAN MORITZ, MICHAEL F TONEY, SSRL Materials Science Division, SLAC National Accelerator Laboratory and Stanford University, THOMAS DEVEREAUX, SRI CHAITANYA DAS PEMMARAJU, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory and Stanford University — High energy density rechargeable batteries are essential to meet the ever growing global energy demand. Recently, cathode materials which have redox activity of both transition metal and oxygen are found to be very promising in this regard. However, the exact mechanism for the oxygen redox is yet to be understood. Resonant inelastic x-ray scattering (RIXS) has been established as a reliable probe of the critical oxygen states involved in battery electrodes with oxygen redox activities. The interpretation of specific O -K RIXS features; however, has not yet been achieved. To this end, we have performed theoretical calculations using new algorithm we developed to understand the spectroscopic feature from first principle. We aim to shed light on the physics of cathode materials and suggest design schemes for cathodes with exceptional capacity.

Impact of Humidity on the Mobility of an Ionic Liquid Confined in Ti$_3$C$_2$T$_x$ MXene

NARESH OSTI (Presenter), Neutron Scattering Division, Oak Ridge National Laboratory, MATTHEW W THOMPSON, Department of Chemical and Biomolecular Engineering, Vanderbilt University, KATHERINE VAN AKEN, MOHAMED ALHABEB, Department of Materials Science and Engineering, Drexel University, MADHUSUDAN TYAGI, NIST Center for Neutron Research, JONG KEUM, Neutron Scattering Division, Oak Ridge National Laboratory, PETER THOMAS CUMMINGS, YURY GOGOTSI, Department of Chemical and Biomolecular Engineering, Vanderbilt University, EUGENE MAMONTOV, Neutron Scattering Division, Oak Ridge National Laboratory — MXenes are two-dimensional materials with a potential in energy storage applications, especially as electrode materials in supercapacitors. MXenes provide high volumetric capacitance, but still have some limitations affecting their power capabilities. On the other hand, high energy and power density can be achieved using room temperature ionic liquids (RTILs) as an electrolyte that withstands a high operational potential window. Here, as an effort to overcome the high voltage limitation, and to provide a guidance for the development of most robust energy storage systems in the future, we have investigated the microscopic dynamics of a RTIL, [EMIm$^+$$][\text{Tf}_2\text{N}^-]$, confined in a Ti$_3$C$_2$T$_x$ MXene. We have found that the ionic liquid was confined between the stacks rather than in between the layers of the MXene, thus showing a diffusion coefficient at about a half of the bulk value. This result is consistent with the unchanged c-lattice parameter revealed by X-ray diffraction measurement after the ionic liquid intercalation. An increase in the overall cation diffusivity after water vapor exposure, as revealed from quasi-elastic neutron scattering (QENS) and molecular dynamics simulations, will be presented.

*Department of Energy, Office of Science, Office of Basic Energy Sciences
10:24AM A47.00013: Symmetrical supercapacitors with α-MnO2 nanorods/carbon nanofiber (CNF) composite as electrode material  PRASADA RAO TALAKONDA (Presenter), AJAY KUMAR, Department of Physics & Astronomy, Wayne State University, VAMAN M NAIK, Department of Natural Sciences, University of Michigan-Dearborn, RATNA NAIK, Department of Physics & Astronomy, Wayne State University — α-MnO2 nanorods have been grown on the surface of CNF for enhancing the electrical conductivity of MnO2. α-MnO2/CNF (0-5 wt%) nanocomposites were synthesized using a co-precipitation method. The XRD results confirm the formation of a single phase α-MnO2 and SEM/TEM images reveal the formation of α-MnO2 nanorods. While α-MnO2/CNF(1.25 wt%) exhibits the largest surface area (381 m²/g) and only a slight increase in the electrical conductivity (0.05 S/cm), α-MnO2/CNF(5 wt%) shows the least surface area (131 m²/g) but an order of magnitude higher electrical conductivity (0.67 S/cm), compared to pure α-MnO2 nanorods. C-V measurements show improved performance in all α-MnO2/CNF supercapacitors compared to that of pure α-MnO2. Ragone plot shows that although α-MnO2/CNF(1.25 wt%) exhibits the highest specific capacitance (313 F/g at 1 A/g) and hence the highest energy density of 32.8 Wh/kg, it has a lower power density of 2720 W/kg. On the other hand, α-MnO2/CNF(5 wt%) shows the least energy density of 7.9 Wh/kg, but has a higher power density of 4640 W/kg. Results demonstrate that one can optimize both energy and power densities by controlling the amount of CNF in the nanocomposites.

10:36AM A47.00014: Flexible supercapacitors with vertically aligned multiwalled carbon nanotubes (MWCNT) directly synthesized on a metal foil.* THUSHANI DE SILVA (Presenter), COLE DAMERY, ROBINSON KARUNANITHY, RANA ALKHALDI, PRASANNA DNYANESHWAR PATIL, MILINDA WASALA, POOPLASINGAM SIVAKUMAR, SAIKAT TALAPATRA, Physics, Southern Illinois University Carbondale — We will present the results of our investigation on all solid-state flexible supercapacitors using MWCNT directly grown on ultrathin Inconel foil. A poly(vinyl alcohol)/phosphoric acid (PVA/H₃PO₄) polymer gel has been used as both the electrolyte and the separator. Since the aligned MWCNT has a higher effective surface area and the direct synthesis on a metal decreases the resistance at the interface, these supercapacitors display improved performance with the highest measured areal specific capacitance of 19.6 mF/cm². Key device parameters, measured and analyzed with standard electrochemical circuit modeling will also be presented. The flexibility of the devices was validated by testing them under different bending angles. These devices can withstand a large amount of such bending cycles, making them more durable and robust energy storage devices.

*Authors CD and ST acknowledge the support through the NSF REU Grant # 1757954 and DoD ASSURE programs. Partial support through NSF-CHE Grant # 1506277 is also acknowledged.

10:48AM A47.00015: Metal Organic Framework high performance supercapacitors fabricated by electrophoretic deposition* FATIMA AMIR (Presenter), DARIEN K. NGUYEN, Winthrop University — 2D ultrathin nanomaterials have attracted a significant interest because of their applications as energy storage devices. Metal organic frameworks (MOFs) a subset of these 2D nanomaterials are believed to be a key solution for energy storage devices such as electrochemical capacitors. In this work, we report the fabrication of the MOF Ni3(2,3,6,7,10,11-hexaaminotriphenylene)2 (Ni3(HITP)2) supercapacitor electrodes using electrophoretic deposition. The morphologies of the Ni3(HITP)2 electrodes were characterized using scanning electron microscopy, and transmission electron microscopy. The structure of the Ni3(HITP)2 electrodes was analyzed using x-ray diffraction. The MOF-based supercapacitor exhibited excellent capacitive performance in 0.5M Na₂SO₄ with an areal capacitance of 15.58mF/cm². Furthermore, the supercapacitor exhibited an outstanding cycling stability with a capacitance retention of 81% over 50,000 cycles indicating excellent long term electrochemical stability. These results pave a promising route for the design and manufacture of a new generation of devices for energy storage applications.

Session A48 DFD DBIO GSNC: Swimming, Motility and Locomotion  BCEC 251 - Amy Lang, University of Alabama
8:00AM A48.00001: Sperm motility in modulated microchannels*  SEBASTIAN RODE (Presenter), JENS ELGETI, GERHARD GOMPPPER, Institute of Complex Systems (ICS-2), Forschungszentrum Jülich —
Sperm cells swim through the fluid by a periodic wave-like beating of their flagellum [1-3]. At low Reynolds numbers and in confinement, the directed motion of sperm and other microswimmers is strongly influenced by steric and hydrodynamic surface interactions [1]. We model sperm motility in mesoscale hydrodynamics simulations by imposing a planar traveling bending wave along the flagellum [2]. Sperm are simulated swimming in curved, straight, shallow and zigzag-shaped microchannels. Changes in the sidewall modulations and the imposed beat pattern allow the identification of a strong dependence of the surface attraction on the beat-shape envelope of the sperm cell. The simulations reveal a strong dependence of the deflection angle on the orientation of the beat plane with respect to the channel sidewall, and thus deepen the understanding of sperm navigation under strong confinement. Detachment of sperm, while swimming along curved walls, is dominated by either the emergence of a nonplanar component of the flagellar beat with increasing wavelength or the strong confinement in shallow channels.

8:12AM A48.00002: Development of a Microfluidic Device to Sort Sperm based on their Swimming Potential against the Flow  AFROUZ ATAEI (Presenter), ANDY W.C. LAU, WASEEM ASGHAR, Florida Atlantic University — The first step of in-vitro fertilization is to sort out the motile sperm from the non-motile ones. Currently, centrifugation based sperm swim-up and density gradient separation are common methods to sort sperm. However, these methods reduce sperm quality during the repetitive centrifugation steps and isolate sperm with high DNA fragmentation. In this work, we construct a microfluidic device based on the observation that motile sperm can swim against the flow within a specific range of flow rates. This sperm sorting device consists of two chambers, separated by a filter. After 45 minutes the sorted motile sperm are collected from the top retrieval chamber and is placed on a glass slide for visual inspection and data collection. We find that the most motile and functional sperm pass selectively through the micropores against the flow, showing that our device provide an efficient way to sort sperm.

8:24AM A48.00003: Varying pH influences the motility of Helicobacter pylori more strongly in porcine gastric mucin solutions than in broth.*  CLOVER TING-YI SU (Presenter), KATARZYNA BIENIEK, RAMA BANSIL, Boston University — Helicobacter pylori, a pathogen which inhabit the gastric mucus has to swim across the naturally occurring pH gradient in the mucus layer varying from 2-4 in the lumen to 7 on the epithelial surface. The mucus has a pH-dependent viscoelasticity forming a gel at low pH, whereas at higher pH it is solution-like. Previous studies have shown that H. pylori were immobile in porcine gastric mucin (PGM) below pH 4. How much of this effect is due to gelation of PGM and how much due to the effects of pH on the flagellar motors is unclear. To address this question we compared the translation and rotational motion of the bacteria in PGM versus broth at different pH. In broth, H. pylori swimming speed increased as pH was lowered from pH 7 to 4, followed by a drop in speed below pH4 indicating decrease of proton motive force, whereas in PGM the speed peaked at pH 5 and bacteria became immobile below pH3, indicating the increase in viscosity in PGM dominating the loss of motility. The body rotation rate is weakly dependent on pH in broth. in PGM the bacteria stuck in the low pH gel rotate much faster than the mobile bacteria at higher pH’s, indicating that bacteria can sense the environment’s mechanical properties and attempt to free themselves from being immobilized.

8:36AM A48.00004: Experimental Evidence of Passive Separation Control by Shortfin Mako Shark Scale Bristling*  
AMY LANG (Presenter), LEONARDO SANTOS, ANDREW BONACCI, University of Alabama, PHILIP MOTTA, University of South Florida, MARIA LAURA HABEGGER, Florida Southern College, KEVIN DU CLOS, BRAD GEMMELL, University of South Florida, SEAN DEVEY, University of Alabama — The shortfin mako has scales (on the order of 0.2 mm in size) flexible to angles in excess of 40 degrees, but only in the direction of reversing flow and strategically placed on the body, such as flank and fins, for controlling flow separation to reduce pressure drag. Various experiments have been carried out to document the separation control capability of mako skin samples, including high-speed video evidence of passive, flow-actuated scale bristling. In water tunnel studies, a flat plate boundary layer was grown to Re > 10^5 and passed over flank skin samples whereon flow separation was induced by a controllable adverse pressure gradient produced by a rotating cylinder located above the test area. Velocity measurements, both instantaneous and time-averaged, were captured using Digital Particle Image Velocimetry (DPIV). Results confirm separation control was achieved under both laminar and tripped turbulent boundary layer conditions as quantified by backflow coefficient, or the percentage of time the flow was reversed. We hypothesize that the width of a single shark scale corresponds to the sizing of the reversing flow, which induces scale actuation, documented within the turbulent boundary layer case as occurring within a low speed streak.

8:48AM A48.00005: How Hummingbirds Reorient Forces During Maneuvering Flight*  
BEN HIGHTOWER (Presenter), RIVERS INGERSOLL, DANIEL SHORR, DIANA D CHIN, DAVID LENTINK, Stanford University — Hummingbirds are among the most agile of birds with the unique ability to hover in flight. While their flight kinematics have been studied extensively, their aerodynamic forces have primarily been studied using indirect methods like inverse dynamics and particle image velocimetry, which are insufficient to capture the full weight support of the bird. Here we present in vivo force recordings of maneuvering Anna's hummingbirds feeding from a moving flower using a novel 3D aerodynamic force platform. The pressure field generated by the maneuvering bird travels to the boundaries of the flight arena, and the six instrumented plates mechanically integrate the resulting pressure and shear distribution at a high enough sample rate to record wingbeat-resolved forces. With these data, we can determine the tracking effectiveness of hummingbirds as well as the control methods they employ during feeding from moving flowers as well as in-flight prey capture. Unraveling how hummingbirds manipulate aerodynamic forces with their wings to maneuver has profound applications to the study of other flying animals and the development of more maneuverable aerial robots.

*The authors would like to thank the National Science Foundation and the Stanford Graduate Fellowship for support.

9:00AM A48.00006: DNS of squirmers (spherical microswimmers) with rotlet*  
RYOICHI YAMAMOTO (Presenter), FEDERICO FADDA, JOHN JAIRO MOLINA, Dept. Chemical Engineering, Kyoto University — The squirmer model introduced by Lighthill and later extended by Blake allows the description of microorganisms such as algae and bacteria. It consists in a spherical particle with a prescribed tangential surface velocity, neglecting the radial component, responsible for the self-propulsion. If the microorganism repels fluid along its axis and repels it to the sides it is called pusher (like the bacterium Escherichia Coli); in the opposite case it is called puller (like the alga Chlamydomonas Reinardti). In this study the squirmer model is incorporated into the Smoothed Profile Method, an efficient DNS scheme to simulate solid objects into a fluid taking fully into account the hydrodynamics, which has already been successfully used in the past to study collective motion and interactions of squirmers. Now the traditional squirmers (pusher and puller) are modified by introducing a rotlet term, an azimuthal component of surface velocity to give a more realistic description of the motion of microorganisms like bacteria whose flagellar and body rotate in the opposite direction.

From Single to Many: Swimming at Intermediate Reynolds Numbers*  THOMAS DOMBROWSKI (Presenter), SHANNON K JONES, UNC Chapel Hill, GEORGIOS KATSIKIS, Massachusetts Institute of Technology - MIT, AMNEET BHALLA, San Diego State University, BOYCE E. GRIFFITH, DAPHNE KLOTSA, UNC Chapel Hill — We propose a simple, self-propelled model swimmer which uses steady streaming flows for propulsion at intermediate Reynolds numbers (Re). Our model swimmer is composed of two unequal spheres that are tethered and oscillate in antiphase. For all Re>0, our reciprocal swimmer swims and interestingly, as Re increases, switches swimming direction from a small-sphere-leading to a large-sphere-leading regime. Varying a broad range of parameters (viscosity, amplitude, distance between the spheres, sphere radii and sphere-radii ratio), we identify a universal swimming transition at a critical Re. Flow fields are analyzed, and we determine that propulsion occurs as a result of the interfering steady streaming flows of the two spheres forced to oscillate close to one another. We also show that their bi-directional behavior is linked to their reversal in steady streaming flows. We continue by investigating interactions between multiple swimmers in both swimming regimes.

Propulsion of asymmetric bodies through soft lubricated tubes  BHARGAV RALLABANDI (Presenter), University of California, Riverside, MARY-CASWELL STODDARD, Princeton University, JENS G EGGERS, University of Bristol, HOWARD A STONE, Princeton University — The motion of tightly fitting objects through soft tubes is a scenario that frequently arises in physiological processes. An example is that of avian egg laying, where observations across avian species suggest that eggs move through the oviduct pointy-end first, even though they are usually then laid blunt-end first. We investigate the mechanistic implications of this observation by considering the motion of fore-aft asymmetric intruders moving through lubricated elastic tubes. Using asymptotic theory, we find that the thickness of the lubricating fluid layer scales inversely with the square root of the slope of the intruder surface near its nose, in the direction of motion. Consequently, the force required to drive motion scales with the square root of this slope, and also depends on the translation velocity, the viscosity of the lubricant and the elasticity of the tube walls. Our findings show that asymmetric objects are more efficiently moved pointy-end-first through lubricated soft tubes, suggesting a mechanistic rationalization for the observed orientation of eggs moving in avian oviducts.

Hydrodynamic interactions between artificial swimmers and obstacles  FLORENCIO BALBOA USABIAGA (Presenter), Center for Computational Biology, Flatiron Institute, Simons Foundation, QUENTIN BROSSEAU, Courant Institute of Mathematical Sciences, New York University, YANG WU, Department of Chemistry, New York University, ENKELEIDA LUSHI, Department of Mathematical Sciences, New Jersey Institute of Technology, LEIF RISTROPH, JUN ZHANG, Courant Institute of Mathematical Sciences, New York University, MICHAEL WARD, Department of Chemistry, New York University, MICHAEL SHELLEY, Center for Computational Biology, Flatiron Institute, Simons Foundation — Bimetallic micro-rods swimming in hydrogen peroxide solutions are a standard example of self-propelled particles used in a large number of experiments. Here, we present how micro-rods can be designed to propel like pullers, pushers or symmetric swimmers.

We combine experiments and numerical simulations to investigate the dynamics of rods swimming around obstacles. We find that the characteristic residence time around an obstacle is longer for symmetric swimmers than for puller or pushers. When the obstacles form a lattice the swimmer speed and its residence time control the long time diffusion coefficient; for non-symmetric obstacles the displacement bias is different for each kind of rod. These differences suggest that microfluidic devices can be used to sort self-propelled particles with different swimming natures.
9:48AM A48.00010: A Robotic Fast-Start Fish Utilizing Post-Buckling Dynamics of Slender Column Under Compression to Passively Produce Rapid Underwater Locomotion  TODD CURRIER (Presenter), YAHYA MODARRES-SADEGHI, University of Massachusetts Amherst — An experimental study is conducted on a robotic fish designed to emulate the fast-start response. The fish body is constructed of 3D-printed materials and a light spring steel spine. The body is actuated using pressurized pistons. A total of two pistons are supplied with pressure through lightweight high-pressure service lines. The source of pressure is carbon dioxide with a 4.82 MPa peak operating pressure resulting in a body response that emulates a C-start maneuver in milliseconds. The motion of the fish is controlled using a programmable microprocessor. The buckling modes of a slender column in compression are used to produce organic movements in the body with only two sources of actuation. The interaction of the fluid with the underactuated structure results in a travelling wave in the body of the robotic fish that is kinematically similar to the live fish. The effect of the tail is considered using the model to test performance changes with various geometries.

10:00AM A48.00011: Rotation-translation coupling in a highly symmetric propeller at low Reynolds number* JOHANNES SACHS (Presenter), Micro Nano Molecular Systems, Max Planck Institute for Intelligent Systems, KONSTANTIN I MOROZOV, Department of Chemical Engineering, Technion, ODED KENNETH, Department of Physics, Technion, ALEXANDER LESHANSKY, Department of Chemical Engineering, Technion, PEER FISCHER, Micro Nano Molecular Systems, Max Planck Institute for Intelligent Systems — Nature has developed several strategies to generate locomotion at low Reynolds (Re) numbers. Ciliates and sperm cells beat cilia in a non-reciprocal way to overcome the scallop-theorem. Bacteria use the inherently symmetry-broken shape of a rotating helical flagellum to create translational motion. Artificial corkscrew propellers were successfully employed to mimic the rotation-translation coupling of the latter [Nanoscale, 3, 557-563 (2011)]. A long time ago Purcell stated: “Turn anything - if it isn't perfectly symmetrical, you'll swim.” [Am. J. Phys. 45, 3 (1977)]. All these examples inevitably indicate the close connection between an object's symmetry and its propulsion dynamics at low Re. In turn, this raises the question if all propellers have to be chiral to be propulsive? Can highly symmetrical, achiral shapes be propulsive too? We provide a rigorous symmetry analysis of an achiral, planar V-shaped object and experimentally prove that this shape can be indeed propulsive when driven by an external field. This is, to our knowledge, the first demonstration of a truly achiral micro-object that propels; showing that chirality is not prerequisite for propulsion at low Reynolds number.

10:12AM A48.00012: Maximum in density heterogeneities of active swimmers* FABIAN JAN SCHWARZENDAHL (Presenter), MARCO G. MAZZA, Dynamics of complex fluids, Max-Planck-Institute for Dynamics and Self-Organization — Suspensions of unicellular microswimmers such as flagellated bacteria or motile algae can exhibit spontaneous density heterogeneities at large enough concentrations. We introduce a novel model for biological microswimmers that creates the flow field of the corresponding microswimmers, and takes into account the shape anisotropy of the swimmer's body and stroke-averaged flagella. By employing multiparticle collision dynamics, we directly couple the swimmer's dynamics to the fluid's. We characterize the nonequilibrium phase diagram, as the filling fraction and Péclet number are varied, and find density heterogeneities in the distribution of both pullers and pushers, due to hydrodynamic instabilities. We find a maximum degree of clustering at intermediate filling fractions and at large Péclet numbers resulting from the competition of hydrodynamic and steric interactions between swimmers. We develop an analytical theory that supports these results. This maximum might represent an optimum for the microorganisms' colonization of their environment.

**10:24AM A48.00013: Experimental observation of catalytic Janus colloid microswimmer flow fields**

STEPHEN EBBENS (Presenter), ANDREW CAMPBELL, University of Sheffield, PIERRE ILLIEN, ESPCI Paris, PSL Research University, RAMIN GOLESTANIAN, Physics of Complex Systems, Max Plank Institute — A key current goal for micro-swimmer research is to understand and control collective behaviour. This has the potential to allow access to a wide range of dynamic, responsive non-equilibrium configurations and enable new applications. Hydrodynamic interactions play a significant role in determining collective behavior: however, the nature of the flow fields around synthetic micro-swimmers has to date largely been incorporated into simulations and theory based on assumed propulsion mechanisms. It is important to check how realistic these flow field approximations are for realizable systems. Here we address this by analysing the motion of tracer particles near to catalytic Janus colloids, a well-studied micro-swimmer system, in order to experimentally determine flow fields. The resulting data can be used to select the most appropriate far field description for swimmer hydrodynamics when modelling this system, and reveals additional near field details. We also use analytical theory to relate the flow fields to the micro-swimmer propulsion mechanism and slip velocity profile. Finally we report the ability to vary micro-swimmer flow field by geometric control of the colloids catalytic activity.

**8:00AM A49.00001: In-situ X-ray and thermal imaging of 3D printed PLA**

MIRIAM RAFAILOVICH (Presenter), YUVAL SHMUELI, JIAOLONG JIANG, YUCHEN ZHOU, Department of Materials Science and Chemical Engineering, Stony Brook University, GUANGCUI YUAN, SUSHIL K SATIJA, Center for Neutron Research, NIST, SUNGSIK LEE, APS, Argonne National Laboratory, TAEJIN KIM, Department of Materials Science and Chemical Engineering, Stony Brook University, GAD MAROM, Casali Institute for Applied Chemistry, Hebrew University of Jerusalem, DILIP GERSAPPE, Department of Materials Science and Chemical Engineering, Stony Brook University — In-situ WAXS together with FLIR imaging was performed during 3D FDM printing of PLA filaments. The results highlighted the importance of the temperature profiles during printing on the structure/property relationships of the samples. Printing along short axis resulted in increased thermal retention, higher degrees of crystallinity and mechanical strength relative to samples printed along the long axis. Neutron reflectivity used to construct a model of the interdiffusion between filaments as a function of time and temperature. Lattice Boltzmann calculations were used to determine the temperature of the filament as a function of nozzle temperature and extrusion speed. The thermal conduction between filaments in the vertical and horizontal direction was measured at four different nozzle temperatures and the interdiffusion was determined by scanning electron microscopy. The data showed large difference during printing between adjacent filaments. Fusion, was shown to occur when the diffusion length exceeded $R_g$ of PLA, occurred first in horizontal direction when the nozzle temperature exceeded 215°C and in the vertical direction when it exceeded 245°C.

XPCS in operando Monitoring of Dynamic Recovery in 3D Printed Thermoset Nanocomposites

Additive manufacturing has made big strides in metals and polymer-based material processing applications; however, the processing of structural composites is still a challenge that requires a number of technical engineering and material improvements. State of the art, off the shelf, feedstock materials do not offer sufficient thermal and mechanical properties to compete with resin systems that are currently used in conventional polymer matrix composites. The goal of this work is to capture multiscale and temporal morphology and dynamics within thermosetting composite inks to get a better understanding of parameters that govern the printing process and establish a processing-structure-performance relationship that enables scientists and engineers to design optimal materials and processes to obtain additively manufactured parts with properties that, at minimum, come close to those known for conventional polymer matrix composites. Herein we use X-ray Photon Correlation Spectroscopy to reveal both morphology and dynamics of a thermoset composite ink composed of a rheology modifier (layered-silicate Cloisite 30B) and epoxy resin (EPON 826) during the printing process in real time and at critical locations along the print processing path.

Processing, Morphology, and Crosslink Network in Model Liquid Crystalline Thermosets for Additive Manufacturing

The additive manufacturing (AM) of high-temperature thermosetting resins would enable rapid functional prototyping and on-demand production of high-performance aircraft parts; however, limitations of current feedstock materials have prevented AM of such parts to date. The use of liquid crystalline thermosetting polymers could overcome several critical challenges in fused deposition modeling, such as tuning the rheology during print and cure and improving final mechanical properties. The shear-alignment of liquid crystal domains by the nozzle could also allow for the controlled design of anisotropic properties. Here, a model liquid crystal thermoset system based on epoxide chemistry is studied with respect to AM processing. We examine the effect of shear on morphology before, during, and after crosslinking, both in a controlled, uniform shear environment and at the printing nozzle. We explore how viscosity and final morphology (and therefore final properties) can be controlled by exploiting liquid crystallinity.

Feedstock development and in-operando experiments for 3D printing of polymer matrix composites for demanding defense applications [Invited]

Additive manufacturing, especially extrusion-based 3D printing, plays a critical role in areas where traditional composite manufacturing is too labor intensive, costly or even impossible. The ability to produce previously un-manufacturable designs combined with attractive economic and lead time benefits has led to significant interest in industry and government to invest in polymer-based 3D printing. Complexity enabled capabilities, part reduction and rapid prototyping are key drivers for DoD applications. While the current state-of-the-art in engineering solutions is progressing at a fast pace, the physics-based understanding of the process is lacking and at best poorly implemented in commercial machines. This inevitably leads to the issue of poor reproducibility with vastly different results from the same equipment conducted in different laboratories, between two pieces of the same equipment within a single laboratory and even between builds in different build plate locations of the same equipment. The fast, non-equilibrium processing space necessitates implementation of novel in-situ metrology controls. In addition, demanding applications that require materials to survive higher temperatures and survive extreme conditions with optimal thermo-oxidative stability are not available in commodity polymer feedstock. This presentation summarizes our efforts in designing and creating new feedstock materials for polymer matrix composite manufacturing via fused deposition modeling (high temperature thermosets) or direct write processes (carbon fiber reinforced epoxy thermosets), including advanced concepts for real-time, in-operando characterization of materials during the additive manufacturing process. The ultimate goal is to provide real-time data for closed-loop feedback control that leads to a sufficiently robust process.
9:12AM A49.00005: In-situ X-ray and thermal characterization of nanocomposites in FDM 3D printing*  YUVAL SHMUELI (Presenter), Department of Materials Science and Chemical Engineering, Stony Brook University, SUNGSIK LEE, APS, Argonne National Laboratory, TAEJIN KIM, Department of Materials Science and Chemical Engineering, Stony Brook University, GAD MAROM, Casali Institute for Applied Chemistry, Hebrew University of Jerusalem, DILIP GERSAPPE, MIRIAM RAFAILOVICH, Department of Materials Science and Chemical Engineering, Stony Brook University — In-situ synchrotron WAXS simultaneously with high resolution infra-red imaging were used to study the correlation between the extrusion parameters, the filaments deposition directionality and the internal structure of the nanocomposite in 3D printing by placing an “open-walled” FDM printer in the beamline. We used microbeam synchrotron SAXS to study the variance in the crystalline macrostructure formed as function of radial position in the filaments (from core to adjacent interfaces). We observed the effect of extrusion shear forces on the orientation of the nanoparticles and the influence of the particle/polymer interactions on the polymer crystallization. We show how thermal properties improved by directionality and transcrysallization. We used Raman, electron microscopy and rheological techniques to study the interactions between the polymer matrix and the nanoparticles.

9:24AM A49.00006: Molecular weight dependence of weld formation in material extrusion additive manufacturing JON SEPPALA (Presenter), National Institute of Standards and Technology — Material extrusion (MatEx) additive manufacturing (AM), after several decades of development, is now an established production method for small volume or highly complicated parts. While MatEx has transitioned from prototyping to end use production, little is known about the mechanisms that dominate strength development between layers. Previously we reported on a framework for determining weld time and weld strength of MatEx processed welds, comparing those results to traditional polymer-polymer weld formation. Here we extend that work by systematically varying the weight average molecular weight ($M_w$) of entangled bisphenol-A-poly carbonate (PC) MatEx filaments and measuring weld time and weld strength. The resulting weld formation will be discussed in the context of traditional polymer-polymer welding and weld thickness during the unique shear and thermal history produced by the MatEx process.

9:36AM A49.00007: Geometrical and Mechanical Characterization of Interlayer Bonding Quality in Fused Filament Fabrication* LI CHEN FANG (Presenter), YISHU YAN, OJASWI AGARWAL, KEVIN HEMKER, SUNG KANG, Johns Hopkins University — Fused filament fabrication (FFF) is one of the most popular additive manufacturing processes. However, advanced applications of FFF are still limited by the large variation of mechanical property and mesoscale structural geometry of printed parts. To develop a fundamental understanding of those issues, we focus on the interlayer bonding region of Polycarbonate FFF samples, and perform full 3D geometrical characterizations using X-ray micro computed tomography (Micro-CT). The result reveals large geometry variance brought by different printing conditions, including parameters like nozzle movement speed and layer thickness, and environmental factors like chamber temperature and humidity. The findings are further validated by mechanical peel/tear tests, showing the direct relationship between bonding zone geometry and bonding strength. The outcomes could guide printing parameter selections, as well as provide validations for future theoretical and simulation models.

*We would like to acknowledge the support of the National Science Foundation (DMREF-1628974), and the start-up fund from the Whiting School of Engineering at Johns Hopkins University.

9:48AM A49.00008: Effect of processing on semicrystalline morphology in the additive manufacturing of poly(lactic acid) ANTHONY KOTULA (Presenter), JONATHAN SEPPALA, National Institute of Standards and Technology, CLAIRE MCILROY, School of Mathematical Sciences, University of Nottingham — Material extrusion additive manufacturing processes force molten polymer through a printer nozzle at high (>100 s$^{-1}$) wall shear rates prior to cooling and crystallization. These high shear rates can lead to flow-induced crystallization in common polymer processing techniques, but the magnitude and importance of this effect is unknown for additive manufacturing. Of critical importance in semicrystalline polymer additive manufacturing is the semicrystalline morphology near the weld between extruded layers, which can affect mechanical properties. Here, we present a systematic study of printing conditions on the semicrystalline morphology of parts printed from poly(lactic acid) (PLA). The slow crystallization kinetics of PLA generate parts with low crystallinity, however a secondary annealing process at high temperatures (140 °C) generate a space-filled spherulitic texture, with smaller spherulites near the weld zone between the extruded layers. This spherulite size distribution is attributed to a higher nucleation density templated into the part by the temperature and deformation history of the printing process. We show that theoretical modeling of flow-induced crystallization processes can predict the spatial distribution of spherulites observed in experiment.
CLAIRE MCILROY (Presenter), University of Nottingham, ANTHONY KOTULA, JONATHAN SEPPALA, National Institute of Standards and Technology, RICHARD STEPHEN GRAHAM, University of Nottingham — The most common 3D printing method is known as fused filament fabrication (FFF). This process involves melting a thermoplastic, followed by layer-by-layer extrusion, cooling and re-solidification. The main concern with FFF is the strength at the welds between printed filaments; bulk strength is never achieved in these regions and the reason is currently unclear. Advancing FFF relies on a molecular understanding of how thermoplastics behave during the printing process. We employ a non-isothermal molecularly-aware model for FFF processing of a semi-crystalline polymer melt to show how typical FFF conditions can stretch the polymer molecules prior to cooling. Enhanced nucleation due to residual polymer stretch leads to accelerated crystallisation times at the surface of a deposited filament, whilst the bulk of the filament is governed by slower quiescent kinetics. Consequently we find a cross-sectional variation in the crystal morphology of single filament, with smaller spherulites forming in an outer skin layer. Furthermore, our model of a multi-filament walls reveals significant variations in crystal morphology from filament to filament.

*CM is grateful to the Royal Commission for the Exhibition of 1851 for funding. RSG gratefully acknowledges funding from the EPSRC (EP/P005403/1).

MEISHA SHOFNER (Presenter), EMILY FITZHARRIS, DAVID ROSEN, Georgia Institute of Technology — Among the additive manufacturing (AM) techniques available, material extrusion additive manufacturing (MEAM) has been widely researched due to its increased availability and relatively simple manufacturing method. This AM method has generally been limited to amorphous polymeric materials as feedstocks, but more recent research has investigated high performance semicrystalline polymers as potential feedstocks with varying levels of success. In this work, we have used two techniques to evaluate how the crystallization of a promising feedstock, polyphenylene sulfide (PPS), affects its use with MEAM. We have used fast scanning calorimetry (FSC) to more fully understand how the crystallization of PPS is affected by cooling rates relevant to MEAM. Additionally, we have used the Taguchi method to analyze the mechanical properties of printed parts when exposed to post-processing heat treatment steps. Overall, the results showed that PPS can be used effectively with MEAM and that its crystallization kinetics provide unique benefits to its processing with MEAM.

*The research described in this presentation was funded by the Kimberly-Clark Corporation.

NEIKO LEVENHAGEN (Presenter), MARK DADMUN, University of Tennessee — Minimizing anisotropy in parts prepared by fused deposition modeling (FDM) remains a key area of research in the development of robust and mechanically useful 3D printed objects. Due to the bulky nature of polymer chains and the complex thermal environment experienced by adjacent filaments, interaction of polymer chains in between layers is minimized. Weak interfaces and poor layer adhesion results. In recent years, our group has addressed these issues through the introduction of low molecular weight surface segregating additives (LMW-SuSAs). LMW-SuSAs are smaller than the polymer chains of the neat material and can more readily diffuse and entangle in adjacent layers. In the current research, we report, bimodal blends containing linear and 3-arm PLA LMW-SuSAs terminated with methacrylate groups and crosslinked by UV irradiation. In situ irradiation of the printed layers results in drastic increases in the transverse tensile stresses of the printed layers up to ~140% and ~200% for the linear and 3-arm LMW-SuSAs respectively. Additional experiments examine the effect of UV power on the process. By controlling the UV power, printed parts can be prepared with minimal interfilamentous voids and substantially robust interfaces.

10:36AM A49.00012: Axisymmetric Simulation of Viscoelastic Filament Thinning and Laser-Induced Forward Transfer with the Oldroyd-B Model* EMRE TURKOZ (Presenter), LUC DEIKE, CRAIG ARNOLD, Princeton University — A fundamental understanding of the filament thinning of viscoelastic fluids is important in practical applications such as spraying and printing of complex materials. Here, we present direct numerical simulations of the two-phase axisymmetric momentum equations using the volume-of-fluid technique for interface tracking and the log-conformation transformation to solve the viscoelastic constitutive equation. The numerical results for the filament thinning are in excellent agreement with the theoretical description developed with a slender body approximation. We show that the off-diagonal stress component of the polymeric stress tensor is important and should not be neglected when investigating the later stages of filament thinning. In addition, we use this numerical model to simulate the blister-actuated laser-induced forward transfer process, which is a nozzle-less laser-based printing technique. We reveal the effect of viscoelasticity on the ejected droplet size, derive criteria for optimum printing conditions, and compare the numerical results with experiments.

*This work is supported by National Science Foundation (NSF) through a Materials Research Science and Engineering Center program (DMR-1420541).

10:48AM A49.00013: Laser sintering of polymer particle pairs studied by in-situ visualization* PRAKHAT HEJMADY, RUTH CARDINAELS (Presenter), LAMBERT VAN BREEMEN, PATRICK D ANDERSON, Eindhoven University of Technology — A novel in-house developed experimental setup is used to perform laser sintering experiments on polystyrene (PS) particle doublets while performing in-situ visualization of the sintering dynamics. From the recorded images, the evolution of the growth of the neck radius formed between both particles is analyzed as a function of time. Sintering conditions such as heating chamber temperature, laser pulse energy and duration, laser spot size and particle size are precisely controlled and systematically varied. A non-isothermal viscous sintering model is developed that allows to qualitatively predict the observed effects of the various parameters. The sintering kinetics is determined by a complex interplay between the transient rheology caused by the finite relaxation times of the polymer and the time-dependent temperature profile which also affects the polymer viscosity. The combination of a full material characterization with sintering experiments under well-defined conditions has resulted in a general understanding of the effects of material and process parameters on laser sintering.

Session A50 DPOLY GSOFT DBIO: Chirality in Polymers and Soft Matter I: From Molecular to Hierarchical Scales BCEC 252B - Nicholas Kotov, University of Michigan - Tag(s): Focus

8:00AM A50.00001: Confinement-induced liquid crystalline transitions in amyloid fibril tactoids GUSTAV NYSTROM (Presenter), EMPA, MARIO ARCARI, RAFFAEOLE MEZZENGA, ETH Zurich — Chirality is ubiquitous in nature and plays crucial roles in biology, medicine, physics and materials science. Understanding and controlling chirality is therefore an important research challenge with broad implications. Unlike other chiral colloids, such as nanocellulose or filamentous viruses, amyloid fibrils form nematic phases but appear to miss their twisted form, the cholesteric or chiral nematic phases, despite a well-defined chirality at the single fibril level. In this contribution, I will report about our discovery of cholesteric phases in amyloids, using β-lactoglobulin fibrils shortened by shear stresses. The physical behavior of these new cholesteric materials exhibits a large structural complexity, with confinement-driven ordering transitions between at least three types of nematic and cholesteric tactoids. We use energy functional theory to rationalize these results and observe a chirality inversion from the left-handed amyloids to right-handed cholesteric droplets. These findings contribute to our understanding of cholesteric phases as well as their use in soft nanotechnology, nanomaterial templating and self-assembly.
experimental and simulation results point to the possibility of self-limitation by the spontaneous twisting of the assumption of bundles due to the build-up of the costs of geometric frustration with lateral diameter. Common to all these models is organogel fibers. Several theoretical models have shown that assembly twist can lead to a thermodynamic self-limitation. Chains are common architectures in a range of supramolecular materials, from protein filaments to self-stacking, (achiral filaments) should be expected only up to diameter of a few filaments wide. Of chiral bundles may reach mesoscopic (multi-filament) dimensions, while self-limitation of spontaneously twisting fibers evolution of pitch with lateral size as well as possible ranges of self-limitation. This analysis argues that self-limited fibers filament bundles of various states of order (e.g. columnar, solid, polymer nematic). I will contrast predictions for the evolution of pitch with lateral size as well as possible ranges of self-limitation. This analysis argues that self-limited fibers of chiral bundles may reach mesoscopic (multi-filament) dimensions, while self-limitation of spontaneously twisting fibers (achiral filaments) should be expected only up to diameter of a few filaments wide.

This work was funded by the NSF.

Twisted by fate, or screwing up purpose: self-limiting fibers from achiral vs. chiral filament assembly* GREGORY GRASON (Presenter), University of Massachusetts Amherst — Twisted bundles of cohesive filaments or chains are common architectures in a range of supramolecular materials, from protein filaments to self-stacking, organogel fibers. Several theoretical models have shown that assembly twist can lead to a thermodynamic self-limitation of bundles due to the costs of geometric frustration with lateral diameter. Common to all these models is the assumption of intrinsic chirality of the constituent filaments as the driving force for collective twist. However, recent experimental and simulation results point to the possibility of self-limitation by the spontaneous twisting of achiral fibers. In this talk, I describe a generic continuum elastic framework for comparing formation of twisted fibers of chiral vs. achiral filament bundles of various states of order (e.g. columnar, solid, polymer nematic). I will contrast predictions for the evolution of pitch with lateral size as well as possible ranges of self-limitation. This analysis argues that self-limited fibers of chiral bundles may reach mesoscopic (multi-filament) dimensions, while self-limitation of spontaneously twisting fibers (achiral filaments) should be expected only up to diameter of a few filaments wide.

From Molecules to Helical Ribbons - Emergence of Elasticity* MINMING ZHANG, DORON GROSSMAN (Presenter), The Racah institute of Physics, The Hebrew University of Jerusalem, Jerusalem, Israel, DGANIT DANINO,Faculty of Biotechnology and Food Engineering, Technion - Israel Institute of Technology, Haifa, Israel, ERAN SHARON, The Racah institute of Physics, The Hebrew University of Jerusalem, Jerusalem, Israel — Self assembly of molecules into supramolecular structures is an important process through which no trivial structures are formed in nano-metric scale. The resulting structure depends on chemical and physical principles that govern the process, and may be sensitive to the exact condition in which they are formed. Typically, such self assembled structures are residually stressed, due to mismatch of the constituent element. Identifying the principles and way in which different structures are formed significantly affect the ability to control, guide and manipulate self assembly. In this research we relate chemical and physical properties of single (or few) molecules to the shape and mechanics of the resulting, residually stressed, elastic helical structure which is a common motif. We then continue to show the unique thermodynamics of the ribbons stemming from these residual stressed. Our predictions are quantitatively confirmed experimentally, suggesting a new framework for quantitative study of a large variety of self-assembled nanostructures.

9:00AM A50.00006: Mechanical basis for the morphology of fibrillar aggregates*  THOMAS MICHAELS (Presenter), L MAHADEVAN, Harvard University — The self-assembly of fibrillar aggregates is of importance in biology, biomedicine and materials science, yet understanding the range of possible shapes for these structures remains an open question. We propose a coarse-grained approach that averages over specific molecular details to suggest that the spatial complexity of self-assembling fibrillar structures is due to the competing effects of (the bending and twisting) elasticity of individual filaments and the adhesive interactions between them. We show that a theoretical framework accounting for this allows us to capture a number of diverse fibril morphologies observed in natural and synthetic systems, ranging from Filopodia to multi-walled carbon nanotubes, and leads to a phase diagram of possible fibril shapes. We also show how the extreme sensitivity of these morphologies can lead to spatially chaotic structures. Together, these results suggest a common mechanical basis for the micronscale fibril morphology as a function of the nanoscale mechanical properties.

*We acknowledge support from the Swiss National Science Foundation.

9:12AM A50.00007: Phase Behavior of Frustrated ABC2 Miktoarm Star Triblock Copolymer*  QI ZHANG (Presenter), WEI-HUA LI, Fudan University — The phase behavior of ABC triblock copolymer can be classified into “nonfrustrated” and “frustrated” cases according to the relative strength of the three Flory-Huggins interaction parameters. In the frustrated case, $\chi_{ACN}$ is much weaker than $\chi_{ABN}$ and $\chi_{BCN}$. Thus, the triblock copolymers prefer to form structures with $ABC$ interfaces. Under the competition of interfacial energy and the entropic energy, the phase behavior of ABC triblock copolymer is more complex, and it can form the phases of the Knitting pattern, double and triple helices on cylinders. However, stable single helical structure has not been reported yet. In order to get the stable single helical structure, we designed the molecule structure of ABC$_2$ miktoarm star triblock copolymer. Our design principle sheds light on the phase behavior of the frustrated case as well as the spontaneous curvature induced by the conformational asymmetry. Through the calculation of Self-Consistent Field Theory (SCFT), the triangular phase diagram shows the region of stable single helical structure as well as the knitting pattern phases.

9:24AM A50.00008: Amplification of vibrational circular dichroism in chiral block copolymers driven by self-assembly  KAI-CHIEH YANG (Presenter), RONG-MING HO, National Tsing Hua University — Herein, various self-assembled phases including double gyroid (DG), double diamond (DD) and helical (H*) phases could be obtained from the self-assembly of chiral block copolymers with equivalent volume fraction of chiral segment, giving building blocks with equal contribution of the optical activities for self-assembly. Interestingly, with comparable chiral segment fraction as evidenced by electronic circular dichroism (ECD), significant enhancement of vibrational circular dichroism (VCD) signals could be found in the chiral H* phase while the VCD signals in the achiral phases of DD and DG remain after microphase separation for ordering, reflecting that the VCD enhancement is attributed to the formation of hierarchical helices with preferential handedness; the observed behaviors are represented as VCD enhancement by self-assembly. This finding provides a new concept to boost optical activities in the applications of chiroptic from self-assembly.

9:36AM A50.00009: Effects of Polymer Helical Chain Shape on Block Copolymer Self-Assembly*  BEIHANG YU (Presenter), SCOTT DANIELSEN, ANASTASIA PATTERSON, EMILY C DAVIDSON, GLENN FREDRICKSON, RACHEL SEGALMAN, University of California, Santa Barbara — While helical chain shapes in block copolymers have been shown to produce unique morphologies, the details of how chain shape influences the thermodynamics of self-assembly are unclear. Here, we utilize model coil–coil and coil–helix block copolymers based on polypeptoids, for which the chain shape can be tuned from helix to coil via monomer chirality with constant chemistry. This model block copolymer system is used to probe the effects of chain helicity on block copolymer self-assembly. With identical domain spacings in the lamellar morphology, the coil–helix block copolymer has a lower order–disorder transition temperature ($T_{ODT}$) than its coil–coil analogue. There is minimal difference in the enthalpic contribution to mixing. The most significant contribution in lowering the $T_{ODT}$ of the coil–helix block copolymer is the helical chain experiencing larger chain stretching penalties in the lamellar morphology, which leads to a larger entropic gain upon disordering. This yields insight into the importance of space filling and chain stretching of polymer chains in block copolymer self-assembly.

*NSF DMR-1608297
isotactic polypropylene*  

10:00AM A50.00011: Aligning stem orientation: confined chiral and epitaxial growth of the α-phase crystals of isotactic polypropylene*  

YAN CAO (Presenter), XINGMING ZENG, Institute for Advanced Study, Shenzhen University, HIROSHI JINNAI, Interdisciplinary Multidisciplinary Research for Advanced Materials (IMRAM), Tohoku University, SHUAILIN ZHANG, Department of polymer science, The University of Akron —  

In the past, soft materials under soft or hard confinement have been extensively studied due to size effect at a small scale. Polymer nanorods confined to the anodic aluminum oxide (AAO) template have been examined in terms of crystal nucleation and orientation. So far, few molecular studies have been done on the polymer nanostructure under cylindrical confinement. In this research, we have fabricated isotactic polypropylene (i-PP) into a rod-shaped nanomaterial. We carried out 2D wide-angle x-ray diffraction (WAXD) and electron diffraction (ED) experiments of transmission electron microscopy (TEM) to analyze the chiral and epitaxial growth effect on hierarchical structure of i-PP nanorod. We found that stems of mother lamellae prefer to align with the rod long-axis (nanopore axis of AAO) and stems of daughter lamellar tilt 100 degree clockwise or counterclockwise with respect to the rod long-axis under 2D confinement.

10:12AM A50.00012: Chirality Enabled Liquid Crystalline Physical Gels with High Modulus but Low Driving Voltage*  

HUAN RUAN, HAIYAN PENG, XIAOLIN XIE (Presenter), Huazhong University of Science and Technology —  

Liquid crystalline physical gels, which stabilize the fluidic liquid crystals by non-covalent three-dimensional fibrous network, are not only able to maintain the unique electro-optical response capability but also capable of affording the self-supporting function. In the past, soft materials under soft or hard confinement have been extensively studied due to size effect at a small scale. Herein, we report liquid crystalline physical gels with high modulus but low driving voltage. This behavior is enabled by chirality transfer from molecular level to three-dimensional fibrous networks during the self-assembly of 1,4-benzenedicarboxamide phenylalanine derivatives. Interestingly, the critical gel concentration is as low as 0.1 wt%. Our findings open doors to understanding and exploiting the role of chirality in organic gels.

10:24AM A50.00013: Universal Effects of Chirality on the Self-Assembly of Chiral Block Copolymers and Polymers* [invited]  

RONG-MING HO (Presenter), Chemical Engineering, National Tsing Hua University, Taiwan —  

Here, we aim to investigate the universal effects of chirality on the self-assembly of chiral block copolymers (BCPs*) and polymers. Poly(cyclohexylglycolide) (PCG)-containing BCPs* have been synthesized for self-assembly to give systematic comparisons with polylactide (PLA)-containing BCPs*. Opposite handedness of PCG helical chains in enantiomeric BCPs* were identified by the vibrational circular dichroism (VCD) results of carbonyl group (C=O) stretching due to intramolecular chiral interactions. By taking advantage of intermolecular chiral interactions as evidenced by the VCD results of C-O-C vibration, the self-assembly of the PCG-containing BCP* gave helical phase (H*) with preferential handedness as recognized by electron microscopy tomography, suggesting the chirality effect on BCP self-assembly and the homochiral evolution from molecular to hierarchical scales; the results are in line with theoretical prediction based on chiral orientational self-consistent field theory. For chiral polylactides, twisted lamellae in crystalline banded spherulite with preferred handedness could be formed, reflecting the homochiral evolution in crystallized chiral polylactides.

Session A51 DPOLY: Big Data, Polymers, and Soft Matter: New Developments in Machine Learning, Data Mining and High-Throughput Studies

BCEC 253A - Debra Audus, National Institute of Standards and Technology - Tag(s): Invited

8:00AM A51.00001: Machined-learned softness as a structural order parameter for understanding glassy systems*

[Invited] ANDREA LIU (Presenter), University of Pennsylvania — All solids flow at high enough applied stress and melt at high enough temperature. Crystalline solids flow and premelt via localized particle rearrangements that occur preferentially at structural defects known as dislocations. The population of dislocations therefore controls both how crystalline solids flow and how they melt. In disordered solids, there is considerable evidence that localized particle rearrangements induced by stress or temperature occur at localized flow defects but all attempts to identify them directly from the structure have failed. Here we describe an application of machine learning data mining methods to diagnose flow defects, or “soft” particles from their local structural environments. We follow the softness of each particle as it evolves under deformation or temperature. Our results show that machine learning methods can be used to gain a conceptual understanding of glassy dynamics and of plasticity that has not been achieved with conventional approaches.

8:36AM A51.00002: Accelerated Discovery in Polymer Materials Domain: Knowledge Extraction and Representation

[Invited] DMITRY ZUBAREV (Presenter), IBM Almaden Research Center — Acceleration of scientific discovery requires resolution of multiple bottlenecks along the flow connecting the perception of the available data, data analysis and hypothesis generation, and data acquisition via experiments. The challenges of a) ingestion of fast-growing volume of unstructured scientific data, and b) efficient generation of actionable hypotheses come from the limitations of human cognition. We investigate various approaches to the augmentation of the respective capabilities of human subject matter experts in the domain of polymer materials. Transition from curated datasets/databases to scientific knowledge graphs (sKGs) plays central role in this effort. In this talk, I discuss the technical aspects of the construction of sKGs from unstructured data in polymer materials domain, and utilization of sKGs for hypothesis generation, including human-in-the-loop approaches.

9:12AM A51.00003: Exploring Free Energy Landscapes with Neural Networks*

[Invited] JONATHAN WHITMER (Presenter), University of Notre Dame — The use of adaptive sampling algorithms is an indispensable part of modern molecular simulations. A wide array of techniques have been developed to accelerate the sampling of phase behavior and molecular conformations, with those exhibiting the proper mix of simplicity and power gaining wide acceptance within the simulation community. Here, we discuss recent efforts to incorporate machine-learning techniques, in particular, artificial neural networks, to drive sampling and efficiently obtain free energy landscapes from incomplete representations of the mean force and partition functions. We will discuss conceptual and numerical aspects of these approaches, presenting new improvements alongside applications of the algorithms to soft and biological materials.

*This work was supported by the Midwest Integrated Center for Computational Materials (MICCoM), as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy.
Text and Data Mining for Material Synthesis

ELSA OLIVETTI (Presenter), EDWARD KIM, Massachusetts Institute of Technology — Data has become a fundamental ingredient for accelerating and optimizing materials design and synthesis. Molecular synthesis planning, driven by advances in machine learning, has recently achieved human-level performance for the retrosynthetic design of organic molecules. The acceleration of data-driven synthesis planning and related analyses has, in part, been enabled by access to massive datasets which tabulate known chemical reactions. While macromolecule, polymer and inorganic materials databases also exist, the focus of these databases is primarily on materials structures and properties, rather than reactions and synthesis. Indeed, there is currently no comprehensive dataset which organizes the methods by which these materials are synthesized or even extensive property information. Comprehensively extracting the knowledge contained within written inorganic materials syntheses, without the use of significant human effort, is a key step towards reducing the overall discovery and development time for novel materials. This presentation will describe work to extract information from peer reviewed academic literature across a range of inorganic solid state materials synthesis approaches. We have demonstrated not only the potential of the natural language processing (NLP) approach to assemble materials data from the literature, but we have also shown that one can develop hypotheses for what synthesis conditions drive a particular target material outcome using learning approaches.

Data-driven learning of collective variables to understand and accelerate biomolecular folding

ANDREW L FERGUSON (Presenter), Institute for Molecular Engineering, University of Chicago — Data-driven modeling and machine learning have opened new paradigms and opportunities in the understanding and design of soft and biological materials. Nonlinear dimensionality reduction and deep learning present a powerful means to identify the underlying dynamical modes governing the assembly and folding of soft materials such as colloids, peptides, and polymers by direct analysis of molecular simulation data. Recovery of these modes, together with nonlinear collective variables with which to parameterize them, provides fundamental understanding of the microscopic forces and emergent dynamical motions governing the long-time evolution of the molecular system. We will discuss our use of diffusion maps, deep neural networks with novel topologies and loss functions, and enhanced sampling techniques to recover the high variance and/or slow collective variables from molecular dynamics simulations of protein folding, and our subsequent use of these coordinates to understand folding mechanisms and guide and accelerate sampling.

Session A52 DPOLY: Advanced Morphological Characterization of Polymers I: Imaging

8:00AM A52.00001: Topological Defects in Tubular Network Block Copolymers

EDWIN THOMAS (Presenter), HUA GUO, XUEYAN FENG, Rice University — Materials based on the double gyroid multicontinuous tubular structure can exhibit an array of exotic properties due to the unique 3D network structure. The nature, frequency and potential influence of topological defects present in the interpenetrating gyroid networks on various physical properties is an open question. We examined a polystyrene – polydimethylsiloxane copolymer possessing the double gyroid microdomain morphology in order to identify the types of topological defects present in high fidelity 3D reconstructions made by slice and view scanning electron microscopy tomography. Large volume tomograms were made by repeated sequentially ion beam milling of a thin section and then using a normal incidence electron beam to image the sample surface. We found node functionality “f defects” where the normal node functionality of 3 rose to 4 and to 5, broken network struts, bridging struts linking the two different networks as well as donut loops comprised of 5 or 6 node rings instead of the characteristic 10 node ring of the (10,3)-a gyroid network. We term the 5 node donut loops as 5-4,3 and 5-4,4,3 defects while the 6 node donut loop is termed a 6-4,3,4 defect to indicate, following Wells, the number of struts in the loop as well as the node functionality and sequence.

Three-dimensional morphological analysis of polymer blends through combined ToF-SIMS/AFM

HAO MEI, Chemical and Biomolecular Engineering, Rice University, ADELINE MAH, TRAVIS LAWS, Chemical and Biomolecular Engineering, University of Tennessee, WEI LI, Materials Science and Engineering, Northwestern University, TANGUY TERLIER, Shared Equipment Authority, Rice University, RAJEEV KUMAR, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, GILA E STEIN, Chemical and Biomolecular Engineering, University of Tennessee, RAFAEL VERDUZCO (Presenter), Chemical and Biomolecular Engineering, Rice University — Time-of-flight secondary ion mass spectroscopy (ToF-SIMS) enables three-dimensional compositional analysis using a focused ion beam along with an argon cluster beam for depth profiling. Combined with atomic force microscopy (AFM), topographical and compositional information can be acquired simultaneously. We apply ToF-SIMS to study the phase behavior of blends of bottlebrush polymers with linear polymers and generate a phase diagram for interfacial segregation. We quantify the composition of bottlebrush throughout the film by calibration of ion intensity ratios, and self-consistent field theory calculations elucidate the enthalpic and entropic contributions to segregation. We further analyze the three-dimensional morphology of phase-separation in thin film polymer blends using combined ToF-SIMS/AFM. ToF-SIMS/AFM is a powerful technique that enables analysis of unlabeled polymer blends, composites, and self-assembling systems.

The authors thank the National Science Foundation for financial support under CMMI-174045 and CMMI-1563008 and CBET-1626418 for the TOF-SIMS/AFM at Rice. Portions of the work were conducted at the Center for Nanophase Materials Sciences at Oak Ridge National Laboratory, which is a US Department of Energy Office of Science User Facility.

STM Characterization of Metallic Graphene Nanoribbons

DANIEL J RIZZO (Presenter), Physics, University of California - Berkeley, GREGORY VEBER, Chemistry, University of California - Berkeley, JINGWEI JIANG, CHRISTOPHER BRONNER, TING CHEN, STEVEN G. LOUIE, Physics, University of California - Berkeley, FELIX R FISCHER, Chemistry, University of California - Berkeley — Graphene nanoribbons (GNRs) are narrow strips of graphene that can host a wide range of 1-dimensional phenomena, including non-trivial topology and magnetism. The advent of molecule-based bottom-up synthesis techniques has enabled GNR properties to be tuned via the precise placement of individual carbon atoms. Realization of robust metallicity in bottom-up GNRs, however, remains elusive. The ability to engineer the frontier band structure of GNRs via hybridization of topologically-protected interface states suggests a strategy for inducing GNR metallicity by symmetrizing the hopping between adjacent interface states. Using this approach we have realized metallic GNR superlattices that are gapless by virtue of the symmetric placement of π-radical states along the GNR backbone. Scanning tunneling microscopy and spectroscopy (STM/STS) performed in conjunction with first-principles calculations confirms that these GNR superlattices possess a non-zero density of states (DOS) through EF, a hallmark of metallicity. Strategies for increasing the bandwidth of metallic GNRs will be discussed.

nano-FTIR nanoscopy based identification of polymers at the 10nm length scale

ANDREAS HUBER (Presenter), STEFAN MASTEL, TOBIAS GOKUS, ALEXANDER GOVYADINOV, neaspec GmbH — Scattering-type Scanning Near-field Optical Microscopy (s-SNOM) employs the strong confinement of light at the apex of a sharp metallic AFM tip to create a nanoscale optical hot-spot. Analyzing the scattered light from the tip enables the extraction of the optical properties below the tip and yields nanoscale resolved images simultaneous to topography [1]. Recently, the technology has been advanced to enable FTIR-spectroscopy on the nanoscale (nano-FTIR) [2].

Applying nano-FITR near-field spectroscopy to measure the spectroscopic signature enables identification of i.e. polymers at a spatial resolution given only by the size of the AFM tip [3]. For example, nano-FTIR spectra of a phase-separated PS/LDPE polymer blend of only 50nm thickness enable to identify the samples polymer materials.

Results presented demonstrate that nano-FTIR can be an ideal analysis method to characterize complex material systems and to identify polymer materials at the nanoscale spatial resolution and unmatched sensitivity.

9:24AM A52.00008: Morphological Characterization of Well-Ordered Nanonetwork Materials via Real- and Reciprocal-Space Imaging  
POTING CHIU (Presenter), YUCHENG CHIEN, RONG-MING HO, Department of Chemical Engineering, National Tsing Hua University — The morphological evolution of network phases from templated electroless plating using block copolymer as a template was investigated as an exemplary system for the characterization of developing complex gyroid and diamond phases from self-assembly. By taking advantage of the nucleation and growth mechanism of templated electroless plating, network-structured Au could be successfully fabricated through the development of Au nanoparticle, tripod/tetrapod and branched tripods/tetrapods, finally network structure. Hence, the morphological evolution of each stage could be examined by combining real-space observation of transmission electron microscopy with reciprocal-space investigation using small-angle X-ray scattering. A simple approach for the fitting of the scattering results was established at which the fingerprint scattering profiles of the building block for network phases were fitted with the form factor of sphere (i.e., the nanoparticle) and the diffraction results of final morphology (i.e., the network phases) could be well addressed by combined scattering of the form and structure factors, revealing the difference between the curvatures of gyroid and diamond phases from self-assembly.

9:36AM A52.00009: Recent developments of morphological characterization in nano-composite materials by electron microscopy [Invited] 
HIROSHI JINNAI (Presenter), Tohoku University — In order to truly understand various interesting properties of soft materials, it is crucial to directly visualize their morphologies both in quiescent state and under deformation. The interfacial region between fillers and polymer matrix, the interphase region for short, is believed to be one of the key morphological elements in nanocomposite materials. Direct visualization of such interphase region has been a subject for many years. Although transmission electron microscopy (TEM) is a powerful tool to visualize nano-scale polymeric morphologies, however, because the interphase region consists of the same polymeric species as the matrix, it is invisible under TEM. Atomic force microscopy (AFM), on the other hand, clearly demonstrates regions with higher elastic modulus (than the matrix) around the fillers, indicating the existence of the interphase region. However, because the mechanical properties can be easily affected by the structures underneath the measurement points, the high elastic regions around the fillers may not truly reflect the interphase region. Thus, we used transmission electron tomography, a nano-scale three-dimensional (3D) visualization method, to investigate the internal 3D structure of rubber nano-composite at exactly the same places as the AFM force measurements. In doing so, it became possible to accurately determine the interphase regions for the first time.

Morphological characterization under deformation is another crucial factor for fundamental understanding of mechanical properties of nano-composites. We have developed a tomography holder for in-situ tensile deformation. Because both ends of specimen are stretched simultaneously at the same stretching rate in this new holder, drifting of field of view for TEM observations becomes minimum. The newly-developed holder was used to observe deformation processes of a rubber nano-composite. Details of the structural deformation will be discussed at the conference time.

10:12AM A52.00010: Construction of 3D Models From USAXS on Aggregate Structures*  
ALEX MCGLASSON (Presenter), ANDREW J MULDERIG, GREG BEAUCAGE, KABIR RISHI, Chemical and Materials Engineering, University of Cincinnati, VIKRAM K KUPPA, University of Dayton Research Institute — An accurate 3D model of aggregate structures is desirable for comparison with TEM micrographs and as an input to computer simulations of aggregate transport and growth. For example, we have used such 3D models for polymer nanocomposites with carbon black and silica. Ultra-small angle X-ray scattering was coupled to a hierarchical scattering model, the unified scattering function, to obtain topological parameters that describe 9 average features of aggregates including details of the branched structure. A simple diffusion limited aggregation model was simulated and used to generate aggregates using two free parameters, the degree of aggregation, z, and the sticking probability, p [1]. USAXS measurements resulted in z for input to the simulation and the single parameter p was varied from 0 to 1 until a value that could reproduce the 8 remaining USAXS aggregate descriptors was found. The simulated average aggregates agreed well with TEM micrographs of the same samples. This approach can be used to depict complex morphological differences in ceramic oxide and carbon black aggregates and has the potential to be applied to a wide range of other aggregated materials.

*NSF grants CMMI-1635865 and CMMI-1636036.
10:24AM A52.00011: Self-Assembled Morphologies of Poly(styrene-b-1,4-butadiene) Confined within Cone-Shaped Templates

YOUNGKEOL KIM (Presenter), Seoul National University, TAKESHI HIGUCHI, Tohoku University, SUNGYOUL HWANG, Seoul National University, ANCHANG SHI, McMaster University, BAOHUI LI, Nankai University, HIROSHI JINNAI, Tohoku University, KOOKHEON CHAR, Seoul National University — Block copolymers (BCPs) self-assembled under nanoscale confinement have distinctive nanostructures, which do not appear in bulk state. Especially, depending on different dimensionality of confinement spaces, shape and morphology of block copolymers and their optical properties are affected. In this study, we report phase-separated morphologies of polystyrene-block-1,4-polybutadiene (PS-b-PB) confined in conical templates with various size, shape and surface properties. Based on experimental observation using transmission electron microscopy (TEM) and theoretical calculation of simulated annealing method, we found that phase separation of PS-b-PB in the conical confinement system are competitively affected by three thermodynamic factors; (1), (2) the interfacial energy between two different block and surrounding environment (air and substrates) and (3) the entropic penalty associated with large curvature at the vertices of conical pores. In addition, 3D imaging of TEM tomography were also performed in an attempt to identify internal nanostructures of BCP thoroughly.

10:36AM A52.00012: The distinctive microstructures in bitumen and their indication of bitumen’s phase stability

XIAOKONG YU (Presenter), NANCY BURNHAM, Worcester Polytechnic Institute, SERGIO GRANADOS-FOCIL, Chemistry, Clark University, MINGJIANG TAO, Worcester Polytechnic Institute — Bitumen, similar to some amorphous polymeric systems, display diverse microstructures that are related to bitumen's bulk physical and rheological properties; yet the chemical-microstructural-mechanical relationships for bitumen have been very challenging to establish due to bitumen's complicated molecular interactions. To tackle this challenge, we chose two pristine bitumen (i.e., ABD and AAD), separated them into their asphaltene and malthene fractions, and prepared derivative bitumen by remixing their corresponding asphaltenes and maldenes at different ratios. We studied the microstructures of the two pristine bitumen and their derivatives using atomic force microscopy (AFM), and their phase stability using differential scanning calorimetry and their rheology using dynamic shear rheometry. Our results suggest that AAD-based derivatives had phase separation; in contrast, ABD-based samples were phase stable. The difference in phase stability between the two groups of bitumen is largely relevant to the aggregation behavior of their respective asphaltene fraction that was measured via NMR.

Session A53 GSNP: Geophysical Applications of Granular Flows

8:00AM A53.00001: Geophysical applications of granular flows: probing earthquakes applying machine learning

[Invited] PAUL JOHNSON (Presenter), BERTRAND ROUET-LEDUC, Earth and Environmental Sciences, Los Alamos, CLAUDIA HULBERT, Laboratoire de Géologie, l'Ecole normale supérieure — The influence of granular flows is widespread in geophysics, from the physics of earthquakes, avalanche and landslide, to debris flow to the effects of strong ground motion due to earthquakes. In this presentation I focus on earthquakes and the influence of the granular core of the fault—the fault gouge. Earthquakes take place when two juxtaposed fault blocks are stressed sufficiently to overcome the frictional force holding them in place and they abruptly slip relative to each other. Earthquake faults exhibit a continuum of behaviors ranging from stick slip associated with strong shaking, to slow slip which is primarily aseismic, to very slow slip that is essentially aseismic and can take place over hours to months. The different slip behaviors appear to be controlled by the combined elasticity of the fault gouge the adjacent fault blocks. As faults slip, the fault core emits elastic waves. We analyze these waves applying machine learning continuous acoustic data streams in the laboratory and continuous seismic data streams in Earth. We use as labels characteristics of the measured fault slip behavior in the laboratory such as the fault friction, shear displacement and fault thickness. In Earth, we use surface displacement as determined by Global Positioning Systems (GPS). We find that the laboratory acoustic data and the Earth seismic data are a type of Rosetta Stone revealing fault characteristics at all times and fault displacements. This is a surprising observation because previously we believed most or much of the signal was noise. Here we describe an overview of recent work in this area and also describe recent efforts on parallel problems such as volcanoes and geysers.

8:36AM A53.00002: Incipient Motion in Granular Beds Driven by Shear Flows* [Invited] NICHOLAS OUELLETTE
(Presenter), Stanford University — Granular packings on Earth's surface are regularly subjected to shear flows, as they are typically exposed either to moving water or air. These flows agitate the packings, and may erode them by removing grains given sufficient flow strength. Incipient motion of the packings (that is, the point in parameter space when a nonzero net downstream flux of grains appears) is typically thought to occur at a critical value of the Shields number, which balances the shear stress delivered to the grains with the weight of a grain. However, such a simple framework cannot directly account for additional but common physics, including granular packing effects, turbulent flow fluctuations, or the stress delivered to the bed by other mobile grains. I will discuss both simple numerical models and laboratory experiments aimed at elucidating the consequences of these effects on describing incipient motion, with particular application to the armoring phenomenon observed in gravel-bedded rivers.

9:12AM A53.00003: Shear jamming in packings of frictional disks* [Invited] MARK SHATTUCK (Presenter), The City College of New York, FANSHENG XIONG, PHILIP WANG, Yale University, ABE CLARK, Naval Postgraduate School, NICHOLAS OUELLETTE, Stanford University, COREY SHANE O’HERN, Yale University —
The mechanical properties of geotechnical structures depend on the history that generated them. Examples include riverbed hardening and delta formation. Similar history or protocol dependence also occurs on the particle scale. For example, the seminal experiments by D. Bi, et al. in Nature 480 (2011) 355, showed that simple and pure shear can generate jammed packings of thin cylinders whose properties are different from those generated via isotropic compression. In our recent computational studies, we showed that for frictionless disks, shear- and isotropically jammed packings possess the same packing fraction. However, shear-jammed packings possess nonzero stress anisotropy, whereas isotropically jammed packings possess zero anisotropy in the large-system limit. Here, we describe discrete element modeling simulations to prepare jammed packings of frictional disks via isotropic compression and simple shear. We compare the contact number and packing fraction at jamming onset versus the friction coefficient for packings generated via isotropic compression and simple shear. We also address whether the ensemble of jammed packings generated via simple shear and that generated via isotropic compression are the same.

9:48AM A53.00004: Yielding in granular materials: from riverbeds to renormalization group [Invited] ABE CLARK (Presenter), Naval Postgraduate School — Granular media, like many other amorphous materials, possess a yield stress. The nature of yielding in granular materials is relevant to many industrial and geophysical problems, such as the onset of sediment motion in riverbeds or near-shore environments. When the applied shear stress $\Sigma$ is below the yield stress $\Sigma_c$, grains move temporarily, but only until finding a mechanically stable (MS) configuration that is able to resist the applied shear stress. When $\Sigma > \Sigma_c$, the material is no longer able to find MS configurations. However, the geometrical reasons why MS states vanish at the yield stress is not well understood. In this talk, I will show evidence from molecular dynamics simulations, both in a riverbed-like geometry as well as simple shear, that yielding in granular materials is akin to a second-order critical point, where the behavior near the yield stress is dominated by a correlation length $\xi$ that diverges at the yield stress as $\xi \sim |\Sigma - \Sigma_c|^{-\nu}$. MS states exist above the yield stress for finite systems, but they vanish as the system size becomes large according to a critical scaling function. The packing fraction and coordination number for MS states are independent of the applied shear stress, implying that the critical behavior we observe is distinct from the jamming scenario. Additionally, the critical behavior persists for overcompressed systems, confirming that jamming and yielding are distinct. Instead, we observe that MS states at nonzero shear stress possess anisotropic force and contact networks, suggesting that the yield stress is set by the maximum anisotropy that can be realized in the large-system limit.
Naturalistic Granular Flows: Using Experiments to Apply Granular Physics to Geophysical Shear Systems* 

EMILY BRODSKY (Presenter), STEPHANIE E TAYLOR, University of California, Santa Cruz, SHALEV SIMAN-TOV, Geological Survey of Israel — Granular flows are ubiquitous in nature and deviate in potentially important ways from idealized systems. Shearing in fault zones, landslides and debris flows involve water-saturated, rough particles of varying composition and particle size accelerating through a range of velocities while abutting stationary grains. In addition, the types of observations that can be made in nature also differ from laboratory and experimental situations. Here we present a range of experiments that attempt to isolate these naturalistic features and elucidate their implications. Specifically we find that: (1) Natural, rough particles emit acoustic energy during shear, which can affect the flow behavior at intermediate velocities, (2) The acoustic energy observed in the lab depends on the particle diameter cubed, (3) Mineralogy affects the intermediate to high velocity flow behavior primarily through the combination of elastic, fracture and plastic material properties captured by the critical slip distance required for fracture nucleation, (4) high and low shear rate regions of the flow are coupled through acoustic waves, creating a non-trivial boundary condition at the base of a landslide or other natural shear system, (5) Fluid-saturation can result in dilation at high velocities regardless of the initial compaction state and therefore dilatary drainage is expected even in repeated activation of the same shear flows, and (6) preserved, fine-grained apparent shear bands in the geological record can be indicative of fine grains migrating at high velocities. These experimental observations suggest important directions for theoretical development in order to bring granular physics to bear on natural systems.

Session A54 DPOLY GSOFT DBIO: Smart and Responsive Polymers and Soft Materials I: Micro-Length Scale Phenomena

Mechanochromic Polycarbonate: Seeing Plasticity with Color* 

STEVEN YANG (Presenter), YUVAL VIDAVSKY, MEREDITH SILBERSTEIN, Mechanical and Aerospace Engineering, Cornell University — We use force-driven chromism to detect plasticity in polycarbonate. We create this functionality by embedding spiropyran, a mechanochromic compound, in the polymer backbone. While there are many examples of force-driven functionality in elastomers, there are few for glassy polymers. In prior experiments, the activation of spiropyran in glassy polymers was limited to tests near Tg, or with an added plasticizer. With glassy polycarbonate, we demonstrate tensile activation at room temperature. Spiropyran activation begins after yield and increases with hardening during plastic flow. For monotonic tensile tests, the activation is inversely related to the strain rate, while the stress is comparable. These results suggest that for glassy polymers, the activation of mechno-responsive compounds is coupled with stress, plastic flow, and time. Understanding how these factors contribute to activation will enable using mechano-responsive polymers for quantitative sensing.

*A statistical mechanical model for the electrostriction of polymers* 

MATTHEW GRASINGER (Presenter), KAUSHIK DAYAL, Carnegie Mellon University — Dielectric elastomers (DEs) are soft materials that polarize in the presence of an electric field. Using statistical mechanics, the thermodynamics of a DE chain subject to electrical loading and kinematic constraints is investigated. The equations of the monomer orientation density and the approximate chain free energy are derived. Solutions are presented in the small chain stretch limit and near the fully stretched limit. A closed-form approximation for the free energy of a DE chain is developed using asymptotic matching and shown to agree well with the numerical solutions. Next, averaging over chain orientations, the chain-scale response is built up to an electromechanically coupled DE constitutive model. Some preliminary results from the constitutive model are presented, which includes a contribution, at the macromolecular scale, to the electrostriction of DEs. The contribution to electrostriction is shown to be dependent on the lengths and orientations of chains in the DE network.

*The authors acknowledge the Army Research Office, Office of Naval Research, and Air Force Office of Scientific Research for funding this work.
8:24AM A54.00003: Simulating Polymeric Microstructures With Encoded Pre-Determined Deformability  JAMES WATERS (Presenter), University of Pittsburgh, JOANNA AIZENBERG, Harvard University, ANNA CHRISTINA BALAZS, University of Pittsburgh — Biological systems are able to translate stimuli into meaningful actions, reshaping themselves in response to changes in their environments. Liquid crystalline elastomers (LCE’s) represent a synthetic means of achieving this type of behavior, undergoing large deformations when nematic-isotropic phase transitions occur within the material. We use a finite element simulation method to predict the thermal response of LCE microplates, in a particular instance of this phenomenon. The shape changes are dictated by the director orientation in the nematic state, programmed in by a magnetic field present during cross-linking. After calibrating our simulation parameters against experimental results, we are able to accurately predict the observed experimental response of LCE microplates with a range of initial nematic orientations.

8:36AM A54.00004: Rational Design of Strain-Adaptive Elastomers through Polymer Architectures*  HEYI LIANG (Presenter), Department of Polymer Science, University of Akron, MOHAMMAD VATANKHAH-VARNOSFADERANI, SERGEI SHEIKO, Department of Chemistry, University of North Carolina at Chapel Hill, ANDREY DOBRYNIN, Department of Polymer Science, University of Akron — Designing materials capable of mimicking the mechanical properties of soft biological tissues is important for tissue engineering, soft robotics, and wearable electronics. The biological tissues show a unique combination of the mechanical softness and strong strain-stiffening, which make it difficult to replicate in synthetic elastomers composed of linear polymers. Using a combination of theoretical calculations and molecular dynamics simulations, we have developed a universal materials design strategy which encodes the stress-strain curve of soft materials into the molecular architecture of graft polymer networks. Such networks can be made either by chemical crosslinking of graft polymer strands or by self-assembly of linear-bottlebrush-linear triblock copolymers. The mechanical response of such networks is controlled by the architectural parameters (i.e. network strand length, side chain length, grafting density, and composition of triblock copolymers). Our approach is verified by synthesizing PDMS networks of combs and bottlebrushes with mechanical properties of jellyfish, lung, and arterial tissue. This technique lays the foundation for computationally driven design of soft materials.

8:48AM A54.00005: Detecting Bond Breakage and Fracture in Tough Hydrogels Using Mechanoluminescence*  GABRIEL SANOJA (Presenter), ESPCI, RINT SIJBESMA, TU Eindhoven, COSTANTINO CRETON, ESPCI — Synthetic hydrogels are soft materials composed of 3-D polymer networks swollen with water. They are promising synthetic analogues of tissues but their excessive brittleness remains an important limitation. Though there have been advances in the design of tough hydrogels, it is not yet possible to quantitatively predict toughness from molecular design. A promising strategy towards this endeavor is based on the incorporation of mechanoluminescent probes in these materials. Upon force-induced bond breakage, emission of visible light allows for spatio-temporal mapping of molecular bond scission during failure. We have incorporated a mechanoluminescent probe based on bis(adamantyl)-1,2-dioxetane into a model double-network hydrogel composed of stiff PAMPS and soft PAAm. Due to the low quantum yield of the emitter ketone resulting from force-induced ring-opening, we explored a range of FRET agents to detect bond scission during deformation. This information serves not only to establish a relation between polymer network structure and fracture energy, but also to develop multi-scale physical models of fracture in soft materials.

9:00AM A54.00006: Light-Actuated Liquid Crystal Elastomer Waveguides*  ALEXA KUENSTLER (Presenter), RYAN HAYWARD, University of Massachusetts Amherst — The ease with which light can be spatially and temporally modulated makes it an attractive stimulus for the actuation of soft materials. However, many devices require direct line-of-sight access for deployment, severely compromising their utility in confined geometries where remote control is required. One way to circumvent these limitations is to employ actuators that act as waveguides to deliver light over distances that make flood illumination impractical. To this end, we present a method to fabricate liquid crystal elastomer fibers that can adopt defined 3D conformations in response to waveguided visible light due to localized photothermal deformation. By exploiting the photo-mediated reduction of gold salt, spatially-defined regions of nanoparticles are patterned in aligned fibers to define the location and direction of bending. Fibers are demonstrated to bend simultaneously in orthogonal directions on a characteristic time scale of seconds. Furthermore, these fibers are shown to waveguide light, thereby removing the need for line-of-sight access to achieve complex shape change.

*NSF EFRI-ODISSEI 1332271
Fracture of soft materials involves large deformations before eventual macroscopic failure occurs and the damage to the material is much less localized at the crack tip than in stiff and brittle materials such as inorganic glasses. Although fracture of simple elastic networks made of flexible polymers connected by covalent bonds, obeys relatively well the classical Lake and Thomas theory, fracture of complex soft materials is much harder to predict from knowledge of the molecular structure and architecture. Organic chemists have recently developed new molecules that can be incorporated in networks and give an optical signal (fluorescence, luminescence or change in absorption) in response to the application of a force. These optical signals can then be used to obtain quantitative information about bond scission and energy dissipation during a macroscopic fracture event. Previous work\(^1\) has shown that it is possible to toughen and stiffen soft materials by incorporating a minority percolating filler into a stretchable matrix. Using model interpenetrated networks we demonstrate here, by incorporating mechanophore molecules in the filler or in the matrix network, how such materials break in two stages, by first softening the stiff filler network, losing mechanical percolation, and then breaking the stretchable matrix. Such mechanisms active at the crack tip are responsible for the much higher toughness of these stiffened materials and should be widely generalizable to elastomers and hydrogels reinforced by particles forming a percolating network.

**This project has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (grant agreement n° 695351), from the Chinese Scholarship Council through the fellowship of YC, and from Royal DSM through the fellowship of PM.**

**Electric field induced bending of Ionic polymer electrolyte membrane**

CHATHURANGA PRAGEETH RAJAPAKSHA (Presenter), Department of Physics, Kent State University, Kent, OH 44240, USA, CHENRUN FENG, Liquid Crystal Institute, Kent State University, Kent, OH 44240, USA, CAMILO PIEDRAHITA, JINWEI CAO, THEIN KYU, Department of Polymer Engineering, University of Akron, OH 44325, USA, ANTAL ISTVAN JAKLI, Department of Physics, Kent State University, Kent, OH 44240, USA — Electroactive polymers (EAPs) are promising candidates for future soft robotics due to their light weight, low cost and ease of fabrication. Among different kinds of EAPs Ionic electroactive polymers (IEAPs) are more attractive, since they are low voltage driven. Here we report about electric field induced studies of solid-state ionic polymer electrolyte membranes (IPEMs). Three different kinds of electrodes (gold, carbon and PEDOT: PSS based) were tested to optimize performance. Highly ionic conductive IPEMs were prepared by using Poly (ethylene glycol) diacrylate (PEGDA), thiosiloxane and ionic liquid(1-Hexyl-3-methylimidazolium hexafluorophosphate) as described by Piedrahita et al \(^1\). Different ionic liquid concentrations were tested to achieve large bending displacements. In addition to the reversible short-term low voltage (<3V) responses, we also studied responses up to 20V ac and dc voltages in wide-range of time scales. Not only non-linearity and hysteresis, but also a so far not understood inversion of displacement was also observed at large voltages and large time scales. These studies will provide important information on electrode effects and applicability limits of IEAPs.

**Programmable Assembly of Responsive Capillary Multipoles**

JINHYE BAE (Presenter), University of California, San Diego, NAKUL P BENDE, ARTHUR A EVANS, JUNHEE NA, CHRISTIAN SANTANGELO, RYAN HAYWARD, Univ of Mass - Amherst — The ability to program inter-particle interactions with well-defined selectivity, directionality, strength, and range remains a central challenge in efforts to realize complex materials by self-assembly of simple building blocks. Capillary attraction or repulsion owing to the geometrical distortion of the three-phase contact line by non-spherical particles has emerged as a powerful means to program two-dimensional assembly. To date, however, the focus has been almost exclusively on assembling rigid particles having shapes of limited complexity, restricting both the types of assemblies and their reconfigurability. We take advantage of the stimuli-responsiveness and the low-energy bending deformation of hydrogel particles, to show stimulus-controlled modulation of shape-induced capillary assembly. We anticipate that such surface tension-driven modification of the capillary interaction will suggest a rich area for fundamental studies and opportunities to further tailor the inter-particle interactions.

10:12AM A54.00010: Structure Dependent Ice Inhibition in Physically Crosslinked Hydrogels by Crystallization of Hydrophobic Crosslinks*  

PABLO SEPULVEDA-MEDINA (Presenter), Polymer Engineering, University of Akron, CHAO WANG, Chemical & Biomolecular Engineering, University of Delaware, BRYAN VOGT, Polymer Engineering, University of Akron — 

Confined water at the nanoscale can enable significant supercooling that is not possible in bulk water, but common strategies to confine water lead to low water content. We have recently demonstrated near complete ice inhibition in physically crosslinked hydrogels that use the hydrophobic association of perfluorinated moieties to crosslink and confine the water. However, the confining structure and water content in these hydrogels are coupled, which leads to some questions about the underlying physics. Here we demonstrate a similar route to modulate the nanostructure of a physically crosslinked hydrogel based on 2-hydroxyethyl acrylate (HEA) and n-octadecyl acrylate (ODA) without changing the copolymer composition and water content by crystalline crosslinks. Crystallization in the dry state leads to sheets of crystalline ODA, while melting and re-crystallizing the ODA in a hydrated copolymer leads to spherical nanodomains. The temperature-dependent structure was probed by SAXS, WAXS and SANS. DSC revealed that crystallization in the state leads to significantly more unfrozen water inside the hydrogel (10 to 15 wt%). The hydrogel morphology appears to control the unfrozen water content in these hydrogels under cryogenic temperatures.

*Work funded by NSF grant CBET-1606685.

10:24AM A54.00011: Rheological Signature of a Thermally-Gelling Nanoemulsion*  

MEYSAM HASHEMNEJAD (Presenter), ABU ZAYED MD BADRUDDOZA, Chemical Engineering Department, Massachusetts Institute of Technology, BRADY ZARKET, L’Oréal Research and Innovation, Clark, Nj, PATRICK DOYLE, Chemical Engineering Department, Massachusetts Institute of Technology — We report the rheological behavior of a new thermoresponsive oil-in-water nanoemulsion system. The nanoemulsion undergo a transition to a gel at elevated temperature. The gelation mechanism is entirely different from previous reports and nanoemulsion droplets play a major role in thermoresponsive behavior. The formulation contains FDA approved amphiphilic triblock copolymer as gelling agents. Nanoemulsions were also prepared using a low-energy process. The thermogelling formulation exhibits unique rheological behaviors. The power-law shear thinning behavior at sol and gel states were observed. Yielding behavior of the nanoemulsion gels was characterized using large amplitude oscillatory shear (LAOS) experiments. These gels display strain-softening behavior under application of large shear-deformation prior to failure of the material. The material turn back to the initial state simultaneously after cessation of applied high shear stress/strain.

*We acknowledge L’Oréal for financial support of the work.

10:36AM A54.00012: Oscillating chemo-mechanical Belousov-Zhabotinsky (BZ) hydrogels*  

BAPTISTE BLANC (Presenter), Physics, Brandeis University, NING ZHOU, Chemistry, Brandeis University, ERIC LIU, Chemical and Biological engineering, Tufts University, S.ALI AGHVAMI, Physics, Brandeis University, BING XU, Chemistry, Brandeis University, HYUNMIN YI, Chemical and Biological engineering, Tufts University, SETH FRADEN, Physics, Brandeis University — 

Yoshida [JACS 1996] developed a gel that undergoes cyclic swelling and deswelling without external stimuli. This self-oscillating gel undergoes an oxidation-reduction cyclic reaction, leading to a cyclic change of solubility of the gel. We present a new synthesis technique, offering high modularity in the gel composition and shape. We present simple experimental techniques to characterize the properties of the spherical BZ gels, such as their elasticity, timescale of swelling, density and catalyst content. Moreover, we find that a single spherical BZ gel needs to be larger than a critical size to chemically oscillate, thereby limiting the amplitude of its mechanical oscillation. We finally show how the remarkably high sensitivity of the BZ gel to its chemical environment can be harvested to enhance its actuation.

*We acknowledge financial support from the NSF DMREF-1534890 and the microfluidics facility of the NSF MRSEC DMR-1420382.
10:48AM A54.00013: The Effects of Mesogen Spacer and Linker on the Actuation of Liquid Crystal Elastomers — JAN-MICHAEL CARRILLO (Presenter), BOBBY G SUMPTER, Oak Ridge National Laboratory, SUK-KYUN AHN, Pusan National University — Experiments have shown that the actuation temperature of thermo-responsive main-chain liquid crystal elastomers (LCE) can be controlled by adjusting the spacer length ($N_L$) of reactive mesogen (i.e., LC monomer). Actuation occurs when the order parameter of LC mesogens changes at the nematic-isotropic transition temperature ($T_{NI}$). The precursor LC oligomers, which are connected LC units via linking thru an alkyl diamine chain extender, exhibits an increasing $T_{NI}$ as $N_L$ is increased. This behavior is opposite to what is observed in LC monomers. To elucidate this behavior, we performed isothermal-isobaric (NPT) ensemble coarse-grained molecular dynamics simulation of stiff-chains that are connected to flexible spacers at different temperatures, where $T_{NI}$ is determined when the smoothly decaying orientational correlation function, $g_2(r)$, transitions to an oscillating decay function. Simulations show that increasing $N_L$ decreases $T_{NI}$ for both monomers and oligomers. However, the dangling beads ($N_D$), representing the alkyl length of the diamine linkers in the experiments, amplifies the decrease of $T_{NI}$ when the linker length ($N_L$) is short. We infer that the combination of $N_L$ and $N_D$ changes the shape anisotropy of the LC mesogen, affecting its ability to transition to the nematic phase.

Session A55 DPOLY GSOFT: Broadband Dielectric Spectroscopy of Polymers and Soft Matter

8:00AM A55.00001: Broadband dielectric spectroscopy on miscible polymer blends in the bulk and in nanometer thick films - Comparison of the different confinement situations* [Invited] ANDREAS SCHOENHALS (Presenter), PAULINA SZYMONIAK, SHERIF MADKOUR, Department 6.6, Federal Institute of Materials Research and Testing — Broadband dielectric spectroscopy in the frequency range from $10^{-1}$ to $10^9$ Hz is employed to revisit the segmental dynamics of the miscible blend system of poly(vinyl methyl ether)/polystyrene (PVME/PS) in dependence on the composition first in the bulk state. Here, the case of high polystyrene concentrations is considered especially. It is important to note that the dipole moment of polystyrene is negligible, thus only the molecular dynamics of PVME segments, as affected by PS, is observed. Three relaxation processes are found, which are due to fluctuations of differently constrained or confined PVME segments. The degree of the confinement of PVME segments due to PS is discussed in dependence on the composition. Secondly, a spatial confinement is considered by investigating thin films of the PVME/PS blend, where the film thickness varies from 100 nm down to 5 nm. Two concentrations of PVME/PS (50/50 wt% and 25/75 wt%) are investigated. To measure nanometer thick films a novel electrode system based on nanostructured electrodes was employed. Nanostructured electrodes can be considered as a cut-edge technology in dielectric spectroscopy. The relaxation spectra of the films showed multiple processes, which are discussed in dependence on the film thickness.

*German Science Foundation DFG Grant number SCHO 440/20-2

8:36AM A55.00002: Thin supported polymer films: Modified mobility at the interfaces* EMMANUEL MAPESA (Presenter), NOBAHAR SHAHIDI, EMMANOUIL DOXASTAKIS, JOSHUA SANGORO, Department of Chemical and Biomolecular Engineering, University of Tennessee, Knoxville — Using a nanostructured electrode arrangement that effectively offers two different interfaces to the thin polymer layers under study, Broadband Dielectric Spectroscopy (BDS) is employed to characterize interfacial dynamics in thin supported poly(vinyl acetate) (PVAc) films. By analyzing the dielectric loss peak due to the dynamic glass transition, it is demonstrated that although the mean relaxation times for thin films remain bulk-like, there are indeed layers at the polymer/substrate and polymer/air interfaces that exhibit modified mobility in dependence on both overall film thickness and temperature. Preliminary molecular dynamics simulations corroborate these findings.

*E.M. and J.S. are grateful for support from the National Science Foundation, Division of Materials Research, Polymers Program, award DMR-1508394.
8:48AM A55.00003: The Cooperative Free Volume Rate Model: Applications to Pressure Dependent Dynamics and Dynamics under Confinement*  
RONALD WHITE (Presenter), JANE E LIPSON, Dartmouth College — In this talk we discuss our recent work in modeling and predicting alpha relaxation times (τ) using the cooperative free volume rate model (CFV), an approach where the system's free volume determines the molecular cooperativity, and thus the activation energy. The term "free volume" carries some historical baggage, having been ill-defined and, at times, over-enthusiastically applied. However, our definition of free volume is grounded in analysis of experimental volumetric information (PVT data) using our locally correlated lattice (LCL) model equation of state. We have shown, for both polymers and small molecules, that the LCL predicted free volume is very effective in representing a system's volume-based contribution to dynamics. Another essential feature (ignored in historical models) is that the CFV model incorporates an independent temperature-based contribution. We have shown this contribution acts in a product form together with an inverse $V_{\text{free}}$ dependence, a result that follows mechanistically from the rate model. This presentation will summarize some of our applications of the CFV $\tau(T,V_{\text{free}})$ form to experimental systems, with a particular focus on pressure dependent dynamics and dynamics under confinement.

*This work is supported by NSF, DMR-1708542.

9:00AM A55.00004: Dielectric Phenomena in Polymers and Multilayered Dielectric Films*  
LEI ZHU (Presenter), Case Western Reserve University — High dielectric constant and low dielectric loss are desirable electrical properties for next-generation polymer dielectrics that show promise for applications in pulsed power, power electronics, and printable electronics. Unfortunately, the dielectric constant of polymers is often limited to 2-5, much lower than that of inorganic dielectrics, because of the nature of hydrocarbon covalent bonds for electronic and atomic polarizations. It is essential to understand the fundamental physics of different types of polarization and the associated loss mechanisms in polymers. In this presentation, we discuss the characteristics of each polarization and explain how to enhance the polarization using rational molecular designs without causing significant dielectric losses. Among various approaches for high dielectric constant and low loss polymers, the multilayer film technology is of particular interest because a multilayer film is a unique one-dimensional system with tailored material choices, layer thicknesses, and interfaces. By minimizing the disadvantageous polarizations and enhancing the advantageous polarizations, multilayer films hold promise as advanced dielectrics for future polymer film capacitors.

9:12AM A55.00005: Deciphering Relaxation Spectra of Amorphous Polymers through Dielectric Spectroscopy of an Epoxy  
DANIEL WILCOX (Presenter), GRIGORI MEDVEDEV, YELIN NI, AKASH PATIL, BRETT SAVOIE, BRYAN BOUDOURIS, JAMES M CARUTHERS, Purdue University — In contrast to the crystalline solid and gaseous phases, the mechanism behind the behavior of liquids and amorphous solids remains a significant challenge, where current descriptions of relaxation behavior in these materials are highly empirical with tenuous physical significance. Recently, we have found that the dynamic mechanical relaxation behavior of an epoxy resin is better described using a small, finite number of discrete relaxation processes instead of the continuous spectrum of relaxation times that are typically employed. In this work, the broadband dielectric spectroscopy of the same epoxy material is investigated, where isotherms were measured from liquid nitrogen temperatures to well above the glass transition temperature. By comparing the loss spectra between the two techniques, we observe that the same discrete set of relaxation times unifies the description of both mechanical and dielectric data. Each of the discrete relaxation processes exhibits its own temperature dependence that is the same for mechanical and dielectric experiments, although the strength of the individual spectral components is different. The implications of the existence of discrete relaxation spectrum for developing theory of amorphous materials will be discussed.
Rigid Amorphous Phase in Polymer Nanocomposites as Revealed by Dielectric Relaxation Spectroscopy and Fast Scanning Calorimetry

Paulina Szymoniak (Presenter), Andreas Schoenhalts, Bundesanstalt für Materialforschung und -prüfung, Berlin, Germany — For inorganic/polymer nanocomposites a so-called Rigid Amorphous Phase (RAF) is formed in the interfacial region by adsorption of polymer segments onto the nanoparticles. The segmental dynamics of RAF is expected to be altered, as compared to the pure matrix, which might percolate into the entire system, affecting the overall nanocomposite properties. A combination of two relaxation spectroscopy techniques (Broadband Dielectric Spectroscopy (BDS) and Specific Heat Spectroscopy (SHS)), as well as Fast Scanning Calorimetry (FSC) was employed to investigate the structure and molecular mobility of nanocomposites based on Epoxy and Layered Doubled Hydroxides.

First, BDS investigations proved the existence of a process, which is present only for nanocomposites, assigned to the dynamics of polymer segments within RAF. Second, the amount of RAF was quantified by analyzing the change of specific heat capacity step of nanocomposites, comparing to the pure material.

Thirdly, the glass transition of nanocomposites was studied with FSC, applying high heating rates (500-10 000 K/s). Considering that all techniques probe the same molecular process, an activation plot was constructed, delivering a complete picture of the molecular mobility and structure of the polymer nanocomposites including RAF.

Network dynamics in hydrogen-bonding telechelic polymers: associate lifetime, structural relaxation and phase separation

Martin Tress (Presenter), Kun Yue Xing, Department of Chemistry, University of Tennessee, Knoxville, Peng-fei Cao, Chemical Sciences Division, Oak Ridge National Laboratory, Shi Wang Cheng, Department of Chemical Engineering and Material Science, Michigan State University, Tomonori Saito, Chemical Sciences Division, Oak Ridge National Laboratory, Vladimir Novikov, Alexei P Sokolov, Department of Chemistry, University of Tennessee, Knoxville — Supra-molecular networks formed by reversible bonds between polymer chains exhibit extraordinary properties, e.g. extreme toughness and elongation at break, self-healing. We study short telechelic polymers with different H-bonding end-groups and backbone flexibility [1]. The H-bonds increase the glass transition temperature (Tg), though in flexible polydimethyl siloxanes (PDMS) it does not vary with H-bond strength whereas in much stiffer telechelic polypropylene glycol (PPG) Tg varies significantly. In contrast, viscosity strongly depends on the H-bond strength in PDMS while it remains similar in PPG. Complementary measurements of shear modulus and dielectric relaxation indicate that this can be explained by competing lifetimes of the supra-molecular associations and the chain relaxation. Only if the former exceeds the latter, viscosity increases. Furthermore, the viscoelastic properties can be enhanced tremendously by phase separating ends, controlled primarily by Tg of the aggregations. Our analysis reveals that the concept of bond lifetime renormalization [2] describes the results qualitatively but fails on a quantitative level.

Dynamics of freeze-dried proteins embedded in organic glasses revealed by broadband dielectric spectroscopy

Simone Capaccioli (Presenter), Physics, University of Pisa, Maria Pachetti, Physics, University of Trieste, Gaia Ciampalini, Physics, University of Pisa, KIA L. Ngai, Elpidio Tombari, IPCF-CNR Pisa, Alessandro Paciaroni, Physics, University of Perugia — We present extensive broadband dielectric spectroscopy (BDS) studies of dynamics in freeze-dried, de-hydrated, binary mixtures of proteins and excipients. The latter have been selected among hydrogen bonding glass-formers, with different viscosity and molecular mass, spanning more than 150 K in glass transition temperatures Tg. Apart from interfacial relaxation and Maxwell-Wagner polarization effects we found the ubiquitous presence of three relaxation processes: one has a Vogel-Fulcher-Tamman temperature behavior, it is strongly influenced by the type of solvent and it share the same timescale of the process, revealed by calorimetry, bringing the system to vitrify; the other two processes are faster and active also in the glassy state. The intermediate process shows activated dynamics independent on the excipient but it appearing to evolve on ageing.

Combining BDS data with calorimetry and neutron scattering experiments a complex scenario emerges, where some dynamic processes of proteins appear to be coupled to solvent dynamics in the range from ns to ks, as predicted also for faster dynamics by the “slaving” assumption, but other processes seem to have a more peculiar behavior. In particular, their dynamics is not suppressed in the glassy state of freeze-dried proteins.
10:00AM A55.00009: Hard versus soft confinement effects on molecular dynamics of 4-hexyl-4′-isothiocyanatobiphenyl liquid crystals* MALGORZATA JASIUKOWSKA-DELAPORE (Presenter), TOMASZ ROZWADOWSKI, Department of Soft Matter Research, The Henryk Niewodniczanski Institute of Nuclear Physics, Polish Academy of Sciences, ANNA BARANOWSKA-KORCZYC, Faculty of Chemistry, University of Warsaw, EWA EWA JUSZYNSKA-GALAZKA, MARIA MASSALSKA-ARODZ, Department of Soft Matter Research, The Henryk Niewodniczanski Institute of Nuclear Physics, Polish Academy of Sciences — The purpose of this work is to examine the dynamic properties of 4-hexyl-4′-isothiocyanatobiphenyl (6BT) experiencing different forms of confinement. Hard confinement was achieved by the infiltration of LCs into nanoporous aluminium oxide (AAO) templates with non-intersecting, cylindrical, channels. Soft confinement derived from the interactions between polymer and guest liquid crystalline molecules was investigated on an example of electrospun polymer/liquid crystal composite fibres. We prepared composite fibres for three different mass ratios of polycaprolactone (PCL) and 6BT. The formation of liquid crystalline domains in fibres was confirmed by polarizing microscope observations and their distribution was illustrated by Raman. The intra-molecular interactions in composite fibres were revealed by analysis of the temperature dependencies of specific infrared (IR) absorption bands. By a combination of broadband dielectric spectroscopy with the other spectroscopic methods, the microscopic picture of role of soft and hard confinement on molecular dynamics and a crystallization process in liquid crystals is obtained.

10:12AM A55.00010: On the Fragility of Hydroxypropyl Methylcellulose as Measured via Broadband Dielectric Spectroscopy WILLIAM WOODWARD (Presenter), MICHAEL LESNIAK, TIRTHA CHATTERJEE, KEVIN O’DONNELL, ROBERT SAMMLER, TRAVIS MCINTIRE, YONGFU LI, MARK RICKARD, DAVE MEUNIER, Dow Chemical Company — A special class of hydroxypropyl methylcellulose polymer (HPMC) has been developed for the production of amorphous solid dispersions of active pharmaceutical ingredients by hot-melt extrusion. This has produced the opportunity to acquire frequency-dependent Tg measurements of HPMC via broadband dielectric spectroscopy (BDS). Our study revealed that the fragility (m) of this polymer is very low (m = 16.9 ± 0.4). Although the measurements herein are limited to this type of HPMC, it is hypothesized that this low fragility is not unique to this particular grade of HPMC.

10:24AM A55.00011: Role of α and β relaxations in Collapsing Dynamics of a Polymer Chain in Supercooled Glass-forming Liquid MRINMOY MUKHERJEE (Presenter), JAGANNATH MONDAL, SMARAJIT KARMAKAR, Tata Institute of Fundamental Research Hyderabad — Understanding the effect of glassy dynamics on the stability of bio-macromolecules and investigating the underlying relaxation processes governing degradation processes of these macromolecules are of immense importance in the context of bio-preservation. In this work we have studied the stability of a model polymer chain in a supercooled glass-forming liquid at different amount of supercooling in order to understand how the dynamics of supercooled liquids influence the collapse behavior of the polymer. Our systematic computer simulation studies find that apart from long time relaxation processes (α relaxation), short time dynamics of the supercooled liquid, known as β relaxation plays very important role in controlling the stability of the model polymer. These observations are in stark contrast with the common belief that only long time relaxation processes are the sole players (vitrification hypothesis). We also show that anti-plasticizing effect found in this context can be rationalized using the β-relaxation process. We believe that our results will lead to understand the primary factors in protein stabilization in the context of bio-preservation.

10:36AM A55.00012: Insights into the role of dynamic heterogeneity in reorientational and translational dynamic measurements from simulations in the isoconfigurational ensemble* DANIEL MAURICIO DIAZ VELA (Presenter), Polymer Engineering, The University of Akron, DAVID SIMMONS, Chemical and Biomedical Engineering, University of South Florida — A major question in the study of the glass transition over the last 50 years has been the origin of stretched exponential relaxation and its connection to the observations of non-Gaussian dynamics and decoupling phenomena such as Stokes-Einstein breakdown. The proposition that these phenomena all emerge from averaging over spatial dynamic heterogeneity has emerged as a major view of the common origin of these phenomena. However, significant questions remain, such as the frequent observation that stretching exponents obtained from dielectric spectroscopy commonly do not exhibit the pronounced temperature dependence expected to accompany growing dynamic heterogeneity on cooling. Here we employ molecular dynamic simulations of glass-forming dimers and bead-spring polymers in the isoconfigurational ensemble to quantify the extent to which each of these phenomena emerge from spatial averaging vs locally anomalous dynamics. Results point to important differences between the role of dynamic heterogeneity in reorientational and translational dynamic quantities such as those measured by dielectric spectroscopy and neutron scattering respectively.

*This material is based in part on work supported by the National Science Foundation NSF Career Award grant number DMR1554920.
Recently we reported [1] that the super-Arrhenian temperature dependence of the relaxation time for 21 molecular glass formers is quantitatively described by a single-parameter model based on the excess enthalpy, where the excess entropy based model of the Adam-Gibbs form fails to describe the data. For these molecular glass formers the liquid/crystalline enthalpy/entropy were obtained by straightforward integration of the heat capacity data, where excess enthalpy/entropy was obtained by subtracting the crystalline value from the liquid value and the independently measured heat of fusion fixes the value of integration constant. For polymeric glass formers the crystalline values are unavailable; consequently, the glassy heat capacity was used in place of the crystalline heat capacity to obtain the configurational (vs. excess) enthalpy/entropy, and the glassy PVT surface is used to determine these quantities at elevated pressures. We show that the resulting configurational enthalpy model describes the mobility data for 12 amorphous polymers, including both the temperature and pressure dependence of the relaxation time above Tg. The configurational entropy model in the Adam-Gibbs form fails to describe the mobility data.

**8:48AM A56.00003: Discovering the genes mediating the interactions between chronic respiratory diseases in the human interactome**

ENRICO MAIORINO (Presenter), Harvard Medical School, ALBERT-LASZLO BARABASI, Northeastern University, SCOTT WEISS, BENJAMIN A. RABY, AMITABH SHARMA, Harvard Medical School — Biological networks are powerful resources for the discovery of potential candidate genes and for the investigation of the mechanisms underlying human complex disease like asthma and chronic obstructive pulmonary disease (COPD). Recent network-based computational studies have shown that disease genes encoding proteins have a strong tendency to interact with each other and to agglomerate in specific ‘disease modules’ identified as connected localized neighborhoods in the network [1]. In this scenario, perturbations originating within one disease module can diffuse through the network and affect other close diseases [2].

Recognizing the genes mediating such perturbations is crucial for understanding the biological pathways responsible for the comorbidity of similar diseases such as asthma and COPD. In this work, we identify the topological modules of these two diseases in the protein-protein interaction network and determine their mediators by defining a variant of betweenness centrality measure, called ‘flow centrality’. The biological role of the observed flow central genes sheds light on the hypothesized common genetic origin of asthma and COPD [3].

**9:00AM A56.00004: The New Field of Network Physiology: Mapping the Human Physiolome**

PLAMEN IVANOV (Presenter), XIYUN ZHANG, FABRIZIO LOMBARDI, Physics Department, Boston University — The human organism is an integrated network where complex physiological systems continuously interact to optimize and coordinate their function. Organ-to-organ interactions occur at multiple levels and spatiotemporal scales to produce distinct physiologic states. Disrupting organ communications can lead to dysfunction of individual systems or to collapse of the entire organism. Yet, we do not know the nature of interactions among systems and sub-systems, and their collective role as a network in maintaining health. The new field of Network Physiology aims to address these fundamental questions.

Through the prism of concepts and approaches from statistical and computational physics and nonlinear dynamics, we will present a new framework to identify and quantify dynamic networks of organ interactions. We will demonstrate how physiologic network topology and systems connectivity lead to integrated global behaviors representative of distinct states and functions.

The presented investigations are initial steps in building a first Atlas of dynamic interactions among organ systems and the Human Physiolome, a new kind of BigData of blue-print reference maps that uniquely represent physiologic states and functions under health and disease.

*We acknowledge support from W M Keck Foundation.

**9:12AM A56.00005: Complex statistical interactions in biology**

ISTVAN KOVACS (Presenter), ALBERT BARABASI, Department of Physics, Northeastern University — Although each individual carries dozens of deleterious mutations, each of which should have a dramatic impact on our health, life carries on due to extensive genetic buffering. Therefore, interpreting genetic information requires the understanding of not only the impact of individual mutations but also their interactions. Genetic interactions occur when the combined impact of two mutations results in an unexpected phenotype, for example a positive interaction in the case of genetic buffering. Negative interactions are even more striking, such as synthetic lethality, where two individually mild mutations lead to cell death. Understanding and predicting (even higher order) genetic interactions is a key to better understand complex traits, missing heritability and genetic buffering in humans. In the talk we will overview the major sources of data and recently developed statistical methods to analyze and predict it. Our results enable us to better understand the emergence of biological function under both healthy and pathological conditions and directly contribute to improved disease module identification, drug target prediction, and drug combination design.

Reconstructing model humans from observed health data*  SPENCER FARRELL (Presenter), ANDREW RUTENBERG, Dalhousie University — Human aging can be understood as a stochastic process of damage accumulation. This stochasticity is evident in the heterogeneity of health trajectories and lifespans of individuals. Measurements of health “deficits” can be used to quantify an individual's state of health. We model human aging using a network of interacting health deficits with stochastic damage/repair. Our model incorporates both “observed” nodes, corresponding to observed deficits, and “hidden” nodes, representing the large amount of health aspects that are not measured. We use maximum likelihood techniques to estimate parameters with observed human data of deficits and death ages. We then generate individuals from our model using these estimated parameters, so that they have health trajectories distributed approximately the same as the data. This lets us extrapolate from observed data to future health trajectories and lifespans.

Emergence of Laplace-Distributed Growth Rates in Network Dynamics  CHIA-HUNG YANG (Presenter), Network Science Institute, Northeastern University, SEAN CORNELIUS, Center of Complex Network Research, Northeastern University — The dynamical state of a complex network is rarely stationary in time, often exhibiting sufficiently erratic fluctuations so as to seem random. Previous observational studies on annual fish catches, flock sizes of migrating birds, and company sales have revealed that the growth rates follow a Laplace (double exponential) distribution, which is characterized by a higher probability of large increases/decreases relative to the Gaussian growth statistics predicted by typical null models. Yet despite the prevalence of Laplacian growth rates in disparate systems, their mechanistic origin has remained elusive. Here we show that Laplacian growth statistics emerge generically from the interplay between two ubiquitous features in real complex systems — multistability and noise. Under specific conditions, these factors combine to allow frequent transitions between the underlying attraction basins, which broadens tails of the growth distribution relative to that produced by a random walk. Our results suggests that “boom and bust” behavior may be the rule rather than the exception in networks with nonlinear dynamics, with implications for problems ranging from sustainable ecosystem management to financial system stability.

Spreading dynamics of forget-remember mechanism*  SHENGFENG DENG (Presenter), Department of Physics, Virginia Tech, WEI LI, College of Physical Science and Technology, Central China Normal University — We study extensively the forget-remember mechanism (FRM) for message spreading, originally introduced in [Eur. Phys. J. B 62, 247 (2008)]. The freedom of specifying forget-remember functions governing the FRM can enrich the spreading dynamics to a very large extent. The master equation is derived for describing the FRM dynamics. By applying the mean field techniques, we have shown how the steady states can be reached under certain conditions, which agrees well with the Monte Carlo simulations. The distributions of forget and remember times can be explicitly given when the forget-remember functions take linear or exponential forms, which might shed some light on understanding the temporal nature of diseases like flu. For time-dependent FRM there is an epidemic threshold related to the FRM parameters. We have proven that the mean field critical transmissibility for the SIS model and the critical transmissibility for the SIR model are the lower and the the upper bounds of the critical transmissibility for the FRM model, respectively.

Measuring and Modeling the Flow of Information Online and on Networks*  JAMES BAGROW (Presenter), University of Vermont, LEWIS MITCHELL, University of Adelaide — We propose a model for the flow of information in the form of symbolic data. Nodes in a graph representing, e.g., a social network take turns generating words, leading to a symbolic time series associated with each node. Information propagates over the graph via a quoting mechanism, where nodes randomly copy short symbolic sequences from each other. We characterize information flows from these data via information-theoretic estimators, and we derive analytic relationships between model parameters and the values of these estimators. We explore and validate the model with simulations on small network motifs and larger random graphs. Tractable models such as ours that generate symbolic data while controlling the information flow allow us to test and compare measures of information flow applicable to realistic data. In particular, by choosing different network structures, we can develop test scenarios to determine whether or not measures of information flow can distinguish between true and spurious interactions, and how topological network properties relate to information flow.

Complex contagion and network structure*  
JULIAN KATES-HARBECK (Presenter), MICHAEL DESAI, Physics, Harvard University — Social networks provide the grounds for the spread of physical infections, ideas, memes, behaviors, or opinions. Socially spreading information and ideas can represent "complex contagions" where, in contrast to physical infections, the probability of the contagion spreading to a new individual on the network need not be a linear function of the fraction of affected neighbors. Here we explore the relationship between complex contagions and the underlying structure of interaction networks, and show that nonlinear adoption produces qualitatively novel spreading behaviors that are strongly affected by network structure. In particular, we demonstrate the effects of network sparsity, community structure, and degree distributions on the contagion. Finally, we demonstrate that complex contagions can undergo a phase transition where sufficiently cohesive community structures and sufficiently sparse networks can allow for global epidemics even for very large networks.

Scale-free Networks Well Done*  
IVAN VOITALOV (Presenter), PIM VAN DER HOORN, Department of Physics and Network Science Institute, Northeastern University, REMCO VAN DER HOFSTAD, Department of Mathematics and Computer Science, Eindhoven University of Technology, DMITRI KRIOUKOV, Department of Physics, Department of Mathematics, Department of Electrical and Computer Engineering, and Network Science Institute, Northeastern University — We bring rigor to the vibrant activity of detecting power laws in empirical degree distributions in real networks. We first provide rigorous definitions of scale-free and power-law distributions, the latter equivalent to the definition of regularly varying distributions in statistics. These definitions allow the distribution to deviate from a pure power law arbitrarily but without affecting the power-law tail exponent. We then identify three estimators of these exponents that are proven to be statistically consistent - that is, converging to the true exponent value for any regularly varying distribution - and that satisfy some additional niceness requirements. Finally, we apply these estimators to a representative collection of synthetic and real data to find that real scale-free networks are definitely not as rare as one would conclude based on the popular but unrealistic assumption that real data comes from power laws of pristine purity, void of noise and deviations.

Network architecture of energy landscapes in mesoscopic quantum systems  
ABIGAIL N. POTESHMAN, EVANGELIA PAPADOPOULOS (Presenter), University of Pennsylvania, EVELYN M TANG, Max Planck Institute for Dynamics and Self-Organization, DANIELLE BASSETT, LEE BASSETT, University of Pennsylvania — Mesoscopic quantum systems exhibit complex many-body phenomena. Even simple, non-interacting theories display a rich landscape of energy states, where many-particle configurations are linked by spin- and energy-dependent transition rates. This collective energy landscape is difficult to characterize, especially in regimes of frustration. Here, we use network science to quantify the organization of these state transitions. Using a computational model of electronic transport through quantum antidots, we construct networks where nodes represent energy states and edges represent allowed transitions. We explore how current and conductance, which measure transport, are reflected in the network topology in response to changes in external voltages. We find that the state-transition networks exhibit Rentian scaling, which is characteristic of efficient computer and neural circuitry, and which measures the interconnection complexity of a network. Remarkably, networks corresponding to points of frustration in transport exhibit enhanced complexity relative to networks not experiencing frustration. Our results demonstrate that network-based analyses can capture salient properties of quantum transport, and motivate future efforts using network science to understand complex quantum systems.
8:00AM A57.00001: Ab initio molecular dynamics, machine learning and complex liquids* [Invited] ROBERTO CAR (Presenter), Princeton University — Using liquid water as an example I will show that deep neural networks allow us to greatly accelerate ab-initio molecular dynamics simulations without loss of accuracy. The approach naturally leads to models with different levels of coarse-graining both for the electronic ground-state and the atomic structure information. The basic procedure was outlined in two recent papers [1,2].

8:36AM A57.00002: A viscoelastic hydrodynamic theory of density fluctuations in liquids ZHIKUN CAI (Presenter), YANG ZHANG, University of Illinois at Urbana-Champaign — Long-wavelength longitudinal phonons can propagate in liquids, but whether transverse phonons exist in liquids has been long debated. Moreover, according to the classic hydrodynamic theory, it was believed that the transverse modes have no causal relation to the density fluctuations. However, these points of view are challenged by the recent data measured in the generalized hydrodynamic regime from computer simulations and scattering experiments. Hence, in this work, a viscoelastic hydrodynamic approach is proposed to describe the density fluctuations of supercooled liquids in the generalized hydrodynamic regime. Based on the generalization of the Navier-Stokes stress-strain constitutive relation, viscoelastic temporal response and spatial anisotropic effect are integrated into the framework of the hydrodynamic theory using a time-dependent relaxation tensor. As a result, it is found that liquids may exhibit either transverse excitations or transverse kinetic relaxations, depending on specific viscoelastic responses. Moreover, it is demonstrated that anisotropy naturally leads to a hybrid contribution of longitudinal dynamics and transverse dynamics to the density and current correlation functions.

8:48AM A57.00003: Study of the Correlated Molecular Dynamics in D₂O using Inelastic Neutron Scattering* YADU KRISHNAN SARATHCHANDRAN (Presenter), University of Tennessee, YUYA SHINOHARA, WOJCIECH DMOWSKI, University of Tennessee/Oak Ridge National Laboratory, DOUGLAS L ABERNATHY, Oak Ridge National Laboratory, TAKESHI EGAMI, University of Tennessee/Oak Ridge National Laboratory — We report the real-space correlated molecular dynamics in heavy water (D₂O). Dynamic structure factor, S(Q, E), obtained from high-resolution inelastic neutron scattering data over large Q (momentum transfer) and E (energy transfer) is double-Fourier transformed to obtain the Van Hove function, which is a time-dependent pair-correlation function. A two-step relaxation is observed in the intermolecular dynamics of D₂O. Its relaxation time and amplitude depends on the temperature. By comparing the results with classical MD simulations of D₂O and inelastic x-ray scattering measurements of H₂O[1][2], correlated dynamics of water molecules in ps time-scale is discussed.

9:00AM A57.00004: Elucidating the role of vapor-liquid interfaces on ice nucleation SARWAR HUSSAIN (Presenter), AMIR HAJI-AKBARI, Chemical and Environmental Engineering, Yale Univ — Vapor-liquid interfaces are known to accelerate heterogeneous ice nucleation at their vicinity, in a phenomenon known as contact freezing [1]. Their impact on homogeneous nucleation, however, is more ambiguous, as the experimental evidence for surface freezing [2], or enhancement of homogeneous nucleation at free interfaces, is not conclusive. Computational investigations of surface freezing also predict conflicting qualitative behaviors for different water models [3-4]. It has, however, been suggested that contact and surface freezing are related, as if a free interface can enhance heterogeneous nucleation, it must also have the same effect on homogeneous nucleation. In this work, we use forward-flux sampling [5] to explore this relationship, and observe that tetrahedral liquids undergoing surface freezing will also exhibit accelerated heterogenous nucleation kinetics when the crystal-nucleating agent is very close to the free interface. We attribute this finding to instabilities induced at a free interface due to the proximity of the nucleating surface.

9:12AM A57.00005: Transient Structured Fluctuations in a 2D Liquid* ZACH KREBS, ARI ROITMAN, LINSEY NOWACK (Presenter), CHRISTOPHER M LIEPOLD, BINHUA LIN, STUART A RICE, University of Chicago — Using the Aperture Cross Correlation Function as diagnostic, we find the existence of transient structured fluctuations in the liquid phase of a two-dimensional system with a repulsive, core-softened pair potential [1]. This system supports several hexagonal solid phases, a square solid phase, liquid and hexatic phases, and a quasi-crystalline phase with 12-fold symmetry. Our computer simulations suggest the surprising results that deep within the liquid region and approaching transition boundaries, the structured fluctuations favor only the same symmetries supported in the ordered phases of the system, i.e. three-fold, four-fold, and twelve-fold. To our knowledge, no theory to date suggests why such a system would not display local fluctuations of other symmetries well within the liquid phase.

9:24AM A57.00006: A new scenario describing `water-like` thermodynamic anomalies - the double liquid-liquid critical point scenario* DOMAGOJ FIJAN (Presenter), MARK WILSON, Department of Chemistry, University of Oxford — Thermodynamic `water-like` anomalies in liquids have been a long unsolved problem in terms of origin and implications for nature of the liquid (and other similar states). The widely accepted thermodynamic scenario that describes this behaviour in water models and Stillinger-Weber (SW) potential silicon is the second (liquid-liquid) critical point (LLCP) scenario. In this work we present simulation evidence for a novel scenario in wide range of SW liquids. In this scenario the locus of liquid density anomalies (the density minimum and maximum) encloses a region of thermodynamic space with two liquid-liquid critical points connected by a first order transition. We scan the parameter space of the SW potential (tetrahedrality and ideal bond angle parameter) and observe limiting instances where density anomalies disappear. We observe the interactions of density anomaly with the compressibility anomaly, heat capacity anomaly and spinodal line and confirm they show thermodynamically consistent behaviour.

9:36AM A57.00007: Molecular Dynamics Simulations for Optical Kerr Effect of Liquid and Supercooled Water* TENG-MING WU (Presenter), Inst. of Physics, National Chiao Tung University — The optical Kerr effect (OKE) spectroscopy measured with heterodyne detection (HD) is a useful tool to provide information regarding intermolecular vibrations and structural relaxations in liquid water. Recently, the measurements of the OKE spectroscopy have been extended to supercooled water [1]. Though the measured results can be well described by using a phenomenological model, the time-resolved OKE spectroscopy of liquid and supercooled water still need a comprehensive understanding. In this paper, we investigated the OKE nuclear response functions for a novel scenario in wide range of SW liquids. In this scenario the locus of liquid density anomalies (the density minimum and maximum) encloses a region of thermodynamic space with two liquid-liquid critical points connected by a first order transition. We scan the parameter space of the SW potential (tetrahedrality and ideal bond angle parameter) and observe limiting instances where density anomalies disappear. We observe the interactions of density anomaly with the compressibility anomaly, heat capacity anomaly and spinodal line and confirm they show thermodynamically consistent behaviour.

9:48AM A57.00008: Systematic investigations of Infrared spectra of liquid water by first-principles methods JIANHANG XU (Presenter), MOHAN CHEN, XIFAN WU, Temple University — The infrared spectroscopy (IR) is a powerful experimental technique to probe the dynamic dipole fluctuations of water molecules, which are strongly correlated through the H-bond network of liquid water. Here, we compute the infrared spectra of liquid water based on ab initio molecular dynamics simulations by using maximally localized Wannier functions as basis, in which both the generalized gradient approximations (GGA) level exchange-correlation (XC) functional and meta-GGA level strongly constrained and appropriately normed (SCAN) XC functionals are employed. For comparison, the vibration frequencies of the water vapor are computed as well. Our theoretical studies show that the theoretical predictions of spectral features are systematically improved by better liquid water structural predictions through the more physical description of H-bond strengths as well as the capture of intermediate range van der Waals interactions by the SCAN meta-GGA functional.
Emergence of local slow dynamics of water molecules induced by sodium chloride* YUYA SHINOHARA (Presenter), WOJCIECH DMOWSKI, University of Tennessee, Knoxville, TAKUYA IWASHITA, Oita University, DAISUKE ISHIKAWA, JASRI/SPring-8, ALFRED Q R BARON, RIKEN, TAKESHI EGAMI, University of Tennessee, Knoxville — We report on the real-space correlated motion of water molecules in sodium chloride aqueous solution. Measurements of high-resolution inelastic X-ray scattering spectra, \( S(Q, E) \), over wide energy transfer (\( E \)) and momentum transfer (\( Q \)) enabled us to determine the Van Hove function, \( G(R, t) \), by Fourier transform of \( S(Q, E) \) over \( Q \) and \( E \). The results show that the addition of sodium chloride induces the emergence of a slow decay component at the first neighbor peak in the Van Hove function. The intensity of the slow decay and that of the fast decay are proportional and inversely proportional to the salt molality, respectively, whereas their decay time is independent of the molality. This indicates that the slowed correlated dynamics of water molecules is localized in the hydrated shell around ions whereas the dynamics of bulk water is not influenced by the salt.

Session A58 GSOFT: Self-Assembly I

8:00AM A58.00001: Bundling of Rod-Like Colloids via Depletion Forces* JONATHAN ADAMS (Presenter), HENDRICK W DE HAAN, Modelling and Computational Science, University of Ontario Institute of Technology — Self assembly of rod-like colloids in to bundles can be driven by entropic processes. We use Coarse Grained Molecular Dynamics simulations to investigate using depletion forces to induce bundling in a suspension of rod-like colloids. The colloids are approximated as bead-spring polymers, with persistence lengths much larger than the length of the polymer. Depletion forces are an effective attractive force between colloids due to the presence of particles significantly smaller than the colloids, called depletants. Depletion forces are modelled as an implicit entropic force between colloids. Bundling begins to occur when the occupied volume fraction occupied by depletants is above a critical value. This volume fraction is dependent on the length and stiffness of the rod-like colloids. We investigate using this property to induce bundling only in rods above a certain length or certain persistence length.

8:12AM A58.00002: Self Assembly of Colloidal Polymers Using Isotropic Potentials DEBAPRIYA BANERJEE (Presenter), BETH A LINDQUIST, RYAN B JADRICH, THOMAS TRUSKETT, University of Texas at Austin — Self-assembly of spherical colloids into fluidic chains with no directional bonding or external perturbation promises to be a facile approach to engineer “designer” materials for enhanced surface transport, catalysis, optics, etc. Employing an Inverse Design technique (Relative Entropy optimization), we discern radially-symmetric pair potentials that result in the formation of fluidic, single-stranded, polydisperse colloidal strings (“colloidomers”). Comparing these potentials with those that form size-selective, compact, isotropic colloidal clusters, we find that the ranges of attraction (\( \delta_A \)) and repulsion (\( \delta_B \)) between the two are distinctly different. The energetics combined with the ranges determine the resulting structural motifs. A simple universal potential form is proposed whose morphological phase diagram predicts a gamut of microstructures as a function of \( \delta_A \) and \( \delta_B \) at fixed energetics and packing fraction. Four main broad classes of structures are observed - (i) dispersed monomeric fluid, (ii) ergodic, short chains as well as porous, space-spanning, one-monomer diameter thick, percolated strings, (iii) clusters and (iv) thick cylindrical structures including the tri-helical Bernal spirals.
Encapsulation of circular DNA and non-organic particles inside virus-Like DNA origami icosahedrons.  

S. ALI AGHVAMI (Presenter), Physics, Brandeis University, CHRISTIAN SIGL, ELENA MARIE WILLNER, HENDRIK DIETZ, Physics, Technical University of Munich, SETH FRADEN, Physics, Brandeis University — The principle of quasi-equivalence, announced by Caspar and Klug in 1962, articulates how icosahedral viruses can be constructed using a minimal number of distinct sub-units. Following this scheme, we used DNA origami to construct 5MDa monomers of 3-fold symmetry, which interact through base stacking and shape complementarity and self-assemble into icosahedrons. We encapsulated cargo by functionalizing the interior facing portion of the monomers with single stranded DNA that was complementary to strands on cargo. Two categories of cargo were utilized. The first type of cargo were gold colloids, which were functionalized with complementary ssDNA to the monomers. These colloids were smaller than a monomer and did not bridge between monomers. The second type of cargo was 2.5 MDa circular ssDNA, which could bridge between monomers. The assembly yield was studied as a function of the monomer concentration, interaction strength, and amount of encapsulated cargo.

Nucleation rate in a heterogeneous quartic system

SARAH DAWSON (Presenter), ANCHANG SHI, McMaster University — The nucleation of a stable phase from a metastable phase is studied using the string method applied to a model Ginzburg-Landau system with a quartic potential. A temperature-like parameter is varied in order to move the system between its binodal and spinodal points. A heterogeneity is added to the system in the form of a wedge-shaped substrate. The effect of the heterogeneity on the nucleation barrier height is obtained from the string method. The results are compared with those of the classical nucleation theory. Our results highlight the value of the string method, as well as the validity and limitations of the classical theory.

Light controlled crystallization of DNA coated particles

ETIENNE DUCROT (Presenter), New York University, ILJA VOETS, Eindhoven University of Technology, DAVID J PINE, New York University — DNA coatings have been proposed and successfully applied as a versatile tool for programming the self-assembly of micrometer size particles into numerous crystalline structures. The DNA-mediated interaction is highly temperature dependent. For given buffer conditions, a set of complementary DNA-coated particles present a melting temperature Tmelt that marks the transition between aggregated and melted states. Without a change of environment, one has no further control over Tmelt and a local control of the interaction is challenging.

Here we present a strategy that uses the combination of DNA coatings and an azobenzene photo-switch to access fine control of the interaction between particles, independently from temperature. Azobenzenes reversibly switch between trans and cis conformations, an exposure to UV or blue light shifts the population towards the cis or trans respectively. Once attached to the backbone of a DNA sticky-end, the flat trans form can intercalate in the double helix and stabilize the duplex. On the contrary the kinked cis azobenzene disrupts the hybridization. We harvest this molecular behavior to modulate the melting temperature of DNA-coated particles, pattern their melting or aggregation, correct defects on the crystals and switch between crystal structures.

Exploring nucleation pathways and solid-solid transitions in two-dimensional binary colloidal crystallization

HUANG FANG (Presenter), STEFAN PAQUAY, MICHAEL F HAGAN, WILLIAM B ROGERS, Brandeis University — Crystals are prevalent in many natural and manmade systems, including metals, minerals, proteins, and colloids. Although the crystal structures themselves are often well understood, the microscopic pathways by which crystals form are difficult to observe or predict. We use a combination of simulations and microscopy experiments to investigate the crystallization pathways of DNA-coated colloids. We observe a rich diversity of behaviors, including one-step and two-step nucleation pathways, as well as a spontaneous solid-solid phase transition during the crystallization of two-dimensional binary mixtures. In this talk, I will present the results of free energy calculations which indicate that the two-step nucleation transition arises from a competition between the free-energy landscapes of two different structures. I will also explore the possibility that the critical size governing this transition can be tuned by changing the relative strengths of interactions. These results may help shed light on fundamental aspects of nucleation, as well as provide new methods for controlling the self-assembly of materials made from colloids.

Entropy Driven Assembly of Truncated Colloidal Tetrahedra into Diamond Lattice

ZHE GONG (Presenter), STEFANO SACANNA, New York University — Building blocks with non-trivial shape are thought to bear invaluable information that largely determines both pathway and final product in self-assembly system. Packing of polyhedra leads to a large diversity of hierarchical structures, among which tetrahedra with various degrees of truncation have been of particular interest due to its unique symmetry. However, the experimental realization of colloidal tetrahedra remains challenging. Here for the first time, surface tension assisted by geometric constraints is used to synthesize truncated colloidal tetrahedra via colloidal fusion, with high size and morphology regularity. The entropy driven assembly of truncated tetrahedral particles was carefully studied via depletion interaction and sedimentation. In both cases, particles exhibit strong face-to-face contact tendency induced by directional entropic force, leading to hexagonal and cubic diamond structures. This study provides information about shape-structure relationship in the packing of truncated tetrahedra, and may further enhance the understanding of crystallization of diamond and its stacking hybrid.

Stochastic Yield Catastrophes and Robustness in Self-Assembly

FLORIAN M GARTNER, ISABELLA R GRAF (Presenter), PATRICK WILKE, PHILIPP M GEIGER, ERWIN FREY, Ludwig Maximilian University of Munich — A guiding principle in macromolecular self-assembly is that, for high production yield, nucleation of structures must be significantly slower than their growth. However, details of the mechanism that impedes nucleation are broadly considered irrelevant. Here, we analyze a generic stochastic model for self-assembly into finite-sized target structures, and investigate two key scenarios to delay nucleation: (i) by introducing a slow activation step for the assembling constituents and, (ii) by decreasing the dimerization rate. These scenarios have widely different characteristics. While the dimerization scenario exhibits robust behavior even in the limit of small particle numbers, the activation scenario is highly sensitive to stochastic effects, which can completely suppress yield. Our results reveal that stochasticity is an important limiting factor for self-assembling systems and, in general, details of the nucleation process play a significant role for the final yield.

Measuring crystal nucleation and growth of DNA-grafted colloidal particles

ALEXANDER HENSLEY (Presenter), WILLIAM B ROGERS, Brandeis University — Grafting DNA onto microscopic colloidal particles can `program' them with information that tells them how to self-assemble into a variety of interesting crystal structures. However, the dynamic pathways by which these crystals self-assemble are largely unknown. In this talk I will present progress on an experimental study of the nucleation and growth of colloidal crystals due to DNA hybridization. Specifically, I will describe a microfluidics-based approach in which we produce hundreds of monodisperse, isolated droplets filled with colloidal particles and then track the formation of crystals within each drop as a function of time. We find that the initial nucleation of crystals from a supersaturated solution involves overcoming a free-energy barrier, and that the height of this barrier decreases dramatically with decreasing temperature. We also find that once nucleated, the crystals grow at a rate that is limited by the diffusive flux of colloidal particles to the growing crystal surface. These findings may help us to devise strategies to tune the nucleation rates and crystal growth kinetics independently, which will be helpful as we try to engineer higher quality or more complex self-assembled structures.

Measuring crystal nucleation and growth of DNA-grafted colloidal particles*

ALEXANDER HENSLEY (Presenter), WILLIAM B ROGERS, Brandeis University — Grafting DNA onto microscopic colloidal particles can `program' them with information that tells them how to self-assemble into a variety of interesting crystal structures. However, the dynamic pathways by which these crystals self-assemble are largely unknown. Nanoparticle superlattice self-assembly via interpolymer complexation

NATHAN HORST (Presenter), ALEX TRAVESSET, Iowa State University — Controlled self-assembly of nanoparticles into ordered structures is an auspicious strategy for fabricating novel devices in nanotechnology. As the number of successful strategies for synthesis increases, emphasis shifts to those that are general, versatile, inexpensive and scalable. To this end, nanoparticle superlattices formed via interpolymer complexation offer a promising route towards a stable, usable class of materials. Understanding the interactions that drive these systems to equilibrium is a primary goal of the theoretical and computational community, as we develop models that capture the configurational characteristics of the system and ultimately predict experimental results. Making use of molecular dynamics simulations, we present our efforts towards understanding nanoparticle superlattices created via interpolymer complexation.

10:00AM A58.00011: Aqueous Electrostatic Colloidal Crystallization  THEODORE HUECKEL (Presenter), New York University, JEREMIE PALACCI, Physics, University of California, San Diego, STEFANO SACANNA, New York University — The complementarity demonstrated by atomic ions is an effective strategy to form a range of complex structures from relatively simple building blocks. Due to van der Waals forces, however, mixtures of oppositely charged colloids in water only form disordered aggregates. Consequently, formulating sets of complementary particles has required intensive surface chemistry, despite the availability of these naturally charged starting materials. Here we employ a straightforward technique to stabilize and tune the bonds between oppositely charged colloids to promote ordered self-assembly. After introducing surfactants that can reliably hold particles physically separated, the long-range electrostatic attraction is tuned via charge screening until particles spontaneously crystallize. Single crystals on the centimeter scale are produced in solution that become permanently fixed when introduced to deionized conditions, after which they become robust enough to survive drying for SEM analysis and further processing.

10:12AM A58.00012: Understand Janus particle assembly assisted by surface active molecules*  SHAN JIANG (Presenter), AYUNA TSYRENOVA, KYLE MILLER, MUHAMMAD FAROOQ, JARED ANDERSON, Iowa State University — Janus particles assemble into remarkable superstructures due to different chemistry on the two sides of a single particle. The directional interactions between particles can lead to clusters, chains and stripes, which present new structures and physics of colloidal systems. However, how Janus particles assemble in the presence of surface active molecules has not been systematically studied. On the contrary, most of the previous studies have focused on purified Janus particles in the absence of surface active species. In our experiment, surface active molecules have drastically changed the assembly behavior of Janus particles. Using real time imaging and particle tracking algorithm, we studied the dynamics the Janus particles. We also observed intriguing new crystal structures with highly correlated orientation formed by amphiphilic Janus particles assembled with ionic liquid molecules.

10:24AM A58.00013: Phase behavior of hard colloidal bipyramid family  YEIN LIM (Presenter), SANGMIN LEE, SHARON GLOTZER, Chemical Engineering, University of Michigan — Colloidal particles with bipyramidal shape are experimentally obtainable today, and some of them are known to self-assemble into highly complex crystals such as clathrates and quasicrystals by maximizing face-to-face alignment, e.g. via DNA-programmable assembly or via entropy maximization. We present a study of the effect of shape variation on the self-assembly of hard bipyramids using Monte Carlo simulation. We report the phase behavior as a function of the number of vertices in the base polygon and the aspect ratio. From geometric and thermodynamic analysis, we identified over 10 different crystalline structures with varying complexity and symmetry. Our results offer guidance to experiments by providing information about entropically driven self-assembly in the bipyramidal shape family.

10:36AM A58.00014: Crosslinking 2D gold nanoparticle assembly at the air-water interface*  BINHUA LIN (Presenter), IREM KOSIF, University of Massachusetts, Amherst, SIHENG YOU, Harvard University, MRINAL K BERA, University of Chicago, BRIAN LEATHY, Harvard University, TODD EMRICK, University of Massachusetts, Amherst, KA YEE C LEE, University of Chicago — We report the results of crosslinking of two-dimensional gold nanoparticle (Au-NP) assemblies at the air-water interface in situ. We introduce an aqueous soluble ruthenium benzylidene catalyst into the water subphase to generate a robust, elastic two-dimensional network of nanoparticles containing cyclic olefins in their ligand framework. The most striking feature of the crosslinked Au-NP assemblies is that the extended connectivity of the nanoparticles enables the film to preserve much of its integrity under compression and expansion, features that are absent in its non-crosslinked counterparts. The crosslinking process appears to “stitch” the nanoparticle crystalline domains together, allowing the crosslinked monolayers to behave like a piece of fabric under lateral compression.

10:48AM A58.00001: Linker-mediated binding of DNA-grafted colloids: how competition affects phase behavior*
JANNA LOWENSOHN (Presenter), Physics, Brandeis University, BERNARDO OYARZÚN, Physics, Université Libre de Bruxelles, GUILLERMO NARVAEZ PALIZA, Physics, Brandeis University, BORTOLO MATTEO MOGNETTI, Physics, Université Libre de Bruxelles, WILLIAM B ROGERS, Physics, Brandeis University — DNA is a promising tool for programming the self-assembly of new materials: its interactions are chemically specific, tunable, and predictable. In principle, DNA can be grafted to colloids to favor the formation of a predetermined aperiodic structure. In this talk, I promote linker-mediated binding of DNA-coated colloids as an experimental system that could create these hundreds of specific interactions in practice. Here, DNA-coated particles interact through DNA linker strands dissolved in solution. Using optical microscopy, we study the melting transition of our linker system as a function of linker concentration, grafting density, and DNA sequences. We find a phase diagram different from that of directly hybridizing DNA-coated colloids, featuring a reentrant melting transition at high linker concentrations and a region of stable coexistence between solid and fluid. We also examine how the introduction of hundreds of competing linker strands might affect linker-mediated interactions and show that the system can accommodate many interacting linkers simultaneously. These results show the tunability and capacity of our linker-mediated system, and demonstrate how it might expand the design space for aperiodic and adaptive structures.

Session A59 GSOFT GSNP: Rheology and Flow of Particulate Matter I

8:00AM A59.00001: Toward General Rheological Models of Dry and Fluid-Saturated Granular Media [Invited] KEN KAMRIN (Presenter), Mechanical Engineering, Massachusetts Inst of Tech-MIT — Dry and fluid-saturated granular media display multiple modeling challenges from a continuum perspective. Foremost is the search for quantitative and robust constitutive models, in order to robustly predict the flow and stress fields in a flowing body. However, a major challenge is also to find methods to implement these theories in non-trivial geometries up to huge deformations. Methods able to do this are needed not just to implement models in realistic settings of practical interest, but also to test the versatility and correctness of any proposed model, especially models that employ higher-order effects. In this talk we will discuss various continuum modeling approaches for dry and for fluid-saturated granular media. We will also present two numerical techniques for running these models in general geometries. Key challenges on the modeling front include the importance (or lack thereof) of grain size, the various influences of an interstitial fluid phase, and modeling the granular “phase transition” between solid-like, dense-flowing, and disconnected gas-like regions of material.

8:36AM A59.00002: Continuum modeling of flow and size-segregation in dense, bidisperse granular mixtures*
DAREN LIU, DAVID HENANN (Presenter), Brown University — Dense granular systems, consisting of particles of disparate sizes, segregate based on size during flow, resulting in complex, coupled segregation and flow patterns. In this talk, we study size-segregation in three dense granular flow configurations: (1) gravity-driven flow down a long vertical chute with rough parallel walls, (2) annular shear flow with rough inner and outer walls, and (3) planar shear flow with gravity. We perform two-dimensional discrete element method (DEM) simulations of flow of dense, bidisperse granular systems in all three configurations, while varying system parameters, such as the flow rate, flow configuration size, fraction of large/small grains, and grain-size ratio, and we study the effects of these parameters on the segregation dynamics. Our simulations inform continuum constitutive equations for both the size-segregation flux as well as the diffusion flux. When coupled with the nonlocal granular fluidity model - a nonlocal continuum model for dense granular flow - we show that both the flow field and segregation dynamics may be simultaneously captured using this closed, coupled, continuum system of equations.

Near-contact dynamics of a sphere-wall collision in a viscous medium

SUMIT KUMAR BIRWA (Presenter), International Centre for Theoretical Sciences, Bangalore, NARAYANAN MENON, Physics, University of Massachusetts Amherst, RAMA GOVINDARAJAN, International Centre for Theoretical Sciences, Bangalore — As a sphere falling under gravity through a viscous medium approaches a wall, there is a large increase in the pressure in the thin layer of fluid being squeezed out between the sphere and wall. At low enough Stokes number, this leads to settling, and above a threshold Stokes number, the sphere bounces. Our earlier experiments have shown that even near this threshold, bouncing involves direct mechanical contact with the bottom plate [SK Birwa et al., Physical Review Fluids, 3(4), 044302, (2018)]. This is in contradiction with lubrication theory (LT) which says that the pressure diverges in the fluid and contact is not made in finite time. To study this difference, we conduct experiments to measure optically and interferometrically the dynamics of a sphere until the micrometer scale preceding the normal collision. The sphere is found to be decelerating slower than predicted by LT. We present an attempt to go beyond LT by accounting for the inertial terms neglected while making the boundary layer approximation, and by defining an appropriate non-orthogonal coordinate system. We obtain a single parametric differential equation which provides us with the time-evolution of the velocity profiles at different radii.

Normal Stresses in Steady-State and Transient Frictional Granular Flows

ISHAN SRIVASTAVA (Presenter), JEREMY LECHMAN, GARY GREST, Sandia National Laboratories, LEONARDO SILBERT, School of Math, Science and Engineering, Central New Mexico Community College — Steady flow of sheared frictional granular matter is well-described by a plastic yield criterion along with a rate-dependent viscoplastic rheology. However, existing constitutive formulations focus exclusively on steady-state simple shear rheology. Using stress-controlled discrete element simulations, we highlight that normal stresses are crucial in the rheology of granular matter, both in steady flow above yield stress and transient creep flow below yield stress. The evolution of shear and normal stress components with strain rate is described in terms of friction-dependent viscometric flow functions, and the effect of friction on the directionality of stress and strain rate tensors is assessed. Additionally, correlations between the evolution of bulk stress tensor and granular fabric—both in transient and steady-state flows—are also described. These results provide important inputs toward formulating rheological constitutive equations that predict stresses during arbitrary deformations of frictional granular matter.

Dynamics of the granular fluidity field

SEONGMIN KIM (Presenter), School of Engineering and Applied Sciences, Harvard University, KEN KAMRIN, Department of Mechanical Engineering, Massachusetts Institute of Technology — A collection of densely-packed solid grains such as sand, rice, and sugar can flow like liquids. A key issue for dense granular flows is rheology: what is the relation between stress and strain rate? The mu(I) rheology postulates a local rheology for steady-state inertial flows. Modified from the local rheology, the non-local granular fluidity (NGF) model has been proposed to explain non-local phenomena due to finite grain size. In the NGF model, an order parameter called ‘granular fluidity’ diffuses away following a partial differential equation in a form of the reaction-diffusion equation. This PDE, however, has only been verified in steady-states. Using the discrete element method, we observe dynamics of the order parameter in different configurations and verify the PDE of the NGF model in transient states.

Fluid-driven transport of spherical sediment particles: from discrete simulations to continuum modeling

QIONG ZHANG (Presenter), KEN KAMRIN, Massachusetts Institute of Technology — Empirical bedload transport expressions commonly over- or underpredict sediment flux by more than a factor of two, even under controlled laboratory conditions. In this work, the discrete element method and lattice boltzmann method are coupled together to simulate 3D fluid-driven transport problems of spherical particles. After comparisons with flume experiments are made to test the numerical simulations, the grain-scale physics is studied, such as the flow field around individual particles and higher order descriptions of the granular motion. A more robust continuum model, unifying empirical models under various conditions and in different regimes, is further proposed based on the new grain-scale understanding of the mechanisms.
Dynamics of ultrasonically levitated granular rafts

MELODY LIM (Presenter), University of Chicago, ANTON A SOUSLOV, Physics, University of Bath, VINCENZO VITELLI, HEINRICH M JAEGGER, University of Chicago — Macroscopic particles in an acoustic trap can self-assemble into close-packed granular rafts consisting of hundreds of particles. These rafts are formed and stabilised due to a sonic depletion force mediated by scattering, which establishes short-range attractions between the constituent particles [1]. We show that this cohesive granular material displays fluid-like behaviour, forming circular “granular droplets” with an emergent surface tension and viscosity. These droplets interact with the acoustic field, inducing forces and torques that drive the droplets to merge, deform, and break-up. We focus on a rotational instability that provides a persistent torque to objects moving in the acoustic field. As the angular momentum of a granular droplet is increased, it deforms from a circle to an ellipse, eventually pinching off into two separate droplets. We use hydrodynamic models for rotating liquid drops to describe the granular dynamics and extract the droplet surface tension.

Material stability and localization in the nonlocal granular fluidity model for dense granular flow∗

SHIHONG LI (Presenter), Brown University — A common and successful continuum model for steady, dense granular flows is the inertial rheology. Recent work has shown that under certain conditions, the inertial rheology displays a linear instability in which short wavelength perturbations grow at an unbounded rate - i.e., a Hadamard instability. This observation indicates that the inertial rheology is capable of describing strain localization; however, it also raises concerns regarding the robustness of numerical solutions. It has been shown that the inclusion of higher-order velocity gradients into the rheology can suppress the Hadamard instability, while not precluding the modeling of strain localization into diffuse shear bands. In this talk, we consider the nonlocal granular fluidity (NGF) model - which also involves higher-order flow gradients and has been shown to quantitatively describe a wide variety of steady, dense flows - and show that the NGF model successfully regularizes the Hadamard instability of the inertial rheology. We further apply the NGF model to the problem of strain localization in quasi-static plane-strain compression using nonlinear finite-element simulations in order to demonstrate that the model is capable of describing diffuse strain localization in a mesh-independent manner.

*NSF-CBET-1552556

Suspension clogging fronts in a leaky pipe

JEREMY S. YODH (Presenter), Department of Physics, Harvard University, L MAHADEVAN, SEAS, Physics, OEB, Harvard University — A particle suspension flowing through a leaky microfluidic channel forms clogs that propagate backwards against the incident flow direction indefinitely. We study the speed and shape of clogs in such situations and show how we can control them. Further, we show that the particulate order in the clog can be controlled by tuning the geometry of the leaky walls. Time permitting, the implications of this for flow through parallel channels will also be addressed.

On the reversibility of granular rotations and translations∗

ANTON PESHKOV (Presenter), IREAP, University of Maryland, College Park, MICHELLE GIRVAN, Departments of Physics, IPST and IREAP, University of Maryland, College Park, DEREK C. RICHARDSON, Department of Astronomy, University of Maryland, College Park, WOLFGANG LOSERT, Departments of Physics, IPST and IREAP, University of Maryland, College Park — We analyze reversibility of both displacements and rotations of spherical grains in three-dimensional compression experiments. Using transparent acrylic beads with cylindrical holes and index matching techniques, we are not only capable of tracking displacements but also, for the first time, analyze reversibility of rotations. We observe that for moderate compression amplitudes, up to the bead diameter, the translational displacements of the beads after each cycle become mostly reversible after an initial transient. By contrast, granular rotations are largely irreversible. We find a weak correlation between translational and rotational displacements, indicating that rotational reversibility depends on more subtle changes in contact distributions and contact forces between grains compared with displacement reversibility.

10:24AM A59.00011: Drag and interactions of rigid bodies moving through submerged granular beds

BENJAMIN ALLEN (Presenter), RAUSAN JEWEL, ARSHAD KUDROLLI, Clark University — We discuss experimental investigation of the forces encountered by a rod moving through a fluid-saturated granular medium to understand the dynamics of intruders and organisms in sedimentary beds at the bottom of lakes and oceans. By dragging vertically oriented rods through a granular bed of glass spheres, immersed in a fluid, we probe the observed transition from a quasi-static granular-like response to a viscous fluid-like behavior of the medium with speed. The relative importance of inertia, gravitational, and viscous forces is probed in terms of the dimensionless Stokes number, inertial number, and viscous number by varying the rod speed, rod depth, rod diameter, and the viscosity of the fluid. We find that the measured drag is best scaled with the integrated hydrostatic pressure along the rod and the Stokes number at low drag speeds corresponding to the quasi-static region. The transition between the quasi-static and fluid behavior scales with the viscous number, which is the ratio of viscous stress and gravity. We further discuss the interaction of two intruders as a function of the distance of separation compared with their diameter and length.

*Supported by NSF-CBET 1805398.

10:36AM A59.00012: Transition to Steady State in Sheared Dense Granular Materials

HAN-HSIN LIN (Presenter), MELANY HUNT, Caltech — Jamming and shear-thinning are interesting, time-dependent behaviors found in granular materials; however, most prior research has focused on the steady-state behavior under different shear rates. We study the transition phenomenon from unsteady to steady state by using a Couette cell and controlling the torque and speed of the inner cylinder. When controlling the torque, the system cannot reach a steady state when it is below a critical stress. When controlling the speed of the boundary, the shear stress at the wall increases slowly over a period of time that depends on the initial state of the bed, wall friction, shear rate, and flow along the free surface. At steady state, the stress decreases at the highest rotation speeds. Simulations show a recirculation cell driven by gravity and the free surface, which results in the increasing stress observed in the measurements. The effective friction of the inner wall matters. When using the smooth cylinder, the system needs more time to reach a steady state than using the rough cylinder. At steady state, its wall stress decreases more significantly at the highest rotation speeds compared to the rough cylinder.

High thermoelectric performance, or ZT, necessarily depends on achieving the contradictory combination of low thermal conductivity $\kappa$ and high electrical conductivity (along with a large Seebeck coefficient). However, for ultralow $\kappa$ materials (defined here as $\kappa < 1$ W/m-K at 300 K) the electrical conductivity requirement is proportionally reduced. There may therefore exist a new opportunity for such materials in the thermoelectric arena. Examples of such materials are Tl$_3$VSe$_4$ [1], AgBiSe$_2$ [2], and SnSe [3].

However, there are several scientific issues that must resolved prior to usage of any of these materials in an actual application. Ultralow $\kappa$ materials tend to occur near to a ferroelectric transition or other structural instability, due primarily to the large anharmonicity near such an instability. This usually renders materials such as PbTe [4,5,6] unsuitable for device applications due to unfavorable mechanical properties. Is proximity to a structural instability a necessary condition for ultralow $\kappa$? Similarly, another ultralow $\kappa$ route to high ZT is the use of mobile cations, such as Cu in Cu$_2$Se [7], which presents another hurdle for device applications. Can one create a robust thermoelectric device using a material with a structural instability, or mobile structural disorder, in the operating temperature range? The author will discuss these issues.

Energy supply by fossil fuels only has a limited lifetime and is responsible for an increasing environmental pollution, influencing also climate change. A rapid transition to more sustainable solutions is thus also in the focus of modern research. Renewable fuels are meant to circumvent supply fluctuations arising from energy sources like PV and wind, at the cost of infrastructural adaptations. Direct renewable energy storage is thus highly desirable, but expansive and complicated.

Herein, we report an earth-abundant polymeric material, which for the first time enables the synergistic coupling of two key functions of energy conversion within one single material: visible light harvesting and electrochemical energy storage. The “solar battery” anode material, a 2D cyanamide-functionalized polyheptazine imide (NCN-PHI), is the first of its kind being capable of storing large amounts of photogenerated electrons, operating even in aqueous conditions. Charge compensation and stabilization is realized by pseudocapacitive effects enabled by various aqueous alkali metal ions. Energetically, this occurs at energies well above the reversible hydrogen electrode, allowing for stable aqueous batteries with increased cell voltages.

Limitations arise from low conductivity and hole shuttling to a suitable cathode material. We herein present approaches that address these issues and present our work on hybrid material solutions for full aqueous solar batteries. As such, we aim to provide a sustainable and cheap, earth abundant solution to overcome the intermittency of solar irradiation and other renewable electrical energy sources at a time.

Power generation from direct conversion of infrared radiation from a thermal source.*

PAUL DAVIDS (Presenter), JOSHUA SHANK, JARED KIRSCH, ANDREW STARBUCK, ROBERT JARECKI, DAVID PETERS, Sandia National Laboratories — In this talk, we will describe a new photo-thermoelectric conversion device that consists of a large-area nanoantenna-coupled metal-oxide-silicon (MOS) tunnel diode that directly converts infrared radiation into electrical power. This infrared photonic device needs only view a moderate temperature thermal source to generate a direct photocurrent. A resonant photonic frequency selective surface and a polar oxide material with longitudinal optical phonon resonance are arranged to spectrally overlap and enhance transverse field confinement in an extreme sub-wavelength MOS tunnel barrier. The enhanced field confinement is shown to drive photon-assisted tunneling resulting in large infrared photocurrent in the room temperature device. The measurement of photon-assisted tunneling photocurrent across a matched load impedance is shown to arise due to direct rectification of infrared radiation and a new radiative micropower supply will be described.

*Funding for this work was provided by Sandia's Laboratory Directed Research and Development (LDRD) program. Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, a wholly owned subsidiary of Honeywell International Inc., for the United States Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

Advanced Materials for Energy Storage*

GEORGE CRABTREE (Presenter), Joint Center for Energy Storage Research (JCESR) — Batteries are central to fundamental changes in transportation through electric vehicles, in the electricity grid through renewable energy integration, replacement of natural gas peaker plants and customized electricity service, and in electric flight through drones, air taxis, package delivery and short-haul passenger service. Next generation batteries to meet these diverse applications require new high-performance materials for anodes, cathodes, electrolytes and interfaces. Using new approaches for simulation and characterization at the atomic and molecular level, these materials can now be designed from the bottom up, atom-by-atom and molecule-by-molecule, where each atom or molecule plays a prescribed role in producing targeted overall materials behavior. Examples will be given for advanced materials for several beyond-lithium-ion batteries.

*This talk is supported by the Joint Center for Energy Storage Research (JCESR), an Energy Innovation Hub funded by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences (BES).

Session A61 GSOFT GSNP: Nonequilibrium Statistical Mechanics of Driven Systems and Pattern Formation I

Phase Coexistence in a 2D System of Granular Self-propelled Particles*

ZHEJUN SHEN (Presenter), NARAYANAN MENON, University of Massachusetts Amherst — We study a system of vibrated self-propelled granular particles on a horizontal plate within a circular boundary covered by an acrylic top. The particles are square and designed to have polar activity along one body diagonal. With fixed particle size, we find that the activity of particles (quantified by the persistence length of motion along the mobility direction) can be controlled by varying the gap between top cover and bottom base. We then study the phase behaviour of the particles as the total number of particles in the system is varied. For a fixed value of activity, particles are uniformly distributed in the system at low density. As the density is increased, particles separate into a high-density ordered region at the boundary of the system, while the remaining particles remain uniformly distributed in the in the central area. Thus the system shows phase coexistence between a mobile, liquid phase and a dense, low-mobility ordered phase.

**8:12AM A61.00002: Calculation of Critical Nucleation Rates by the Persistent Embryo Method: Application to Quasi Hard Sphere Models**

SHANG REN (Presenter), Department of Physics and Astronomy, Iowa State University, YANG SUN, FENG ZHANG, Ames Laboratory, ALEX TRAVESSET, Department of Physics and Astronomy, Iowa State University, CAI-ZHUANG WANG, Ames Laboratory, KAI-MING HO, Department of Physics and Astronomy, Iowa State University — We study crystal nucleation of the Weeks-Chandler-Andersen (WCA) model, using the recently introduced Persistent Embryo Method (PEM). The method provides detailed characterization of pre-critical, critical and post-critical nuclei, as well as nucleation rates that compare favorably with those obtained using other methods (umbrella sampling, forward flux sampling or seeding). We further map our results to a hard sphere model allowing to compare with other existing predictions. Implications for experiments are also discussed.

*Work at Ames Laboratory was supported by the US Department of Energy, Basic Energy Sciences, Materials Science and Engineering Division, under Contract No. DE-AC02-07CH11358, including a grant of computer time at the National Energy Research Supercomputing Center (NERSC) in Berkeley, CA. The Laboratory Directed Research and Development (LDRD) program of Ames Laboratory supported the use of GPU-accelerated computing.

**8:24AM A61.00003: Magnetotactic bacteria droplets: a controllable motor**

BENOIT VINCENTI (Presenter), PMMH Laboratory - ESPCI Paris, GABRIEL RAMOS, MARIA-LUISA CORDERO, Departamento de Física, FCFM - Universidad de Chile, CARINE DOUARCHE, Laboratoire de Physique des Solides - Université Paris-Sud, RODRIGO B SOTO, Departamento de Física, FCFM - Universidad de Chile, ERIC CLEMENT, PMMH Laboratory - ESPCI Paris — We confine magnetotactic bacteria in spherical droplets suspended in oil. The application of a uniform and constant magnetic field induces a focusing of the bacteria at the North and South poles of the droplets due to both alignment with the magnetic field and confinement by the droplet curvature. The focusing of the bacteria at these particular points can eventually create a vortex when the bacteria are densely packed. The spatial characteristics of the vortex flow are extracted with PIV analysis. The dependences of the vortex flow with respect to the magnetic field strength and the droplets radii are quantitatively analyzed and correlated to the flow created outside the droplet by the collective rotation of bacteria. The outstanding applications allowed by such a system are finally discussed in terms of energy harvesting.

**8:36AM A61.00004: Boosted Annealing of Colloidal Monolayers using Active Dopants**

SOPHIE RAMANANARIVO (Presenter), University of California, San Diego, ETIENNE DUCROT, Department of Physics, NYU, JEREMIE PALACCI, University of California, San Diego — Active particles are microscopic particles, which can inject energy locally and made available by recent progress in colloidal science. They are ideal “pump-probes” to explore the emergent properties in non-equilibrium soft systems and control the behavior of soft matter and self-assembly at the microscale.

In this talk, we will demonstrate how active particles added to a material to regulates its activity internally and boost the annealing of a colloidal monolayer. It opens a broad range of novel opportunities to thermal treatments, where the properties of matter are not controlled macroscopically but microscopically and in real time by active dopants.

*This material is based upon work supported by the National Science Foundation under Grant No. DMR-1554724. J.P. thanks the Sloan Foundation for support through grant FG-2017-9392. **8:48AM A61.00005: Rectification in non-equilibrium gyroscopic networks**

ZHENGHAN LIAO (Presenter), WILLIAM T. M. IRVINE, SURIYANARAYANAN VAIKUNTANATHAN, University of Chicago — One of the goals of molecular engineering is to find design principles for rectification in microscopic conditions, which could lead to the fabrication microscopic motors. Past studies have successfully achieved rectifications in few-body or terminal systems, however, the extension to many-body system is not straightforward. We study energy rectification in a many-body model that combines the active bath and the gyroscopic metamaterials, and numerically and theoretically show that spontaneous heat rectification is achieved at the steady state. We then focus on understanding two issues: the mechanism of this rectification, and the relationship between the network geometry and the flow pattern. Given the knowledge of chiral eigenmodes in isolated gyroscopic networks, the rectification mechanism can be understood as a result of the weighted excitation of these modes. By expanding the heat flux as a summation over paths in the weak interaction regime, we can understand the flow pattern in a complex network from simple paths, which in turn enables us to control the rectification by the design of the network geometry.
Characterizing elusive correlation lengths by computable information density

**STEFANO MARTINIANI (Presenter), Center for Soft Matter Research, New York University, YUVAL LEMBERG, Physics, Technion - IIT, PAUL M CHAIKIN, Center for Soft Matter Research, New York University, DOV LEVINE, Physics, Technion - IIT** — The analysis of computable information density (CID) has recently been introduced as a general approach to quantifying order in equilibrium and non-equilibrium many-body systems, both discrete and continuous, even when the underlying form of order is unknown. The approach has been shown to reliably identify phase transitions, determine their character, and to quantitatively predict certain dynamical critical exponents without prior knowledge of the order parameters. A natural question is whether CID may also inform us on the existence of diverging correlation lengths, and their exponents, in the proximity of phase transitions. We study the CID flow under a renormalization group transformation, and show how this can be exploited to extract correlation lengths and their critical exponents without knowledge of the system's specific correlation functions. To demonstrate the greater generality of the approach, we consider a system for which a simple analysis based on pair-correlation functions cannot detect the diverging correlation length. Hence, with this work, we introduce a new approach for the identification of elusive correlation lengths.

Surfactant effect on collective dynamics of surface-associated bacterial particles

**MINGFEI ZHAO (Presenter), XIN YONG, Binghamton University** — Bacteria exhibit collective behavior on moist agar surface to expand and acquire new territories. Self-produced surfactant could entail a significant surface activity due to the reduction of the interfacial friction between moving bacteria and substrates. The bacteria density determines surfactant concentration, so that surface motility will vary locally. The contribution of the density-dependent motility to the collective behavior of bacteria communities remains unclear. We use a discrete self-propelled particle model to simulate an ensemble of rod-like bacteria without the background fluids. The self-propulsion speed is coupled with the local surfactant concentration, solved by a diffusion equation that describes the surfactant production and transport. Simulations between constant self-propulsion speeds will serve as the comparison to test the influence of surfactant. Our investigation will provide a deep understanding of how surfactant influence the collective behavior of bacteria, and further inspire new designs of active materials.

Transverse Temperature Interfaces in the Katz-Lebowitz-Spohn Driven Lattice Gas

**RUSLAN MUKHAMADIAROV (Presenter), PRIYANKA , UWE CLAUS TAUBER, Virginia Tech** — We explore the intriguing spatial patterns that emerge in a two-temperature Katz-Lebowitz-Spohn (KLS) model in two dimensions, a driven lattice gas with attractive nearest-neighbor interactions and periodic boundary conditions. The domain is split into two regions with hopping rates governed by different temperatures $T > T_c$ and $T_c$, respectively, where $T_c$ indicates the critical temperature for phase ordering, and with the temperature boundaries oriented transverse to the drive. In the hotter region, the system behaves like the (totally) asymmetric exclusion processes (T)ASEP, and experiences particle blockage in front of the interface to the critical region. We argue that transport in the subsystem is impeded by the lower current in the cooler region, which tends to set the global stationary particle current value. We observe the density profiles in both high-and low-temperature subsystems to be strikingly similar to the well-characterized coexistence and maximal-current phases in (T)ASEP models with open boundary conditions. If the lower temperature is set equal to $T_c$, we instead detect the corresponding critical power law density decay.

Dynamical fine-tuning to external forcing in disordered networks of bistable springs

**HRIDESH KEDIA (Presenter), DENG PAN, JEREMY L ENGLAND, Physics, Massachusetts Institute of Technology** — A driven many-body system can absorb energy from an external drive quite differently depending on the system’s internal configuration. Thus, the nonequilibrium exploration of configuration space can be strongly biased by the matching between external drive and system response properties. We demonstrate such emergent, adaptive fine-tuning in simulations of an externally forced, disordered mechanical network of bistable springs under a variety of driving conditions.

9:48AM A61.00010: Ordering and Synchronization in Driven Systems  PRASHANT SHARMA (Presenter), Suffolk University — Active matter systems display a rich phenomenology of ordered phases and dynamic pattern formation that can be described by models of self-propelled particles with interactions. We introduce a class of models relevant for studying magnetic nanoparticles (and magnetotactic bacteria) in a fluid at low Reynolds number, and explore the different ordered structures observed in these models and their relevance to experimental systems. We analyze the stability of the ordered structures using ideas of stochastic thermodynamics and discuss how this approach solves the problem of general stability analysis of non-stationary ordered states of active matter.

10:00AM A61.00011: Chemical oscillators on star graphs, theory and experiment*  MICHAEL NORTON (Presenter), NATHAN D P TOMPKINS, BAPTISTE BLANC, MATTHEW CAMBRIA, JESSE HELD, SETH FRADEN, Brandeis University — Oscillator networks represent a large class of physical systems in both the natural and engineered worlds. Here we present experimental data for chemical oscillators on star graphs with inhibitory coupling. We examine dynamics as a function of star-degree (number of nodes coupled to a central hub) and coupling strength. We control both by loading a water-in-oil Belousov-Zhabotinsky emulsion (drops ∼100μm) into etched-Si wafer wells. We observed three dynamical attractors: (1) a phase locked state in which the arm-nodes form a synchronized cluster, (2) center-silent dynamics in which the hub well is inhibited by the arm nodes and (3) unlocked dynamics. We developed theory at two levels: a chemically realistic discrete reaction-diffusion model and a phase model; we found excellent agreement to experiment. In particular, in the locked state, we find non-trivial dependence of the locking angle between the arm nodes and the hub as a function of star degree. Finally, we demonstrate that the system can be dynamically reconfigured through photo-inhibition of targeted drops.

10:12AM A61.00012: Control of a microfluidic three-ring chemical oscillator network*  MARIA ELENI MOUSTAKA (Presenter), MICHAEL NORTON, CHRIS SIMONETTI, SETH FRADEN, Brandeis University — Inspired by the collective behavior and synchronization patterns, which are a common phenomenon in nature, our work focuses on studying the non-linear dynamics of microfluidic networks of Belousov-Zhabotinsky (BZ) chemical oscillators. In our experiments, the auto-catalytic, light-sensitive, BZ reaction is confined to micro-fabricated wells constructed from the elastomer PDMS. Using soft lithography, PDMS networks are arranged into wells with controlled topology. Each well can be regarded as a single network node that sends and receives inhibitory signals. We are particularly interested in the dynamics of a 3-node ring network. This network exhibits spontaneous chiral behavior. In theory, control over the chirality can be achieved by exploiting the light sensitivity of the BZ catalyst, which can modulate the frequency of a node. In experiment, we perturb the network by changing the light intensity and duration in each of the three BZ wells. This technique provides a model of gait switching in central pattern generators and a dynamic method of information storage.

10:24AM A61.00013: Minimal Model for an Energy Cascades in Driven Nonequilibrium Systems*  GURAM GOGIA (Presenter), JUSTIN BURTON, Emory University — Complex systems that are fed energy at their constituent-level frequently exhibit self-organizational and emergent properties. The external driving can be periodic, but more commonly it comes in the form of noise. Here we show how a spatially extended layer of charged particles exhibits intermittent switching between crystalline and gas-like states. The particles are driven by individual charge fluctuations which feed energy into one vibrational degree of freedom. A small amount of disorder leads to recurrent energy cascades (melting) in the system. Using normal mode analysis, we show that the fraction of vertical vibrational modes with low participation ratio determine the response of the system to the noisy driving. We propose a minimal model of the transfer of the kinetic energy between vertical and horizontal degrees of freedom using modified Lotka-Volterra equations. The model reproduces all of the salient features of the energy cascades observed in the experiment and simulation. Similar to the Reynolds number in fluid flow, we characterize a dimensionless number that is the ratio of the energy input and dissipation. Intermittent energy cascades are observed for a narrow range of this number, in striking resemblance to transition to turbulence in pipe flow.

10:36AM A61.00014: Thermodynamic Efficiency in Dissipative Chemical/Supramolecular Processes*  EMANUELE PENOCCHIO (Presenter), RICCARDO RAO, MASSIMILIANO ESPOSITO, University of Luxembourg — Out-of-equilibrium chemistry is not anymore a prerogative of nature. In recent years, fuel-driven self-assembly became a paradigmatic example of how chemists were able to access the realm of nonequilibrium processes. In the meantime, theoretical physicists achieved a deep understanding of these phenomena, which resulted in rigorous formulations of nonequilibrium thermodynamics for chemical systems. In this work, we crossbreed experimental and theoretical cutting edge research by building a quantitative thermodynamic description for two classes of chemical dissipative processes: energy storage and dissipative synthesis, which boast experimental examples in supramolecular chemistry. The former consists in storing chemical energy in the form of high-energy molecules, whereas the latter in synthesizing molecules by consuming fuel species. As nascent thermodynamics did for heat engines, we treat these systems as chemical engines and develop a quantitative framework for evaluating their efficiency. In doing so, we set the foundation for performance analysis of generic dissipative chemical processes.

8:00AM A62.00001: Inequivalence of the zero-momentum Limits of Transverse and Longitudinal Dielectric Response in the Cuprates*  [Invited]  CHANDAN SETTY (Presenter), BIKASH PADHI, KRIDSANAPHONG LIMTRAGOOL, ALI HUSAIN, MATTEO MITRANO, PETER ABBAMONTE, PHILIP PHILLIPS, Physics, University of Illinois at Urbana-Champaign — In this talk, I will address the question of the mismatch between the zero momentum limits of the transverse (optical conductivity) and longitudinal (momentum resolved EELS) dielectric functions observed in the cuprates. This question translates to whether or not the order in which the longitudinal and transverse momentum transfers are taken to zero commute. While the two limits commute for both isotropic and anisotropic Drude metals, I will argue that a scaleless vertex interaction is sufficient to achieve non-commutativity of the two limits even for a system that is inherently isotropic.

8:36AM A62.00002: Quasi-Continuous Mott Transition from a Spin Liquid to a Fermi Liquid at Low Temperatures  [Invited]  TETSUYA FURUKAWA (Presenter), Department of Applied Physics, Tokyo University of Science — For a long time, the Mott transition has been believed to be the first-order transition with a clear discontinuity at low temperatures, as shown by various experiments and the celebrated dynamical mean-field theory. Recent theoretical works, however, suggest that the transition can be continuous if the Mott insulator carries a spin liquid with a spinon Fermi surface[1,2]. Indeed, recent several experimental studies have suggested the existence of such spin liquids[3]; an organic triangular-lattice system κ-(ET)$_2$Cu$_2$(CN)$_3$ is one of the spin-liquid candidates with a spinon Fermi surface. In the present study, we demonstrate the case of a quasi-continuous Mott transition from a Fermi liquid to a spin liquid in κ-(ET)$_2$Cu$_2$(CN)$_3$[4]. We performed electric transport experiments under fine pressure tuning and found that as the Mott transition is approached, the Fermi-liquid coherence temperature continuously falls to the scale of kelvins, with a divergent quasi-particle decay rate on the metal side, and the charge gap gradually closes on the insulator side. A Clausius-Clapeyron analysis of the pressure-temperature phase diagram provides thermodynamic evidence for the extremely weak first-order nature of the Mott transition. These findings provide additional support for the existence of a spinon Fermi surface, which becomes an electron Fermi surface when charges are delocalized.

9:12AM A62.00003: Coherent Spin Excitations and Correlated Fermi Liquid in Genuine Mott Systems [invited] ANDREJ
PUSTOGOW (Presenter), 1. Physikalisches Institut, Universität Stuttgart — Recent success in determining the electronic
Correlation strength in Mott insulators by means of optical spectroscopy [1] enables a quantitative comparison among (i)
different materials and (ii) between experiment and theory. We identify frustrated molecular conductors as ideal
realizations of the single-band Hubbard model in contrast to transition-metal oxides with a more complicated band
structure, such as the charge-transfer insulator Herbertsmithite [2]. This finally allows us to selectively probe specific
regions in the unified phase diagram and unveil exotic phenomena in absence of magnetic order [1,3]. Deep in the
insulating state of a quantum spin liquid, coherent spin excitations show up in the optical conductivity when the charge
degrees of freedom are sufficiently suppressed within the Mott gap [3,4]. Turning to the correlated metallic state, we can
unambiguously identify the spectral features of coherent and bad-metallic transport. We observe a pronounced quadratic
temperature and frequency dependence of the scattering rate in the Fermi-liquid state. All data collapse on a generalized
energy scale in excellent agreement with the theoretical framework of Landau and Gurzhi from the 1950’s. We monitor the
effective mass enhancement as correlations increase and infer that the Fermi liquid retains its intrinsic properties towards
the Mott transition.

9:48AM A62.00004: A unified perspective on cuprates and layered organic superconductors* [invited] ANDRE-MARIE
TREMBLAY (Presenter), CHARLES-DAVID HÉBERT, Institut quantique, RQMP, Université de Sherbrooke, PATRICK SEMON,
Brookhaven National Laboratory — Layered organic superconductors of the BEDT family are model systems for
understanding the interplay of the Mott transition with magnetic order and frustration, ingredients that are essential to
understand superconductivity also in cuprate high-temperature superconductors. Cellular Dynamical Mean-Field Theory
yields a unified theoretical perspective on the corresponding phase diagrams containing superconducting,
antiferromagnetic and spin-liquid phases. In particular, the superconducting dome is tied to the Mott transition and its
continuation as a transition (Sordi transition) separating pseudogap phase from correlated metal in doped BEDT
compounds, as in the cuprates. Contrary to heavy fermions, the maximum of the dome is not attached to an
antiferromagnetic quantum critical point. The experimental superfluid stiffness shows highly non-BCS behavior that can
also be explained. A few experimental predictions follow. In particular, destroying superconductivity with a magnetic field
in the doped compounds should reveal the normal state transition between pseudogap and correlated metal.

Transistor* [invited] YOSHITAKA KAWASUGI (Presenter), RIKEN, KAZUHIRO SEKI, SISSA, JIANG PU, TAISHI TAKENOBU, Nagoya
University, SEIJI YUNOKI, RIKEN, HIROSHI YAMAMOTO, Institute for Molecular Science, REIZO KATO, RIKEN — Yoshitaka
Kawasugi: The electron correlation in solids, or the Mott physics, offers intriguing phenomena in materials such as
unconventional superconductivity. The key parameters for controlling the Mott physics are the electronic band filling and
bandwidth. However, the simultaneous control of these parameters has been lacking so far, leaving a comprehensive
phase diagram of correlated materials inaccessible. By combining electrostatic doping and bending-strain techniques, we
are able to control the band filling and bandwidth of an organic Mott insulator κ-(BEDT-TTF)2Cu[N(CN)2]Cl in a single
sample. As a result, doping-asymmetric ambipolar superconductivity has been observed in the proximity of the Mott
transition.

8:00AM A63.00001: The role of tolerance in the evolution of antibiotic resistance: from mathematical analysis to observations in the clinic* [invited] NATHALIE BALABAN (Presenter), Physics, Hebrew University of Jerusalem — The evolution of antibiotic resistance is a fascinating example of the versatility of bacterial evolution, as well as a burning health issue. Resistance mechanisms include efflux pumps that directly lower the intracellular drug concentration, mutations that reduce binding affinity of the drug to its target, enzymes that degrade the drug, etc. These mechanisms result in a decrease of the effective concentration of the antibiotic. However, bacteria were shown to be able to cope with antibiotic treatments that are supposed to kill them also using a different strategy termed "tolerance". Tolerant bacteria are not able to reduce the concentration of the antibiotic, but to make the duration of the treatment less effective. For example, bacteria that remain transiently dormant during the antibiotic treatment can survive because many different types of antibiotics require active growth to be able to kill. We developed a mathematical and experimental framework to characterize and measure the evolution of tolerance in vitro(1) and in vivo(2). By following the evolution of tolerance and resistance closely, we show that tolerance evolves fast and promotes the subsequent evolution of resistance.

Mathematical analysis of the way tolerance promotes the evolution of resistance reveals unexpected routes by which tolerance acts as a stepping stone for the subsequent evolution of resistance.

8:36AM A63.00002: Enzyme Evolution and Emergence of Novel Catalytic Functions ADITYA BALLAL (Presenter), Physics, Rutgers Univ, PAUL O'MAILLE, Stanford Research Institute, ALEXANDRE V MOROZOV, Physics, Rutgers Univ — Enzyme evolution underlies major expansions of metabolic complexity with profound biological implications. In this talk, I will discuss emergence of cyclization reactions catalyzed by terpene synthases. Cyclic terpenes mediate numerous biological functions in modern plants and provide bioactive compounds for human use, including artemisinin, the most effective treatment for malaria currently available. Guided by the available structural, kinetic, and sequence data, we have constructed mutant libraries which include combinations of amino acids responsible for inducing cyclization reactions in an enzyme that produces E beta-farnesene, a linear hydrocarbon chain. We have used measurements of kinetic rates and mass spectrometry in order to assess catalytic efficiency and specificity of the mutant enzymes. Inspired by spin glass models adapted from statistical physics, we have developed a model which predicts properties as a function of enzyme sequence. Using this model we have inferred evolutionary patterns of enzyme energetics. We have also developed a bio-physical model on fitness of an enzyme based on its catalytic properties. Our studies provide quantitative insights into evolutionary dynamics of a major enzyme family, and highlights the importance of epistasis.

8:48AM A63.00003: Nonlinear dispersal and growth change the phylogenetic structure of expanding populations GABRIEL BIRZU (Presenter), Physics, Boston University, OSKAR HALLATSCHEK, Physics and Integrative Biology, University of California, Berkeley, KIRILL KOROLEV, Physics, Boston University — Range expansions have shaped the evolutionary history of many organisms, from microbes to humans. Here, we study how the specifics of growth and dispersal affect the genealogical structure of expanding populations. The genealogical structure plays an important role in fixation of alleles, maintenance of genetic diversity, and genomic inference. Previous studies suggest that genealogies of expanding populations could be nontrivial because organisms at the expansion edge are expected to have an unusually large number of descendants. Indeed, we find these structures can be described by a family of Λ-coalescents, controlled by a single parameter: the ratio between the expansion velocity and the geometric mean of the dispersal and growth rates at low densities. For high values of this ratio, which occur when populations grow or disperse cooperatively, the genealogies are described by a Kingman coalescent. For low values—when the velocity is determined by growth and dispersal at the edge—we find a family of coalescents in which many lineages can merge simultaneously, including the Bolthausen-Sznitman coalescent at one end. These findings show that genealogies in expanding populations have a much richer structure than previously thought.
9:00AM A63.00004: Coevolution of multiple growth traits in microbial populations under serial dilution  JIE LIN (Presenter), School of Engineering and Applied Science, Harvard University, MICHAEL MANHART, Institute of Integrative Biology, ETH Zurich, ARIEL AMIR, School of Engineering and Applied Science, Harvard University — The relative fitness of mutants in a microbial population depends on multiple cellular traits. In the most widely-used evolution experiment protocol, serial dilution (where cells grow, enter stationary phase, and are diluted into a fresh medium), three major traits determining fitness are the growth rate, lag time (the duration of time cells do not grow when exiting stationary phase), and yield (number of cells per unit resource). Here we investigate how these traits coevolve in laboratory evolution experiments using a minimal model of population dynamics, where the only interaction between cells is competition for a single resource. We find that the fixation probability of a beneficial mutation depends on a linear combination of its growth rate and lag time relative to the background strain. The relative selective pressure on growth rate and lag time is set by the dilution factor; for example, a larger dilution factor favors adaptation of growth rate over the adaption of lag time. This result applies equally to the regime of large populations and high mutation rate, where there is abundant clonal interference, as well as the regime of sequential mutations. Moreover, we find an emergent correlation between growth rate and lag time even if mutations have uncorrelated effects.

9:12AM A63.00005: Rugged landscapes and evolutionary paths to variations in extreme size  THOMAS DAY (Presenter), SHANE JACOBEEN, COLIN BRANDYS, Physics, Georgia Institute of Technology, WILLIAM RATCLIFF, Biology, Georgia Institute of Technology, PETER YUNKER, Physics, Georgia Institute of Technology — The evolutionary transition to multicellularity transformed life on earth, allowing for the evolution of large, complex organisms. While multicellularity can be strongly advantageous, its earliest stages bring unique physical challenges, including the need to mitigate internal and external stresses. Previous work (Jacobeen et.al. *Nature Physics* 2018 and Jacobeen et.al. *PRE* 2018) used the model experimental system “snowflake yeast”, a baker's yeast (*S. cerevisiae*) genetically modified to remain attached via uncut chitin bonds during mother-daughter budding. However, so far these studies have focused on unimpeded directional selection for large size. Here, we varied the selection protocol to probe the effects of a more complex and rugged fitness landscape on the evolutionary trajectory of nascent multicellular clusters by subjecting the population to external compression prior to selection for larger size. We find that despite this challenge, the maximum cluster size achieved over eight weeks of experimental evolution is unchanged by the presence of compression. This indicates that significant evolutionary changes are possible even under harsh environmental conditions, and that very different selection environments can yield similar phenotypic variation.

9:24AM A63.00006: Protein evolution under multiple opposing selective forces*  ERDAL TOPRAK (Presenter), Green Center for Systems Biology, University of Texas Southwestern Medical Center — Evolution on a multidimensional adaptive landscape is the rule, not an exception in biological systems. When multiple opposing selection factors are simultaneously present or rapidly fluctuating in an environment, evolution is a genetic search on a convoluted fitness landscape with several pitfalls due to incompatibilities between genetic changes. Using a bacterial membrane protein as a model system, I will address (i) how evolutionary constraints on multiple fitness conditions arranged in a protein sequence and, (ii) how the rate and mechanism of protein evolution can vary under different (opposing or overlapping) selection conditions.

9:36AM A63.00007: Plastic tradeoffs in evolution: a simple theoretical model*  MIKHAIL TIKHONOV (Presenter), Physics, Washington University, St. Louis, SHAMIT KACHRU, Physics, Stanford University, DANIEL S FISHER, Applied Physics, Stanford University — Performance tradeoffs are fundamental to evolutionary thinking, but in most models, are simply postulated. This approach is justified for tradeoffs enforced by rigid biophysical or biochemical constraints; unsurprisingly, the best-understood examples are in this class. However, experimental results suggest that many relevant tradeoffs are not rigid, but can themselves evolve. We propose a simple theoretical framework for studying how an evolving tradeoff structure both shapes and is shaped by the evolutionary trajectory. We show that this feedback loop naturally leads to non-intuitive behaviors. For instance, although strongly diverging tasks might be expected to result in stronger tradeoffs, evolution can reverse this trend. We also show that within our model, pre-evolving a genome in one environment can predictably impede or facilitate its subsequent speed of adaptation in another. Our results extend previous work relating modularity and "evolvability" to a more general discussion of flexible tradeoff architectures and their impact on evolutionary dynamics.

9:48AM A63.00008: Homologous recombination rates of bacteria  EDO KUSSELL (Presenter), New York University —
Bacteria can take up DNA from their environment and incorporate it into their genomes using various recombination mechanisms. To quantify recombination rates in different environments requires a robust method that operates efficiently using large scale sequencing datasets. In this talk, I present such a method, based on exact solutions of population genetic models, and apply it in a wide range of bacteria.

10:00AM A63.00009: Tuning Spatial Profiles of Selection Pressure to Modulate the Evolution of Drug Resistance*
MAX DE JONG (Presenter), Physics, University of Michigan, KEVIN WOOD, Biophysics, Physics, University of Michigan — Spatial heterogeneity plays an important role in the evolution of drug resistance, but relatively little is known about resistance in complex spatial profiles of selection pressure. Here we use a toy model of stochastic microbial dynamics to investigate how different spatial profiles of selection pressure impact the time to fixation of a resistant allele. Using mean first passage time calculations, we show that spatial heterogeneity accelerates resistance evolution when the rate of spatial migration is sufficiently large relative to mutation but slows fixation for small migration rates. We also demonstrate that optimal tuning of the spatial profile can dramatically slow the spread and fixation of resistant subpopulations, even in the absence of a fitness cost for resistance. Finally, we incorporate a fitness cost associated with the resistant allele and observe that the intermediate regime in which spatial heterogeneity can speed or slow resistance is much larger and the effect of heterogeneity can be greatly amplified. Our results may lay the groundwork for optimized, spatially resolved drug dosing strategies for mitigating the effects of drug resistance.

10:12AM A63.00010: Evolutionarily stable strategies in dynamic population models with applications to bird migration*  SAMUEL CHO (Presenter), SIMON LEVIN, Princeton University — Dynamic state variable models have been widely used to understand individual animal behaviors.1 However, when a population is studied, frequency-dependence and density-dependence often provide incentives to switch strategies, which are not captured in traditional dynamic models. In the discrete states and discrete time problem, we have a coupled forward-backward system, solution of which gives the evolutionarily stable policies determining the strategies for a given state. With the recent development of mean field game theory2, we can find general ecological conditions under which evolutionarily stable policies exist, and can be numerically found. We will also apply the results to understand various strategies during bird migration, such as choice of intermediate sites, foraging rates, and timing of arrival.

10:24AM A63.00011: Environmental heterogeneity limits the action of selection  MATTI GRALKA (Presenter), OSKAR HALLATSCHEK, University of California, Berkeley — Evolutionary dynamics is fundamentally shaped by stochastic processes: mutations enter populations randomly, and the fate of a mutant lineage is determined by the competition between (random) genetic drift and (deterministic) selection. In populations undergoing range expansions, fluctuations in the reproductive process and the local motion of individuals are enhanced within a small subpopulation at the edge of the population. Geographical heterogeneities could therefore have a dramatic impact on evolutionary dynamics if they shape the local advance of the population front.

To test this, we track the dynamics of spontaneous mutations with a tunable fitness effect in colonies of E. coli grown on randomly disordered surfaces and find that environmental heterogeneity can dramatically reduce the efficacy of selection. Time lapse microscopy and computer simulations suggest that this effect is a general consequence of a local "pinning" of the expansion front, whereby stretches of the front are slowed down on a length scale that depends on the structure of the environmental heterogeneity. This pinning focuses the range expansion into a small number of individuals with access to expansion paths, increasing the importance of chance and thus limiting the efficacy of selection.
The Replicator Dynamics for Multilevel Selection in Evolutionary Games

DANIEL COONEY (Presenter), Princeton University — We consider a stochastic model for evolution of cooperation in the Prisoner's Dilemma played in group-structured populations. Selection operates at two levels: individuals compete with individuals in their group, while groups compete with other groups. In the limit of infinite population size, we derive a non-local PDE describing the probability distribution of groups in the population. We characterize the long-time behavior of our system, with an emphasis on understanding the most frequent group compositions at steady state.

When average payoff of groups is maximized by all-defector groups, steady state composition ranges from all-defector groups when individual-level selection dominates to all-cooperator groups when group-level selection dominates. When group payoff is maximized by a mix of cooperators and defectors, then the steady state features a fewer cooperators than required for the optimal mix, even in the limit where group-level selection is infinitely stronger than individual-level selection. In such cases, the conflict between the two levels of selection cannot be decoupled, and cooperation cannot survive when between-group competition favors perfect coexistence of cooperators and defectors.

Evolution of weak cooperative interactions for biological specificity

ANG GAO (Presenter), KRISHNA SHRINIVAS, PAUL LEPEUDRY, HIROSHI I SUZUKI, PHILLIP SHARP, ARUP K CHAKRABORTY, Massachusetts Institute of Technology — A hallmark of biological systems is that particular functions and outcomes are realized in specific contexts, such as when particular signals are received. One mechanism for mediating specificity is described by Fisher's "lock and key" metaphor, exemplified by enzymes that bind selectively to a particular substrate via specific finely tuned interactions. Another mechanism relies on multivalent weak cooperative interactions. Its importance has recently been illustrated by the recognition that liquid-liquid phase transitions underlie the formation of membraneless condensates that perform specific cellular functions. Based on computer simulations of an evolutionary model, we report that the latter mechanism likely became evolutionarily prominent when a large number of tasks had to be performed specifically for organisms to function properly. We find that the emergence of weak cooperative interactions makes organisms more evolvable. Specificity mediated by weak cooperative interactions results in some useful cross-reactivity, but also increases susceptibility to mis-regulation.

Monday, March 4, 2019 8:00 AM - 11:00 AM

Session A64 DBIO: Physics in Synthetic Biology

Synthetic Biology: Physical Biology by Design [Invited] JAMES COLLINS (Presenter), Massachusetts Institute of Technology — Synthetic biology is bringing together physicists and biologists to model, design and construct biological circuits out of proteins, genes and other bits of DNA, and to use these circuits to rewire and reprogram organisms. These re-engineered organisms are going to change our lives in the coming years, leading to cheaper drugs, rapid diagnostic tests, and synthetic probiotics to treat infections and a range of complex diseases. In this talk, we highlight recent efforts to create synthetic gene networks and programmable cells, and discuss a variety of synthetic biology applications in biophysics, biotechnology and biomedicine.

Designing Physical Synthetic Biology [Invited] CHRIS VOIGT (Presenter), MIT — TBD
9:12AM A64.00003: Multiscale Effects of Temperature on Synthetic Gene Circuits  
DANIEL CHARLEBOIS (Presenter), KEVIN HAUSER, Laufer Center for Physical and Quantitative Biology, Stony Brook University, SYLVIA MARSHALL, Laufer Center for Physical and Quantitative Biology, Department of Biochemistry and Cell Biology, Stony Brook University, GABOR BALAZSI, Laufer Center for Physical and Quantitative Biology, Department of Biomedical Engineering, Stony Brook University — Synthetic gene circuits are rationally designed gene networks that perform predefined functions, and have promising applications in many areas including agriculture, bioenergy, and biomedicine. However, synthetic gene circuits are built and characterized in laboratory settings where extracellular variables, such as temperature, are maintained at optimal levels. To study how nonoptimal temperatures (as in real-world conditions) affect the function of synthetic gene networks, we combined multiscale computational modeling with experiments in genetically engineered budding yeast Saccharomyces cerevisiae. We discovered that nonoptimal temperatures induce a cell fate choice between stress resistant and growth arrested phenotypes. Overall, we found that four key effects are required to fully predict the effect of nonoptimal temperatures across different biological scales: 1) cell fate choice between arrest and resistance, 2) slower growth rates, 3) Arrhenius dependence of reaction rates, and 4) changes in protein structure. These findings advance our understanding of how temperature affects living systems and enable more robust genetic engineering for real-world applications.

9:24AM A64.00004: On the noise of gene expression in membrane-bound picolitre biochemical reactors  
ZIANE IZRI (Presenter), BYUOTA SAKAMOTO, Kyushu University, VINCENT NOIREAUX, Physics and Nanotechnology, University of Minneapolis, YUSUKE T. MAEDA, Kyushu University — A clonal population, sharing exactly the same genetic information, eventually displays variability in its observed metabolic properties, such as protein concentrations. In this presentation will be shown a new microfluidic setup that allows the screening of gene expression in a large number (N>1000) of identical picolitre microwells sealed by a biological membrane.

Gene expression of GFP using a cell-free transcription-translation system is performed in picolitre microreactors sealed by a membrane made of a mixture of phospholipids. Each experiment stands for a model clonal population. Although the kinetics of gene expression follows the same master curve for all the microwells, the end-points of the gene expression revealed a variability in the amount of protein produced, with a long right-tail distribution. This observation holds regardless of the composition of the outer phase, emphasizing this intrinsic property of the artificial cells.

9:36AM A64.00005: CRISPRgates: Programmable and Orthogonal Gene Circuit Elements  
DAVID SPECHT (Presenter), GUILLAUME LAMBERT, Cornell University — While CRISPR may be better-known as a gene editing tool, it can also be used as a tool for selective repression of genes using a catalytically-dead CRISPR nuclease. Here, we exploit both the freedom in the CRISPR identification region as well as the freedom in promoter design to create a set of 128 synthetic ‘barcoded’ promoters in E. coli, each of which is keyed to a specific CRISPR guide RNA. These synthetic promoters can then be used to drive chosen genes in modular fashion. We take a multiplexed approach using ‘randomized’ promoter barcodes to demonstrate orthogonality of the ‘CRISPRgates’ on a large scale. This method is immediately transferrable to many different CRISPR nucleases, including Cas9, Cas12a, Cas13a, and CasX, and we use it to study and contrast the behavior of these different systems and probe their properties, including the crRNA structure and PAM site sequence. We then explore how these orthogonal circuit elements can be exploited to create complex genetic circuits. These gates function as transcriptional NOT gates but are Boolean-complete and can in principle be assembled to produce time-dynamic gene circuits.

9:48AM A64.00006: Development of a new measurement standard for synthetic circuit design*  
BIN SHAO (Presenter), CHRIS VOIGT, Department of Biological Engineering, MIT — Large-scale engineering of biological circuits requires reliable measurements of genetic parts and a deep understanding of interactions between synthetic circuits and the host cell. However, the widespread adoption of non-physical units of measurement makes it difficult to parameterize synthetic parts and cellular context, which hinders the efforts to model multi-component synthetic circuits in a predictable way. Here we present a new measurement standard in which DNA- and RNA- binding proteins fused with spectrally well-separated fluorescent proteins are used to visualize plasmid and mRNA simultaneously. By combining quantitative fluorescence microscopy with a customized image processing pipeline, we are able to quantify promoter copy number, RNA production and protein abundance at the single cell level. This allows us to determine biophysical parameters of genetic devices, such as the RNA polymerase flux of a standard promoter. We also show that the new measurement standard can be further applied to investigate the transcriptional power of bacteria cells.

*NIST award 70NANB16H164
10:00AM A64.00007: Quantification of randomized programmable CRISPR-based toggle switches in Escherichia coli

YASU XU (Presenter), GUILLAUME LAMBERT, Cornell University — Recent developments and advances in CRISPR-Cas (Clustered regularly interspaced short palindromic repeats and CRISPR-associated proteins) systems have ushered a new generation of powerful genetic engineering tools in synthetic biology. In particular, a catalytically 'dead' version of CRISPR-Cas proteins that lack nuclease activity can essentially function as a logic NOR gate by selectively binding to a promoter sequence and preventing initiation of transcription by RNA polymerase. In this work, we create programmable and compact genetic toggle switches using pairs of mutually repressible orthogonal CRISPR-based NOR gates and measure the strength of these toggle switches in parallel using a next-generation sequencing method called “Cross-Seq”. Pairs of tandem positioned CRISPR toggle switch with randomized target barcode are inserted into plasmid and transformed into E. coli cells. Each toggle switch output controls a selectable or counter-selectable marker and, by the positively and negatively selecting for bacteria survival, we are able to measure the output of co-repressing NOR gates in all possible combinations and simultaneously quantify the relative strength and stability of dozens of toggle switches in parallel.

10:12AM A64.00008: Out-of-equilibrium microcompartments for the bottom-up integration of metabolic functions in population of artificial microsystems*

THOMAS BENEYTON, CRPP, CNRS, Univ. Bordeaux, DOROTHEE KRAFFT, CLAUDIA BEDNARZ, CHRISTIN KLEINBERG, CHRISTIAN WOELFER, IVAN IVANOV, TANJA VIDKOVIC-KOCH, KAI SUNDMACHER, Process Systems Engineering, Max Planck Institute for Dynamics of Complex Technical Systems, JEAN-CHRISTOPHE BARET (Presenter), CRPP, CNRS, Univ. Bordeaux — Self-sustained metabolic pathways in microcompartments are the corner-stone for living systems. From a technological viewpoint, such pathways are a mandatory prerequisite for the reliable design of artificial cells functioning out-of-equilibrium. We develop microfluidic platforms for the miniaturization and analysis of metabolic pathways in man-made compartments formed of water-in-oil droplets [1]. In a modular approach, we integrate a nicotinamide adenine dinucleotide (NAD)-dependent enzymatic reaction and a NAD-regeneration module as a minimal metabolism. We show that the functionalized microcompartments sustain a metabolically active state until the substrate is fully consumed. Reversibly, the external addition of the substrate reboots the metabolic activity of the microcompartments back to an active state. We therefore control the metabolic state of thousands of independent monodisperse microcompartments, a step of relevance for the construction of large populations of metabolically active artificial cells. The next challenges would be the coupling of our chemical functionalization with mechanical functions to design active micro-systems with life-like properties.

10:24AM A64.00009: Synthetic Gene Circuits Controlling Precise Biological Pattern Formation in Multicellular-Mammalian Systems*

TYLER GUINN (Presenter), GABOR BALAZSI, Stony Brook University — Small molecules offer a diverse range of tools for probing fundamental principles of biological organization and hierarchy in biological physics. Yet, despite their strengths for controlling temporal biological functions, they are limited in exploring questions relevant to biological pattern formation. To address this need for studying spatiotemporal phenotypes in multicellular systems, we have created a toolbox of multiple light-inducible gene circuits that can tune gene expression and control levels of transcriptional noise at the single cell level. We accomplish this by engineering the tetracycline gene-expression system to convert light stimuli information into cellular response proteins in a spatiotemporal context with single-cell resolution. These circuits are built using the light responsive proteins LOV2 & VVD, a small peptide synthesized by the cell, and a light-inducible degradation tag. The resulting tools provide a platform for robust gene expression control in a spatiotemporal fashion, allowing easy exchange for genes of interest and probing physical biology questions in the context of cell-to-cell communication.

10:36AM A64.00010: Drop chemostats on a chip  ELAD STOLOVICKI (Presenter), LLOYD UNG, ROY ZIBLAT, DAVID A WEITZ, Harvard University — The adaptation process of biological system to novel challenge has a lot of variability. To investigate the spectrum of possible adaptation trajectories requires large ensemble of identical twin population. To address this challenge, we are developing a drop-based microfluidic device with hundreds of chemostats on a single chip. The chemostat is a continuous-culture apparatus that enables growth of cells in a well-controlled environment. The controlled conditions of the chemostat enable the measurement of population response to specific factor by varying only one environmental factor at a time. In the drop microfluidic approach, the chemostat vessel is ~1µL media drop surrounded by inert oil. Every population in every drop is an independent chemostat population. Each chemostat droplet is continuously diluted with fresh media. The flow of the chemostat drop insure the mixing of nutrient and suspension of the cells. The surrounding oil reduce the fouling of cells to the channel walls. The measurements can be done on the whole chemostat drop or only on the subtracted fraction. The subtracted fraction from the chemostat can be used to monitor the cells and environment in the drop using variety of distractive assays without interfering the chemostat experiment.

10:48AM A64.00011: Nanoelectronic lab-on-a-chip sensors to detect and monitor DNA hybridization  DELPHINE BOUILLY (Presenter), CLAUDIA MARCELA BAZAN, MADLINE SAUVAGE, MOHAMED OUQAMRA, AMIRA BENCHERIF, Université de Montréal — Nanoelectronic circuits are emerging as a promising technology for lab-on-a-chip, molecular-scale biosensors. In this presentation, I will present the design of such sensors using functionalized nanocarbon materials and their principle of operation to detect and monitor the hybridization of DNA sequences. Carbon nanotubes or graphene ribbons are immersed in a microfluidics platform and functionalized with single-stranded DNA. Hybridization of the tethered DNA with its complementary sequence induces a specific change in the electrical conductance of the devices. First, I will present recent experiments based on this design to detect specific DNA sequences. Second, I will describe the miniaturization of this approach to the single-molecule scale, and its application to monitor DNA hybridization dynamics with single-molecule resolution. Finally, I will discuss applications of this emerging technique for lab-on-a-chip biomedical technology.

Monday, March 4, 2019 8:00 AM - 10:48 AM

Session A65 DBIO: Physics of Behavior t BCEC 260 - Greg Stephens, Vrije Universiteit - Tag(s): Focus

8:00AM A65.00001: Reading the mind of the worm: Brain-wide neural dynamics predict behavior in C. elegans  [Invited]  MONIKA SCHOLZ (Presenter), ASHLEY N LINDER, FRANCESCO RANDI, ANUJ K SHARMA, XINWEI YU, JOSHUA SHAEVITZ, ANDREW M LEIFER, Princeton University — We record calcium activity from the majority of head neurons in freely moving C. elegans to reveal where and how natural behavior is encoded in a compact brain. We find that a sparse subset of neurons distributed throughout the head encode locomotion. A linear combination of these neurons’ activity predicts the animal’s velocity and body curvature and is sufficient to infer its posture. This sparse linear model outperforms single neuron or PCA models at predicting behavior. Among neurons important for the prediction are well-known locomotory neurons, such as AVA, as well as neurons not traditionally associated with locomotion. We compare neural activity of the same animal during unrestrained movement and during immobilization and find large differences between brain-wide neural dynamics during real and fictive locomotion.

8:36AM A65.00002: Root Circumnutation Facilitates Effective Subterranean Surface Exploration  ERIN N MCCASKEY (Presenter), Georgia Institute of Technology, KEVIN R LEHNER, ISAIAH TAYLOR, Biology, Duke University, YASEMIN OZKAN AYDIN, ENES AYDIN, Georgia Institute of Technology, PHILIP BENFEY, Biology, Duke University, DANIEL GOLDMAN, Georgia Institute of Technology — Circumnutation is the oscillatory movement first described by Darwin of a variety of plant organs including roots. A number of root traits have been suggested to improve tip penetration in environments where soil mechanical impedance is a limiting factor in growth, though little is known about the roles of circumnutation. After observing a root coiling phenotype on flat surfaces in non-circumnutating mutant rice roots, we hypothesized that root tip circumnutation facilitates effective root-surface exploration. To model a surface environment of a compact soil horizon with biopores we used plates with 2mm holes equally spaced at different densities. Mutant and wild-type (WT) rice were grown in a clear gel-based media and an automated high-throughput system acquired images to visualize the root growth. As hole density decreased mutants showed reduced success in finding a hole. WT roots had higher success indicating WT roots are more effective in flat surface exploration and less affected by sparse hole density, providing a plausible mechanism to buffer against environmental uncertainty inherent in soil exploration. We propose circumnutation provides a mechanism to break the intrinsic root coiling pattern seen in mutants, and that this movement consequently promotes root exploration.
Worm blob dynamics under thermal stress  YASEMIN OZKAN AYDIN (Presenter), DANIEL GOLDMAN, SAAD BHAMLA, Georgia Institute of Technology — Aggregate formation and clustering are common behaviors observed from bacteria to humans, and can facilitate the survival of the collective [Allee, 1978]. Here we discuss aggregation behavior in aquatic worms and its potential biological function. We first show how aquatic worms can be induced to aggregate into ensembles of thousands of worms that knot together, forming an active viscoelastic ‘blob’. This worm blob can be modulated from an elastic solid-like state to a viscous liquid-like state by changing the surrounding temperature. To establish how this complex transition occurs, we measure both the dynamics of individual worms and the collective. In single worms, we find that activity of an individual worm increases with temperature and reaches a peak value (0.05 cm/s) around 32°C. Thus, in groups at lower temperature (10°C), individual worms are less active and entangle together, while at higher temperatures (35°C), individual worms are more active and disentangle. More specifically, the steady-state density of the cluster decreases from 75% to 33% as temperature increases from 15 to 35°C, respectively. Our results suggest that worm's aggregates may serve as a robust survival strategy of the collective against environmental thermal stresses.

Dynamics of lateral undulation in legged terrestrial locomotion*  FABIO GIARDINA (Presenter), L MAHADEVAN, SEAS, Harvard — Although undulatory locomotion is commonly associated with limb-less animals such as snakes, there exist instances of slender multi-legged animals where undulation is also observed. In centipedes, for example, lateral body undulations emerge when they move fast, although the causes for the appearance of undulations have not been unequivocally clarified. A key unresolved question is whether undulation in myriapod locomotion arises due to the natural dynamics of the organism or if it is neurally enforced. To answer this question, we developed and studied a dynamical model that accounts for biologically plausible leg kinematics and morphologies. The insights obtained from the model analysis will be presented together with their implications for the evolution of locomotor morphology in many-limbed organisms, the principles of propulsion in terrestrial locomotion, and the design of robotic locomotion systems.

Inertial Tail-like Appendage Use in Quadrupeds Improves Stability in Diagonal Sequence Walking Gaits  HAOSEN XING (Presenter), Carnegie Mellon University, BAXI CHONG, Georgia Institute of Technology, GUILLAUME SARTORETTI, JULIAN WHITMAN, Carnegie Mellon University, YASEMIN OZKAN AYDIN, DANIEL GOLDMAN, Georgia Institute of Technology, HOWIE CHOSET, Carnegie Mellon University — There are two main sequences of footfall patterns for quadrupedal walking: lateral, adopted by most quadrupedal animals, and diagonal, preferred by quadrupedal primates. We observe that, compared with the lateral sequence (LS) gait, the diagonal sequence (DS) gait produces a larger stride displacement (i.e., higher average speed) but at the cost of decreased body stability. This work aims to increase the stability of the DS gait by investigating the use of an inertial tail-like appendage. We model this actuated tail as a multi-link manipulator whose dynamics describe how the system moves in response to joint torques. Employing a Lagrangian analysis, we derive tail oscillations that can resist the gravitational torque that drives the system off-balance. We validate our approach on a servo-based quadruped robot with an actuated tail, and compare the stride displacements of the LS and stabilized DS gaits. There, we experimentally show that with the help of an actuated tail, such a quadruped can take advantage of the higher stride displacement (larger) of the DS gait while maintaining stability. Future work will consider the use of an actuated tail to stabilize locomotion on unstructured terrain, as well as to balance dynamic trotting gaits.

Active sensing of particles suspended in unsteady flow*  DAISUKE TAKAGI (Presenter), Mathematics, University of Hawaii at Manoa, J. RUDI STRICKLER, Biological Sciences, University of Wisconsin Milwaukee — Animals can generate highly unsteady flow around their body. We explore how the flow on their mechanical sensors may help in remotely detecting and locating particles suspended in the surrounding fluid. A simple analytical model demonstrates the basic physical principle, which is analogous to active sonar except with flow instead of sound. The model shows that particle-induced fluctuations in pressure or shear on the sensors can be used to reconstruct a hydrodynamic image revealing the size and position of the particle. Our findings suggest that a variety of organisms and devices may actively agitate their surroundings to enhance their sensory range.

### Kuramoto Model of Weakly Conformed Oscillators

**Presenter:** HUNG-YI LY, KUO-AN WU, National Tsing Hua University, HUAN-YU KUO, University of California San Diego — Conformity is a common phenomenon which is observed in social psychology, group decision making, and animal behavior. Inspired by the experiments of Moiseff and Copeland, in which they found that the response of female *Photinus carolinus* to computer flashes depends grossly on the synchrony of flashes, we consider a Kuramoto model with weakly conformed oscillators to study the effects of conformity on synchronization. In our model, the tendency of individual oscillator catching up each other varies with the degree of synchronization that mimics the conformity effect. While considering unimodal frequency distribution, a hysteresis loop emerges in the bifurcation diagram and the branch of unstable fixed points corresponds to the threshold, or "quorum", over which systems move toward more synchronized states. This result is similar to quorum response of consensus decision making, which a consensus decision is finally reached by entire group (oscillators reach synchronized states) once the population supporting it exceeds a quorum (once the degree of synchronization exceeds the threshold).

### Geometric mechanics and locomotion in dissipative environments

**Presenter:** JENNIFER RIESER, Physics, Georgia Institute of Technology, HENRY ASTLEY, Biology, University of Akron, JOE MENDELSON, Zoo Atlanta, CHAOHUI GONG, JIN DAI, Carnegie Mellon University, BAXI CHONG, Georgia Institute of Technology, PERRIN SCHIEBEL, YASEMIN OZKAN AYDIN, Physics, Georgia Institute of Technology, ALEX M HUBBARD, Georgia Institute of Technology, JEFFREY W RANKIN, KRIJN MICHEL, Royal Veterinary College, ALFREDO NICIEZA, Universidad de Oviedo, JOHN R HUTCHINSON, Royal Veterinary College, ROSS L HATTON, Oregon State University, HOWIE CHOSET, Carnegie Mellon University, DANIEL GOLDMAN, Physics, Georgia Institute of Technology — Sustained movement through complex terrain arises from the coupling of environmental interactions with cyclic self-deformation patterns generated by animals. Using both biological experiments and mathematical modeling, we explore the importance of body coordination and morphology for both limbless and limbed animals moving though a widely-encountered environment: on and within sand. Given the highly-dissipative nature of sand, we model environmental forces using granular resistive force theory (RFT) and use geometric mechanics (GM) to map local body deformations to body-frame displacements. We find that undulatory snakes and lizards swimming within sand use waveforms that produce near-maximal displacements per undulation cycle. Recently, we have found that granular RFT also applies to movement at the surface of dissipative materials, even when contact is intermittent. We apply surface granular RFT and GM to animals with cyclic ground contact patterns (e.g., legged locomotors). We find that the coordination between foot placement and spinal flexion observed in walking salamanders produces near-maximal displacements per gait cycle. These results highlight the broad applicability of these tools to understand coordination and self-deformation patterns in dissipative environments.

### Behavioral pattern transitions and habituation to pulsed mechanical vibration in crawling Drosophila larvae

**Presenter:** ALEXANDER BERNE, University of Miami, TOMOKO OYHAMA, McGill University, MASON KLEIN, University of Miami — How the brain receives, stores, and deploys information to create an adaptive response depends on external stimuli. Mechanical vibrations affect animal behavior, and are useful tool for understanding the correlation between neuron function and response. Using the Drosophila larva model system, a slow-moving animal with readily quantifiable behavior, we elicit a discrete set of observable avoidance responses: pause, turn, and reversal (strong) with vibration. We characterize in detail how each response type depends on vibration timing (pulse spacing and duration) and intensity (frequency and amplitude). Through precise larva tracking, we find that intensity above a threshold value increases the frequency of the reverse crawl behavior. Stimulus timing affects the probability of the each behavior: both prolonged and repeated vibration bursts over time reduce the proportion of animals reverse crawling (habituation). Additionally, memory deficient fly mutants show altered responses to repeated and sustained vibrations, suggesting the possible mechanism underlying habituated response. Drawing an analogy to a capacitor charging circuit, we model the possible relationship between biological mechanisms and habituated behavior in general.
10:12AM A65.00010: A minimal reaction-diffusion neural model generates *C. elegans* undulation  
HAROLD HASTINGS (Presenter), Bard College at Simon’s Rock, JENNY MAGNES, Physics, Vassar College, SIMON ELLIS, Computer Science, Vassar College, KATHLEEN SUSMAN, Biology, Vassar College, CHERIS C CONGO, MIRANDA R HULSEY-VINCENT, RIFAH TASNIM, Physics, Vassar College — The small (1 mm) nematode *Caenorhabditis elegans* has become widely used as a model organism; in particular the *C. elegans* connectome has been completely mapped (c.f. Jabr 2012) and *C. elegans* locomotion has been widely studied. The purpose of this paper to describe a minimal reaction-diffusion model for the *C. elegans* central pattern generator (CPG) (c.f. Xu et al. 2018, Wen et al. 2012). We use simulation methods to show that a small network of FitzHugh (1961)-Nagumo (et al.1962) neurons (one of the simplest neuronal models) based on a skeleton model of the *C. elegans* CPG can reproduce key features of *C. elegans* undulation (c.f. Magnes et al. 2017) and thus locomotion, compare the neuromechanical model of Izquierdo and Beer (2015). We also investigate dynamics and stability of the model. See Stephens et al. (2011) for the role of simple models in analyzing neurons and behavior.

10:24AM A65.00011: Comparative undulatory locomotion in complex environments  
KELIMAR DIAZ (Presenter), PERRIN SCHIEBEL, School of Physics, Georgia Tech, JIMMY L DING, Department of Bioengineering, Georgia Tech, HANG LU, Department of Chemical and Biomolecular Engineering, Georgia Tech, DANIEL GOLDMAN, School of Physics, Georgia Tech — Despite the difference in size, slithering animals from mm scale nematodes to m scale snakes are resistive-force dominated systems. These animals press lateral body bends against heterogeneities in their surroundings to overcome drag on the elongate, limbless body. To search for general principles of control in undulatory locomotion we studied the desert-specialist *C. occipitalis* and the nematode *C. elegans* traversing sparse lattices of rigid cylindrical posts, a model heterogeneous terrain. We challenged *C. occipitalis* to move through square arrays of 0.64 cm diameter posts embedded in a low-friction substrate and *C. elegans* with fluid filled PDMS lattices of comparable size. Both animals used a waveform which was largely preserved throughout a trial resulting in bouts of locomotion-when the body contacted an opportune obstacle-interspersed with large-slip-when the substrate alone provided propulsion. *C. elegans'* performance was comparable to *C. occipitalis*; when the animals did not contact posts they moved at ~0.2 body lengths per cycle (BL/cyc) while when they were in contact with the posts they moved at ~0.35 BL/cyc by bouts of motion. This suggests the strategies employed by both animals were similar despite the difference in size.

10:36AM A65.00012: Accurate quantification of bumblebee foraging  
DAVID HOFMANN (Presenter), AHMED ROMAN, DONNA ROSA MCDERMOTT, BERRY BROSI, ILYA NEMENMAN, Emory University — Bumblebees have been shown to learn simple forms of tool use and to transmit these skills to other members of the colony. They are thus an excellent animal model system to study learning and social interactions. However, such studies are complicated by the difficulty of precisely quantifying bumblebee behavior and interactions with the environment even in simple tasks, such as foraging. To address this, we designed a flight chamber with 3D printed artificial flowers to accurately quantify individual and collective bumblebee foraging. A radio frequency identification (RFID) system is employed to identify the individual foragers and detect their presence in flowers. A microfluidic system releases carefully controlled sucrose solution droplets of varying sizes in each flower in response to the presence of specific bees, and we then detect when the droplets are consumed. We quantify individual foraging behavior of naive bees exposed to two flowers with different reward probabilities in the course of multiple days. This mimics the setting of the well studied two-armed bandit problem in behavioral economics. We analyze the operant learning of the relation between a flower and a reward probability by the bees, and we compare the observations to predictions of various theoretical models.
8:36AM A66.00002: Hierarchical “buckling without bending” and cerebellar shape* MAHESH CHANDRASEKHAR
GANDIKOTA (Presenter), JM SCHWARZ, Syracuse University — While studies of brain shape development have focused on the cerebrum, the cerebellum, otherwise known as the little brain, typically houses more neurons than the cerebrum. Mammalian cerebella have 8-10 primary lobes which subsequently branch into smaller lobes. Recently, a “buckling without bending” model has been introduced to quantify the onset of shape change in the developing cerebellum and other brain organs/organoids. It consists of an inner incompressible core of cells and an outer fluid-like cortical layer of dividing cells encased by a pia membrane. Additionally, there are two types of fibrous cells - ones spanning the cerebellum and ones spanning the cortical layer. The onset of shape change is a consequence of mechanical constraints on the outer fluid-like cortical layer as it proliferates. Predictions of the model have been recently supported by experimental studies of the developing mouse cerebellum. Here, we generalize the model beyond the onset of shape change to predict shape development at later stages. We implement a hierarchical version of the above model to predict subsequent branching of the smaller lobes. Predictions are compared with various mammalian cerebella exhibiting varied counts of branching generations.

8:48AM A66.00003: Wrinkles on Tori XIAOXIAO ZHANG, Mechanical and Aerospace Engineering, Syracuse university, PATRICK MATHER, Chemical Engineering, Bucknell University, MARK BOWICK, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, TENG ZHANG (Presenter), Mechanical and Aerospace Engineering, Syracuse university — Wrinkling patterns in soft materials have been extensively studied due to their important roles in determining surface morphologies in biological structures and developing multifunctional devices. Most existing work focuses on relatively simple geometries, such as flat structures and curved structures with constant curvature such as the cylinder and 2-sphere. In this talk we discuss wrinkling patterns on a torus, the Gaussian and mean curvatures of which vary along the poloidal direction. We observe eight different wrinkling patterns from large-scale finite element simulations and construct a phase diagram for these patterns. We further show that the non-uniform curvature and anisotropic deformation play critical roles in determining the formation and evolution of these wrinkling patterns. The anisotropic deformation along the toroidal and poloidal directions controls pattern transitions from stripes to hexagons and the non-uniform curvatures determine the nucleation sites of the wrinkling patterns. Our results show that global deformations of a torus lead to strong coupling between elasticity and curvature which may enlarge the design space as well as the dynamically control of wrinkling patterns.

9:00AM A66.00004: Pattern formation in elastic bilayer systems through substrate pre-stretching FRANCISCO LOPEZ JIMENEZ (Presenter), University of Colorado, Boulder, RASHED A AL-RASHED, Massachusetts Institute of Technology, JOEL MARTHELOT, Princeton University, PEDRO REIS, Ecole polytechnique federale de Lausanne — Compressing a thin film bonded to an elastic substrate beyond a critical stress results in an elastic instability, often referred to as wrinkling or ruga, that generates complex surface deformation. Although the best-known example is the sinusoidal wrinkling that appears under uni-axial compression of the film, other loading conditions and actuation mechanisms result in a diverse range of self-organized patterns. We will present experiments in which the substrate is pre-stretched prior to the adhesion of the film, which when released results in film compression. We will show that with only moderate variations in the system and control parameters we can transition between a wide range of patterns, with a well-defined phase diagram spanning periodic wrinkles, creases, folds, and high aspect ratio ridges. We will also explore the dynamics that control the pattern formation, as well as the effect of repeated unloading and reloading, in an effort to rationalize how the specific details of the pattern are determined.

9:12AM A66.00005: Mechanical Principles Underlying Development of Bacterial Biofilm Morphology CHENYI FEI (Presenter), SHENG MAO, JING YAN, RICARD ALERT, HOWARD A STONE, BONNIE BASSLER, ANDREJ KOSMRILJ, NED WINGREEN, Princeton University — Surface-attached bacterial communities called biofilms display diverse morphologies. Our recent experiments demonstrated that growth-induced mechanical instabilities – including wrinkling and delamination – underlie the morphogenesis program of biofilms growing at the air-solid interface, and determine the characteristic wavelength of surface undulations. Yet, how the interplay between mechanics and biofilm growth determines colony expansion and morphogenesis remains unclear. Here, we define the physical mechanism underlying biofilm mecano-morphogenesis by combining microscopic and continuum models. We show that surface friction affects the thickness and edge propagation angle of colony biofilms. Moreover, this friction, along with a non-uniform pattern of growth due to nutrient depletion at the biofilm center, gives rise to anisotropic stress patterns. Interestingly, we also find that the combination of active exponential growth near the edge and linear increase of contour length contributes to a constant accumulation of tangential stress. This residual stress can be relaxed by subsequent mechanical instabilities. Finally, we propose a coarse-grained model to characterize the post-wrinkling/delamination expansion of biofilms.
Mechanical Feedback in Gut Looping

ADITI CHAKRABARTI (Presenter), SEAS, Harvard University, CLIFFORD J TABIN, Genetics, Harvard Medical School, LAKSHMINARAYANAN MAHADEVAN, SEAS, Physics, OEB, Harvard University

The midgut of most organisms consists of a long coiled tube that is dorsally attached to a thin sheet called the mesentery. Previous work has established that the physical foundations of the looping patterns arise from the differential growth between the gut tube and the mesentery in the context of their respective geometric and elastic properties, and that these looping patterns are evolutionarily modulated, at least in part, through species-specific variation in BMP2 levels, affecting the growth rates within the developing mesentery. However, how BMP2 signaling itself is modulated in an endogeneous setting remains unknown. We explore the possibility that tension in the mesentery feedbacks onto the tissue to regulate levels of BMP2, thereby controlling looping morphogenesis, using in-ovo and explant experiments. Quantifying this idea closes the feedback loop linking molecular signaling and gut morphogenesis in the chick embryo, and suggests an evolutionary pathway for exploring gut looping across organisms at a mechanistic level.

Modeling bio-inspired morphing mechanisms in hydrogel micro capsules

PAOLA NARDINOCCHI (Presenter), Sapienza University of Rome

We study changes in shape and size triggered by external stimuli in structures made of soft active materials. In particular, we consider morphing mechanisms driven by hydration and dehydration processes in capsule-like bodies which can hydrate and dehydrate causing the lateral collapse of the capsule body and the change of shape of the capsule. Typical examples come from Nature. In fern sporangium, the cells in the crest to one side of a spherical capsule enclosing the spores lose water by evaporation, so determining tension building up within them, and lateral walls collapsing internally [1,2]. In Sphagnum Moss, dehydration of the capsules cause them to change shape from spherical to cylindrical and to increase the internal air pressure [3].

In both the examples, the coupling between the dehydration process and the change in internal pressure determines a fast mechanism which allows to realize spore dispersal.

The goal of our study is to identify the mechanical determinants of the mechanism and investigate the role of the key geometrical and material parameters.

We acknowledge Sapienza Università di Roma for funding

Stress-Free Morphing

LUCIANO TERESI (Presenter), Mathematics & Physics, University Roma Tre, Italy

We study the morphing of soft materials within the framework of non-linear elasticity with large distortions: a distortion field induces a target metric, and the configuration which is effectively realized by a body is the one that minimizes the distance, measured through the elastic energy, between the target metric and the actual one.

Deformations due to distortions, in contrast to those generated by forces, can have a peculiar feature: they can be stress-free; if this is the case, the distortions field is called compatible.

We maintain that the morphing through compatible distortions is a key strategy exploited by many soft biological materials, which can exhibit very large shape-change in response to distortions controlled by chemicals or by temperature changes, while keeping their stress state almost null.

Thus, the study of compatible distortions, and of the related shape-changes, is quite important. Here, we show how the notions of metric tensor and of Riemannian curvature can be used to assess the compatibility of a distortion field.
10:00AM A66.00009: Modeling hemodynamic fluctuations: the brain vasculature as an excitable network  
MIGUEL RUIZ GARCIA (Presenter), ELENI KATIFORI, University of Pennsylvania — Multiple studies have examined blood oxygen level dependent (BOLD) signals of functional magnetic resonance imaging (fMRI) showing spontaneous fluctuations when the brain is at rest, sleeping or even anesthetized. These fluctuations are found at lower frequencies (around 0.1 Hz) than respiratory or cardiac functions. In addition, recent experimental works seem to rule out their relation with neural activity, suggesting a non-neural origin.

We propose a minimal model for microcirculation that only assumes a nonlinear relation between the current supported by each vessel and the pressure drop between its starting and final nodes, and a dispersive relation for volume accumulation. This simple approach qualitative reproduces the main characteristics of the observed behavior. The fluctuations emerge spontaneously under constant boundary conditions as self-sustained oscillations, forming different patterns depending on the topology of the network.

We expect that this model can shed light on the nature of spontaneous fluctuations on brain vasculature and its interplay with the properties of the network. Finally, the simplicity of the model makes it suitable for its use with different nonlinear flow networks exhibiting complex dynamical behavior.

10:12AM A66.00010: A simple developmental model recapitulates complex insect wing veination patterns (A wingkle in time)*  
JORDAN HOFFMANN (Presenter), Harvard University, SETH DONOUGHE, University of Chicago, KATHY LI, Columbia University, MARY SALCEDO, CHRISTOPHER RYRCROFT, Harvard University — Geometric patterns in nature have long been a matter of fascination and intrigue. Veins bifurcate insect wings into a diverse and complicated menagerie of shapes. For many insect species, even the left and right wings from the same individual have veins with unique topological arrangements, and little is known about how these patterns form. We present a quantitative study of the fingerprint-like “secondary veins.” We compile a dataset of wings from 232 species and 17 families from the order Odonata (dragonflies and damselflies), a group with particularly elaborate vein patterns. We characterize the geometric arrangements of veins and develop a simple model of secondary vein patterning. Last, we show that our model is capable of recapitulating the vein geometries of species from other, distantly related winged insect clades.

10:24AM A66.00011: Self-organization of tubular networks by fluid flows  
JEAN-DANIEL JULIEN, KAREN ALIM (Presenter), Max Planck Institute for Dynamics and Self-Organization — Long-ranged dynamic patterns are important for development and functioning of large-scale organisms. In the tubular networks of plasmodial slime molds the tubes’ periodic contractions organize in a traveling wave on scales of up to several centimeters. What drives communication across the network? What drives the self-organization of the tube’s cortex to form long-wavelength patterns? Searching for the mechanism of signal propagation we find that flows are hijacked by signals to propagate through the network. Signals promote their own transport by invoking a propagating front of increased flow. This mechanism is sufficient to explain complex dynamics of the organism like finding the shortest path through a maze. Importantly, we find that distant parts within the tubular network communicate by fluid flow. We investigate the mechanism behind the self-sustained contractile waves by developing a minimal model, coupling the mechanics of a cell’s cortex to a contraction-triggering chemical. The chemical itself is spread with the fluid flows that arise due to the cortex contractions. Through theoretical and numerical analysis, we find that the oscillatory component of the flows can give rise to robust scaling of contraction waves with system size—much beyond predicted length scales.
10:36AM A66.00012: Patterned smooth muscle constrains and constricts the airway epithelium during branching morphogenesis* KATHARINE GOODWIN (Presenter), ANDREJ KOSMRLJ, CELESTE NELSON, Princeton University — During branching morphogenesis, a simple tube of cells gives rise to an arborized epithelial network. In the mouse lung, the airway epithelium develops concomitantly with a layer of smooth muscle, which is derived from the surrounding mesenchyme and wraps circumferentially around the airways. We examined the role of smooth muscle in shaping domain branches that establish the underlying architecture of the lung. We found that branches begin as wide buds that thin at their bases as they extend. At the same time, there is an increase in the amount of smooth muscle wrapped around the parent bronchus at the base of each nascent domain branch. Perturbing the pattern of smooth muscle differentiation causes abnormal epithelial branching. Loss of smooth muscle results in ectopic branching events and slows branch thinning. Enhanced smooth muscle differentiation suppresses branch initiation and extension. Combining experiments with computational modeling revealed that patterned smooth muscle wrapping constrains and constricts the growing epithelium to properly position and physically sculpt domain branches.

10:48AM A66.00013: Smooth Muscle Mechanically Sculpts the Airway Epithelium in Birds and Reptiles MICHAEL PALMER (Presenter), CELESTE NELSON, Princeton University — The reptilian lung, with its basic sac-like structure, is considered to be the most evolutionarily basic among amniotes. In comparison, mammalian and avian lungs are much more complex and finely branched. Smooth muscle (SM) is required for branching in the early mouse lung but to date this tissue remains uninvestigated in other amniotes. The respiratory system of birds contains a network of connected airways that begin as terminal structures but fuse as embryonic development progresses. We found that prior to airway fusion in the domestic chicken, Gallus gallus, the airways initiate branches in the direction of their target, which will make the first contact. These new branches occur in regions devoid of SM, implying a role for it in shaping the airway epithelium prior to fusion. We have also examined early development of reptile lungs using the brown anole, Anolis sagrei, as a model organism and found that SM is present in a mesh-like arrangement and regulated by the same signaling pathways as in the murine lung. Contraction of SM defines the shape of the epithelium. Despite the fact that the tissue forms at different periods in development and in varying patterns, these data suggest an evolutionarily conserved mechanism for SM as a physical force in airway morphogenesis.

8:00AM A67.00001: In-Operando Characterization and Investigation of Individual Defects in GaAs Solar Cells* SUNNY Y ZHANG (Presenter), QIONG CHEN, University of North Carolina at Charlotte, CHANG-KUI HU, Wuhan University of Technology, TIMOTHY HURLEY GFROERER, Davidson College, MARK W WANLASS, National Renewable Energy Laboratory, YONG ZHANG, University of North Carolina at Charlotte — The ultimate constraint for a solar cell to reach its theoretical efficiency limit is the quality of the absorber material. It is common knowledge that the existence of structural defects degrades device performance. However, in a real device, it is unclear (1) how individual defects affect performance via different cell parameters, (2) how the impact depends on the operation conditions, and (3) how the impact varies from one defect to another. This work answers these questions through investigating individual dislocation defects in GaAs solar cells under different illumination conditions. An array of correlative and spatially-resolved techniques, including electroluminescence, photoluminescence, Raman, and current-voltage (I-V) characteristics, is used to identify and characterize the defects. By comparing the I-V characteristics with the laser beam focused at the defect and defect-free site, the adverse impact of the defects is quantitatively measured through changes in the key device parameters, including short-circuit current, open-circuit voltage, fill factor, energy-conversion efficiency, and shunt resistance. This study provides insights for both a fundamental understanding of defect physics and practical knowledge of defects in the single defect level.

8:12AM A67.00002: Charge-transfer-state energy reduction at various donor/acceptor interfaces*  
SARA ANJUM (Presenter), Physics, Princeton University — Organic solar cells have several properties that make them desirable over inorganic solar cells such as cost-effectiveness, flexibility, and lightweight. While organic solar cells tend to exhibit energy losses due to the need to break up charge-transfer (CT) states, a phenomenon that does not exist in its inorganic counterparts, highly-crystalline rubrene is a donor that has been shown to allow for delocalized CT states. This project aimed to examine the effects of the acceptor choice in the delocalization of charge transfer states by examining the energies of these states in the acceptors Cl6-subPc-Cl and Cl12-subPc-Cl. We found that the CT state energy dropped by 0.38 eV when going from amorphous to crystalline rubrene with Cl12-subPc-Cl as the acceptor. The CT state energy dropped by 0.38 eV when going from amorphous to crystalline rubrene with Cl12-subPc-Cl, which compares to the energy drop of 0.38 eV observed with C60 as the acceptor. This indicates that the choice of acceptor does have an impact on the CT-state energies.

*I would like to thank Prof. Rand and his lab for providing the funding necessary for my project.

8:24AM A67.00003: Determining the Interface Conductivity of Nb-SrTiO3 (Nb-STO) with Various Electrodes*  
GILLIAN HAGEN (Presenter), Physics, Mount Holyoke College, DAEHEE LEE, RUIYUN HUANG, SOSSINA HAILE, Materials Science and Engineering, Northwestern University — Solid oxide fuel cells have the potential to function within efficient systems of energy infrastructure. Nb-doped SrTiO3 (Nb-STO) (001) is an n-type semiconductor which has the potential to provide electrical contact for application in solid oxide fuel cells. We study the interface conductivity of Nb-STO with various metal and oxide contacts as a function of temperature (200°C-550°C) and oxygen partial pressure (10^-5 - 0.2 atm). We consider the interface of Nb-STO with metal contacts of Cr and oxide contacts of vertically aligned STO (100) and Sm-doped ceria (SDC) (100) through the fabrication of symmetric electrode devices. This presentation examines the interface electrical characteristics of Nb-STO with the two electrode materials studied. Overall, we demonstrate that Cr metal can provide contact to Nb-STO without resulting in a Schottky barrier, while vertically aligned STO (100) and Sm-doped ceria (100) nanocolumns cannot provide contact at elevated temperatures. The results of this study have implications on the use of single crystal Nb-STO as a conductive substrate for electrolyte materials in solid oxide fuel cells.

8:36AM A67.00004: Ultrafast Carrier Dynamics of Exfoliated Transition Metal Dichalcogenides with Optical-Pump Terahertz-Probe Microscopy*  
KENNETH LIN (Presenter), Department of Physics, University of Massachusetts Amherst, SATOSHI KUSABA, TAKASHI ARIKAWA, Department of Physics, Kyoto University, FRANÇOIS BLANCHARD, Department of Electrical Engineering, École de technologie supérieure, KOICHIRO TANAKA, Department of Physics, Kyoto University — Atomically thin two-dimensional transition metal dichalcogenides (TMD) exhibit extraordinary properties similar to graphene but features an intrinsic bandgap, opening vast potential applications in photonics and optoelectronics as semiconductors. The characterization of these materials is essential for developing such technologies and the emerging technique of terahertz (THz) microscopy enables contactless probing that directly reveals the carrier dynamics of TMDs. We employ a unique, optical-pump THz-probe microscope to measure the electric field response of mechanically exfoliated bulk TMD MoS2. We measure the decay lifetime of bulk MoS2 electron carriers with a temporal resolution of approximately 500 femtoseconds in the 1 THz range. We observe the relaxation of free carriers to be uneven on a single sample and the decay constant was found to vary with position from 36.9 ps to 82.5 ps. Using atomic force microscopy, we demonstrate a correlation between the thickness of a given position on the MoS2 sample with the decay rate, where a thinner region or sample edge position corresponded to a faster decay. We attribute this nonuniform carrier relaxation rate to the edge state and surface defect effects.

8:48AM A67.00005: Development of Low Cost Room Temperature STM for the Preliminary Analysis of 2D Materials and Twisted Graphene Bilayers*  
PARAM PATEL (Presenter), MICHAEL ALTVATER, GUOHONG LI, EVA ANDREI, Physics, Rutgers University — Scanning tunneling microscopy (STM) is a valuable tool for studying atomic positions, electronic energy properties of materials, and distributions of electrons at the surface of a material. Using 3D printing, we developed a cost-effective room temperature STM for the analysis of 2D materials. After noise reduction and calibration, we can examine Moiré patterns in CVD-grown twisted bilayer graphene to efficiently identify the relative angle between the bilayers. This work demonstrates how modern tunneling microscopes can be used as a cost-effective preliminary diagnostic tool for studying atomic positions and electronic superlattices at material surfaces.

Thermal and Structural Properties of Alkali Modified TeO2 Glasses

MARTHA JESUIT (Presenter), MICHAEL JOSEPH PACKARD, Coe College — The structural and thermal properties of lithium, sodium, and potassium tellurite glasses, written as JM2O-TeO2 where M is an alkali metal, were studied. Raman spectra were measured on all glasses along with the glass transition onset (Tg), crystallization (Tx), and melting (Tm) temperatures. All thermal measurements were measured on a Perkin-Elmer DSC-7. The thermal measurements were compared to the coordination of the tellurium. Coordination data was found by deconvoluting Raman spectra using Igor Pro to find the percent of Q4 and Q3 units in the glass.

Pure amorphous TeO2 was made using the water-quenching method then thermally tested against time to see how the glass transition onset and crystallization changed. We measured Tx and Tg every 30 minutes on glassy TeO2. Since TeO2 has a strong crystallization tendency, the samples were prepared in a nitrogen glovebox to minimize the effect that water could have on the recrystallization.

Effect of varying the gate voltage scan rate in a MoS2/ferroelectric polymer field effect transistor

LUIS RIJOS (Presenter), NICHOLAS PINTO, Physics and Electronics, University of Puerto Rico at Humacao, MENGQIANG ZHAO, WILLIAM PARKIN, ALAN T JOHNSON, Physics and Astronomy, Univ. of Pennsylvania — A ferroelectric field effect transistor (FE-FET) using chemical vapor deposition (CVD) grown monolayer MoS2 as the semiconductor was fabricated and tested at room temperature. Ferroelectric poly(vinylidene fluoride-trifluoroethylene)-PVDF-TrFE was used as the gate insulator, and the effects of varying the gate voltage scan rate from 200 mV/s to 4 mV/s on device performance were investigated. Prior to the device switching on, a negative trans-conductance was observed for all scan rates. It was followed by a rapid increase in the channel current to the on state, corresponding to the polarized down configuration of the FE. This effect was independent of the drain-source voltage. Our results revealed a narrowing in the memory window width, an increase in the mobility (μ) from 0.02 – 10 cm²/V-s, and a decrease in the sub-threshold voltage swing (SS) as the scan rate was lowered. These parameters appeared to stabilize at slower scan rates suggesting an asymptotic limit to their values. A model based on nucleation and unrestricted domain growth was used to explain these results. By lowering the gate voltage scan rate, the performance of polymer based FE-FET's can therefore be improved.

Fabrication of planar tunnel junctions on bulk Pb1-xSnxSe

RAKIN BATEN (Presenter), DERRICK VANGENNENP, TIFFANY PAUL, JAMES HAMLIN, Department of Physics, University of Florida — The topological crystalline insulator Pb1-xSnxSe can undergo a trivial to non-trivial transition as a function of temperature or pressure. Angle-resolved photoemission spectroscopy (ARPES) and scanning tunneling spectroscopy (STS) are both useful measurements for studying the nature of these topological transitions. However, ARPES and STS are incompatible with high pressure conditions. Planar tunneling spectroscopy (PTS) can provide similar information as STS but can be deployed at high pressure. I will discuss our efforts to fabricate Pb-alumina-Pb1-xSnxSe planar tunnel junctions and will present the results obtained thus far.

*This work was supported by National Science Foundation (NSF) CAREER award DMR-1453752.
REBELLO SOUSA DIAS, Physics, University of Richmond — Despite previous investigations on the fabrication and optical sheet resistance as low as 19.8 Ω for a composition of Zn_{0.25}Cd_{0.75}O. Moreover, the thin films have an average increasing Cd concentration, we notice a nonlinear red-shift. Also, we find that most of our films were conductive with a range. We show that the optical band gap of ZnO is in the ultraviolet region of the electromagnetic spectrum, and while samples through spectroscopy ellipsometry and transmittance measurements in the [300 nm – 3200 nm] wavelength range. In this work, we deposited Zn_{1-x}Cd_{x}O alloyed thin films via the spray pyrolysis method. We optically characterized the quality of (BixSb_{1-x})_{2}Te_{3} films. With RHEED and XRD we obtained information about different aspects of the crystal structure and how they were correlated. Further, we made devices of these films and measured their transport properties allowing us to correlate their structural and electronic properties.

OMAR AGUILAR (Presenter), Physics, University of Richmond, SUELEN DE CASTRO, MARCIO P. F. GODOY, Physics, Federal University of Sao Carlos, MARIAMA REBELLO SOUSA DIAS, Physics, University of Richmond — Despite previous investigations on the fabrication and optical characterization of Zn_{1-x}Cd_{x}O thin films spanning the whole composition range, the permittivity has yet to be determined. In this work, we deposited Zn_{1-x}Cd_{x}O alloyed thin films via the spray pyrolysis method. We optically characterized the samples through spectroscopy ellipsometry and transmittance measurements in the [300 nm – 3200 nm] wavelength range. We show that the optical band gap of ZnO is in the ultraviolet region of the electromagnetic spectrum, and while increasing Cd concentration, we notice a nonlinear red-shift. Also, we find that most of our films were conductive with a sheet resistance as low as 19.8 Ω for a composition of Zn_{0.25}Cd_{0.75}O. Moreover, the thin films have an average transmittance of 0.8 over a wide range of the electromagnetic spectrum. Understanding the optoelectronic properties of Zn_{1-x}Cd_{x}O thin films can pave the way to a more efficient Transparent Conducting Oxide (TCO).

MICHAEL O’CONNOR (Presenter), MANOJ SINGH, MICHAEL C BOYER, Clark University — A material is typically considered low-dimensional if electron movement within the material is limited, for example, to within a particular ionic plane or along an axis. When strain is introduced to an ideal material, lattice deformations may cause substantial changes in structural and electronic properties. Studying the effects strain have on a material can lead to basic insights into the physics governing the material as well as an understanding of how a material's properties can be manipulated for use in applications. Strain can be introduced to a low-dimensional material through processes such as sample cleaving, elemental doping, chemical pressure, and external mechanical application. Here we detail our efforts to implement a system for controlled external straining of a sample. We present resistivity measurements showing the effects strain has on the bulk phase transition temperature of a charge density wave compound. We will discuss how this system can be used in further studies which characterize strain on the nanoscale.

AHMAD MATAR ABED (Presenter), Physics and Electronics, University of Puerto Rico at Humacao, TIMOTHY PILLSBURY, RUN XIAO, ANTHONY RICHARDELLA, NITIN SAMARTH, Physics, Pennsylvania State University — Topological insulators are in the focus of research due to their unique characteristics. Their unusual metallic surface states allow the spin of electrons moving through them to be controlled and used for spintronics and even potentially quantum computing. Here we present a structural analysis of bismuth antimony telluride (Bi_{x}Sb_{1-x})_{2}Te_{3} thin films grown using molecular beam epitaxy. The films were analyzed using the in-situ characterization technique reflection high-energy electron diffraction (RHEED) as they were grown and afterward using ex-situ x-ray diffraction (XRD). The work focused on having a better analysis for understanding the crystal quality of (Bi_{x}Sb_{1-x})_{2}Te_{3} films. With RHEED and XRD we obtained information about different aspects of the crystal structure and how they were correlated. Further, we made devices of these films and measured their transport properties allowing us to correlate their structural and electronic properties.

10:24AM A67.00013: Cassie-Baxter Transition: Gibbs Energy Analysis and CFD Simulations Using Newly Developed, Validated Algorithms  CHAE ROHRS (Presenter), PING HE, ARASH AZIMI, Lamar University — A liquid droplet on a textured substrate equalizes into either the Cassie-Baxter, or Wenzel state. In addition, metastable states between these conditions are reported in the literature. The Cassie-to-Wenzel transition has been understood as the intersection of the Cassie-Baxter and Wenzel equations, which are functions of the Young's angle; however, a major issue exists: the texture shape and dimensions are not considered. What's more, the transition point of the Young's model has not been experimentally verified. Because changing texture dimensions will also cause the droplet to transit from one state to another, we plan to build a new transition model through a Gibbs energy analysis of a liquid-gas-solid system. The Young's angle is held constant and the wetting phenomena are computed as a function of texture dimensions. Each dimension set will have an equilibrium state identified by its penetration depth and apparent contact angle. Lastly, the energy barrier describing the obstacle to a droplet moving from a meta-stable state toward the stable state can simultaneously be computed. Our newly developed, experimentally validated CFD method will be used to confirm our Gibbs energy analysis, and to explore the dynamic behaviors of a droplet during the Cassie-to-Wenzel transition.

10:36AM A67.00014: Magnetic vortex disks for magneto-mechanotransduction*  GEORGIA NELSON (Presenter), MEREDITH XU, XIAO WANG, ANDY CLARK, Department of Physics, Bryn Mawr College, DAVID KEAVNEY, The Advanced Photon Source, Argonne National Laboratory, RALU DIVAN, DAFEI JIN, Center for Nanoscale Materials, Argonne National Laboratory, XUEMEI CHENG, Department of Physics, Bryn Mawr College — A magnetic vortex, the ground state existing in micron- and submicron-sized ferromagnetic disks, is a three-dimensional spin structure that consists of a circulating in-plane magnetization and an out-of-plane vortex core. Magnetic vortex disks are promising mechanotransduction toolkits due to their capabilities in spatiotemporal manipulation of mechanical forces via the magnetic field. Here we report fabrication and magnetic imaging of patterned magnetic vortex disks. An array of Fe80Ni20 (Py) disks 3 um in diameter and 40 nm in thickness were fabricated using the photolithography, sputtering deposition, and lift off process. Element-specific photoemission electron microscopy imaging at the Ni L3 edge, performed at Beamline 4-ID-C of the Advanced Photon Source of Argonne National Laboratory, confirmed that the magnetic configuration of these Py disks are indeed magnetic vortices as expected. In the future, these fabricated magnetic vortex disks will be used as force or torque transducers in biomedical systems.

10:48AM A67.00015: Thermoelectric Effects in a Double Mushroom Phase Change Memory Cell*  NOAH DEL CORO (Presenter), Electrical Engineering and Computer Science and Engineering, University of Connecticut, JAKE SCOGGIN, ALI GOKIRMAK, Electrical and Computer Engineering, University of Connecticut — Phase change memory (PCM) is a non-volatile memory that uses crystalline (set) and amorphous (reset) states to hold information. We use a finite-element PCM model1,2 to demonstrate thermoelectric effects in a cell with a novel “double mushroom” geometry. We analyze the impact of thermoelectric power (Peltier and Thomson heating) on device performance. We also compare the double and single mushroom cell write (reset and set) requirements and find better performance in the double mushroom due to enhanced thermal isolation.

Session A69 FHP: The Author in Dialogue: David Kaiser's "How the Hippies Saved Physics"  BCEC 052A - Paul Cadden-Zimansky, Bard College - Tag(s): Invited, Undergraduate

8:00AM A69.00001: How the Hippies Saved Physics: Adventures with Bell's Theorem, Then and Now [invited]  DAVID KAISER (Presenter), Massachusetts Institute of Technology — In this talk I will describe the historical questions that led me to write my book, "How the Hippies Saved Physics". I will summarize some of the main findings, with a focus on how topics like Bell's theorem, and research on the foundations of quantum theory more broadly, moved from the margins to the mainstream of physics research. I will also reflect on the catalytic role that the historical project has played in my own, more recent research, including the recent "Cosmic Bell" experiments.
(Presenter), Williams College — John Wheeler arrived at the University of Texas at Austin in 1976. A year later he introduced a new graduate seminar, "Theory of Measurement," which, in addition to covering well-established topics such as the Wigner-Araki-Yanase theorem, also addressed more speculative concepts such as backward-in-time causation. Students were encouraged to try out their own ideas toward resolving some of the questions raised by quantum theory. This course, mentioned in David Kaiser's book, How the Hippies Saved Physics, provides an example of imaginative thinking about foundational issues within the mainstream physics community in the 1970's.

9:12AM A69.00003: Groovy Physics [Invited] PATRICK MCCRAY (Presenter), University of California, Santa Barbara — If the 1960s represented a boom time for physics, the 1970s presented something totally different. From a general backlash against Cold War-fueled research to the collapse of the job market for physicists, the Me Decade was mean decade. Despite these challenges – or perhaps because of them – a new ensemble of ideas and communities emerged. This talk provides a historical frame for appreciating David Kaiser's book How the Hippies Saved Physics while offering some observations on the various ways new kinds of physics emerged in response to changes in American values, society, and the economy.

9:48AM A69.00004: Embarking on a PhD to test Bell's inequalities in 1974: the most exciting subject I had ever encountered* [Invited] ALAIN ASPECT (Presenter), Laboratoire Charles Fabry — When I read Bell's paper[1] in 1974, it was like love at first sight. I immediately decided that this would be the subject of my PhD thesis. The paper clearly explained that one could experimentally settle the debate on the interpretation of Quantum Mechanics, between Einstein's position, which was totally convincing, and Bohr's point of view, which was the mainstream. A young professor at Institut d'Optique, Christian Imbert, allowed me to perform a Bell's test it in his lab. At that time, two pioneering experiments, one in Harvard (Holt and Pipkin) and one in Berkeley (Clauser and Freedman) had provided opposite results.

Beyond settling that contradiction, my goal was to work out an improved experimental scheme, in which the tension between quantum mechanics and relativity would be tested[3]. After some time, it was clear that this tension was subtle: even if standard quantum mechanics would be vindicated, it did not mean that one could use quantum non-locality to transmit "operational" information faster than light[4]. It had become clear to the physicists interested in that question, and I was one of them, that this "no signaling" was linked to the fundamental randomness of each individual quantum measurement and to the impossibility to duplicate a photon without perturbing its state.

[2] For a general review of the tests of Bell's inequalities, see for instance A. Aspect, Viewpoint: Closing the Door on Einstein and Bohr's Quantum Debate, Physics, 8 (2015) 123. 10.1103/Physics.8.123

Session B01 DCMP: Defects in Topological Materials BCEC 106 - Jennifer Cano
transport characterization. We have demonstrated this method by carving a 2μm x 5μm x 10μm piece of SmB6 and placing
methods due to the inability to grow macroscopic crystalline samples. However, using standard TEM sample preparation
exist a large number of new quantum materials that are difficult to characterize using standard electrical transport
quantities and to understand the role of magnetization due to vacancies in the electronic propagation. The last is responsible for spin-flip processes. We use a self-consistent recursive Green's functions technique to calculate the
transport of graphene in the QSH phase in the presence of those magnetic vacancies. We use an unrestricted Hubbard mean field
Hamiltonian to model the electron-electron interaction, which enables both out-of-plane and in-plane magnetization.

For a monolayer graphene device, there exists one topological kink state, and the oscillation of the transmission
coefficients has a single period. The π Berry phase and the linear dispersion relation of kink states can be extracted from the
transmission data. For a bilayer graphene device, there are two topological kink states with two oscillation periods.
Our proposal provides an experimentally feasible route to manipulate and characterize the valley-polarized topological
kink states in classical wave and electronic graphene-type crystalline systems. The realization of the proposal in photonic
graphene is also discussed.

Partial lattice defects in higher order topological insulators  RAQUEL QUEIROZ, Department of Condensed Matter Physics, Weizmann Institute of Science, ION COSMA FULGA, Institute for Theoretical Solid State Physics, IFW Dresden, NURIT AVRAHAM, HAIM BEIDENKOPF, Department of Condensed Matter Physics, Weizmann Institute of Science, JENNIFER CANO (Presenter), Department of Physics and Astronomy, Stony Brook University, and the Center for Computational Quantum Physics, Flatiron Institute — Non-zero weak topological indices are thought to be a necessary condition to bind a single helical mode on lattice dislocations. In this work we show that higher-order topological insulators (HOTIs) can, in fact, host a single helical mode along screw or edge dislocations (including step edges) in the absence of weak topological indices. This helical mode is necessarily bound to a dislocation characterized by a fractional Burgers vector, locally detected by the existence of a stacking fault. The robustness of a helical mode on a partial defect is demonstrated by an adiabatic transformation that restores translation symmetry in the stacking fault. We present two examples of HOTIs, one intrinsic and one extrinsic, that show helical modes at partial dislocations. Since partial defects and stacking faults are commonplace in bulk crystals, the existence of such helical modes can in principle significantly affect the expected conductivity in these materials.

Honey, I Shrunk the Transport Geometry, or Carving Micro-Crystals of Topological Insulators for Transport Experiments  DMITRI MIHALIOV (Presenter), ALEXA RAKOSKI, SHRIYA SINHA, CAGLIYAN KURDAK, Physics, University of Michigan, PRISCILA ROSA, Los Alamos National Laboratory, ZACHARY FISK, Physics and Astronomy, University of California, Irvine, BOYOU N KANG, MYUNG-SUK SONG, BEONGKI CHO, Gwangju Institute of Science and Technology — There exist a large number of new quantum materials that are difficult to characterize using standard electrical transport methods due to the inability to grow macroscopic crystalline samples. However, using standard TEM sample preparation methods, it is possible to carve 10s of microns size crystalline pieces and place them on an insulating substrate for transport characterization. We have demonstrated this method by carving a 2μm x 5μm x 10μm piece of SmB6 and placing it on a Si substrate. The Hall bar was subsequently wired using Pt contacts deposited via FIB. We are also developing more demanding transport structures, such as double-sided Corbino rings with the goal of studying transport through individual threading dislocations. We will present challenges associated with sample preparation at the micro crystalline scale.

12:03PM B01.00005: Topological gravity, defects, and topological phases protected by both spatial and internal symmetries*  
BO HAN, university of illinois, HUAJIA WANG, UCSB, PENG YE (Presenter), Sun Yat-sen University — A substantial attention of quantum gravity has been paid in different areas of physics, from high energy physics, condensed matter physics to quantum information science. In this paper, we explore the topological quantum gravity from the perspective of symmetry-protected topological (SPT) phases. To be specific, we study the gravitational effect on the classification and response of 3+1d topological phases protected simultaneously by both spatial and internal symmetries from the topological response theory. The latter describes how geometric defect (e.g. disclination) and internal symmetry defect (e.g. domain wall) are topologically entangled. New topological terms involving nontrivial geometries are proposed, which are extensions of purely internal topological theories discussed before. Physical observables derived from these response theories are discussed and compared with their analogs in 2+1d systems, some of which have been well-studied in quantum Hall (QH) systems, like the Wen-Zee (WZ) term. Generalizations to symmetry-enriched topological (SET) phases are also discussed (arXiv:1807.10844).

12:15PM B01.00006: Kondo Signatures of a Quantum Magnetic Impurity in Topological Superconductor*  
XIAOQUN WANG (Presenter), RUI WANG, Shanghai jiao tong University, WEI SU, Nanjing University, JIAN-XIN ZHU, Los Alamos National Laboratory, CHIN-SEN TING, HAI LI, University of Houston, CHANGFENG CHEN, University of Nevada, BAIGENG WANG, Nanjing University — We study the Kondo physics of a quantum magnetic impurity in two-dimensional topological superconductors (TSCs), either intrinsic or induced on the surface of a bulk topological insulator, using a numerical renormalization group technique. We show that, despite sharing the p + ip pairing symmetry, intrinsic and extrinsic TSCs host different physical processes that produce distinct Kondo signatures. Extrinsic TSCs harbor an unusual screening mechanism involving both electron and orbital degrees of freedom that produces rich and prominent Kondo phenomena, especially an intriguing pseudospin Kondo singlet state in the superconducting gap and a spatially anisotropic spin correlation. In sharp contrast, intrinsic TSCs support a robust impurity spin doublet ground state and an isotropic spin correlation. These findings advance fundamental knowledge of novel Kondo phenomena in TSCs and suggest experimental avenues for their detection and distinction.

12:27PM B01.00007: Impurity-induced bound states as a signature of chiral p-wave superconductivity in Pb_{1-x}Sn_xTe*  
SARBAJAYA KUNDU (Presenter), VIKRAM TRIPATHI, Tata Institute of Fundamental Research — The recent observation of surface superconductivity on the (001) surface of the topological crystalline insulator Pb_{1-x}Sn_xTe is intriguing, but the nature of the superconducting order is yet to be ascertained. In this context, we have recently proposed that a chiral p-wave superconducting order can be realized on the (001) surface of Pb_{1-x}Sn_xTe, in the presence of weak electronic correlations. In this talk, I will discuss impurity-induced subgap bound states as a possible experimental signature of the chiral p-wave order. In particular, I will introduce two parameter regimes: the normal band gap regime where the subgap bound states are smoothly connected to impurity states in semiconductors, and the inverted band gap regime, where they nontrivially depend on the existence of chiral p-wave superconductivity. I will further discuss properties of the analytically obtained bound state wavefunctions that are peculiar to the chiral p-wave order. For a point defect, these include the quasi-localized nature of the bound-state wavefunctions, and an internal SU(2) rotational symmetry of the zero-energy bound states that enables their use as a possible quantum qubit.

**12:39PM B01.00008: Fractional Chern insulator edges and layer-resolved lattice contacts**  
CHRISTINA KNAPP  
(Presenter), ERIC SPANTON, ANDREA YOUNG, CHETAN NAYAK, University of California, Santa Barbara, MICHAEL ZALETEL, Physics, UC Berkeley — Fractional Chern insulators (FCIs) realized in fractional quantum Hall systems subject to a periodic potential are topological phases of matter for which space group symmetries play an important role. In particular, lattice dislocations in an FCI can host topology-altering non-Abelian topological defects, known as genons. Genons are of particular interest for their potential application to topological quantum computing. In this work, we study FCI edges and how they can be used to detect genons. We find that translation symmetry can impose a quantized momentum difference between the edge electrons of a partially-filled Chern band. We propose layer-resolved lattice contacts, which utilize this momentum difference to selectively contact a particular FCI edge electron. The relative current between FCI edge electrons can then be used to detect the presence of genons in the bulk FCI. Recent experiments have demonstrated graphene is a viable platform to study FCI physics. We describe how the lattice contacts proposed here could be implemented in graphene subject to an artificial lattice, thereby outlining a path forward for experimental detection of non-Abelian topological defects.

**12:51PM B01.00009: Quasiparticle interference and nonsymmorphic effect on a floating band surface state of ZrSiSe**  
ZHEN ZHU (Presenter), Shanghai Jiao Tong University, FENGQI SONG, Nanjing University, HSIN LIN, Academia Sinica, WEI KU, HAO ZHENG, JINFENG JIA, Shanghai Jiao Tong University — Nonsymmorphic crystals are generating great interest as they are commonly found in quantum materials, like iron-based superconductors, heavy-fermion compounds, and topological semimetals. A new type of surface state, a floating band, was recently discovered in the nodal-line semimetal ZrSiSe, but also exists in many nonsymmorphic crystals. Little is known about its physical properties. Here, we employ scanning tunneling microscopy to measure the quasiparticle interference of the floating band state on ZrSiSe (001) surface and discover rotational symmetry breaking interference, healing effect and anomalous half-missing Umklapp scattering. Using simulation and theoretical analysis we establish that the phenomena are characteristic properties of a floating band surface state. Moreover, we uncover that the half-missing Umklapp process is derived from the glide mirror symmetry, thus identify a nonsymmorphic effect on quasiparticle interferences. Our results may pave a way towards potential new applications of nanoelectronics.

**1:03PM B01.00010: Topological 0D defect states in 3D insulators**  
FRANK SCHINDLER, STEPLAN TSIRKIN (Presenter), TITUS NEUPERT, Department of Physics, University of Zurich, ANDREI B BERNEVIG, BENJAMIN WIEDER, Department of Physics, Princeton University — There has been intense interest in relating the electronic states bound to crystal defects to the bulk electronic structure of pristine crystals. By mapping the momentum-space Hamiltonians of Brillouin zone surfaces to the real-space surfaces between crystal defects, we develop a general formulation of topological (crystalline) defect states. We introduce topological invariants for these states using (nested) Wilson loops and Topological Quantum Chemistry. Our framework captures all previous results, including fractional charges bound to point defects in inversion-symmetric Chern insulators and helical modes bound to screw dislocations in weak topological insulators (TIs). However, we also discover new examples. In particular, we show that screw dislocations and edge disclinations in 3D higher-order TIs (HOTIs) can bind anomalous 0D higher-order “end states,” which are equivalent to the fractionally charged corner modes of 2D “fragile” TIs and obstructed atomic limits, and persist under the relaxation of particle-hole symmetry, which is not present in real materials. Using density functional theory and tight-binding calculations, we demonstrate the presence of higher-order defect end states in the HOTI and topological crystalline insulator SnTe.

**1:15PM B01.00011: Complete description of symmetry-protected topological properties of Sn_xPb_1-xTe_ySe_1-y topological crystalline insulators with a step edge**  
WOJCIECH BRZEZICKI, MARCIN WYSOKINSKI, TIMO HYART (Presenter), International Research Centre MagTop, Institute of Physics, Polish Academy of Sciences — Surfaces of multilayer semiconductors typically have regions of atomically flat terraces separated by atom-high steps. Here we investigate the properties of the low-energy states appearing at the surface atomic steps in Sn_xPb_1-xTe_ySe_1-y. We identify the important approximate symmetries and use them to construct relevant topological invariants. We calculate the dependence of mirror- and spin-resolved Chern numbers on the number of layers and show that the step states appear when these invariants are different on the two sides of the step. Moreover, we find that a particle-hole symmetry can protect one-dimensional Weyl points at the steps. Since the local density of states is large at the step the system is susceptible to different types of instabilities, and we consider an easy-axis magnetization as one realistic possibility. We show that magnetic domain walls support a pair of zero-energy states because the regions with opposite magnetization are topologically distinct in the presence of non-symmorphic chiral and mirror symmetries, providing a possible explanation for the zero-bias conductance peak observed in the recent experiment [Mazur et al., arXiv:1709.04000].

*The work is supported by the Foundation for Polish Science through the IRA Programme co-financed by EU within SG OP.*
1:27PM B01.00012: Dynamically Induced Topology in the Fermi Sea* DANIEL DAHAN, EYTAN GROSFELD, Ben Gurion University of the Negev, BABAK SERADJEH (Presenter), Indiana University Bloomington — We study the dynamics of topological bound states following their coupling to the Fermi sea of a topologically trivial, gapless lead. Specifically, we study the quench dynamics of solitons in the Su-Schrieffer-Heeger model and of Majorana zero modes of Kitaev model. Remarkably, we find bound states propagate through the lead preserving their topological nature, such as fractional charge and exchange statistics. We explain this phenomenon as a manifestation of dynamically induced topology in the Fermi sea arising from the entanglement between the topological and gapless systems. We obtain, both analytically and numerically, topological features of propagating bound states, including their fractional charge, charge fluctuations, entanglement entropy, and fractional statistics. This allows us to characterize the coherence time over which these topological features relax. We also study the effects of interactions and disorder in the lead on the integrity of the topological bound states and the coherence time of dynamically induced topology.

*Supported by ISF grants 401/12 and 1626/16, the EU Seventh Framework Programme (FP7/2007-2013) grant 303742, BSF grant 2014345, and NSF grants PHY-1607611 and DMR-1350663.

1:39PM B01.00013: The influence of 1D topological states on the thermoelectric properties of Bi₂Te₃ from the perspective of coupled Tomonaga-Luttinger liquids (TLLs).* PIOTR CHUDZINSKI (Presenter), Queen's University Belfast — Bi₂Te₃, the first discovered strong 3D topological insulator is also one of the best known thermoelectric materials at ambient conditions. It has been recently discovered that in such 3D topological insulator each skew dislocation will host a pair of 1D topological states – a helical TLL. Any 1D state gives rise to huge Seebeck coefficient, a fact that is used in thermoelectricity enhancement by engineering of low dimensional nano-structures. One could then ascribe the outstanding thermoelectric properties of Bi₂Te₃ to these 1D topological states. However, in order to achieve a non-zero Seebeck coefficient, a mechanism that will induce curvature and backscattering of the 1D states is needed. One also needs a good description of 3D electronic states within a dense network of dislocations and proof that a large overlap with the 1D states is possible. In this study we show how to overcome these obstacles and then derive an exact analytic formula for Seebeck coefficient within a framework of coupled TLLs. Our study is applicable either to the regime of an extremely weakly n-doped material or to the case where the transport is activated by photo-excitations.

1:51PM B01.00014: Probing the Topological Classification of Bismuth with Topological Defects NURIT AVRAHAM (Presenter), ABHAY K NAYAK, JONATHAN REINER, RAQUEL QUEIROZ, HUIXIA FU, Weizmann Institute of Science, CHANDRA SHEKHAR, CLAUDIA FELSER, Max Planck, Dresden, BINGHAI YAN, HAIM BEIDENKOPF, Weizmann Institute of Science — The growing diversity of topological classes may lead to ambiguity in the classification of materials. Such is the case of Bismuth. While most theoretical models indicate that Bismuth possesses a trivial topological order, other theoretical and experimental studies suggest other classifications such as a strong, a weak, and a higher order topological insulator (TI), all of which host helical modes on their boundaries. We use scanning tunneling microscopy to investigate the response of the topological edge mode, in Bismuth, to a topological defect in the form of a screw dislocation. We find that the edge mode extends over a wider energy range than previously thought, and withstands crystallographic irregularities, without showing any signs of backscattering and gapping. Moreover, it seems to bind to the bulk screw dislocation, as expected for a TI with non-vanishing weak indices. These observations disfavor its recent identification as a hinge mode of a high order TI. We argue that the small scale of the bulk $L$ gap positions Bismuth within the critical region of a topological phase transition to a strong TI with non-vanishing weak indices. Consequently, the observed boundary modes are approximately helical already on the trivial side of the topological phase transition.

2:03PM B01.00015: Static analogues of driven phases of matter IAN MONDRAGON (Presenter), Department of Physics, Yale University, BRAHYAM RIOS, BORIS RODRIGUEZ, Instituto de Fisica, Universidad de Antioquia, MENG CHENG, Department of Physics, Yale University — Driven phases of matter are often said to arise only in nonequilibrium conditions. We here show that analogues of driven phases can be created as time-independent eigenstates of matter interacting with quantum light. These phases are characterized by a hidden geometric phase, referred to here as optical Berry phase, which is related to the average photon number of the system. We illustrate our results by studying an analogue of a driven topological state, the so called Anomalous Floquet Anderson Insulator. We show that the optical Berry phase manifests itself as a topological pumping of photons at the boundary equal to the bulk invariant. Finally, we discuss how the tools of cavity QED systems can be brought to bear in the study of these phases of light and matter.
11:15AM B02.00001: Clamped-ion flexoelectricity from first principles [Invited] CYRUS DREYER (Presenter), Department of Physics and Astronomy, Stony Brook University, Stony Brook, NY, USA; and Center for Computational Quantum Physics, Flatiron Institute, New York, NY, USA, ANDREA SCHIAFFINO, Institut de Ciència de Materials de Barcelona (ICMAB-CSIC), Campus UAB, Bellaterra, Spain, MASSIMILIANO STENGEL, ICREA-Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain; and Institut de Ciència de Materials de Barcelona (ICMAB-CSIC), Campus UAB, Bellaterra, Spain, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, USA — The flexoelectric (FxE) effect, where polarization is induced by a strain gradient, is universal in all insulators. As devices shrink to the micro and nano scale, large strain gradients can occur, and therefore the FxE effect can play a significant role in their electrical and mechanical properties. Also, the FxE effect can be exploited for novel device design paradigms such as piezoelectric "meta-materials" constructed from nonpiezoelectric constituents, or mechanical switching of ferroelectric polarization. One of the crucial limitations to understanding and exploiting the FxE effect is the lack of an efficient first-principles methodology to calculate all of the components of the bulk FxE tensor; the clamped-ion transverse and shear components in particular are problematic. In this work we develop such a methodology based on density functional perturbation theory to calculate the full bulk, clamped-ion FxE tensor from a single unit cell, by calculating the current-density response to the adiabatic displacement of atoms from a long wavelength acoustic phonon. In this talk I will outline our methodology, including recent developments relating to the implementation of a “metric wave” formalism, and apply it to calculate the clamped-ion flexoelectric constants in the context of cubic and distorted perovskite oxides.

11:51AM B02.00002: Spatial dispersion effects in ferroic oxides: Dynamical quadrupoles and flexoelectric tensor MASSIMILIANO STENGEL, ICMAB-CSIC and ICREA, MIQUEL ROYO (Presenter), ICMAB-CSIC — In condensed-matter physics, spatial dispersion refers to the dependence of many material properties on the wavevector $q$ at which they are probed, and is ultimately due to the nonlocality of the response to a given external field (electric, magnetic, strain). A remarkable example is the flexoelectric tensor, describing the polarization response to a gradient of applied strain, or equivalently the electrical current that is produced by an acoustic phonon at second-order in $q$. Density-functional perturbation theory (DFPT) appears as the ideal framework to compute these effects from first principles, but the general computational tools to deal with the long-wavelength limit are currently missing. Here we present a general formalism, based on the analytical long-wavelength expansion of the second-order DFPT energies, that enables the direct calculation of spatial dispersion quantities at a computational cost that is comparable to that of a uniform-field response calculation. We present results for the clamped-ion flexoelectric tensor in SrTiO$_3$ and the dynamical quadrupoles (the higher-order multipolar counterpart of the Born effective charges) in tetragonal PbTiO$_3$. The quadrupoles relate to the clamped-ion piezoelectric tensor as predicted by R. Martin in his 1972 seminal paper.

12:03PM B02.00003: Flexoelectricity and Twins in LaAlO$_3$* CHRISTOPHER MIZZI (Presenter), BINGHAO GUO, LAURENCE MARKS, Materials Science, Northwestern University — Flexoelectricity in complex oxides has recently garnered much interest due to its ubiquity, intrinsic scaling at the nanoscale, and device applications. Although this has resulted in a dramatic increase in the number of publications on this phenomenon, an abundance of fundamental questions persists. In particular, the role of microstructure on the flexoelectric response of oxides is scanty considered in the existing literature. Twinned oxides are well-posed to elucidate this question because they naturally bridge the gap between single crystals and polycrystalline ceramics. In this work, a dynamic mechanical analyzer in a three-point bending configuration was used to study the flexoelectric response of $\{100\}_{pc}$-LaAlO$_3$ with lamellar twin microstructures as a function of temperature. We found the flexoelectric response of LaAlO$_3$ is dominated by its twinned microstructure and tunable by two orders of magnitude via changing the number of twins, domain wall orientation, and domain wall mobility.

12:15PM B02.00004: Ferroelectric Materials for Photocatalytic Water-Splitting – Strained Mixed Anion Perovskites*
NATHALIE VONRÜTI (Presenter), ULRICH ASCHAUER, University of Bern — Polarity, for example in ferroelectric materials, can significantly increase a catalyst's performance by improving charge-carrier separation. However, polar distortions also increase the band gap as shown for epitaxially strained SrTiO\textsubscript{3} (1). While this band-gap increase is small for oxides, our density functional theory calculations show a much larger increase for oxynitrides: The enhanced covalency due to reduced electronegativity of nitrogen compared to oxygen results in larger strain-induced polar distortions and therefore more strongly increased band gaps by up to 1.5 eV. The reduced electronegativity, which leads to a higher valence band in oxynitrides and therefore a band gap in the visible that is attractive for photocatalysis, thus also has a detrimental effect on photo absorption when polar distortions are present. This results in a trade-off between small band gaps and polarity. We will discuss different strategies on how to overcome this trade-off with mixed anion perovskite compounds, which have not yet been considered for photocatalytic water-splitting.

*Swiss National Science Foundation PP00P2_157615

12:27PM B02.00005: Bulk- and Flexo-Photovoltaic effects*
[Invited] MARIN ALEXE (Presenter), MING-MIN YANG, DONG-JIK KIM, ZHENGDONG LUO, University of Warwick — Two years after the invention of modern prototype solar cells, it was found that BaTiO\textsubscript{3} exhibits a photovoltaic effect distinct from that of \textit{p-n} junctions, later called the bulk photovoltaic (BPV) effect. Under uniform illumination, a homogeneous ferroelectric material gives rise to a short-circuit current and produces an anomalously large photo-voltage well exceeding the bandgap energy. The microscopic origins of this effect supposed to originate from the asymmetric distribution of photoexcited non-equilibrium carriers in \textit{k}-space, caused by absence of centrosymmetry. The talk will present a short history and the basics of the bulk photovoltaic effect, tip enhancement, as well as the electronic origin of the anomalous BPV in some materials such as BiFeO\textsubscript{3}. Potential applications such as energy harvesting or light-induced reversible switching of ferroelectric polarization at room temperature will be addressed. I will show how the BPV effect may be used in optical switching tunnel junctions or other similar devices. Finally, I will discuss a new photovoltaic effect which turns the BPV effect into a universal effect allowed in all semiconductors by mediation of the flexoelectric effect. [M.-M. Yang D. J. Kim, & M. Alexe, Flexo-Photovoltaic Effect, Science 360, 904 (2018)]

1:03PM B02.00006: Complex chalcogenides as highly-polarizable semiconductors*
STEPHEN FILIPPONE, Massachusetts Institute of Technology, SHANYUAN NIU, Department of Chemical Engineering and Materials Science, University of Southern California, KRISTOPHER WILLIAMS, WILLIAM A TISDALE, Massachusetts Institute of Technology, YI-YANG SUN, Shanghai Institute of Ceramics, Chinese Academy of Sciences, JAYAKANTH RAVICHANDRAN, Department of Chemical Engineering and Materials Science, University of Southern California, RAFAEL JARAMILLO (Presenter), Massachusetts Institute of Technology — Ternary sulfides and selenides in the distorted-perovskite and related structures ("complex chalcogenides") are predicted to be semiconductors with band gap in the visible-to-infrared, and may be useful for optical, electronic, and energy conversion technologies. The crystal structures familiar to complex oxides, together with larger chalcogenide anions, suggest that complex chalcogenides will be highly polarizable semiconductors.

We will report theoretical and experimental progress towards establishing the fundamentals of highly-polarizable complex chalcogenide semiconductors. We use computational thermodynamics to predict the phase diagrams for select materials, highlighting windows of equilibrium between solid and vapor phases – relevant to growing films by molecular beam epitaxy (MBE). We then report on progress towards MBE growth of complex chalcogenide films, focusing on control of H\textsubscript{2}S and H\textsubscript{2}Se gas precursors. We will also report experimental results on complex chalcogenides in the Ba-Zr-S system, including time-resolved photoluminescence suggesting slow minority carrier recombination, and impedance spectroscopy providing evidence of highly-polarizable materials with band gap below 2 eV.

Understanding Negative Thermal Expansion in Layered Perovskites
CHRIS ABLITT (Presenter),
Department of Materials, Imperial College London, NICHOLAS C BRISTOWE, School of Physical Sciences, University of Kent, MARK S SENN, Department of Chemistry, University of Warwick, ARASH A MOSTOFI, Department of Materials and Department of Physics, Imperial College London — Negative thermal expansion (NTE) is an unusual phenomenon where a material shrinks rather than expands with increasing temperature. We will present recent results showing that in layered perovskites there is a significant enhancement of elastic anisotropy due to symmetry breaking that results from the combined effect of layering and frozen rotations of oxygen octahedra. This feature, unique to layered perovskites of certain symmetry, is what allows uniaxial NTE to persist over a large temperature range [1]. Since the structure of this phase facilitates cooperative strains in-plane and along the layering axis without necessitating the deformation of stiff nearest neighbour bonds, it has been possible to derive a mathematical description of this mechanism in an idealised system using simple geometrical models [2]. This insight has allowed us to investigate how changing structural features, such as the layer thickness [3]; physical features, such as temperature [1]; and chemistry, by substitutional doping [4] may all be used to control the thermal expansion of the material.

Reduction of the thermal conductivity in PbTiO3 thin-films by ferroelectric domain walls.*
ERIC LANGENBERG, Materials Science and Engineering, University of Cornell, DAVIG BUGALLO-FERRÓN, University of Santiago de Compostela, DIPANJAN SAHA, Mechanical Engineering, Carnegie Mellon University, ELAS FERREIRO-VILA, University of Santiago de Compostela, JONATHAN A MALEN, Mechanical Engineering, Carnegie Mellon University, DARRELL G. SCHLOM, Materials Science and Engineering, University of Cornell, FRANCISCO RIVADULLA (Presenter), University of Santiago de Compostela — The development of materials with switchable thermal conductivity have been limited to small low/high thermal conductivity ratios. We experimentally demonstrate that the thermal conductivity of PbTiO3 films can be significantly reduced through ferroelectric domain wall engineering. Ferroelectric domain walls (DWs) are effective phonon scattering sites, whose density and spacing can be controlled by an electric field, and therefore offer a unique opportunity to modulate the thermal conductivity by an external stimulus. In our experiments, we significantly reduced thermal conductivity by engineering the type and configuration of the DWs, as well as the DW density, through epitaxial strain and impurity doping.

Intrinsic Piezoelectricity above Curie temperature in BaTiO3*
SERGEI PROKHORENKO (Presenter),
YOUSRA NAHAS, Physics Department and Institute for Nanoscience and Engineering, University of Arkansas, IGOR KORNEV, Laboratoire Structures, Propriétés et Modélisation des Solides, CentraleSupélec, DARIUSZ KAJEWSKI, Institute of Physics, Institute of Silesia, DANIEL RYZT, Forschungsinstitut für mineralische und metallische Werkstoffe, Edelsteine/Edelmetalle (FEE) GmbH, KRISTIAN ROLLEDER, Institute of Physics, Institute of Silesia, LAURENT BELLAICHE, Physics Department and Institute for Nanoscience and Engineering, University of Arkansas — Barium titanate, a classical ferroelectric compound, is known to exhibit non-trivial precursor properties above the Curie temperature that directly point to the polar character of its “paraelectric” phase. In this study we combine theoretical analysis, large scale effective Hamiltonian simulations and experiments performed on high quality single crystals to revisit the origins of precursor effects in BaTiO3. Our results demonstrate that the non-trivial piezoelectric response at temperatures far above Tc is an intrinsic feature of BaTiO3 not related to structural defects or sample fabrication conditions but rather a consequence of complex high-temperature dipolar structure and strong order-disorder nature of local ionic potential of this material.

First-principles study on piezoelectricity in Bi(Fe,Co)O₃

HIROSHI KATSUMOTO (Presenter), KUNIHIKO YAMAUCHI, TAMIO OGUCHI, The Institute of Scientific and Industrial Research, Osaka University — The perovskite solid solution BiFe₁₋ₓCoₓO₃ (BFCO) is composed of BiFeO₃ and BiCoO₃, which have rhombohedral and tetragonal structure, respectively. BFCO is a promising lead-free piezoelectric material, since the morphotropic phase boundary (MPB) was discovered around 0.2 < x < 0.4 region at room temperature, where monoclinic phase is present [1]. A typical multiferroic material, BiFeO₃ shows ferroelectricity and G-type antiferromagnetic order at room temperature. On the other hand, BiCoO₃ shows high tetragonality and C-type antiferromagnetic order. The enhancement of piezoelectric coefficients and polarization rotation can be expected in a vicinity of the MPB as in PZT. The monoclinic crystal structure is √2×√2×1 perovskite cell which accommodates the antiferromagnetic configuration. The spontaneous polarization and the piezoelectric coefficients have not been measured in the bulk system so far, owing to the large leakage current. In this context, we performed first-principles calculations of the spontaneous polarization and the piezoelectric response of a Fe/Co chemically ordered model of BFCO. Based on the results, we discuss the ferroelectric distortion and the microscopic mechanism of the piezoelectric effect in BFCO.

Lithium niobate single crystal as a novel host for persistent luminescence

SHAO PENG LIN (Presenter), HUASHAN LI, CHEN WEI XIONG, DECAI MA, Sino-French Institute of Nuclear Engineering and Technology, Sun Yat-sen University, BIAO WANG, School of Physics, Sun Yat-sen University — LiNbO₃ (LN) is one of the most versatile and widely used materials in photonics with broad applications such as holographic storage, electro-optical modulator, optical switch, on-chip waveguide circuit, harmonic generator and micro-electro-mechanical system, etc. In the past decades, LN has presented various mysterious optical properties based on ions-doping engineering. However, persistent luminescence (PersL) has not been reported so far. In this study, bright red PersL was found in Mg²⁺ and Pr³⁺ co-doped congruent LiNbO₃ single crystal excited with ultraviolet at room temperature. Photoluminescence, photoluminescence excitation, thermoluminescence glow curves and afterglow decay curves have been investigated. Accordingly, a transition mechanism based on energy level distribution has been proposed to describe PersL, wherein both Mg²⁺ and Pr³⁺ ions play essential roles. Given the outstanding ferroelectric, piezoelectric, electro-optical, and mechanical properties of host material, our findings open an opportunity to couple various responses to external stimuli, and thus to develop novel applications based on multifunctional persistent luminescence phosphors.

Session B03 DCMP: Novel Excitations in Topological Systems

Splitting the hinge mode of higher-order topological insulators

RAQUEL QUEIROZ (Presenter), Condensed Matter Physics, Weizmann Institute of Science — We study the effect of the coupling of a helical mode in a two-dimensional topological insulator without inversion symmetry — focusing at the surface of a higher order topological insulator (HOTI) — to a proximate ferromagnet and to a proximate s-wave superconductor. We find that in contrast to the helical modes of inversion symmetric systems, which are gapped by these couplings, when inversion is broken the helical modes generically remain gapless and spatially split. The ferromagnet turns the helical mode into a chiral mode that surrounds the magnetized region, and the superconductor, when strong enough, turns that mode to two helical Majorana modes that surround the superconducting region. The enclosed superconductor comprises a two dimensional, time-reversal invariant, topological superconductor. We propose that this state can be measured in electrical transport by an extension of previously proposed interferometry experiments.
11:27AM B03.00002: Magneto Optic Kerr Effects of an Antiferromagnet - Topological Insulator Heterostructure*
TONMOY BHOWMICK (Presenter), AMRITANAND DE, ROGER LAKE, University of California, Riverside — We investigate the magneto-optic memory applications of a topological insulator proximity coupled to an anti-ferromagnet. We find that this gives rise to a high figure of merit magneto optic Kerr effects. The optical dielectric tensor elements are calculated using the Kubo formula and are based on a tight-binding electronic structure model. We calculate the Fermi level dependence of the MOKE signature and explore the AFM-TI optical phase diagram. This system can lead to applications such as a topologically protected high density antiferromagnetic magnetic optic memory device with ultra-low error rates.

11:39AM B03.00003: Glide-resolved photoemission spectroscopy: measuring topological invariants in nonsymmorphic space groups*
ARIS ALEXANDRADINATA (Presenter), Yale University, ANDREI B BERNEVIG, ZHIJUN WANG, Princeton University, MICHAEL ZALETEL, University of California, Berkeley — The two classes of 3D, time-reversal-invariant insulators are known to subdivide into four classes in the presence of glide symmetry. Based on ab-initio calculations, we predict materials that realize all three, nontrivial insulating phases. We further elucidate the smoking-gun experimental signature of each class in the photoemission spectroscopy of surface states. Measuring the Z_4 invariant relies on identifying the glide representation of the initial Bloch state before photo-excitation -- this is accomplished with relativistic dipole selection rules, combined with standard spectroscopic techniques to resolve both momentum and spin. As an orthogonal by-product of our method, we propose how to generate a source of 100% spin-polarized photoelectrons, which have diverse applications in solid-state spectroscopy.

11:51AM B03.00004: Bulk-edge correspondence in 1D non-Hermitian systems
KAZUKI YOKOMIZO (Presenter), SHUICHI MURAKAMI, Tokyo Institute of Technology — Recently, the role of the topology in non-Hermitian systems is attracting much attention. It is known fact is that the conventional bulk-edge correspondence breaks down in non-Hermitian systems if the Bloch wavevector $k$ is set to be real. Here, to restore the bulk-edge correspondence, the non-Bloch factor $\beta=\exp(ik)$, $k\in \mathbb{C}$ is introduced in the SSH model with the asymmetric hopping [1]. In this case, one can show the bulk-edge correspondence by defining the winding number by using $\beta$. However, it is not obvious how to systematically calculate $\beta$ in general case. In this talk, we show how to calculate $\beta$ in general 1D models for constructing the continuum bulk-bands. It is non-trivial because the states in the continuum bulk-bands do not extend over the bulk, unlike those in the Hermitian systems. We also discuss the bulk-edge correspondence in general cases by defining the generalized Brillouin zone in terms of $\beta$. [1] S.Yao, et al., Phys. Rev. Lett. 121, 086803 (2018)

12:03PM B03.00005: Quantum Control of Current Partition at Trifurcating Topological Channels*
TAO HOU (Presenter), Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China, YUJIE QUAN, YAFEI REN, Department of Physics, University of Science and Technology of China, JEIL JUNG, Department of Physics, University of Seoul, WEI REN, Physics Department, Shanghai University, ZHENHUA QIAO, Department of Physics, University of Science and Technology of China — Topological channels can emerge a network along the domain walls that separate AB and BA stacking regions in minimally twisted bilayer graphene, which have been imaged by using scanning tunneling microscope recently. Here, we design a six-terminal graphene device to study how the incoming valley-polarized current will partition at the topological crossing point. We find that the incoming current not only can be partitioned into the two adjacent topological channels, but also goes straight along the incoming topological channel, which together form a trifurcating beam splitter. We provide a further systematic study on how to externally tune the trifurcating current partition by means of manipulating the system size, Fermi-energy, magnetic field, relative masses.

12:15PM B03.00006: Metallicity at the Ioffe-Regal limit in a topological insulator thin film*  ILAN ROSEN (Presenter), Stanford University, INDRA YUDHISTIRA, GIRISH SHARMA, National University of Singapore, MARYAM SALEHI, JISOO MOON, DEEPTI JAIN, SEONGSHIK OH, Rutgers University, MARC KASTNER, Stanford University, SHAFFIQUE ADAM, National University of Singapore, DAVID GOLDHABER-GORDON, Stanford University — The topological surface states of time-reversal invariant 3D topological insulators have applications for spintronics, metrology, and the realization of topological superconductivity. Initial excitement around these surface states, however, focused on the prediction that they should be robust against Anderson localization, even under strong disorder. This prediction has never been directly confirmed by transport measurements. We present low-temperature transport measurements of a gate-tunable Sb$_2$Te$_3$ topological insulator thin film that features high mobility and low carrier density. We find that metallicity is preserved at conductivities well below $e^2/h$, where two dimensional electron systems conventionally scale to an insulating state. Near the charge neutrality point, we observe an unusual magnetoconductance response, which we associate with known weak localization/anti-localization behavior, but beyond the Ioffe-Regal limit $k_F l \sim 1$.

12:27PM B03.00007: High order band topology and fractional charges of vortex bound states*  EUNWOO LEE (Presenter), BOHM-JUNG YANG, Physics and Astronomy, Seoul National University — In a one-dimensional system described by the SSH model, a half-integer electric charge can be localized at the domain wall between topological and trivial systems. A similar phenomenon can also occur in certain two dimensional systems in which fractional electric charge can be localized at a vortex core. We show that the origin of the zero-mode bound to a vortex comes from the higher order topological physics. Considering several concrete examples, we show that vortex bound states can generally be understood as a spatial charge pump between higher order topological phase and trivial phase. In particular, when PT symmetry exists, we show that the pumping of the second Stiefel-Whitney invariant $w_2$ corresponds to the number of zero modes localized at the vortex core.

12:39PM B03.00008: Topological phases of non-Hermitian systems*  FLORE KUNST, Stockholm University, VATSAL DWIVEDI (Presenter), University of Cologne — Non-Hermitian fermionic systems are known to exhibit features strikingly different from their Hermitian counterparts, a quintessential example being the lack of a bulk-boundary correspondence in the conventional sense. In this talk, I will describe a transfer matrix approach to these systems. The algebraic structure of the transfer matrix and a Riemann surface associated with the complex energies provide a clear and intuitive picture of various topological aspects of these systems.

12:51PM B03.00009: Many-Body Invarinats for Electric Multipoles in Higher-order Topological Insulators  BYUNGMIN KANG (Presenter), HYUNWOONG KWON, KWON PARK, Physics, Korea Institute for Advanced Study, GIL YOUNG CHO, Physics, Pohang University of Science and Technology — According to the modern theory of polarization, the electric polarization in solids is defined via Berry phase, which definition is fundamentally different from the classical definition of polarization involving charge distribution. In certain classes of crystalline topological insulators, the electric polarization is known to take quantized value due to underlying crystalline symmetries. Recently, the theory of multipole moments in crystalline insulators was developed where the quadrupole moment and higher-order multipole moments can be defined quantum mechanically. Although crystalline symmetries are useful they are not essential in understanding multiple moments, and so far the theory is only applicable to non-interacting crystalline band insulators. In this talk, I will introduce a many-body order parameter for quadrupole moment which provides a way to extend the quantum theory of multipole moments to the most general setting including interacting case. I will also discuss the bulk-boundary correspondence for quadrupole moment, relating seemingly unrelated quantities from the bulk and from the boundary.
1:03PM B03.00010: Spin Transport in Topological Material - Graphene Heterostructures

DMITRII KHOKHRIAKOV, ANDRE DANKERT, SAROJ DASH (Presenter), Chalmers University of Technology — Topological insulators are known to have unique electronic and spintronic properties [1]. On the other hand, graphene and h-BN are proven to be excellent materials for long distance spin transport [2] and a large tunnel spin polarization [3], respectively. Here, we combine graphene with topological materials and semiconductors in van der Waals heterostructures to demonstrate the emergence of a strong proximity-induced spin-orbit interaction in graphene [4,5]. By performing spin transport and precession measurements, we discover a strong tunability and suppression of the spin signal and spin lifetime due to a strong hybridization of their electronic bands [4,5]. The enhanced spin-orbit coupling strength is estimated to be nearly an order of magnitude higher than in pristine graphene. These findings in 2D materials heterostructures could open interesting opportunities for exploring exotic physical phenomena and new spintronic device functionalities.

1:15PM B03.00011: Dynamical Phase Transitions in Topological Insulators

NICHOLAS SEDLMAYR (Presenter), Department of Physics and Medical Engineering, Rzeszow University of Technology, MICHAEL FLEISCHHAUER, Technical University of Kaiserslautern, JESKO SIRKER, University of Manitoba — The traditional concept of phase transitions has, in recent years, been widened in a number of interesting ways. The concept of a topological phase transition separating phases with a different ground state topology, rather than phases of different symmetries, has become a large widely studied field in its own right. Additionally an analogy between phase transitions, described by non-analyticities in the derivatives of the free energy, and non-analyticities which occur in dynamically evolving correlation functions has been drawn. Here we focus in particular on the way in which these dynamical phase transitions themselves can be used to shed light on topological phase transitions and topological phases. We consider, firstly, the effect of the topologically protected edge states, which are one of the interesting consequences of topological phases, on dynamical phase transitions. Secondly we consider what happens in the experimentally relevant situations where the system is either in a thermal state rather than the ground state, or connected to an external environment.

1:27PM B03.00012: Spin Stiffness and Domain Walls in Dirac-Electron Mediated Magnets*

SAHINUR REJA, HERBERT FERTIG (Presenter), Indiana University Bloomington, LUIS BREY, Instituto de Ciencia de Materiales de Madrid — We consider the problem of ordering of classical magnetic impurities which are indirectly coupled by two-dimensional Dirac electrons, as might be present in graphene or at the surface of a topological insulator. For chemical potential at a Dirac point, the magnetic order parameter develops an emergent long-range form of the spin stiffness, becoming truly long-range as the magnetization density becomes very small. It is demonstrated that this leads to screened Coulomb-like interactions among domain walls. A transfer matrix analysis demonstrates that the interaction takes this form from a subtle cancellation between energy contributions from in-gap bound states and phase shifts of scattered electrons. Detailed studies of graphene and a topological crystalline insulator surface are used to illustrate the behavior. The non-analytic behavior of the stiffness on magnetization density is shown to have interesting consequences for the phase diagram of these systems.

*Supported by the NSF, BSF, and MEyC-Spain.
1:39PM B03.00013: Topological tunability from even-odd order parameter mixing of monolayer 1T-TaSe₂ charge density wave*  
MING-CHIEN HSU (Presenter), SHIN-MING HUANG, Department of Physics, National Sun Yat-sen University, 
BAHADUR SINGH, College of Optoelectronic Engineering, Shenzhen University, CHUANG-HAN HSU, Department of Physics, National University of Singapore, SUYANG XU, Department of Physics, Massachusetts Institute of Technology, Cambridge, HSIN LIN, Institute of Physics, Academia Sinica, CHENLIANG SU, SZU-NUS Collaborative Center and International Collaborative, Laboratory of 2D Materials for Optoelectronic Science & Technology, Engineering Technology Research Center for 2, ARUN BANSIL, Department of Physics, Northwestern University — Monolayer 1T-TaSe₂ has been found to have charge density wave (CDW) experimentally. The primary CDW order parameter takes the M₁⁻ symmetry having odd parity and will change parity of electronic states of the system. Due to the coexistence of three q vectors from the primary order parameter, a secondary order parameter of even parity is induced inevitably. The mixture of the two opposite-parity order parameters will break inversion symmetry, which fails connection between symmetry and topology. Here we propose a method to decouple the parity-odd and parity-even CDW gaps, so that we can perform continuously the inversion-asymmetric CDW state into an inversion-symmetric one. In this way it helps to understand topological phase transitions in inversion asymmetric systems from the inversion-symmetry point of view.

*The project is supported by the Ministry of Science and Technology (MoST) in Taiwan under grant No. 105-2112-M- 110-014-MY3 and also by the NCTS of Taiwan.

1:51PM B03.00014: Spectral weight suppression as a gap-like feature in the non-magnetic states of topological insulators*  
TURGUT YILMAZ (Presenter), University of Connecticut, ANNA PERTSOVA, Nordita, WILLIAM HINES, University of Connecticut, ALEXANDER BALATSKY, Nordita, BORIS SINKOVIC, University of Connecticut — Here, we present an answer to one of the much debated questions in the topological insulator research, i.e., the opening of an energy gap-like feature at the Dirac point without long range ferromagnetic order. This is in sharp contrast to the topological protection of the surface states against non-magnetic perturbations. We carried out a systematic photoemission study on Cr-doped Bi₂Se₃ films grown on pristine Bi₂Se₃ films which allow us to monitor the evolution of the topological electronic structure. Our angle-resolved photoemission spectroscopy experiments revealed a gap-like feature appears just below the Dirac point leaving the Dirac point unaffected by the doping. Furthermore, the Dirac point is buried under the bulk conduction band which prevented it from being resolved in previous photoemission experiments. The spectral weight suppression just below the Dirac point leads to the gap-like feature being mistakenly identified as an energy gap at the Dirac point.

*This work was funded by the University of Connecticut under the UCONN-REP (Grant No. 4626510) and also by the Institute for Materials Science and LDRD XWNK at Los Alamos National Laboratory.

2:03PM B03.00015: Anomalous dielectric response in insulators with a topological π Zak phase*  
SHUICHI MURAKAMI (Presenter), YUSUKE AIHARA, Dept. of Physics, Tokyo Institute of Technology, MOTOAKI HIRAYAMA, CEMS, RIKEN — In the topological phase of the Su-Schrieffer-Heeger model, the Zak phase is equal to π. While it corresponds to the e/2 polarization, there is no electric dipole moment because of inversion symmetry. We find that an external electric field gives rise to an abrupt rise of the dipole moment, close to e/2. This sudden uprise of the dipole moment is attributed to the midgap state at the two ends of the system. We also extend this idea to two- and three-dimensional insulators with the π Zak phase over the whole Brillouin zone, and show that similar sudden uprise of the polarization by an external electric field happens also in these cases, if the midgap boundary states due to the π Zak phase has sufficiently flat dispersions. Finally, we discuss possible candidate materials for this behavior, including the (111) surface of Si and the (111) surface of a topological electride Sc₂C.

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B04 DMP GMAG: Dirac/Weyl Semimetals -- Magnetic Topological Semimetals BCEC
107C - Zhiqiang Mao - Tag(s): Focus
11:15AM B04.00001: Magnetic Weyl Semimetal in Quasi Two-dimensional Half Metallic Co$_3$Sn$_2$S$_2$  QIUNAN XU (Presenter), Max Planck Institute for Chemical Physics of Solids, ENKE LIU, Institute of Physics, Chinese Academy of Sciences, WUJUN SHI, School of Physical Science and Technology, ShanghaiTech University, LUKAS MUECHLER, Chemistry, Princeton University, JACOB GAYLES, CLAUDIA FELSER, YAN SUN, Max Planck Institute for Chemical Physics of Solids — A Weyl semimetal can exist in a time reversal or inversion symmetry breaking system. Since the Berry curvature is odd under time reversal, the Berry curvature from Weyl points are expected to generate a large anomalous Hall effect in time reversal symmetry breaking Weyl semimetals. In this work, we find a Weyl semimetal phase in half metallic ferromagnet Co$_3$Sn$_2$S$_2$ with Weyl points only 60 meV away from the Fermi level, which derive from nodal lines that are gapped by spin-orbit coupling. Therefore, the Weyl-related physics should be easy to detected by both ARPES and bulk transport measurements. Due to the Berry curvature deriving from the gapped nodal lines and Weyl points, its anomalous Hall conductivity can reach up to 1200 S/cm. Substituting S by Se, Co$_3$Sn$_2$Se$_2$ shows very similar property. Moreover, since Co$_3$Sn$_2$S$_2$ is easily grown quasi two-dimensional compound, it provides an ideal platform for the study of magnetic Weyl physics and its future application in topological material based spintronic devices.

11:27AM B04.00002: Topological Weyl semimetals in Full Heusler Co$_2$MnX (X = Si, Ge, Sn)*  ABHISHEK SHARAN (Presenter), University of Delaware, FELIPE CRASTO DE LIMA, Instituto de Física, Universidade Federal de Uberlândia, SHOAIB KHALID, ANDERSON JANOTTI, University of Delaware — Topological semimetals exhibit band crossing in the bulk and exotic surface states, called Fermi arcs, which are protected by topology of the associated wavefunctions. These states are characterized by their connectivity and dimensionality in the momentum space. Using first-principles calculations we show that ferromagnetic full Heusler compounds Co$_2$MnX (X = Si, Ge, Sn) belong to the category of topological semimetals called Weyl semimetals. Based on electronic structure calculations, we show that these materials show multiple nontrivial band crossings called Hopf links or entangled nodal lines and chain-like nodal lines, in absence of spin-orbit coupling, which are protected by mirror symmetry of the lattice. On breaking the time-reversal symmetry, we find that these band crossings are protected along multiple zero-dimensional Weyl points with different chiralities. We further explore the possibility of identifying non-trivial Fermi arc surface states connecting projection of these Weyl points on surface of opposite chiralities.

*DOE/BES (DE-FG-02-05ER46200) and GBMF4547 (EPIQS initiative)
12:15PM B04.00004: Inelastic Neutron Scattering in Semimetallic YbMnBi2* TIMOTHY REEDER (Presenter), WESLEY T FUHRMAN, Department of Physics and Astronomy, Johns Hopkins University, QUINN GIBSON, Department of Chemistry, Princeton University, JOSE A RODRIGUEZ, YIMING QIU, NIST Center for Neutron Research, National Institute of Standards and Technology, MATTHEW BRANDON STONE, ALEXANDER I KOLESNIKOV, Spallation Neutron Source, Oak Ridge National Laboratory, ROBERT CAVA, Department of Chemistry, Princeton University, COLLIN BROHOLM, Department of Physics and Astronomy, Johns Hopkins University — Layered pnictide AMnBi2 (A=Eu, Sr, Ca, Yb) compounds host quasi-2D square antiferromagnetic layers with alternating Bi square nets responsible for relativistic Dirac bands. Novel transport and peculiar optical conductivity that could be brought on by the coupling of these Dirac bands to the square-lattice antiferromagnetic Mn has garnered further interest in these materials, with the hopes of achieving the magnetically ordered Weyl semimetallic phase. We show that the magnetic lattice in YbMnBi2, fits to a frustrated J1-J2 model with antiferromagnetic J1 and J2 interactions, and J2/J1 less than the critical value, 1/2. While we rule out an ordered ferromagnetic coupling that would give rise to a Weyl Semimetal, we explore the relation between relativistic electronic band structure and anisotropic magnetic degrees of freedom.

Access to MACS was provided by the Center for High Resolution Neutron Scattering, a partnership between NIST and the NSF under Agreement No. DMR-1508249

12:27PM B04.00005: Complicated magnetic phases interplayed with charge density waves in a new topological semimetal SHIMING LEI (Presenter), Princeton University, JÜRGEN NUSS, VIOLA DUPPEL, BETTINA LOTSCH, Max Planck Institute for Solid State Research, LESLIE SCHOOP, Princeton University — Topological semimetals have attracted a lot of attentions as they provide a new platform for studies of quantum matter as well as offer a new paradigm for next-generation electronics. Within these discovered topological materials, there is a class of materials that share the same structural motifs—sheets of square-arranged atoms, such as that in ZrS1S, CeSbTe and SrMnBi2. Within these materials, CeSbTe stands out as one unique system that offers the opportunities to study its tunable Weyl and Dirac states due to the existence of field-induced magnetic phase transitions. Here in this work, we present the synthesis and characterizations of a new series of square-net-based magnetic topological semimetals. Based on a comprehensive structural characterization by powder x-ray diffraction, single crystal x-ray analysis, and transmission electron microscopy on this series of compounds, we observed a crystal symmetry evolution from an orthorhombic phase to a tetragonal one, in accompany with a tunable charge density wave (CDW) modulation. Besides the structural characterizations, we have also performed a comprehensive study on the magnetic properties. The impact of crystal symmetry evolution and CDW on the linear crossing band is also discussed.

12:39PM B04.00006: Creating Weyl Nodes and Tuning Their Energy by Magnetization Rotation in a Metallic Ferromagnet* MADHAV PRASAD GHIMIRE (Presenter), Central Department of Physics, Tribhuvan University, JORGE FACIO, JHIH-SHIH YOU, Institute for Theoretical Solid State Physics, IFW Dresden, LINDA YE, JOSEPH CHECKELSKY, Massachusetts Institute of Technology, SHIANG FANG, EFTHIMIOS KAXIRAS, Harvard University, MANUEL RICHTER, JEROEN VAN DEN BRINK, Institute for Theoretical Solid State Physics, IFW Dresden — Weyl nodes are robust topological features of the electronic structure that can occur at any momentum and energies. To observe the large anomalous effects Weyl nodes need to be close to or at the Fermi-level. However, most materials Weyl nodes are observed slightly away from the Fermi-level. Here we propose a novel strategy to tune the Weyl node energy close to or even precisely at the Fermi energy that relies on the interplay between the magnetism and the energy dispersion in the time-reversal symmetry breaking Weyl semimetals. We show that magnetization effect is strong enough to create new Weyl nodes close to the Fermi surface and, vice versa annihilate other Weyl pairs. We focus on Co3Sn2S2, a ferromagnet recently found to be a Weyl semimetal and to display a large anomalous Hall effect. Performing ab initio density-functional calculations we show that canting the magnetization away from the easy axis leads to large displacements of the Weyl points in energy and in momentum space such that, at different orientations, Weyl fermions can be placed exactly at the Fermi surface.

12:51PM B04.00007: Hole Doping and Antiferromagnetic Correlations above the Néel Temperature of Topological Semimetal SrMnSb₂⁺

YONG LIU, FARHAN ISLAM, Ames Laboratory, Iowa State University, WEI TIAN, Oak Ridge National Laboratory, THOMAS HEITMANN, The Missouri Research Reactor, University of Missouri, BENJAMIN UELAND, ANDREAS KREYSSIG, ALAN IRA GOLDMAN, ROBERT J. MCQUEEN, DAVID VAKNIN (Presenter), Ames Laboratory, Iowa State University —

Neutron diffraction and magnetic susceptibility studies of orthorhombic single crystal SrMnSb₂ and hole doped Sr₀.₉₇K₀.₀₃MnSb₂ confirm the three dimensional antiferromagnetic (AFM) ordering of the Mn²⁺ moments at $T_N = 297(3)$ K for SrMnSb₂ and $T_N = 305(3)$ K for the hole doped compound. Neutron scattering show strong quasi two-dimensional AFM correlations that persist to almost twice $T_N$. In conjunction with susceptibility measurements, this observation seems to rule out a recently suggested ferromagnetic phase above $T_N$ in SrMnSb₂. We also report detailed analysis of de-Haas van- Alphen oscillations observed on the parent and doped compounds.

1:03PM B04.00008: Impact of antiferromagnetic order on Landau level splitting of quasi-two-dimensional Dirac fermions in EuMnBi₂

HIDETOSHI MASUDA (Presenter), University of Tokyo, HIDEAKI SAKAI, Osaka University and JST-PRESTO, MASASHI TOKUNAGA, University of Tokyo, MASAYUKI OCHI, Osaka University, HIDEFUMI TAKAHASHI, KAZUTO AKIBA, ATSUSHI MIYAKE, University of Tokyo, KAZUHIKO KUROKI, Osaka University, YOSHINORI TOKURA, University of Tokyo and RIKEN-CIMS, SHINTARO ISHIWATA, University of Tokyo and JST-PRESTO —

Dirac fermions in solids have been of current interest for their unique transport properties. The interplay of Dirac fermion with magnetism in magnetic Dirac materials is recently of particular interest. Among them, EuMnBi₂ is a rare compound that exhibits quantum transport of Dirac fermions coupled with the field-tunable magnetic order. However, it remains elusive how and to what extent the Dirac-like band dispersion is affected.

In this study, we report spin-split Landau levels of quasi-two-dimensional Dirac fermions in EuMnBi₂, as revealed by interlayer resistivity measurements in a tilted magnetic field up to ~35 T. The amplitude of Shubnikov–de Haas (SdH) oscillation in interlayer resistivity is strongly modulated by changing the tilt angle of the field, i.e., the Zeeman-to-cyclotron energy ratio. The effective g factor estimated from the tilt angle, where the SdH oscillation exhibits a phase inversion, differs by approximately 50% between two antiferromagnetic phases. This observation signifies a marked impact of the magnetic order of Eu sublattice on the Dirac-like band structure. The origin may be sought in strong exchange coupling with the local Eu moments, as verified by the first-principles calculation. [H. Masuda, H. Sakai et al., Phys. Rev. B 98, 161108(R) (2018)]

1:15PM B04.00009: Observation of Magnetic Bubble Domains in the Quasi-2D Kagomé Ferromagnetic Weyl Semimetal Co₃Sn₂S₂

PAUL SASS (Presenter), WEIDA WU, Rutgers University, New Brunswick, LINDA YE, JOSEPH CHECKELSKY, Department of Physics, Massachusetts Institute of Technology —

The Co-based shandite, Co₃Sn₂S₂, is a Weyl³ semi-metal hosting an itinerant ferromagnetic quasi-2D Kagomé lattice of Co ions. This system exhibits strong c-axis anisotropy with a curie temperature ~ 174 K and a spontaneous moment of ~ 0.3 μB/Co.² Low-field magnetization and AC susceptibility measurements have revealed an anomalous magnetic phase above ~ 126 K and below ~ 40 mT, indicating a possible skyrmion phase. To this end, we carried out variable-temperature magnetic force microscopy studies on Co₃Sn₂S₂ single crystals. MFM images under zero-field cooling revealed fingerprint-like magnetic domains, while low-field cooling through $T_C$ resulted in seemingly periodic magnetic bubble domains, which is consistent with the quasi-2D nature of the magnetic ordering. Detailed temperature and cooling field dependence of the magnetic domain patterns will be presented.

*¹This work is supported by DOE BES under award DE-SC0018153.
ANH PHAM (Presenter), PANCHAPAKESAN GANESH, Oak Ridge National Laboratory — Materials that can host a magnetic-Weyl semimetallic phase represent a novel platform for fundamental physics studies and can also be potentially applicable for quantum computing. The search for such magnetic-Weyl semimetals is ongoing given the recent discovery of Weyl semimetals which show absence of time reversal or inversion symmetry [1, 2]. In our study, we demonstrate a new pathway to engineer magnetic Weyl semimetals by doping topological crystalline insulators (TCI) such as SnTe with a magnetic transition metal element, such as Cr. The magnetic dopant breaks both time reversal and inversion symmetry while maintaining the band inversion between Sn-p and Te-p orbitals, thus resulting in Weyl nodes in the bulk. These Weyl nodes were characterized through chirality calculation, large intrinsic anomalous Hall conductivity (AHC), and presence of Fermi arcs in the surface. Furthermore, the Weyl semimetallic phase is maintained even under dilute dopant concentrations, suggesting experimental feasibility of realizing this system.

*This research was funded by ORNL-LDRD (Project ID: 8988).

CUNEYT SAHIN (Presenter), Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, DUNG VU, Department of Mechanical and Aerospace Engineering, The Ohio State University, WENJUAN ZHANG, NANDINI TRIVEDI, Department of Physics, The Ohio State University, JOSEPH P C HEREMANS, Department of Mechanical and Aerospace Engineering, The Ohio State University, MICHAEL FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa — Bi and Sb alloys exhibit novel physical phenomena depending on the antimony concentration, such as semimetal-semiconductor transitions, giant spin Hall conductivities, and topologically protected phases including Weyl semimetal phases. Although the band structures of Bi and Sb are well studied in terms of k.p or tight-binding Hamiltonians, it is still a challenge to predict the behavior of the band edges as a function of the alloy concentration. Simple linear virtual crystal approximations lack the correct symmetries of the electron and hole pockets; on the other hand, alternative VCA approaches are insufficient to describe band crossings at different Sb concentrations. In this work, we introduce a new VCA parametrization describing the symmetries and crossing of the band edges using a 16 band tight-binding Hamiltonian. Then, from that Hamiltonian, we derive and calculate g-tensors of the electrons and holes and show that the large spin-orbit couplings of Bi and Sb result in giant effective g-factors whose axes of symmetry differ from the crystallographic axes. We also show that the band gap between symmetric and antisymmetric bands at the L point can be closed by a moderate magnetic field due to large g-factors. The closing of this gap produces a Weyl state.

*NSF DMR-1420451

RISHI BHANDIA (Presenter), BING CHENG, Department of Physics and Astronomy, Johns Hopkins University, TOBIAS L BROWN-HEFT, SEAN HARRINGTON, SHOUVIK CHATTERJEE, CHRIS PALMSTROM, Materials Department, University of California, Santa Barbara, PETER ARMITAGE, Department of Physics and Astronomy, Johns Hopkins University — Weyl semimetals are a class of topological materials that been the subject of intense research in the past few years. While there have been definitive examples of inversion symmetry breaking Weyl semimetals, good examples of time-reversal symmetry breaking Weyl semimetals remain elusive. In addition to being of great interest to the spintronics community due to its half-metallicity, the Heusler alloy Co2TiGe has attracted interest recently due to theoretical predictions suggesting it hosts time-reversal symmetry breaking Weyl semimetal states. Recently, MBE-grown thin films of Co2TiGe have become available, allowing for time-domain THz spectroscopy (TDTS) measurements. We present results of the low frequency optical conductivity of Co2TiGe and discuss our results in the context of prevailing theories.
Zeeman Splitting Induced Topological Nodal Structure in ZrTe$_5$*

YICHL CHOI (Presenter), Physics, Virginia Tech, JOHN VILLANOVA, Physics, University of Arkansas, KYUNGLWA PARK, Physics, Virginia Tech — When time-reversal symmetry is broken by an external Zeeman field in a Dirac semimetal or small-gap insulator, rich nodal structures can be induced, including Weyl nodes or nodal lines. ZrTe$_5$ is known to be located near the phase boundary between strong and weak topological insulator, and recent experiments showed intriguing magnetic transport properties including anomalous Hall effect and the chiral magnetic effect. This indicates that Weyl nodes are developed in ZrTe$_5$ due to Zeeman splitting. However, a concrete theoretical study of the nodal structure of ZrTe$_5$ under Zeeman splitting covering the full Brillouin zone is still missing. We construct a Wannier-function based tight-binding model from first principles to investigate the effect of Zeeman splitting in ZrTe$_5$ and to fully explore the nodal structure near the Fermi level. We calculate the topological character of induced band crossings and examine the importance of magnetic field direction effect on the nodal structure.

Session B05 DCMP: General Talks BCEC 108

Mechanics of Rugby Union Scrums: stability and collective production of force* CAROLINE COHEN (Presenter), CORENTIN REISS, DAVID QUERE, LadHyX, Ecole polytechnique, ANETTE E. HOSOI, MIT, CHRISTOPHE CLANET, LadHyX, Ecole polytechnique — Rugby Union is a contact sport played by two 15-players teams. During scrummaging, two 8-players groups called packs confront each other in a 3-4-1 configuration. The objective of each team is to push the opponent backwards while staying stable. A surprising fact is that there is a loss in collective force produced by the pack : 8 international level players in the pack able to generate together only 75% of the sum of forces produced individually.

We study experimentally both the stability of the scrum with a simple beam analogy, and the origin of the loss in collective force produced by players of Racing 92, a top level team of Top 14, the French national championship. We perform experiments at the « Atelier de la mêlée », the Rugby French Federation training tool to measure the forces produced by players and packs. By coupling forces measurements with a Particle Image Velocimetry (PIV) analysis of videos taken from above, we show that there is a correlation between force fluctuations and the lack of synchronization of the 8 players pushing together.

*Racing 92 Federation Francaise de Rugby

Theory of Direction KAUSTAV B. ARYA (Presenter), Assam Jatiya Bidyalay — The law of gravitation indicates that every object of the universe attracts each other. On the other side we determine our earth’s magnetic poles as north and south. The magnetism describes that different poles attract each other. Therefore, the connection points of any two objects always face with different directions (poles) because they have attraction. Otherwise without this principle of nature the system may will be collapsed. So, in this way the author tries to find the procedure of different directions causing the gravitation. This journey propells the path of all moving objects and their neighbor matters in which they create attraction by opposite poles. Before all, the main thing is the final decision will be relative as the universe is still out of reach fully. Here, mentioned theory will be based on either rotatory or annual motion of the objects or both in space. Finally, the whole method will explain how the gravitation works by opposite directions in space. The research shows that like earth’s magnetic poles north and south it may possible to have poles with the directions west and east in the universe. In this huge universe it is always possible to have such objects which rotate vertically from north to south in their rotatory motion.

Sources of Biconformal Gravity* WALTER MUHWEZI (Presenter), Physics, Utah State University — Biconformal gravity is a 2n-dimensional conformal gauge theory with a curvature linear action that has been shown to reproduce scale invariant general relativity on the cotangent bundle of n-dimensional spacetimes. We explore Yang-Mill's sources for biconformal gravity. The questions we seek to clarify are whether the augmented field equations reduce the Yang-Mill's sector to n-dimensional Yang-Mill's theory and yield the appropriate energy momentum tensor as the gravitational source.

*Keith Taylor Award, Utah State University.
Gravity and electromagnetism are two sides of the same coin, which is the clue of this unification. Gravity and electromagnetism are represented by two mathematical structures, symmetric and antisymmetric respectively. Einstein gravitational field equation is the symmetric mathematical structure. Electrodynamics Lagrangian is three parts, for electromagnetic field, Dirac field and interaction term. The definition of canonical energy momentum tensor was used for each term in Electrodynamics Lagrangian to construct the antisymmetric mathematical structure; symmetric and antisymmetric gravitational field equations are two sides of the same Lagrangian.

---

The authors of a neutron interferometer experiment published in Physical Review in 1992 said that neither they, nor quantum mechanics could not explain their data. It is unusual to find an experiment that QM cannot explain. If we follow that trail of evidence, where does it lead? It leads to the Elementary Wave hypothesis, according to which Schrödinger waves convey probability amplitudes that particles follow backwards. Should we put so much emphasis on one peculiar finding? This hypothesis explains the double slit experiment in a logical and coherent way; something that QM has been unable to do. It indicates that wave function collapse occurs when a particle is emitted, not when it is detected. That profoundly changes the measurement problem.

---

In shooting sports, champions develop an aiming strategy in order to maximize the precision of their shot. We study experimentally the aiming dynamics of different shooting sports such as archery, rifle and laser-run, with international level athletes. We observe that the movement of the arm exhibits notable differences among the shooting sports, according to the particular constraints of the sport. We build a simple mechanical model for the control of an aiming movement. This model shows that the movement naturally chosen by the athletes corresponds to an optimal trajectory for their sport. In shooting sports where athletes have to shoot fast, such as laser run or speed shooting, it minimizes the shooting time. In contrary, in archery where the force needed to lengthen the bow string is quite large, it minimizes the energy spent in the movement.

---

We propose to investigate the mechanism of cosmological inflation and expansion through the physical properties of space-time [1]. We demonstrate that a cosmological inflation scenario occurs when the bulk modulus of space-time $K=1.64 \times 10^{109} \text{N.m}^{-2}$, and show that the dark energy density is decreased by a factor of $10^{122}$ while the scaling factor expands from $10^{-60}$ to $10^{-32}$ during a time of the order of $10^{-42} \text{s}$. At the end of the presentation, we discuss a microscopic interpretation of the inflation mechanism and future investigations on longitudinal waves.

There is an active quest to discover new topologically quantized physical properties of topological quantum states of matter, similar to the quantized Hall conductance in quantum Hall states. The motivation is to discover not only new fundamental physics in exotic materials, but also technologically desirable robust physical properties which are unaffected by modest disorder and manufacturing variations. We establish that a novel topological response is found in a wide variety of topological quantum states — we term this the topological gravitational response — and comment on the still-unknown topological physics underlying the quantization of the corresponding response coefficient, the gravitational coupling constant.
The interface of Internet-connectivity and automotive technology promises to dramatically improve transportation. However, with these known benefits come unknown risks, especially since Internet-connected vehicles have become targets for computer hacking. Vehicles, unlike sensitive data, can collide or physically interact when their systems become compromised, and there is a broad class of scenarios generically leading to Internet-connected vehicles being suddenly and simultaneously disabled. Here, we investigate how large-scale hacking affects traffic flow using agent-based simulations, and discover the critical relevance of percolation for predicting outcomes on a multi-lane road. Inspired by this discovery, we develop and validate an analytic percolation-based model to rapidly assess the effect of hacking. We then apply our analytic model to investigate the outcomes on the street network of Manhattan (NY, USA), revealing a latent risk. A small number of disabled vehicles can gridlock the city and substantially reduce access to emergency services. By discovering percolation as the phenomenological driver of city-wide disruption, we simultaneously uncover a strategy for risk-mitigation.

**Five dimensional rotating regular black holes and shadow**

We present a five-dimensional ($5D$) rotating regular black hole metric, with a deviation parameter $k \geq 0$, that interpolates between the $5D$ Kerr black hole ($k = 0$) and $5D$ Kerr-Newman ($r \gg k$), and is an exact solution of general relativity coupled to nonlinear electrodynamics. Interestingly, for a given value of parameter $k$ there exits a critical value of rotation parameter $a = a_E$ which corresponds to extremal rotating regular black hole with degenerate horizons, while for $a < a_E$, one has non-extremal rotating regular black hole with outer and inner horizons. Owing to the correction factor ($e^{-k/r^2}$), due to nonlinear electrodynamics, the ergoregions and black hole shadows get modified.

**Reconciliation of the Rosen and Laue theories of special relativity in a linear dielectric medium**

We show that the incompatible Laue and Rosen treatments of special relativity in a dielectric are both correct but have different regimes of applicability. The Laue theory has a fundamental physical basis in Einstein's special relativity and the relativistic velocity sum rule. The Rosen version of dielectric special relativity was derived heuristically. Consequently, the Rosen theory and its consequences are almost completely ignored in the scientific literature and there is little to no discussion about the incompatibility of the two theories of relativity in a dielectric. We derive both versions of relativity using inertial reference frames moving at constant velocity along the interface between a simple linear dielectric medium and the vacuum. We show that the Rosen theory applies to relativistic physics in the interior of a simple linear dielectric medium and the Laue theory is used to relate these physics to a Laboratory Frame of Reference in the vacuum where measurements can be performed.

**A Novel Interpretation of the Lorentz Transformations**

While 'interpretations of a theory' are most commonly associated with quantum mechanics, they can become important in other branches of physics as well. Here we present a novel interpretation of the Lorentz Transformations in which length contraction is re-conceptualized as the abatement of a body's dimensionality, and time dilation as the abatement of its duration of existence within a given coordinate time interval. The re-interpretation of length contraction makes it possible to understand the invariance of the speed of light and the relationship between classical electric and magnetic fields at a deeper level. The re-interpretation of time dilation makes it possible to integrate the heretofore purely philosophical concept of existence into physics. Together, they lead to a recognition of the importance of two invariance principles and two corresponding spacetime symmetries which are under the prevailing paradigm so obvious that it usually goes unnoticed, and thereby set the stage for recognizing new fundamental relationships in other areas of physics, in particular quantum mechanics.
1:39PM B05.00013: Synchronization of human network  MOTI FRIDMAN (Presenter), Bar-Ilan University, NIR DAVIDSON, Physics of Complex Systems, Weizmann Institute of Science — The synchronization of human networks is essential for our civilization and understanding the motivations, behavior, and basic parameters which govern the dynamics of human networks are important for many aspects of our lives. We studied complex human networks in different configurations with full control over the network connectivity, the coupling strength of each connection and the delay between coupled individuals. Our system is based on coupling violin players in different configurations and measuring the synchronization of their phase, period, frequency and volume. In our system, each player is connecting it's violin output to our computer system and has headphones for the input.

We found that humans tend to find a non-trivial solution for frustration situations and spontaneously change the connectivity of the network in order to reach a stable solution. We also found that out-of-phase synchronized state is highly stable and usually is preferable by the entire network. Our results are important for understanding the dynamics of human networks in different conditions and are the first experiments in which human networks are investigated with full control over the network parameters.

1:51PM B05.00014: On the origin of kinetic energy in The Physical Universe including the Godforsaken area of turbulence  SIMON BERKOVICH (Presenter), George Washington University — There is a popular parable attributed to W. Heisenberg: "When I meet God, I am going to ask him two questions: Why relativity? And why turbulence? I really believe he will have an answer for the first." Answers to diverse problems in physics can be obtained with a Cellular Automaton (CA) Model (see our recent minireview [1], with pertinent references) CA model combines divergent functionalities that otherwise difficult to imagine. The CA generates steady relocating formations - corresponding to the basic stable constituents of the physical world: electrons, protons, photons, and neutrinos, they exist only in continuous motion. Quantum behavior of micro-objects results from the specifics of the CA measurements.. As to macro bodies, they are split into fragments dragged by conflicting velocities. In seismology, this leads to rifts of tectonic plates causing abrupt mechanical impacts. Similar rifts occur in turbulence lamina, although they are far away from cosmic phenomena. Emulated in closed cycles such laminar cracks can lead to extraction of heat from the fragments dragged by of the CA Universe.

2:03PM B05.00015: Quantum materials research at the upgraded CHESS-U facility: Introducing <QM>2*  JACOB RUFF (Presenter), CHESS, Cornell University — The recent CHESS-U project comprised a significant upgrade of the Cornell High Energy Synchrotron Source. CHESS-U enables running with a single, lowered-emittance 6 GeV positron beam in CESR, and has also funded the construction of 6 new hard x-ray undulator beamlines. One of these is the <QM>2 beamline, dedicated to high-precision studies of quantum materials in reciprocal space. In this talk, I will (i) introduce the <QM>2 beamline; (ii) identify the scientific questions that motivated its construction; (iii) explain the design decisions that enable its function; and (iv) highlight the unique new capabilities that it offers to users in the quantum materials community.

*Research conducted at CHESS is supported by the NSF under award DMR-1332208.

Session B06 DCMP: Cuprates and Related  BCEC 109A - Jasminka Terzic, National High Magnetic Field Laboratory - Tag(s):
Focus

11:15AM B06.00001: Magnetic-field-tuned superconducting quantum phase transition in highly overdoped Bi2+xSr2-xCuO6+δ*  JASMINA TERZIC (Presenter), PAUL G. BAITY, BAL K POKHAREL, LILY STANLEY, DRAGANA POPOVIC, Department of Physics and National High Magnetic Field Lab, Florida State University, SHIMPEI ONO, Central Research Institute of Electric Power Industry, Japan — The conventional picture of overdoped cuprates as BCS d-wave superconductors has been recently challenged, with the roles of disorder and quantum fluctuations under debate. To address these questions, we focus on the highly overdoped regime, which we have explored via measurements of linear transport and voltage-current characteristics on the hole-doped, La free, Bi2+xSr2-xCuO6+δ (Bi2201) single crystals with zero-resistance transition temperatures Tc ~ 5 K. Measurements were performed in magnetic fields (H) up to 45 T and temperatures (T) down to 17 mK. We discuss the nature of the H-field-tuned superconducting quantum phase transition and the high-field ground state, and present the T-H phase diagram for the highly overdoped Bi2201.

*Supported by NSF DMR-1707785 and NHMFL via NSF DMR-1644779 and the State of Florida.
11:27AM B06.00002: Scale-Invariant transport in high-temperature superconductors* ARKADY SHEKHTER (Presenter), National High Magnetic Field Laboratory, BRAD RAMSHAW, Laboratory of atomic and solid state physics, Cornell university, KIMBERLY MODIC, Max Planck Institute for chemical physics of solids, LAUREL WINTER, National High Magnetic Field Laboratory, SEIKI KOMIYA, SHIMPEI ONO, CRIEPI, FEDOR BALAKIREV, JONATHAN B BETTS, GREGORY SCOTT BOEBINGER, ROSS MCDONALD, National High Magnetic Field Laboratory — We report high-magnetic-field (up to 93T) Hall measurements in LSCO cuprates superconductor near critical doping (x=0.20). The observed Hall behavior exhibits a crossover from a low-field to high-field behavior in a broad range of temperatures. Such Hall behavior is incompatible with Fermi surface quasiparticle transport in the strange metal state.

*National High Magnetic Field Laboratory is supported through the National Science Foundation Cooperative Agreement numbers DMR-1157490 and DMR-1644779, The United States Department of Energy, and the State of Florida.

11:39AM B06.00003: Optical Thermal Diffusivity Measurement in Bad Metals* JIECHENG ZHANG (Presenter), ERIK KOUNTZ, AHARON KAPITULNIK, Physics, Stanford University, RICHARD L. GREENE, Physics, University of Maryland — Local measurements of thermal diffusivity are used to analyze the transport of heat in the bad metallic regime of several strongly correlated materials. Thermal diffusivity DQ was measured for several cuprate systems in their so-called bad metal regime, including both electron and hole doped cuprates. The temperature dependence of normal state resistivity of these systems are either linear or close-to-quadratic, while the overall magnitudes exceed the Mott-Ioffe-Regel limit at approximately 250K, indicating failure of the conventional quasiparticle transport picture. We found that the various doping of (Nd/Pr/Sm)1-xCe_xCuO_4 all have T-linear DQ^-1. We interpret our results through a strong electron-phonon scattering picture where both electron and lattice system saturates a quantum scattering time bound of ~h/kBT, and the slope of the T-linear DQ^-1 is associated with a characteristic intermediate speed between the speed of sound and the Fermi velocity. Our results suggest that neither well-defined electron nor phonon quasiparticles might be present in these systems, and that thermal transport is carried out by a collective “soup” of strongly coupled electrons and phonons.

*Supported by the Gordon and Betty Moore Foundation through the EPiQS Initiative, Grant GBMF4529.

11:51AM B06.00004: High Temperature Electrical Transport in Electron-Doped Cuprates* NICHOLAS PONIATOWSKI (Presenter), TARAPADA SARKAR, PAMPA MANDAL SARKAR, RICHARD L. GREENE, Department of Physics, University of Maryland, College Park — Although the origin of high-temperature superconductivity in the cuprates has eluded the community for decades, the normal state of these materials is similarly enigmatic. The universal T-linear electrical resistivity observed in hole-doped compounds such as YBCO and LSCO, persistent to high temperatures, is thought to violate the Mott-Ioffe-Regel (MIR) limit on the scattering rate, where traditional Boltzmann theories of transport break down. Consequently, the normal state of these and other strongly correlated materials are now considered a new phase of matter, the “strange metal.” We report resistivity and magnetoresistivity (MR) measurements of the electron doped cuprate La_{2-x}Ce_xCuO_4 (LCCO) from 100K to above room temperature and relate our findings to the hole-doped side of the phase diagram. By studying slightly underdoped samples (x=.08, .10) in proximity to the antiferromagnetic phase (without a field), we are able probe the strange metallic regime in the vicinity of the MIR bound without having to resort to excessively high temperatures. For other dopings, we report new MR data.

*This work is supported by the NSF under Grant No.DMR-1708334.
12:03PM B06.00005: Hall coefficient in two-dimensional metals with spiral magnetic order and application to cuprate high-\(T_c\) superconductors  
Johannes Mitscherling (Presenter), Walter Metzner, Max Planck Institute for Solid State Research — Charge transport measurements in high magnetic fields recently shed new light on the non-superconducting ground state in cuprate high-\(T_c\) superconductors [1]. In particular, Hall measurements yield a drop of the Hall number indicating a phase transition associated with a Fermi surface reconstruction. On the theoretical side, spiral magnetic order (or quasi-order) remains a hot candidate for the Fermi surface reconstruction mechanism.

The electromagnetic response of spiral magnetic states has already been analyzed by Voruganti et al. for small relaxation rates [2]. However, the relaxation rate in the cuprate samples studied experimentally is sizable. We have, thus, derived, for the first time, a complete formula (including all interband contributions) for the Hall conductivity in the low field limit \(\omega_c \tau \ll 1\). [3]

We use the complete expressions to study the importance of a sizable relaxation rate and show that the observed Hall number drop in cuprates can be fitted with realistic parameters.

12:15PM B06.00006: Correlation between scale-invariant normal state resistivity and superconductivity in an electron-doped cuprate*  
Tarapada Sarkar (Presenter), Pampa Mandal Sarkar, Nicholas R. Poniatowski, University of Maryland, College Park, Mun Keat Chan, Los Alamos National Laboratory, Richard L. Greene, University of Maryland, College Park — An understanding of the normal state in the high-\(T_c\) superconducting cuprates is crucial to the understanding of the long-standing problem of the origin of the superconductivity itself. This so-called “strange metal” state is thought to be associated with a quantum critical point (QCP) hidden beneath the superconductivity. In electron-doped cuprates, it is possible to access the normal state at very low temperatures and low magnetic fields to study this putative QCP and to probe the \(T \to 0 \) K state of these materials. We report measurements of the low temperature normal state magnetoresistance (MR) of the n-type cuprate system (LCCO) and find that it is characterized by a linear-in-field behavior, which follows a scaling relation with applied field and temperature, for doping \(x\) above the putative QCP \((x=0.14)\). This unconventional behavior suggests that magnetic fields probe the same physics that gives rise to the anomalous low-temperature linear-in-T resistivity. The magnitude of the linear MR decreases as \(T_c\) decreases and goes to zero at the end of the superconducting dome \((x \sim 0.175)\) above which a conventional quadratic MR is found. we discuss the correlation between Linear-in-T and Linear-in-H resistivity with the superconductivity.

*NSF-DMR-1708334 and AFOSR-FA9550-14-1-0332.

12:27PM B06.00007: short-range pair density wave in cuprates  
Zhehao Dai (Presenter), Yahui Zhang, Senthil Todadri, Patrick Lee, Massachusetts Institute of Technology — We analyze recent STM results on period-8 density wave in the cuprate vortex halo and provide a theory of short-range pair density wave to explain quantum oscillation above \(H_c^2\) and the electron gap in the anti-nodal region in underdoped cuprates.

12:39PM B06.00008: Gauge theory for the cuprates near optimal doping*  
Subir Sachdev, Harley Scammell, Matthias Scheurer (Presenter), Grigory Tarnopolsky, Department of Physics, Harvard University — We propose a SU(2) gauge theory with fermionic low-energy excitations as an effective field theory for the cuprate high-temperature superconductors. For the hole-doped compounds, the theory describes fluctuating incommensurate spin-density waves. While we recover the conventional Fermi-liquid state as the confining phase of the theory at large doping, there is a quantum phase transition to a Higgs phase corresponding to the pseudogap at low doping. Depending on details of the theory, the Higgs phase shows one or more of charge-density wave, Ising-nematic, scalar spin chirality, and \(Z_2\) topological order. For the electron-doped systems, we assume commensurate spin-density wave fluctuations and there is only a crossover between the confining and the Higgs regime, with an exponentially large confinement length deep in the Higgs regime. For both the electron- and hole-doped systems, the electronic spectral function shows small Fermi surfaces at scales shorter than the confinement length. Finally, we present a large-N analysis of the deconfined quantum criticality of the Higgs transition.

12:51PM B06.00009: Normal-state optical conductivity and linear resistivity of the cuprates from tightly bound pre-formed pairs  LONG ZOU (Presenter), SHENTAO JIANG, WEI KU, Shanghai Jiao Tong University — We investigate anomalous normal-state in-plane resistivity and optical conductivity of cuprates by using multi-orbital bose-liquid model. Specifically, we assume that the charge carriers in cuprate are tightly bound pre-formed pairs. We show the low-energy optical spectrum involving both intra- and inter-band excitation. While inter-band excitation explain the continuous spectrum and its contribution around the van-Hove singularities of the pre-formed pairs can reproduce the experimental observed onset near 1000 cm\(^{-1}\), the intra-band excitation will mainly contribute to low frequency conductivity and gives rise to linear behavior originate from the continuously decreasing height of low-frequency peak since its weight transfers to high energy region with temperature. Our study reveals the bosonic nature of the low-energy carriers and provides a strong support for the picture of tightly bound preformed pairs in describing the high-temperature superconductivity and other low-energy physics of the cuprates.

1:03PM B06.00010: Slow magnetic fluctuations in the pseudogap phase of YBa\(_2\)Cu\(_3\)O\(_y\)† JIAN ZHANG (Presenter), State Key Laboratory of Surface Physics, Department of Physics, Fudan University, Shanghai 200433, People's Republic of China, DOUGLAS E. MACLAUGHLIN, Department of Physics and Astronomy, University of California, Riverside, Riverside, CA 92521, USA, ZHAOFENG DING, CHENG TAN, State Key Laboratory of Surface Physics, Department of Physics, Fudan University, Shanghai 200433, People's Republic of China, OSCAR BERNAL, Department of Physics and Astronomy, California State University, Los Angeles, CA 90032, USA, PEI-CHUN HO, Department of Physics, California State University, Fresno, CA 93740, USA, GERALD D MORRIS, TRIUMF, Vancouver, British Columbia V6T 2A3, Canada, AKIHIRO KODA, Muon Science Laboratory and Condensed Matter Research Center, Institute of Materials Structure Science, High Energy Accelerator Research Organization (KEK), ADRIAN HILLIER, STEPHEN P. COTTRELL, PETER J. BAKER, P. K. BISWAS, ISIS Facility, Science and Technology Facilities Council Rutherford Appleton Laboratory, Harwell Science and Innovation Campus, Didcot, Didcot OX11 0QX, UK, YANXING YANG, ZHAO ZHU, State Key Laboratory of Surface Physics, Department of Physics, Fudan University, Shanghai 200433, People's Republic of China, JUN QIAN, YAN WAN, XIN YAO, State Key Lab for Metal Matrix Composites, Key Laboratory of Artificial Structures and Quantum Control (Ministry of Education), Department of Physics and Astronomy, Shanghai, LEI SHU, State Key Laboratory of Surface Physics, Department of Physics, Fudan University, Shanghai 200433, People's Republic of China. — We report broken time-reversal symmetry in the pseudogap state of underdoped single crystalline YBa\(_2\)Cu\(_3\)O\(_y\) using muon spin relaxation technique. Slow magnetic fluctuations are observed below the characteristic pseudogap onset temperature T\(^*\), signaled by the Redfield relation between the Lorentzian relaxation rate of the positive muons and the applied field along the muon initial spin polarization. We measured the temperature dependence of the local field and compared it with the order parameter measured by neutron scattering. The slow frequency scale of the fluctuations, 5 orders of magnitude below the energy scale of the pseudogap energy, implies that time-reversal symmetry is broken for properties intermediate between the two scales, but raises the question of the nature of the quantum fluctuations responsible for time-reversal not being absolutely broken.

1:15PM B06.00011: Imaging Domains and Domain Walls in High-Temperature Superconductor* TADESSE ASSEFA (Presenter), Brookhaven National Laboratory, YUE CAO, ROSS HARDER, Argonne National Laboratory, IAN KEITH ROBINSON, JOHN TRANQUADA, GENDA GU, Brookhaven National Laboratory — Phase transition, Symmetry breaking and recovery in condensed matter systems are closely related to the exotic physical properties of strongly correlated materials such as superconductivity, magnetism, ferroelectricity, etc. A key signature of broken symmetry is the formation of structural domains of few nanometer size. Bragg coherent X-ray diffraction techniques can enable novel experimental opportunities to directly visualize symmetry changes in these materials through domain structure. We have pushed Bragg Coherent Diffractive Imaging (BCDI) into the cryogenic regime where most phase transitions in quantum materials reside. Utilizing coherent photons at 34-ID-C beamline of the Advanced Photon Source, we image the structural domain evolution of La\(_{2-x}\)Ba\(_x\)CuO\(_4\), x=1/8 sample during the low-temperature-orthorhombic (LTO) to high temperature tetragonal (HTT) phase transition. These phases break the local four-fold rotational symmetry of its high temperature tetragonal (HTT) structure and our preliminary data suggests the low-temperature-orthorhombic (LTO) phase is not pinned to local crystal disorder or defects.

1:27PM B06.00012: What happened at 19% doping in Bi2212: an ARPES perspective

SUDI CHEN (Presenter), Applied physics, Stanford University, MAKOTO HASHIMOTO, SLAC National Accelerator Laboratory, YU HE, Applied physics, Stanford University, DONGJOON SONG, National Institute of Advanced Industrial Science and Technology, KEJUN XU, JUNFENG HE, Applied physics, Stanford University, DONGHUI LU, SLAC National Accelerator Laboratory, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, ZHIXUN SHEN, Applied physics, Stanford University — In the hole-doped cuprate superconductors, the special doping p = 0.19 has attracted considerable research interest. Various anomalies have been observed at this doping and associated with fascinating physics, for example the change from small to large Fermi surface, the termination of the pseudogap, the recovery of coherence, and the possibility of a quantum critical point. In this talk we present a systematic ARPES study across 84 temperature-doping points in Bi2212 near p = 0.19. The results provide important insights about the nature of this special doping and the phenomenology of the cuprates.

1:39PM B06.00013: Anomalous Dimensions for Conserved Currents from Holographic Dilatonic Models to Superconductivity

PHILIP PHILLIPS (Presenter), KRIDSANAPHONG LIMTRAGOOL, GABRIELE LA NAVE, University of Illinois at Urbana-Champaign — Anomalous Dimensions for Conserved Currents from Holographic Dilatonic Models to Superconductivity

It is well known that the dimension of conserved currents is determined simply from dimensional analysis. However, a recent proposal is that what is strange about the conserved currents in the strange metal in the cuprate superconductors is that they carry anomalous dimensions. The basic model invoked to exhibit such behaviour is a holographic dilatonic one in which the field strength couples to the radial coordinate. I will show that the anomalous dimension in such cases arises from a fractional electromagnetism[1] that can be thought of as a general loop-hole in Noether's second theorem. The general mechanism operative is a mass term in the IR that couples to the UV current. I will also show that even the Pippard kernel invoked to explain the Meissner effect in traditional low-temperature superconductors is a special case of the non-local action found here.

1:51PM B06.00014: A novel solution of the 2D Hubbard model within a 4-pole approximation: electronic dispersion and Fermi surface evolution

ANDREA DI CIOLO (Presenter), ADOLFO AVELLA, Dipartimento di Fisica “E.R. Caianiello”, Università degli Studi di Salerno, I-84084 Fisciano (SA), Italy — We present and characterize a novel solution of the 2D Hubbard model within the Composite Operator Method [1,2] in a 4-pole approximation [3]. We have chosen a basis of four fields: the two Hubbard operators plus two fields describing the Hubbard transitions dressed by nearest-neighbor spin fluctuations, which play a crucial role for strong correlations. This 4-pole solution performs very well once compared with advanced (semi-)numerical methods for all relevant values of interaction, doping and temperature, being considerably less computational-resource demanding. By carefully treating spin fluctuations and featuring momentum selectivity, this solution can address the underdoped-cuprate puzzle (Fermi arcs, pseudogap, non-Fermi liquid behavior, ...). We adopt this approximation to study the single-particle properties of the model in the strong coupling regime, where spin fluctuations are responsible for anomalous features in the analyzed properties. We focus on the investigation of the electronic dispersion and of the Fermi surface, studying their evolution with doping and temperature.

Session B07 DCMP GMAG: Correlated Magnetism and Other Ordered Phases

Wei, Florida State University
**11:15 AM B07.00001: Enhanced Magnetic Ordering in Sm Metal under Extreme Pressure**

YUHANG DENG (Presenter), JAMES S SCHILLING, Physics, Washington University, St. Louis — The dependence of the magnetic ordering temperature $T_0$ of Sm metal was determined through four-point electrical resistivity measurements to pressures as high as 127 GPa. A strong increase in $T_0$ with pressure was observed above 40 GPa. In this pressure range Sm ions alloyed in dilute concentration with superconducting Y exhibit giant Kondo pair breaking. Both results suggest that for pressures above 40 GPa Sm enters a highly correlated electron state, likely related to a Kondo lattice, with an unusually high value of $T_0$. Similar results were found previously for Nd [1], Tb [2], and Dy [3] and their dilute magnetic alloys with superconducting Y. Both Y(Sm) and Y(Nd) alloys display record-high pair breaking $\Delta T_c$ as large as 40 K/at.%.

**11:27 AM B07.00002: Superparamagnetic clusters in antiferromagnetic Eu$_{0.52}$Ca$_{0.48}$B$_6$ seen by Small Angle Neutron Scattering (SANS)**

GABRIELLE BEAUDIN (Presenter), ANDREA BIANCHI, Universite de Montreal, MARK LAVER, ROBERT ARNOLD, School of Metallurgy and Materials, University of Birmingham — Since the term was introduced by Pekar in 1946, polarons have been thought to underpin a range of prominent phenomena from high-$T_c$ superconductivity to colossal magnetoresistance. Polarons are quasiparticles consisting of charge carriers “dressed” by lattice distortions. Similarly, magnetic polarons are charge carriers dressed with spins. In the europium chalcogenides, magnetic polarons are thought to be formed as a spin polarization of the mobile charge carriers by the localized 4f moments. This leads to the formation of magnetic “bubbles” and the localization of charge carriers within them. Here we report on experiment which extends an earlier experiment on EuB6 where SANS indicated the presence of magnetic polarons. The experiment was carried out at the Institut Laue Langevin (ILL) in Grenoble. It shows the presence of superparamagnetic clusters well above the critical temperature in 48% Ca doped-EuB6. Unlike EuB6, Eu$_{0.52}$Ca$_{0.48}$B$_6$ does not undergo an insulator to metal phase transition, and its resistivity grows rapidly below 10 K. A metallic state can be obtained through the application of a magnetic field greater than 2 T. In Eu$_{0.52}$Ca$_{0.48}$B$_6$, the charge carrier stay trapped inside the magnetic polarons, leading to an increasing resistivity at lower temperature.

**11:39 AM B07.00003: NMR Studies of TmVO$_4$**

ZHIPAN WANG (Presenter), ZIWEN MEI, University of California, Davis, PAULO MENEGASSO, Instituto de Física “Gleb Wataghin”, UNICAMP, TANAT KISSIKOV, University of California, Davis, PIERRE MASSAT, IAN R FISHER, Stanford University, NICHOLAS CURRO, University of California, Davis — TmVO$_4$ undergoes a tetragonal to orthorhombic structural phase transition below 2.2K due to a cooperative Jahn-Teller distortion. The Tm ions experience a crystal-field effect with a non-Kramers ground state doublet. We have performed $^{51}$V NMR in a single crystal to investigate the role of magnetic and quadrupolar fluctuations. We find that the spin lattice relaxation rate varies strongly with field orientation, which reflects the role of quadrupolar(nematic) fluctuations near the critical temperature. We have also observed strong angular dependence of the $^{51}$V NMR Knight shift.

**11:51 AM B07.00004: NMR Studies of Nematicity in TmVO$_4$ and TmAsO$_4$**

ZIWEN MEI, ZHIPAN WANG, University of California, Davis, PAULO MENEGASSO, Physics, Campinas State University, PIERRE MASSAT, IAN R FISHER, Physics, Stanford University, NICHOLAS CURRO (Presenter), University of California, Davis — The crystal field ground state of Tm ions in certain crystal symmetries is a non-Kramers doublet, with a vanishing g-factor. In such cases strain can couple to the quadrupolar moment of the Tm ions, and a cooperative Jahn-Teller effect leads to Ising orbital-nematic order of the Tm moments. Application of a magnetic field along the $c$-axis suppresses the nematic order continuously and gives rise to a nematic quantum critical point. We have studied the critical nematic fluctuations via $^{51}$V and $^{75}$As NMR in TmVO$_4$ and TmAsO$_4$. These nuclei have quadrupolar moments that couple to the nematic degrees of freedom of the Tm. Fluctuations of both the Tm magnetic moments and the quadrupolar moments contribute to the spin-lattice relaxation of the nuclei, and we demonstrate how both the dynamical magnetic and dynamical nematic susceptibilities can be extracted from the spin-lattice relaxation rate.

*We acknowledge support from the NSF Grant number DMR-1807889.*
ANNA GALLER (Presenter), LEONID POUROVSKII, SILKE BIERMANN, Centre de Physique Théorique, Ecole Polytechnique — Designing new materials for permanent magnet applications is currently a very active field of research. While, at present, the best permanent magnets are based on the expensive rare-earth elements Nd, Sm or Dy (e.g. Nd$_2$Fe$_{14}$B), efforts are made to replace them with more available elements like Ce, with the hope to discover compounds with even better performance and lower production costs. Theoretical efforts to assist this quest encounter challenges related to the correlated nature of the rare-earth 4f states. In particular, in the family of potential Ce-based permanent magnet materials a key question is the localized vs. heavy-fermion behavior of the Ce-4f electrons. In this context, we investigate the role of electronic correlations in CeFe$_2$, CeFe$_{12}$ and CeFe$_{11}$Ti from first principles by using combined density functional and dynamical mean-field theory. We solve the corresponding quantum impurity problem by means of a continuous-time Quantum Monte Carlo solver and analyze the resulting electronic structure focusing on the degree of localization of the Ce-4f states as well as the magnetic properties of the compounds.

RYOSUKE YAMAMURA (Presenter), TAKASHI HOTTA, Tokyo Metropolitan University — In recent decades, multipole ordering in f$^2$-electron systems such as Pr and U compounds have attracted continuous attention in the research field of condensed matter physics. In fact, peculiar modulated antiferro non-Kramers $\Gamma_3$ quadrupole ordering in PrPb$_3$ has been reported in 2005 [1], but the mechanism has been still under debate. To understand such incommensurate $\Gamma_3$ quadrupole ordering in PrPb$_3$, we develop a microscopic theory of multipole ordering in f$^2$-electron systems from an itinerant picture on the basis of a j-j coupling scheme [2]. For the purpose, we introduce the $\Gamma_7$-$\Gamma_8$ Hubbard model on a simple cubic lattice with the effective interactions which induce local $\Gamma_3$ states. By evaluating multipole susceptibility in a random phase approximation, we find that the hybridization between $\Gamma_7$ and $\Gamma_8$ orbitals plays a key role for the emergence of $\Gamma_3$ quadrupole ordering. We propose that $\Gamma_3$ quadrupole ordering can be explained from a combined concept of “multipole nesting”, which contains a couple of pieces of information about nesting properties and multipole density distribution on the Fermi surfaces.

ELLIOTT ROSENBERG (Presenter), IAN R FISHER, Stanford University — Electronic nematicity, in which the electronic degrees of freedom break the rotational symmetry of the lattice, has been exhibited by many materials including various high-temperature superconductors. A local realization of electronic nematicity is also seen in 4f intermetallic materials undergoing ferroquadrupolar order. In these materials the lattice of local 4f electronic multiplets collectively and spontaneously break the rotational symmetry of the point group of the lattice. Here we measure the quadrupole-strain (nematic) susceptibility of TmAg$_2$, which exhibits a ferroquadrupolar phase transition at 5.0K. We implement an elastoresistivity technique previously used in probing another 4f intermetallic, YbRu$_2$Ge$_2$, and extend this technique to investigate the nematic behavior of TmAg$_2$ while applying a “transverse” magnetic field to suppress the ferroquadrupolar phase transition to 0K.

*Funded by the Moore Foundation
12:39PM B07.00008: Ferromagnetic spin correlations in the filled skutterudite SrFe$_4$As$_{12}$ revealed by $^{75}$As NQR-NMR studies*  
YUJI FURUKAWA (Presenter), QING-PING DING, KHUSBOO RANA, Iowa State University, KOHEI NISHINE, JUN-ICHI HAYASHI, YUKIHIRO KAWAMURA, CHIHIRO SEKINE, Muroran Institute of Technology — Recently new filled-skutterudite compounds Sr$_3$T$_{4}$As$_{12}$ ($T$ = Fe, Ru, Os) have been synthesized, which provides a new opportunity of systematic studies of the effects of different d electron of 3d, 4d and 5d in the systems. In this study, as the first step for the systematic studies, we have carried out nuclear quadrupole resonance (NQR) and nuclear magnetic resonance (NMR) measurements on the filled skutterudite SrFe$_4$As$_{12}$ in order to investigate the magnetic properties from a microscopic point of view. Using the NQR spectra under small magnetic field, we have succeeded in determining Knight shift $K$. The temperature dependences of both $K$ and the nuclear spin-lattice relaxation rate divided by temperature, $1/T_1T$, have been reasonably explained by the simple model in which a concave-shaped band structure near the Fermi energy is assumed. The Korringa ratio parameter is found to be much smaller than unity, indicating the existence of ferromagnetic fluctuations. These NMR/NQR results evidence that SrFe$_4$As$_{12}$ is a metal with ferromagnetic spin correlations.

*USDOE under Contract No. DE-AC02-07CH11358.

12:51PM B07.00009: Antiferromagnetic order in Sr(Co$_{1-x}$Ni$_x$)$_2$As$_2$ revealed by single-crystal neutron diffraction*  
JOHN WILDE (Presenter), ANDREAS KREYSSIG, DAVID VAKNIN, SANGEETHA N. S., BING LI, BENJAMIN UELAND, DAVID C JOHNSTON, ROBERT MCQUEENEY, ALAN IRA GOLDMAN, Ames Laboratory, Iowa State University — SrCo$_2$As$_2$ has the same tetragonal lattice as the 122 Fe-based high Tc superconductors. It does not order magnetically, but inelastic neutron scattering experiments find antiferromagnetic (AF) fluctuations found in many of the 122 superconductors. Here we show results from neutron diffraction and magnetization experiments on single-crystals of Sr(Co$_{1-x}$Ni$_x$)$_2$As$_2$. However, the AF order is not stripe-type. Instead, the AF structure consists of ferromagnetic layers (with moments in the layer) that are stacked along c with an incommensurate propagation vector (0, 0, $q_z$). The propagation vector is doping dependent, suggesting spin density wave order. Using high-energy x-ray diffraction, we also find no evidence for a structural phase transition accompanying the AF order.

*Work at Ames Lab was supported by US DOE, BES, DMSE under DE-AC02-07CH11358. This research used resources at Oak Ridge National Laboratory and Argonne National Laboratory, both DOE BES user facilities.

1:03PM B07.00010: Electronic Structure and the Origin of the Phase Transition in BaAg$_2$As$_2$ Revealed by ARPES and REXS Studies  
XIA LOU (Presenter), Physics, Fudan University — Transition metal pnictides in 122 families are rich with fantastic quantum phenomena such as spin density wave (SDW) in BaFe$_2$As$_2$[1], superconductivity (SC) and charge density wave (CDW) in SrP$_2$As$_2$[2] and BaP$_2$As$_2$[3]. In the meanwhile, BaP$_2$As$_2$ and SrP$_2$As$_2$ shares CaBe$_2$Ge$_2$-type structure while BaFe$_2$As$_2$ crystallizes in ThCr$_2$Si$_2$-type structure. Studying the interplay among SDW, SC and CDW and their relationship with crystal structure and structural transition is of wide interests. BaAg$_2$As$_2$, as a newly-discovered transition metal pnictide adopted to ThCr$_2$Si$_2$-type structure, possess a phase transition at 138K in resistivity whose origin is still unknown[4]. To study the mechanism, we applied systematic angle-resolved photoemission spectroscopy (ARPES) combined with resonant elastic soft X-ray scattering (REXS) and identified the exact structural transition and density-wave-like transition in it for the first time.

propagation vector of (0, 0, 0.5) for both samples. The ordered moment lies along with present and discuss quantitative results from neutron and high-energy x-ray diffraction experiments on single crystals.

No structural phase transitions accompany the AFM transitions. Current and magnetic field configurations. Its possible origin will be discussed.

CaMn2Bi2 forms a hexagonal structure, consisting of alternately stacked Ca and Mn2Bi2 layers. Instead of ferromagnetic ordering seen in MnBi, CaMn2Bi2 orders antiferromagnetically below TN ~ 150 K, as reflected in the magnetization, specific heat, and electrical resistivity. Although it is considered as a narrow-gap semiconductor, our resistivity shows metallic behavior with a sharp drop at TN and a little bump at Tp ~ 20 K. Below Tp, large positive magnetoresistance with non-monotonic field dependence is observed in all current and magnetic field configurations. Its possible origin will be discussed.

Recent research are focused on perovskite materials because of their interesting properties. Among others, double perovskites La2-xNa1+x+xMnMoO6 shows magnetocaloric effect and large magnetoresistance making it appropriate substance for magnetic refrigeration applications at room temperature. Here, we investigate the electronic and magnetic properties of this recently synthesized material. We found that consistent with the experiment, for x~1.5, a ferromagnetic (FM) ground state is observed. With increase in La concentration, the charge transfers to Mn and Mo sites with increasing moment. It is interesting to note that magnetic phase transition occurs when doping concentration varies for x≤1. The electronic behavior shows metallic with major contribution from Mo-4d on Fermi level. The calculated net magnetic moment is 5.78 Bohr magneton which is in good agreement with the experimental value of 5.55 Bohr magneton. Our results reveals that interaction between the nearest neighbor and next nearest neighbor among Mn3+(t2g3eg1) and Mo5+(t2g1eg0) ions on the octahedral sites shows ferromagnetic coupling for x>1.

*Work at the Ames Laboratory was supported by the U.S. DOE, BES, DMSE under Contract No. DE-AC02-07CH11358. This research used resources at the High Flux Isotope Reactor and Advanced Photon Source, which are U.S. DOE Office of Science User Facilities.
2:03PM B07.00015: Band structure induced electronic correlations in nickel and iron: van-Hove singularities vs. Earth’s core conditions

ANDREAS HAUSOEL (Presenter), MICHAEL KAROLAK, Department for theoretical physics, University of Wuerzburg, Germany, ERSOY SASIOGLU, Institute for Physics, University of Halle, Germany, ALEXANDER I. LICHTENSTEIN, Institute for theoretical physics, University of Hamburg, Germany, KARSTEN HELD, Institute of Solid State Physics, TU Vienna, Austria, ANDREY A. KATANIN, Ural Federal University Ekaterinburg, Russia, ALESSANDRO TOSCHI, Institute of Solid State Physics, TU Vienna, Austria, GIORGIO SANGIOVANNI, Department for theoretical physics, University of Wuerzburg, Germany — Some Bravais lattices have a particular geometry and can slow down the motion of Bloch electrons: a 'pre-localisation' due to band structure properties. Another known source of electronic localisation in solids is the Coulomb repulsion in partially-filled d- or f-orbitals, which leads to the formation of local magnetic moments. The combination of these two effects has been viewed so far as mainly an academic issue. Here we show with ab-initio calculations of unprecedented accuracy and model studies, that their synergy represents instead the underlying physical mechanism in two of the most important ferromagnets: nickel and iron. Furthermore in nickel, the van-Hove singularity is essential for ferromagnetism to appear. Nickel's electron-electron scattering rate is linear in temperature, in violation of the conventional Landau theory of metals. This is true even at Earth's-core conditions, at which iron is instead a good Fermi-liquid. The importance of nickel in models of geomagnetism may therefore be reconsidered.

Monday, March 4, 2019 11:15 AM - 2:03 PM

Session B08 DCMP: Superconductivity: Copper Oxide - ARPES

11:15AM B08.00001: Three observations on the ARPES data of the cuprate superconductors - what the AF spin fluctuation can do and what it cannot Tao Li Renmin University of China, Beijing, China

TAO LI (Presenter), Physics, Renmin University of China — We discuss the origin of the pseudogap phenomena in the cuprate superconductors from the perspective of the spin-Fermion model. We find that the vanishing of the pseudogap around (\pi,0) as observed recently in Pr_{1.3-x}La_{0.7}Ce_{x}CuO_{4} is consistent with the AF band folding picture of the pseudogap in the electron-doped cuprates, if we assume a strongly momentum dependent quasi-particle scattering rate on the Fermi surface[1,4]. However, we find that the pseudogap in the hole-doped cuprates is unlikely an AF band folding gap. In particular, we show that electron pairing is indispensable to eliminate the Fermi level crossing along (\pi,0)-(\pi,\pi) in a way consistent with the ARPES observation on the underdoped Bi-2201 system around T*[2,4]. Nevertheless, we find that the AF spin fluctuation in the hole-doped cuprates is responsible for the high energy hump structure, the mismatch between the hump back-bending momentum and the bare Fermi momentum, and in particular, the extremely flatness of the anti-nodal quasi-particle dispersion in the superconducting state [3,4].

11:27AM B08.00002: Temperature Dependence of the Anisotropic Gap in YBa_{2}Cu_{3}O_{7}∗

GUANG-LIN ZHAO (Presenter), Southern University — Due to the complexity of the material structures, the experimental results for high Tc cuprates, including YBa_{2}Cu_{3}O_{7} (YBCO), are far more difficult to understand than those for conventional low Tc superconductors of simple structures. It is our view that many experimental results cannot be understood without careful first-principles calculations to include realistic electronic structures and electron-phonon (e-ph) interaction effect in these materials. We present the results of first-principles calculations for the electronic structure, e-ph interaction, and the temperature dependence of the anisotropic superconducting gap in YBCO. Our calculations show that the smaller gaps at some k-points on the Fermi surface of YBCO collapse earlier than the larger ones as the temperature increases, that leads to gapless state on the Fermi surface of YBCO even below Tc. The work was funded in part by NSF (Award # HRD 1736136 ) and ARO (Award # W911NF-15-1-0483).

*The work was funded in part by NSF (Award # HRD 1736136 ) and ARO (Award # W911NF-15-1-0483).
11:39AM B08.00003: Study of the interplay between pseudogap and antiferromagnetic correlations in electron-doped cuprates via TR-ARPES MARTA ZONNO (Presenter), FABIO BOSCHINI, ELIA RAZZOLI, MATTEO MICHIAIRD, RYAN P DAY, BEREND ZWARTSENBERG, PASCAL NIGGE, Department of Physics & Astronomy, University of British Columbia, EDUARDO DA SILVA NETO, Department of Physics, University of California Davis, ANDREAS ERB, Walther-Meissner-Institute for Low Temperature Research, SERGEY ZHDANOVICH, GIORGIO LEVY, Department of Physics & Astronomy, University of British Columbia, CLAUDIO GIANNETTI, Universita’ Cattolica del Sacro Cuore, DAVID J JONES, ANDREA DAMASCELLI, Department of Physics & Astronomy, University of British Columbia — In recent years, various angle-resolved photoemission spectroscopy (ARPES) studies focused on electron-doped cuprate superconductors to explore the similarities and differences between the two sides of the cuprates phase diagram. The pseudogap (PG) is a well-known phenomenon in the physics of high-temperature superconductors but despite numerous theoretical and experimental works, the origin of the PG in the cuprates is still under debate. Contrary to the hole-doped counterpart, antiferromagnetic (AF) correlations in the electron-doped side are stronger, offering the unique opportunity to explore the close interplay between AF, superconductivity, PG and other underlying phases. By exploiting time-resolved ARPES, we investigate the transient evolution of the low-energy density of state of the optimally doped Nd$_{2-x}$Ce$_x$CuO$_4$ (NCCO, x=0.15). In particular, by studying the temperature-dependence of the PG spectral features, we demonstrate the direct relation between PG and spin correlation length and provide evidence for the primary role of AF correlations in determining the PG in electron-doped cuprates.

11:51AM B08.00004: Strong electron-phonon coupling in Hg1201* MING YI, Physics and Astronomy, Rice University, JAYITA NAYAK, Physics, University of California, Davis, ZACHARY ANDERSON, YANG TANG, MARTIN GREVEN, Physics and Astronomy, University of Minnesota, ROBERT J BIRGENEAU, Physics, University of California Berkeley, INNA VISHIK (Presenter), Physics, University of California, Davis — Among single-layer cuprate high temperature superconductors, some materials have maximum $T_c$ ($T_{c,\text{max}}$) near 40K while others have $T_{c,\text{max}}$ near 100K, and the origin of this discrepancy is still unsettled. We present doping-dependent angle-resolved photoemission spectroscopy (ARPES) studies on HgBa$_2$CuO$_{4+\delta}$ (Hg1201), a single-layer cuprate with higher $T_{c,\text{max}}$ with a focus on spectral features which differ from more commonly studied single layer cuprates with lower $T_{c,\text{max}}$. Our studies indicate two different aspects of enhanced electron-phonon coupling in this system with distinct momentum dependence.

*JN and IV supported by Air Force Office of Scientific Research grant #FA9550-18-1-0156.

12:03PM B08.00005: Micro-ARPES study on the cuprate superconductor YBCO HIDEAKI IWASAWA (Presenter), Graduate School of Science, Hiroshima University, NIELS SCHRÖTER, Paul Scherrer Institut, Swiss Light Source, TAKAHIKO MASUI, Department of Physics, Kindai University, SETSUKO TAJIMA, Department of Physics, Osaka University, TIMUR KIM, Diamond Light Source, MORITZ HOESCH, Photon Science, Deutsches Elektronen-Synchrotron — Utilizing angle-resolve photoemission spectroscopy with several tens of microns spot size (micro-ARPES), we disentangled surface electronic inhomogeneity of the high-$T_c$ cuprate superconductor YBa$_2$Cu$_3$O$_y$. Two surface terminations consisting of either a CuO or BaO layer are identified through a chemical-states-specified core-level intensity distribution. This enables us to perform termination-selective ARPES measurements that uncover the different charge fillings and electronic configurations depending on the surface termination. By combining the real-space and electronic information, we propose a simple model to explain the termination-dependent surface electronic reconstruction. Further, we will also present new observations of peculiar superconducting states as well as zero-energy surface states on the heavily overdoped BaO surface.

12:15PM B08.00006: Hidden Spin-Momentum Texture in High $T_c$ Cuprate Superconductor CHIU-YUN LIN (Presenter), KENNETH GOTLIEB, University of California, Berkeley, MAKSYM SERBYN, Institution of Science and Technology Austria, WENTAO ZHANG, Shaqihai jiao Tong University, China, CHRISTOPHER L SMALLWOOD, San Jose State University, CHRIS JOZWIAK, Lawrence Berkeley National Lab, Berkeley, USA, HIROSHI EISAKI, Electronics and Photonics Research Institute National Institute of Advanced Industrial Science and Technology, Japan, ASHVIN VISHWANATH, Havard University, ZAHID HUSSAIN, Lawrence Berkeley National Lab, Berkeley, USA, ALESSANDRA LANZARA, University of California, Berkeley — Spin-orbit coupling (SOC) in cuprate superconductors was not a focus of condensed matter research due to the negligible SOC value of the conducting orbitals comparing with the strong electronic correlations and its centrosymmetric crystal structure. By using spin- and angle-resolved photoemission spectroscopy, we unveiled a nontrivial spin-momentum locking pattern in Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$. The asymmetry of the spin-up and spin-down channel suggests the strength of SOC is in the same order of the bilayer interaction. This poses an intriguing question of how the high temperature superconducting state emerges in the presence of SOC.
**12:27PM B08.00007: Fermi Surface Topology and Energy Gap of Heavily Underdoped Bi2212 Studied by Laser ARPES**

QIANG GAO (Presenter), PING AI, JING LIU, CHENG HU, GUODONG LIU, XINGJIANG ZHOU, The Chinese Academy of Sciences, Institute of physics — The high temperature cuprate superconductors exhibit a number of exotic properties especially in the underdoped region. Here we have carried out high resolution angle-resolved photoemission (ARPES) measurements on heavily underdoped Bi2Sr2CaCuO8 (Bi2212) superconductors by using our new laser-based ARPES system equipped with angle-resolved time-of-flight analyzer and 7 eV and 11 eV laser sources. We have synthesized high quality heavily underdoped Bi2212 single crystals with different dopings by Dy substitution of calcium and vacuum annealing. Taking advantage of our high resolution laser-ARPES, we have systematically studied the Fermi surface topology, the energy gap and the many-body effects in these heavily underdoped Bi2212. Implications of these results will be discussed.

*This work is supported by the National Key Research and Development Program of China (Grants No. 2016YFA0300300 and No. 2017YFA0302900).

**12:39PM B08.00008: ARPES study of the phase diagram of superconducting BSCCO-2212 with in-situ control of surface doping**

ILIYA K DROZDOV (Presenter), CMPMSD, Brookhaven National Laboratory — In high-Tc cuprates, the doping of carriers into the parent Mott insulator induces unconventional superconductivity. In most materials, including the widely studied Bi-2212, the doping level p cannot be determined from the chemical composition but is rather derived from the superconducting transition temperature, Tc, which is, in turn, measured in transport, relying on the assumption that Tc dependence on doping is universal across all the cuprate families. I will present angle-resolved photoemission studies of Bi2Sr2CaCu2O8+δ single crystals cleaved and annealed in ultra-high vacuum or in ozone to reduce or increase the doping on-demand. Such in-situ annealing technique allows mapping of a wide doping range, covering not only the superconducting dome but also previously experimentally inaccessible for this material family, metallic, non-superconducting phase on the overdoped side (OD0K). Evolution of the Fermi surface with doping shows surprisingly smooth dependence across the superconducting dome while the evolution of spectroscopic features corresponding to electron-boson coupling can be continuously tracked across the entire phase diagram including the extreme overdoped region.

*US DOE BES contract # DE-AC02-98CH10886; BNL Gertrude and Maurice Goldhaber Distinguished Fellowship

**12:51PM B08.00009: Co-substitution effect on electronic structure of high-Tc cuprate superconductor, Bi2Sr2Ca(Cu1-xCox)2O8**

TAKEO MIYASHITA (Presenter), WUMITI MANSUER, HITOSHI TAKITA, TAKUYA KUBO, SATOSHI ISHIZAKA, HIDEAKI IWASAWA, Graduate School of Science, Hiroshima University, EIKE F SCHWIER, KENYA SHIMADA, MASASHI ARITA, Hiroshima Synchrotron Radiation Center, Hiroshima University, YOSHINORI NUMATA, TATSURO UTO, AZUSA MATSUDA, School of Advanced Science and Engineering, Waseda University, AKIHIRO INO, Faculty of Engineering, Kurume Institute of Technology — Conventional superconductivity occurs when electron pairs are formed. However, the pairing mechanism of high-Tc superconductivity is still controversial. One may expect that experimental clues to this problem can be obtained from the behavior of superconducting gap, which represents the binding energy of an electron pair. It has previously been reported that the decrease in critical temperature, Tc, of Bi2Sr2Ca(Cu1-xCox)2O8 is proportional to Co substitution, x. Thus, it gives us a good opportunity to investigate the relation between Tc and the energy gap. Here, we report a high-resolution angle-resolved photoemission study of Bi2Sr2Ca(Cu1-xCo0.4)2O8 by using ultraviolet laser and synchrotron radiation. Even though Tc decreases from 91 K to 55 K with 4 % substitution of Co for Cu, almost no decrease in the superconducting gap has been observed. We also measured the residual intensity within the gap as a function of temperature. We have found that the residual intensity for Co 4% samples is larger than that for pristine samples. These results suggest that the Co substitution results in reduction of the density of the electron pairs rather than the change in the binding energy of the electron pairs.
1:03PM B08.00010: Deviation between magnetic quantum- and Lifshitz- critical point in electron doped cuprate $Pr_{1-x}La_{x}CuO_{4-δ}$

DONGJOON SONG (Presenter), IBS-CCES, Seoul National University, SUHEON LEE, Physics, Chung-Ang University, WOOBIN JUNG, IBS-CCES, Seoul National University, SEUNG-RYOUNG PARK, Physics, Incheon National University, SHIGEYUKI ISHIDA, YOSHIYUKI YOSHIDA, HIROSHI EISAKI, AIST, KWANG-YONG CHOI, Physics, Chung-Ang University, CHANGYOUNG KIM, IBS-CCES, Seoul National University — Since high-$T_{c}$ superconductivity in copper oxide (cuprate) and Fe-based material arises near the anti-ferromagnetic (AF) order phase boundary, relation between the magnetic quantum criticality and superconductivity has attracted extensive interest. On the other hand, there is an argument in many novel superconductors that the key role in inducing superconductivity is played by Lifshitz transition which leads to Fermi surface transformation without symmetry breaking.

We performed systematic doping and temperature dependent muon spin rotation ($\mu$SR) measurement and angle resolved photoemission spectroscopy (ARPES) on the electron-doped cuprate $Pr_{1-x}La_{x}CuO_{4-δ}$ in order to resolve the interplay among the magnetic quantum criticality, Lifshitz criticality, and superconductivity. Surprisingly, while the long-range AF order phase boundary is located around heavily under doped regime, the Lifshitz transition associated with nodal hole pocket takes place in the vicinity of optimal doping concentration. In this talk, we will present the magnetic and electronic phase diagram of electron doped cuprate $Pr_{1-x}La_{x}CuO_{4-δ}$ and discuss the implication of our results on the generic phase diagram of high-$T_{c}$ superconductors.

1:15PM B08.00011: Doping Evolution of Energy Gaps in Bi$_2$Sr$_2$CaCu$_2$O$_{8+δ}$ superconductors studied by Laser-based ARPES

PING AI (Presenter), QIANG GAO, LIU JING, JIANWEI HUANG, YING DING, GUODONG LIU, GENDA GU, XINGJIANG ZHOU, Chinese Academy of Sciences — The energy gap is a key quantity in understanding the high temperature superconductivity mechanism in cuprate superconductors. We have carried out comprehensive angle-resolved photoemission (ARPES) measurements on Bi$_2$Sr$_2$CaCu$_2$O$_{8+δ}$ (Bi2212) superconductors by utilizing our high resolution laser-based ARPES system equipped with an angle-resolved time-of-flight (ARToF) electron energy analyzer and lasers with 7 and 11 eV photon energies. With high instrumental resolution (~1 meV) and wide coverage of the momentum space, we will report detailed doping, momentum and temperature dependences of the energy gap (superconducting gap and pseudogap) in Bi2212. Implications of these results will be discussed.

1:27PM B08.00012: Doping evolution of kink from the contionously doped cuprate surface

YIGUI ZHONG (Presenter), JIANYU GUAN, JIN ZHAO, Chinese Academy of Sciences, JIANHAO ZHANG, ZHENG-YU WENG, Tsinghua University, GENDA GU, Brookhaven National Laboratory, YIJIE SUN, HONG DING, Chinese Academy of Sciences — We present the doping evolution of the kink dispersion at node by in-situ ARPES measuring on a continuously doped surface of Bi2212 using our recently pronounced surface treating technique of ozone/vacuum annealing [1]. We demonstrate the Fermi velocity (<5meV) decreases and the band velocity of middle energy (25~55 meV) is a constant when doping decreases. However, the band velocity beyond ~70 meV is larger and larger when goes to UD region. We propose a splendid scenario as a possibility to explain these exotic velocities of kink dispersion. We speculate there is an additional renormalisation to the Fermi velocity for the reason that the kink at ~ 10 meV comes from the coupling to boson modes like phonons. The band at middle energy constitutes by the "bared electron", so its band velocity is independent with doping due to the rigid-band shift nature of Bi2212 [2]. However, for band dispersion higher than the ~70 meV, the electrons are fractionalized then they acquire a greater velocity. And this fractionalized effect becomes stronger when comes to more and more UD, so the band velocity becomes bigger and bigger.

1:39PM B08.00013: Fermi surface reconstruction in electron-doped cuprates without antiferromagnetic long-range order  JUNFENG HE (Presenter), Physics, University of Science and Technology of China, COSTEL R. ROTUNDU, Stanford University, MATHIAS SCHEURER, Harvard University, YU HE, MAKOTO HASHIMOTO, KEJUN XU, Stanford University, YAO WANG, Harvard University, EDWIN HUANG, TAO JIA, SUDI CHEN, BRIAN MORITZ, DONGHUI LU, YOUNG SANG LEE, THOMAS DEVEREAUX, ZHIXUN SHEN, Stanford University — Fermi surface (FS) topology is a fundamental property of metals and superconductors. In electron-doped cuprate Nd_{2-x}Ce_xCuO_4 (NCCO), an unexpected FS reconstruction has been observed in optimal- and over-doped regime (x=0.15-0.17) by quantum oscillation measurements (QOM). This is all the more puzzling because neutron scattering suggests that the antiferromagnetic (AFM) long-range order, which is believed to reconstruct the FS, vanishes before x=0.14. To reconcile the conflict, a widely discussed external magnetic field-induced AFM long-range order in QOM explains the FS reconstruction as an extrinsic property. Here, we report angle-resolved photoemission (ARPES) evidence of FS reconstruction in optimal- and over-doped NCCO. The observed FSs are in quantitative agreement with QOM, suggesting an intrinsic FS reconstruction without field. This reconstructed FS, despite its importance as a basis to understand electron-doped cuprates, cannot be explained under the traditional scheme. We discuss the possible origin.

1:51PM B08.00014: In situ angle-resolved photoemission spectroscopy measurements of cuprate thin films grown by molecular beam epitaxy  ZHUOYU CHEN (Presenter), SLAVKO REBEC, TAO JIA, GLAM, Stanford University, MAKOTO HASHIMOTO, DONGHUI LU, SSRL, SLAC, ZHIXUN SHEN, GLAM, Stanford University, ROBERT G MOORE, SIMES, SLAC — Utilizing the oxide molecular beam epitaxy (MBE) in situ connected to beam-line angle-resolved photoemission spectroscopy (ARPES) in Stanford Synchrotron Radiation Lightsource (SSRL), high-quality cuprate films grown atomic-layer-by-layer enable measurements of electronic structure tuned by various parameters, such as epitaxial strain and surface termination, which have not been possible before with bulk materials. With the in situ connected scanning tunneling microscopy (STM), we are able to further resolve electronic properties of these films in spatial dimensions. In this talk, the newest results coming from this interconnected system will be presented.

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B09 DCMP: Superconductivity: Theory/Computational

BCEC 151A - Brian Moritz, SLAC National Accelerator Laboratory

11:15AM B09.00001: Pairfield fluctuations in the 2D Hubbard Model*  THOMAS MAIER (Presenter), Computational Sciences and Engineering Division and Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, DOUGLAS J SCALAPINO, Physics Department, University of California, Santa Barbara — The nature of the pseudogap phase out of which superconductivity emerges in the cuprates remains an open problem. Pairfield fluctuations above the superconducting transition temperature provide information on the nature of this phase. Here we report numerical calculations of the d-wave pairfield susceptibility of a 2D Hubbard model for dopings which have a pseudogap and for dopings which do not. One knows that in both cases there will be a region of Kosterlitz-Thouless fluctuations as the transition at TKT is approached. Above this region, we find evidence that the pseudogap limits the growth of the local pairfield and provides an environment in which phase fluctuations determine the temperature dependence of the pairfield susceptibility. In contrast, in the overdoped regime where there is no pseudogap, the temperature dependence of the pairfield is consistent with Ginzburg-Landau amplitude fluctuations. We discuss an experiment that can be used to measure this characteristic difference.

11:27AM B09.00002: Superconducting symmetry of the extended Hubbard model below Tc  FRANK MARSIGLIO (Presenter), JOEL HUTCHINSON, University of Alberta — The two-dimensional extended Hubbard model on a square lattice is known to host s-wave, d-wave and p-wave superconducting phases depending on the values of the on-site and nearest-neighbour interactions. By examining the free energy functional of the gap in this model, we find that these symmetries are often dependent on temperature. The critical points of this functional are highly constrained by the lattice symmetry and allow us to formulate stringent conditions on the temperature profile of the gap function, applicable to other models as well. In this talk, we discuss the finite temperature phase diagram of the extended Hubbard model, and point out the existence of first and second order symmetry transitions below Tc. Understanding such transitions may be important for assessing the symmetry of some unconventional superconductors such as UPt_3.
11:39 AM B09.00003: An accurate indicator for unconventional superconductivity using charge-spin coupling

RODRIGUES (Presenter), LUCAS WAGNER, Department of Physics, University of Illinois at Urbana Champaign — A data-based prediction model for unconventional superconductivity is constructed, which has three ingredients: a layered crystal structure, stable local magnetic moments and an intermediate spin-orbital (as opposed to spin-orbit) coupling. This classifier is sufficiently specific to clearly distinguish cuprate and iron-based superconductors from other materials in the same structural class. We discuss some of the putative false positives and whether they might be good candidates for new unconventional superconductors.

*This work was supported by the Center for Emergent Superconductivity, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DEAC0298CH1088. The computational resources used in this work were provided by the University of Illinois Campus Cluster and the Blue Waters sustained-petascale computing project, which is supported by the National Science Foundation (awards OCI-0725070 and ACI-1238993) and the state of Illinois. Blue Waters is a joint effort of the University of Illinois at Urbana-Champaign and its National Center for Superconducting Applications. All data will be available through the Materials Data Facility.

11:51 AM B09.00004: Ground state phase diagram of doped Hubbard model on 4-leg cylinders

YIFAN JIANG (Presenter), THOMAS DEVEREAUX, HONG-CHEN JIANG, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory and Stanford University — We report a large-scale density-matrix renormalization group study of the lightly doped Hubbard model on 4-leg cylinders in the presence of next-nearest hopping t'. By keeping a large number of states for long system sizes, we are able to reveal a rich phase diagram consisting of a variety of distinct phases, including (1) The Luther-Emery (LE) liquid with quasi-long-range superconductivity (SC) and charge-density-wave (CDW) order, but with a gap in the spin sector; (2) Insulating phase with "filled" charge stripe and long-range CDW order but no long-range SC, and (3) Luttinger liquid phase with dominant single-particle correlation and subdominant SC and CDW correlations. In particular, at δ=12.5% doping concentration, we found that a tiny t'∼-0.01t is enough to drive the system out of the insulating state at t'=0 to the LE phase. Aside from t', the effect of Coulomb repulsion and doping concentration has also been explored. Our results indicate that a route to robust long-range superconductivity involves destabilizing insulating charge stripes in the doped Hubbard model.

12:03 PM B09.00005: Study of nodal gap in t-J model via renormalized mean field theory

YIHSUAN LIU (Presenter), WEI-LIN TU, Institute for Solid State Physics, The University of Tokyo, TING-KUO LEE, Institute of physics, Academia Sinica — Angle-resolved photoemission (ARPES)[1] and scanning tunnelling microscopy (STM) [2] results show that Bi$_2$Sr$_{2-2y}$La$_y$CuO$_{6+δ}$ exhibit a gap, instead of a node, near the nodal region for x < 0.1. A similar gap has also been found in lightly doped La$_{2-x}$Sr$_x$CuO$_4$[3]. All these experiment results indicated that spin density wave (SDW) and nodal gap(NG) are closely related. However, why the NG close when the insulator-superconductor transition occurs remains unclear.

From the theoretical point of view, various degenerate intertwined order states have been investigated via renormalized mean field theory(RMFT) [4]. Among these states, we found that only the states accompanied by SDW open the nodal gap. Otherwise, there is either node or arc near nodal region. In this work, we will discuss the mechanism of the gap formation and show the gap evolution upon doping.

*The authors are grateful for the support of the Taiwan Ministry of Science and Technology Grant MOST 106-2112-M-001-020 and MOST 107-2112-M-001-034.
CHEN SHUAI (Presenter), Tsinghua University — We study a ground-state ansatz for the single hole doped t-J model in two dimensions via a variational Monte Carlo method. Such a single hole wavefunction possesses a composite structure with a finite angular momentum associated with hidden spin currents, which gives rise to a novel ground state degeneracy in agreement with recent ED and DMRG results. We further show that the wavefunction is composed of a quasiparticle component and an incoherent momentum distribution in excellent agreement with the DMRG results up to an 8×8 lattice. But the quasiparticle spectral weight determined by the VMC vanishes in a power-law fashion, indicating that the doped hole becomes a non-Landau quasiparticle in the large sample-size limit. Here the bare hole propagator decays much faster as compared to the composite hole over a spatial distance, supporting the picture that a bare hole must be turned into a “twisted” quasiparticle in order to propagate more coherently in an antiferromagnetic background. However, by turning on the phase string induced by the hole hopping in the t-J model, a normal Bloch-wave wavefunction with a finite quasiparticle spectral weight and conventional quantum numbers can be simply recovered in the so-called σt-J model, again well agreeing with the ED and DMRG results.

HONG-CHEN JIANG (Presenter), SLAC National Accelerator Laboratory — We report a large-scale density-matrix renormalization group study of lightly doped t-J-type model on the square lattice, which hosts a quantum paramagnetic state at half-filling. We observe an interesting interplay between d-wave superconductivity and spin and charge density wave (CDW) order. Despite the tendency of CDW order on thinner cylinders is strong, our results on wider systems suggest that the CDW order may disappear in the thermodynamic limit. The spin correlations are found to decay exponentially, on the contrary, the superconducting pair-field correlations decay power-law with an exponent significantly smaller than the spatial dimension. Our results suggest that a uniform d-wave superconductivity emerges in doping the quantum paramagnet on the square lattice. The connection of our results to two dimensions is also discussed.

MASON PROTTER (Presenter), RUFUS BOYACK, FRANK MARSIGLIO, University of Alberta — The standard BCS approach to superconductivity considers only particle-particle pairing interactions, meaning that Cooper pairing arises as an instability of an otherwise well-defined Fermi surface. In a more generic situation, other interactions can compete with the Cooper instability and lead to a breakdown in the formation of a Fermi surface, which as a result changes the properties of the ground state. We explore a functional-integral method for rigorously incorporating particle-hole fluctuation corrections to the BCS theory of superconductivity. These corrections arise naturally as the result of a multi-channel Hubbard-Stratonovich decomposition of an attractive Hubbard interaction. Differences between this approach and previous models of particle-hole corrections to BCS theory are considered.

YONGYOU ZHANG (Presenter), FAN YANG, School of Physics, Beijing Institute of Technology — Superconductivity in quasicrystal has been discovered in experiments [1] for Al–Zn–Mg quasicrystal with \( T_c \approx 0.05 \) K. In this presentation, we systematically studied the quasicrystal superconductor properties on Penrose lattices. Within two-particle approximation the negative U Hubbard model shows that the Cooper binding energy is proportional to exp(−1/U) and Anderson Law works well. Besides, the negative U Hubbard model was studied by the mean-field method with which the superconductor gap, superconductor density of states, entropy, specific heat, and current density are analyzed. The superconductor gap decreases to zero when the temperature is larger than \( T_c \), simultaneously the lines entropy and specific heat show the superconductor phase by their discontinuities. The paramagnetic and diamagnetic superconductor currents also have discontinuities at \( T_c \) and cancel each other when \( T>T_c \). Different from periodical lattices the superconductor current has a finite value when \( T = 0 \), which shows the difference of the superconductor behavior between the quasicrystals and common crystals.

Proximity induced superconductivity in quasicrystal-superconductor hybrid rings

Gautam Rai (Presenter), University of Southern California, Anuradha Jagannathan, Laboratoire de Physique des Solides, L’université Paris Sud, Stephan Wolfgang Haas, University of Southern California — Quasicrystals with their exotic long range spatial order are expected to host an exotic superconducting state. As a first step to understanding these new kinds of superconducting systems, we have studied proximity-induced superconductivity in a hybrid 1D chain. The hybrid system is modeled using the Bogoliubov-de Gennes approach, consists of a non-interacting Fibonacci chain coupled to a periodic superconductor. This quasiperiodic chain has topological properties which have been explored in a number of experimental/theoretical works. We show that an inhomogeneous superconductivity is induced in the normal chain, and, in particular, how edge states affect the induced pairing amplitudes.

Bond disproportionation and electron-phonon driven oxygen-bismuth hybrid hole pairing in bismuth perovskites

Kateryna Foyevtsova (Presenter), Arash Khazraie, Ilya Elfimov, George Albert Sawatzky, Stewart Blusson Quantum Matter Institute — In this talk, we will present the recently developed theory describing the bismuth perovskites ABIO₃ (A = Sr or Ba) as bond- (as opposed to charge-) disproportionated insulators where Bi-O hybridization and the presence of oxygen holes lead to formation of molecular orbitals and strong polaronic effects, which might be the prime mechanism driving these materials towards superconductivity upon doping. In particular, we will first use electronic structure methods to demonstrate that oxygen holes indeed condense into A₁g molecular orbitals centered at collapsed BiO₆ octahedra and then to derive an appropriate tight-binding (TB) model, as well as to estimate electron-phonon coupling and an effective attraction between the two holes in the A₁g symmetry in this collapsed “BiO₆ molecule”, emphasizing that these two parameters are strong enough to sustain polaronic superconductivity. We will also explore the parameter space of the TB model, finding a cross-over from the bond- into the charge-disproportionated insulating phase, as well as a metallic phase with a non-bonding character of the oxygen holes.

Pressure-enhanced high temperature superconductivity in XH₃ (X=As, Se, Br, Sb, Te and I)

Po-Hao Chang (Presenter), Swabir Silayi, Dimitrios A Papaconstantopoulos, George Mason University, Michael Mehl, US Naval Academy — The discovery of high critical temperature Tc superconductivity in highly compressed H₃S has opened up the question of searching for strong electron-phonon coupling in the hydrides outside the transition metal series. In this work, we performed linearized augmented plane wave (LAPW) calculations for many different volumes in the Im3m structure for XH₃ (X=As,Se,Br,Sb,Te and I), We then applied the multiple scattering-based theory of Gaspari and Gyoorffy to obtain the Hopfield parameters and the McMillan-Allen-Dynes theory to estimate λ and Tc. Based on our analysis, all considered materials share similar trends of Tc enhancement under increasing pressure. H₃Se in particular, could potentially go to a Tc well over 200 K. Finally, in addition to pressure enhanced electron-phonon coupling, by applying rigid band model we predict that a small amount of alloying with a neighboring element could lead to even further increase of Tc.
1:39PM B09.00013: First-principles evolutionary structural searches for new high-pressure phases of Nb3Al*
JIANJUN MAO (Presenter), YUE CHEN, The University of Hong Kong — High cost and poor stability have inhibited the large-scale applications of high-temperature cuprate superconductors. Intermetallic niobium compounds such as Nb3Sn and Nb3Al attract significant research interest due to their potential superconducting applications. Herein, we have combined evolutionary algorithms with density functional theory to perform structural searches for ground-state crystal structures of Nb3Al under high pressures. At ambient pressure and low temperature, a new phase with distorted Nb atomic chains is found to be energetically more stable than the well-known A15 phase. Because the Nb atomic chains are believed to be closely related to the superconducting properties, the electron-phonon coupling of this new phase has been further studied using density functional perturbation theory. Moreover, we identify a pressure-induced structural phase transition of Nb3Al under high pressures. Base on ab-initio molecular dynamics simulations, the temperature effects on the structural phase transitions of Nb3Al have also been investigated.

*This work is supported by the Research Grants Council of Hong Kong under project numbers 27202516, 17200017 and 17300018, and the National Natural Science Foundation of China under project number 51706192.

1:51PM B09.00014: Magnetism of the low-dimensional orbital-selective Mott insulators
JACEK HERBRYCH (Presenter), University of Tennessee, JONAS HEVERHAGEN, MARIA DAGHOFER, University of Stuttgart, GONZALO ALVAREZ, Oak Ridge National Laboratory, ADRIANA MOREO, ELBIO R DAGOTTO, University of Tennessee — The magnetic properties of low-D iron-based superconductors belonging to the 122 (Rb_xFe_ySe_2) and 123 (BaFe_2Se_3) families [1-2] proved to be a challenge for the theoretical description. Investigation of the orbital-selective Mott phase in 1D (relevant for 123 family) [3,4] revealed the existence of an exotic block spin order, namely AFM coupled FM spin islands. In parallel, inelastic neutron scattering experiments on quasi-1D BaFe_2Se_3 [2] and 2D Rb_xFe_ySe_2 [1] confirmed the relevance of these spin-block phases. The theoretical description of the latter requires long-range interaction and strong dimerization if within spin-wave models. In our work [4,5] we show that the magnetic properties of the orbital-selective Mott phase can be properly described by (short-range) multiorbital Hubbard models. Furthermore, we argue that the electronic correlations of itinerant orbitals are important for block-magnetism and that the minimal model which properly captures such a physics is the generalized Kondo-Heisenberg model.

BOQUN SONG (Presenter), MANH CUONG NGUYEN, CAI-ZHUANG WANG, PAUL CANFIELD, KAI-MING HO, Physics, Iowa State University — The recently discovered 1144-phase [1-2] suggests a new type of composite alloys, namely hetero-crystals. The author will present its definition and demonstrate wide existence. The hetero-crystals consist of the layered skeleton and hetero-cations alternatively located on both sides of the skeleton. Tuning cation species leads to significant modifications to structures, granting an exceptional chance to manipulate the emerging phases. The 1144-phase is examined as a case study of hetero-crystals. Various 1144-arsenide and phosphides are examined by combining first principle calculation and ideal solution approximation, wherein configurational, vibrational and electronic degrees of freedom are fully considered. Remarkably, the seemingly random occurrence of the 1144 phases is governed by a rule that involves two factors: elastic distortion and charge balance. Derived from 1144-phosphides, the rule, nevertheless, is heuristic and generic, which leads to an outlook of other hetero-crystals promising to be stabilized. [1] B. Q. Song, et. al. Physical Review B 97 (9), 094105 (2018). [2] B. Q. Song, et. al. Physical Review Materials 2 (10), 104802 (2018)

*The work was performed at Ames Laboratory, operated for U.S. DOE by Iowa State University under contract DE-AC02-07CH11358.

Session B10 DMP: Fe-based Superconductors II BCEC 151B - Vitalii Vlasko-Vlasov, Argonne National Laboratory - Tag(s): Focus
11:15AM B10.00001: Elastoresistive and elastocaloric anomalies in iron pnictides* [Invited] MATTHIAS IKEDA
(Presenter), Geballe Laboratory for Advanced Materials, Stanford University — Electronic nematicity is a prominent feature in Fe-based superconductors, but is also present in at least some cuprates, and heavy fermion superconductors. Being a possible common thread for unconventional superconductivity, the role of nematic fluctuations for superconductivity needs to be assessed. This calls for new techniques that allow for tuning nematicity continuously towards quantum criticality. In the first part of this talk I will discuss how to disentangle the response of nematicity to strain components of different symmetry, and will show that both symmetric (A1g) and antisymmetric (B1g) strain are suitable means to tune the critical temperature of the nematic phase transition in Fe based superconductors. In the second part of the talk, I will outline recent experimental advances exploring the thermoelastic properties of these materials. In particular, the finite response of nematicity to strain causes anomalies in the elastocaloric effect as well as in the elastoresistivity which can be measured via an AC technique. These anomalies are proportional to the corresponding heat capacity anomalies and are understood to be a direct consequence of the strain dependence of the nematic and the antiferromagnetic transition temperatures. A similar mechanism should more generally be expected for any phase transition tunable by strain.

*This work was supported in part by the Gordon and Betty Moore Foundations EPiQS Initiative through grant GBMF4414 and by the Department of Energy, Office of Basic Energy Sciences, under Contract No. DEAC02-76SF00515.

11:51AM B10.00002: Suppression of T_C in an underdoped iron-based superconductor through uniaxial strain*
PAUL MALINOWSKI (Presenter), SHUA SANCHEZ, JOSHUA Mutch, QIANNI JIANG, University of Washington, JONG-WOO KIM, PHILIP RYAN, Advanced Photon Source, Argonne National Labs, JIUN-HAW CHU, University of Washington — The iron-based superconductors generically have been shown to host the electronic nematic phase which competes with superconductivity. Previous work has also shown that anisotropic strain is particularly well suited as a tunable, symmetry breaking field that can couple to the nematic order parameter. In this work, we present electrical transport, magnetic susceptibility, and single crystal x-ray diffraction measurements demonstrating that the superconducting transition in an underdoped iron-based superconductor is efficiently tuned towards zero temperature through the application of large, uniaxial strain that enhances the orthorhombic distortion. This demonstrates that application of mechanical strain is a novel external parameter that is able to tune a superconductor to metal transition in a three-dimensional system.

12:03PM B10.00003: Elastoresistivity measurements in a 65 T pulsed magnet on Fe-based superconductors*
JOSHUA STRAQUADINE (Presenter), JOHANNA PALMSTROM, PHILIP WALMSLEY, ALEXANDER T HRISTOV, Stanford University, FRANZISKA WEICKERT, FEDOR F. BALAKIREV, MARCELO JAIME, ROSS MCDONALD, IAN R FISHER, Pulsed Field Facility, National High Magnetic Field Laboratory — One of the most striking signatures of the nematic transition in the underdoped iron-based superconductors is a diverging elastoresistivity, which is the linear response of the resistivity anisotropy to the corresponding symmetry-breaking strain. Elastoresistivity, however, cannot be measured in the superconducting state; tracking the nematic fluctuations down to the putative quantum critical point near optimal doping necessitates the use of extreme magnetic fields to suppress superconductivity. We report the first elastoresistivity experiments in pulsed magnetic fields up to 65 T on near-optimally-doped Ba(Fe1-χCoχ)2As2 at temperatures down to 1.3 K, and discuss the technical advances required to make such a measurement possible within the few millisecond window when the field is above Hc2. These new techniques expand the applicability of elastoresistivity measurement for disentangling the role of nematic fluctuations in strongly correlated systems.

12:15PM B10.00004: Changing nature of superconductivity in tetragonal FeS under pressure  MAKOTO SHIMIZU, Department of Physics, Okayama University, NAYUTA TAKEMORI, Research Institute for Interdisciplinary Science, Okayama University, DANIEL GUTERDING, Fachbereich Mathematik, Naturwissenschaften und Datenverarbeitung, Technische Hochschule Mittelhessen, HARALD JESCHKE (Presenter), Research Institute for Interdisciplinary Science, Okayama University — Tetragonal FeS is an iron chalcogenide superconductor with similarities to FeSe but without nematic phase and with weaker electronic correlations. In contrast to pure FeSe, however, FeS shows two superconducting domes under pressure. We use electronic structure and spin fluctuation theory calculations for tetragonal FeS in order to study the nature of the superconducting order parameter [1]. In the random phase approximation, we find a gap function with d-wave symmetry at ambient pressure which is in agreement with several reports of a nodal superconducting order parameter in FeS. We find that, as a function of pressure, the superconducting pairing strength decreases until a Lifshitz transition takes place at 4.6 GPa. As a hole pocket with a large density of states appears at the Lifshitz transition, the gap symmetry is altered to sign-changing s-wave. At the same time the pairing strength is severely enhanced and increases up to a new maximum at 5.5 GPa. Therefore, our calculations explain the occurrence of two superconducting domes in FeS without any structural phase transition.

12:27PM B10.00005: Specific heat measurements of the high-temperature magnetic superconductor RbEuFe4As4* KRISTIN WILLA, ROLAND WILLA, JINKE BAO, ALEXEI E KOSHELEV, DUCK YOUNG CHUNG, Argonne National Laboratory, MERCOURI KANATZIDIS, Department of Chemistry, Northwestern University, WAI-KWONG KWOK (Presenter), ULRICH WELP, Argonne National Laboratory — We report specific heat measurements on the newly discovered magnetic superconductor RbEuFe4As4. We investigated the superconducting transition at Tc = 38K and extracted the phase boundary for in and out of plane magnetic fields and obtained an anisotropy ratio of 1.8. At small fields near the magnetic transition temperature Tm ~ 14.9K, we resolved a cusp-like behavior in the temperature dependence of the specific heat curve that shifts to lower temperatures for fields along the c-axis and a broad shoulder that shifts to higher temperatures for in-plane fields. We can reproduce our measured calorimetry data quantitatively by Monte-Carlo simulations of an anisotropic easy-plane 2D Heisenberg model that suggests that the cusp in specific heat is due to a BKT transition and the high temperature hump at higher fields marks a crossover from a paramagnetically disordered to an ordered state.

12:39PM B10.00006: Superconducting phase diagram of magnetically ordered superconductor RbEuFe4As4 in pulsed fields up to 65 T* MATTHEW SMYLIE (Presenter), Physics and Astronomy, Hofstra University, KRISTIN WILLA, JINKE BAO, ROLAND WILLA, ALEXEI E KOSHELEV, WAI-KWONG KWOK, DUCK YOUNG CHUNG, Argonne National Laboratory, MERCOURI KANATZIDIS, Northwestern University, JOHN SINGLETON, FEDOR BALAKIREV, Los Alamos National Laboratory, PRASHANTA NIRAULA, EIMAN BOKARI, ASGHAR KAYANI, Western Michigan University, ULRICH WELP, Argonne National Laboratory — The superconducting phase diagram of single-crystal RbEuFe4As4 (Tc ~ 36.5 K), which has long-range Eu magnetic order at Tm ~ 15 K, has been measured in pulsed magnetic fields up to 65 T using a proximity diode oscillator technique. Upon decreasing temperature, the anisotropy Hc2ab/Hc2c decreases from 1.8 near Tc towards unity indicating significant Pauli paramagnetic limiting effects for both H // (110) and H // (001). This is born out in theoretical fits for a Fermi surface in the form of warped cylinders, yielding a high in-plane Maki parameter of ~2.4, suggesting that a low temperature FFLO state may exist above 65 T. Irradiation with 5 MeV protons to a dose of 5x1016 p/cm² suppresses Tc by ~ 3K, a substantial increase in vortex pinning and a reversal in anisotropy at temperatures below 15K.

DING HU (Presenter), PENGCHENG DAI, Rice University, ZHIPING YIN, Department of Physics, Beijing Normal University — Superconductivity in BaFe2(As1−xPx)2 iron pnictides emerges when its nematic phase and stripe AF order at TN (Ts = TN) are gradually suppressed with increasing x, reaching optimal superconductivity around x = 0.30 with Tc ≈ 30 K. We show that a moderate uniaxial pressure along the c-axis in BaFe2(As0.70P0.30)2 spontaneously induces a 3D collinear antiferromagnetic order with TN = Ts > 30 K, while only slightly suppresses Tc. Furthermore, c-axis pressure pushes the underdoped BaFe2(As0.72P0.28)2 to optimal superconductivity with Tc = 30K without AF order firstly, then AF order emergences at higher pressure region. We find that a c-axis pressure compresses the c-axis lattice while expanding the in-plane lattice and increasing the nearest-neighbor Fe–Fe distance, it barely changes the average iron-pnictogen height in BaFe2(As0.70P0.30)2. Therefore, the pressure-induced antiferromagnetic order must arise from a strong in-plane magnetoelastic coupling, suggesting the universal phase diagram under c-axis pressure in BaFe2(As1−xPx)2.

MARTA CIEPLAK (Presenter), IRYNA ZAYTSEVA, IRINA ABALOSZEWA, KATARZYNA KOSYL, DARIUSZ GAWRYLUK, Polish Academy of Sciences — The structural disorder, frequently present in crystals of iron chalcogenides, sometimes leads to unexpected improvement of superconducting properties, as reported in the case of FeTe0.65Se0.35 crystals [1]. In an effort to find the origin of such behavior, here we study the structure, the Hall effect, and the angle-dependent magnetoresistance (AMR) of the Fe1−yNiyTe0.65Se0.35 crystals, with y in the range from 0 to 0.08, grown by Bridgman's method with different cooling rates, slow (S) and fast (F). The S crystals with single, tetragonal phase show inferior superconducting properties to these shown by F crystals, in which an admixture of monoclinic phase is found. The Hall effect of crystals with y>0.03, in which superconductivity is suppressed, confirms the electron doping of both types of crystals, while the AMR is an order of magnitude larger in F crystals, with y-dependent anisotropy at low temperatures (T < 8K), which disappears on warming. The analysis of the AMR suggest that it may originate in the magnetism of monoclinic inclusions, most likely of the type Fe3(Se-Te)4. The relation of these findings to superconductivity will be discussed.

*Supported by Polish NSC Grant No. 2014/15/B/ST3/03889.

NIKOLA MAKSIMOVIC (Presenter), IAN M HAYES, VIKRAM NAGARAJAN, University of California, Berkeley, JOHN SINGLETON, FEDOR BALAKIREV, Los Alamos National Laboratory, JAMES G. ANALYTIS, University of California, Berkeley — The "strange metal" parent phase of high-temperature superconductors displays a resistivity that scales linearly with temperature. Recent experiments reveal that the resistivity of these compounds also increases linearly with applied magnetic field, and is characterized by a striking scaling law between magnetic field and temperature. It has been suggested that this behavior is governed by physics beyond the standard quasiparticle picture of metals, but it is necessary to determine to what extent conventional transport theory is applicable; for example, elastic scattering from lattice imperfections typically has a well-defined effect on magnetotransport. In this study, we measure high-field transport of systematically disordered samples of a high-Tc iron-pnictide superconductor near an antiferromagnetic instability. Our data suggest that antiferromagnetic fluctuations dominate at low temperatures, producing robust transport scaling between temperature and magnetic field which is intimately tied to the onset of superconductivity.

1:27PM B10.00010: Precision Controlled Detwinning of Orthorhombic Twin Domains in Underdoped BaFe$_2$As$_2$

SHUA SANCHEZ (Presenter), JIUN-HAW CHU, University of Washington, PHILIP RYAN, JONG-WOO KIM, Argonne National Labs — Underdoped BaFe$_2$As$_2$ exhibits an orthorhombic structural phase transition driven by electronic nematic ordering. In the past, the relation between lattice distortion and electronic anisotropy above the phase transition has been studied comprehensively by the technique of elastoresistivity. In contrast, the relation between spontaneous orthorhombicity ($(a-b)/(a+b)$) and spontaneous resistivity anisotropy ($(R_a - R_b)/(R_a + R_b)$) below the phase transition has never been measured to the same level of precision. Several previous detwinning experiments have used samples under a constant uni-axial stress, which results in additional lattice distortion especially close to phase transition. Here we present x-ray diffraction data on a crystal sample in which in-situ tunable uniaxial stress is used to precisely control the detwinning of domains. Lattice constant data showing both the relative domain populations and the elastic response to stress are matched with simultaneous resistivity measurements to yield a precise determination of the domain resistivity anisotropy. Elastoresistivity tensor coefficients are also computed in the fully detwinned single domain state, which cannot be inferred from macroscopic strain measurements alone.

1:39PM B10.00011: Post annealing effect on Ca(Fe$_{1-x}$Co$_x$)$_2$As$_2$ and AeFe$_2$As$_2$ (Ae = Ca, Sr, Ba) single crystals

SHUYUAN HUYAN (Presenter), LIANGZI DENG, YANFENG LYU, ZHENG WU, HANMING YUAN, FEI TIAN, The Texas Center for Superconductivity, University of Houston, YUANYUAN ZHAO, School of Physics and Optoelectronic Engineering, Nanjing University of Information Science and Technology, KUI ZHAO, Advanced Micro-Fabrication Equipment Inc., JINGYING SUN, MELISSA GOOCH, JAMES K MEEN, SHUO CHEN, ZHIFENG REN, CHING-WU CHU, The Texas Center for Superconductivity, University of Houston — Through post annealing & quenching process, we could induce superconductivity in the non-superconducting single crystals of Ca(Fe$_{1-x}$Co$_x$)$_2$As$_2$ and AeFe$_2$As$_2$ (Ae = Ca, Sr, Ba) grown by self-flux solution method, with onset-$T_c$ below 15 K, 16 K, 22 K and 24 K, respectively. A series of experiments were designed in order to look for the differences between as-grown samples and post annealed samples. By systematical characterization, including resistivity, Hall coefficient, magnetization, X-ray diffraction and wavelength dispersive spectroscopy results, the possible cause for the superconductivity in these samples is discussed. These experimental results help to shed light on the underlying mechanism for the repotted superconductivity in Fe-based 122 system.

Session B11 DMP DCOMP FIAP: Defects in Semiconductors -- Device Materials

Peelaers, University of Kansas - Tag(s): Focus

11:15AM B11.00001: First-principles calculations on dislocation-point defect interactions in Cu(In,Ga)Se$_2$ solar cell absorbers* [Invited] KARSTEN ALBE (Presenter), DANIEL A. BARRAGAN-YANI, FB Material- und Geowissenschaften, TU Darmstadt — In Cu(In,Ga)Se$_2$ based commercial solar cells, power-conversion efficiencies of more than 15% can be achieved, although significant dislocation densities are present. This implies that lattice dislocations in CIGSe-based absorbers are per se electrically inactive or possibly passivated by solute or impurity atoms.

While intrinsic point defects in this material class have been completely characterized by density functional theory calculations using hybrid functionals [1], studying dislocations remains a challenge for electronic structure calculations. In this talk, I will present a supercell approach using dislocation dipoles, that allows to study the influence of chemical reconstruction and solute segregation on the electrical activity of mixed dislocations in CISE and CGSe. I will discuss the interaction of various dislocation types with intrinsic [3] and extrinsic point defects [3] and address the importance of mechanical driving forces. Moreover, the computational results are directly compared with experimental data from high-resolution electron microscopy [4].

11:51AM B11.00002: Observation of Enormous Non-Linearity in the Output Electroluminescence Characteristics of Room-Temperature GaN-Based Microcavities*  
ANIRUDDHA BHATTACHARYA (Presenter), Department of Electrical Engineering and Computer Science, University of Michigan at Ann Arbor — Highly non-linear light ($\lambda \sim 380$ nm)-current characteristics are observed in a bulk GaN-based laterally-emitting microcavity diode at room temperature. The value of the non-linear slope, when plotted in a double logarithmic scale, increases from $\sim 2$ to $\sim 40$ at the threshold ($\sim 5$ kA/cm$^2$). The spectral characteristics remain essentially invariant with increasing excitation and no signatures of coherence are observed at any injection. Control measurements indirectly show that the electroluminescence originates from the p-type Mg:doped GaN contact layer. These phenomena are at least partially and qualitatively similar to previous observations of super-linear photoluminescence characteristics in Zn:doped GaN epilayers at $\sim 180$ K [1]. In our case, the super-linearity originates, most possibly, due to the redistribution of injected carriers between the radiative and non-radiative pathways over a particular excitation regime. Further analysis of these effects is in progress and will be presented.

12:03PM B11.00003: The Near-Surface Electrostatic Environment of n-Doped Silicon Probed with a Moveable Dangling Bond Point Probe  
TALEANA HUFF (Presenter), THOMAS DIENEL, MOHAMMAD RASHIDI, ROSHAN ACHAL, WYATT VINE, ROBERT A WOLKOW, Physics, University of Alberta — With nanoelectronics reaching the limit of atom-sized devices, it has become critical to characterize how irregularities in the local environment can affect device functionality. This includes unwanted charge defects detuning binary logic atomic patterns [1], delicately coupled quantum computing states [2], and supra-layer molecular electronics [3]. In this work, we characterize charged subsurface defects on a hydrogen terminated silicon (100) sample, adding a possible explanation for a heretofore contentious negatively-charged defect. Through contact potential difference maps, taken with non-contact atomic force microscopy, variations in the electrostatic topography on a nanometer length scale are shown and correlated with alterations in the behavior of dangling bond charge state transitions. In addition, the spectroscopic signature of a single electron charge transition in a dangling bond is used as a charge sensor to directly probe the depth of charged defects, the local Debye screening length, and the effective dielectric constant close to the surface.

12:15PM B11.00004: Extinction of Random Telegraph Switching by “Cryogenic Annealing” in Small Area Si MOS Transistors*  
GANGYI HU, MARK LEE (Presenter), HISASHI SHICHIJO, University of Texas at Dallas, CLINT A NAQUIN, HAL EDWARDS, Texas Instruments, Inc. — Random telegraph switching (RTS) showing a slow decay in switching rate at cryogenic temperatures that leads to eventual extinction of the discrete fluctuations has been observed in the drain-source current ($I_{DS}$) of small area Si n-channel metal-oxide-semiconductor (NMOS) transistors. The RTS was characterized by $I_{DS}$ fluctuations between two discrete levels over a finite interval of gate bias. In all devices showing RTS, the average switching rate gradually diminished to zero over a time of 1 to 2 hours at 15 K while maintaining nearly constant fluctuation amplitude, so that the RTS eventually ceased. This decay in switching rate may be due to a metastable oxygen vacancy defect that gradually repairs itself after repeated capture and emission of charge. Once gone, RTS did not reappear in any subsequent measurements even after bias and temperature cycling, suggesting a mechanism to deactivate at least some forms of RTS through a “cryogenic anneal”.

**12:27PM B11.00005: Hyperdoping silicon for intermediate band photoconductivity**  
YINING LIU (Presenter), Department of Electro-Optics and Photonics, University of Dayton, SHAO QI LIM, WENJIE YANG, Research School of Physics and Engineering, Australia National University, PHILLIPPE K CHOW, US Army ARDEC-Benet Labs, IMAD AGHA, Department of Physics, University of Dayton, JAMES S WILLIAMS, Research School of Physics and Engineering, Australia National University, JEFFREY M WARRENDER, US Army ARDEC-Benet Labs, JAY MATHEWS, Department of Physics, University of Dayton — Intermediate band formation in silicon could lead the way for photodetection well below the Si band gap. By incorporating transition metals into Si at levels well above the solid solubility limit, intermediate band absorption can lead to photoconductivity induced by photons with less than the energy of the band gap. These supersaturated solutions can be fabricated using the method of ion implantation followed by pulsed laser melting. This concept has been demonstrated with Si hyperdoped with Au or Ti, but the photoresponse of detectors based on this idea have low quantum efficiency. Here we report on enhancements in the photoresponse of Si:Au and Si:Ti based detectors from varying the implantation and laser melting conditions, as well as the formation of high-quality Ohmic contacts.

**12:39PM B11.00006: The evolution of atomic structure and chemical states of ultra-low energy high-dose Boron implanted Si via UV laser annealing**  
KUANG YAO LO (Presenter), FU-YING LEE, ZONG-ZHE WU, LI-CHI KAO, FENG-MING CHANG, Physics, National Cheng Kung University, Taiwan, YU-MING CHANG, Center for Condensed Matter Sciences, National Taiwan University, Taiwan — One of the most critical issues in the nano-device fabrication is to confirm the atomic structure evolution of the ultrathin shallow junction. In this report, UV Raman spectroscopy, X-ray absorption near edge structure (XANES), X-ray photoelectron spectroscopy (XPS) and reflective second harmonic generation (RSHG) are used to analyze the pulse laser induced atomic structure evolution of ultralow-energy high-dose Boron implanted Si(110) at the room and cold substrate temperature. The formation of Si-B bond after the laser irradiation was indicated by a peak feature around 480 cm\(^{-1}\) resolved in UV Raman spectra. Meanwhile, the evolution of absorption peak (\(-197\) eV) in XANES and the red shift of binding energy of Si element (\(-99\) eV) in XPS reveal that the changes in the chemical states of ultra shallow junction strongly correlate to the activation process of Boron implantation. These results were confirmed by RSHG measurement, which exhibits the form symmetrical Si-B bonds. The observation of HRTEM agreed with the substrate temperature effect in the recrystallization of Boron implanted region.

*Thanks the Ministry of Science and Technology of the Republic of China, Taiwan for financially supporting, MOST 106-2112-M-006-007, MOST 105-2112-M-006-012 and 105-2119-M-002-046-MY3.

**12:51PM B11.00007: Defect studies in Ge and GeSn thin films grown on Si**  
CHRISTINA SCOTT (Presenter), IMAD AGHA, JAY MATHEWS, Department of Physics, University of Dayton — Silicon (Si) is often used in electronics because of its beneficial conductive properties and cost efficiency. However, it has poor optical properties in the infrared. Si infrared photonic devices could be used for a number of military and civilian applications. One approach to solving this problem is to use epitaxy to grow materials with more favorable optical properties on top of Si, such as germanium (Ge) and germanium tin (GeSn). One challenge for epitaxy is minimizing threading dislocations in the epitaxial layers due to lattice mismatch. In this work, we investigate the quality of Ge and GeSn materials grown on Si using a new remote plasma enhanced chemical vapor deposition (CVD) process. The newly grown material was subjected to etch pit density tests in order to determine the density of threading dislocations. The results show that using this new method results in high quality achieved using traditional CVD methods while also increasing growth rates.

*Funding for this work was provided by an Air Force Office of Scientific Research Young Investigator Award, Grant No. FA95501710146.
1:03PM B11.00008: Crystal growth, electronic structure and optical properties of BaZrS$_3$ and its Ruddlesden-Popper phases*  

SHANYUAN NIU (Presenter), Mork Family Department of Chemical Engineering and Materials Science, University of Southern California, KRISTOPHER WILLIAMS, Department of Chemical Engineering, Massachusetts Institute of Technology, WEI LI, Department of Materials Science and Engineering, University of Delaware, DEBARGHYA SARKAR, Ming Hsieh Department of Electrical Engineering, University of Southern California, FEI HOU, School of Materials Science and Engineering, University of New South Wales, BOYANG ZHAO, Mork Family Department of Chemical Engineering and Materials Science, University of Southern California, KEVIN YE, Department of Materials Science and Engineering, Massachusetts Institute of Technology, ELISABETH BIANCO, MICHAEL E MCCONNEY, Materials and Manufacturing Directorate, Air Force Research Laboratory, RALF HAIGES, Loker Hydrocarbon Research Institute and Department of Chemistry, University of Southern California, DAVID SINGH, Department of Physics and Astronomy, University of Missouri, JAN SEIDEL, School of Materials Science and Engineering, University of New South Wales, RAFAEL JARAMILLO, Department of Materials Science and Engineering, Massachusetts Institute of Technology, REHAN KAPADIA, Ming Hsieh Department of Electrical Engineering, University of Southern California, WILLIAM A TISDALE, Department of Chemical Engineering, Massachusetts Institute of Technology, ANDERSON JANOTTI, Department of Materials Science and Engineering, University of Delaware, JAYAKANTH RAVICHANDRAN, Mork Family Department of Chemical Engineering and Materials Science, University of Southern California —

Transition metal perovskite chalcogenides (TMPCs) are a new class of semiconductors with $d^0$ configuration. The less electronegative chalcogen, compared to oxides, lead to reduced band gap, more covalent bonding, and other interesting physical properties. We report the crystal growth and physical property study of BaZrS$_3$, Ba$_3$Zr$_2$S$_7$ and Ba$_2$ZrS$_4$. Photoluminescence (PL) measurements were performed to study the optical properties. Scanning Kelvin probe microscopy and Hall measurements were carried out to study the electronic structure and transport phenomena. Optical band gap of 1.82, 1.28 and 1.33 eV for BaZrS$_3$, Ba$_3$Zr$_2$S$_7$, and Ba$_2$ZrS$_4$, respectively, were extracted from PL. Such band gap evolution trend is different from that observed in oxide and halide counterparts. Potential effect of octahedra tilting and Zr-S covalent bonding in determining the electronic structure were explored. External luminescence efficiency up to 0.2% and effective minority carrier lifetime longer than 65 ns in Ba$_3$Zr$_2$S$_7$ was also obtained by quantitative and time-resolved PL, respectively.

1:15PM B11.00009: Source of $p$-type conductivity in ultrahigh thermal conducting cubic boron arsenide*  

JOHN LYONS (Presenter), United States Naval Research Laboratory, JOEL BASILE VARLEY, Lawrence Livermore National Laboratory, EVAN RICHARD GLASER, JAIME A. FREITAS, JR., JAMES CLIFFORD CULBERTSON, United States Naval Research Laboratory, FEI TIAN, GEETHAL AMILA GAMAGE, HAORAN SUN, HAMID REZA ZIYAE, ZHIFENG REN, University of Houston — Cubic boron arsenide (c-BAs) exhibits an ultrahigh thermal conductivity (κ) near 1300 W/m-K at room temperature. However, c-BAs is believed to incorporate high concentrations of crystal imperfections that can both quench κ and act as sources of unintentional $p$-type conductivity. This behavior has been attributed to native defects, but direct evidence of their presence in c-BAs crystals is lacking. Here we evaluate the properties of native defects in c-BAs using hybrid density functional theory. These calculations indicate that native defects cannot give rise to free holes; instead, we find that impurities such as Si and/or C readily incorporate on the As site and as shallow acceptors. These results are in excellent agreement with optical and magnetic resonance spectroscopy measurements, which reveal impurity-related processes including donor-acceptor pair recombination and evidence for effective-mass-like shallow acceptors.

1:27PM B11.00010: Point defects and dopants of boron arsenide from first-principles calculations: donor compensation and doping asymmetry*  
SIEUN CHAE (Presenter), KELSEY MENGLE, JOHN HERON, EMMANOUIL KIOUPAKIS, University of Michigan — BAS has received attention due to its unusually high thermal conductivity, yet, its defect properties are relatively unknown. Particularly, point defects crucially affect its electronic, thermal, and optical properties as a semiconductor. Here, we apply hybrid density functional theory calculations to identify the formation energies and thermodynamic charge transition levels of native point defects, common impurities, and shallow dopants in BAS [1]. We find that AsB, VB, BAS, Bi-VB, AsB-BAS, are the dominant intrinsic defects, while CAs, CB, Hi are common impurities. BeB, SiAs and GeAs are predicted to be excellent shallow acceptors with low ionization energy (< 0.03 eV) and negligible compensation by other point defects. However, donors such as SeAs, TeAs, SiB, and GeB have a relatively large ionization energy (~0.15 eV) and are likely to be passivated by native defects such as BAS and VB, as well as CAs, Hi, and HB. The hole and electron doping asymmetry originates from the heavy effective mass of the conduction band due to its boron orbital character, as well as from boron-related intrinsic defects that compensate donors.

1:39PM B11.00011: Effect of substitutional defects on the thermal conductivity of boron arsenide*  
NAKIB PROTIK (Presenter), Physics, Boston College, MAURO FAVA, NATALIO MINGO, LITEN, CEA-Grenoble, JESÚS CARRETE, GEORG MADSEN, Institute of Materials Chemistry, Technical University of Vienna, NAVANEETHA KRISHNAN RAVICHANDRAN, DAVID A BROIDO, Physics, Boston College — Cubic boron arsenide (BAs) has recently been confirmed as having unconventional ultrahigh thermal conductivity, $k$, [1-3], which is particularly sensitive to the presence of vacancy defects [4]. Here, using density functional theory based first principles methods, we calculate the effect of various defects on the lattice thermal conductivity of BAs. We treat the phonon-defect scattering using both the Born approximation and the infinite-order T-matrix method and assess the difference between the results from these two approaches. The phonon-defect scattering rates are combined with the three-phonon and four-phonon scattering rates to obtain a full solution of the phonon Boltzmann transport equation. The calculated thermal conductivities are compared with the most recent experimental measurements.

*N.H.P. and D. B. acknowledge support from ONR MURI Grant No. N00014-16-1-2436.

1:51PM B11.00012: Beyond diffusion limit defect imaging and independent determination of the spatial profiles of electron and hole density near a dislocation defect by combining Raman and photoluminescence (PL) imaging*  
CHANG-KUI HU, University of North Carolina at Charlotte and Wuhan University of Technology, QIONG CHEN, University of North Carolina at Charlotte, FENGXIANG CHEN, University of North Carolina at Charlotte and Wuhan University of Technology, TIMOTHY HURLEY GROERER, Davidson College, MARK W WANLASS, National Renewable Energy Laboratory, YONG ZHANG (Presenter), University of North Carolina at Charlotte — Although a large carrier diffusion length (DL) indicates high material quality, ironically it implies more carrier depletion by an individual extended defect. It also obscures the spatial resolution (SR) in PL imaging, where the SR is dictated by the carrier DL rather than by the optical diffraction limit. Raman imaging of the LO phonon-plasmon (LOPP) coupled mode can be used to recover the intrinsic SR of the optical system [1], as demonstrated by Raman imaging of dislocation defects in GaAs, achieving a 10-fold improvement in SR. Furthermore, by combining Raman and PL imaging near a dislocation defect, we can independently determine the electron and hole spatial profile, radiative and nonradiative recombination rate, which has not been possible using other techniques. We find that in GaAs the dislocation defect tends to behavior as a hope trap: the defect only depletes the electrons in a short range, whereas the impact range of the defect is much larger in PL imaging. The mismatch in the electron and hole distribution implies the formation of a polarization field near the defect. The imbalance between the two charge distributions suggests the diffusion is non-ambipolar. [1] Hu et al., Light: Sci. & Appl. 7, 23 (2018).

Monday, March 4, 2019 11:15 AM - 2:15 PM
11:15AM B12.00001: Reconfigurable Carbon Nanotube Network Devices

PRATHAMESH DHAKRAS (Presenter), SAMUEL LAGASSE, Colleges of Nanoscale Science and Engineering, State University of New York Polytechnic Institute, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, SHENG WANG, LIAN-MAO PENG, Key Laboratory for the Physics and Chemistry of Nanodevices and Department of Electronics, Peking University, JI UNG LEE, Colleges of Nanoscale Science and Engineering, State University of New York Polytechnic Institute — Semiconducting single-walled carbon nanotubes (SWNTs) are an attractive channel material for a wide range of applications, from flexible, low cost printed electronics to high performance field effect transistors. Though recent advances in developing high purity semiconducting SWNT solutions have yielded devices with excellent on/off ratios and improved ON currents, determining the true nature of conduction of a network with a mixture of metallic and semiconducting nanotubes remains a challenge. Here, we fabricated split-gate devices that can reconfigure as either a metal-oxide-semiconductor field effect transistor (MOSFET) or a p-n diode. The spacing between the split gates was varied from 10 μm down to 100 nm to allow a detailed comparison between properties of unipolar conduction (MOSFET) and that of ambipolar transport dominated by minority carriers (p-n Diode). In addition, we varied the metallic concentration of SWNTs in the network channel. We show that the conduction is determined not only by the metallic concentration, but also by the environment that acts as strong generation and recombination centers.

XUAN WANG, Beijing National Laboratory for Condensed Matter Physics, WEILU GAO, XINWEI LI, QI ZHANG, Electrical Engineering, Rice University, SÉBASTIAN NANOYT, Laboratoire Charles Coulomb, Université de Montpellier, ERIK H HAROZ, Explosive Sciences and Shock Physics Division, Los Alamos National Laboratory, JUNICHIRO KONO, Electrical Engineering, Rice University, WILLIAM RICE (Presenter), Physics and Astronomy, University of Wyoming — Single-wall carbon nanotubes (SWCNTs) exhibit a wide range of chirality-dependent physical phenomena. This dependency complicates in-depth understanding of ensemble behavior, since nanotube networks contain numerous chiralities. In particular, electronic-type mixing greatly hinders the development of a comprehensive picture of SWCNT ensemble electrical transport. Here, we systematically study temperature-dependent magnetoconductivity (MC) in semiconductor and metal SWCNTs. In the semiconductor-enriched network, we observe 2D variable-range hopping conduction from 5 to 290 K. Low-temperature MC reveals a large, negative MC from which we determine the wavefunction localization length and Fermi energy density of states. In contrast, the metal-enriched film shows positive MC that increases with decreasing temperature, a behavior we attribute to 2D weak localization. Using this model, we determine carrier phase coherence and describe the temperature-dependent conductivity. These extensive transport measurements on type-enriched SWCNTs provide insights, which pave the way for nanotube solid-state devices.

MITCHELL J. SENGTER (Presenter), DANIEL MCCULLEY, LEE ASPITARTE, Physics, Oregon State University, NEDA LOTFIZHAD, VIKRAM DESHPANDE, Department of Physics and Astronomy, University of Utah, ETHAN D. MINOT, Physics, Oregon State University — Metallic carbon nanotubes (m-CNTs) exhibit a remarkably large energy gap for electronic excitations. The gap often exceeds 100 meV when the m-CNT is suspended in free space, but the gap disappears when the m-CNT lies on a metal surface. The theoretical description of this gap remains controversial and more experiments are needed. We have built ultra-clean suspended CNT devices from CNTs of known diameter and chiral angle. The CNT chirality is identified with spectrally resolved scanning photocurrent microscopy and the energy gap is determined by measuring thermally-activated electron transport. Our results show that the gap scales exactly as 1/D, with no dependence on chiral angle. We also demonstrate that the gap can be tuned by submerging the suspended m-CNT in dielectric liquids. Our results put new constraints on competing theoretical descriptions of a Mott insulator state versus an excitonic insulator state.

11:51 AM B12.00004: Field-Enhanced Exciton Dissociation in Carbon Nanotube Photodiodes* DANIEL MCCULLEY (Presenter), MITCHELL J. SENGERT, Oregon State University, ANDREA BERTONI, CNR Nano, ETHAN D. MINOT, Oregon State University — Low-dimensional materials may be useful for building solar cells that harness carrier multiplication and circumvent the Shockley-Queisser limit. For example, quantum dot solar cells with an internal quantum efficiency (IQE) > 100% have been reported. In this work, we search for carrier multiplication effects in CNTs. We use individually-contacted, ultra-clean, suspended, semiconducting carbon nanotubes of known chiral index. Previous work on this system showed an IQE ~ 30% when the built-in electric field was ~ 4 V/μm. Here we report an IQE ~ 80% when the electric field is increased to ~ 15 V/μm. At these high fields, photocurrent spectroscopy reveals extreme broadening of low-energy exciton peaks. We compare our results to theoretical predictions for field-induced exciton dissociation in CNTs, and develop a framework to describe the energy dissipation pathways.

*This work is funded by NSF grant 1709800.

12:03 PM B12.00005: Tip-enhanced Raman spectroscopy of CNTs in a picocavity KAI NAN (Presenter), SHARAD AMBARDAR, DMITRI VORONINE, Physics department, University of South Florida — Carbon nanotubes (CNTs) have optical and electronic properties which allow promising applications. Conventional atomic force microscopy (AFM) and tip-enhanced Raman scattering (TERS) provide topographic and chemically specific images that reveal nanoscale structure-functional relationships. By placing CNTs in a picocavity formed by a plasmonic scanning probe tip and a metallic surface we control the relative intensities of various CNT signals. We investigate the tip-sample distance dependence in the nanometer classical and sub-nanometer quantum plasmonic regimes. This quantum picophotonics approach provides a new platform for exploration of enhanced properties of low dimensional materials.

12:15 PM B12.00006: Exciton Relaxation in Carbon Nanotubes via Electronic-to-Vibrational Energy Transfer* KIRILL VELIZHANIN (Presenter), Los Alamos National Laboratory — Covalent functionalization of semiconducting single-wall carbon nanotubes (SWCNTs) can introduce new localized photoluminescent states that are strongly red-shifted from the emission commonly observed from the nanotube band-edge E_{11} exciton state. In addition to being the source of new photophysical behaviors, these states are drawing significant interest as the basis for emerging functionality. A particularly important feature of such exciton localization at defect sites is that, because the exciton is no longer free to diffusively sample photoluminescent quenching sites along the length of the SWCNT, its lifetime is significantly extended. We have recently demonstrated that an important recombination channel of such localized excitons is the electronic-to-vibrational energy transfer (EVET). This process is analogous to the Förster resonance energy transfer (FRET) except for the final state of this process is not electronically, but vibrationally excited molecules of the medium (e.g., solvent). In this talk we will discuss the basic physics of EVET and then proceed to estimating the EVET rate for a localized exciton in the SWCNT.

12:27 PM B12.00007: Binding Energy and Lifetime of Excitons in Metallic Nanotubes* LEI SHAN, MEGHA AGARWAL (Presenter), EUGENE MISHCHENKO, University of Utah — Due to the large screening of Coulomb interaction between electrons in higher dimensions in metallic materials, a bound state of electron-hole pair cannot be formed. However, in lower dimensional materials such as carbon nanotubes due to less effective screening of electrons allows the formation of bound state of electron-hole pair whose radius, R_{ex} ~ R. This is particularly unique to metallic nanotubes in a sense that the problem of describing excitons can now be considered 1D as compared to semiconducting nanotubes where exciton radius R_{ex} ~ R and excitons are neither 1D nor 2D. We are thus able to determine the binding energy of excitons in metallic nanotubes, is about 0.08 v/R. Additionally, because of the presence of the gapless subbands, there are processes where bound excitons are scattered into unbound electron-hole pairs belonging to the gapless subbands. Such processes lead to a finite exciton lifetime and the broadening of its spectral function. We calculate the corresponding decay rate of the excitons.

*This work was supported by DOE, Office of Basic Energy Sciences, Grant No. DE-FG02-06ER46313.
12:39PM B12.00008: Organic molecule adsorption effects on air-suspended carbon nanotubes* SHUNSUKE TANAKA (Presenter), AKIHIRO ISHII, YUICHIRO K. KATO, RIKEN — Environmental screening effects are large in carbon nanotubes due to their atomically thin nature, and therefore it is possible to control the optical properties with molecular adsorption [1,2]. Here, we investigate adsorption effects of copper phthalocyanine molecules on excitons and trions in air-suspended carbon nanotubes. By averaging the photoluminescence excitation spectra for tubes with the same chiralities, we observe that the exciton emission energy redshifts gradually with molecular deposition thickness. The trion emission is also observed at large deposition amounts, which could be due to charge transfer between the phthalocyanine molecules and carbon nanotubes. Analyzing the spectra for individual tubes, we find a good correlation between the exciton-trion energy separation and the exciton emission energy.

*Work supported in part by RIKEN (Incentive Research Projects), JSPS (KAKENHI JP16H05962), and MEXT (Nanotechnology Platform). We thank K. Kimura, H. Imada, and Y. Kim for the thermal evaporator. We acknowledge the Advanced Manufacturing Support Team at RIKEN for technical assistance.

12:51PM B12.00009: Interlayer interactions and radial breathing mode in double- and triple-walled carbon nanotube bundles JIA WERN HUE (Presenter), Department of Physics and Astronomy, The University of Alabama, Tuscaloosa, Alabama 35487, USA, THOMAS CH HIRSCHMANN, Attocube Systems AG, Königstraße 11a, 80539 Munich, Germany, STEPHEN K. DOORN, Center for Integrated Nanotechnologies, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, YOONG AHM KIM, School of Polymer Science and Engineering, Chonnam National University, 77 Yongbong-ro, Buk-gu, Gwangju, 61186, Republic of Korea, NEWTON M BARBOSA NETO, Instituto de Ciências Exatas e Naturais – Programa de Pós-graduação em Física, Universidade Federal do Pará, Belém PA 66075-110, Brazil, PAULO T ARAUJO, Department of Physics and Astronomy, The University of Alabama, Tuscaloosa, Alabama 35487, USA — A double-walled carbon nanotube (DWNT) can be considered a inner single-walled carbon nanotube (SWNT) protected by an outer SWNT. Likewise, a triple-walled carbon nanotube (TWNT) can considered an inner DWNT encapsulated by an outer SWNT. The signature in resonant Raman spectroscopy for carbon nanotubes is the radial breathing mode (RBM). For radial breathing modes (RBM), double- and triple-walled carbon nanotubes can be considered as coupled oscillators. The RBM frequency, $\omega_{\text{RBM}}$, is sensitive to environmental factors and interlayer interactions. For interlayer interactions, it is necessary to take into account curvature effects, particularly for smaller tubes, whether the constituent tubes are commensurate, and whether the inner tubes are really isolated from the environment from the outer tubes. Another matter of interest is how do the magnitudes of the interlayer interactions compare. Resonant Raman spectra of a DWNT bundle and TWNT bundle were taken. From those spectra, chiral indices were assigned and tube diameters calculated. Then, a comparison to the SWNT $\omega_{\text{RBM}}$ was made and the questions presented above answered.

1:03PM B12.00010: Energy barrier for carbon nanotube collapse RODRIGO CAPAZ (Presenter), RAFAEL RODRIGUES DEL GRANDE, Federal University of Rio de Janeiro, Brazil, ALEXANDRE FONSECA, Unicamp, Brazil — Small-diameter carbon nanotubes have circular cross section shapes, but the ground state of large diameter tubes correspond to a collapsed structure, stabilized by the van der Waals attraction of opposite sides of the nanotube wall. For those tubes, the circular cross section shape is metastable and it is interesting to investigate the energy barrier for jumping from one configuration to another. Previous theoretical works calculate the energy barrier by considering a transition pathway in which the nanotube collapses uniformly along its length, normally using periodic boundary conditions along the nanotube axis. This assumption is unphysical since it would give an infinite barrier for a nanotube of infinite length. In this work, we calculate the true energy barrier for carbon nanotube collapse by considering a transition pathway that consists of a local deformation that propagates itself along the carbon nanotube axis. This leads to finite and physically meaningful energy barriers in the limit of infinite nanotubes. For typical nanotube diameters, the energy barriers are so large that effectively prevent the collapse induced by temperature of an infinite nanotube. We also perform classical molecular dynamics that confirm these results.
Snap-Through Buckling Bi-Stability in Suspended Carbon Nanotube Resonators

Mechanical bi-stability based on snap-through (ST) buckling is a well-known phenomenon in micro-electromechanical systems (MEMS) which serves as the underlying mechanism for many practical applications such as switches, actuators, sensors, filters, and memory elements, to name a few.

Here, we report the first realization of a suspended carbon nanotube (CNT) based bi-stable resonators exhibiting ST buckling phenomena. Both the static and dynamic responses of the system were obtained through conductance and resonance frequency measurements, respectively. In both measurements, non-linear effects such as jumps, hysteresis, softening and hardening, and super and sub-harmonic excitations were observed.

Apart from these resonators being the smallest bi-stable electromechanical system based on ST buckling to date, our devices could also serve as excellent sensors with ultrahigh sensitivities, reaching electrostatic tunability values beyond 100MHz/V, which are also attractive for realization of mechanical quantum-bits.

Finally, we developed a comprehensive theoretical model based on the Euler-Bernoulli beam equation to support our findings.

Solution Sorting of 10 µm Long Single-Walled Carbon Nanotubes

Single-walled carbon nanotubes (SWCNTs) that are ultralong (>10 µm) and electronically pure may enable stretchable thin film transistors, ballistic conductors, and ultra-strong fibers. However, nanotubes are cut to short pieces (typically less than 1 µm) by sonication during solution processing. In this presentation, I will discuss an invention from our lab called “superacid-surfactant exchange (S2E)” which allows for non-destructive dispersion and scalable sorting of ultralong SWCNTs in aqueous solutions. The length of the isolated SWCNTs readily reaches 10 µm, with a narrow distribution. We further show that these ultralong nanotubes can be further sorted by electronic type to attain an electron mobility exceeding 90 cm² V⁻¹ s⁻¹ in fabricated thin film transistors.

Synthesis and Characterization of Single Walled Carbon Nanotubes (SWNT) Through Direct Decomposition Ferrocene

Carbon-based nanostructures, specifically carbon nanotubes due to their unique surface adsorption properties can become the choice materials for several applications. Here we present our results on synthesis and characterization of single walled carbon nanotubes (SWNT) through direct decomposition of metallocene. Specifically, ferrocene was utilized in this study. The effect of growth conditions on physical properties of these SWNT materials were studied in detail through volumetric gas adsorption measurements, Raman spectroscopic characterization as well as UV-Vis spectroscopy measurements. The correlation of some of the physical properties as it related to the growth conditions will be discussed in light of these characterization results.

Measuring the Electron Beam Induced Plasmon Response in Single-Walled Carbon Nanotube Devices

In this work, we examine the transport properties of individual single-walled carbon nanotubes, configured with split gates, as it is excited by a finely focused electron beam. We conduct the experiment in a scanning electron microscope (SEM) equipped with multiple nanopores. We measure the current from both ends of the nanotube as the electron beam is rastered to determine the mechanism of transport. Our analysis shows that the energetic beam launches plasmon excitations along the nanotube, which we measure as a sharp change in the current. The sign of the current on both ends of the nanotube is the same, which rules out other competing mechanisms, including electron-hole generation and thermal effects. We examine the transport properties as a function of beam energy and position, and nanotube doping.
Intrinsically Ultrastrong Plasmon-Exciton Interactions in Crystallized Films of Carbon Nanotubes

ABRAM FALK (Presenter), PO-HSUN HO, DAMON FARMER, PHAEDON AVOURIS, IBM Thomas J. Watson Research Center — We show that carbon nanotubes can be crystallized into chip-scale, two-dimensionally ordered films and that this new material enables intrinsically ultrastrong emitter-cavity interactions: rather than interacting with external cavities, nanotube excitons couple to the near-infrared plasmon resonances of the nanotubes themselves [1]. Our polycrystalline nanotube films have a hexagonal crystal structure, ~25 nm domains, and a 1.74 nm lattice constant. With this extremely high nanotube density and nearly ideal plasmon-exciton spatial overlap, plasmon-exciton coupling strengths reach 0.5 eV, which is 75% of the bare exciton energy and a near record for room-temperature ultrastrong coupling. Crystallized nanotube films provide a compelling foundation for high-ampacity conductors, low-power optical switches, and tunable optical antennas.

Session B13 DMP: Materials (General) -- Modeling and Characterization

Model of the piezoelectric coefficient of hexagonal two-dimensional materials

LOK LEW YAN VOON (Presenter), University of West Georgia, MORTEN WILLATZEN, ZHONG-LIN WANG, Beijing Institute of Nanoenergy and Nanosystems — A quantum-mechanical microscopic model of the piezoelectric effect in two-dimensional materials is developed. The piezoelectric coefficient requires the calculation of an internal atomic displacement and an effective piezoelectric charge. The internal displacement is obtained from minimizing the strain energy given by a Keating-like model, while the effective charge takes into account the atomic displacements and also a redistribution of the electronic charge; a bond-orbital model is used to compute the latter. The final theory only requires atomic energies and the elasticity constants of the materials as input parameters. The piezoelectric coefficients of a number of II-V, III-V and IV-IV materials that could stably form in the planar hexagonal structure are computed; results for the IV-IV materials are obtained for the first time.

Nucleation Kinetics of Structural Phase Changes in Two-Dimensional Transition Metal Dichalcogenides

ADITI KRISHNAPRIYAN (Presenter), QIAN YANG, YAO ZHOU, Stanford University, EKIN D CUBUK, Google Brain, EVAN REED, Stanford University — Predictive capabilities for kinetic processes in materials are in their infancy, but kinetics are critical for a spectrum of energy applications ranging from phase change materials, catalysis, materials synthesis, and combustion. The structural phase transition between the metallic 1T or 1T' and semiconducting 2H structures in two-dimensional transition metal dichalcogenide materials is important to understand for synthesis and may provide exciting new opportunities for energy-efficient electronic and optical devices. However, very little is known about the mechanisms and kinetics of these phase changes or how to engineer the kinetics. We propose a novel electronic structure based method to determine the nucleation kinetics and timescales of this phase change. Furthermore, we discuss the curious fact that the interface energies between phases for this challenging problem are mathematically ill-defined. We also point to strategies on the engineering of kinetics in these phase change materials that take into account nucleation barriers and nucleation time.

11:39 AM B13.00003: Effective k.p models for phosphorene including the interband spin-orbit coupling* PAULO DE FARIA JR. (Presenter), University of Regensburg, MARCIN KURPAS, University of Silesia, MARTIN GMITRA, P. J. Safarik Univ. in Kosice, JAROSLAV FABIAN, University of Regensburg — Phosphorene is a two-dimensional semiconductor with direct band gap and promising spin-dependent properties[1,2]. In this study, we investigate effective k.p models for phosphorene including the interband spin-orbit coupling[3], a term previously overlooked in the literature. The inclusion of such interband spin-orbit coupling provides a reliable description of the anisotropic dipole transition and of the effective g-factors. We also investigate excitonic effects and found very good agreement with reported results in the literature. To obtain reliable k.p parameters we use a robust fitting approach that takes into account not only the band structure but also the k-dependence of the effective mass. With the increasing interest in two-dimensional systems, our effective k.p Hamiltonians can be combined with other already available models to investigate novel physical phenomena in van der Waals heterostructures. 11:51 AM B13.00004: Spin-orbit-torque magnetic manipulation with 2D materials* [Invited] DANIEL RALPH (Presenter), Cornell University — Current-induced spin-orbit torques provide a promising strategy for efficient manipulation of nonvolatile magnetic memory and logic technologies. For best performance, both the layer of material that provides the spin-orbit torque and the magnetic layer being manipulated should be as thin as possible. Here we discuss experiments which probe the ultimate limits in which 2D materials are used for either the spin-orbit layer or the magnetic layer. We will also discuss initial experiments in which recently-discovered 2D magnetic materials are integrated with spin-orbit materials. Using mechanically exfoliated thin flakes of the insulating 2D ferromagnet Cr₂Ge₂Te₆ combined into a bilayer structure with tantalum, we have observed current-induced deflections of the out-of-plane magnetic moment of Cr₂Ge₂Te₆ and characterized the strength of the spin-orbit torque.

*This work was performed with G. M. Stiehl, V. Gupta, M. H. D. Guimaraes, D. MacNeill, N. D. Reynolds, R. Li, S. Karimeddiny, J. Mittelstaedt, N. Sivadas, I. El Baggari, L. F. Kourkoutis, C. Fennie, J. Park, and R. A. Buhrman, with support from DOE and SRC/DARPA.

12:27 PM B13.00005: Strain-induced structural phase transformation in two-dimensional molydenum tungsten diselenide alloy* AMEY ANANT APTE (Presenter), VIDYA KOCHAT, Materials Science & NanoEngineering, Rice University, PANKAJ RAJAK, ARAVIND KRISHNAMOORTHY, Physics & Astronomy, University of Southern California, PRAVEENA MANIMUNDA, Bruker Nano Surfaces, JORDAN HACHTEL, JUAN IDROBO, Center for Nanophase Materials Science, Oak Ridge National Laboratory, SYED ASIF AMANULLA, Bruker Nano Surfaces, PRIYA VASHISHTA, AIICHIRO NAKANO, RAJIV KALIA, Physics & Astronomy, University of Southern California, CHANDRA SEKHAR TIWARY, PULICKEL M AJAYAN, Materials Science & NanoEngineering, Rice University — Two-dimensional transition metal dichalcogenides (TMDs) show intriguing mechanical properties compared to their bulk counterparts. This behavior can be modified in alloyed TMDCs due to doping and defects. In this work we develop CVD synthesis of large-area monolayer MoWSe₂ alloy film on sapphire substrate. With Raman spectroscopy and mapping, we investigate the microscopic behavior of this alloy film transferred onto a flexible substrate as function of increasing bending strain. We observe the nature of crack propagation through the Mo and W-dominated regions in this 2D alloy film with differing stress concentration near the W-rich precipitates. Our molecular dynamics simulations illustrate how stress buildup at propagating crack tip in the film result in a 2H-1T phase transformation which is verified at micro- and nanoscale using Raman mapping and HAADF-STEM imaging. The MD simulations also predict increased crack resistance and healing in alloys compared to unalloyed pristine samples.

*This work was supported as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy (DoE), Office of Science, Basic Energy Sciences, under award number DE-SC00014607 and authored by UT-Battelle, LLC under contract no. DE-AC05-00OR22725 with the U.S. DoE.
12:39PM B13.00006: Quantum plasmonic imaging of 2D transition metal dichalcogenides  ALINA ZHUKOVA  
(Presenter), DMITRI VORONINE, University of South Florida —
Two-dimensional (2D) transition metal dichalcogenides (TMDs) are of particular interest due to their unique optoelectronic properties. Nano-optical imaging techniques such as tip-enhanced Raman spectroscopy (TERS) and tip-enhanced photoluminescence (TEPL) are useful tools for investigating the nanoscale properties of materials below the diffraction limit. We investigated the topography and optical properties of monolayer TMDs using atomic force microscopy (AFM), TERS, and TEPL. Near-field TEPL and TERS signals have been found to be successful in identifying distinct crystalline boundaries with higher spatial resolution compared to far-field imaging. Subwavelength optical characterization techniques are necessary to study nanoscale phenomena such as the lateral heterojunctions of 2D materials. We also performed tip-sample distance dependence experiments and observed quantum plasmonic effects. Specifically, manipulating the plasmonic tip location results in nano-optical imaging capabilities and plasmon-induced hot-electron injection. As a result, there is significant potential for applying quantum plasmonic effects to nanodevices with tunable photoresponse.

12:51PM B13.00007: Missing links towards understanding equilibrium shapes of hexagonal boron nitride: algorithm, hydrogen passivation, and temperature effects*  JINGZHAO ZHANG, WENJING ZHAO (Presenter), JUNYI ZHU, Physics, The Chinese University of HongKong — There is a large discrepancy between the experimental observations and the theoretical predictions in the morphology of hexagonal boron nitride (h-BN) nanosheets. Theoretically-predicted hexagons terminated by armchair edges are not observed in experiments; and experimentally-observed triangles terminated by zigzag edges are found theoretically unstable. There are two key issues in theoretical investigations, namely, an efficient and accurate algorithm of absolute formation energy of h-BN edges, and a good understanding of the role of hydrogen passivation during h-BN growth. Here, we first proposed an efficient algorithm to calculate asymmetric edges with a self-consistent accuracy of about 0.0014 eV/Å. This method can also potentially serve as a standard approach for other two-dimensional (2D) compound materials. Based on this algorithm, we constructed Wulff plot and discovered that only when edges are passivated by hydrogen atoms and temperature effects are taken into account can experimental morphology be explained.  
*This work was supported by the start-up funding, HKRGC funding with the Project Code of 14319416, and direct grants with the Project Codes of 4053233, 4053134, and 3132748, at CUHK.

1:03PM B13.00008: Plasmon excitations in trilayer AAB-stacked graphene  GODFREY GUMBS (Presenter), Physics Department, Hunter College/CUNY, CHIUN-YAN LIN, BOR-LUEN HUANG, MING-FA LIN, Physics Department, National Cheng Kung University — We report on the fascinating electronic properties and distinct plasma excitations for low-symmetry trilayer AAB-stacked graphene. For the undoped structure, there are three pairs of unusual valence and conduction subbands which give rise to nine allowed interband excitations, for which the imaginary (real) part of the polarizability exhibits 1D square root asymmetric peaks and 2D shoulder structures (pairs of antisymmetric peaks and logarithm type symmetric peaks). The low frequency acoustic plasmon, appearing as a prominent peak in the energy loss spectrum, can survive in a narrow gap system with large density-of-states from the valence band. This type of plasmon mode is similar to that in a narrow gap carbon nanotube. The mechanism responsible for this plasmon is the intraband conduction state excitations. Its frequency, intensity and critical momentum exhibit a non-monotonic dependence on the Fermi energy.

1:15PM B13.00009: Correlated SPM–TERS Imaging: Revealing Unexpected Nanoscale Heterogeneities in 2D Semiconductors.  ANDREY KRAYEV (Presenter), HORIBA Scientific — Here I report on the application of scanning probe microscopy (SPM) cross-correlated with tip enhanced Raman scattering (TERS) and photoluminescence (TEPL) imaging for detection of unexpected heterogeneities in TMDs. I'll demonstrate that few-layer flakes of WSe₂ exfoliated to gold or silver may possess doping heterogeneity with domains within 30-300nm range. These domains identified by Kelvin probe imaging showed different TERS response and generated photocurrent of opposite polarity. I'll further discuss how scanning capacitance microscopy can identify the grain boundaries (GB) in CVD-grown MoSe₂ crystals, while TERS characterization of such crystals transferred to gold reveals possible etching of MoSe₂ along GB during the transfer, an effect beneficial for photocatalytic activity. 3-rd example of the use of cross-correlated SPM and TERS/TEPL imaging of 2D semiconductors is a discovery of the nature of strong PL of WS₂ and WSe₂ transferred to gold via heat-assisted exfoliation. Through TERS/TEPL it was identified that PL is coming from nanoscale bubbles formed in TMD layers. Exciton funnelling towards the bubbles was also discovered, which resulted in strong enhancement of Raman/PL response from the bubbles, and in significant suppression of TERS/TEPL signal in adjacent area.
1:27PM B13.00010: Real-Space Mapping of Polaritons in 2D Materials  
TOBIAS GOKUS (Presenter), STEFAN MASTEL, ALEXANDER GOVYADINOV, Applications, neaspec GmbH — The performance of the next-generation electronic devices based on graphene and other 2D materials is strongly influenced by the structure-function relationship. Scattering-type scanning near-field optical microscopy (s-SNOM) is the ideal technology to investigate such material systems at the nanoscale. s-SNOM combines the best of two worlds: (i) the high spatial resolution of Atomic Force Microscopy (AFM) and (ii) the analytical power of optical microscopy and spectroscopy. Achieving an unmatched spatial resolution below 10 nanometer this technology opens a new era for modern nano-analytical applications such as chemical identification, free-carrier profiling and plasmonic near-field mapping. Recent research highlights on graphene and other 2D materials include contact-free access to the local conductivity, the electron mobility, and the intrinsic electron doping by resolving propagating phonon-, plasmon-, and exciton-polariton directly in space and time. In this presentation we will introduce the basic principles of near-field microscopy for imaging and spectroscopy with 10 nanometer spatial resolution and address their impact and key applications in the field of 2D materials.

1:39PM B13.00011: Real time optical observation and control of transition metal dichalcogenide synthesis*  
TALIP KASIRGA (Presenter), HAMID REZA RASOULI, NAVEED MEHMOOD, ONUR ÇAKIROĞLU, Materials Science and Nanotechnology, Bilkent University — Synthesis of atomically thin transition metal dichalcogenide (TMC) crystals have attracted tremendous amount of attention in the past few years. The common technique for the synthesis is to use a tubular split furnace with gas and exhaust connections. The precursors and the target substrate are placed in the hot zone of the furnace. The major shortcoming of the setup is the inaccessibility of the growth for real time characterizations. Thus, the growth has to be shut down blindly and the intermediate products that may lead to the growth has to be analysed later. Here, we developed a compact CVD chamber that allows real time optical observation of the crystal synthesis. Among our findings, for the first time we observed the formation of the atomically thin TMCs in real time, and characterized the various synthesis routes for several TMCs. By using the unique abilities we have with our chamber, we also observed the formation of the heterostructures. Furthermore, we demonstrated a directed synthesis of TMCs with prepatterned structures on a substrate.

*This work is supported by TUBITAK under Grant no:116M224

1:51PM B13.00012: Oxidation effect on WTe2 using optical second harmonic generation*  
YUJIN CHO (Presenter), University of Texas at Austin, NA HYUN JO, PAUL CANFIELD, Iowa State University, MICHAEL C DOWNER, University of Texas at Austin — A transition metal dichalcogenide WTe2 has recently drawn many researchers' attention because this material is Type-II Weyl semimetal in bulk and it is a topological insulator in a monolayer at low temperature. This material is known to be particularly sensitive to oxidation, which could alter its electronic and mechanical properties. Optical Second Harmonic Generation (SHG) microscopy is a good way to probe the small change at the surface due to its hypersensitivity to the structural changes. We used Ti:Sapphire laser, with 76 MHz repetition rate and 150 fs pulse, to see the oxidation effect on the rotational anisotropic SHG at a discrete oxidation level. We found out that the oxidation greatly affects SHG intensities in s-in/s-out polarization configuration. In this talk, I will be presenting a systematic study of oxidation effect on the bulk WTe2 as well as its spectroscopic response.

Visualization of Photo-carrier Diffusion in Monolayer Transition Metal Dichalcogenides

ZHAODONG CHU (Presenter), JIAMIN QUAN, CHUN YUAN WANG, DAVID WANNLUND, Department of Physics, The University of Texas at Austin, ALI HAN, Physical Sciences and Engineering Division, King Abdullah University of Science and Technology, KEVIN HERRERA, DI WU, Department of Physics, The University of Texas at Austin, LAIN-JONG LI, Physical Sciences and Engineering Division, King Abdullah University of Science and Technology, CHIH-KANG SHIH, XIAOQIN (ELAINE) LI, KEJI LAI, Department of Physics, The University of Texas at Austin — Understanding of the spatial and temporal evolution of photo-generated charge carriers in atomically thin transition metal dichalcogenides (TMDs) is of critical importance for their application in optoelectronic devices. Using a light-assisted microwave impedance microscope (MIM), we demonstrate the first quantitative mapping of photo-carrier diffusion on monolayer TMDs. When the sample is illuminated by above-gap laser, the circular profile of local photoconductivity measured by the MIM is clearly broader than that of the laser spot. Numerical simulation shows that the free-carrier diffusion length of is on the order of micrometers, corresponding to a carrier lifetime of tens to hundreds of nanoseconds. Our work provides important insights to the remarkable electrical and optical properties of TMDs.

Session B14 DCMP: 2D Materials (Metals, Superconductors, and Correlated Materials) -- Magnetism BCEC 153C - Andrew May, Oak Ridge National Laboratory - Tag(s): Focus

11:15AM B14.00001: Magnetism in two dimensions [Invited] XIAODONG XU (Presenter), University of Washington — Selected by the organization chairs Kin Fai Mak and Cory Dean.

11:51AM B14.00002: Gate-tunable Room-temperature Ferromagnetism in Two-dimensional Fe₃GeTe₂ YUJUN DENG (Presenter), YIJUN YU, YICHEN SONG, Fudan University, JINGZHAO ZHANG, The Chinese University of Hong Kong, NAI ZHOU WANG, University of Science and Technology of China, ZEYUAN SUN, YANGFAN YI, YI ZHENG WU, Fudan University, JUNYI ZHU, The Chinese University of Hong Kong, JING WANG, Fudan University, XIANHUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Fudan University — The advent of two-dimensional van der Waals crystals creates new possibilities in developing novel spintronic devices. Recent experiments have demonstrated that it is possible to obtain two-dimensional ferromagnetic order in insulating Cr₂Ge₂Te₆ and CrI₃ at low temperatures. Here, we developed a new device fabrication technique, and successfully isolated monolayers from layered metallic magnet Fe₃GeTe₂. We found that the itinerant ferromagnetism persists in Fe₃GeTe₂ down to monolayer. The ferromagnetic transition temperature, T_c, is suppressed in pristine Fe₃GeTe₂ thin flakes. An ionic gate, however, dramatically raises the T_c up to room temperature. The gate-tunable room-temperature ferromagnetism in two-dimensional Fe₃GeTe₂ opens up opportunities for potential voltage-controlled magnetoelectronics.

12:03PM B14.00003: Magnetic properties of vanadium selenide epitaxial thin films* MASAKI NAKANO (Presenter), SATOSHI YOSHIDA, SAEED BAHRAMY, YUE WANG, HIDEKI MATSUOKA, YUKI MAJIMA, Department of Applied Physics, The University of Tokyo, YOSHIMITSU KOHAMA, The Institute for Solid State Physics, The University of Tokyo, YUTA OHIGASHI, YUTA KASHIWABARA, MASATO SAKANO, KIYOKO IISHIZAKA, YOSHIHIRO IWASA, Department of Applied Physics, The University of Tokyo — The discoveries of ferromagnetism in atomically-thin Cr₂Ge₂Te₆ and CrI₃ have opened up an opportunity for integration of magnetic 2D materials into van der Waals heterostructures. Moreover, the recent discovery of emergent room-temperature ferromagnetism in monolayer VSe₂ [1], which has been known as a paramagnetic metal in its bulk form, should provide an important step toward spintronics applications based on 2D materials, although the existence of ferromagnetism in monolayer VSe₂ is still controversial [2]. We have recently found that vanadium selenide epitaxial thin films fabricated by molecular-beam epitaxy (MBE) with our growth recipe [3] exhibit peculiar magnetic properties with clear anomalous Hall effect down to 2D limit. In this presentation, we will show transport properties of our MBE-grown vanadium selenide epitaxial thin films, and discuss possible origins of this emergent ferromagnetism in our samples. [1] M. Bonilla, et. al., Nat. Nanotechnol. 13, 289 (2018). [2] J. Feng, et. al., Nano Lett. 18, 4493 (2018). [3] M. Nakano, et. al., Nano Lett. 17, 5595 (2017).

12:15PM B14.00004: Gate-controlled charge-doping of a Mott insulator in Graphene/α-RuCl₃ Heterostructures*

BOYI ZHOU (Presenter), JESSE BALGLEY, Washington University, St. Louis, PAULA J KELLEY, DAVID GEORGE MANDRUS, Oak Ridge National Laboratory, ERIK HENRIKSEN, Washington University, St. Louis — The layered antiferromagnetic Mott insulator α-RuCl₃ exhibits many phenomena consistent with the existence of a Kitaev quantum spin liquid. While most works on α-RuCl₃ so far have focused on pristine bulk samples, this material can be readily exfoliated down to monolayer thicknesses. Here we study the electronic transport of van der Waals heterostructure devices containing thin α-RuCl₃ flakes in contact with monolayer graphene Hall bars. We find an anomalously large conductivity implying the RuCl₃ has become charge-doped and is now conducting. The Hall coefficient data show a sharp increase in the density of the second conducting band (in the α-RuCl₃) as graphene is gated from hole- to electron-doped. Additionally, the resistivity at low temperature shows clear signals associated with magnetic phase transitions at temperatures 2-3 times higher than the native antiferromagnetic transition in α-RuCl₃.

*We acknowledge support from the Institute of Materials Science and Engineering at Washington University in St. Louis. A portion of this work was supported under NSF DMR-1810305.

12:27PM B14.00005: Ab initio mismatched interface theory of graphene on α-RuCl₃: doping and magnetism* ELI GERBER (Presenter), YUAN YAO, TOMAS ARIAS, EUN-AH KIM, Cornell University — The possibilities for creating van der Waals heterostructures are limitless with the rich palette including Mott insulating α-RuCl₃ and semi-metallic graphene. However, the study of such “mismatched interfaces” calls for an innovative way of capturing the underlying physics of these complex systems, that goes beyond standard ab initio methods. We propose a general strategy for studying such interfaces, “mismatched interface theory,” and apply it to a α-RuCl₃-graphene heterostructure in which there is significant lattice mismatch between the two crystals. Our results indicate charge transfer from graphene to the Ru layer in α-RuCl₃ directly proportional to the number of carbon atoms present in the system, corresponding to uniform doping of 4.7% in the α-RuCl₃-graphene heterostructure. We further demonstrate that this doping may be tuned by applying uniaxial pressure to the heterostructure, and investigate the effects of the doping on the zigzag- and ferromagnetic-ordered low-energy stable states of α-RuCl₃ which lie close to the antiferromagnetic Kitaev spin liquid.

*The authors acknowledge support through the NSF MRSEC program (DMR-1719875) and the Materials Innovation Platform grant DMR-1539918.

12:39PM B14.00006: Crystal Structure Reconstruction on Surface of Quantum Spin Liquid Candidate: α-RuCl₃ * ZHONGWEI DAI (Presenter), Center for Functional Nanomaterials, Brookhaven National Lab, JIE-XIANG YU, Department of Physics, University of New Hampshire, BOYI ZHOU, Department of Physics, Washington University in St. Louis, SAMUEL TENNEY, Center for Functional Nanomaterials, Brookhaven National Lab, PAIGE LAMPEN-KELLEY, Materials Science and Technology Division, Oak Ridge National Laboratory, DAVID GEORGE MANDRUS, Department of Material Science and Engineering, University of Tennessee, ERIK HENRIKSEN, Department of Physics, Washington University in St. Louis, JERZY T. SADOWSKI, Center for Functional Nanomaterials, Brookhaven National Lab, KARSTEN POHL, JIADONG ZANG, Department of Physics, University of New Hampshire — α-RuCl₃ has emerged as a novel 2D material that potentially hosts quantum spin liquid state (QSL). Recent experimental reports of neutron scattering and thermal quantum Hall effect have provided indirect but promising evidence for the existence of QSL in α-RuCl₃. However, numerous controversies still remain in the current literatures about α-RuCl₃, such as its crystal structure and electronic structure. We used a unique surface sensitive technique, low energy electron microscopy (LEEM), combined with dynamical selected-area low energy electron diffraction (μLEED-IV) to study the 2D crystal structure of α-RuCl₃. We found an unexpected diffraction pattern on the surface of α-RuCl₃, which indicates intrinsic surface reconstruction that forms a superlattice. The superlattice most likely originates from the slight shift of atomic positions which results in unit cell distortion. The existence of a surface superlattice may significantly impacts the electronic and magnetic properties which in turn would potentially influence the existence of QSL in α-RuCl₃.

DAVID MACNEILL (Presenter), Massachusetts Institute of Technology — Layered magnetic insulators that can be exfoliated are highly desirable, as we can potentially create topological states (e.g., quantum anomalous Hall effect) by incorporating them in van der Waals heterostructures. Such materials were finally realized in 2017 with the isolation of monolayer CrI3 and bilayer CrGeTe3. However, this field is in its infancy and few layer films seem to have complex properties different from bulk, such as the ferromagnetic to antiferromagnetic transition in CrI3. In this talk, I will discuss the use of electron tunneling through ultrathin magnetic insulators as a probe of their magnetic ground state and excitations [1]. We report giant magnetoresistance effects when tunneling through CrI3 and CrCl3 barriers with graphite electrodes, resulting from polarization of their antiferromagnetic ground states under an applied magnetic field. In CrI3 we also find inelastic electron tunneling suggesting the observation of Dirac magnon excitations. Finally, we note a large enhancement of the interlayer exchange in thin CrCl3 compared to bulk, and discuss its origins.

DAHLIA KLEIN (Presenter), DAVID MACNEILL, QIAN SONG, Massachusetts Institute of Technology, MINGYU XU, RAQUEL RIBEIRO, PAUL CANFIELD, Iowa State University, RICCARDO COMIN, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — The family of layered chromium trihalides has been studied for decades due to its rich magnetic phases coupled with insulating properties. The recent isolation of monolayer CrI3 has renewed interest in these materials to incorporate magnetism into 2D van der Waals heterostructures. Transition metal halide magnets have revealed intriguing ground states differing from the bulk when cleaved to thin films but this phenomenon is not yet understood. Here, we use electron tunneling through few-layer crystals of the layered antiferromagnet CrCl3 to probe its magnetic order in the ultrathin limit. By measuring the magnetoresistance in spin filter magnetic tunnel junctions, we measure the interlayer exchange in CrCl3 barriers two to four layers in thickness and find that it is greatly increased in thin films compared to bulk.

*NSF Graduate Research Fellowship: NSF Grant No. 1122374; Center for Integrated Quantum Materials: NSF Grant No. DMR-1231319; EPiQS Initiative: Gordon and Betty Moore Foundation Grant No. GBMF4541 & GBMF4411; Ames Laboratory Contract No. DE-AC02-07CH11358

SEUNG WOO JANG (Presenter), MIN YONG JEONG, HONGKEE YOON, SIHEON RYEE, MYUNG JOON HAN, Department of Physics, Korea Advanced Institute of Science and Technology (KAIST) — We performed a detailed microscopic analysis of the inter-layer magnetic couplings for bilayer CrI3. As the first step toward understanding the recent experimental observations and utilizing them for device applications, we estimated magnetic force response as well as total energy. Various van der Waals functionals unequivocally point to the ferromagnetic ground state for the low-temperature structured bilayer CrI3 which is further confirmed independently by magnetic force response calculations. The calculated orbital-dependent magnetic forces clearly show that eg-t2g interaction is the key to stabilize this ferromagnetic order. By suppressing this ferromagnetic interaction and enhancing antiferromagnetic orbital channels of eg-eg and t2g-t2g, one can realize the desirable antiferromagnetic order. We showed that high-temperature monoclinic stacking can be the case. Our results provide unique information and insight to understand the magnetism of multi-layer CrI3 paving the way to utilize it for applications.
FAZLE SUBHAN, JISANG HONG (Presenter), Pukyong National University — Two dimensional CrI3 system has attracted extensive research interest because it is an intrinsic 2D ferromagnetic material with a band gap. It has been found that the monolayer of CrI3 possesses an intrinsic ferromagnetic ordering with a finite band gap of 1.1 eV and it has also a strong perpendicular magnetocrystalline anisotropy. Besides, it has been experimentally reported that the anti-ferromagnetic interlayer coupling in bilayer CrI3 structure could be change by external charge doping. Nonetheless, despite a few experimental works on CrI3 system, it is rare to find the theoretical studies on bilayer CrI3. We investigated the magnetic properties of bilayer CrI3 using density functional approach. We found that the pristine bilayer CrI3 had an anti-ferromagnetic ground state. Interestingly, we obtained that the external pressure could induce a transition from anti-ferromagnetic to ferromagnetic state in bilayer CrI3 and the perpendicular magnetic anisotropy was still preserved even under the external pressure.

HIDEKI MATSUOKA (Presenter), MASAKI NAKANO, YOSHIHIRO IWASA, University of Tokyo — Emerging properties of van der Waals (vdW) materials at two-dimensional (2D) limit have been broadening their varieties, ranging from spin-orbit coupled transport properties, valley-polarized luminescence, spin-valley-locked superconductivities, to topological quantum transport. As one of big advantages of 2D materials, 2D physical phenomena could be more and more enriched by integrating different 2D materials into a heterostructure, so-called vdW heterostructures, providing a new high-quality platform for 2D physics. One recent breakthrough in 2D physics is observation of magnetism in vdW materials, which turned out to survive down to 2D limit. This type of magnet, so-called 2D magnet, has been integrated into various types of vdW heterostructures, while tuning magnetism itself at vdW heterostructures has been less investigated so far. Here we created magnetic vdW heterostructures by molecular-beam epitaxy, where a new type of 2D magnet, vanadium selenide epitaxial thin film, was incorporated. In the presentation, we will show transport properties of those heterostructures, and discuss the interface effect on 2D magnetism.

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B15 DMP: 2D Materials (Semiconductors) -- Multilayers & Heterostructures I

11:15AM B15.00001: Twist-angle dependent Optical Second-Harmonic Generation from Transition Metal Dichalcogenides (TMD) Heterostructures WONTAEK KIM (Presenter), SUNMIN RYU, Pohang University of Science and Technology — Optical second-harmonic generation (SHG) by single and few-layer transition metal dichalcogenides (TMD) is highly efficient and sensitive to their structural symmetry. The SHG signal from artificially-stacked MoS2 bilayers can be understood as a superposition of SHG fields from the individual layers. However, this model has not been verified for TMD heterostructures. Here, we studied the SHG behavior of TMD hetero-bilayers of varying twist angle in comparison with homo-bilayers. When homo-bilayers were rotated over 2pi-azimuth with a fundamental beam normally incident on their basal planes, the polarization-resolved SHG signal exhibited a six-petal pattern with six azimuthal nodes, which agreed with the superposition model. The heterostructures, however, lacked the angular nodes because of an azimuth-independent signal in addition to the six-petal pattern. The fractional contribution of the constant signal was larger for more staggered hetero-bilayers. To explain these results, we propose that the anomaly originates from a non-zero phase difference between SHG fields generated in the individual monolayers. In addition, we show that the degree of the anomaly is sensitive to the fundamental's wavelength, as the phase depends on photon energy.
11:27AM B15.00002: Observation of negative photoconductance in van der Waals heterostructures* YU WANG (Presenter), Nanjing University, ERFU LIU, University of California, Riverside, WEIDA HU, Shanghai Institute of Technical Physics, SHIJUN LIANG, FENG MIAO, Nanjing University, — Van der Waals (vdW) heterostructures made of different two-dimensional (2D) materials exhibit interesting optoelectronic properties. For example, photodetection and photo-controllable memory devices are two of intriguing applications based on vdW heterostructures. However, the operating principle for most of these devices rely on the positive photoconductance (PPC) effect. Negative photoconductance (NPC) has not yet been observed in vdW heterostructures, which holds promise in constructing optoelectronic devices with low power consumption and high-speed frequency response. In this work [1], we for the first time observed the NPC phenomenon in ReS$_2$/h-BN/MoS$_2$ vdW heterostructures-based floating gate phototransistor. The devices show excellent memory properties. More importantly, we realized the transition between the PPC and the NPC in the floating gate phototransistor. With these findings, the vdW heterostructures may open up a novel avenue for the fabrication of photoelectronic nonvolatile memory devices and multifunctional photoconductive devices.

11:39AM B15.00003: Interlayer translations in commensurately stacked transition metal dichalcogenide bilayers* MADELEINE PHILLIPS (Presenter), C STEPHEN HELLBERG, U.S. Naval Research Laboratory — Transition metal dichalcogenide (TMD) bilayers are promising candidates for optoelectronic device components. In addition to being semiconductors that are optically active in the visible light range, they can exist in a vast array of stacking orientations due to the weak van der Waals bonding between layers. To take advantage of this geometric flexibility, it is essential to understand how changes in stacking orientation affect the properties of TMD bilayers. In this work, we use density functional theory (DFT) to study the stacking variations brought about by interlayer translations in 0 and 180-degree stacked WSe$_2$/MoSe$_2$ and WS$_2$/MoS$_2$ bilayers. We show that the 180-degree stacked bilayers have a single ground state geometry, while the 0-degree stacked bilayers have two degenerate ground state stackings. We also describe how stacking orientation correlates with interlayer distance and electronic structure, and we suggest ways to probe stacking geometry in photoluminescence experiments.

*M.P. holds a National Research Council fellowship at NRL.

11:51AM B15.00004: Interlayer excitons in bilayer MoS2 with strong oscillator strength up to room temperature* BERNHARD URBASZEK (Presenter), IANN GERBER, EMMANUEL COURTADE, SHIVANGI SHREE, CEDRIC ROBERT, XAVIER MARIE, CNRS/INSA, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS Tsukuba — Coulomb bound electron-hole pairs, excitons, govern the optical properties of transition metal dichalcogenides (TMDs) like MoS$_2$ and WSe$_2$. TMD bilayers allow studying several exciton species: intralayer excitons with electrons and holes in the same layer and also interlayer excitons with the electron and the hole residing in different layers.

In this combined experimental and theoretical work we report on the observation of interlayer excitons in a high quality homobilayer MoS$_2$ sample encapsulated in hexagonal boron nitride (hBN). The interlayer exciton transition is located between the intralayer A and B excitons and is observable in reflectivity between 4 and 300 K, whereas no such transition is observed for the monolayer in the same structure in this energy range. Our peak attribution is supported by DFT calculations solving the Bethe-Salpeter equation after GW bandstructure calculations. We find in the calculated absorption spectrum a strong, spin allowed transition situated in energy between A and B intralayer excitons stemming from an electron residing on one and the hole residing in the other layer, both at the K-point of the Brillouin zone. We discuss the possibility of hybridization of exciton species and compare with our results on homotrilayer MoS$_2$.

*ANR 2D-vdW-spin
Saturation and photon-energy dependence of ultrafast charge transfer in vdW heterostructures

ERIC YUE MA (Presenter), BURAK GUZELTURK, Stanford University, GUOQING LI, LINYOU CAO, North Carolina State University, ZHI-XUN SHEN, AARON M LINDENBERG, TONY F HEINZ, Stanford University — We have directly monitored the interlayer charge transfer after photoexcitation in type-II van der Waals heterostructures of monolayer transition metal dichalcogenides. Charge transfer is found to occur on the fs time scale by recording the electromagnetic transient emitted at THz frequencies using THz time-domain spectroscopy. This approach, insensitive to spectral changes of the materials and competing charge-neutral processes, is ideal for studying the dynamics at high excitation fluences and as a function of excitation photon energy. At low excitation fluence, we observe a linear increase in the interlayer current with fluence. However, as the fluence is increased, we see a clear saturation. We analyze this effect in terms of band re-alignment induced by the electric field from charge transfer itself. Such unavoidable saturation puts a limit on the power handling capability of these heterostructures and needs to be carefully characterized for practical applications. With further calibration, such measurements also offer a new route to determine band offsets. We further report the insensitivity of charge transfer dynamics to excitation photon energy within the instrument response. We discuss its implication on the mechanism of interlayer charge transfer.

MoS2/Si and WS2/Si 2D/3D heterojunction photodiodes fabricated by low-temperature plasma enhanced CVD

SOYEONG KWON (Presenter), Physics, Ewha Womans University, YONGHUN KIM, Korea Institute of Materials Science (KIMS), JUNGEUN SONG, DONGRYE CHOI, EUNAH KIM, Physics, Ewha Womans University, JUNG-DAE KWON, Korea Institute of Materials Science (KIMS), BYUNGJIN CHO, Advanced Materials Engineering, Chungbuk National University, DONGWOOK KIM, Physics, Ewha Womans University — We prepared MoS2 and WS2 tri-layers directly on Si substrates using atmospheric-pressure plasma enhanced chemical vapor deposition (AP-PECVD). High pressure (over 100 Torr) plasma formation and low-temperature (under 200°C) growth of AP-PECVD enabled high-quality 2D/3D semiconductor (SC) heterojunctions on a large area (over 4 inch) at a high deposition rate (10 minutes for 2 inch). The fabricated devices showed clear rectifying behaviors and large shunt resistance, indicating formation of uniform heterojunction diodes. Relatively large dark current of the heterojunctions under reverse bias could be attributed to band-to-band tunneling and avalanche multiplication process. Temperature dependence of ideality factor was studied to understand the major recombination processes, based on the conventional 3D SC model. Both of the MoS2/Si and WS2/Si heterojunctions exhibited large and fast photocurrent responses to the laser illumination (wavelength: 532 nm). The measured photocurrent was linear to the laser power, indicating interfacial defect states could not suppress photo-generated carrier collection. All the results demonstrated high quality 2D/3D SC heterojunction photodiodes with clean interfaces were prepared by AP-PECVD.

High Degree Valley-Polarization from Interlayer Exciton in van der Waals Heterostructure

LONG ZHANG (Presenter), RAHUL GOGNA, University of Michigan, WILL W BURG, JASON HORNG, University of Texas at Austin, EUNICE PAIK, YU-HSUN CHOU, University of Michigan, KYOUNGHWAN KIM, EMANUEL TUTUC, University of Texas at Austin, HUI DENG, University of Michigan — Two-dimensional semiconductors promise valleytronics applications, where the valleys of the electronic bands, in addition to spin and charge, become a new degree of freedom for quantum engineering and information processing. Yet electron-hole exchange interactions lead to rapid valley depolarization and low valley polarizations (VPs) in monolayer materials. Here, by precisely aligning the momentum valleys of a WSe2 monolayer to a MoSe2 monolayer, we form a hetero-bilayer with bright interlayer excitons that inherit and preserve the VP from the intralayer ones while at the same time with greatly suppressed electron-hole exchange interactions. Using these heterobilayers, We demonstrate brightened spin triplet inter-layer excitons localized at the potential minimum of the moiré lattice with a VP up to 80% and a valley lifetime of 33 ns. Spin singlet transition localized at the same registry is also measured, with an as high but opposite VP. Our work leads the way of using van der Waals semiconductor heterostructures to control the charge transfer, VP, optical selection rules and other novel optoelectronic properties.

12:39PM B15.00008: Van der Waals TMDC Heterostructures: electronic structure dependence on number of layers*
MUHAMMAD SUFYAN RAMZAN (Presenter), AGNIESZKA BEETA KUC, Jacobs University Bremen — Two-dimensional (2D) transition metal dichalcogenides (TMDCs) of type MX\textsubscript{2} (M = Mo, W; X = S, Se) have attracted considerable attention in electronics and optoelectronics due to their extraordinary properties, which differ strongly between single layers and bulk materials. Moreover, weak van der Waals interactions between layers make it possible to exfoliate them and stack with different TMDC layers to form heterostructures, which offer remarkable electronic properties. In this work, we have studied interlayer coupling between various TMDC layers, which differ either in chalcogen or transition-metal atoms. Furthermore, we have investigated stacking on 3, 4, and 5 layers. The property we were interested in was the electronic structure, in particular, which stacking yields direct band gap materials. For instance, stacking a monolayer of WSe\textsubscript{2} on top of MoS\textsubscript{2} multi-layer (2 or more layers) can yield direct (type-II) band gap for up to 6-layers system (i.e., 1L WSe\textsubscript{2} and 5L MoS\textsubscript{2}) whereas vice versa yields in-direct gap for even 5-layers system (i.e., 1L MoS\textsubscript{2} and 4L WSe\textsubscript{2}). We believe that our findings could greatly contribute to the potential applications of heterostructure TMDCs in photovoltaics, energy harvesting, and solar cells.

12:51PM B15.00009: Characterization of the contact resistance in transition metal dichalcogenide heterojunctions
ADAM PFEIFLE, MARCELO KURODA (Presenter), Auburn University — Semiconducting (2H) transition metal dichalcogenides (TMDs) are known to form high resistance contacts with most metals. Recently, lateral heterojunctions formed by 2H and metallic (1T') phases of TMDs have been proposed to reduce the contact resistance in these systems. Here we combine first principles and quantum transport calculations to rationalize the contact resistance of heterojunctions accounting for their phases (2H and 1T'), composition (WTe\textsubscript{2}, MoTe\textsubscript{2}, WSe\textsubscript{2}, and MoSe\textsubscript{2}), and channel length. We find that telluride 1T' phases in metal/metal junctions are nearly ideal close to the Fermi level as Bloch states remain delocalized through the metal electrode and channel. Mixtures of 1T' selenides and tellurides depart from this ideal scenario due to the momentum mismatch of Bloch states that limit carrier injection. The coupling between metallic (1T') and semiconducting (2H) channels also shows large barriers (> 0.3 eV). The crossover between transport regimes governed by thermionic emission and tunneling is analyzed for the different compositions. We also discuss the presence of edge states in these heterostructures. This work may prove valuable to attaining low contact resistance suitable for optoelectronic applications based on two-dimensional materials.

1:03PM B15.00010: Quantum Transport in Transition Metal Dichalcogenide Monolayers and Twisted Bilayers*
[Invited] JAMES HONE (Presenter), Columbia University — This presentation will review our recent progress in studies of the magneto-transport properties of transition metal dichalcogenides. This work utilizes materials exfoliated from ultrahigh-purity single crystals grown by a flux synthesis technique, and encapsulation by h-BN to minimize external disorder. Ohmic contacts are achieved by work function control and dual-gating. These samples are studied in high magnetic fields by a combination of electrical transport measurements and probing the density of states using capacitance. I will describe a number of systems studied in this way, including WSe\textsubscript{2} monolayers, bilayers, and bilayers with small interlayer twist angles. In addition, recent studies of semiconducting and metallic forms MoTe\textsubscript{2} will be described.

*Sample synthesis and studies of MoTe2 are supported under NSF DMR-1420634
Studies of monolayer WSe2 are supported under DOE SC-0016703
Studies of twisted bilayer materials are supported under DOE DE-SC0019443

1:39PM B15.00011: Photon-Induced Suppression of Interlayer Tunneling in Van Der Waals Heterostructures*
WANG KONG TSE (Presenter), WOO-RAM LEE, University of Alabama — We present a theory for interlayer tunneling in van der Waals heterostructures driven under a strong electromagnetic field, using graphene/hBN/graphene as a paradigmatic example. Our theory predicts that strong anti-resonances appear at bias voltage values equal to an integer multiple of the light frequency. These features are found to originate from photon-assisted resonant tunneling transitions between Floquet sidebands of different graphene layers, and are unique to two-band systems due to the interplay of both intraband and interband tunneling transitions. Our results point to the possibility of tunneling localization in van der Waals heterostructures using strong electromagnetic fields.

**1:51PM B15.00012: Ab initio Study and Search of Chalcogenide-oxide Interfaces**

YUXIN YIN (Presenter), JENNIFER COULTER, PRINEHA NARANG, Harvard University — The discovery of interface enhanced superconductivity has sparked interest in studying interfacial properties of quantum materials. Experimental and theoretical efforts highlight the relevance of spin fluctuation, orbital order and electron-phonon coupling to the onset enhanced superconducting behavior. However, the exact mechanism responsible for increased Tc is still not well-understood. Inspired by recent observations of interface enhanced superconductivity in FeSe/SrTiO3 system and ultrathin film CuS2, we use ab initio theoretical tools to investigate interfacial properties. We investigate interfacial effects on electronic structure, electron-electron and electron-phonon interactions, as well as study the effect of interlayer coupling in chalcogenide-oxide structures. Additionally, we aim to use our methods to identify superconducting interfaces in other chalcogenide material and substrate combinations. These theoretical investigations provide avenues to design and search for superconducting chalcogenide-oxide interfaces.

*We acknowledge support from ONR: N00014-18-1-2691 grant on High-Tc Superconductivity at Oxide-Chalcogenide Interfaces.

**2:03PM B15.00013: Effect of stacking orientation on the electronic and optical properties of 2D nitride heterostructures**

NOCONA SANDERS (Presenter), EMMANOUIL KIOUPAKIS, University of Michigan — Given the successful synthesis of 2D GaN and investigations into the properties of freestanding 2D nitrides, heterostructures of these materials are now of particular interest. Extreme quantum confinement is a viable method to shift light emission to shorter wavelengths, but in 2D nitrides this is counteracted by the quantum-confined Stark shift due to the strong inherent polarization perpendicular to the 2D plane. We report the electronic and optical properties of 2D BN, GaN, AlN, and InN in various stacking orientations, such that the electric fields are either aligned or anti-parallel in two possible configurations. We employ density functional theory and quasiparticle corrections with the GW method, as well as the Bethe-Salpeter Equation, to derive accurate band structures, exciton binding energies, and luminescence energies. Through understanding how the stacking arrangement influences the underlying electronic and optical properties, critical insight will be gained in how to improve 2D III-nitride-based optoelectronics through accessing the additional degree of freedom provided by polarization.

**Session B16 DMP: Transport in Nanostructures -- Single Molecules and Molecular Devices**

BCEC 155 - Han Htoon, Los Alamos National Laboratory - Tag(s): Focus

E-DEAN FUNG (Presenter), YAPING ZANG, LATHA VENKATARAMAN, Columbia University — The basic mechanism for light emission in Scanning Tunneling Microscopes (STM) is described by inelastic tunneling electrons which couple to localized surface plasmons. There is also growing interest in charge transfer plasmons which appear when electrically coupling metallic nanoparticles. Here, we use single molecules to form conductive bridges between an STM tip and substrate and study the complex relationship between tunneling electrons, charge transfer plasmons, and luminescence in molecular junctions. We employ the STM break junction technique to form thousands of Au point contacts and molecular junctions at ambient conditions and room temperature and measure the light emitted from these junctions using a Si photomultiplier. Since the current, junction bias, and emission signals are collected simultaneously, fluctuations in light emission can be correlated with changes in current and junction bias. Because the break junction procedure continuously modifies the local geometry, limits on the emission efficiency are experimentally determined. Finally, we explore the effect of different molecules on light emission.

*This work was supported primarily by the Center for Precision Assembly of Superstratic and Superatomic Solids at Columbia University NSF MRSEC (award no. DMR-1420634)*
NATHAN BAMBERGER (Presenter), JEFFREY IVIE, Department of Chemistry and Biochemistry, University of Arizona, ROLAND HIMMELHUBER, College of Optical Sciences, University of Arizona, OLIVER MONTI, Department of Chemistry and Biochemistry, University of Arizona — Designing circuits based on individual molecules has the potential to produce smaller and more powerful electronic devices. However, a continued challenge to studying the properties of such single molecule circuits is understanding the behavior of the linker group used to connect the molecule to electrodes. This linker plays a critical role because it controls both the electronic coupling and the available binding configurations for the molecule-electrode connections. We have studied a series of single molecule circuits using a mechanically controlled break junction set-up with custom high-speed amplification electronics. By changing both the identity and chemical environment of the molecular linker groups we can gain insight into how and why these linkers affect the value of and variation in molecular conductance. We also develop and use novel data analysis tools including advanced clustering methods to help disentangle the different types of junction behavior in an unbiased manner.

11:39AM B16.00003: Two-stage Kondo effect in single Manganese phthalocyanine molecule transistor*  
XIAO GUO (Presenter), QIUHAO ZHU, WENJIE LIANG, Institute of Physics, Chinese Academy of Sciences — Charge and spin manipulation over single molecule is important for understanding various fundamental physical processes down to molecular level. In single molecule device, when the coupling between molecule and electrodes is enhanced, localize electron spin strongly interacts with electrons in the electrodes, forming Kondo effect. In this talk, I will discuss our efforts on manipulation of Kondo effect in single Manganese Phthalocyanine (MnPc) device. We use electromigration method fabricating single MnPc molecule field effect transistor successfully. Two stage Kondo and S=1/2 Kondo resonance were observed in different charge states. Two-stage Kondo effect was examined against temperature and electric field. Evolution of Kondo temperatures of the two stages in the field will be discussed. We also observed magnet field induced quantum phase transition between spin singlet and spin triplet in this system. These results illustrate spin control in multi electrons system at single molecule scale.

11:51AM B16.00004: Many-body states description for transport and optical properties of molecular junctions with intra-molecule Coulomb interaction*  
KUNIYUKI MIWA (Presenter), MICHAEL GALPERIN, Department of Chemistry and Biochemistry, University of California San Diego — Recent progress of nano-fabrication and laser techniques at nanometer scale makes it possible to perform optical measurements in current-carrying molecular junctions. These advances give rise to the new branch of research coined molecular optoelectronics. With electrons involved in both quantum transport and optical scattering, theoretical challenge is description of these processes on the same footing. Here, we present theoretical analysis of quantum transport and optical response in molecular junctions with strong intra-molecule Coulomb interaction. The study employs molecular many-body states as a basis of consideration, which allows to take intra-molecular interactions exactly. To account for molecule-contacts coupling we use diagrammatic technique for the Hubbard nonequilibrium Green's functions (NEGF). We verify the methodology by comparing with other available techniques at the model level, and apply it to analyze experimental measurements of electroluminescence and photocurrent generation in molecular junctions.

12:03PM B16.00005: Polaronic transport on conductive metal-organic frameworks from first principles  SEBASTIAN E REYES-LILLO (Presenter), Ciencias Fisicas, Universidad Andres Bello, JEFFREY B NEATON, Molecular Foundry, LBNL; UC Berkeley; Kavli ENSI — Hybrid organic-inorganic materials are an emerging class of functional materials with important technological applications in solar energy conversion, catalysis and carbon capture. Among these, metal-organic frameworks (MOFs) correspond to three-dimensional porous materials with potential applications in batteries and fuel cells. Recent studies have shown that polarons, localized quasi-particles formed by excess electronic charge and its self-induced local lattice distortion, play an important role in the transport and optoelectronic properties of electrically conductive MOFs; and therefore, in their overall performance in real devices. In this work, we revisit recent experimental results [1,2] and use theoretical and computational first principles methods to investigate the structural stability and electronic properties of electron polarons, as well as their transport properties. We describe our theoretical results for two specific hybrid organic-inorganic materials: the metallic doped system KxFe2(BDP)3 (0 < x < 2; BDP2− = 1,4-benzenedipyrrozolate) [1], and the two-dimensional ferrimagnetic and conductive system CrCl2(py2)2 (py = pyrazine) [2]. References: [1] Aubrey et al., Nature Materials 17, 625 (2018); [2] Pedersen et al., Nature Chemistry 10, 1056 (2018).

12:15PM B16.00006: Extracting Quantitative Information of electronic structures from Tunneling Molecular Junction I-V Characteristics using a Compact Analytical Model  ZUOTI XIE (Presenter), C. DANIEL FRISBIE, Chemical Engineering and Materials Science, University of Minnesota — One of the central challenges of molecular electronics is to establish clear connections between molecular structure, the ensuing electronic structure, and the current-voltage (I-V) characteristics of molecular junctions. In particular, the offset εh of the Fermi level relative to the appropriate frontier molecular orbital (HOMO in this case) and the electrode-molecule coupling strength Γ are recognized as two main factors that determine the electrical properties of a typical molecular junction. We show that a compact analytical model derived from the Landauer formalism provides a quantitative fit to the I-V data and yields values of εh and Γ that vary systematically with molecular structure and choice of electrode materials. We will present transport data and theoretical analysis of tunnel junctions based on oligophenylene monoand dithiols – with systematically varying lengths – and electrodes fabricated from Ag, Au and Pt metals. Furthermore, Ultraviolet photoelectron spectroscopy (UPS) was employed to determine the εh to be compared with the values predicted by the model from transport data. We will emphasize that the compact analytical analysis facilitates structure-property correlations and a powerful physical organic chemistry approach to molecular electronics.

12:27PM B16.00007: Angstrom-distance rulers using single molecule conductance measurements  NICHOLAS MILLER (Presenter), Boston University, MARIA KAMENETSKA, Physics and Chemistry, Boston University — Electron transport through single metal-molecule-metal junctions are exquisitely sensitive to the atomic scale geometry of the junction. Here, we use conductance signatures of single molecules on metal electrodes measured using the Scanning Tunneling Microscope-based Break Junction (STM-BJ) technique to map the Angstrom-scale arrangement of the atoms in the junctions. Using our “pull-push” technique, where we repeatedly pull apart, hold and then push the electrodes together in the presence of diamine molecules, we determine the conductance and geometry signatures of a series of these molecules. We find that the molecular conductance can be used to determine the distance between electrodes with Angstrom-scale precision. We discover that the odd or even number of carbon atoms in an alkanediamine molecule affects the mean elongation that the single molecule junction can sustain. Furthermore, by analyzing the statistical probability of forming the junctions with molecules of different lengths, we can infer the average shape of our electrodes.

12:39PM B16.00008: Single Molecule Conductance of Ferrocene at Cryogenic and Room Temperature  BRENT LAWSON (Presenter), MARIO KAMENETSKA, Physics, Boston University — Ferrocene and other metallocenes are organometallic species with a metal atom sandwiched between two aromatic rings whose overall spin, spectrum and other properties can be tuned synthetically by choice of metal atom. There is interest in these molecules as candidates for applications in single molecule electronics and spintronics. However, few electron transport measurements of single metallocene molecules on metal have been performed to date. Previous conductance measurements of ferrocene using single molecule break junctions employed anchoring groups to attach the ferrocene to the electrodes, thereby changing the molecular orbitals energy levels and attenuating electron transport. Here, we use Scanning Tunneling Microscope-based break junction technique to measure conductance of ferrocene on gold at room temperature and at 4 K in UHV. We are able to effectively trap the molecule between the tip and substrate while pushing the junction together and find that the molecule binds to gold directly through carbon atoms in the cyclopentadiene organic ligands sandwiching the iron, and has an average conductance of 0.012 G0. Using this technique, we investigate the effect of the metal atom on transport properties by measuring conductance through other metallocene molecules.
12:51PM B16.00009: Signatures of Conformational Dynamics and Electrode-Molecule Interactions in the Conductance Profile During Pulling of Single-Molecule Junctions  LEOPOLDO MEJIA RESTREPO (Presenter), IGNACIO FRANCO, Chemistry, University of Rochester — We demonstrate that conductance can act as a sensitive probe of conformational dynamics and electrode-molecule interactions during the equilibrium and non-equilibrium pulling of molecular junctions. To do so, we use a combination of classical molecular dynamics simulations and Landauer electron transport computations to investigate the conductance of a family of Au-alkanedithiol-Au junctions as they are mechanically elongated. The simulations show an overall decay of the conductance during pulling that is due to a decrease in the through-space electrode-molecule interactions, and that sensitivity depends on the electrode geometry. In addition, characteristic kinks induced by level alignment shifts (and to a lesser extent by quantum destructive interference) were also observed superimposed to the overall decay during pulling simulations. The latter effect depends on the variation of the molecular dihedral angles during pulling and therefore offers an efficient solution to experimentally monitor conformational dynamics at the single-molecule limit.

1:03PM B16.00010: charge transport in molecular transistor incorporating a pair of Mn-phthalocynine molecule*  WENJIE LIANG (Presenter), XIAO GUO, Institute of Physics — charge transport phenomena of single molecule transistor are of great interests not only to understand quantum transport in confined structure, but also to study molecular properties at individual molecule level. Single molecule transistors have been realized successfully in the past years and findings including Kondo resonance, quantum phase transition among others were discovered. In this talk, we will discuss our new experimental findings when two molecules were incorporated in a molecular devices. When two Mn phthalocynine molecules are close to each other, they will coupled to each other though electric static field and in some case exchange electrons in between, leading to unique and different physics picture depending on coupling strength. molecular gating and exchange coupling will be adressed.

1:15PM B16.00011: Origin of high thermal conductivity in complex molecular crystals: an ab initio study of polythiophene  PEISHI CHENG (Presenter), AUSTIN MINNICH, NINA SHULUMBA, Caltech — Thermally conductive molecular crystals are of fundamental and practical interest in part because they are unlike typical complex crystals, which conduct heat poorly owing to their large phonon scattering phase space. While molecular crystals with high thermal conductivity in the range of tens of Wm⁻¹K⁻¹ have been known experimentally for decades, the microscopic origin of this property has remained unclear. Ab-initio methods that have been successfully applied to simple crystals have proved difficult to adapt to molecular crystals due to quantum nuclear motion and their complex primitive cells. Here, we report the thermal transport properties of crystalline polythiophene with 28 atoms per primitive cell using an ab-initio approach that rigorously includes finite temperature anharmonicity and quantum nuclear effects. The calculated room temperature thermal conductivity is 176 Wm⁻¹K⁻¹, a high value that arises from exceptional phonon focusing along the chain for certain branches and despite short lifetimes in the picosecond range. Our finding suggests that many complex molecular crystals with stiff intra-chain bonds are intrinsically good thermal conductors as phonon focusing occurs in any crystal with anisotropic bonds.

1:27PM B16.00012: Modeling structure and conductivity of atomic-scale break junctions  MO LI, EVAN MORAVANSKY, MANUEL SMEU (Presenter), Physics, Binghamton University - SUNY — A large number of single-molecule conductance measurements rely on the break junction approach in which a metal wire (typically Au) is stretched to the breaking point in the presence of the molecule of interest. As the wire breaks, a single molecule can bridge the gap between the electrodes and its conductance can be measured. This is a complex process during which many atomic rearrangements occur, resulting in complicated current versus distance traces that are difficult to interpret. We employ density functional theory (DFT) structure relaxations to investigate the possible geometries during a break junction experiment with and without the presence of molecules. Our focus is on Au electrodes, but we also consider other elements such as Ag and Pt. Next, we the relaxed structures and study their conductance properties with the non-equilibrium Green's function technique coupled with DFT (NEGF-DFT). Our results reveal an intriguing relationship about the evolution of conductance as the junction is stretched, which can be attributed to atomic rearrangements and orbital alignment. These computational analyses can provide guidance in interpreting experimental data.
ZHI LI (Presenter), University of Rochester, ALEXANDRE TKATCHENKO, University of Luxembourg, IGNACIO FRANCO, University of Rochester — We propose a computationally efficient strategy to accurately model nonreactive molecule−surface interactions that adapts density functional theory calculations with the Tkatchenko–Scheffler scheme for van der Waals interactions into a simple classical force field. The resulting force field requires just two adjustable parameters per atom type that are needed to capture short-range and polarization interactions. The developed strategy allows for classical molecular dynamics simulation of molecules on surfaces with the accuracy of high-level electronic structure methods but for system sizes (10^3 to 10^7 atoms) and timescales (picoseconds to microseconds) that go well beyond what can be achieved with first-principles methods. Parameters for H, sp^2 C, and O on Au(111) are developed and employed to atomistically model experiments that measure the conductance of a single polyfluorene on Au(111) as a continuous function of its length. The simulations qualitatively capture both the gross and fine features of the observed conductance decay during initial junction elongation and lead to a revised atomistic understanding of the experiment.

1:51PM B16.00014: Ab initio study of the single molecule conductance of TCNQ and F_4TCNQ using NEGF-DFT  
STUART SHEPARD (Presenter), MANUEL SMEU, Binghamton University — By investigating the conductance of single molecules we gain insight into the fundamental physics of electron transport. Such an understanding can lead to molecular-based electronic components and sensors. We study the transport properties of tetracyanoquinodimethane (TCNQ) and tetrafluoro-TCNQ (F_4TCNQ) at the level of density functional theory within the non-equilibrium Green's function formalism (NEGF-DFT). Experiments show at least three distinct conductance values for a single molecule of TCNQ and F_4TCNQ. We construct a model system which consists of two gold electrodes connected via a single molecule arranged in different orientations. Four orientations are defined: bidentate-bidentate (bi-bi), mono-bi, mono-mono, and flat. We find that conductance depends on the molecule's orientation between the electrodes which ranges over an order of magnitude. In both molecules, the bi-bi and mono-bi produce lower conductance (0.02 - 0.1 G_0) while the flat orientation gives a slightly higher conductance of 0.2 G_0. Surprisingly, the mono-mono shows the largest conductance at 0.4 and 0.6 G_0 for F_4TCNQ and TCNQ respectively. The results are in qualitative agreement with scanning tunneling microscopy break junction (STM-Bj) experiments, which find two low and one high conductance value.

2:03PM B16.00015: Auxiliary quantum master equation for nonequilibrium dual-fermion approach*  
FENG CHEN (Presenter), University of California, San Diego, GUY COHEN, School of Chemistry, Tel Aviv University, MICHAEL GALPERIN, University of California, San Diego — We introduce auxiliary quantum master equation - dual fermion approach (AQME-DF) and argue that it presents a convenient way to describe steady states of non-equilibrium correlated impurity systems. The combined scheme yields an expansion around a reference system much closer to the true system than in the previous considerations. This scheme also avoids long time propagation and hence is numerically cheaper. Results for Anderson impurity model (AIM) are presented as a benchmark.

11:15AM B17.00001: Near room temperature superconductivity in superhydrides at megabar pressures* [Invited]
RUSSELL HEMLEY (Presenter), School of Engineering and Applied Science, The George Washington University — Recent predictions and experimental observations of high $T_c$ superconductivity in hydrogen-rich materials at very high pressures are driving the search for superconductivity in the vicinity of room temperature. We confirmed the existence of a new class of such materials – superhydrides ($MH_x$, with $x > 6$) – and developed preparation techniques for their syntheses and characterization, including measurements of structural and transport properties, at megabar pressures. Four-probe electrical transport measurements of lanthanum superhydride samples display signatures of superconductivity at temperatures ranging from 150 K to above 280 K near 200 GPa. The experiments are supported by pseudo-four probe conductivity measurements, critical current determinations, low-temperature x-ray diffraction, and magnetic susceptibility measurements. These measurements of near-room temperature superconductivity are in good agreement with density functional and BCS theory-based calculations.

11:51AM B17.00002: High-Tc Conventional Superconductivity in Clathrate Hydrides: What can we learn from Electronic Structure?* LILIA BOERI (Presenter), Sapienza University of Rome, CHRISTOPH HEIL, SIMONE DI CATALDO, Institute for Theoretical and Computational Physics, Graz University of Technology, GIOVANNI BACHELET, Sapienza University of Rome — The current record-holder for superconductivity is a lanthanum superhydride ($LaH_{10}$), which crystallizes in a clathrate structure, in which hydrogen forms a dense lattice of interconnected cages. The highest $T_c$ reported is close to room temperature (265 K). $T_c$'s comparable, or even higher than this, have been predicted to occur in other clathrate hydrides with chemical formula $XH_6$ and $XH_{10}$, with $X$=Sc,Y,Mg,Ca.

In this contribution, using ab-initio Migdal-Eliashberg theory, we study the superconducting properties of this new broad class of superconductors, and trace them back to their unique electronic structure.

12:03PM B17.00003: Synthesis of cerium superhydride CeH$_9$ with 3-dimensional atomic hydrogen sublattice
NILESH SALKE (Presenter), Center for High Pressure Science & Technology Advanced Research (HPSTAR), Shanghai, 201203, China, M. MAHDI DAVARI ESFAHANI, Department of Geosciences, Center for Materials by Design, and Institute for Advanced Computational Science, State University of New York, Stony Brook, New York 11794-2100, U, YOUJUN ZHANG, Institute of Atomic and Molecular Physics, Sichuan University, Chengdu 610065, China, IVAN KRUGLOV, Department of Problems of Physics and Energetics, Moscow Institute of Physics and Technology, 9 Institutskiy Lane, Dolgoprudny City, Moscow Region 141700, Russia, JIANSHI ZHOU, YAGUO WANG, Department of Mechanical Engineering, The University of Texas at Austin, Austin, Texas 78712, USA, ERAN GREENBERG, VITALI PRAKAPENKA, Center for Advanced Radiation Sources, University of Chicago, Illinois, 60637, USA, ARTEM OGANOV, Skolkovo Institute of Science and Technology, Skolkovo Innovation Center, 3 Nobel Street, Moscow 143026, Russia, JUNG-FU LIN, Department of Geological Sciences, The University of Texas at Austin, Austin, Texas 78712, USA — Hydrogen-rich super/polyhydrides were considered as an alternative to the monatomic metallic hydrogen to achieve superconductivity close to room temperature at relatively lower pressure. Concomitantly, superconductivity was reported in H$_3$S at record high $T_c$ of 203 K at 200 GPa. Synthesis of superhydrides is very challenging as most of these super/polyhydrides stabilize at very high pressure for e.g., FeH$_5$ and LaH$_{10}$ stabilized at 130 and 170 GPa respectively. However, it would be always useful if superhydrides are synthesized at lower possible pressure. With this motivation, we carried the experimental and theoretical studies on Ce-H system. We have successfully synthesized superhydride CeH$_9$ around 100 GPa in the laser-heated diamond anvil cell. Theoretical calculations were carried to understand the structure, stability and superconductivity of CeH$_9$. CeH$_9$ crystallized in a $P6_3/mmc$ clathrate structure with 3-dimensional atomic hydrogen sublattice. Synthesis of CeH$_9$ at feasible pressure range is very promising and hints towards the future possibility to achieve higher $T_c$ value with the lowest possible pressure in hydride superconductors. This study will also help to further investigate and understand hydride superconductivity at feasible pressure range.
Theoretical Investigation of Ternary Hydrogen-Rich Materials under Pressure

TIANGE BI (Presenter), EVA ZUREK, Chemistry, University at Buffalo — Investigations of chemical compounds under pressure has led to the discovery of novel materials with unique properties and chemical compositions that cannot form at ambient conditions. Hydrogen is believed to become metallic and even superconducting under pressure with a high transition temperature, but the metallization pressure has not been reached by current experiments. Our research mainly focuses on predicting the structures of novel superconducting hydrogen-rich materials using the open-source evolutionary algorithm XTALOPT coupled with density functional theory (DFT) calculations. Given only the chemical composition, this combination allows us to find the most stable structure of a solid under extreme conditions. Therefore, we present our predictions of ternary hydrides at high pressures including analysis of structural and electronic properties.

Strong Electron-Hole Symmetry Breaking in the High Temperature Superconductor H$_3$S.

SOHAM GHOSH (Presenter), WARREN E PICKETT, University of California, Davis — A favorable combination of strong electron-phonon coupling (EPC), high phonon frequency and substantial density of states (DOS) near the Fermi energy was predicted\(^1\) to produce a record superconducting critical temperature $T_c$ around 200K at high pressure, quickly followed by the experimental discovery by Drozdov et al.\(^2\) up to 203K at 160 GPa pressure. Several theoretical papers have confirmed and elaborated on the new phenomena that arise in H$_3$S. Here we employ first principles methods that reveal new aspects of H$_3$S. The electron and phonon self energies are calculated using the EPW code, and we analyze effects of the two nearby van Hove singularities (vHs) that create a sharp and narrow peak of the electron DOS in this material. Several features emerge: The interacting DOS (the spectral density) is severely affected by the strong electron-phonon coupling, and the electronic spectrum displays extreme examples of band renormalization and broadening that have been suggested to arise from strong EPC. Phonon self-energy features will also be presented.

High Field Magnetotransport in Superconducting Hydrides under Pressure

SHIRIN MOZAFFARI, LUIS BALICAS, National High Magnetic Field Lab, Florida State University, Tallahassee, USA, VASILY S. MINKOV, DMITRY KNYAZEV, MIKHAIL EREMETS, Max-Planck-Institut fur Chemie, Hahn-Meitner-Weg 1, 55128 Mainz, Germany, MARI EINAGA, KATSUYA SHIMIZU, Osaka University, Machikaneyamacho 1-3, Toyonaka, Osaka, 560-8531, Japan, DAN SUN, FEDOR BALAKIREV (Presenter), National High Magnetic Field Lab, Los Alamos National Laboratory, Los Alamos, USA — Hydrogen sulfide forms metallic phase under high pressure above one million atmospheres and becomes superconducting at temperatures as high as 203K at 160GPa. Despite record-breaking $T_c$ the basic properties of superconducting sulphur hydride/deuteride are found to be consistent with conventional Bardeen-Cooper-Schrieffer (BCS) theory. Early measurements of the superconducting phase diagram in magnetic fields up to 7T estimate upper critical fields of the order of 70T. We report magnetotransport studies of superconducting sulphur hydride in DC fields up to 35T and pulsed fields up to 65T. We find that upper critical field generally follow the Werthamer, Helfand and Hohenberg (WHH) formalism at low fields, while noticeable deviations from WHH appear at experimental limit of 65T.

*The work at NHMFL was supported by the National Science foundation under cooperative Grant Nos. DMR-1157490 and DMR-1644779, the U.S. DOE, and the State of Florida, and DoE-BES DE-SC0002613

High superconductivity in hydrides at high pressures

XUE LI (Presenter), State Key Laboratory of Superhard Materials, College of Physics, Jilin university, HANYU LIU, YANMING MA, Innovation Center for Computational Physics Methods and Software, College of Physics, Jilin university — The mechanisms for the strong electron-phonon coupling predicted for hydrogen-rich compounds with high superconducting critical temperature were examined within the Bardeen-Schrieffer-Cooper and Midgal-Eliashberg theory. In this study, we have explored some candidate structures for hydrides at high pressures. Electron-phonon coupling calculations predict the existence of new superconducting phases, some even exhibiting superconductivity in the range of room temperature. Further analysis shows that hydrogen-hydrogen vibrations played acritical role in enhancing electron-phonon coupling parameters. Moreover, the calculated stabilities indicate the materials are likely to be synthesized at pressures that are currently accessible in the laboratory. The results open the prospect for the design, synthesis, and recovery of new high-temperature superconductors with potential practical applications.
1:03PM B17.00008: Electronic Structure and Properties of Calcium and Iron Polyhydrides Under Pressure

EVA ZUREK (Presenter), Department of Chemistry, University at Buffalo — The recent synthesis of the calcium and iron polyhydride phases under pressure has inspired theoretical investigations of their structures and electronic structures. First principles calculations have helped to characterize a newly synthesized \( C2/m \) symmetry \( \text{Ca}_2\text{H}_5 \) phase at 25 GPa and an \( I4/mmm \) symmetry \( \text{CaH}_4 \) phase at 120 GPa. Both of these phases contain atomic and molecular hydrogen. The H-H distances in the molecular units are elongated as compared to those in elemental \( \text{H}_2 \) at the same pressure. Electronic structure calculations illustrate that the bond-lengthening mechanism under pressure in the solid state resembles the one responsible for lengthening the H-H bond in Kubas like molecular complexes. Crystal structure prediction techniques have also been employed to predict stable and metastable high hydrides of iron between 150-300 GPa that have not been discussed in other studies. Density functional theory calculations show that neither the \( I4/mmm \) nor the \( Cmca \) symmetry \( \text{FeH}_5 \) phases found to be stable are superconducting.

1:15PM B17.00009: Bipartite character of electronic structure in compressed \( \text{H}_3\text{S} \) and its relation to the high-Tc superconductivity*

RYOSUKE AKASHI (Presenter), University of Tokyo — The sulfur superhydride \( \text{H}_3\text{S} \) has attracted enormous interest since the discovery of the 200K superconductivity in this material under extreme pressure. According to the previous studies, its \( T_c \) is boosted by the peaked structure in the density of states (DOS) and its presence is robust against substitution of sulfur atoms to phosphorus etc.. Its persistence has been thought to emerge through some complicated interplay of the sulfur 3s, 3p and hydrogen 1s orbitals but clear explanation on it has yet been established. We disentangle the “complicated interplay” to clarify how the DOS peak emerges. In particular, we find that a sublattice model with decorated simple cubic structure well represents the electronic structure in this system near a two-dimensional manifold in the Brillouin zone, which is due to small inter-sublattice coupling dependent on the crystal wavenumber. We discuss this point and its possible relation to the robust DOS peak.

*MEXT Element Strategy Initiative to Form Core Research Center in Japan

1:27PM B17.00010: A New Analysis of Strong Electron-Phonon Coupling in Compressed Metal Hydrides*

YUNDI QUAN (Presenter), WARREN E PICKETT, University of California, Davis — The experimental discovery that \( \text{H}_3\text{S} \) becomes superconducting at 200 K under 160 GPa pressure has re-invigorated interest in metal hydrides under compression. Understanding the role of hydrogen relative to that of metal atom and the crystal structure is essential for designing materials with even higher \( T_c \). Importantly for \( \text{H}_3\text{S} \) and other hydrides, various physical quantities including the phonon spectra, the coupling strength \( \lambda \), and matrix elements can be clearly identified as contributions from either hydrogen or the metal atom. We systematically study a few classes of binary hydrides, viz. \( \text{H}_3\text{S} \), \( \text{CaH}_6 \), \( \text{MgH}_6 \) and recently reported lanthanum hydride to carry out this separation and gain a unique type of insight into the origin of strong electron-phonon coupling and high \( T_c \) in hydrides.

Probing Hydrogen in Metal Hydrides: Proton-NMR study of FeH up to 1.9 Mbar

THOMAS MEIER (Presenter), SAIANA KHANDEKHAeva, Bavarian Geoinstitute, Bayreuth University, SYLVAIN PETITGIRARD, Department of Earth Sciences, Institute of Geochemistry and Petrology, STELLA CHARITON, Bavarian Geoinstitute, Bayreuth University, TIMOFEY FEDOTENKO, NATALIA DUBROVINSKAIA, Material Physics and Technology at Extreme Conditions, Laboratory of Crystallography, University of Bayreuth, L. S. DUBROVINSKY, FLORIAN TRYBEL, GERD STEINLE-NEUMANN, Bavarian Geoinstitute, Bayreuth University — Investigation of electronic structures of metal hydrides remains an elusive challenge in high pressure laboratories. Using a novel high pressure NMR technique [1,2,3] we study face centred cubic iron hydride, FeHx with x = 1.0(1), synthesized in-situ in a diamond anvil cell at 30 GPa and temperatures above 1000 K by reaction of iron powder and paraffin. Signals stemming from metallic FeH were identified at protonic Knight shifts of about -1200 ppm. Measurement of the Korringa relation shows that FeH preserve Fermi-liquid like electronic behaviour between 30 and 63 GPa and from 154 GPa towards the highest pressures in this study. Between 63 GPa and 154 GPa the volume dependence of the Proton Knight shift shows an unexpected deviation of the free-electron V^2/3 Knight Shift curvature, indicating an electronic topological transition of the Fermi surface. This study demonstrates the possibility to investigate the electronic structures of hydrogen under chemical pre-compression in metal hydride systems at pressures not accessible by comparable methods.

*This study was financed by the Bavarian Geoinstitute and free state of Bavaria.

Spin-Lattice Model of Plutonium Hydride Nucleation

RYAN MULLEN (Presenter), NIR GOLDMAN, Materials Science Division, Lawrence Livermore National Laboratory — Plutonium hydride forms when plutonium is exposed to hydrogen gas or water vapor. The mechanism of plutonium hydride nucleation is a key material property in this process. Conducting experiments with plutonium is difficult and expensive due to its toxicity and radioactivity. Computer models allow us to probe the phase transition to plutonium hydride without physically handling plutonium.

We develop a spin-lattice model of plutonium hydride, PuH₂, wherein the presence of a hydrogen atom in an interstitial site is a binary variable. We parameterize the site energy of each interstitial as a function of the number of nearest-neighbor occupied sites from the DFT energies of a small system (N_{Pu} = 32). We then compute the phase equilibrium between Pu and PuH₂ from the spin-lattice model using a combination of Wang-Landau sampling and histogram reweighting. The size of the critical PuH₂ nucleus is then computed using a much larger system than would be accessible with DFT (N_{Pu} = 500,000).

Session B18 DCOMP DCMP DAMOP: Machine Learning Material and Experimental Data II

BCEC 156B - Christof Weitenberg, University of Hamburg - Tag(s): Focus

Identifying quantum phase transitions using artificial neural networks on experimental data

CHRISTOF WEITENBERG (Presenter), University of Hamburg — Machine learning techniques such as artificial neural networks are currently revolutionizing many technological areas and have also proven successful in quantum physics applications. Here we employ an artificial neural network and deep learning techniques to identify quantum phase transitions from single-shot experimental momentum-space density images of ultracold quantum gases and obtain results, which were not feasible with conventional methods. We map out the complete two-dimensional topological phase diagram of the Haldane model and provide an accurate characterization of the superfluid-to-Mott-insulator transition in an inhomogeneous Bose-Hubbard system. Our work points the way to unravel complex phase diagrams of general experimental systems, where the Hamiltonian and the order parameters might not be known.

*We acknowledge financial support from the Deutsche Forschungsgemeinschaft via the Research Unit FOR 2414 and the Collaborative Research Center SFB 925.
11:51AM B18.00002: Classifying Snapshots of the Doped Hubbard Model with Machine Learning  
ANNABELLE BOHRDT (Presenter), Technical University of Munich, CHRISTIE S CHIU, GEOFFREY JJ, MUQING XU, DANIEL GREIF, MARKUS GREINER, EUGENE DEMLER, Physics Department, Harvard University, FABIAN GRUSDT, MICHAEL KNAP, Technical University of Munich — Quantum gas microscopes for ultracold atoms can provide high-resolution real-space snapshots of complex many-body systems. We implement machine learning to analyze and classify such snapshots of ultracold atoms, which realize the Fermi-Hubbard model on a square lattice. At half-filling, we find that machine learning successfully identifies a crossover in the character of magnetic correlations with increasing temperature, in concurrence with the peak of the uniform spin susceptibility. We then extend the approach to assess two theoretical descriptions of doped antiferromagnets: a doped quantum spin liquid and a geometric string theory describing hidden spin order. Up to intermediate doping values, our algorithm tends to classify experimental snapshots as geometric-string-like, as compared to the dosed spin liquid or to experimental images at high temperatures. Our results demonstrate the potential for machine learning in processing the wealth of data obtained through quantum gas microscopy for new physical insights.

12:03PM B18.00003: Detecting nematic order in STM/STS data with artificial intelligence†  
JEREMY GOETZ (Presenter), Binghamton University, YI ZHANG, MICHAEL LAWLER, Department of Physics, Cornell University — Detecting the subtle yet phase defining features in Scanning Tunneling Microscopy and Spectroscopy (STM/STS) data remains an important challenge in quantum materials. We meet the challenge of detecting nematic order from local density of states data with supervised machine learning and artificial neural networks for the difficult scenario without sharp features such as visible lattice Bragg peaks or Friedel oscillation signatures in the Fourier transform spectrum. We train the artificial neural networks to classify simulated data of isotropic and anisotropic two-dimensional metals in the presence of disorder. The supervised machine learning succeeds only with at least one hidden layer in the ANN architecture, suggesting the classification scheme is non-linear. We apply the finalized ANN to experimental STM data on CaFe$_2$As$_2$ and it predicts nematic symmetry breaking with 99% confidence (probability 0.99), in agreement with previous analysis.

12:15PM B18.00004: Revealing Patterns in Scanning Probe Microscopy Data via Machine Learning Techniques*  
ERIC HUDSON (Presenter), RJJU BANERJEE, LAVISH PABBI, ANNA BINION, KEVIN CRUST, WILLIAM DUSCH, Pennsylvania State University — Machine Learning (ML) techniques have become prevalent in many diverse fields of research, with the goal of helping extract information from large, complex datasets. Its penetration into condensed matter physics is still however relatively shallow, even for application to results from techniques such as scanning tunneling microscopy (STM), where the image-based nature of the data would naturally seem to lend itself to now standard ML investigations. Here we present results of ML techniques applied to both topographic and spectroscopic STM data, demonstrating the power of these techniques to reveal previously hidden connections between the two and hence help improve our understanding of the relationship between structure and electronic properties at the atomic scale.

*This work was supported by the National Science Foundation Grant MRI-1229138.

12:27PM B18.00005: Crystal Structure Prediction by Bayesian Optimization and Evolutionary Algorithm†  
TOMOKI YAMASHITA (Presenter), National Institute for Materials Science, SHINICHI KANEHIRA, Osaka University, NOBUYA SATO, National Institute of Advanced Industrial Science and Technology, HIORI KINO, National Institute for Materials Science, KOJI TSUDA, The University of Tokyo, TAKASHI MIYAKE, National Institute of Advanced Industrial Science and Technology, TAMIO OGUCHI, Osaka University — Crystal structure prediction methods such as random search (RS) and evolutionary algorithm (EA) have attracted attention. Previously we have developed a searching algorithm accelerated by Bayesian optimization (BO). BO is a selection-type algorithm which can efficiently select potential candidates by machine learning. First, we compared searching efficiency among RS, EA, and BO in the small system of Si$_{16}$. In each algorithm, a hundred structures were searched. The importance of random generation is found compared with evolutionary operations even in EA. RS could be the most efficient for small systems. Furthermore, we develop a hybrid algorithm of BO and EA, and discuss the searching efficiency in large systems.

*This work was supported in part by Materials research by Information Integration Initiative (MI2I) project of the Support Program for Starting Up Innovation Hub from Japan Science and Technology Agency (JST), by Japan Society for the Promotion of Science (JSPS) KAKENHI Grant Number JP 18K13474, and by Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan as a social and scientific priority issue (Creation of new functional devices and high-performance materials to support next-generation industries; CDMSI) to be tackled by using a post-K computer.
12:39PM B18.00006: Phonon Calculations of Phase Change Materials Using Machine-Learning Methods  YOUNGJAE CHOI (Presenter), WOOIL YANG, SEUNG-HOON JHI, POSTECH, Korean Physical Society — Machine-learning (ML) methods for constructing the potential-energy-surface (PES) have been developed and being widely applied to the systems that may be inaccessible by conventional \textit{ab initio} calculations [1, 2, 3]. Dynamical properties of the systems can also be analyzed utilizing calculated PES from the ML methods [2, 4]. One issue that should be addressed for proper application of the ML methods is the transferability of the PES, in particular for calculation of the dynamical properties in various phases. In this study, we used the ML methods to calculate the PES and phonon modes of phase change materials and carried out the transferability analysis by controlling the training sets and force errors.

12:51PM B18.00007: Developing computationally efficient potential models by genetic programming  ALBERTO HERNANDEZ (Presenter), ADARSH BALASUBRAMANIAN, FENGLIN YUAN, TIM MUELLER, Johns Hopkins University — The length and time scales of atomistic simulations are limited by the computational cost of the methods used to predict material properties. We have developed a machine learning algorithm based on genetic programming to discover computationally efficient and parsimonious potential models. Genetic programming is an evolutionary algorithm that can search the space of functional forms, facilitating the optimization of the computational efficiency without the need of selecting an expression a priori. Our approach was validated by rediscovering the Lennard Jones potential and the Sutton Chen embedded atom model from training data generated using these models. By using training data generated from density functional theory calculations, we found simple and fast potential models for elemental systems. We present our approach, the forms of the discovered models, and assessments of their transferability, accuracy and speed.

1:03PM B18.00008: ICA method for identifying collective modes  YADONG WU (Presenter), HUI ZHAI, Tsinghua University — The independent component analysis method is applied to images of ultra-cold atoms. We present this model-independent method to identify the collective modes which are mixed together in a Bose-Einstein condensate from large sets of images. Machine learning method can extract features very well and ICA method can separate these mixed modes very well.

1:15PM B18.00009: "Perfect crime" of machine-learning potentials: 100-fold speed-up with no detectable trace of using machine learning in the final result*  KONSTANTIN GUBAEV, EVGENY PODRYABINKIN, Skolkovo Institute of Science and Technology, GUS HART, Physics and Astronomy, Brigham Young University, ALEXANDER SHAPEEV (Presenter), Skolkovo Institute of Science and Technology — Machine-learning interatomic potentials have been showing significant progress in accelerating atomistic modeling while preserving near DFT accuracy. To make use of such potentials, one must prepare a training dataset of atomistic configurations evaluated with DFT. This can be automated by active learning, allowing one to develop algorithms for automatically predicting materials properties with near-DFT accuracy with speedups of a few orders of magnitude. The only downside of such algorithms is a numerical error in the final answer arising from the deviation of a machine-learning potential from DFT. In my talk, I will show that, in some applications, one could develop algorithms that are free even from that numerical error. For the application of obtaining thermodynamically stable ternary alloy structures I will present an algorithm for screening out high-energy structures, thus accelerating a baseline DFT-based high-throughput algorithm by a factor of 100, leaving zero error in the final answer when compared to DFT. This alludes to the "perfect crime": machine-learning potentials offer very large speed-ups, but the final result is indistinguishable from the one obtained by pure DFT.

Deep Learning of Lennard-Jones Potential Parameterization

ALIREZA MORADZADEH (Presenter), N. R. ALURU, Department of Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, IL, USA — In this study, a deep neural network is developed to parameterize van der Waals interactions at various thermodynamic states based on the pair-correlation functions obtained through MD simulation of about 52 μs. After training, the network not only performs with high accuracy and fidelity for van der Waals particles but also performs well for correlations obtained from all-atom MD simulation of complex molecules. The network is capable of developing coarse-grained force fields within the theoretical limitation and accuracy imposed by van der Waals interactions. The accuracy and fidelity of the method are investigated by computing the total variation in the radial distribution function and the Kullback-Leibler divergence for the coarse-grained model development, while the mean-squared error is used to characterize the performance for the vdW particles. Our results show that deep learning is able to obtain the solution to inverse-problem of liquid-state theory under the assumption of a predetermined pair potential in both all-atom and coarse-grained models with a computational cost that is several orders of magnitude faster than other available methods in the literature.

A direct and local deep learning model for atomic forces in solids

NATALIA KURITZ, Physical Electronics, Tel-Aviv University, GOREN GORDON, Industrial Engineering, Tel-Aviv University, AMIR NATAN (Presenter), Physical Electronics, Tel-Aviv University — We demonstrate a direct and local Deep Learning (DL) model for atomic forces. We apply this model for bulk aluminum, silicon and sodium and show that the model errors are comparable to other state of the art algorithms. Our model allows the calculation of forces in large cells using a training data that we built from smaller cells that were calculated with Density Functional Theory (DFT). In addition, we examine the question of temperature transferability of the model and show that we can train the model with data that was produced at a high temperature and then test it on data that was produced at lower temperatures. We also explore the physical properties of the system (e.g. number of nearest neighbors) effect on the model convergence with respect to some of its parameters. Finally, we discuss why the performance of such local models is better in some materials in comparison to others.

Machine Learning Correlates CDW Properties with Local Gap in Cuprates

KAYLIE HAUSKNECHT (Presenter), TATIANA WEBB, Department of Physics, Harvard University, MICHAEL C BOYER, Department of Physics, Clark University, YI YIN, Department of Physics, Zhejiang University, TAKESHI KONDO, ISSP, University of Tokyo, TSUNEHIRO TAKEUCHI, Toyota Technological Institute, HIROSHI IKUTA, Department of Materials Physics, Nagoya University, ERIC HUDSON, Department of Physics, Pennsylvania State University, JENNIFER HOFFMAN, Department of Physics, Harvard University — With the advent of atomic resolution imaging techniques comes the challenge of disentangling the intrinsic electronic properties of materials from their stochastic atomic-scale disorder. In the past decade, machine learning (ML) image analysis techniques have rapidly evolved, and their applications in physics are just emerging. Here, we use ML to test correlation hypotheses between spatially resolved measurements of disordered materials to overcome the limitations of standard Fourier analysis techniques. We apply artificial neural networks to uncover the doping-dependence of the density wave (DW) structure in the cuprate superconductor (Pb,Bi)_{2}(Sr,La)_{2}CuO_{6+δ} (Bi-2201) imaged via scanning tunneling microscopy. In Bi-based cuprates, the electronic inhomogeneity, caused by local variations in doping, limits the precision of DW wavevector measurements. Our ML algorithm overcomes this limitation and allows clear differentiation between commensurate and incommensurate DW instabilities with physically distinct mechanisms. More broadly, our work lays the foundation for a ML approach to quantify intrinsic periodic order and correlations from datasets where these trends are masked by disorder.

Session B19 DCOMP DCMP: Precision Many Body Physics II

Session B19 DCOMP DCMP: Precision Many Body Physics II
BCEC 156C - Boris Svistunov, University of Massachusetts Amherst - Tag(s): Focus
11:15AM B19.00001: Spatial Charge and Spin Correlations in the 2D Fermi-Hubbard Model: Comparison between quantum Monte Carlo simulations and optical lattice emulators* [Invited] NANDINI TRIVEDI (Presenter), Ohio State University — I will report on the current status and challenges faced by quantum Monte Carlo simulations to obtain quantitative information about the spatially resolved charge and spin correlations in the two-dimensional Fermi-Hubbard model. The computational results will be compared with those obtained in site-resolved imaging experiments with fermionic atoms in optical lattices. I will also discuss results with and without a Zeeman field at a wide range of temperatures, including temperatures below currently reachable in experiments. Some of the open questions I will discuss are: (1) Are there signatures of fractionalization of the fermionic spectral function? (2) How close are we to observing d-wave superconductivity in the simulations and experiments? (3) What is the sign problem and in which regions of parameter space is it most problematic?

* (a) NSF Division of Materials Research grant 1309461; (b) partial support by a grant from the Simons Foundation (343227)

11:51AM B19.00002: Metal to insulator crossover and non-Fermi-liquid physics in the half-filled 2d Hubbard model AARAM JOO KIM, Department of Physics, King's College London, FEDOR SIMKOVIC, Collège de France, EVGENY KOZIK (Presenter), Department of Physics, King's College London — We present a controlled study of the finite-temperature crossover from the metallic to insulating regime in the half-filled 2D Hubbard model using Diagrammatic Monte Carlo techniques in the thermodynamic limit. Our results for one- and two-body properties confirm absence of the metal- to-insulator transition at any non-zero coupling and relate the insulating behavior to development of extended antiferromagnetic (AFM) correlations. The crossover is marked by the AFM correlation length extending beyond one lattice constant and involves an intermediate non-Fermi-liquid regime with a partially gapped Fermi surface. We observe the peculiar behavior of thermodynamic observables at the crossover indicative of the Slater-type insulator scenario.

12:03PM B19.00003: Pair Density Wave in the doped t-J model with ring exchange on triangular lattice XIAO YAN XU (Presenter), KAM TUEN LAW, Department of Physics, Hong Kong University of Science and Technology, PATRICK LEE, Department of Physics, Massachusetts Institute of Technology — In our former work (PRL 121 046401 (2018)), we found a quantum spin liquid with spinon Fermi surface in the two dimensional spin-1/2 Heisenberg model with four-spin ring exchange on triangular lattice. In this work we dope the spinon Fermi surface phase by studying the t-J model with four-spin ring exchange. We perform density matrix renormalization group calculations on four-leg cylinders of triangular lattice and find clear signatures of pair density wave. The pair correlation function is oscillatory, even though it decays rapidly with distance with a power law larger than 2. The doping dependence of the decay and the period are studied. This is the first example where the pairing density wave is the dominate pairing in a system without a spin gap.

12:15PM B19.00004: An Auxiliary Field Quantum Monte Carlo study of the Hubbard Kanamori model* HONGXIA HAO (Presenter), BRENDA RUBENSTEIN, Brown University, HAO SHI, Simons Foundation — In the eld of strongly-correlated many-electron systems, the Hubbard Kanamori model has been extensively studied as a prototype for transition-metal oxides, to accurately describe interesting problems like magnetic properties, phase transitions, and unconventional superconductivity. The model is multiorbital in nature and contains Hunds coupling terms. However, due to the sign problem, it is mainly studied in the framework of Dynamical Mean-Field Theory (DMFT). We study the model using the ground state Auxiliary Field Quantum Monte Carlo (AFQMC) method. Different decomposition strategies for the Hunds coupling and pair-exchange terms are proposed for Hubbard-Stratonovich transformation. The Constrained Path Approximation and Phaseless Approximation are used to control the sign and phase problem. Systematic tests are carried out and shown the high accuracy of this approach. The ground state properties of real material Ca2RuO4 will be discussed.

*Supported by Center for Computation and Visualization (CCV) at Brown University and Extreme Science and Engineering Discovery Environment (XSEDE). The Flatiron Institute is supported by the Simons Foundation.
12:27PM B19.00005: Study of competing phases in the half filled Hubbard-Holstein model by "sign-free" determinantal Langevin simulations
SEHER KARAKUZU (Presenter), SANDRO SORELLA, International School for Advanced Studies — Understanding the properties of strongly correlated models is a challenging problem since many analytical tools cannot be applied due to the complicated nature of the problems. Here, we apply numerical methods in order to investigate the ground state thermodynamic limit properties of the so-called Hubbard-Holstein model in two spatial dimensions. We show that it is possible to perform "sign-problem-free" path integration for the model at half-filling by an appropriate choice of Hubbard-Stratonovich transformation and exact integration of phononic degrees of freedom. We apply an efficient first-order accelerated Langevin dynamics algorithm to evaluate all relevant correlation functions of the model. Preliminary calculations at $U/t=4$ and $U/t=1$, $\omega_0/t=1$, indicate a strong competition of antiferromagnetic and charge-density-wave orders. We observe signatures of a quite extended region around $U\approx g^2/\omega_0$ without either antiferromagnetic or charge-density-wave orders, separating into two quantum critical points at zero temperature. Furthermore, the phase diagram of the model will be presented for moderate phonon frequencies $\omega_0$. The possible extension of the current technique to finite temperature is under study.

12:39PM B19.00006: Hubbard model analysis with dynamical mean-field theory and selective configuration interaction
CARLOS MEJUTO ZAERA (Presenter), NORM TUBMAN, BIRGITTA K WHALEY, University of California, Berkeley — The two-dimensional square lattice Hubbard model has been one of the most investigated Hamiltonian systems in condensed matter physics during the last few decades. Despite extensive efforts and numerous theoretical studies, there is still debate about its zero temperature phase diagram. Here, we present numerical results obtained using adaptive selected configuration interaction (ASCI) techniques for both finite size clusters and the thermodynamic limit, with the latter obtained by combining ASCI with dynamical mean-field theory (DMFT). We study basic spectral properties together with two-point correlation functions of spin and charge, for a variety of particle fillings and interaction strengths. Away from half-filling and for a wide range of interaction strengths, the finite size cluster results indicate that the ground state wave function presents a shell structure similar to that of atomic or molecular systems. In the bulk ASCI-DMFT calculations we study the effect of the bath discretization on the spectral properties.

*We thank the Fundacion Bancaria La Caixa for financial support.

12:51PM B19.00007: Crossovers caused by the Mott transition away from long-range ordered phases
CHARLES-DAVID HÉBERT (Presenter), Institut quantique, RQMP, Université de Sherbrooke, MAXIME CHARLEBOIS, Institut quantique, RQMP, Université de Sherbrooke — The dynamical mean-field description of the Mott transition explains high-temperature crossovers caused by local correlations. However, these crossovers can be wiped out by long-range order. Frustrated lattices are generally necessary to prevent long-range magnetic order. Yet many calculations are done on unfrustrated clusters. Using cluster extensions of dynamical mean-field theory for system sizes up to $4x4$, we compare the results obtained on the square and on the triangular lattices to identify possible modifications of the crossovers that could arise from antiferromagnetic correlations. In particular, we verify whether on the triangular lattice, the first order Mott transition extends above the antiferromagnetic order, as seen in some materials.

1:03PM B19.00008: Recent advances in Diagrammatic Monte Carlo
RICCARDO ROSSI (Presenter), Simons Foundation — In this talk, I will present some of the recent advances obtained in the automatic high-order computations of Feynman diagrams for fermionic systems. I will discuss in particular the Connected Determinant Monte Carlo algorithm (CDet) [1, 2] and its extensions, and I will present results for the Fermi-Hubbard model as the paradigmatic strongly-correlated fermionic system.

1:15PM B19.00009: Functional renormalization group study of the three-dimensional Hubbard model*  JANNIS EHR LICH (Presenter), Peter-Gruenberg-Institut, Forschungszentrum Juelich, CARSTEN HONERKAMP, Inst. for Theoretical Solid State Physics, RWTH Aachen University — We present the extension of the truncated unity functional renormalization group (TUfRG) approach to three-dimensional lattice models for interacting fermions. This provides a flexible method for detecting ordering tendencies which treats all fluctuation channels on equal footing.

As a first example, we study the Hubbard model on the simple cubic lattice. We determine the leading ordering tendencies for low temperatures and the corresponding energy scales for ordering. At half filling and for repulsive interaction, the transition scale to an antiferromagnetic (AFM) ground state shows good agreement with other numerical methods. In addition, we investigate the competition between AFM and d-wave superconducting ordering away from half filling.

*We acknowledge financial support by DFG RTG 1995

1:27PM B19.00010: Multiloop functional renormalization group for the two-dimensional Hubbard model: Loop convergence of the response functions  AGNESE TAGLIAVINI, CORNELIA HILLE, University of Tübingen, FABIAN B. KUGLER, LMU, SABINE ANDERGASSEN (Presenter), University of Tübingen, ALESSANDRO TOSCHI, TU Vienna, CARSTEN HONERKAMP, RWTH Aachen University — We present a functional renormalization group (fRG) study of the two dimensional Hubbard model, performed with an algorithmic implementation which lifts some of the common approximations made in fRG calculations. In particular, in our fRG flow; (i) we take explicitly into account the momentum and the frequency dependence of the vertex functions; (ii) we include the feedback effect of the self-energy; (iii) we implement the recently introduced multiloop extension which allows us to sum up all the diagrams of the parquet approximation with their exact weight. Due to its iterative structure based on successive one-loop computations, the loop convergence of the fRG results can be obtained with an affordable numerical effort. In particular, focusing on the analysis of the physical response functions, we show that the results become independent from the chosen cutoff scheme and from the way the fRG susceptibilities are computed, i.e., either through flowing couplings to external fields, or through a “post-processing” contraction of the interaction vertex at the end of the flow. The presented substantial refinement of fRG-based computation schemes paves a promising route towards future quantitative fRG analyses of more challenging systems and/or parameter regimes.

1:39PM B19.00011: Ground-State Superfluid Phase Diagram of the Two-Dimensional Fermionic Hubbard Model with Next-Nearest-Neighbour Hopping*  FEDOR SIMKOVIC (Presenter), Department of Physics, King's College London, YOUJIN DENG, Hefei National Laboratory for Physical Sciences at Microscale and Department of Modern Physics, University of Science and Technology of China, EVGENY KOZIK, Department of Physics, King's College London — In this work, we employ the Bold Diagrammatic Monte Carlo method to establish the superfluid phase diagram in terms of density and interaction strength and for several values of next-nearest-neighbour hopping. We find that although a multitude of superfluid states persists up to moderate interactions the picture changes severely compared to the weak-coupling interaction limit. We investigate into how relative proximity to the Van Hove filling affects superfluid order parameters and find that this effect diminishes with increasing interaction strength.

*Simons Collaboration on the Many-Electron Problem

1:51PM B19.00012: Superconducting paring induced by the Mott stripe in t-J ladders*  CHEN CHENG (Presenter), RUBEM MONDAINI, Beijing Computational Science Research Center, MARCOS RIGOL, Department of Physics, The Pennsylvania State University — Stripe formation is ubiquitous in the doped cuprates family and in corresponding numerical studies on 2D lattices. However, the complex competition of different orders makes it difficult to understand how they precisely affect the superconducting pairing in high-temperature superconductors. Alternatively, we study a simplified ladder system with doped outer-legs and a Mott stripe core, produced by the interplay of strong repulsion and the large negative on-site potential in the inner legs. By using the density matrix renormalization group method in 4-leg ladders, we show that, for anisotropic exchange couplings, a novel singlet-pair superconducting phase occurs with the fermions in the pairs residing on different sides of the Mott insulating stripe. In this phase, the binding energy is negative and the interleg singlet-pair correlation function decays algebraically with distance, in contrast to other correlations that are exponentially decaying. We expect our findings to shed light on the pairing mechanisms for the high-temperature superconductivity, and potentially highlight novel types of pairing mechanisms in AMO experiments. Part of this work is published as Phys. Rev. B 98, 121112(R) (2018).

Superconductivity in the Hubbard model: a hidden-order diagnostics from the Luther-Emery phase on ladders  

LUCA FAUSTO TOCCHIO (Presenter), Institute for Condensed Matter Physics and Complex Systems, Politecnico di Torino, Italy, FEDERICO BECCA, Democritos National Simulation Center, Istituto Officina dei Materiali del CNR and International School for Advanced Studies (SISSA), Trieste, Italy, ARIANNA MONTORSI, Institute for Condensed Matter Physics and Complex Systems, Politecnico di Torino, Italy — Short-range antiferromagnetic correlations are known to open a spin gap in the repulsive Hubbard model on ladders with $M$ legs, when $M$ is even. We show that the spin gap originates from the formation of correlated pairs of electrons with opposite spin, captured by the hidden ordering of a spin-parity operator. Since both spin gap and parity vanish in the two-dimensional limit, we introduce the fractional generalization of spin parity and prove that it remains finite in the thermodynamic limit. Our results are based upon variational wave functions and Monte Carlo calculations: Performing a finite size-scaling analysis with growing $M$, we show that the doping region where the parity is finite coincides with the range in which superconductivity is observed in two spatial dimensions. Our observations support the idea that superconductivity emerges out of spin gapped phases on ladders, driven by a spin-pairing mechanism, in which the ordering is conveniently captured by the finiteness of the fractional spin-parity operator.

Session B20 DCOMP DMP: First-principles Modeling of Excited-state Phenomena in Materials II: Many-body Perturbation Theory (Techniques and Applications)

Correlated multi-particle excitations: Green's function formalism for trions and biexcitons*  

FELIPE DA JORNADA (Presenter), ANDREA CEPELLOTTI, STEVEN G. LOUIE, UC Berkeley and Lawrence Berkeley National Lab — With the experimental isolation of atomically thin one- and two-dimensional materials, it is now possible to measure a variety of charged and neutral multiparticle excitations (trions, biexcitons, etc.) in these systems, many of which display large binding energies. On the theory side, however, while quasiparticle and neutral optical excitations have been successfully treated in many materials with the first-principles GW and GW plus Bethe-Salpeter equation (GW-BSE) approaches, respectively, similar many-body and parameter-free approaches are not available to compute and understand correlated multi-particle excitations. Accordingly, past theoretical studies were often limited to treatments based on model Hamiltonians. In this talk, we present results from a new ab initio approach based on the interacting 3- and 4-particle Green's function formalism to compute multiparticle excitations [1]. Our new diagrammatic approach that makes use of appropriate screened Coulomb interactions, combined with a high-performance computing implementation, allows us to predict without adjustable parameters that trions and biexcitons in carbon nanotubes are stable at room temperature, and also to reveal in details electronic correlation in these multiparticle excitations. We will also comment on how this formalism can be employed to investigate other high-order excited-state phenomena in the bulk and at the nanoscale.

*This work was supported by the Center for Computational Study of Excited-State Phenomena in Energy Materials (C2SEPEM) at LBNL, funded by the U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources provided by NERSC and XSEDE.
FULVIO PALEARI (Presenter), University of Luxembourg, HENRIQUE MIRANDA, Université Catholique de Louvain, ALEJANDRO MOLINA-SANCHEZ, University of Valencia, LUDGER WIRTZ, University of Luxembourg — We present an ab initio method to calculate phonon-assisted absorption and emission spectra when strong excitonic effects are present. We apply the method to bulk hexagonal BN, a material with indirect band gap which exhibits strong luminescence in the UV range. We first calculate the excitons at the wave vector $q_i$ of the indirect gap with the Bethe-Salpeter equation. The coupling of these excitons with the various phonon modes at $q_i$ is investigated with group theory and then expressed in terms of a product of the mean square displacement of the atoms and the second derivative of the optical response function with respect to atomic displacement along the phonon eigenvectors. The derivatives are calculated numerically with a finite difference scheme in a supercell commensurate with $q_i$. We use detailed balance arguments to obtain the intensity ratio between emission and absorption processes. Our results[1] explain recent luminescence experiments[2] and reveal the exciton-phonon coupling channels responsible for the emission lines.

XIAO ZHANG (Presenter), ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — The Bethe-Salpeter equation (BSE) is a theoretical spectroscopy technique that accurately describes optical absorption by considering the screened electron-hole Coulomb interaction. In practice, the frequency dependence of screening is oftentimes neglected to reduce computational cost. This static approximation is often valid due to small exciton-binding energies in bulk inorganic semiconductors, compared to plasmon frequencies. However, for materials with large exciton-binding energies, such as finite and low-dimensional systems, dynamical screening can become important. To explore this, we incorporated dynamical electronic screening into the BSE approach and quantify its impact from first-principles calculations. We study the optical absorption of linear oligoacene crystals and show that the exciton binding energy is on the order of 1 eV. Furthermore, we compute corrections due to dynamic screening, and show that these can be of comparable size, i.e. an order of magnitude larger than in inorganic semiconductors. We also show that including this effect significantly improves agreement of exciton binding energies with experimental results.

*This work is supported by the NSF (DMR-1555153) and Blue Waters (OCI-0725070, ACI-1238993, and the state of IL).

TIANLUN HUANG (Presenter), SAHAR SHARIFZADEH, Boston University — Perylene-3,4,9,10-tetracarboxylic diimide (PTCDI) are promising optoelectronic materials; they possess strong optical absorption and emission properties, along with a propensity for self-assembly and excellent stability. We utilize density functional theory and many-body perturbation theory within the GW/BSE approximation to investigate the optoelectronic properties of a periodic assembly of PTCDI DNA base surrogates. We predict a bandstructure with significant bandwidth (~0.8 eV) and several spatially delocalized low-energy optically excited-states. By incorporating electron-phonon interactions, we determine that at finite temperature, the bandwidth is reduced and exciton binding increased, leading to localization of excited-states.

*We are grateful for funding from NSF (DMR-1610031).

SIVAN REFAELY-ABRAMSON (Presenter), Materials and Interfaces, Weizmann Institute of Science, Israel, JONAH HABER, FELIPE DA JORNADA, STEVEN G. LOUIE, JEFFREY B NEATON, Physics, University of California, Berkeley — We study structural effects on single- and multi-exciton processes in organic molecular crystals. We use many-body perturbation theory within the GW approximation and the Bethe-Salpeter equation approach to calculate and compare the quasiparticle and excitonic band structures of different polymorphs of solid pentacene, and explore their implications for excited-state processes. We find that structural differences between known phases can lead to large effects on exciton-exciton interactions; and in particular, we predict very different singlet fission rates, revealing a strong sensitivity between singlet fission efficiency and crystal phase. We explore the effect of phonons on this picture, and discuss the implications of our findings on design principles and pathways to optimize photogeneration processes in organic crystals. This work supported by the Department of Energy; computational resources provided by NERSC.
12:39PM B20.00006: Computational discovery of new materials for intermolecular singlet fission in the solid state*  
[invited] NOA MAROM (Presenter), Carnegie Mellon University — Intermolecular singlet fission (SF) is the conversion of one photogenerated singlet exciton into two triplet excitons localized on different molecules. SF has the potential to significantly enhance the conversion efficiency of organic solar cells by harvesting two charge carriers from one photon. However, few materials are presently known to exhibit intermolecular SF in the solid state. Using many-body perturbation theory in the GW approximation and Bethe-Salpeter equation (BSE), we have elucidated the effect of crystal packing on the excitonic properties of molecular crystals. To assess the likelihood of new materials to exhibit SF, we have proposed a two-dimensional descriptor based on the thermodynamic driving force for SF and the degree of singlet exciton charge transfer character. To evaluate the latter we have developed the double-Bader analysis method for exciton wave-functions from BSE calculations. We have identified several promising candidates for intermolecular SF in the solid state including monoclinic rubrene, quaterrylene, and phenylated pentacene derivatives.

1:15PM B20.00007: Phenylated Acene Derivatives as Candidates for Intermolecular Singlet Fission  
XIAOPENG WANG (Presenter), XINGYU ALFRED LIU, RITHWIK TOM, Carnegie Mellon University, CAMERON COOK, BOHDAN SCHATSCHNEIDER, Cal Poly Pomona, NOA MAROM, Carnegie Mellon University — Singlet fission (SF), the conversion of one singlet exciton into two triplet excitons, may improve the efficiency of organic photovoltaics. Only a few materials have been experimentally observed to undergo intermolecular SF, most of which are acenes and their derivatives. Using many-body perturbation theory in the GW approximation and the Bethe-Salpeter equation (BSE), we systematically investigate the electronic and excitonic properties of tetracene, pentacene, and their phenylated derivatives in the gas phase and solid state. Their potential for SF is evaluated with respect to the thermodynamic driving force and the singlet exciton charge transfer character. In both gas phase and solid state, pentacene and its derivatives are more promising than tetracene and its derivatives. Within a group of phenylated derivatives with the same acene backbone, increasing the number of phenyl side groups is detrimental for SF in the gas phase. However, solid state properties are additionally affected by intermolecular interactions. We find that a higher number of phenyl side groups results in crystal structures with weak π-stacking and slip stacking, which exhibit higher SF driving force in the solid state.

1:27PM B20.00008: The Spin-Flip BSE approach and applications to simple molecular systems*  
BRADFORD BARKER (Presenter), DAVID STRUBBE, Physics, University of California, Merced — The spin-flip (SF) method allows for description of multi-reference states by considering excitations of a single high-spin reference state, and it has been successfully used in time-dependent density-functional theory (SF-TDDFT) and configuration interaction (SF-CI) approaches to describe molecules with unpaired spins. While SF-TDDFT is significantly less computationally expensive than SF-CI, it has difficulty describing double excitations, Rydberg states, and bond-breaking with conventional functionals. Just as the GW/Bethe-Salpeter (BSE) approach, with its ab initio long-ranged and non-local interaction kernel, allows for a systematic improvement of calculated optical absorption spectra over TDDFT, we consider a spin-flip BSE (SF-BSE) approach to improve SF-TDDFT. This method has a more moderate expense than SF-CI and can be used also for extended systems. We present the theory of SF-BSE and apply it to simple molecular examples of bond-breaking and unpaired spins.

1:39PM B20.00009: Conjugation length dependence on the electronic and optical properties of oligothiophene-F4TCNQ complexes*  
ANA VALENCIA (Presenter), CATERINA COCCHI, Department of Physics, Humboldt-Universitaet zu Berlin, Germany — To understand how the donor conjugation length affects the doping mechanisms in organic semiconductors [1], we investigate a series of charge transfer (CT) complexes formed by oligothiophene molecules of increasing length doped by the acceptor F4TCNQ. Using hybrid DFT as a starting point, we assess the electronic and optical properties of these systems from many-body perturbation theory (GW and the Bethe-Salpeter equation). We find that the frontier orbitals (HOMO and LUMO) have CT character in all complexes, while deeper occupied and higher virtual states depend on the nT length. The first bright excitation is dominated by the HOMO-LUMO transition occurring approximately at the same energy in all systems. At increasing donor length, higher-energy peaks exhibit different character depending on the donor conjugation length. The rationale offered by our results contributes to clarify the excitation processes in organic donor/acceptor complexes.

1:51PM B20.00010: First-principles prediction of free-electron screening of the electron-hole interaction in hybrid perovskite MAPbI3* JOSHUA LEVEILLEE (Presenter), ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — Hybrid organic-inorganic perovskite MAPbI3 has captivated the solar cell community as a high-efficiency photovoltaic material. Recent reports find high intrinsic charged defect concentrations in MAPbI3 which donate free electrons to the material. Due to these, the Coulomb potential between electrons and holes is further screened and the exciton binding energy decreases. We use first-principles methods based on many-body perturbation theory to determine the influence of free-electron screening on the predicted excitonic properties and the optical spectrum of MAPbI3. Electronic band structures and gaps are predicted using Hedin's GW approximation, including the spin-orbit interaction. Electron-hole excitation energies and optical spectra are calculated using the Bethe-Salpeter framework. Our calculations show that exciton binding energies span the experimentally observed range of 31 to 2.5 meV as the free-electron concentration varies between $10^{12}$ and $10^{19}$ cm$^{-3}$. The corresponding optical spectra are found in good agreement with experimental results, suggesting that free-carrier screening plays an important role in the optical response of MAPbI3.

2:03PM B20.00011: First-principles Studies of Tl Activated Halide Scintillator Phosphor Materials: Towards an Understanding of the Scintillation Mechanism* ANDREW CANNING (Presenter), MAURO DEL BEN, EDITH BOURRET, Lawrence Berkeley National Laboratory — Tl doped halide scintillator phosphors are amongst the most commonly used gamma ray detector materials for medical imaging, high energy physics and nuclear materials detection applications (e.g. CsI:Tl, NaI:Tl). Even so the complete scintillation process in these materials is still poorly understood. In particular in recent years there has been great interest in co-doping these materials to try and improve their detection performance. We have performed first-principles studies based on GGA, hybrid functionals and the GW/BSE method in tandem with experiments to understand the scintillation mechanism in these materials and how it could be improved by co-doping. In particular we have looked at the Tl exciton optical emission states and energy transfer mechanisms from the gamma ray to the Tl. Recently there has also been interest in new Tl bulk scintillators such as TLYC (Tl$_2$LiYCl$_6$) which we have also studied.

Session B21 DCOMP DBIO DMP GSOFT: Exploring Free Energy Landscapes in Biology and Materials Science I BCEC 157B - Pratyush Tiwary, University of Maryland, College Park - Tag(s): Focus

11:15AM B21.00001: Incorporating experimental data into long timescale simulations of macromolecules* [Invited] CECILIA CLEMENTI (Presenter), Department of Chemistry, Rice University — Recent breakthroughs in experimental technologies and in high-performance computing have enabled unprecedented measurements and simulations of complex biophysical systems such as macromolecules. However, experiments provide only a partial view of macromolecular processes and are limited in their temporal and spatial resolution. On the other hand, atomistic simulations are still not able to sample the conformation space of large complexes, thus leaving significant gaps in our ability to study molecular processes at a biophysically relevant scale. We present our efforts to bridge these gaps, by using experimental data as a starting point in a computational modeling approach. We use models at different resolutions and “anchor” them to experimental measurements, to provide quantitatively accurate representations of systems of interest, and address open biophysical questions.

Helix Mediated Aggregation in Poly-Glutamine Tracts

In protein aggregation related neurodegenerative diseases, a disease specific host protein misfolds and adopts a metastable, aggregation prone conformation. For Huntington's disease, the htt exon I domain is the smallest physiological N-terminal fragment that forms disease related poly-glutamine rich fibrils. Exon I consists of a glutamine tract, flanked by a 17 amino acid long fragment (httNT) and a proline rich fragment. The presence of httNT fragment has been shown to significantly accelerate the formation of poly-glutamine rich fibrils. In this study, we test the helix mediated aggregation mechanism of glutamine tracts as proposed by the Wetzel group by using molecular dynamics simulations. Analysis of httNT fragment in bulk water suggests only a weak helix propensity. However, when several fragments come into contact they adopt the alpha-helix conformation and form bundles. When the httNT fragment is flanked to the poly-glutamine tract, these bundles lead to a dramatic increase in glutamine concentration. By using a coarse grained model, we study the beta-sheet formation and show that, in agreement with the Wetzel group's hypothesis, beta-sheet propensity significantly increases in these bundles compared to the isolated poly-glutamine tracts.

*TUBITAK (project no 116z512)
12:51PM B21.00007: Nonlinear and Hierarchical Discovery of Slow Molecular Modes using Sequential Learning with Natural Constraints  WEI CHEN (Presenter), Physics, University of Illinois at Urbana-Champaign, HYTHEM SIDKY, ANDREW L FERGUSON, Institute for Molecular Engineering, University of Chicago — Discovering the slow modes governing molecular dynamics can unveil new mechanistic understanding and provide collective variables along which to direct enhanced sampling. Time-lagged independent component analysis (tICA) is a well-developed method that discovers linear combination of molecular features as slow modes. The linearity of tICA, however, hampers its capacity to discover nonlinear modes. Nonlinear feature engineering can prove profitable but is typically reliant on human intuition or expensive preprocessing. Kernel tICA integrates tICA and kernel trick to effect nonlinear discovery, but is computationally expensive and selection and tuning of the kernel limits its generalizability. Time-lagged autoencoders and variational dynamics encoders are neural networks that can identify the slowest mode but are unable to resolve higher-order modes. In this work, we introduce a sequential learning method that we term hierarchical dynamics encoder (HDE) as a novel neural network that sequentially learns hierarchical nonlinear slow CVs. Each CV is orthogonal to all previously learned CVs, and orthogonality is imposed naturally without regularization. We demonstrate HDEs for several toy systems where the true slow modes are known, and in simulations of peptides and proteins.

1:03PM B21.00008: Learning reaction coordinate on-the-fly for sampling complex biomolecular systems with SGOOP and metadynamics  DEBABRATA PRAMANIK (Presenter), Chemistry and Biochemistry and Institute for Physical Science and Technology, University of Maryland, College Park, USA, ADAM KELLS, Department of Chemistry, King's College London, United Kingdom, ZACHARY SMITH, Biophysics Program and Institute for Physical Science and Technology, University of Maryland, College Park, USA, PRATYUSH TIWARY, Chemistry and Biochemistry and Institute for Physical Science and Technology, University of Maryland, College Park, USA — Understanding functioning and stabilizing/destabilizing forces of biomolecules such as protein-ligand and protein-DNA are highly desirable due to implication in basic biology as well as diseases. Experiments can be useful in measuring various thermodynamic quantities, but they cannot, at least directly, provide microscopic details and kinetics, pathways etc. Here, we complement experiments with all-atom molecular dynamics (MD) simulations. Unfortunately MD is limited by a huge time scale problem. We attempt to solve it through developing sampling methods based on statistical mechanics and demonstrate progress on model systems and in ambitious systems such as protein-ligand interactions and transcription factor-DNA interactions. One of the specific issues we will address is the need to know beforehand an accurate reaction coordinate (RC), which is a challenge for any biased simulation. Recently, we have shown how to construct a 1-dimensional RC by a method called “spectral gap optimization of order parameters (SGOOP)”. Here we will show how to extend its scope by introducing a simple but powerful extension based on the notion of conditional probability factorization for systems with inherent complexity and where a 1-d RC is not enough to accurately capture the energy landscape.

1:15PM B21.00009: Understanding Binding Dynamics in Host-Guest Systems with Advanced Sampling Simulations  ANNE LEONHARD (Presenter), JONATHAN WHITMER, University of Notre Dame — Host-guest complexes are useful for applications in biomaterials science and engineering, including drug delivery, separations, transport regulation, and novel hydrogels. Highly-specific binding interactions are a key feature of such systems, and as such knowledge of systems' binding affinity, free energy landscapes, and binding pathways is critical. Here, we propose that advanced sampling techniques, such as the Adaptive Biasing Force and Artificial Neural Network methods, are promising ways to explore free energy landscapes of host-guest systems due to their ability to quickly sample the full phase space. We apply these methods to calculation of binding affinities between an array of small molecules and curcurbit[n]uril hosts. These binding affinities calculated with advanced sampling methods are compared to previously-published experimentally- and computationally-obtained values and obtain exceptional agreement with each. We also discuss how such methods might be generalized to more complex systems of interest in the biomolecular and materials simulations communities.
Ζ-Glycine: Insight into the Mechanism of a Polymorphic Phase Transition

CRAIG L. BULL, GILES FLOWITT-HILL, ISIS Neutron and Muon Source, STEFANO DE GIRONCOLI (Presenter), EMINE KUCUKBENLI, International School for Advanced Studies, SIMON PARSONS, The University of Edinburgh, CONG-HUY PHAM, International School for Advanced Studies, HELEN PLAYFORD, ISIS Neutron and Muon Source, MATTHEW G. TUCKER, Oak Ridge National Laboratory — Glycine is the simplest amino acid and a great test-bed for studying polymorphism in molecular crystals. With five phases having been structurally characterized at atmospheric or high pressure, it is a well-studied system both experimentally and theoretically. Yet a sixth form, the ζ phase, was discovered over a decade ago as a short-lived intermediate upon decompression of a high-pressure phase. However, its structure has remained unsolved despite several theoretical investigations to glycine polymorphism. We have recently reported [1] the structure of the elusive ζ phase, which was resolved thanks to the collaboration between crystal structure prediction procedure based on fully ab initio total energy calculations combined with a genetic algorithm, and neutron powder diffraction data obtained on a sample trapped at 100 K. Here we will discuss the approach that led to the successful theoretical prediction of this phase, the lessons that can be learnt and applied to similar systems, and mention remaining challenges for a predictive ab initio crystal structure prediction process.

A Climbing Multi-String Method to Map Free-Energy Saddles and Minima*

GOURAV SHRIVASTAV (Presenter), CAMERON ABRAMS, Department of Chemical and Biological Engineering, Drexel University — Finding stationary points, minima or saddles, on hyperdimensional free energy surface is crucial to gain insights about the possible transition events and to compute the associated transition rates. Though minima can be easily found, the tasks of locating saddles and measuring their energies relative to their associated minima remain challenging, especially in high-dimensional spaces. We propose here a modified climbing string method to locate multiple saddles by initiating multiple strings in one go. For a given minimum, strings propagate by gradient flow in the path space, with one end fixed and other end climbing across the free energy profile to locate a saddle. The convergence of multiple strings to a common saddle is avoided by checking repulsive forces between the climbing ends. The presence of multiple images along the string helps to ensure the direct connectivity between the minimum and saddles and to compute the free energy along the path. Hence, the climbing multi-string method can be used to map the network of directly connected stationary points in the free energy hypersurface. We demonstrate this method to locate saddle points in two-dimensional and four-dimensional free energy surface of alanine dipeptide and alanine tripeptide, respectively.

*NIH GM 100472.

Conformational free energy surface of cyclooctane from metadynamics in the collective variable space of autoencoder neural network*

BUMJOON SEO (Presenter), SEULWOO KIM, MINHWAN LEE, YOUNWOO LEE, WON BO LEE, Seoul National University — For rare event problems in which the important free energy basins are separated by large barriers, enhanced sampling methods provide the means to perform simulations within tractable timescales. Metadynamics simulation, which is one of the widely used enhanced sampling methods, requires the definition of a set of collective variables for accumulating the bias potentials. An important aspect of the collective variables is their dimensionality because the efficiency of the method decreases exponentially with the dimensionality. We present here a methodology of incorporating the codes from an autoencoder neural network as the collective variables for metadynamics simulations. This dimensionality reduction of an eight-dimensional space of dihedral angles into a three-dimensional space of features enables the computation of the conformational free energy surface of cyclooctane.

*This research was supported by Creative Materials Discovery Program through the National Research Foundation of Korea (NRF) funded by Ministry of Science and ICT (2018M3D1A1058624).
Disordered peptide chains in a coarse-grained model*  

MAREK CIEPLAK (Presenter), LUKASZ MIODUSZEWSKI, Institute of Physics, Polish Academy of Sciences — We construct a one-bead-per-residue coarse-grained dynamical model to describe intrinsically disordered proteins at significantly longer timescales than in the all-atom models. It yields structural results that are consistent with many all-atom and experimental data on these systems. We demonstrate that the geometrical properties of various homopeptides differ substantially in this model. The (breakable) contacts between the beads are determined during the course of the time evolution.\n

*Funded by the EU Joint Programme in Neurodegenerative Diseas project (JPND CD FP-668-059) through the NCN grant 2014/15/Z/NZ1/0037 (Poland)

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B22 DCOMP DMP DCP DBIO: Building the Bridge to Exascale: Applications and Opportunities for Materials, Chemistry, and Biology II

11:15AM B22.00001: Towards catalysis modeling with QMC*  
VIRAAJ JAYARAM (Presenter), University of Chicago, RYAN PEDERSON, LIANG LI, ANOUAR BENALI, YE LUO, MARIA CHAN, Argonne National Lab — Predictive modeling of catalytic processes on surfaces is challenging because of large uncertainties in computed energetics using density functional theory (DFT), and exponential dependence of catalyst performance on energies. In particular, the use of various DFT functionals and approximations results in qualitatively different results. The problem is compounded when treating transition metal oxides where a host of DFT errors persist. In this work, made possible by leadership scale high performance computers, we use quantum Monte Carlo (QMC) to determine the adsorption energies of the CO molecule on CuO (110) surface for various geometries determined by different DFT approximations. The relationships between geometry and energies, and between DFT and QMC results, will be discussed.

*An award of computer time was provided by the Innovative and Novel Computational Impact on Theory and Experiment (INCITE) program. This research used resources of the Argonne Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC02-06CH11357.

11:27AM B22.00002: Accelerating quantum Monte Carlo simulations on many-core processors via OpenMP nested threading*  
YE LUO (Presenter), Argonne National Laboratory —

The massively parallel nature of quantum Monte Carlo is ideally suited to petascale computers which have enabled a wide range of applications to relatively large molecular and extended systems. The current scheme to achieve the shortest time-to-solution is placing one walker per core on multi/many-core processors. However, this strategy meets a great challenge from upcoming Exascale computers where much larger problem will be solved. The time to advance a walker and the memory need of it scale cubically and quadratically as a function of the electron counts in the system. On current computers, large problems already force us to leave cores idle for fitting them in memory. In addition, adding more walkers reduces the production steps for a given amount of samples but do not reduce the equilibration steps, which causes even more waste. In order to reduce the time-to-solution and reduce the memory footprint, we introduce nested threading to distribute the computation of each walker over several cores. We explore threading algorithms with minimal overhead and demonstrate a good scaling.

*This research was supported by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of the U.S. Department of Energy Office of Science and the National Nuclear Security Administration.
11:39AM B22.00003: Structure and magnetism in bulk and uniaxially strained LaCoO$_{3-x}$ through ab-initio diffusion quantum Monte Carlo*  
KAYAHAN SARITAS (Presenter), JARON KROGEL, HO NYUNG LEE, FERNANDO REBOREDO, Materials Science and Technology Division, Oak Ridge National Laboratory — Advances in high-performance computing (HPC) is allowing the use of ambitious methods in materials science with unprecedented accuracy. Density Functional Theory (DFT) accuracy is not sufficient for challenging problems, as it depends critically on the empirical corrections applied, such as Hubbard-U and exchange mixing. For example, DFT has not yet been able to discern the microscopic origin of the ferromagnetic (FM) state in uniaxially strained LaCoO$_3$ thin films. In contrast, Diffusion quantum Monte Carlo (DMC) method treats electrons explicitly, solving the many-body Schrodinger equation with minimum approximations. DMC has been applied to an increasingly larger set of materials with excellent agreement. In this presentation, we report ground state energies, magnetism, defect formation energies in uniaxially strained LaCoO$_{3-x}$ using DMC. DMC yields an antiferromagnetic ground state for bulk uniaxially strained LaCoO$_3$ which agrees with the recent experiments. A transition between high-spin AFM and FM structures is also identified in the uniaxially strained structures, which may help explain the spin transition in thin films.

*The work was supported by the US Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

11:51AM B22.00004: Accelerating Large-Scale GW Calculations on Many-Core and Hybrid CPU+GPU HPC Systems*  
MAURO DEL BEN (Presenter), Lawrence Berkeley National Laboratory, FELIPE DA JORNADA, University of California at Berkeley and Lawrence Berkeley National Laboratory, ANDREW CANNING, Lawrence Berkeley National Laboratory, STEVEN G. LOUIE, University of California at Berkeley and Lawrence Berkeley National Laboratory, JACK DESLIPPE, National Energy Research Scientific Computing Center (NERSC), Lawrence Berkeley National Laboratory — The novel electronic and optical properties found in complex materials represent the basis for the development of many emerging technologies. The rational design of such technologies requires an accurate quantum mechanical predictive capability (e.g., the GW approximation within many-body perturbation theory and beyond) that can run in reasonable timescales on available high performance computing (HPC) facilities. In this talk we summarize the advances in method development and code optimization of the BerkeleyGW software package targeted for many-core and hybrid CPU+GPU architectures. In particular showing how we have combined methods to reduce the prefactor of the calculations with an optimal implementation suitable for many-core architectures which allowed us to achieve excellent parallel scalability (>500k cores), high fraction of peak performance and thus excellent time to solution for systems up to thousands of atoms. We show how these developments can be combined to take advantages of GPU accelerators.

*Work supported by the Center for Computational Study of Excited-State Phenomena in Energy Materials (C2SEPEM) at LBL, as part of the Computational Materials Sciences Program, funded by the U.S. DOE under Contract No. DE-AC02-05CH11231. Computational resources provided by NERSC.

12:03PM B22.00005: Large scale GW and BSE calculations using interoperable software building blocks*  
MARCO GOVONI (Presenter), Materials Science Division and Institute for Molecular Engineering, Argonne National laboratory, HE MA, NGOC LINH NGUYEN, University of Chicago, FRANCOIS GYGI, Computer Science, University of California Davis, GIULIA GALLI, University of Chicago — The modeling of light-matter interaction in complex heterogenous systems is key to several materials design problems. A microscopic modeling of two-particle correlation functions requires the solution of the Bethe-Salpeter equation (BSE) based on many body perturbation theory. However, the application of BSE-GW calculations to complex nanostructured, disordered or defective materials has been hindered by high computational costs. We present a method, implemented into interoperable software building blocks, to compute optical spectra and exciton binding energies based on the solution of the Liouville equation and the calculation of the screened Coulomb interaction in finite field. The method does not require the explicit evaluation of dielectric matrices nor of virtual electronic states, and can be easily applied to large systems, beyond the random phase approximation. Localized orbitals obtained from Bloch states using bisection techniques are used to reduce the complexity of the calculation and enable the efficient use of hybrid functionals. We will discuss the advantages of this paradigm, and provide results for the calculation of spectroscopic features of promising materials for spin qubits.

*This work was supported by MICCoM, as part of the CMS Program funded by the U.S. DOE.
12:15PM B22.00006: Pushing the Accuracy Limits of Scalable Fixed-Node Diffusion Monte Carlo for Noncovalent Interactions* MATUS DUBECKY (Presenter), Physics, University of Ostrava — Single-determinant (SD) fixed-node diffusion Monte Carlo (FNDMC) gains popularity as a benchmark tool scalable to large noncovalent systems although its accuracy limits are not yet fully mapped out. Some of the recent results suggest that accuracy of SD FNDMC is capable of achieving benchmark accuracy for a rich class of noncovalent systems, larger than expected before. The talk will summarize recent progress and current accuracy limits of bias-cancellation-based SD FNDMC for molecules and noncovalent crystals. The best available “recipe” suitable for a wide class of noncovalent systems will be sketched out.

*Financial support by Czech Science Foundation (18-24321Y) and University of Ostrava (UO, IRP201826) is gratefully acknowledged.

12:27PM B22.00007: Deep Machine Learning for Atomically-Resolved Imaging Experiments: Physics Extraction and Feedback* [Invited] MAXIM ZIATDINOV (Presenter), Oak Ridge National Laboratory — Development of the imaging tools such as electron, optical, and scanning probe microscopy in the last decade of 20th century has opened floodgates of imaging data, in the form of images, movies, and hyperspectral data sets. These contain information on the minute details of atomic structure and electronic, magnetic, and phonon functionalities, chemical transformation mechanisms, and quantum phenomena. However, the bottleneck in analysis and knowledge extraction from large volumes of raw imaging data is often human domain expert. Here I will show how utilization of deep artificial neural networks (aka deep learning) offers a path to overcome limitations of human analysis. I will specifically discuss applications of deep learning for rapid fully automated identification of individual atomic types and positions from scanning transmission electron microscopy images, using theoretical or labeled experimental images as a training set. We used this approach to construct reaction pathways for point defects in 2D materials, trace the structural evolution of atomic species during the electron beam manipulation, and create the library of defect configurations in silicon- and vacancy doped graphene. I will discuss specific examples where we showed that coupling of sulphur vacancy to molybdenum dopants in tungsten disulfide and reactions of silicon impurity on the edge and in the bulk of graphene can be explored quantitatively and mapped on the Markov model, giving rise to the transition probabilities on single atomic defect level. The work on genetic engineering optimization framework for automatic design of deep learning network architecture and hyperparameters optimal specifically for electron microscopy datasets will be addressed. Finally, I will discuss how a synergy of deep learning image analytics and real-time feedback allows harnessing beam-induced atomic and bond dynamics to enable direct atom-by-atom fabrication.

1:03PM B22.00008: Decoding Inverse Imaging Problems in Materials with Distributed Deep Learning* NOUAMANE LAANAIT (Presenter), ALBINA Y BORISEVICH, Oak Ridge National Laboratory, ALEXANDER SERGEEV, Uber Technologies, Inc., SEAN TREICHLER, NVIDIA Corporation, MICHAEL A. MATHESON, Oak Ridge National Laboratory — Materials physics abounds with challenging inverse problems, from inverse materials design to reconstruction of material properties from imaging/scattering data. One of the oldest inverse problems in materials is the reconstruction of the local atomic scattering potential from convergent beam electron diffraction (CBED). In this talk, we will present results on a potential reconstruction approach based on deep neural networks (DNN). In particular, we used data parallelism to distribute the training of a DNN over 12,000 GPUs on the Summit supercomputer. By efficient utilization of Summit’s burst buffer and half-precision arithmetics, the data processing rates of the DNN reached upwards of 100 GB/s, allowing for the processing of local CBED patterns from 60,000+ crystal structures in the matter of minutes. We will present challenges encountered in distributed training at these scales, such as I/O bottlenecks and DNN convergence and how they can be mitigated. Finally, initial results on our DNN-based reconstruction of local atomic potentials of strontium irridate superlattices will be presented.

ExaTN - A Scalable Exascale Math Library for Hierarchical Tensor Network Representations and Simulations

ExaTN is a math library of parallel numerical primitives for processing operations based on hierarchical tensor representations. Our library provides a scalable infrastructure for building a performance portable framework for simulating strongly correlated quantum systems on heterogeneous HPC platforms such as Titan and Summit. Our framework is the first to deliver a massively parallel implementation of the multiscale entanglement renormalization ansatz (MERA), a promising hierarchical tensor decomposition scheme capable of expressing local expectation values in strongly entangled quantum systems efficiently. In this talk, we will present our integrated framework for processing hierarchical tensor representations on exascale HPC systems via a multi-level asynchronous task-based programming model. This provides scientists with a capability for simulating strongly entangled systems in condensed matter physics.

2:03PM B22.00013: UV/vis absorption spectra database auto-generated for optical applications via the Argonne data science program*  EDWARD J. BEARD, Cavendish Laboratory, Department of Physics, University of Cambridge, GANESH SIVARAMAN (Presenter), ALVARO VAZQUEZ-MAYAGOITIA, VENKATRAM VISHWANATH, Argonne Leadership Computing Facility, Argonne National Laboratory, JACQUELINE M COLE, Cavendish Laboratory, Department of Physics, University of Cambridge — A large corpus of material and experimental data exists in historic scientific literature. Natural language processing and data-mining approaches can be applied to curated scientific literature to extract chemical information for targeted functionality and applications. This talk focuses on development of a UV/vis absorption spectra database by means of a complex quantum chemistry workflow built on the top of the ChemDataExtractor tool [1] by leveraging DOE Argonne leadership computing facilities as a part of the data science project allocation. We show results of retrieving chemical information and experimental properties from a large sample of scientific literature (~ 400,000) with chemdataextractor. Some electronic structure properties of a large subset of compounds are modeled using quantum chemistry workflows for benchmarking and validation. Finally, the quality of the database is discussed based on validation metrics and its applicability to optical applications.

*This research used resources of the Argonne Leadership Computing Facility, which is a DOE Office of Science User Facility supported under Contract DE-AC02-06CH11357.

Session B23 GIMS: Advances in Scanned Probe Microscopy I: Novel Approaches and Ultrasensitive Detection BCEC 158 - Tag(s): Focus

11:15AM B23.00001: Nanoscale magnetometry using scanning single spin quantum sensors [Invited]  RICHARD MALETINSKY (Presenter), University of Basel — tbd

11:51AM B23.00002: Three-dimensional AFM imaging of hydration and flexible surface structures at solid-liquid interfaces* [Invited]  TAKESHI FUKUMA (Presenter), Kanazawa University — At a solid-liquid interface, water interacts with a surface to present a non-uniform distribution referred to as hydration structure. In addition, if the surface consists of soft organic or biological molecules, the flexible surface structures often exhibit thermal fluctuations to present a three-dimensional (3D) distribution. These 3D hydration and flexible surface structures play critical roles in various interfacial phenomena such as protein folding, crystal growth, self-assembly, molecular recognition, metal corrosion, friction and anti-fouling. However, these 3D structures are hard to visualize by conventional imaging techniques. Here, we aim to solve this problem by 3D-AFM [1]. In 3D-AFM, a tip is scanned in vertical and lateral directions to cover the 3D interfacial space. During the scan, the tip interacts with the surrounding molecules so that the measured 3D force distribution shows molecular-scale contrasts reflecting the molecular distributions. So far, several groups have shown that the method can visualize 3D hydration structures on minerals (e.g. mica, calcite and fluorite) and biological molecules (e.g. bR, GroEL and DNA). In addition, it was shown that 3D-AFM can visualize 3D distribution of fluctuating molecules such as lipid headgroups at a membrane surface [2] and surfactants on an HOPG substrate. More recently, the possibility of visualizing 3D hydrations above heterogeneous structures such as point defects and complex minerals have been explored. Furthermore, there has been an attempt to visualize dynamic changes of the 3D hydration structures by improving the operation speed of 3D-AFM. In this study, we present an overview of these advanced 3D-AFM techniques and their applications.

12:27PM B23.00003: Single-atom nuclear magnetic resonance (NMR) using scanning tunneling microscopy*  

KAI YANG (Presenter), PHILIP WILLKE, YUJEONG BAE, IBM Almaden Research Center, ALEJANDRO FERRÓN, Universidad Nacional del Nordeste, JOSE LADO, ETH Zurich, ARZHANG ARDAVAN, University of Oxford, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory (INL), ANDREAS HEINRICH, Center for Quantum Nanoscience, Institute for Basic Science (IBS), CHRISTOPHER LUTZ, IBM Almaden Research Center — Nuclear spins are sensitive probes in chemistry and materials science as well as promising candidates for quantum information processing. Manipulating nuclear spins in condensed matter systems is difficult due to the small nuclear magnetic moment, leading to low polarizations, and addressing them individually is particularly challenging. Here, we demonstrate NMR of individual atoms on a surface in a scanning tunneling microscope (STM) [1]. To achieve NMR, we first polarize nuclear spins using spin-polarized tunneling current. By employing the flip-flop hyperfine interaction, the spin angular momentum of tunneling electrons is transferred to the nucleus. The nuclear polarization is controlled by the current, and read out by electron spin resonance [2, 3]. We further use NMR to sense the local magnetic environment of the electron spin of a single atom. The electrical polarization and driving of the nuclear spin states enable the local spin manipulation for nuclear spintronics and detection of the atomic-scale magnetic environment in nanomagnets.

12:39PM B23.00004: Downscaling of multiprobe STM experiments: towards atomic level understanding of transport phenomena*  

MAREK KOLMER (Presenter), WONHEE KO, AN-PING LI, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Multiprobe scanning tunneling microscopy (STM) based techniques allow determination of electronic and spin transport in variety of systems supported on surfaces of solid materials. Classical 2- and 4-probe methods are currently considered as universal tools for in-situ transport measurements on mesoscopic scales (typically hundreds of nanometers). Alternatively, application of scanning tunneling potentiometry (STP) visualizes potential change during such mesoscopic charge current transport with a nominal nanometer resolution. Here, on chosen examples we would like to discuss our efforts towards changing of this mesoscopic experimental paradigm by downscaling of 2-probe STM and STP experiments towards the atomic level. In this case the charge and spin current supplying probes are positioned in atomically defined locations with respect to the characterized nanosystem. In such configuration multiprobe techniques could directly visualize quantum nature of coherent carriers.

*Part of this work was conducted at the Center for Nanophase Materials Sciences (CNMS), which is a DOE Office of Science User Facility.

12:51PM B23.00005: Array atomic force microscopy for real-time multi-parametric analysis*  

QINGQING YANG (Presenter), Materials Science and Engineering, UC San Diego, QIAN MA, ZHAOWEI LIU, Electrical and Computer Engineering, UC San Diego, RATNESH LAL, Bioengineering, UC San Diego — Nanoscale multipoint structure-function analysis is essential for deciphering complexity of multiscale biological and physical system. Here, we describe a prototype of dispersive optics-based array AFM capable of simultaneously monitoring multiple probe-sample interactions in air and in liquid. A single supercontinuum laser beam is utilized to spatially and spectrally map multiple cantilevers, so that the beam deflection from individual cantilever can be isolated and recorded by distinct wavelength selection. This new design provides a remarkably simplified yet effective solution to overcome optical crosstalk, while maintaining high sensitivity and compatibility with probe-based sensors. We demonstrate the versatility and robustness of our system on parallel multi-parametric imaging, as well as monitoring live hearts cells intercellular activity. This approach provides new opportunities for studying emergent properties of atomic-scale mechanical and physicochemical interactions in a wide range of biological and physical networks.

*This work was supported by the National Institute on Aging of National Institutes of Health (Grant AG028709).
1:03PM B23.00006: Nanofabricated tips as a platform for double-tip and device based scanning tunneling microscopy
MAARTEN LEEUWENHOEK (Presenter), RICHARD NORTE, Delft University of Technology, KOEN BASTIAANS, DOOHEE CHO, IRENE BATTISTI, Leiden University, YAROSLAV BLANTER, Delft University of Technology, MILAN P ALLAN, Leiden University, SIMON GROEBLACHER, Delft University of Technology — We introduce a new kind of tip for scanning tunneling microscopy (STM) and report on its fabrication and performance [1]. By fully incorporating a metallic tip on a silicon chip using modern micromachining and nanofabrication techniques, we realize so-called smart tips and show the possibility of device-based STM tips. Contrary to traditional etched/grinded wire tips, these can be integrated in lithographically defined electrical circuits, photonic circuits and mechanical systems. We experimentally demonstrate the high performance of the smart tips, both in stability and resolution. In situ tip preparation methods are possible and we verify that they can resolve the herringbone reconstruction and Friedel oscillations on Au(111) surfaces. Smart tips can allow to considerably extend the range of STM, for example by enabling high-frequency tips to study noise on majorana zero modes and spin resonances, local gating using two tips or spin sensitive devices. As an example we present in detail two isolated tips with sub-50 nm apex-to-apex distance and calculations of how this can be used to measure electron correlations at the nanoscale.

1:15PM B23.00007: FEBID-grown iron and cobalt nanowires as magnetic force sensors*
HINRICH MATTIAT (Presenter), NICOLA ROSSI, BORIS GROSS, University of Basel, JAVIER PABLO-NAVARRO, CÉSAR MAGÉN, JOSE MARIA DE TERESA NOGUERAS, Physics, Universidad de Zaragoza, MARTINO POGGIO, University of Basel — Nanowires (NW) fabricated by focused electron beam induced deposition (FEBID) of magnetic materials such as iron and cobalt [1] are ideal candidates as magnetic force transducers [2]. The ability to produce nanometer-scale structures with extremely high aspect ratios should allow for magnetic probes with both high force sensitivity and fine spatial resolution. Here, we characterize the mechanical properties of magnetic FEBID-grown NWs using optical interferometry. Furthermore, we study their magnetic behavior through measurements of dynamic torque magnetometry [2]. Due to the large shape anisotropy, the equilibrium magnetization points along the NW, giving rise to a tiny magnetic monopole-like tip for magnetic force sensing. We confirm such behavior by scanning the NW over a micron-sized, current-carrying wire and recording its mechanical response driven by the Biot-Savart magnetic field. Our results, combined with ongoing progress in FEBID manufacturing of nanowires, hold great promise for new types of mechanical sensors for magnetic field imaging at the nanometer-scale.

1:27PM B23.00008: Imaging and Controlling Pseudospin and Berry Phase of Dirac Fermions by Symmetry-Assisted Coherent Scattering
YI-TING CHEN (Presenter), MORGAN BRUBAKER, HARI MANOHARAN, Stanford University — In lattice materials, the solution of the Schrödinger equation is a set of Bloch waves. The dispersion of these components defines the band structure and is crucial to electronic transport and thermodynamic properties. Scanning tunneling microscopy (STM) is a powerful tool to study electronic properties with exceptional spatial resolution. Because coherent scattering induced by impurities strongly depends on the band structure of a material, by imaging the pattern of coherent scattering, the band structure can be probed in momentum space as well. Using atom manipulation with STM, we show that the coherent scattering term can be separated from the non-scattering term. As a result, the contrast of the coherent scattering pattern is amplified and the details of the band structure of Dirac fermions in graphene, including complete Dirac cones and their trigonal warping, are revealed. Furthermore, by tuning the symmetry of the scattering center using atom manipulation, we show that pseudospin can be resolved and that a signature of the underlying Berry phase can be observed. The results indicate that the interplay of the symmetry of wave functions and that of a single scattering center provides a new way to image and control the internal degrees of freedom of quantum matter.

*Swiss NSF (200020-178863); ERC Starting Grant NWScan (334767).
1:39PM B23.00009: Using real space pseudopotentials to simulate non-contact atomic force microscopy images of organic molecules*  
DINGXIN FAN (Presenter), JAMES CHELIKOWSKY, University of Texas at Austin — Non-contact atomic force microscopy (nc-AFM) is a popular instrument to visualize the nano world with unprecedented resolution. nc-AFM, with a CO functionalized probe tip, can be used to distinguish different organic molecules, and serves as a very powerful analytical tool in organic chemistry research to identify the molecular structures of reactants, intermediates and products. However, a one-to-one mapping between the functional groups and nc-AFM images is often lacking. We employ a real-space pseudopotential method to simulate nc-AFM images and to provide a “database” for various functional groups, such as -C≡C-, -C=C-, and -C=O. We will also assess new functionalized tips by performing calculations to simulate nc-AFM images.

1:51PM B23.00010: Subtleties in the use of a quadrant cell photodiode in an optical lever*  
PAUL NAKROSHIS (Presenter), BENJAMIN MONTGOMERY, University of Southern Maine — Quadrant cell photodiodes are often used in an optical lever to deliver a digital “zero-crossing” signal (either for determining the period or for a static position signal). However, one can also continuously monitor the analog output of a quad-cell photodiode to determine time dependent positioning information (albeit over a narrow range). Unfortunately, the response of a quadrant cell photodiode to the passage of a gaussian laser beam is a non-trivial function of the beam radius. We have created a detailed (python based) computational model of a quadrant cell photodiode, and compared the model to experimental measurements. We remark the accuracy of the model as well as some important frequency spectrum implications of the detector response which are very relevant when analyzing the power spectrum of a quadrant cell signal.

*Funding for this work came from the University of Southern Maine.

Session B24 DAMOP: Open Quantum Systems BCEC 159 - Barry Sanders - Tag(s): Focus

11:15AM B24.00001: Dissipative quantum error correction and application to quantum sensing with trapped ions  
[Invited] FLORENTIN REITER, Harvard University, ANDERS SORENSEN, Niels Bohr Institute, PETER ZOLLER, University of Innsbruck, CHRISTINE MUSCHIK (Presenter), Institute for Quantum Computing — Quantum-enhanced measurements hold the promise to improve high-precision sensing ranging from the definition of time standards to the determination of fundamental constants of nature. However, quantum sensors lose their sensitivity in the presence of noise. To protect them, the use of quantum error correcting codes has been proposed. Trapped ions are an excellent technological platform for both quantum sensing and quantum error correction. Here we present a quantum error correction scheme that harnesses dissipation to stabilize a trapped-ion qubit. In our approach, always-on couplings to an engineered environment protect the qubit against spin- or phase flips. Our dissipative error correction scheme operates in a fully autonomous manner without the need to perform measurements or feedback operations. We show that the resulting enhanced coherence time translates into a significantly enhanced precision for quantum measurements. Our work constitutes a stepping stone towards the paradigm of self-correcting quantum information processing.
**11:51AM B24.00002: Analysis of matter-wave emission into a structured vacuum**  
MICHAEL STEWART (Presenter), JOONHYUK KWON, DOMINIK SCHNEBLE, Stony Brook University — Ultracold atoms in optical lattices realize a tunable open quantum system in the context of matter-wave emission into vacuum. Recent studies [1, 2] have demonstrated drastic departures from Markovian spontaneous emission into a vacuum near an energetic boundary, as well as the existence of a bound matter-wave and emitter state below it. In this talk we theoretically analyze the effects of introducing an emission vacuum with a band structure mirroring that of a photonic crystal. We find exotic decay dynamics arising from the analytic structure of the self-energy, including a beating between bound states at opposite edges of a band. The dynamic depends on the interplay between coupling strength and bandwidth, which can be easily tuned in the optical lattice platform.

**12:03PM B24.00003: Novel Entanglement-preserving approach for universal dissipation mechanisms in quantum nanophotonics**  
ZIHAO CHEN (Presenter), YAO ZHOU, JUNG-TSUNG SHEN, Electrical and System Engineering, Washington University in St. Louis — Ubiquitously in quantum nanophotonics, photons may be scattered off system impurities to the reservoir, or absorbed by reservoir degrees of freedom, which manifest as different dissipation mechanisms of scattering loss or material loss. Conventionally, fruitful density matrix approach (DMA) is adopted to study such effects, which averages out reservoir degrees of freedom in the reduced density matrix dynamics. While such an approach can incorporate the information that shuttles back and forth between system and reservoir, it does not preserve photon-photon entanglement in the system or the system-reservoir entanglement.

Here we present a novel wave-function-based approach that preserves the entanglement information, to study both dissipation mechanisms for an arbitrary photonic Fock state process. For the scattering loss scenario, when the dissipated photon does not return to the system, we show that the effects can be incorporated by using a reduced Hamiltonian description. For the material loss scenario, nonetheless, returning nature of dissipated photons fundamentally modifies multi-photon entanglement to invalidate the reduced Hamiltonian description. Moreover, our approach reveals how scattering matrix and transport properties are modified, which is beyond the scope of DMA.

---

**12:15PM B24.00004: Coherent frequency transfer of optical nonlinearities by feedback control of a non-degenerate optical parametric oscillator**  
EDWIN NG (Presenter), TATSUHIRO ONODERA, RYOTATSU YANAGIMOTO, HIDEO MABUCHI, Stanford University — Strong, coherent optical nonlinearities, such as those found in atom-cavity QED systems, are key resources for ultra-low-power optical information processing. However, such nonlinearities often arise from resonant effects occurring in a narrow band of frequencies, limiting their utility within heterogeneous networks of optical devices. At the same time, optical parametric oscillators (OPOs) are a robust platform for tunable light generation, converting pump light into signal and idler light at potentially vastly different frequencies. Here, we consider a coherent feedback scheme in which a narrowband nonlinear device, modelled as a Kerr cavity, is connected by an optical feedback loop to the signal port of an non-degenerate OPO below threshold. We use the SLH formalism to derive a rigorous input-output quantum model for this composite device, and we show by numerical simulation that the nonlinear input-output behavior of the Kerr cavity can be transferred to the idler port of the OPO, thus implementing a coherent transfer of the optical nonlinearity from one frequency to another.

326 of 3305
RENZO VILLAZON (Presenter), ANATOLI S POLKOVNIKOV, ANUSHYA CHANDRAN, Boston University — Fast forward protocols can be used to engineer rapid adiabatic processes by dynamically tuning available control parameters. For open systems, constructing local transitionless protocols can be a challenging task since one cannot access the bath degrees of freedom needed to prevent non-adiabatic excitations. We present a local fast forward protocol for a particle in a tunable harmonic potential coupled to a bath of optical phonons, which we treat microscopically without making the standard Markovian or Lindbladian approximations. This protocol can be experimentally realized by dynamically tuning the system’s frequency and driving its coupling to the environment with a high-frequency Floquet drive. We show that this protocol effectively implements a rapid isothermal process and apply it to realize a fast heat engine operating near the Carnot efficiency.

12:39PM B24.00006: Non-Gaussian quantum phenomena in synchronously-pumped optical parametric oscillator*  
TATSUHIRO ONODERA (Presenter), EDWIN NG, PETER MCMAHON, ALIREZA MARANDI, HIDEO MABUCHI, Stanford University — The synchronously-pumped optical parametric oscillator (SPOPO) below threshold has been engineered to generate multimode squeezing and entanglement among the various frequency components of the broadband pulses. A natural question to ask is whether new phenomena exist in the above-threshold regime of the SPOPO. To this end, we have developed a quantum input-output model of the SPOPO that is rigorously valid above threshold. In this model, we have found theoretical evidence of rich multimode non-Gaussian quantum phenomena such as the generation of multimode cat states, which can be engineered by designing the pump spectrum and dispersion of the SPOPO appropriately. We also showed that, consistent with classical intuition, field enhancement due to the localization of the pulse envelope in time enhances the effective nonlinearity by the (large) number of interacting modes. Because of this enhancement, we speculate that non-Gaussian states may be experimentally accessible in the future with near-term, on-chip photonic platforms, such as thin-film lithium niobate.

**This work has been supported by the NSF under award number PHY-1648807.

12:51PM B24.00007: Non-Markovian dynamics revealed at the bound state in continuum*  
SAVANNAH GARMON (Presenter), KENICHI NOBA, Osaka Prefecture University, GONZALO ORDONEZ, Butler University, DVIRA SEGAL, University of Toronto — We propose a methodical approach to controlling and enhancing deviations from exponential decay in quantum and optical systems by exploiting recent progress surrounding another subtle effect: the bound states in continuum, which have been observed in optical waveguide array experiments within this past decade. Specifically, we show that by populating an initial state orthogonal to that of the bound state in continuum, it is possible to engineer system parameters for which the usual exponential decay process is suppressed in favor of inverse power law dynamics and coherent effects that typically would be extremely difficult to detect in experiment. We demonstrate our method using a model based on an optical waveguide array experiment, and further show that the method is robust even in the face of significant detuning from the precise location of the bound state in continuum.

1:03PM B24.00008: Two-Photon Scattering in USC regime  VANESSA PAULISCH, Max-Planck-Institute of Quantum Optics, TAO SHI, Institute of Theoretical Physics, Chinese Academy of Sciences, JUAN JOSE GARCIA-RIPELL (Presenter), Institute of Fundamental Physics, CSIC — In this work we study the scattering of pairs of photons by a two-level system ultrastrongly coupled to a one-dimensional waveguide [1]. We describe this problem using a spin-boson model with an Ohmic environment \( J(\omega) = \pi \alpha \omega \). We show that when coupling strength lays is about \( \alpha \leq 1 \), the dynamics is well approximated by a polaron Hamiltonian, under the approximation of a conserved number of excitations. In this regime, we develop analytical predictions for the single- and two-photon scattering matrix computed with a Green's function method. These predictions are verified against time-evolved matrix-product-state simulations of propagating wavepackets interacting with a two-level system, showing the accuracy of the approximation. Our predictions for two-photon scattering can be verified using the scattering tomography techniques from Ref. [2].

1:15PM B24.00009: Bloch state scattering in the Brillouin zone*  LINDA E REICHL, MAX PORTER (Presenter), AARON BARR, ARIEL BARR, University of Texas at Austin — Systems with space-periodic Hamiltonians have unique scattering properties, just as time-periodic ones do. We use Wigner-Eisenbud (reaction matrix) scattering theory to consider a two-dimensional scattering system in which one dimension is a periodic lattice and the other is localized in space. The scattering and decay properties can then be described by sets of channels, where sets are indexed by Bloch momenta and channels within sets are indexed by incident waves' quantized kinetic energy parallel to the lattice. In the case where the lattice unit cell has reflection symmetry we find that the lattice can sustain formation of antisymmetric bound states in the continuum. Breaking the unit cell symmetry then causes those bound states to become quasibound and slowly decay. We also find in the lowest energy channel that reflection probability increases when varying Bloch momentum.

*The authors thank the Robert A. Welch Foundation (Grant No. F-1051) for support of this work.

1:27PM B24.00010: Emergent Finite Frequency Criticality of Driven-Dissipative Correlated Lattice Bosons  ORAZIO SCARLATELLA (Presenter), Institute de Physique Théorique-CEA/Saclay, Université Paris Saclay, France, Gif-sur-Yvette, ROSARIO FAZIO, ICTP, Italy, Trieste. NEST, Scuola Normale Superiore & Istituto Nanoscienze-CNR. Italy, Pisa., MARCO SCHIRO, Institute de Physique Théorique-CEA/Saclay, Université Paris Saclay, CNRS, France, Gif-sur-Yvette — Critical points and phase transitions are characterized by diverging susceptibilities, reflecting the tendency of the system toward spontaneous symmetry breaking. Equilibrium statistical mechanics bounds these instabilities to occur at zero frequency, giving rise to static order parameters. In this work we argue that a prototype model of correlated driven-dissipative lattice bosons, of direct relevance for upcoming generation of circuit QED arrays experiments, exhibits a susceptibility sharply diverging at a finite non-zero frequency, which is an emerging scale set by interactions and non-equilibrium effects. In the broken-symmetry phase the corresponding macroscopic order parameter becomes non-stationary and oscillates in time without damping, thus breaking continuous time-translational symmetry. Our work, connecting breaking of time translational invariance to divergent finite frequency susceptibilities, which are of direct physical relevance, could potentially be extended to study other time-domain instabilities in non-equilibrium quantum systems, including Floquet time crystals and quantum synchronization.

1:39PM B24.00011: Spectral Decomposition of Green's Functions of Open Quantum Systems  MARCO SCHIRO (Presenter), ORAZIO SCARLATELLA, Institute for Theoretical Physics, CEA Saclay, CNRS, AASHISH CLERK, Institute for Molecular Engineering, University of Chicago — We derive a Lehmann-style representation of spectral functions of Markovian driven-dissipative systems, and discuss how this can be employed to obtain physical intuition. Focusing on a specific model of a non-linear driven Kerr cavity, we discuss the connections between spectral functions changing sign and population inversion in the steady state. Surprisingly, we find that dissipation can change the sign of spectral functions, with direct physical implications, even in absence of steady state population inversion.
1:51PM B24.00012: Coarse-grained master equation is valid for a fast bath and any drive* EVGENY MOZGUNOV
(Presenter), USC — We compare three master equations: Davies-Lindblad, Redfield, and the recent Coarse-grained completely positive equation[1]. We note that the Redfield equation is valid for a fast bath regardless of the relative strength of the coupling to the system Hamiltonian. The main obstruction to using it is its non-positivity. We show how an attempt to make Redfield positive results in the Coarse-grained master equation. Our new derivation allows to estimate the error of the resulting completely positive equation. Much like Redfield, this equation is applicable for fast bath even if the system Hamiltonian is driven. We thus present a completely positive open system master equation that is a controlled approximation to true evolution for any time-dependence of the system Hamiltonian. The fast bath assumption includes any bath with time correlation function decaying faster than $1/t^2$ which is the case for the Ohmic bath. For Ohmic bath, equation is still applicable up to a large timescale.

2:03PM B24.00013: A solution ansatz for Lindblad master equation with a dynamical system theory approach* GEHAD SADIEK (Presenter), Department of Applied Physics and Astronomy, University of Sharjah, Sharjah 27272, UAE, ELSAYED I. LASHIN, Department of Physics, Ain Shams University, Cairo 11566, Egypt —

We study interacting quantum systems coupled to a dissipative Markovian environment. We use an ansatz for the solution of Lindblad master equation of the composite system, which splits the time evolution of the system into two parts, unitary evolution of the wave function of the free system and time evolution of the density matrix coefficients of the composite system mainly controlled by the Lindblad operators. We show that the obtained system of first order linear differential equations, autonomous or otherwise, governing the density matrix coefficients can be treated using the machinery of dynamical system theory to reveal all the information about the system dynamics and its asymptotic behavior, fixed points (steady states) and limiting oscillatory behavior (limit cycle), with minimal amount of work. For the sake of illustration, we apply this technique to an interacting spin-1/2 XXZ system coupled to a dissipative environment, which demonstrates the main aspects of the approach.

Session B25 DPOLY: Biopolymers and Sustainable Polymers BCEC 160A - Alexander Klotz, Massachusetts Institute of Technology

11:15AM B25.00001: Fabrication of Nano/micro-fiber Materials from Rigid Rod Peptide Chains via Electrospinning and Their Mechanical Properties* KYUNGHEE KIM (Presenter), CHRISTOPHER KLOXIN, University of Delaware, JEFFERY G SAVEN, University of Pennsylvania, DARRIN POCHAN, University of Delaware — Peptides are ideal candidates for the design and controlled assembly of nanoscale materials due to their potential to assemble with almost atomistic precision as in biological systems. The ability to create rigid rod chains composed of individual peptide bundles and to develop nano/microfibers containing the stiff chains offers the opportunity to develop unique structural features and a remarkable combination of high stiffness, high strength, large elasticity and elongation. This study is to facilitate nano/microfiber electrospinning, focusing on the use of synthetic peptides and to measure initial physical properties of peptide-based fibers. Computationally-designed peptides formed designed coiled coil bundles that serve as supramolecular monomers in chain formation. The bundle chains, or “bundlemers” display rigid-rod character due to intrabundle and interbundle physical and covalent interactions. The resultant rigid chains are employed to fabricate nano/micro-fibers via electrospinning. The mechanical properties of electrospun rod fibers are investigated as a function of bundlemer rod length, intra- or inter-chain interactions (both before and/or after electrospinning), and bundle type included in the bundlemer chains.

**11:27AM B25.00002: Self-Assembly of poly(D-glucose carbonate) Amphiphilic Block copolymers in Solution**

YOUNG LEE (Presenter), University of Delaware, KAREN L. WOOLEY, Chemistry, Texas A&M University, ARTHI JAYARAMAN, DARRIN POCHAN, University of Delaware — With a rising interest in developing and implementing more environmentally-friendly materials, the study of self-assembly behavior of a next generation natural-source based polymers is crucial. Sugar-derived poly(D-glucose carbonate) (PGC) amphiphilic block copolymers with targeted block compositions, chain lengths and side chain chemistries were synthesized. The bulk solution assembly behavior of PGCs was explored using a range of solvent environments (e.g. water-miscible organic solvent compositions or pH-induced structural transitions). The assembled nanostructure shows a morphological transition from a micellar to a fibrillar nanostructure that is dependent on parameters affecting the degree of side chain ionization. These findings allow us to discover a variety of robust nanostructures that can be achieved by non-traditional polymers and their potential to be used in many applications. Additionally, conformations of homopolymer PGC with different side chains were measured via small-angle neutron scattering (SANS) in an effort to better understand the assembly formation behavior of the PGCs when used as blocks in amphiphile creation. Finally, new efforts to correlate scattering, electron microscopy, and simulation data will be presented.

JOHN ATKINSON (Presenter), University of Guelph, JONATHAN NICKELS, University of Cincinnati, MICHELLE MICHALSKI, ADRIAN SCHWAN, University of Guelph, JOHN KATSARAS, Oak Ridge National Lab, JOHN DUTCHER, University of Guelph — Phytoglycogen is a polysaccharide produced in the form of compact nanoparticles by sweet corn. The nanoparticles have exceptional properties that emerge from their highly-branched, dendrimeric structure and their unique interaction with water, which makes them desirable as additives for applications in personal care, food and biomedicine. Our initial small angle neutron scattering (SANS) study on phytoglycogen nanoparticles [1] revealed unique insights into their structure and hydration. By hydrophobically modifying the hydrophilic nanoparticles, we can change the nature of their interactions in a tunable manner. Specifically, we modified phytoglycogen nanoparticles by covalently attaching octenyl succinate anhydride (OSA), for which the octenyl groups convey a hydrophobic character. We used small angle neutron scattering at the Oak Ridge National Laboratory to perform a comprehensive study of OSA-modified phytoglycogen with different degrees of substitution. We synthesized deuterated OSA (dOSA) and used dOSA-phytoglycogen and OSA-phytoglycogen in contrast series SANS experiments to create a comprehensive picture of the radial distribution of the OSA molecules on the phytoglycogen nanoparticles.

**11:51AM B25.00004: Binding of Proteins to Phytoglycogen Nanoparticles, a Novel, Sustainable, Soft Colloid**

KATHLEEN CHARLESWORTH (Presenter), AIDAN MAXWELL, JOHN DUTCHER, University of Guelph — Phytoglycogen is a glucose polymer that occurs naturally in the form of highly branched, compact nanoparticles. Because of their tree-like or dendrimeric structure, phytoglycogen nanoparticles have unique properties, such as a strong interaction with water and uniformity in size, which makes them attractive for use in applications ranging from cosmetics to drug delivery. Many of these applications rely on the binding of small molecules onto phytoglycogen nanoparticles. Surface Plasmon Resonance (SPR) is a sensitive experimental technique, based on the resonant absorption of light within an ultrathin gold film, that can be used to measure the binding kinetics and affinities of small molecules. I will discuss our success in creating a stable phytoglycogen-functionalized gold surface, which has allowed us to use SPR to quantify the binding of various proteins to the phytoglycogen nanoparticles.

**12:03PM B25.00005: Influence of poly(N-isopropylacrylamide) grafting density on the temperature dependent fibril formation of methylcellulose**

MCKENZIE COUGHLIN (Presenter), SVETLANA MOROZOVA, PETER SCHMIDT, S. PIRIL ERTEM, THERESA M. REINEKE, FRANK BATES, TIMOTHY LODGE, University of Minnesota — Methylcellulose (MC) is a water-soluble cellulose ether that is used in a variety of commercial products due to its thermoreversible gelation at ca. 60 °C, near the lower critical solution temperature (LCST) of MC. It is known that this gelation is caused by the formation of a fibrillar network upon heating. Recently, we demonstrated that the MC fibril structure can be modified and that the fibril formation can be suppressed by grafting short poly(ethylene glycol) (PEG) chains onto the MC backbone. With this new understanding, we have grafted poly(N-isopropylacrylamide) (PNIPAm) chains onto the MC backbone at various grafting densities; PNIPAm displays LCST behavior in water at ca. 32 °C. Utilizing static and dynamic light scattering, we characterize the chain conformation and variation in the overall radius of the chains as a function of grafting density and temperature. Small-amplitude oscillatory shear reveals changes in the gelation behavior and modulus of the two polymers. Fibril formation and fibril structure are studied using small-angle X-ray scattering and cryogenic transmission electron microscopy. The influence of PNIPAm grafts on the temperature dependence of MC fibril formation is compared with the results from PEG-grafted MC.
Correlation of Mechanical and Hydration Properties of Soft Phytoglycogen Nanoparticles

MICHAEL GROSSUTTI (Presenter), JOHN DUTCHER, University of Guelph — Phytoglycogen nanoparticles are highly-branched polymers of glucose that are produced as soft, compact nanoparticles by sweet corn. By combining the results of dialysis, ellipsometry and gravimetric analysis experiments, we have constructed a master plot of the osmotic pressure-concentration curve for phytoglycogen nanoparticles with values ranging over seven orders of magnitude. The distinctive shape of the osmotic pressure-concentration curve for phytoglycogen differs significantly from that of dextran, a lightly-branched polysaccharide that is chemically identical but does not occur in the form of particles. Specifically, there is a well-defined plateau in the logarithm of the osmotic pressure at phytoglycogen nanoparticle concentrations corresponding to contact between the particles. By recasting the dependence of the osmotic pressure on concentration in terms of its dependence on the effective separation of the particles, we identify three distinct regimes of interactions between the particles: a weak repulsion before contact; a stronger repulsion upon initial contact and compression (intermediate regime); and an even stronger repulsion for large particle compressions (concentrated regime). This analysis has allowed us to relate the mechanical stiffness to particle hydration.

Tensile properties for solid films of deoxyribonucleic acid containing hydrated ionic liquids

HISAO MATSUNO (Presenter), YUMA MORIMITSU, Kyushu University, NOBORU OHTA, HIROSHI SEKIGUCHI, Japan Synchrotron Radiation Research Institute, ATSUSHI TAKAHARA, KEIJI TANAKA, Kyushu University — Mechanical properties of deoxyribonucleic acid (DNA) solid films strongly depend on the water content; from glassy-like to rubbery-like via semi-crystalline-like. Also, the incorporation of intermolecular cross-linking between DNA strands impacts on them. These imply a possibility of DNA solids as an eco-friendly structural material. However, to accelerate such a trend, there exists a challenging problem that water evaporates from the film in a short time, causing a change of the mechanical properties. In this study, aggregation states and tensile properties of the DNA films containing a hydrated ionic liquid, choline dihydrogen phosphate (CDP), were studied. The stress-strain (S-S) curve was strongly dependent on the amount of CDP in the films. A 8-wt% CDP film behaved like a glassy polymer. As the CDP content increased, the shape of S-S curves changed to ductility-like or rubbery-like polymers. In the case of a 23-wt% CDP film, the yield stress decreased more strikingly and the clear strain hardening, like elastomers, was observed. Overall, the breaking point and energy increased, and the Young's modulus and yield stress decreased with increasing CDP amount. And also, these properties were maintained for more than several days because hydrated CDP could be hardly evaporated.
Early results showed more penetration of acetophenone into the LDPE when the positive electrode was on the acetophenone side. This suggests that acetophenone ionization and electrophoretic transport of the ions enhance acetophenone penetration. Ionization of the crosslinking byproducts and subsequent electrophoretic migration of the charges may be one reason for high local electric fields and ultimate dielectric failure.
1:51PM B25.00014: 1/f Noise in Solid-state Nanopore: Generation Mechanism and Prevention Methods  KAZUMA MATSUI (Presenter), YUSUKE GOTO, RENA AKAHORI, Hitachi, MICHIRU FUJIOKA, Hitachi High-Technologies, TAKESHI ISHIDA, TAKAHIDE YOKOI, ITARU YANAGI, KEN-ICHI TAKEDA, Hitachi — To realize DNA sequencing with solid-state nanopore, reduction of an ionic current noise is an important issue. Especially, low-frequency (1/f) noise causes a serious problem reducing read accuracy of DNA sequencing. Its origin has been heavily debated, but not yet clarified.

In this research, we found that 1/f noise is generated from the surface charge fluctuations due to an exchange reaction of alkali metal ions (M+) and protons (H+) on a nanopore wall. We hypothesized the charge fluctuations are dependent on the equilibrium constants of the reaction, and measured baseline current with various cations. Surprisingly, the order of 1/f noise intensity follows the theoretical one estimated from their equilibrium constants.

We also developed a new 1/f noise reduction method by suppressing the exchange reaction. The nanopore wall was coated with divalent cations, which lead to prevent the adsorption of other ions because those adsorption affinity is higher than other ions. As a result, we successfully and effectively reduced 1/f noise with this method.

2:03PM B25.00015: Elucidating the microstructural basis for the lasting radial strength of poly (L-lactide) bioresorbable vascular scaffolds during hydrolysis*  KARTHIK RAMACHANDRAN (Presenter), TIZIANA DI LUCCIO, ARTEMIS AILIANOU, Chemistry and Chemical Engineering, California Institute of Technology, MARY BETH KOSSUTH, JAMES PAUL OBERHAUSER, Global Product Development, Abbott Vascular, JULIE A KORNFIELD, Chemistry and Chemical Engineering, California Institute of Technology — Drug-eluting metal stents (DES) are the current standard-of-care for restoring blood flow through an occluded artery. However, DES are made from metal alloys that are non-biodegradable and consequently, inhibit arterial vasomotion and pose a risk of thrombosis, a dreaded complication. Bioresorbable vascular scaffolds (BVS) made from poly L-lactide (PLLA) are emerging as a promising alternative to permanent metal stents. The clinically-approved BVS (FDA-approval in 2016) supports the occluded artery for the requisite 3-6 months but is completely resorbed in 2-3 years. As a result, the BVS restores arterial vasomotion and can eliminate the late onset of thrombosis. The clinically-approved BVS presents a paradox as it hydrolyzes in the body – it suffers a ~40% decrease in molecular weight ($M_n$) but shows no decrease in radial strength. Using X-ray microdiffraction, we discovered that the BVS develops a unique microstructure in localized regions that make up <3% of the scaffold. These regions resist hydrolysis and reinforce struts in the BVS that are the most vulnerable to fracture. Thus, the global measure of degradation does not capture the presence of chains with $M_n$ higher than average in regions that have a disproportional impact on strength.

Session B26 DQI: Superconducting Circuits: Remote Entanglement and Waveguide QED

BCEC 160B - Mollie Schwartz, MIT Lincoln Laboratory

11:15AM B26.00001: Particle production in ultrastrong-coupling waveguide QED* NIGUEL GHEERAERT (Presenter), Néel Institute, CNRS and Université Grenoble-Alpes, XIN ZHANG, Department of Physics, Duke University, THÉO SÉPULCRE, Néel Institute, CNRS and Université Grenoble-Alpes, SOUMYA BERA, Department of Physics, Indian Institute of Technology Bombay, NICOLAS ROCHE, Néel Institute, CNRS and Université Grenoble-Alpes, HAROLD U BARANGER, Department of Physics, Duke University, SERGE FLORENS, Néel Institute, CNRS and Université Grenoble-Alpes — In recent years, the field of light-matter interaction has made a further stride forward with the advent of superconducting qubits ultra-strongly coupled to open waveguides. In this setting, the qubit becomes simultaneously coupled to many different modes of the waveguide, leading to a wealth of non-linear dynamical phenomena.

First, I will show how one can tackle the time-evolution of such a non-trivial system using a novel numerical technique based on an expansion of the full state vector in terms of multi-mode coherent states. Inspired by earlier semi-classical approaches, this numerically exact method provides an important advance compared to the state-of-the-art techniques that have been used so far to study the many-mode ultra-strong coupling regime.

I will then move on to present the central prediction of my work concerning the scattering of low-power coherent signals on a qubit. Most remarkably, I will show that the qubit non-linearity, transferred to the waveguide through the ultra-strong light-matter interaction, is able to split photons from the incoming beam into several lower-energy photons. This splitting leads to the emergence of a low-frequency continuum in the scattered power spectrum that dominates the inelastic signal.

Waveguide-mediated interaction of artificial atoms in the strong coupling regime, part 1

XUEYUE ZHANG (Presenter), EUN JONG KIM, MOHAMMAD MIRHOSSEINI, ALP SIPAHIGIL, Caltech, PAUL DIETERLE, Harvard University, ANDREW J KELLER, ANA ASENJO-GARCIA, Caltech, DARRICK CHANG, ICF, OSKAR PAINTER, Caltech — Embedding of multiple quantum emitters to a common one-dimensional radiation channel gives rise to emergent collective effects: collective emission and long-range exchange interaction. Collective emission leads to super- and sub-radiant states while the signature of exchange interaction, coherent cooperative dynamics, has been obscured by the radiative decay into the one-dimensional channel. In this work, we utilize the sub-radiant state to trap the radiation, acting as an atomic cavity, and strongly couple a probe quantum emitter to the sub-radiant state, effectively creating an atom-cavity system [New J. Phys. 15, 063003 (2012)]. We implement the scheme with transmon qubits coupled to a microwave coplanar waveguide. We discuss the building blocks and design of the qubit-waveguide system, and the characterization of individual waveguide-coupled qubits which highlights the requirements for observing coherent cooperative dynamics. arXiv:1809.09752

This work was supported by the AFOSR MURI Quantum Photonic Matter (grant FA9550-16-1-0323), the Institute for Quantum Information and Matter, an NSF Physics Frontiers Center (grant PHY-1125565).

Waveguide-mediated interaction of artificial atoms in the strong coupling regime, part 2

EUN JONG KIM (Presenter), XUEYUE ZHANG, MOHAMMAD MIRHOSSEINI, ALP SIPAHIGIL, Caltech, PAUL DIETERLE, Harvard University, ANDREW J KELLER, ANA ASENJO-GARCIA, Caltech, DARRICK CHANG, ICF, OSKAR PAINTER, Caltech — Photon-mediated interactions of quantum emitters in a one-dimensional radiation channel leads to collective emission and long-range exchange interaction. Observation of coherent cooperative dynamics via such interactions, however, has been obscured by radiative decay into the one-dimensional channel. Here, we employ transmon qubits and a microwave coplanar waveguide as artificial atoms coupled to a one-dimensional channel. We circumvent the radiative decay problem by utilizing the entangled dark state of a qubit array arising from collective waveguide emission. The entangled dark state, with a suppressed decay rate, effectively traps radiation as an atomic cavity while exhibiting a large exchange interaction rate with a designated probe qubit. We report the observation of coherent cooperative dynamics in the strong coupling regime and characterize the coherence properties of the collective states involved in the dynamics. In addition, we discuss potential applications of this platform and practical challenges in such systems. arXiv:1809.09752

Waveguide QED with a giant transmon

A.M. VADIRAJ (Presenter), C.W.S CHANG, IBRAHIM NSANZINEZA, CHRISTOPHER WILSON, Electrical and Computer Engineering, Institute for Quantum Computing, University of Waterloo — In a typical waveguide QED system, a quantum emitter, such as a superconducting transmon qubit, is coupled to a superconducting waveguide in order to study its interaction with the electromagnetic field. In these systems, the emitter is approximated as a point-like object when compared to the wavelength of light. However, recent experiments [1] demonstrated the ability to couple a transmon to surface acoustic waves (SAW) that have a wavelength much smaller than the transmon, thereby creating a “giant” artificial atom. Inspired by these results, there is a recent proposal [2] to couple a transmon at multiple points of a microwave waveguide, with wavelength-scale distances between each coupling point, also making a giant transmon. The proposal predicts the ability to custom design the relaxation rates of different transmon levels and proposes several interesting applications such as single-atom lasing and tunable coupling. We will present preliminary characterization of such a device.

Studying collective effects in 3D waveguide QED with frequency and time-domain resolved spectroscopy

ALEKSEI SHARAFIEV (Presenter), MATHIEU JUAN, Inst Quantum Optics & Quantum Info, MAXIMILIAN ZANNER, University of Innsbruck, JUAN JOSE GARCIA-RIPOLL, Institute of Polymer Science and Technology, Madrid, GERHARD KIRCHMAIR, University of Innsbruck — Collective behavior of coupled quantum emitters has been studied extensively theoretically starting from seminal Dicke's paper. Experimentally however many of the theoretical predictions have never been checked since it requires sophisticated experimental techniques. The recently appeared platform of 3D cQED offers unique opportunities in controlling independent qubits and their respective couplings control as well as long coherence times. We experimentally realized a system, which allows to investigate frequency chirping in a Dicke physics model, as well as to study cooperative behavior against collective noise and parameters spread. We study the system dynamics in frequency, as well as time-domain and compare it to theoretical predictions.
12:15PM B26.00006: Real-time detection of an itinerant microwave photon using dressed-state engineering* 
ZHIRONG LIN (Presenter), RIKEN and Shanghai Institute of Microsystem and Information Technology, SHUMPEI MASUDA, Tokyo Medical and Dental University, KUNIHIRO INOMATA, National Institute of Advanced Industrial Science and Technology, KAZUKI KOSHINO, Tokyo Medical and Dental University, TSUYOSHI YAMAMOTO, NEC Corporation, YASUNOBU NAKAMURA, The University of Tokyo — Several schemes for single microwave photon detection have been proposed and demonstrated lately in circuit quantum electrodynamics. However, all experimental demonstration to date are performed in the time-gated mode. In this presentation, we demonstrate a real-time detection of itinerant microwave photons. In our setup, a superconducting flux qubit is coupled to two resonators, which have substantial difference in the dispersive shifts. Under an adequate choice of the frequency and the power of the qubit drive, one resonator is used to form an impedance-matched Λ system that deterministically captures incoming photons, and the other is used for continuous monitoring of the event. We observe quantum jump produced by an itinerant microwave photon and attain a single-photon-detection efficiency of ~0.35. The detection efficiency of this detector is limited by the relatively short qubit relaxation time.

*This work was supported in part by JST ERATO (Grant No. JPMJER1601), JSPS KAKENHI (No. 16K05497, No. 26220601 and No. 18K03486), and ALS, The University of Tokyo.

12:27PM B26.00007: Quantum non demolition parity measurements of itinerant microwave fields 
JEAN-CLAUDE BESSE (Presenter), SIMONE GASPARINETTI, MICHELE COLLODO, ANTS REMM, CHRISTOPHER EICHLER, ANDREAS WALLRAFF, ETH Zurich — Capitalizing on recent demonstrations of quantum non demolition (QND) detection of individual itinerant microwave photons [1,2] we demonstrate parity measurements applied to input fields with photon number up to ten.

Defining a mode to be characterized by the temporal shape of a displacement field added onto it, we recover its Wigner function without making use of reconstruction or maximum likelihood methods. We present results of this phase space tomography method for propagating fields for various classical and quantum input fields.

The non demolition character of the measurement also allows for heralding highly non-classical states of light, such as multi-photon cat states, which are relevant for quantum information processing.

12:39PM B26.00008: Violating Bell’s Inequality with Remotely-Connected Superconducting Qubits* 
YOUPENG ZHONG (Presenter), HUNG-SHEN CHANG, University of Chicago, KEVIN SATZINGER, UC Santa Barbara; University of Chicago, MING-HAN CHOU, AUDREY BIENFAIT, CHRISTOPHER CONNER, ETIENNE DUMUR, JOEL GREBEL, University of Chicago, GREGORY A PEAIERS, UC Santa Barbara; University of Chicago, RHYS G POVEY, DAVID SCHUSTER, ANDREW N CLELAND, University of Chicago — Quantum communication relies on the efficient generation of entanglement between remote quantum nodes, due to entanglement's key role in achieving and verifying secure communications. Remote entanglement has been realized using a number of different probabilistic schemes, but deterministic remote entanglement has only recently been demonstrated, using a variety of superconducting circuit approaches. However, the deterministic violation of a Bell inequality, a strong measure of quantum correlation, has not to date been demonstrated in a superconducting quantum communication architecture, in part because achieving sufficiently strong correlation requires fast and accurate control of the emission and capture of the entangling photons. Here we present a simple and robust architecture for achieving this benchmark result in a superconducting system.

This work was partially supported by the UChicago MRSEC (NSF DMR-1420709) and made use of the Pritzker Nanofabrication Facility, which receives support from ShyNE, a node of the National Science Foundation’s National Nanotechnology Coordinated Infrastructure (NSF NNCI-1542205).
12:51PM B26.00009: Microwave remote state preparation vs. quantum cryptography

FRANK DEPPE (Presenter), KIRILL FEDOROV, STEFAN POGORZALEK, MINGXING XU, QU-MING CHEN, MICHAEL FISCHER, MICHAEL RENGER, EDWAR XIE, Walther-Meißner-Institut & Physik-Department, Bayerische Akademie der Wissenschaften & Technische Universität München, ACHIM MARX, Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, RUDOLF O GROSS, Walther-Meißner-Institut & Physik-Department, Bayerische Akademie der Wissenschaften & Technische Universität München — Quantum communication protocols employ nonclassical correlations as a resource for an efficient transfer of quantum states [R. Di Candia et al., EPJ Quantum Technol. 2, 25 (2015)]. As a fundamental protocol, remote state preparation (RSP) aims at the preparation of a known quantum state at a remote location using classical communication and quantum entanglement. In our experiment, we use flux-driven Josephson parametric amplifiers and linear circuit elements to generate propagating two-mode squeezed (TMS) microwave states acting as quantum resource [K. G. Fedorov et al., Phys. Rev. Lett. 117, 020502 (2016); K. G. Fedorov et al., Sci. Rep. 8, 6416 (2018)]. Combined with a classical feedforward, we use these TMS states to remotely prepare single-mode squeezed states. Furthermore, we analyze the consumption of quantum discord in our experiment and interpret our results in the framework of a quantum cryptographic protocol analogous to the Vernam cipher.

1:03PM B26.00010: Generating Non-Classical and Spatially-Correlated Photons in a Waveguide QED Architecture

BHARATH KANNAN (Presenter), DANIEL CAMPBELL, RONI WINIK, Research Laboratory of Electronics, Massachusetts Institute of Technology, DAVID K KIM, ALEXANDER MELVILLE, BETHANY M NIEDZIELSKI, JONILYN L YODER, MIT Lincoln Laboratory, Massachusetts Institute of Technology, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, WILLIAM D OLIVER, Department of Physics, Research Laboratory of Electronics, MIT Lincoln Laboratory, Massachusetts Institute of Technology — In waveguide quantum electrodynamics (wQED), atoms interact with a guided continuum of photonic modes. These systems can serve as a platform to study exotic radiation phenomena. The electrical distance between atoms along the waveguide is controllable by tuning the frequency, and thus the wavelength, of light emitted from the atoms. This enables the exploration of a wide variety of radiation phenomena. In this work, we experimentally study devices with multiple superconducting transmon qubits that are strongly coupled to a one-dimensional co-planar waveguide. We present experimental results demonstrating the generation of non-classical and spatially correlated photons in a wQED setting.

1:15PM B26.00011: Quantum Communication with Microwave Photons

ANDREAS WALLRAFF (Presenter), ETH Zurich — Sharing information coherently between physically separated chips in a network of quantum computers could be an essential element for realizing a viable quantum information processing system. A direct, deterministic quantum channel may be advantageous both for larger scale fault-tolerant or non-error-corrected quantum processors realizing universal quantum computation or solving noisy intermediate-scale quantum (NISQ) problems. We implement a deterministic state transfer and entanglement protocol between individually packaged chips connected by coaxial lines [1]. Individual chips may serve as universal nodes capable of sending, receiving, storing, and processing quantum information. Our protocol is based on an all-microwave process, which entangles or transfers the state of a superconducting qubit with a time-symmetric itinerant single photon. We transfer qubit states at rates of 50 kHz, absorb photons at the receiving node with a probability of 98 %, achieve a transfer process fidelity of 80 %, prepare on demand remote entanglement with a fidelity of 79 % and show that time bin encoding can be used to further improve these metrics.

**1:27PM B26.00012: Raman Transitions between two Superconducting Cavity Modules via Parametric Conversion:**

**Part I** JAMES TEOH (Presenter), LUKE BURKHART, CHRISTOPHER J AXLINE, YAXING ZHANG, LUIGI FRUNZIO, MICHEL H. DEVORET, STEVEN GIRVIN, LIANG JIANG, ROBERT J SCHOELKOPF, Yale Univ — We investigate a simple quantum network capable of state transfer and entanglement between superconducting 3D cavities in two spatially separated modules. Bidirectional communication between the cavity modes is established by coupling each cavity to the same standing-wave mode of a superconducting coaxial cable via parametric conversion. The system can be made robust to loss in the cable by using off-resonant conversion to engineer a virtual Raman transition between the three modes (cavity-cable-cavity), which suppresses the population of the lossy cable mode. Preliminary experimental results regarding state transfer will be discussed.

*This work is supported by US Army Research Office grant W911NF-18-1-0212

---

**1:39PM B26.00013: Raman Transitions between two Superconducting Cavity Modules via Parametric Conversion:**

**Part II** LUKE BURKHART (Presenter), JAMES TEOH, CHRISTOPHER J AXLINE, YAXING ZHANG, LUIGI FRUNZIO, MICHEL H. DEVORET, STEVEN GIRVIN, LIANG JIANG, ROBERT J SCHOELKOPF, Yale Univ — Entanglement generation between modules in a quantum network allows for gates between qubits in separate modules. A partial swap of population between two modes can be used to generate entanglement. We engineer such an entangling operation with a virtual Raman transition via a standing-wave mode of a coaxial cable. Preliminary results towards generating on-demand entanglement between two modules will be shown. Schemes for improving the entanglement by making use of multiphoton quantum states will be discussed.

*This work is supported by US Army Research Office grant W911NF-18-1-0212.

---

**1:51PM B26.00014: Generation of a microwave time-bin qubit with a superconducting qubit** JESPER ILVES (Presenter), SHOTA YAMAZAKI, SHINGO KONO, YOSHIKI SUNADA, MINKYU KIM, The University of Tokyo, KAZUKI KOSHINO, Tokyo Medical and Dental University, YASUNOBU NAKAMURA, The University of Tokyo — Quantum information can be encoded in a propagating photonic qubit by constructing a set of computational basis states with one or more modes of light. This encoding scheme defines the characteristic properties of the qubit such as its decoherence properties and how it retains phase information. By encoding the qubit in a basis constructed from two orthogonal temporal modes, as a time-bin qubit, it is possible to detect and correct photon decay during information transfer with a parity measurement. We experimentally demonstrate a protocol for deterministic on-demand generation of a time-bin qubit in the microwave regime through microwave-driven coherent control of a transmon qubit placed in a three-dimensional cavity. To perform quantum state tomography on a prepared time-bin qubit state, we apply iterative maximum likelihood estimation on time-bin encoded single-photon signal squeezed in different quadratures. We also discuss different factors affecting the time-bin qubit state preparation fidelity. Our protocol can be used as a means of realizing robust information transfer in quantum networks.

---

**2:03PM B26.00015: Time-Bin Entanglement Between Remote Superconducting Cavities** EVAN ZALYS-GELLER (Presenter), PHILLIPE CAMPAGNE-IBARCQ, ANIRUDH NARLA, SHYAM SHANKAR, Yale Univ, CHRISTOPHER J AXLINE, ETH Zurich, LUKE BURKHART, Yale Univ, WOLFGANG PFAFF, Microsoft, LUIGI FRUNZIO, ROBERT J SCHOELKOPF, MICHEL H. DEVORET, Yale Univ — Generation of entanglement between qubits connected by a lossy channel is an important primitive for large scale quantum information processing. Time-bin entanglement allows one to counter this imperfection through detection of photon loss errors in the channel. We present an experiment for time-bin entanglement between remote superconducting cavities. Stimulating a particular three-body Raman transition performs an entangling gate between a flying photon, target system, and an ancillary mode used as an entanglement witness. This ancillary mode, equivalent to a photon detector, is used to herald success of the protocol. The success rate of this protocol is expected to reach the transmission of the channel. Through local measurement of the ancillary modes, we can detect photon loss errors in the channel and herald the creation of an entangled Fock state between the remote cavities. We discuss experimental progress towards the implementation of this protocol.

**Monday, March 4, 2019 11:15 AM - 2:15 PM**

**Session B27 DQI: Superconducting Circuits: Quantum Simulations and Many-Body Physics** BCEC 160C
Predicting the dynamics of quantum systems is a primary example of an intensive computational task that could be efficiently solved with a near term quantum computer. To pursue this goal, we have fabricated a 9-qubit linear chain device made of superconducting circuits with nearest neighbor couplings. Our device is unique because it features frequency tunable qubits and an adjustable inter-qubit coupling strength, making it well suited to the simulation of quantum systems. We use the device to generate high-fidelity, multi-qubit, analog dynamics evolving under a Bose-Hubbard Hamiltonian. In this talk, we discuss the calibration of this device for quantum simulation. Once calibrated we use this device to probe the basic physics of thermalization. Specifically, we use transport measurements to distinguish localized and diffusive behavior. To complement this, we use echo techniques to characterize the propagation of entanglement in these regimes. This shows qualitative differences between how energy and entropy flow in the system.

The rich physics of strongly-correlated quantum materials can be explored in synthetic systems built with microwave photons in superconducting circuits in the circuit QED paradigm. However, the intrinsic loss in photonic platforms makes many-body quantum state preparation a challenge. We build a 1D Bose-Hubbard lattice for photons where capacitively coupled transmon qubits serve as lattice sites, and the transmon anharmonicity corresponds to strong photon-photon interaction. We employ an engineered reservoir to realize a dissipatively stabilized site and couple it to the lattice to stabilize a n=1 Mott insulator. Site-resolved microscopy allow detailed studies of the thermalization process through the dynamics of defect propagation and removal in the Mott phase. By probing two-site correlations, we could investigate the emergence of correlations and entanglement in these driven-dissipative systems.

Encoding quantum information in the higher energy levels of the transmon circuit provides a hardware efficient way to harness a larger Hilbert space in existing quantum processors while also increasing their connectivity. Furthermore, a network of qutrits (three-level systems) is naturally suited to experimentally demonstrate recently identified connections between high energy physics and quantum information, such as holographic quantum error correction codes and the physics of scrambling. Here we report on the control of a five-qutrit processor and our progress toward characterizing the scrambling of quantum information. We implement a circuit to measure the decay of out-of-time ordered correlators, a hallmark of scrambling, in a method that distinguishes between decoherence and scrambling. The same circuit can be viewed as a teleportation protocol where quantum information is scrambled by a black hole and then decoded through measurement of emitted Hawking photons.

This work was supported by the Army Research Office and the Department of Energy.

The field of circuit QED has emerged as a rich platform for both quantum computation and quantum simulation. Lattices of coplanar waveguide (CPW) resonators realize artificial photonic materials in the tight-binding limit. In combination with qubit-mediated photon-photon interactions, these systems can be used to study dynamical phase transitions and many-body phenomena in driven-dissipative systems. In this talk, we will show how graph-theory and graph-level operations can be used to tailor the single-particle band structures of such systems. In particular, we will show that the process of taking a line graph produces controllably gapped flat bands at −2 and that subdividing all graph edges produces Dirac cones from formerly quadratic band edges and chiral flat bands at zero energy.

12:03PM B27.00005: Tunable-profile qubit-photon bound state interactions with superconducting circuits*  
BASIL SMITHHAM (Presenter), Princeton University, NEEREJA SUNDARESAN, IBM T.J. Watson Research Center, PRZEMYSLAW BIENIAS, REX LUNGDREN, QI/QuICS NIST/University of Maryland, College Park, ALEXEY V GORSHKOV, QI/QuICS NIST/University of Maryland, College Park, ANDREW HOUCK, Princeton University — Strongly coupling qubits to the band edge of a photonic crystal results in the formation of qubit-photon dressed bound states. The photonic components of these bound states are exponentially localized around the qubit positions and represent the inter-bound state interaction profiles. Tunability of the exponential localization length of bound state interactions has been experimentally demonstrated in superconducting circuits of two transmons coupled to a microwave photonic crystal [1]. To expand the range of 1D quantum models that can be probed with qubits coupled to photonic crystals, proposals have been put forth to engineer non-exponential interaction profiles by further dressing the systems with external driving fields [2]. We present experimental progress towards characterizing the effective bound states of transmons coupled to photonic crystals driven by auxiliary microwave tones. By driving the photonic crystal with multiple tones we aim to engineer non-exponential effective interactions, with the goal of accessing a broader class of tunable spin models.

12:15PM B27.00006: Emulating Majorana Fermions Using Transmon Qubits with Application to Topological Quantum Computing  
ALIREZA NAJAFI-YAZDI (Presenter), Anyon Systems Inc — Majorana Fermions are fermionic modes with non-abelian dynamics and are of significant interest to realize topologically protected quantum processors. There have been significant efforts by the community to realize the Majorana modes in solid-state devices. Despite significant progress, fabricating and operating a Majorana qubit has proven to be extremely challenging.

In this talk, we propose a different approach: instead of trying to realize Majorana modes in solid-state systems such as Superconducting/Semiconducting nanowires, we propose to engineer an array of transmon qubits to realize a meta material with Majorana modes. We will present an example design of such system, the chip layout, as well as discuss braiding, fusion, and readout schemes. We will also discuss intricacies and constraints associated with practical device fabrication procedures.

12:27PM B27.00007: High coherence quantum simulation of coherent backscattering in an effective two-level system composed of two superconducting qubits*  
ANA GRAMAJO (Presenter), Research Laboratory of Electronics, Massachusetts Institute of Technology, Bariloche Atomic Center, DAN CAMPBELL, BHRAT KANNAN, Research Laboratory of Electronics, Massachusetts Institute of Technology, DAVID K KIM, ALEXANDER MELVILLE, MIT Lincoln Laboratory, BETHANY M NIEDZIELSKI, Department of Physics, Massachusetts Institute of Technology, JONILYN L YODER, MIT Lincoln Laboratory, DANIEL DOMÍNGUEZ, MARÍA JOSÉ SÁNCHEZ, Balseiro Institute, Bariloche Atomic Centre, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, WILLIAM D OLIVER, Research Laboratory of Electronics, MIT Lincoln Laboratory, Department of Physics, Massachusetts Institute of Technology — In a recent experiment by Gustavsson et al. [1], a superconducting flux qubit was used to model scattering events using multiple Landau-Zener transitions by driving the qubit periodically back and forth through an avoided crossing. In highly coherent systems, time-reversal symmetry in the driving field should give rise to a dip in the average transition rate (averaged over many quantum trajectories), by analogy with weak localization in condensed matter systems. We experimentally emulate the scattering events with multiple Landau-Zener transitions in an effective two-level system, seeking to demonstrate the theoretically predicted weak localization phenomenon in this system, Ferrón et al. [2]. The effects of system-bath coupling are accurately simulated by a Floquet-Markov master equation.

12:39PM B27.00008: Demonstration of a non-stoquastic Hamiltonian in coupled superconducting flux qubits

ISIL OZFIDAN (Presenter), CHUNQING DENG, MOHAMMAD AMIN, ANATOLY SMIRNOV, TREVOR LANTING, D-Wave Systems —
Currently available quantum annealers (QA) provide solutions to the transverse field Ising model with thousands of magnetically coupled qubits. To achieve a non-stoquastic Hamiltonian with QA, coupling via two canonically conjugate (orthogonal) degrees of freedom is necessary. Furthermore this orthogonal coupling can potentially enhance the performance of QA processors and enable an extended range of quantum simulations. Here we present one- and two-qubit microwave spectroscopy as well as time evolution measurements on two superconducting flux qubits coupled via two orthogonal degrees of freedom, charge and flux. We show that the electrostatic interaction, realized through a coupling capacitor, produces $\sigma_y\sigma_y$ coupling in the computational basis and leads to broken gauge invariance. We also observe emergence of $\sigma_x\sigma_x$ coupling through higher energy states of each rf-SQUID. Finally, we show that the reduced two qubit Hamiltonian is nonstoquastic across a wide range of parameters.

12:51PM B27.00009: Metamaterial Slow-Light Waveguide for Finite Range Interactions and Non-Markovian Dynamics with Superconducting Qubits*

VINICIUS FERREIRA (Presenter), JASH BANKER, MOHAMMAD MIRHOSSEINI, ALP SIPAHIGIL, OSKAR PAINTER, Applied Physics and Material Science, Caltech — The ability to engineer the dispersion of light through subwavelength patterning of bulk materials has been a powerful tool for studying the influence of novel electromagnetic environments on light-matter interactions. Here, we present the experimental realization of an on-chip superconducting metamaterial waveguide composed of an array of coupled resonators of subwavelength size and negligible frequency disorder. By matching the array boundaries to 50Ω coplanar waveguides, our design achieves an 80MHz bandwidth photonic channel with nearly constant group index of ~650, as well as extinction of more than 70dB outside of the passband. Coupling transmon qubits to this metamaterial allows us to study non-Markovian dynamics of a single qubit's interaction with the photonic bath, as well as collective non-Markovian dynamics of multiple qubits. Moreover, far from the passband, we can dynamically measure finite-range qubit-qubit interactions that extend beyond nearest neighbor and depend on detuning from the bandedge. We thus establish our metamaterial design as an attractive platform for studying photon-mediated non-Markovian dynamics and quantum many-body physics.

1:03PM B27.00010: Roadmap to a superconducting quantum many body simulator

YARIV YANAY (Presenter), Laboritory for Physical Sciences, DANIEL CAMPBELL, JOCHEN BRAUMÜLLER, Massachusetts Institute of Technology, WILLIAM D OLIVER, Massachusetts Institute of Technology and MIT Lincoln Laboratory, CHARLES TAHAN, Laboratory for Physical Sciences — A superconducting circuit constructed from a repeating pattern of identical unit cells comprising qubits or resonators can be used to simulate a quantum many body system of spins or bosons. While single or few qubit systems have been repeatedly demonstrated in the last few years, the majority of those require tuning each individual qubit frequency through individual control lines. Here, we propose how a larger two-dimensional system can be realized with far fewer control lines by focusing on qubit designs that can be uniformly fabricated, with deviation from the design frequency acting as disorder. We examine the operating regimes for such a system and the required fabrication accuracy, as well as readout and control schemes. We discuss how a such a superconducting system could be prepared in non-thermal states in different parts of the many-body spectrum, and consider what observables could be accessed and whether they could be used to test assumptions on entanglement entropy and eigenstate thermalization in 2D systems.

1:15PM B27.00011: Synthetic quantum materials in superconducting circuits*

RUICHAO MA (Presenter), BRENDA SAXBERG, CLAI OWENS, JONATHAN SIMON, DAVID SCHUSTER, University of Chicago — Superconducting circuits have emerged as a competitive platform for quantum computation, satisfying the challenges of controllability, long coherence and strong interactions. Here we apply this toolbox to the exploration of strongly correlated quantum matter, building a Bose-Hubbard lattice for photons in the strongly interacting regime. We develop a versatile recipe for the dissipative preparation of incompressible many-body phases through reservoir engineering and apply it in our system to realize the first Mott insulator of photons. Site- and time-resolved readout of the lattice allows microscopic observation of the lattice dynamics. The low entropy Mott state can serve as a starting point for studying other strongly correlated phases, e.g. a Tonks-Girardeau gas of interacting defects. The dissipative preparation demonstrated in this work also enable future exploration of elusive interacting topological phases.

1:27PM B27.00012: Time-Resolved Measurements of Energy Transport in a System of Coupled Superconducting Qubits Inspired by Simulations of Photosynthetic Processes  GRAHAM J. NORRIS (Presenter), ANTON POTOČNIK, MICHELE COLLODO, ABDULKADIR AKIN, SIMONE GASPARINETTI, CHRISTOPHER EICHLER, ANDREAS WALLRAFF, Department of Physics, ETH Zurich — Engineered quantum systems have recently found application as a test-bed for answering open questions about energy transport in complex open quantum systems such as photosynthetic systems. Using a circuit incorporating three superconducting transmon qubits, we simulate energy transport with electron-phonon interactions, where we emulate longitudinal coupling to different types of phononic baths by applying engineered flux noise to the qubits. Previously, we considered the effects of noise on energy transport efficiency in steady-state measurements under continuous driving [1]. To study the transport of single photons, we now switch to pulsed excitations and time-resolved measurements. We verify the quantum nature of the excitations transported through the system in anti-bunching measurements, showing second-order correlation functions with \( g^{(2)}(0) < 0.05 \), observe coherent oscillations of the emitted power indicative of static coherence, and study the efficiency of transport as a function of noise type.

1:39PM B27.00013: Quantum impurity in a 1D photonic crystal* ANDREI VRAJITOAREA (Presenter), Princeton University, REX LUNDGREN, YIDAN WANG, PRZEMYSŁAW BIENIAS, ALEXEY GORSHKOV, JQI-NIST, ANDREW HOUCK, Princeton University — Quantum impurity problems are described in terms of a single quantum-mechanical degree of freedom interacting with a dissipative reservoir. Superconducting circuits offer an ideal platform for studying the quantum dynamics of artificial atoms embedded in the electromagnetic continuum of a one-dimensional waveguide, reaching non-perturbative coupling regimes in the spin-boson model for an ohmic bath. Parallel experiments have explored transmon qubits strongly coupled to a photonic crystal, where the impurity hybridizes with the band structure resulting in a photonic bound state inside the gap. In this talk we present recent efforts in further pushing the coupling strength with the stepped impedance microwave crystal, using an artificial atom with a large magnetic moment, the fluxonium circuit. The goal of this experiment is to explore how photon scattering inside the waveguide is influenced by the significance of counter-rotating coupling terms and by the nonlinear photon dispersion in the crystal.

1:51PM B27.00014: Quantum impurity physics simulation with superconducting circuits I: perturbative regime NITISH JITENDRAKUMAR MEHTA (Presenter), ROMAN KUZMIN, NICHOLAS GRABON, RAY MENCIA, VLADIMIR MANUCHARYAN, University of Maryland, College Park — We report our progress in the field of quantum impurity simulations with superconducting circuits. Our simulator consists of a split Josephson junction terminating a high-impedance transmission line, which is made of a linear chain of up to 40,000 junctions [1,2]. In part I, we start with a relatively large area split-junction, such that its quartic anharmonicity can be treated as a perturbation. In this regime, the system is well-described by a Caldeira-Leggett model of a quantum degree of freedom interacting with an Ohmic bath. The interaction effects are revealed through the measurement of the frequency shifts of over 100 discrete modes of the bath. In part II, we explore small-area impurity junction where the non-linearity is non-perturbative. Now the system can be described by a boundary sine-Gordon quantum impurity model. It is expected that inelastic scattering of single photons becomes the dominant photon loss mechanism, with the loss frequency dependence containing information on the many-body correlation functions. We will present the measurements at various line impedances and impurity parameters.

2:03PM B27.00015: Quantum impurity physics simulation with superconducting circuits II: many-body regime ROMAN KUZMIN (Presenter), NITISH JITENDRAKUMAR MEHTA, NICHOLAS GRABON, RAY MENCIA, VLADIMIR MANUCHARYAN, University of Maryland, College Park — We report our progress in the field of quantum impurity simulations with superconducting circuits. Our simulator consists of a split Josephson junction terminating a high-impedance transmission line, which is made of a linear chain of up to 40,000 junctions [1,2]. In part I, we start with a relatively large area split-junction, such that its quartic anharmonicity can be treated as a perturbation. It is expected that inelastic scattering of single photons becomes the dominant photon loss mechanism, with the loss frequency dependence containing information on the many-body correlation functions. We will present the measurements at various line impedances and impurity parameters.

11:15AM B28.00001: Spurious topological entanglement entropy and subsystem symmetries in compactified cubic code
DOMINIC WILLIAMSON (Presenter), ARPIT DUA, MENG CHENG, Yale Univ — Compactifying one direction of the cubic code results in a family of two dimensional topological orders, equivalent to stacks of toric code enriched by translation symmetry. Surprisingly, some of these models have unbroken rigid 1D subsystem symmetries that lead to spurious contributions to the topological entanglement entropy. These spurious contributions can appear in a bulk computation of the topological entanglement entropy from a linear combination of subregion entropies with cancelling boundary terms. We introduce an entropic quantity that measures the presence of such spurious contributions.

11:27AM B28.00002: Low overhead Clifford gates from joint measurements in surface, color, and hyperbolic codes*
SEYED ALI HOSSEINI LAVASANI (Presenter), MAISSAM BARKESHLI, Department of Physics, University of Maryland College Park — One of the most promising routes towards fault-tolerant quantum computation utilizes topological quantum error correcting codes, such as the $\mathbb{Z}_2$ surface code. Logical qubits can be encoded in a variety of ways in the surface code. However proposed fault-tolerant implementations of the Clifford group in these schemes are limited and often require unnecessary overhead. In this work, we show that within any encoding scheme for the logical qubits, we can fault-tolerantly implement the full Clifford group by using joint measurements involving a single appropriately encoded logical ancilla. This allows us to provide new low overhead implementations of the full Clifford group in surface codes as well as color codes. It also provides the first proposed implementations of the full Clifford group in hyperbolic codes. We further use our methods to propose state-of-the-art encoding schemes for small numbers of logical qubits. To our knowledge, this is the optimal proposal to date, and thus may be useful for demonstration of fault-tolerant logical gates in small near-term quantum computers.

*This work is supported by NSF CAREER (DMR-1753240) and JQI-PFC-UMD.

11:39AM B28.00003: Universal logical gate sets on encoded qubits using constant depth unitary circuits* [Invited]
MAISSAM BARKESHLI (Presenter), Physics, University of Maryland, College Park — A basic question in the theory of fault-tolerant quantum computation is to understand the fundamental space-time overhead required for performing a universal logical set of gates on encoded qubits to arbitrary accuracy. In this talk, I will demonstrate how braiding and Dehn twists in arbitrary (Abelian and non-Abelian) topological codes can be implemented through constant depth unitary circuits, where the depth is independent of the code distance. These circuits consist of a local constant depth unitary circuit followed by a permutation on physical qubits. When applied to the Fibonacci Turaev-Viro codes, they provide the first example of a universal logical gate set through constant depth unitary circuits. Other methods require either measurements, with follow-up gate operations that depend on the results of those measurements, or require local unitary circuits whose depth increases linearly with code distance. Our results can be extended to the context of hyperbolic Turaev-Viro codes as well, which have constant space overhead (constant rate encoding). I will discuss the fault-tolerance properties of these circuits, and how they provide some of the most optimal schemes to date in terms of space-time overhead for universal fault-tolerant quantum computation.

*NSF CAREER (DMR-1753240), Alfred P. Sloan Foundation, JQI-UMD-PFC

12:15PM B28.00004: Exotic quantum wires from symmetry-enriched topological order interfaces*
WEIYI DING (Presenter), SHENGHAN JIANG, JASON ALICEA, Physics, California Institute of Technology — When two identical chiral topological orders merge, the gapless modes at their interface can annihilate—thereby forming a single, uninterrupted topological phase. We study such interfaces when one of the two phases is promoted to a symmetry-enriched topological order exhibiting an anyon-permuting symmetry. In this case symmetry provides an obstruction to gapping the interface; moreover, we show that the gapless, symmetry-preserving interface can realize nontrivial critical points with no fine-tuning required. Such exotic “quantum wires” can provide efficient building blocks for assembling two-dimensional topological orders hosting anyons with universal braid statistics.

*Caltech Summer Undergraduate Research Fellowships (SURF)
National Science Foundation through grant DMR-1723367
CHUN-XIAO LIU (Presenter), Delft University of Technology, CHING-KAI CHIU, Kavli Institute of Theoretical Sciences — Braiding Majorana zero modes is an important approach to understand the physics of the non-Abelian statistics. To experimentally achieve this approach, accurately reading the change of the quantum state through the braiding process is an essential step. In this talk, we propose an experimental protocol to read the braiding change of the Majorana zero modes. The scheme includes four spatially-separated Majorana zero modes on top of a Coulomb blockaded topological superconductor. The reading of the braiding change is implemented by measuring the tunnel conductance in the strong Coulomb blockade regime for two overlapped Majorana zero modes.

*Supported by the Strategic Priority Research Program of the Chinese Academy of Sciences, Grant No. XDB28000000

SAGAR VIJAY (Presenter), Physics, Harvard University — Recently, there has been a growing effort to store quantum information in fermion states, so that a qubit is encoded in the fermion occupation number or the fermion number parity. Using fermions as the carriers of quantum information necessitates a new computational model and new error-correcting codes, as Fermi statistics forbids a mapping of local quantum gates acting on fermions to local gates acting on bosons. Motivated by on-going experiments, we introduce a variety of fermionic quantum codes that are able to correct for fermion parity-preserving and parity-violating (“quasiparticle poisoning”) errors. First, we discuss a surface code of Majorana fermions, along with its implementation, and demonstrate that the threshold error-rates for this code are superior to that of bosonic surface codes. We then introduce a generic construction of fermion codes from weakly self-dual classical, binary error-correcting codes, and use this method to find the shortest fermion code to correct for quasiparticle poisoning errors and other codes that correct higher-weight errors. We conclude by discussing physical implementations of codes with shorter code distance.

Supported by the Harvard Society of Fellows

ZHI LI (Presenter), ROGER MONG, University of Pittsburgh — We consider the finite-temperature topological entanglement entropy (TEE) for topological-ordered systems. We found, quite generally, that the finite-temperature TEE is a piece-wise constant function for CSS codes, which include the toric code and some fracton models like Haah's code and the X-cube model. We also discuss the phase transition structure of CSS codes and possible connections with self-correctness.

OSCAR VIYUELA (Presenter), SAGAR VIJAY, LIANG FU, Department of Physics, Massachusetts Institute of Technology — The Majorana Surface Code (MSC) is a topological quantum code constructed out of interacting Majorana fermions, which can be used to store quantum information and perform topological quantum computation. In this talk, we show how purely fermionic errors (quasiparticle poisoning events) can be corrected provided the error rate is below a certain threshold. In addition, we show how bosonic and measurement errors poses higher error thresholds than spin-based topological memories like the Surface Code and the Color Code. These results together with the inherent protection against thermal fluctuations given by the superconducting gap make the MSC a strong candidate for a robust topological quantum memory.

ARPIT DUA (Presenter), DOMINIC WILLIAMSON, MENG CHENG, Yale Univ — We employ quantities generalizing the two-dimensional S-matrix invariant to categorize 3D stabilizers models into type-I fracton models, type-II fracton models, TQFTs and stacks of 2D Toric codes. These quantities count the numbers of anticommuting string-string, string-membrane and membrane-membrane operators. The scaling behavior of these quantities with the size of the strings and membranes gives a signature of the class of topological order. We also investigate two-dimensional compactifications of three-dimensional fracton models. We find the two-dimensional topological phases produced as a function of compactification radius and uncover translation symmetry-enrichment that leads to twisted boundary conditions. This allows us to interpret the complicated ground space degeneracy of type-II 3D fracton models in terms of the symmetry enriched anyons in the compactified model.
Classifying Subsystem Symmetry Protected Topological Phases

TRITHEP DEVAKUL (Presenter), Princeton University, DOMINIC WILLIAMSON, Yale University, YIZHI YOU, Princeton University, FIONA BURNELL, University of Minnesota, SHIVAJI SONDHI, Princeton University — We discuss symmetry protected topological (SPT) phases in 2D systems with subsystem symmetries: symmetries which act on rigid subsystems, such as along straight lines or fractals. The total symmetry group of such systems grows with system size and is infinitely large in the thermodynamic limit. Systems with linear subsystem symmetries exhibit a phenomenon wherein two states from different phases may differ only along a subsystem — leading to an infinitude of possible phases.

To address this issue we identify and classify the "intrinsic" information of phase which can be measured locally. This may be likened to equivalence classes of phases which differ by only transformations along subsystems.

We show that for linear subsystem SPTs, despite there being infinitely many phases, the classification of this intrinsic information is finite and depends only on the on-site symmetry group.

For fractal subsystem symmetries, this is not necessary: locality is enough to enforce a certain translation symmetry which leads to a number of possible phases.

We give an upper bound for the number of phases in such models where Hamiltonian terms are supported within L-by-L boxes.

These phases showcase how subsystem symmetries can lead to intriguing new physics even in simple cases.

A braiding quantum circuit based on the 4π Josephson effect

JOHN STENGER (Presenter), MICHAEL HATRIDGE, SERGEY M FROLOV, DAVID PEKKER, University of Pittsburgh — We propose a topological qubit in which braiding and readout are mediated by the 4π Majorana-Josephson effect. The braidonium device consists of three Majorana nanowires that come together to make a tri-junction; in order to control the superconducting phase differences at the tri-junction the nanowires are enclosed in a ring made of a conventional superconductor; and in order to perform initialization/readout one of the nanowires is coupled to a fluxonium qubit through a topological Josephson junction. We analyze how flux-based control and readout protocols can be used to demonstrate braiding and qubit operation for realistic materials and circuit parameters.

Session B29 DQI: Superconducting Qubits: Hamiltonian Engineering and Design Tools

11:15AM B29.00001: Quantization of Large Superconducting Circuits with Tensor Networks

KRISTINA COLLADAY (Presenter), MATTHEW WEIPPERT, DAVID FERGUSON, RYAN J EPSTEIN, Northrop Grumman — We introduce a novel method for efficient quantum simulation of large superconducting circuits using matrix product states (MPS) and the density matrix renormalization group (DMRG) technique. We analyze an LC oscillator containing a chain of Josephson junctions, forming a superinductor. We obtain the lowest-lying eigenstates and energies, and calculate physical observables of interest for chain lengths in the range of 5-65 Josephson junctions. We quantify simulation convergence through comparison with exact diagonalization (when possible) and quantum state variance. Our approach reaches far beyond the resource limitations of brute-force exact diagonalization.

*This work is supported by IARPA and ARO.

11:27AM B29.00002: Towards Total Quantum System Characterization

GERARDO PAZ SILVA (Presenter), YA CAO, IVONNE GUEVARA PRIETO, Griffith University, CHRISTOPHER FERRIE, University of Technology Sydney — Quantum enabled technologies promise to deliver the next technological revolution. However, their realization requires a degree of control over quantum systems that is still elusive. The problem stems from our imperfect knowledge of the physical quantities ruling their evolution. To overcome this, system characterization tools such as Hamiltonian learning, noise spectroscopy, and state tomography have been devised. However, the success of each of these schemes often requires the knowledge provided by the other. For example, Hamiltonian learning protocols estimate the parameters of a Hamiltonian ruling the evolution of a set of qubits but require knowledge of any noise affecting them to be successful, while noise spectroscopy protocols can characterize the noise affecting the system of interest but require knowledge of the deterministic part of the Hamiltonian.

In this talk, we will present a limited-access total quantum system characterization tool. We show that it is possible to simultaneously extract the information that Hamiltonian learning, noise spectroscopy, and state tomography of a composite quantum system provide, when only limited-access is available, i.e., when fast and reliable control and measurements are possible in only a subsystem.
**11:39 AM B29.00003: Exact quantization of superconducting circuits**

MOHAMMAD H. ANSARI (Presenter), Forschungszentrum Julich — Circuits consisting of weak anharmonic qubits coupled to cavity multimodes are theoretically quantized beyond dispersive regime. In order to do this, we obtain a unitary transformation that diagonalizes harmonic sector of the circuit. Weak anharmonicity does not alter normal mode basis, however, it modifies energy levels. Using our formalism, we quantify two circuits of: 1) a transmon coupled to a resonator, and 2) two transmons coupled to a bus resonator. In both circuits, we determine dressed frequencies and Kerr nonlinearities in closed form formulas. Our results are valid for arbitrary frequency detuning and coupling within and beyond dispersive regime.

**11:51 AM B29.00004: Numerical Methods for Current Mirror Qubit Simulations**

DANIEL WEISS (Presenter), Department of Physics and Astronomy, Northwestern University, DAVID FERGUSON, MOE S KHALIL, Northrop Grumman Corporation, ANDY C. Y. LI, Scientific Computing Division, Fermi National Accelerator Laboratory, JENS KOCH, Department of Physics and Astronomy, Northwestern University — Current Mirror Qubits (CMQs) are an example of “noise insensitive” superconducting qubits predicted to exhibit longer coherence times than conventional superconducting qubits even when exposed to the same noise environment. CMQs also have the advantage of not requiring detailed tune-up or fabrication precision to achieve noise insensitivity. However, given the large number of circuit components that comprise such qubits, direct numerical diagonalization of the qubit’s Hamiltonian using a product basis is numerically intractable. This presents a challenge for verifying projected noise immunity for realistic circuits that include fabrication imperfections or control offsets. This talk discusses various numerical models for CMQs that address this challenge, and presents initial comparisons between these models and experimental realizations of these qubits.

*This research was supported by the Army Research Office under contract W911NF-17-C-0024.

**12:03 PM B29.00005: Quantum Engineering Design of Superconducting Qubits**

DAVID FERGUSON (Presenter), DAVID CLARKE, Northrop Grumman, DANIEL WEISS, JENS KOCH, Northwestern University — Many novel superconducting qubits have circuits with a large number of quantum components. Such circuits can require quantum engineering design, i.e., the numerical simulation of a large Hilbert space to determine optimal device performance. For this purpose, we introduce the Villain periodically Continued Harmonic Oscillator Basis (VCHOB). This general method allows for automated and efficient numerical diagonalization of superconducting circuits, increasing the types of circuits for which quantum engineering design is possible.

*This research was supported by the Army Research Office under contract W911NF-17-C-0024

**12:15 PM B29.00006: Energy-participation approach to the design of quantum Josephson circuits**

ZLATKO MINEV (Presenter), Department of Applied Physics, Yale University, New Haven, Connecticut 06511, USA, ZAKI LEGHTAS, Centre Automatique et Systèmes, Mines-ParisTech and Laboratoire Pierre Aigrain, École Normale Supérieure, Paris, France, SHANTANU O. MUNDHADA, Department of Applied Physics, Yale University, New Haven, Connecticut 06511, USA, IOAN-MIHAI POP, Physikalisches Institut, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany, LYSANDER CHRISTAKIS, MICHEL H. DEVORET, Department of Applied Physics, Yale University, New Haven, Connecticut 06511, USA — Superconducting circuits incorporating non-linear devices, such as Josephson tunnel junctions and nanowires, are among the leading platforms for emerging quantum technologies. Promising applications require designing and optimizing circuits with ever-increasing complexity and controlling their dissipative and Hamiltonian parameters to several significant digits. Therefore, there is a growing need for a systematic, simple, and robust approach for precise circuit design, extensible to increased complexity. In this talk, we present such an approach to unify the design of dissipation and Hamiltonians around a single concept — the energy participation, a number between zero and one — in a single-step electromagnetic simulation. This markedly reduces the required number of simulations and allows for robust extension to complex systems. The approach is general purpose, valid for arbitrary non-linear devices and circuit architectures. We present experimental results on a variety of circuit quantum electrodynamics (cQED) devices and architectures, 3D and flip-chip (2.5D), which exhibit percent-level agreement for Hamiltonian parameters over five-orders of magnitude and across a dozen devices.

*Work supported by: ARO, ONR, NSF, AFOSR, and YINQE
Circuit quantization serves as a link between physical circuits and quantum Hamiltonians. The standard procedure [1] established decades ago implicitly assumes the external magnetic flux threading a circuit loop to be static. However, time-dependence arises inevitably when flux modulation or noise are considered. Naïve application of the existing circuit-quantization procedure can then lead to inconsistencies in predictions of qubit relaxation times. In this talk, we present a generalized approach to circuit quantization valid in the presence of time-dependent external sources. Our results uncover the reason for the inconsistency and resolve it, and are applicable to a wide range of circuits utilizing time-varying external fields.

*This research was supported by the Center for Applied Physics and Superconducting Technologies, Northwestern University and Fermi National Accelerator Laboratory.

Bayesian inference uses Bayes' theorem to update the probability of a hypothesis and as a result can be used to great effect when trying to learn the Hamiltonian of a quantum system. In comparison to traditional techniques for characterisation it has the benefit of providing statistically relevant information about the learning procedure, enabling more efficient data taking and revealing limits of the model provided to produce the data. It can be used to compare how well different models fit measured data and hence diagnose noise sources. We demonstrate this by applying it to a superconductor semiconductor 'gatemon' qubit and use it to learn the parameters of the Hamiltonian.

The dynamics in a system of coupled qubits is proven to be computationally hard. Harnessing the computation power associated with these complex dynamics requires controlling the evolution with high fidelity, which in turn requires knowing the physical parameters of the system with high accuracy. Using a few coupled superconducting qubits, we discuss a method for extracting the values of the physical parameters of the system. In addition to the direct spectroscopy of the eigen-modes of the system, we generate controlled dynamics and measure the evolution of certain observables to refine the knowledge of the parameters obtained from spectroscopy. We discuss the accuracy of this calibration technique in terms of the requirements for performing a classically challenging computation.

We show that number non-conserving terms in the Josephson anharmonicity lead to a renormalization of the lifetime of microwave-driven superconducting qubits. Using a method of unitary transformations, we account for the frequently neglected number non-conserving terms in the Josephson potential, and show that they generate drive- and anharmonicity-dependent corrections of the qubit and readout resonator relaxation rates. Simultaneously, the number-conserving terms yield the known Kerr corrections to the eigenfrequencies of the system. We present our results in the form of effective master equations with renormalized Hamiltonian and collapse operators. Effective master equations provide an efficient tool to extract drive-, state- and anharmonicity-dependent relaxation rates.
1:15PM B29.00011: Drive-induced lifetime renormalization of superconducting qubits II: The Readout Problem
ALEXANDRU PETRESCU (Presenter), Université de Sherbrooke, MOHAMMAD MOEIN MALEKAKHLAGH, HAKAN TURECI, Princeton University —
Recent experiments found a strong dependence of qubit relaxation rates on the readout drive power. The observed dynamics cannot be fully explained by previous theoretical approaches based on the Jaynes-Cummings, Rabi or Kerr based models. We show that an effective master equation that accounts for renormalization of dissipative parameters due to number non-conserving terms inherent in the Josephson nonlinearity captures with good qualitative agreement this strong dependence. We account for a realistic experimental setting with a finite bath temperature and an additional pure dephasing channel, both of which are shown to significantly enhance the qubit relaxation renormalization with drive. Effective master equations for driven Josephson circuits appear to provide an accurate and computationally resource-efficient approach to experimentally relevant settings.

1:27PM B29.00012: Computational modeling of decay and hybridization in superconducting circuits
MICHAEL SCHEER (Presenter), MAXWELL B BLOCK, Rigetti Computing — We present a circuit theoretic technique for computing the complex frequencies and eigenmodes of superconducting circuits with radiative loss. We show that the transmon loss rates obtained by our method agree with the established approximation C/Re[Y] away from resonance and do not diverge near resonance. Additionally, we demonstrate that in systems with significant radiative loss, couplings between modes cannot be accurately computed if the loss is neglected. Our simulation technique is useful for designing complex superconducting quantum processors.

1:39PM B29.00013: Enablement of near-term quantum processors by architectural yield engineering*
SAMI ROSENBLATT (Presenter), JARED B HERTZBERG, JOSÉ CHAVEZ-GARCIA, NICHOLAS T BRONN, HANHEE PAIK, MARTIN SANDBERG, EASWAR M MAGESAN, JOHN A SMOLIN, JENG-BANG YAU, VIVEKANANDA ADIGA, MARKUS BRINK, JERRY M. CHOW, IBM Thomas J. Watson Research Center — Scaling of near-term quantum processors depends on complex architectures where maintaining low gate error rates relies on utilizing the highest coherence times available. In the case of fixed-frequency transmon qubits coupled via cross-resonance gates, multi-qubit operation is feasible as long as the excitation energies of neighboring qubits are similar but non-degenerate. Meeting this condition consistently in a large lattice of qubits requires precise Josephson junction fabrication and accurate frequency forecasting. In this talk, we will compare measured qubit frequencies to resistance measurements of Josephson junctions, and use a statistical model to suggest strategies for useful device yields at the 50 qubit and larger scale.

*We acknowledge support from IARPA under Contract No. W911NF-16-0114.

1:51PM B29.00014: Frequency trimming of superconducting fixed-frequency qubits
MUSTAFA BAL (Presenter), JUNLING LONG, RUSSELL LAKE, XIAN WU, COREY RAE MCRAE, HSIAANG-SHENG KU, National Institute of Standards and Technology Boulder, JARED B HERTZBERG, NICHOLAS T BRONN, JERRY M. CHOW, IBM T. J. Watson Research Center, DAVID PAPPAS, National Institute of Standards and Technology Boulder — There has been significant progress to increase the number of superconducting fixed-frequency qubits for multi-qubit gates. The variations in fabrication limits the precision in qubit frequency to within ~ 200 MHz of the design value [1], which could lead to undesired frequency crowding. We developed a frequency trimming process to correct the frequencies of the measured qubits. The frequency trimming involves first a chemical process to remove all on-chip wirebonds, followed by lithography and dry etch to trench the dielectric substrate near the qubit to tune the frequency to the target design value. We present fabrication process details, simulations, and qubit measurements.

Session B30 GSOFT: Liquid Crystals I  BCEC 162B - Cristina Martin Linares, Johns Hopkins University

11:15AM B30.00001: Liquid-Liquid Interfaces and Grain Boundaries Engineering of Soft Crystals  XIAO LI (Presenter), University of Chicago, JOSÉ A. MARTÍNEZ-GONZÁLEZ, Universidad Autónoma de San Luis Potosí, XUEDAN MA, Argonne National Laboratory, ORLANDO GUZMÁN, Universidad Autónoma Metropolitana, KANGHO PARK, JUAN DE PABLO, PAUL F NEALEY, University of Chicago — In solid state science, a considerable challenge remains in the development of techniques toward grain-boundary engineering, which is fundamental for designing materials with specific mechanical properties. Meanwhile, in soft matter a significant number of natural phenomena take place at liquid-liquid interfaces. Similar to grain boundaries of solid crystals, liquid-liquid interfaces lack of shape control, placing limits to applications in biosensing, photonics, directed self-assembly and adsorption phenomena. In this work, we build on soft-matter heteroepitaxy to grow, not solids, but single crystals of cubic liquid-crystalline BPs. Specifically, we rely on accurately designed binary-anchoring patterned substrates that facilitate spontaneous BP nucleation over the whole patterned region. This leads to a distortion-free BP-crystal, with a uniform lattice orientation that depends on the symmetry of the pattern used. Based on such liquid-liquid interfacial behavior, we produce large, stable and single-crystal BP-domains can serve as an alternative for engineering materials with accurately localized regions that respond sensitively to contaminants, incident light, electric or magnetic fields and other external stimuli.

11:27AM B30.00002: Cylindrical fiber cored by a double twisted chiral nematic  ADRIAN REYES (Presenter), GERARDO J. VÁZQUEZ, Instituto de Física, Universidad Nacional Autónoma de México — Abstract
We consider an electromagnetic field propagating within a waveguide consisting of a material having double helix, as those found in some chiral nematic materials such as blue phases, which lies along the axis of the fiber. We establish the electromagnetic equation governing the dynamics of the propagating modes and solve them numerically. We found the band structure of the mentioned modes, the profiles field amplitudes and the Poynting vector distributions versus the radius of the fiber. We discuss the composition and conditions for this modes to propagate.

11:39AM B30.00003: First-order smectic-hexatic phase transition in thick liquid crystal films*  IVAN ZALUZHNYY (Presenter), Department of Physics, University of California San Diego, RUSLAN KURTA, European XFEL, NASTASIA MUKHARAMOVA, YOUNG YONG KIM, RUSLAN KHUBBUTDINOV, DMITRY DZHIGAEV, Photon Science, Deutsches Elektronen-Synchrotron DESY, VLADIMIR LEBEDEV, ELENA PIKINA, EFIM KATS, Landau Institute for Theoretical Physics, NOEL ANTHONY CLARK, Department of Physics, University of Colorado Boulder, MICHAEL SPRUNG, Photon Science, Deutsches Elektronen-Synchrotron DESY, BORIS OSTROVSKIĬ, FSRC "Crystallography and photonics", IVAN VARTANYANTS, Photon Science, Deutsches Elektronen-Synchrotron DESY — Synchrotron studies with a focused x-ray beam of the first-order smectic-A – hexatic-B (Sm-A – Hex-B) phase transition in 2-10 μm thick free standing films of 54COOBC compound are presented. The Hex-B phase is distinguished from Sm-A phase by long-range bond-orientational (BO) order, which can be conveniently studied by the angular X-ray cross-correlation analysis (XCCA). Discontinuity in temperature dependence of positional correlation length and the BO order parameter as well as direct observation of phase coexistence clearly indicate the first-order character of the phase transition. Experimental data unambiguously show that the width of temperature region of two phases coexistence increases with film thickness. This effect is explained on the basis of Landau mean-field theory in the vicinity of a tricritical point by anomalous penetration of the Hex-B order parameter into the film interior.

**11:51AM B30.00004: Liquid Crystal Flat Optical Elements**

ZIYUAN ZHOU (Presenter), MIAO JIANG, HAO YU, YUBING GUO, TARAS TURIV, O D LAVRENTOVICH, QI-HUO WEI, Advanced Materials and Liquid Crystal Institute, Kent State University, Kent, Ohio, 44242, USA — Thin liquid crystal films (LCs) with well-defined molecular orientations are an exceptional platform for making flat optical devices based on the Pancharatnam-Berry phase. Here we present a new approach to designing and fabricating liquid crystal flat optical elements such as micro-lenses and beam-shapers. We show the molecular orientation patterns for shaping a light beam into desired intensity profiles can be designed using a generalized Snell's law, and that such liquid crystal flat optical elements can be made with high throughput and high resolution by using a plasmonic-metamask-based photopatterning approach.

**12:03PM B30.00005: Cellulose Nanocrystals confined to polymer microgels**

SUJIN LEE (Presenter), ELSA REICHMANIS, MOHAN SRINIVASARAO, JUNG OK PARK, Georgia Institute of Technology — Liquid crystals that are confined within curved boundaries are of interest to many scientists due to their important role in optoelectronic technologies. As such, intensive research has been conducted with various types of liquid crystals constrained to droplets or cylindrical environments. Such studies are significant because the curvature of liquid crystals costs elastic energy, and hence, we observe rich physical phenomena such as change in the director field that otherwise would have been hidden. Most of the fundamental studies of liquid crystalline phase of the cellulose nanocrystals were conducted as a film type or in the cells with flat boundaries, limited to certain concentrations. Here, we report cellulose nanocrystals confined to pNIPAM microspheres using inverse emulsion polymerization technique with microfluidics device. The chiral nematic phase of cellulose nanocrystals are preserved within the polymer matrix, as characterized by optical microscopy. The droplet radius, R of the microgels can be adjusted by changing the volumetric flow rate of oil phase in a microfluidics device. Notably, the fabricated CNCs-PNIPAM microgels are able to exhibit swelling-deswelling behavior upon temperature change with well-organized structure.

**12:15PM B30.00006: Anisotropic diffusion of islands and topological defects in dipolar chains of islands in freely-suspended SmC liquid crystal films**

CHEOL PARK (Presenter), ERIC MINOR, JOSEPH E MACLENNAN, MATTHEW GLASER, NOEL ANTHONY CLARK, University of Colorado, Boulder — Islands, disk-like inclusions of extra layers in few-layer thick, freely-suspended tilted smectic liquid crystal films, stabilize +2π chiral vortices in the two-dimensional \(XY\) field giving the azimuthal orientation of the local molecular tilt. We have studied the Brownian motion of islands and their companion -1 defects on the background film in a dipolar chain of islands. The mean square fluctuations of the position are strongly anisotropic, the island mobility parallel to the chain direction being up to four times smaller than their mobility perpendicular to the chain. Measurements of thermal fluctuations of islands and topological defects in dipole chains will be compared with theoretical predictions.

*This work was supported by NASA Grants No. NNX-13AQ81G and No. NNX17AC74G and by the Soft Materials Research Center under NSF MRSEC Grants No. DMR-0820579 and DMR-1420736.

**12:27PM B30.00007: Two-Dimensional Hexagonal Boron Nitride Nanosheet as an Ion-Capturing Planar-Alignment Agent in a Liquid Crystal-Based Electro-Optic Device**

RAJRATAN BASU, LUKAS ATWOOD (Presenter), United States Naval Academy — The two-dimensional (2D) hexagonal boron nitride (h-BN) nanosheet is employed as a planar-alignment agent on one side of a liquid crystal (LC) cell, where the other side of the cell has a standard planar-alining polyimide (PI) layer. The LC exhibits uniform planar-alignment in this h-BN/PI hybrid cell. The free-ion impurities in the LC are found to be suppressed dramatically in this h-BN/PI hybrid cell compared to that in a standard PI/PI LC cell. The free-ion concentration is reduced in the hybrid cell due to the 2D h-BN nanosheet's ion-capturing process. The reduction of ionic impurities results in an accelerated electro-optic response of the LC in the hybrid cell. The dielectric anisotropy of the LC is enhanced in the h-BN/PI hybrid cell, indicating an improved orientational order parameter of the LC due to the reduction of ionic impurities.

**12:39PM B30.00008: Study of phase behavior and (meta)stability of model surfactant solutions by microfluidic thermal fluctuation platform**  
HAOYU WANG (Presenter), SEPIDEH KHODAPARAST, JOAO CABRAL, Imperial College London  
— Metastability poses considerable challenges for the practical utilization of surfactant solutions subjected to ubiquitous temperature fluctuations. We first investigate aqueous solutions of a model biodegradable surfactant system (Linear Alkylate Sulfonate, LAS) at low concentrations, examining the mechanism and kinetics of the transition from micellar to multilamellar vesicle (MLV) phase, in the absence of salt and external flow. We then employ a novel microfluidic platform designed to rapidly modulate temperature fields and detect phase changes, coupled with optical microscopy and small angle neutron scattering (SANS). We resolve the MLV structure and decouple the nucleation and growth kinetics across the metastable zone width by imposing the square-wave temperature profiles. Finally, we demonstrate the imposition of complex temperature profiles, mirroring diurnal and seasonal variations, and their consequences to LAS micellar solution stability.

*This work is funded by the Centre for Process Innovation, Procter & Gamble, and BP.

**12:51PM B30.00009: Chiral symmetry-breaking dynamics in the phase transformation of nematic droplets**  
NASSER ABUKHDEIR (Presenter), FRED FU, Chemical Engineering, University of Waterloo  
— Chiral symmetry-breaking equilibrium textures in deformable and nondeformable droplets of achiral nematic liquid crystals (LCs) have long been observed for a broad range of LC compounds and conditions. Most of the observed chiral symmetry-breaking phenomena in achiral nematic LCs have involved spherical nematic droplets, which serve as ideal geometries for studying the interaction between surface and bulk elastic effects on nematic texture.

In this work, continuum simulations are performed of the formation of an initially isotropic phase nematic LC confined within a nanoscale nondeformable droplet with weak homeotropic surface anchoring conditions. Simulation conditions are chosen for the case where the equilibrium nematic texture is uniform. Beginning with an initial quench of the isotropic phase droplet, nematic formation occurs, initially forming an unstable radial-like texture. Subsequently, a spontaneous symmetry-breaking twist-mediated defect escape mechanism is observed for material parameters corresponding to pentyl-cyanobiphenyl (SCB) prior to the droplet evolving to stable uniform texture. Notably, this dynamic mechanism does not occur in simulations using the single-constant elastic constant approximation.

**1:03PM B30.00010: Brownian Dynamics of Particles “Dressed” by Chiral Director Configurations in Lyotropic Chromonic Liquid Crystals**  
ANGEL MARTINEZ (Presenter), University of Pennsylvania, PETER COLLINGS, Swarthmore College, A. G. YODH, University of Pennsylvania  
— We employ video microscopy to study the Brownian dynamics of colloidal particles suspended in the uniaxially aligned nematic phase of a lyotropic chromonic liquid crystal (LCLC), Disodium Cromoglycate (DSCG). DSCG is water soluble, and its nematic phase is characterized by an unusually large elastic anisotropy. Our measurements of the mean-square displacement for polystyrene-based colloidal microspheres show sub-diffusive behaviors along directions parallel and perpendicular to the nematic director. The dynamics parallel to the far-field director is sub-diffusive for lag times as long as several seconds and then diffusive beyond that, while the dynamics perpendicular to the far-field director continues to display complicated and unexpected sub-diffusive behavior for hundreds of seconds of lag time. Also, spherical colloids suspended in LCLCs can induce two symmetrically and energetically distinct director field configurations and we consider the effects of these differences on the diffusion dynamics of LCLC colloids. The origin of these deviations from conventional diffusion theory are discussed and our results are compared to previous diffusion experiments in conventional nematic liquid crystals.

**1:15PM B30.00011: Interaction of liquid crystal skyrmions with curved boundaries**  
AVADH SAXENA (Presenter), AYHAN DUZGUN, Los Alamos National Laboratory  
— A liquid crystal cell is made by confining the liquid crystal material between two plates usually made of glass. In recent years, long-lived skyrmions, which are topological defect structures of the director field, have been realized in chiral nematic liquid crystal cells by means of establishing equilibrium between a background electric field and surface anchoring. These skyrmions interact with each other as well as with field gradients. In this work, we present numerical studies where an additional electric field, surface anchoring or light is used to generate “walls” to guide the motion of skyrmions. Specifically, we explore the motion of skyrmions near curved boundaries and how it is affected by the curvature.
1:27PM B30.00012: Magnetic Effects in Confined Nematic Liquid Crystal Droplets*  
SOPHIE ETTINGER (Presenter), ANGEL MARTINEZ, ALEXIS DE LA COTTE, Physics and Astronomy, University of Pennsylvania, PETER COLLINGS, Physics and Astronomy, Swarthmore College, ARJUN G YODH, Physics and Astronomy, University of Pennsylvania  
We study the structural transition of nematic liquid crystal (NLC) droplets with homeotropic anchoring in a uniform magnetic field. Confining NLC in droplets creates competition between surface anchoring energy and bulk elasticity, giving rise to distortions and defects. The effects of an electric field on the equilibrium director conformation of NLC droplets are well known, but studies using a magnetic field are scarcer due to the low magnetic susceptibility of most NLCs. We have developed a variable magnet mounted on a polarized microscope that can deliver up to 0.5T of uniform field. With this mechanism, we study the stability of hedgehog defects and the resulting Fréedericksz transition in NLC droplets. We confirm, as predicted theoretically, the formation of a ring defect whose radius increases with field strength as the director approaches a uniformly aligned state. We establish stability diagrams for NLC droplets of various radii and conduct comparative analysis of experimental and calculated threshold fields. Overall, this project aims to elucidate the director configurations of NLCs in confined geometries and to explore their bulk response to external magnetic fields.

1:39PM B30.00013: Liquid Crystals and the Optical Theorem  
XI CHEN (Presenter), NOEL ANTHONY CLARK, Soft Material Research Center, Department of Physics, University of Colorado, Boulder CO,80309  
The “optical theorem” is the calculation of plane electromagnetic wave propagation through a transparent dielectric slab, that views the slab as a uniformly distributed collection of point scatterers in a vacuum. The theorem shows that the apparent index of refraction of the slab is the result of the interference of the net forward scattered light with the incident beam. We are exploring this effect for the case where the slab is a nematic liquid crystal, probing in particular the effect of the strong scattering by director fluctuations on refractive index, and thus on phase fluctuations in the outgoing radiation.

*This work was supported by the Soft Materials Research Center under NSF MRSEC Grant DMR-1420736.

1:51PM B30.00014: Bent-Core Liquid Crystal with Polar Electro-optic Switching in the SmE phase  
Authors: Rayshan Visvanathan,1,2 Xi Chen,2, 3 Renfan Shao,2, 3 Min Shuai,2 Alexandra E. Duncan,2, 3 Eva D. Korblova,2, 4 Edward Guzman,2, 4 David M*  
RAYSHAN VISVANATHAN (Presenter), XI CHEN, RENFAN SHAO, MIN SHUAI, ALEXANDRA E DUNCAN, EVA D KORBLOVA, EDWARD GUZMAN, DAVID M WALBA, MATTHEW GLASER, JOSEPH E MACLENNAN, NOEL ANTHONY CLARK, University of Colorado, Boulder  
Polarizing optical microscopy and x-ray scattering measurements show that a new achiral, bent-core liquid crystal compound, W898, with a rigid core and a flexible tail exhibits a biaxial smectic phase with orthorhombic symmetry. Upon cooling from a higher temperature SmAPA phase, a SmE-like phase with long-ranged bond-orientational order and short-ranged, centered rectangular, in-plane positional order with local herringbone correlations forms. In this phase, the layers are macroscopically polar, and an applied electric field couples to the polarization to reorient the molecules, inducing a dramatic and rapid birefringence change in liquid crystal cells with planar alignment.

2:03PM B30.00015: Interpretation of saddle-splay and the Oseen-Frank free energy*  
JONATHAN SELINGER (Presenter), Kent State University  
In this talk, we re-examine the oldest question in liquid-crystal physics: What are the elastic modes of a nematic liquid crystal? For this analysis, we use a recent mathematical construction [1], which breaks the director gradient tensor into four distinct types of mathematical objects. Based on this construction, we suggest an interpretation of saddle-splay as bulk rather than surface elasticity. This interpretation leads to an alternative way to think about several previous results in liquid-crystal physics, including: (1) free energy balance between cholesteric and blue phases, (2) director deformations in hybrid-aligned-nematic cells, (3) spontaneous twist of achiral liquid crystals confined in a torus or a cylinder, and (4) curvature of smectic layers.

*This work is supported by NSF Grant No. DMR-1409658.

Monday, March 4, 2019 11:15 AM - 2:15 PM
11:15AM B31.00001: Structure and reactivity of two-dimensional silica and zeolites* [Invited] JOACHIM SAUER (Presenter), Humboldt University of Berlin — Density functional theory is applied to solve the structures of ultrathin silica and zeolite films on metal substrates based on experimental information including LEED, IR-RAS, and STM. Specifically we discuss crystalline films consisting of one or two layers of corner-sharing TO₄-tetrahedra (T=Si, Al) on Mo(112) and Ru(0001) surfaces. We also discuss the formation of amorphous phases that can be directly imaged in real space by STM, and the substitution of Si with Ti and Fe which is not isomorphous but leads to new structure types. Joined computational – surface science studies on thin film zeolite models provide information for the limiting case of a flat surface corresponding to an infinitely large pore diameter. Whereas the non-specific adsorption energy is smaller on flat surfaces than inside zeolite pores, the acidity is significantly higher as OH frequency shifts on adsorption of molecules indicate. The consequences for understanding the acidity of layered powder materials (ZSM-5 layers) is discussed.

*This work has been funded by German Research Foundation (DFG)

11:51AM B31.00002: Hierarchical Zeolites: Synthesis and Applications [Invited] MICHELE OSTRAAT (Presenter), Advanced Materials, Aramco Services Company — Zeolites have been used extensively as industrial solid-acid catalysts in the oil refining and petrochemical industries due to their unique pore structures, acidity, and stability. Over the past two decades, innovations in synthesizing hierarchical zeolites have received continuous attention in both academia and industry for the potential to optimize catalytic performance of zeolite materials for in a wide range of refining and petrochemical applications that involve conversion of bulky molecules. The manipulation of hierarchy in zeolites can be achieved by different synthetic strategies that result in distinctive zeolites with various morphological, structural, and compositional characteristics. In this talk, we will discuss our recent progress on developing and optimizing hierarchical zeolites using top-down routes as well as bottom-up approaches with hard and soft templates and will summarize many of the unique underlying features for these different synthesis routes and their implications for large-scale industrial production of zeolites. We will also provide highlights on the utilization of these materials for important industrial applications related to oil refining and chemical productions.

12:27PM B31.00003: 2D Materials and Membranes for Biorefining and Hydrocarbon Separations [Invited] SANKAR NAIR (Presenter), Georgia Institute of Technology — The advent of 2D nanoporous materials has created exciting new possibilities in the scalable and economically viable fabrication of membranes for chemical separations. This talk will focus on our recent work in two areas of 2D membrane science and technology. Firstly, we will discuss new advances in the fabrication, modification, and scale-up of graphene oxide (GO) membranes, as well as their use in challenging applications in biorefining such as the fractionation of kraft black liquor and other related processes. Secondly, we will discuss our latest work on fabrication of 2D zeolite membranes on scalable hollow fiber platforms, and their applications in the separation of organic mixtures such as hydrocarbons from petrochemical processes or oxygenated molecules obtained from biomass conversion.

1:03PM B31.00004: Polymer-Grafted Nanoparticle Membranes with Unprecedented Gas-Separation Performance [Invited] SANAT KUMAR (Presenter), Chemical Engineering, Columbia University — Recent work has shown that nanoparticles grafted with polymer chains (GNPs) possess unusual collective properties. Their gas permeability shows non-monotonic behavior with increasing polymer length, with peak permeability increases of 8-20 times relative to the neat polymer. Similarly, their mechanical properties change from brittle to tough around the chain length with peak gas permeability. We show by combining small angle x-ray scattering, x-ray photon correlation spectroscopy and linear rheology that this behavior reflects the transition of the GNP materials from a jammed, soft glass-like state to liquid-like behavior with increasing chain length. For chain lengths below this transition, polymers on adjacent nanoparticles do not interpenetrate. Polymer melt incompressibility then results in a system where the coronas distort so that they tile space yielding a jammed (disordered) colloidal state. At longer chain lengths, this colloidal behavior disappears because chains on adjacent coronas interpenetrate. Since the dynamic properties of these systems, spanning time scale from the ps to the macroscopic, are affected by this transition we postulate that all of their transport properties should show anomalous behavior.
Regioselective Epoxide Ring Opening with Alcohols Using Heterogeneous Lewis Acidic Nano-Zeolites* [Invited] NICHOLAS BRUNELLI (Presenter), AAMENA PARULKAR, NITISH DESHPANDE, ALEXANDER SPANOS, RUTUJA JOSHI, BRIAN DIEP, Ohio State University, AMBARISH KULKARNI, UC Davis — Epoxides are versatile intermediates that can be ring opened using different nucleophiles to produce a wide variety of valuable chemicals. The key challenge for this reaction is selectivity. The regioselectivity of epoxide ring opening reactions for alcohols is examined using Lewis acidic catalysts. Through comparing catalytic activities, it is found that Sn-Beta is more active than other similar Lewis acidic catalytic materials such as Sn-MFI and Sn-SBA-15. For all materials, high regioselectivity of >99% is obtained when using epichlorohydrin with methanol. With large substrates such as epoxy hexane, diffusion limitations are encountered that can be overcome through creating zeolites with particle sizes less than 100 nm such as nano-Sn-MFI. These materials can be readily recycled while retaining high catalytic activity and selectivity. Hot filtration tests demonstrate that these catalysts are heterogeneous in nature and stable. Larger substrates such as epoxy octane result in diffusion limitations. We demonstrate the use of a new SDA to produce nano-Sn-Beta. This material can catalyze even larger structures. Overall, this demonstrates the importance of tuning material design to create highly active catalytic materials.

Monday, March 4, 2019 11:15 AM - 1:15 PM

Session B32 DCP: Gas Phase Clusters - Experiment and Theory in Concert (B): Metal Clusters BCEC 204A - Marie-Pierre Gaigeot - Tag(s): Focus

11:15AM B32.00001: Mass Spectrometry and Theoretical Chemistry in Service of Catalysis Research: A Ménage-à-Trois at Its Best [Invited] HELMUT SCHWARZ (Presenter), Chemistry, Technische Universität Berlin — The ultimate goal in heterogeneous catalysis is to make use of each and every atom of supported (metal) catalysts, i.e. in the extreme to perform single-atom catalysis (SAC). While this arduous task constitutes a non-trivial, if not daunting challenge in 'real-life' chemistry, in the gas phase SAC can be achieved in a rather straightforward manner by conducting experiments with mass-selected species under (near) single-collision conditions. These mass spectrometry-based studies on isolated reactants, when complemented by state-of-the-art computational and spectroscopic work, provide an ideal arena for probing the energetics and kinetics of a chemical process in an unperturbed environment at a strictly molecular level without being obscured by ill-defined side effects. Thus, the concept of SAC can be explored or, more generally, the mechanisms of reactions and the active parts of single-site catalysts, the so-called 'aristocratic' atoms, can be identified.

Examples discussed include:
(i) The room-temperature, cluster-oxide mediated redox reactions of the CO/N₂O couple which, arguably constitute one of the most prominent oxidation processes, and
(ii) novel metal-mediated C-H bond activation and C-C coupling of methane, which are regarded as one of the holy grails in chemistry.

11:51AM B32.00002: From Clusters To Cluster Complexes* [Invited] MASAHIKO ICHIHASHI (Presenter), Cluster Research Laboratory, Toyota Technological Institute, HIDEHO ODAKA, East Tokyo Laboratory, Genesis Research Institute, Inc. — Adsorption and reactions of molecules on metal clusters have been considered as a fundamental model of catalysis, and attracted much attention both in basic science and industrial areas. Then, the elucidation of their geometric and electronic structures provides a helpful insight into the reaction mechanisms to improve the catalytic properties. Infrared spectra of the nanocatalyst in a helium cluster give much information on the structures related to the reactivity. Recently we have developed a technique to form cluster complexes, Coₘ⁺Heₙ and Coₘ⁺NOHeₙ, by use of low-energy collision between helium clusters and metal cluster ions. This technique can provide significant amount of the cluster complexes, and we demonstrate the formation and the spectroscopy of the cluster complexes.

*This work was supported by the Special Cluster Research Project of Genesis Research Institute, Inc. and by JSPS KAKENHI Grant Number 17K04975.
GEREON NIEDNER-SCHATTEBURG (Presenter), Chemistry and Research Center OPTIMAS, Technische Universität Kaiserslautern (TUK) — We are investigating the surface morphology and adsorbate bonding properties of naked transition metal clusters under cryo conditions, and we have conducted a series of spectroscopic, kinetic and computational studies of the N$_2$ adsorption onto size selected Cobalt and Nickel clusters [1-4], as well as a case study of N$_2$ and H$_2$ co-adsorption onto a selected Ruthenium cluster [5]. In the course of these studies we chose to investigate Iron clusters and Iron-Rhodium nanoalloys as well. We found some Iron clusters reluctant to attach neither Nitrogen N$_2$ nor Hydrogen H$_2$. This presentation puts the current level of understanding to the stage.

*This work is supported by the Deutsche Forschungsgemeinschaft (DFG) in the framework of the Transregional Collaborative Research Center 3MET.de on Homogeneous and Heterogeneous Transition Metal Complexes.

LIAM HOWARD-FABRETTO (Presenter), GUNTER G ANDERSSON, Institute for Nanoscale Science & Technology, Flinders University, SCOTT ANDERSON, TIMOTHY GOREY, Department of Chemistry, University of Utah, GREGORY METHA, Chemistry, The University of Adelaide, VLADIMIR GOLOVKO, The MacDiarmid Institute for Advanced Materials and Nanotechnology, University of Canterbury — Metal clusters are groups of metal atoms with sizes ranging between 2 and 100 atoms, possessing unique electronic and catalytic properties. This work aims to measure the valence electron density of states for titania-supported Ru$_3$ clusters using the complimentary techniques UPS and metastable induced electron spectroscopy (MIES), and XPS will be used to determine the elemental composition. Ru clusters have been shown to be among the most active catalysts for industry-relevant reactions such as CO hydrogenation.

Two approaches to cluster deposition will be compared. The first is vaporisation of ligand-protected Ru$_3$(CO)$_{12}$ clusters onto a titania substrate under ultra-high vacuum, and subsequent heat-removal of the CO ligands to leave the bare Ru$_3$. The second is using a size-selected, laser ablation cluster source to deposit bare Ru$_3$ directly onto the substrates. It is known that the properties of supported clusters can differ depending on the deposition method, however these two common methods have never been directly compared for these clusters.

Session B33 FiAP: Advanced Materials for Applications: Fabrication, Lithography and Instrumentation BCEC 204B - Ronald Warzoha - Tag(s): Focus
Strained polymer films are commonly used as dielectric materials in high energy density capacitors, and processed such that they have significant anisotropy in a variety of materials parameters. In order to interrogate the influence of this anisotropy in thermal transport characteristics, we use the Transient Electro Thermal Technique (TET). TET enables characterization of novel materials with micrometer dimensions, without necessitating bulk production, reducing the time and cost of materials research. Using TET, we are able to obtain resolution of anisotropy in strained polymer films simply by modifying the orientation of the measurement. We compare the results of this thermal diffusivity obtained via TET analysis to the expected enhancement in thermal diffusivity results, from molecular dynamics modeling, of mechanically strained polymers. These findings demonstrate the utility of this for use in novel, laboratory-scale, polymer-based dielectric film fabrication.

Origin of long-lived photostriction in molecular ferroelectrics

Croconic Acid (CA) exhibits ferroelectricity due to proton displacement between molecules. Utilizing Time resolved x-ray spectroscopy under UV irradiation, we were able to observe lattice dilation effect with time scale over few seconds indicative of a long-lived metastable structure. The origin of the lattice dilation cannot be attributed to thermal effects due to its anisotropic characteristics. To elucidate the photon-induced electron structure change, current measurements were performed under different irradiation wavelengths of which only UV light exposure gives second-long excitation and relaxation time. Since the energy of the UV radiation is comparable to the bandgap in CA, the origin of photostriction could be solely attributed to the localized proton transfer between adjacent CA molecules.

Theory and simulation of charge injection at metal-polymer interfaces

In this work, we construct in silico atomic and molecular models of metal-polymer interfaces for two polymers commonly used in HVDC applications, namely polyethylene (PE) and polypropylene (PP). Using first-principles electronic structure calculations, we compute charge injection barriers for our interface systems. The effect of chemical and structural features, such as extrinsic chemical defects in the polymer (e.g., C=O and C-Cl groups) and physical morphology (e.g., amorphous vs crystalline regions in the polymer) are also considered.

Our results indicate potential avenues for the rational design of polymeric insulators that are more resistant to charge leakage.

Unravelling The Behaviour in a TCNQ Based Molecular Solid

Molecular solids present many advantages over their inorganic counterparts, however their more work is needed to bring our understanding up to that of other types of materials. One interesting problem is using organic based compounds to create functional materials, pairing the existence of magnetism and electrical behaviour. Within this talk, I will focus on triethylammonium 7,7,8,8-tetracyanoquinodimethane (TEA(TCNQ)₂), a quasi-1D system where an electron is shared between two TCNQ molecules creating a delocalised radical anion. Dielectric measurements have shown anomalies at two temperatures and these match with both a structural and magnetic phase transition. Our recent study has shown that the system enters a 3D Ising ground state and not simply undergoing a spin-transition as was previously thought. This is helping to further our knowledge of the system and highlight it's potential as a functional material.

We would like to acknowledge RIKEN and the ISIS Neutron and Muon Source, STFC, for access to the RIKEN-RAL muon facility.
Ultrafast photoexcited carrier dynamics in violanthrone-79 thin films

Kateryna Kushnir (Presenter), Taylor Trottier, Patrick Devlin Fitzgerald, Andrew Mendizabal, Physics Department, Worcester Polytechnic Institute, Christopher R Lambert, Biomedical Engineering, Chemistry & Biochemistry, Worcester Polytechnic Institute, Lyubov Titova, Physics Department, Worcester Polytechnic Institute — Violanthrone-79 (VO-79) is a promising organic semiconductor, molecules of which consist of large aromatic cores and aliphatic side chains. Strong π - π interactions promote stacking of individual molecules and forming nanoaggregates in solutions when dissolved in polar solvents like toluene and chloroform. Introduction of small amounts of poor solvents such as hexane enhances aggregation and results in highly crystalline morphology. We have studied optical and electronic properties of VO-79 thin films prepared from VO-79/chloroform solution at a concentration above the aggregation threshold, as well as those prepared from VO-79 solutions in chloroform/hexane mix. Using optical pump – THz probe spectroscopy, we have demonstrated that delocalization of π electrons in the film results in band-like carriers that remain free within individual aggregates for tens of picoseconds after photoexcitation. We correlate carrier dynamics in films containing VO-79 nanoaggregates with their morphology and optical properties as revealed by the photoluminescence spectroscopy. Observation of long-lived, mobile photocarriers suggests possible applications of VO-79 in organic optoelectronic and solar energy conversion devices.

Ferroelectric switching kinetics of large area Croconic acid thin films

Shashi Poddar (Presenter), Xuanyuan Jiang, Physics, University of Nebraska Lincoln, Yifan Yuan, Mechanical & Materials Engineering, University of Nebraska Lincoln, Xiaoshan Xu, Physics, University of Nebraska Lincoln — In the present work, large area ferroelectric thin films of Croconic acid with thickness ranging from 10-50 nm have been fabricated by physical vapor deposition on ITO substrates at ~ 30 C. The films, on being annealed up to room temperature, show excellent wetting forming polycrystalline films. The AFM morphology exhibits stable grains with lateral dimensions of 50-200 nm often exhibiting a monodomain polar states which can be reversibly switched as evidenced by piezoresponse force microscopy. Since the switching mechanism here solely relies on the proton tautomerism localized in the -OH- hydrogen bonds, studying local switching kinetics of the individual polar grains may unveil a novel mechanism of domain nucleation and switching in these molecular ferroelectric systems.

Metal-semiconductor contact effects and temperature-dependence of carrier transport in large-grain organic semiconductor thin film transistors

Jing Wan (Presenter), Yang Li, Department of Physics and Materials Science Program, University of Vermont, Jonathan Hollin, Adam Whalley, Department of Chemistry, University of Vermont, Randall Headrick, Department of Physics and Materials Science Program, University of Vermont — The pen-writer solution deposition method is used to deposit 2,7-dioclyl[1]benzothieno[3,2-b][1]benzothiophene (C8-BTBT) organic semiconductor thin films and also polymer dielectric layers. Organic transistors with source/drain contact layers either below or on top of the semiconductor layer and with or without surface treatment are investigated. Contact resistance produces a pronounced non-linearity in the output characteristics at low drain voltage, which is found to be consistent with a Schottky Barrier model. By treating the Au electrode with pentafluorobenzenethiol (PFBT) in a bottom contact geometry, the contact resistance is greatly reduced. An optimized geometry is obtained by using pen-written Cytop™ dielectric in a top-gate/bottom-contact structure, which exhibits a near-intrinsic average mobility, up to 9.0 cm²/V-s for C8-BTBT thin films deposited at high writing speed (25mm/s) and deposition on a heated substrate (60°C). We will report temperature-dependent carrier transport results for individual devices with both a top gate (with cytop dielectric) and bottom gate (with silicon dioxide dielectric) to compare results at both interfaces of the same C8-BTBT thin film.

Entropic elasticity and negative thermal expansion in ScF₃

IGOR ZALIZNYAK, DAVID WENDT, EMIL BOZIN, Brookhaven National Laboratory, KATHARINE L. PAGE, JOERG NEUEFEIND, Oak Ridge National Laboratory, BRENT T FULTZ, California Institute of Technology, ALEXEY TKACHENKO (Presenter), Brookhaven National Laboratory — Negative thermal expansion (NTE) is common in polymers and biomolecules, where its origin can be traced to entropic elasticity, but is rare in solids where it is desirable for applications. We report pair distribution function (PDF) analysis of neutron total scattering tracking the local structure and relative atomic positions in ScF₃ as it shrinks with increasing temperature. In agreement with previous X-ray studies¹,², we find that Sc-F bond slightly expands on warming, while the lattice spacing decreases. The correlation in positions of the neighbor F atoms rapidly fades on warming, consistent with simple model of F transverse thermal motion constrained only by the rigid Sc-F bond. This indicates that entropic stiffness rendered by strong Sc-F bond is at the origin of NTE in ScF₃. We thus observe universality of the NTE phenomenon across hard and soft matter, which opens new avenues for predictive modelling of this effect in solids.

Atomic Calligraphy: A MEMS Based Nanomanufacturing Technique

LAWRENCE BARRETT (Presenter), RICHARD LALLY, THOMAS STARK, JEREMY REEVES, DAVID JOHN BISHOP, Boston University — Atomic Calligraphy is a nanomanufacturing technique with the potential to combine resolutions below 10 nm with high throughputs. It works by combining two technologies, stencil lithography which is essentially shadow masking a flux atoms and microelectromechanical systems (MEMS). Stencil lithography is useable over large areas, inexpensive to implement, useable with fragile materials and on fragile surfaces. However, it has several challenges including: clogging of the stencil, limited resolution due to the dimensions of the evaporation source and the distance to the target, and imprecise alignment between stencil and target. Here, we present on overcoming these challenges using a variety of MEMS technologies including joule heating, precision springs, capacitive sensing and capacitive actuation.

*This work is funded by the DARPA Atoms to Product Program.

Focused Electrohydrodynamic Printing Technology by Incorporating an Einzel Lens

MATTHEW STROHMAYER (Presenter), ATUL DHALL, PUJHITHA RAMESH, NATALYA TOKRANOVA, JAMES CASTRACANE, CARL VENTRICE, SUNY Polytechnic Institute — Additive manufacturing (AM) shows great promise for both research and industrial applications. The main advantages of AM include limited waste and the ability to build complicated structures. The most common techniques for AM are fused deposition manufacturing, digital light printing, and ink jetting. All of these techniques suffer from resolution and material limitations. Recently, a cost-effective, versatile method of high-resolution printing called electrohydrodynamic (EHD) printing has been introduced. This method allows for spatial resolution in the hundreds of nanometers. This method works similarly to a typical ink jetting system, except instead of the ink/polymer being pushed out of a tip, it is pulled out by an applied electric field. This allows for the resultant droplet to be smaller than the needle diameter. Coulomb's law limits the ultimate resolution of this technique. To overcome this resolution limitation, we have incorporated an Einzel lens into the system to focus the droplets. This helps the droplets overcome the repulsive force from Coulomb's law and leads to better spatial resolution.

Superalloy Radiative Heat Transfer in Additive Manufacturing

ERIN CURRY (Presenter), RAINER HEBERT, PAMIR ALPAY, SANJUBALA SAHOO, JASON HANCOCK, University of Connecticut — Direct Laser Metal Sintering (DLMS) is a layer-by-layer additive manufacturing process using a high power focused source such a laser or electron beam. As the metal powder melts, the melt pool experiences non-equilibrium thermalization processes involving convection, evaporation, plasma creation and radiative cooling, expected to be most important at high temperature. Developing a fundamental understanding of the melt pool cooling rate through the radiative cooling is invaluable to controlling microstructure of the final product. In DLMS a high energy melting source is focused to a small spot size on the build plate and travels across the powder layer at a high velocity, all of which parameters make in-situ measurements of melt pool temperature from radiative cooling difficult. We discuss approaches to spatially resolved temperature analysis of the DLMS melt pool as well as a combined experimental and theoretical optical property investigation of superalloys typically used in DLMS.

1:27PM B33.00012: Cathodoluminescence-based nanoscopic thermometry in a lanthanide-doped phosphor
CLARICE D AIELLO (Presenter), Bioengineering Dept., Stanford University, ANDREA D PICKEL, Mechanical Engineering Dept., UC Berkeley, EDWARD BARNARD, Molecular Foundry, Lawrence Berkeley National Laboratory, REBECCA WAI, Chemistry Dept., UC Berkeley, CHRISTIAN MONACHON, Attolight AG, EDWARD WONG, SHAUL ALONI, FRANK OGLETREE, Molecular Foundry, Lawrence Berkeley National Laboratory, CHRIS DAMES, Mechanical Engineering Dept., UC Berkeley, NAOMI GINSBERG, Chemistry Dept., UC Berkeley — Crucial to analyze phenomena as varied as plasmonic hot spots and the spread of cancer in living tissue, nanoscale thermometry is challenging: probes are usually larger than the sample under study, and contact techniques may alter the sample temperature itself. Many photostable nanomaterials whose luminescence is temperature-dependent, such as lanthanide-doped phosphors, have been shown to be good non-contact thermometric sensors when optically excited. Using such nanomaterials, in this work we accomplished the key milestone of enabling far-field thermometry with a spatial resolution that is not diffraction-limited at readout. We explore thermal effects on the cathodoluminescence of lanthanide-doped NaYF₄ nanoparticles. Whereas cathodoluminescence from such lanthanide-doped nanomaterials has been previously observed, here we use quantitative features of such emission for the first time towards an application beyond localization. We demonstrate a thermometry scheme that is based on cathodoluminescence lifetime changes as a function of temperature that achieves ~ 30 mK sensitivity in sub-μm nanoparticle patches. The scheme is robust against spurious effects related to electron beam radiation damage and optical alignment fluctuations.

1:39PM B33.00013: Modeling Performance of Ultra-Sensitive In-Orbit Infrared Telescopes
WILLIAM ATKINSON (Presenter), Boeing — This paper evaluates considerations in minimizing disruptions of scientific data in ultra-sensitive Infrared (IR) spaced-based telescopes by charged particles in space radiation. The particles modeled are protons, alphas, and heavier ions with an atomic number as high as that of iron. Performance results of proposed designs are based on a model developed at Boeing. The components modeled are the spectra of the ion species in cosmic rays and solar flares, the transport of the primary ions and secondary particles produced including neutrons, the generation electron hole pairs (EHPs) by the particles penetrating the focal point array (FPA), and a component modeling transfer of EHPs from generation to recombination. Results indicate noise levels above 100 EHPs by secondary particles alone per pixel in intense space weather events, these observations agree with empirical data sources. Space based IR astronomical observatories now have a noise level of 100 electrons/pixel indicating the need of detailed radiation transport models; in near future designs where the pixel pitch reduces from 25 to 5 microns, the radiation model component becomes even more significant. Measures reducing the number of electrons per pixel below the threshold are discussed.

1:51PM B33.00014: Revisiting the Non-linear transport behaviors in conducting polymer
JIAWEI WANG (Presenter), LING LI, MING LIU, Institute of Microelectronics, Chinese Academy of Sciences — The non-linear transport in conducting polymers usually refers to the non-ohmic current-voltage (IV) relationship at low temperature, and are widely reported in both molecular doped and field effect doped polymers, power-law dependence of conductance on temperature, at low voltage (eV<<k_BT) and current on voltage, at high voltage (eV>>k_BT) are universally observed in the non-linear regime. We investigated the charge transport in polymer materials PBTTT doped with 2,3,5,6-Tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F4TCNQ), very revealing information was obtained via a simple contrast investigation between PBTTT films of different crystalline degrees. We found that only the transport behavior of highly crystalline PBTTT film at low-T could satisfy what Luttinger Liquid theory predicts, while those of poor ordered film showed non-power-law relationship. Simultaneously, fit of other non-linear transport models with our data was investigated. We finally proposed our model based on the microstructure of the PBTTT film with considering the interplay between Fermi liquids and Luttinger liquids.

Session B34 DCMP: Fundamentals of Solid/Aqueous-Electrolyte interfaces BCEC 205A - Jorg Zegenhagen, Diamond Light Source - Tag(s): Invited
11:15AM B34.00001: Probing the charge distribution at the electrochemical interface [Invited] YVONNE GRUNDER
(Presenter), CHRISTOPHER LUCAS, University of Liverpool, YVES JOLY, CNRS, Grenoble INP, Institut Neel — In-situ surface x-ray diffraction has enabled an atomic/molecular-level understanding of the interface under reactive conditions, including its potential and time dependence, to be developed. While information about the atomic structure of the electrode surface in electrochemical in-situ cells has been widely investigated, insight into the charge distribution and the structure of the electrolyte at the interface is still lacking. A fundamental understanding of the nature of the charge transfer, especially the influence of the applied potential and the screening by the electrolyte, is a major goal in electrochemistry to better understand electrochemical processes and charge transfer during adsorption and deposition. [1]

In-situ studies of the chemical bonding are rather difficult due to the presence of the electrolyte, as standard characterisation techniques which are mostly UHV based cannot be applied. Thus combining x-ray spectroscopy and x-ray diffraction to gain site specific information about the charge distribution at buried interfaces is a promising tool. [2,3] Examples of how the use of surface x-ray scattering techniques can help to characterise electrochemical interfaces in-situ in order to link, structure, reactivity and stability will be presented. Advances in these directions offer possibilities in elucidating atomic scale models of the electrochemical interface and thus will help to establish structure-stability-reactivity relationships.

11:51AM B34.00002: Monitoring electrochemical and electrocatalytic interface processes on the atomic and nanometer scale by operando surface X-ray scattering [Invited] OLAF MAGNUSSSEN (Presenter), Experimental and Applied Physics, Kiel University — The need for sustainable energy, reduction of pollutants, and the environmental benign processing of chemicals has spurred worldwide scientific activities in electrochemical energy science and electrocatalysis. These processes occur at the interfaces of solid electrodes in contact with complex liquid environments under conditions, which are difficult to access by most surface analytic techniques. For a better understanding of structure-property relationships and reaction-induced morphological changes, experimental approaches are required that provide direct insight into the atomic and nanoscale interface structure.

Modern synchrotron-based X-ray scattering methods provide unique opportunities for such operando studies. They allow monitoring structural changes at electrode surfaces with high structure sensitivity on (sub-) second time scales. The talk will give an overview of the current state of this field. It will specifically highlight the advantages of using very high photon energies (70 keV) in combination with 2D X-ray detectors. This new approach enables e.g. detailed determination of complex, dynamically changing interface structures and microdiffraction studies of spatially heterogeneous materials. The application of these methods will be demonstrated by studies of Pt oxidation and transition metal oxide catalysts for water splitting. In the first case, a strong dependence of the oxidation mechanism on the Pt surface structure was observed, resulting in pronouncedly different Pt dissolution and nanoscale restructuring. The second example will focus on epitaxial Co oxide thin films, which were monitored in the oxygen evolution regime up to current densities as high as 150 mA cm⁻². Whereas CoOOH(001) films were perfectly stable under these conditions, oxygen evolution on Co₃O₄(111) films occurs on a disordered nm-thick skin layer, which forms highly reversibly at potentials 300 mV negative of the onset of this electrocatalytic reaction.
12:27PM B34.00003: Transition-metal-oxide/liquid interfaces [Invited] ULRIKE DIEBOLD (Presenter), Institute of Applied Physics, TU Wien — Transition metal oxides are promising systems for photo- and electrocatalysis. For a molecular-scale understanding of the underlying mechanisms and processes, experiments on well-characterized samples are necessary, i.e., specific facets of single crystals with a known composition, geometry, and defect structure.

In the talk we will address the question whether the atomic structure of selected oxide surfaces survives the exposure to liquid water. We use a novel apparatus that allows to expose samples to liquids without them leaving the ultrahigh vacuum (UHV) environment [1]. We find that the TiO$_2$(110) surface maintains its (1x1) termination [2] and that the (2x1) overlayer observed after water exposure in air results in an ordered layer of carboxylates. In contrast, exposure to liquid water lifts the TiO$_2$(011)-(2x1) reconstruction and results in full hydroxylation [3]. We have also tested the several iron oxide surfaces [4, 5], and find hints that the pairs of dissociated and intact water molecules that form on these [4] and several other metal oxides are present in the liquid phase as well. Magnetite Fe$_3$O$_4$ was tested for OER in alkaline conditions, and was found to be stable at the nanoscopic scale, with a facet-dependent reactivity [5].

1:03PM B34.00004: Molecular Self-Assemblies as Templates for Electrochemically Deposited Nanostructures [Invited] MANFRED BUCK (Presenter), School of Chemistry, University of St Andrews — Ranging from porous networks to dense layers, the structural and functional versatility of aromatic molecules provides a diversity of options for controlling processes at the liquid/solid interface. This includes the electrochemical interface where the level of control intrinsic to electrochemical processes combines favourably with the control of charge transfer, interfacial energies and chemical functionality by highly organized molecular assemblies.

This combination can be taken advantage of for the generation of nanostructures by templated electrodeposition using molecular patterns produced by either bottom-up self-assembly or top down lithography. While structures down to the 20 nm range are relatively straightforward to achieve, progress in the move towards the bottom end of the nanoscale will be critically dependent not only on the precision of template structures but also on the level of control over the dynamics of processes such as diffusion and nucleation which, ultimately, become the limiting factors. To address these issues requires to go beyond the usual application of organized molecular layers to render electrodes electrochemically passive. As illustrated by the electrodeposition of metals, utilising a more varied design than non-functionalized single component layers offers interesting prospects for the generation of ultrasmall structures such as a reduction in the percolation threshold or self-limiting layer formation enabled by coordination controlled deposition.

Monday, March 4, 2019 11:15 AM - 2:03 PM

Session B35 DQI: Silicon Spin Qubits BCEC 205B - Emily Pritchett, HRL Laboratories - Tag(s): Focus

11:15AM B35.00001: Spin Qubits at Intel [Invited] JIM CLARKE (Presenter), Intel Corporation — Intel is developing a 300mm process line for spin qubit devices using state-of-the-art immersion lithography and isotopically pure epitaxial silicon layers. Both Si-MOS and Si/SiGe devices are being evaluated in this multi-layer integration scheme. In this talk, we will be sharing our current progress towards spin qubits starting with substrate characterization. Transistors and quantum dot devices are then co-fabricated on the same wafer and allow calibration to Intel’s internal transistor processes. Electrical characterization and feedback is accomplished through wafer scale testing at both room temperature and 1.6K prior to milli-kelvin testing. Accelerated testing across a 300mm wafer provides a vast amount of data that can be used for continuous improvement in both performance and variability. This removes one of the bottlenecks towards a large scale system: trying to deliver an exponentially fast compute technology with a slow and linear characterization scheme using only dilution refrigerators.
11:51AM B35.00002: A novel Si/SiGe heterostructure for quantum dot spin qubits  THOMAS MCJUNKIN (Presenter), EVAN R MACQUARRIE, SAMUEL NEYENS, BRANDUR THORGRIMSSON, JOELLE CORRIGAN, JOHN DODSON, Department of Physics, University of Wisconsin-Madison, DONALD E SAVAGE, MAX G LAGALLY, Department of Materials Science and Engineering, University of Wisconsin-Madison, MARK G FRIESEN, SUSAN COPPERSMITH, MARK ALAN ERIKSSON, Department of Physics, University of Wisconsin-Madison — Motivated by a desire to increase the energy splitting between the two low-lying valley states in a silicon quantum well, a Si/SiGe heterostructure is grown via UHV-CVD with a ~1 nm layer of SiGe buried ~2 nm beneath the upper interface of a silicon quantum well. High resolution STEM measurements confirm that this thin epitaxial layer is abrupt on the side facing the substrate and gradual on the side facing the surface. We report Shubnikov-de Haas and quantum Hall measurements, finding a transport mobility in excess of 100,000 cm²/(V s) at 6 x 10¹¹ cm⁻² carrier density and a series of stable oscillations in measurements of the longitudinal voltage as a function of magnetic field and carrier density (a fan diagram). We report both activation energy measurements in the quantum Hall regime and measurements of the excited state spectrum in gate-defined quantum dots fabricated in this material.

12:03PM B35.00003: Coherent control of a semiconductor quantum dot qubit, encoded by valley-states in Si⁺ NICHOLAS PENTHORN, JOSHUA S SCHOENFIELD (Presenter), HONGWEN JIANG, UCLA — Traditionally, spin and charge of individual electrons are used to encode a qubit in gated-defined semiconductor quantum dots. Valley states of electrons in silicon represents another degree of freedom in addition to spin and charge degree of freedoms. In this talk, we demonstrate the coherent control of a semiconductor quantum dot qubit, encoded by valley-states in Si. A double quantum dot device, fabricated on a SiGe hetero-structure, is used for the experiment. We found that either one of the quantum dots can be used to encode a qubit. The left dot has a valley splitting of 5.3 GHz (or 22 ueV), while the right dot has a different splitting of 8.2 GHz (or 34 ueV). The x-axis control of the qubit is done by either timed x-rotation near the anti-crossing point of the two valley eigenstates, or by the Landau-Zener effect using a slowly rising/falling pulse. The z-axis control is done at the region when the energy separation of the two valley levels is nearly detuning independent, which offers a protection against charge noise. Fast qubit operations, in the range of a few GHz, for both x and z rotations, are realized.

*This work is supported by ARO under grant # W911NF-17-1-0242.

12:15PM B35.00004: Spin-Blockade Spectroscopy of Si/SiGe Quantum Dots  EDWARD CHEN (Presenter), HRL Laboratories — We introduce a technique for measuring the singlet-triplet energy splitting in undoped, accumulation-mode Si/SiGe quantum dots [1]. We find that the measured splitting varies smoothly as a function of confinement gate biases and are also consistent to those obtained using photon-assisted tunneling (PAT) spectroscopy at the (2,0)-(1,1) charge transition. Because our technique operates in the limits of both large and small singlet-triplet energy splittings, we are able to show that the splitting can be limited by the lateral orbital excitation energy rather than solely by the valley splitting in the silicon well.

12:27PM B35.00005: Valley and orbital state spectroscopy of a Si/SiGe triple quantum dot  JOHN DODSON (Presenter), JOELLE BAER, JOSE CARLOS ABADILLO-URIEL, NATHAN HOLMAN, TREVOR KNAPP, BRANDUR THORGRIMSSON, EVAN R MACQUARRIE, SAMUEL NEYENS, THOMAS MCJUNKIN, RYAN FOOTE, University of Wisconsin - Madison, LISA EDGE, HRL Laboratories, LLC, MARK G FRIESEN, SUSAN COPPERSMITH, MARK ALAN ERIKSSON, University of Wisconsin - Madison — Valley and orbital states have important consequences for silicon based qubits, and a thorough understanding of their interaction in the few electron regime is crucial in forming robust qubits. While many spin-based qubits operate best with large valley and orbital splittings, valley qubits such as the quantum dot hybrid qubit [1] utilize the valley degree of freedom for its logical states. Here we present measurements of valley and orbital energies using excited state spectroscopy in a triple quantum dot fabricated using an Al-AlₓO₁₋ₓ-Al overlapping gate design. Valley splitting is shown to vary as a function of electron occupancy in the N=1 to N=4 regime between 35 and 70 µeV. We observe that higher lying orbital levels have a larger valley splitting, and we present tight binding simulations consistent with this observation. The spatial dependence of the valley splitting in a linear array of quantum dots is also investigated. Finally, we observe anomalously low orbital splittings of 200-400 µeV that could have potential applications to new readout mechanisms for certain silicon based qubits.

Here, we study the spin relaxation and dephasing in an MBE-grown $^{28}\text{Si}/\text{SiGe}$ device with a residual $^{29}\text{Si}$ concentration of less than 60 ppm. In our devices, instead of using a micromagnet, one of the electrostatic gates is replaced by a cobalt nanomagnet to generate the magnetic field gradient required for electrical dipole spin resonance. We find a maximum $T_1 = 480$ ms and present a detailed study of the spin relaxation time $T_1$ as a function of magnetic field. We observe a spin relaxation hotspot due to enhanced spin-valley mixing at a Zeeman energy of 207 µeV and find this large valley splitting to be tunable with the gate voltages. Finally, we discuss the long spin dephasing times $T_2^*$ and $T_2^{\text{echo}}$ obtained in this device.

*This project is sponsored by the German Research Foundation (DFG).
Charge noise induced spin decoherence in a double quantum dot: Effects of a micromagnet

XINYU ZHAO (Presenter), XUEDONG HU, University at Buffalo, The State University of New York — Charge noise is one of the largest error sources preventing the high-fidelity quantum computing in semiconductor systems. We study the decoherence of an electron spin in a double quantum dot in the presence of an inhomogeneous magnetic field and induced by a non-Markovian charge noise. We derive a master equation based on the stochastic Schrodinger equation. By analyzing the physical process represented by each term in the master equation, we show how the properties of the charge noise affect spin decoherence and how an orbital charge noise affects the spin dynamics through the inhomogeneous magnetic field. We find that a longer correlation time can slow down spin decoherence, particularly during the early stage of an evolution. A relation between the spin relaxation rate and the gradient of the magnetic field is given. The stochastic approach used to derive master equation can be also extended to other semiconductor systems in the presence of charge noise. Our results present a systematic approach to study decoherence processes caused by charge noise, particularly for quantum dots in an inhomogeneous magnetic field.

Spin decoherence in a quantum dot due to micro-magnets

PEIHAO HUANG (Presenter), Shenzhen Institute for Quantum Science and Engineering, and Department of Physics, Southern University of Science and Technology, XUEDONG HU, Department of Physics, University at Buffalo — A spin qubit in a semiconductor quantum dot is a promising candidate for quantum information processing for scalability and miniaturization. Micro-magnets have been proven to be effective to mediate the coupling of a spin qubit to photon and electrical control field. In this work, we study spin decoherence in a quantum dot mediated by the magnetic field gradient created by micro-magnets. The spin relaxation mediated by magnetic field gradient shows different magnetic field dependence compare with spin relaxation mediated by spin-orbit coupling. Furthermore, to the first order of the magnetic field gradient, there is finite spin dephasing due to 1/f charge noise. We discuss the consequence of the new spin decoherence mechanisms on the number of qubit operations.

Targeted enrichment of $^{28}\text{Si}$ for quantum computing

KE TANG (Presenter), HYUN-SOO KIM, ARUNA RAMANAYAKA, DAVID S SIMONS, JOSHUA POMEROY, National Institute of Standards and Technology — We report on the growth of isotopically enriched $^{28}\text{Si}$ epitaxial films with precisely controlled enrichment levels, ranging from natural abundance ratio of 92.2% all the way to 99.99987% (0.832ppm $^{29}\text{Si}$). Isotopically enriched $^{28}\text{Si}$ is regarded as an ideal host material for semiconducting quantum computing due to the lack of $^{29}\text{Si}$ nuclear spins. However, the detailed mechanisms for quantum decoherence and the exact level of enrichment needed remain unknown. Here we use hyperthermal energy ion beam deposition with silane gas to deposit epitaxial $^{28}\text{Si}$. In the meantime, we switch the mass selective magnetic field periodically to control the $^{29}\text{Si}$ concentration. A model predicting the residual $^{29}\text{Si}$ isotope fraction and the corresponding secondary ion mass spectrometry (SIMS) analysis are presented. Cross-sectional SEM/TEM will also been shown for the deposited $^{28}\text{Si}$ film throughout the range of enrichments.

Session B36 GMAG: Exotic Dynamics of Pyrochlore Magnets

Excitation Continuum in a Pyrochlore S=1 Heisenberg Magnet* [Invited] KEMP PLUMB (Presenter), Brown University — The existence of a spin-liquid for Heisenberg spins on the pyrochlore lattice was first speculated by Jacques Villain nearly 40 years ago and it is now recognized that the ground state of this model is a Coulomb spin liquid. However, experimental realizations are scarce. In this talk, I will discuss a new pyrochlore lattice magnet, NaCaNi$_2$F$_7$, which realizes the isotropic Coulomb spin liquid with $S=1$ spins and the complication of random Na$^+$ - Ca$^{2+}$ charge disorder in the crystal structure. I will present neutron scattering and calorimetric measurements that were used to uncover the magnetic correlations in this material and determine the magnetic Hamiltonian. The ionic disorder creates a rugged energy landscape that acts to freeze a small fraction of the magnetic degrees of freedom. However, the energy scale set by this disorder is small, and the Heisenberg interactions prevail. Only a small fraction of the available moment is frozen, and the magnetism in NaCaNi$_2$F$_7$ is dominated by a persistently fluctuating component that appears as a broad continuum of magnetic signal in inelastic neutron scattering measurements. These measurements demonstrate a beautiful realization of the Coulomb spin liquid and provide new insight into the interplay between disorder and magnetic exchange interactions in highly frustrated magnets.

11:51AM B36.00002: Novel Photogalvanic Effects in Weyl Semimetals [Invited] NAOTO NAGAOSA (Presenter), Department of Applied Physics, University of Tokyo — Photovoltaic effect is attracting growing interest from the viewpoint of the geometrical quantal phase of Bloch wavefunctions, i.e., Berry phase. The interband transitions between bands cause the shift of the electrons due to the difference in the intra-cell coordinates encoded as the Berry phase connection, resulting in the shift current without the external bias voltage. On the other hand, it has been known that the Weyl fermion is the source or sink of the Berry curvature, i.e., monopole or anti-monopole in momentum space, and leads to the enhanced Berry phase phenomena. Therefore, it is natural to expect the novel photovoltaic effect there. In this talk, I will describe the physical mechanism of shift current, and its features such as I-V characteristics, dependence on the mean free time, and noise, and discuss its realizations in Weyl semimetals such as the surface state of topological insulator, and TaAs. This talk is based on the works with collaborators T. Morimoto, K.W. Kim, H.Ishizuka, Y.Zhang, J.v. d.Brink, C. Felser, B. Yan, N. Ogawa, T. Hayata, M. Ueda, M. Sotome, M. Nakamura, J. Fujioka, M. Ogino, Y. Kaneko, M. Kawasaki, and Y. Tokura.

12:27PM B36.00003: Metamagnetism, Criticality and Dynamics in the Quantum Spin Ice Pr2Zr2O7 [Invited] NAN TANG (Presenter), AKITO SAKAI, ISSP, University of Tokyo, KENTA KIMURA, GSFS, University of Tokyo, SHOTA NAKAMURA, Department of Physical Science and Engineering, Nagoya Institute of Technology, YOUSKE MATSUMOTO, Max-Planck Institute, TOSHIRO SAKAKIBARA, SATORU NAKATSUJI, ISSP, University of Tokyo — Geometrical frustration may prevent the formation of long-range magnetic order, giving rise to a diverse range of novel ground states. One of such an unusual state is called quantum spin liquid (QSL) possibly realized in quantum spin ice systems. Its excitations behave like charged particles interacting with linearly dispersive “photon”, protected by hidden topological order parameter. Yet, the properties of quantum phase transition between such topological phases remain unknown and are waiting to be established. Pr-based pyrochlore compounds such as Pr2Ir2O7 and Pr2Zr2O7 are known to be quantum spin ice systems. Pr2Ir2O7 is a fascinating material exhibiting various exotic phenomena such as the spontaneous anomalous Hall effect [1]. In contrast to Pr2Ir2O7, the insulating Pr2Zr2O7 renders a simplified platform to explore the physics of quantum spin ice. K. Kimura et al. [2] reported the absence of “pinch points” in the inelastic neutron scattering spectrum of Pr2Zr2O7, suggesting the breakdown of the ice rule owing to quantum fluctuations — a promising hint of a U(1) QSL state. In a recent study [3], it was found that structural disorder acts as a transverse field on the non-Kramers Pr3+ ion in Pr2Zr2O7, stabilizing the QSL state. Under a magnetic field along the [111] axis, classical spin ice materials undergo a 1st-order metamagnetic transition [4]. Although theoretical studies [5] predict the existence of metamagnetic transition in quantum spin ice, a comprehensive investigation is still lacking. Here, we report magnetization, thermal expansion, and magnetostriction measurements on Pr2Zr2O7. These measurements aim to clarify the nature of the metamagnetic transition and to probe possible topological quantum criticality.

1:03PM B36.00004: Magnetic moment fragmentation and dynamical spin ice features in Neodymium pyrochlores [Invited] ALEXANDROS SAMARTZIS, JIANHUI XU, VIVEK K. ANAND, NAZMUL ISLAM, Helmholtz-Zentrum Berlin, JACQUES OLLIVIER, Institut Laue Langevin, TATIANA GUIDI, Rutherford Appleton Laboratory, GEORG EHLERS, Oak Ridge National Laboratory, YiXi SU, Heinz Maier-Leibnitz Zentrum, BELLA LAKE (Presenter), Helmholtz-Zentrum Berlin — Neodymium pyrochlores show rich, complex and exotic physical phenomena. The Nd3+ ions have a well-isolated ground state doublet with octupolar-dipolar symmetry and they interact with each other via highly anisotropic exchange interactions. We have studied two members of this family Nd2Zr2O7 and Nd2Hf2O7. Both show long-range all-in-all-out antiferromagnetic order revealing broken gauge symmetry in the ground state. The lowest energy excitations form a flat, gapped mode with a pinch-point structure factor suggesting a proximate gauge symmetry leading to dynamical spin ice. At higher energies there are dispersive spin-wave modes which touch the flat mode, at the pinch points. They have a pinch point pattern of their own which is rotated with respect to that of the flat mode and which give rise to half-moon features in constant energy slices. The coexistence of long-range magnetic order, the pinch-point mode and half-moon features originate from fragmentation of the Nd3+ magnetic moment into divergence-free and divergence-full parts. Finally at temperatures just above the Neel temperature, the pinch point mode becomes gapless and the spin-waves broaden suggesting a spinon continuum.
Neutron scattering signatures of pyrochlore spin liquids and nematic phases* [Invited] LUDOVIC JAUBERT (Presenter), CNRS / LOMA, University of Bordeaux, OWEN BENTON, RIKEN, HAN YAN, Okinawa Institute of Science and Technology, MATHIEU TAILLEFUMIER, ETH Zurich, NICHOLAS SHANNON, Okinawa Institute of Science and Technology, JAAN OITMAA, University of New South Wales, RAJIV SINGH, University of California, Davis, TOMONARI MIZOGUCHI, University of Tsukuba, RODERICH MOESSNER, MPI-PKS Dresden, MASAFUMI UDAGAWA, University of Gakushuin — Research on spin liquids has gradually evolved from the search of systems that do not order, to the quest of exotic quasi-particles and emergent gauge fields. But how to measure a gauge field in experiments? Neutron scattering certainly offers a helpful microscopic probe, e.g. with Coulomb gauge fields famously identified by pinch points in spin ice materials. But there is no spin-liquid analog of a Bragg peak; the very diversity of spin liquids makes them both fascinating and evasive.

In this talk, we will explore a broad range of pyrochlore physics with anisotropic exchange and further neighbour couplings, in order to explain the connection between several characteristic patterns of neutron scattering, their underlying Hamiltonian models and the strongly correlated magnetic phases they support. For example, "half-moon" patterns are a dispersive complement to the pinch points [1,2] that have been observed in Tb2Ti2O7 [3] and NaCaNi2F7 [4], while in tensor spin liquids, the pinch points may evolve into lines [5] or 4-fold singularities characteristic of higher-rank U(1) gauge fields [6,9]. To conclude, we will discuss the nematic "hidden" order stabilised when the symmetry of the Heisenberg antiferromagnet is lowered by frustrating anisotropic exchange [7,8,9].

Session B37 GMAG DCMP: Spin Liquids: Theory and Experiment

Critical Spin Liquid versus Valence Bond Glass in Triangular Lattice Organic κ-(ET)2Cu2(CN)3*

KIRA M. RIEDL, ROSER VALENTI, STEPHEN WINTER (Presenter), Institute for Theoretical Physics, Goethe University Frankfurt — The organic triangular-lattice antiferromagnet κ-(ET)2Cu2(CN)3 has been extensively discussed as a quantum spin liquid (QSL) candidate. Recently, an intriguing quantum critical behaviour was suggested from low-temperature B/T scaling of the magnetic torque experiments [1]. Through microscopic analysis of all anisotropic contributions, including Dzyaloshinskii-Moriya and multi-spin scalar chiral interactions, we highlight significant deviations of the experimental observations from a quantum critical scenario. Instead, we show that disorder-induced spin defects provide a comprehensive explanation of the low-temperature properties[2]. These spins are attributed to valence bond defects that emerge spontaneously as the QSL enters a valence bond glass phase at low temperature. This theoretical treatment is applicable to a general class of frustrated magnetic systems; similar scaling is also observed in the Kagome lattice antiferromagnet Herbertsmithite[3].

*The work was supported by the Deutsche Forschungsgemeinschaft (DFG) through project SFB/TRR49.
11:27 AM B37.00002: Charge Order without Spin Order in the Layered Frustrated Magnet κ-(BEDT-TTF)$_2$Hg(SCN)$_2$Cl$^*$

TERESA LE (Presenter), ANDREJ PUSTOGOW, HSIN-HUA WANG, YONGKANG LUO, University of California, Los Angeles, ELENA GATI, MICHAEL LANG, Institute of Physics, Goethe-University Frankfurt, STUART E BROWN, University of California, Los Angeles —

There are several quasi two-dimensional materials which do not order magnetically, including a number of geometrically frustrated organic charge transfer salts. To investigate the interplay between charge order (which may affect the frustration) and magnetic order, we use $^1$H NMR spectroscopy to examine the magnetic properties of κ-(BEDT-TTF)$_2$Hg(SCN)$_2$Cl, which exhibits a first-order metal-insulator transition to a charge ordered state at $T_{CO} = 30K$. The high-temperature metallic phase exhibits Fermi-liquid behavior with constant $(T_1T)^{-1}$, while the spin-lattice relaxation rate is subject to an abrupt enhancement at $T_{CO}$ and shows a standard paramagnetic response down to 2 K, below which the relaxation rates decrease as $1/T_1 \sim T^2$. The smooth temperature dependence of $T_1$ and the absence of changes in the NMR spectra rule out magnetic order down to 25 mK suggesting decoupling of the spin and charge degrees of freedom, while the CO is expected to reduce the frustration. These observations are discussed in the context of the ground state without magnetic order. Ongoing field-dependent measurements may elucidate whether the magnetic interactions are subject to 1D physics.

*This work was supported by the National Science Foundation (DMR-1709304).

11:39 AM B37.00003: Quantum valence bond ice and its relation to κ-H$_3$(Cat-EDT-TTF)$_2$

MASAHIKO YAMADA (Presenter), YASUHIRO TADA, Univ of Tokyo-Kashiwanoha — Motivated by the discovery of the coexistence of unfrozen spin and dipole fluctuations in an organic quantum spin liquid called κ-H$_3$(Cat-EDT-TTF)$_2$ [1], we propose a new asymptotically solvable model, where a quantum spin liquid (resonating valence bond) state is accompanied by quantum proton motion, which we name quantum valence bond ice. We can regard this state as a quantum spin-dipole liquid in the sense that quantum spin fluctuations are triggered by the coupling to the quantum proton motion. In the classical version of this model, there are macroscopically degenerate ground states, and quantum fluctuations of the proton motion will lift the degeneracy. The resulting quantum ground state should be regarded as the U(1) spin liquid phase in 3 dimensions, connected to Anderson’s resonating valence bond state [2] in the perturbative level.

11:51 AM B37.00004: Effect of randomness on spin excitations in quantum spin liquid state of 1T-TaS$_2$

HINAKO MURAYAMA (Presenter), YUKI SATO, TOMOYA TANIGUCHI, RYO KURIHARA, XIANGZHUO XING, SHIGERU KASAHARA, YUICHI KASAHARA, Department of Physics, Kyoto University, MASARO YOSHIDA, CEMS, RIKEN, YOSHIHIRO IWASA, Quantum-Phase Electronics Center and Department of Applied Physics, University of Tokyo, MARCIN KONCZYKOWSKI, Laboratoire des Solides Irradies, Ecole Polytechnique, YUJI MATSUDA, Department of Physics, Kyoto University —

Quantum spin liquid (QSL) is a novel state of matter where the ground states are quantum mechanically entangled and have several characteristic features, including fractional excitations. However, the nature of QSLs remains elusive. To tackle this problem, studying the effect of quenched disorder is of vital importance.

Recently, 1T-TaS$_2$ has aroused great interest as a candidate material that hosts a QSL ground state on two-dimensional perfect triangular lattice as suggested both theoretically and experimentally[1, 2]. To study the effect of randomness on the QSL state, we performed thermal conductivity and specific heat measurements on pure, Se-doped and electron irradiated 1T-TaS$_2$. The results indicate the coexistence of itinerant and localized gapless spin excitations, suggesting a novel spin liquid state where itinerant quasiparticles coexist with randomly distributed orphan spins forming localized random singlets. In addition, thermal conductivity reveals the suppression of gapless spin excitations by Se-doping, indicating that the itinerant gapless spin excitations are sensitive to randomness. We will also discuss the effect of randomness on the specific heat.

12:03PM B37.00005: Spin-Liquid-Like State in the Triangular Lattice Antiferromagnet TbInO3*  
MIN GYU KIM  
(Presenter), Rutgers University, New Brunswick, BARRY L. WINN, SONGXUE CHI, ANDREI T SAVICI, Oak Ridge National Lab, JOSE A RODRIGUEZ, NIST, YANBIN LI, XIANGHAN XU, JAE WOOK KIM, SANG-WOOK CHEONG, VALERY KIRYUKHIN, Rutgers University, New Brunswick — Unpolarized and polarized inelastic neutron scattering studies in single crystals of the triangular-lattice (TL) antiferromagnets TbInO3 and TbIn0.95 Mn0.05 O3 are reported. Broad gapless magnetic excitations are located at the TL Brillouin zone boundary. They show a weak enhancement near the M points at the lowest energies, and shift to the K points with increasing energy. At higher energies, a broad dispersing excitation branch, also centered at the zone boundary, is observed after a gap. No signs of magnetic order are found down to the temperatures 100 times smaller than the effective interaction energy given by the excitation bandwidth, indicating a very strong frustration. The fluctuating magnetic moment exceeds one half of the Tb3+ free-ion value and is confined to the TL plane. These observations strongly suggest a triangular-lattice-based spin liquid state in TbInO3.

12:15PM B37.00006: Spin Dynamics of the Elemental Quantum Spin Liquid β-Mn*  
JOSEPH PADDISON (Presenter),  
Department of Physics, University of Cambridge, ROSS STEWART, ISIS Neutron and Muon Source, Rutherford Appleton Laboratory — Pure β-Mn is the only elemental metal that shows quantum spin-liquid-like behavior [1]. Its magnetic Mn atoms occupy a frustrated three-dimensional network of corner-sharing triangles. Unlike all other transition metals, β-Mn does not show long-range magnetic order to the lowest measured temperatures (~0.3 K). Instead, its magnetic response is dominated by strong antiferromagnetic spin fluctuations that persist up to room temperature and exhibit non-Fermi-liquid scaling [2].

We present neutron-scattering measurements of the spin dynamics of β-Mn over a wide range of momentum transfer, energy transfer, and temperature. Our measurements allow us to parameterize an effective Hamiltonian [3] that reveals the temperature dependence of the on-site magnetic moment and the magnetic interactions. Our results shed new light on the unusual magnetic behaviour of this remarkable element and demonstrate an experiment-driven approach to parameterizing magnetic interactions in metals.

12:27PM B37.00007: Dynamical spin structure factor from a variational Monte Carlo perspective*  
[Invited] FEDERICO BECCA (Presenter), National Research Council — The spin dynamical structure factor is computed within a variational framework to study frustrated Heisenberg models in one and two dimensions. Starting from Gutzwiller-projected fermionic wave functions, the low-energy spectrum is constructed by considering two-spinon excitations. Benchmarks on the one-dimensional J1-J2 model are considered. Here, an excellent description of both the gapless and gapped (dimerized) phases is obtained [1]. In the square lattice, we obtain the distinctive spectral signatures of the transition between the Neel and the spin-liquid phases that takes place for J2/J1 ~0.45. By increasing the frustration, the magnon excitation at q=(π,0) and (0,π) broadens, suggesting the tendency towards a spin fractionalization. In addition, its energy softens, indicating the presence of gapless states at the transition and within the spin-liquid phase [2]. On the triangular lattice, we assess the possibility to have the magnon decay, as suggested by using spin-wave approaches for non-collinear magnetic orders [3]. The evolution of the spin dynamical structure factor when approaching the magnetically disordered phase in presence of a next-nearest-neighbor coupling J2 is also included [4]. Preliminary calculations on the kagome lattice are also discussed.

*Support from the National Research Council (CNR) is acknowledged.
We investigate signatures of spin liquids with spinon Fermi surfaces in electron spin resonance experiments. We focus on the magnetic field (h) and temperature (T) dependence of the linewidth $\eta$ of the resonance peak in the ESR absorption spectrum. We show that in the presence of DM interaction, the linewidth is determined by the low-energy U(1) gauge fluctuations resulting in a characteristic $\eta \sim h^{2/3}$ scaling at $T=0$ and a more complicated behavior $T/h + T^{2/3} f(h/T)$, with an explicit form of the scaling function $f(x)$, at finite $T$. We find that exchange anisotropy results in a weaker $h$ and $T$ dependence of $\eta$. We discuss relevance of our findings to experiments on the spin liquid candidate $\kappa$-ET and related materials.

*Supported by NSF DMR-1507054 and DOE DE-FG02-08ER46524.

Coulombic quantum spin liquids (C-QSLs) whose low energy excitations are U(1) gauge fluctuations realize massive quantum entanglement in quantum magnets. They have been suggested to be hosted in several three-dimensional materials including a pyrochlore structure, $\text{A}_2\text{B}_2\text{O}_7$. In this study, we present a phenomenological theory of C-QSLs and their phase transitions in the extended Landau paradigm. Within extended Landau paradigm which can be achieved by enlarging symmetry group, we obtain richer phase diagrams than the conventional order only diagrams. As a specific example, we construct the effective theory of conventional order parameters of a lattice symmetry($G$) and emergent excitations of C-QSLs($\sim G$) in the extended Landau paradigm. Namely, we write down all terms respecting a lattice symmetry and gauge invariance and investigate possible phase structures. For example, we apply our theory to systems with an all-in-all-out (AIAO) order parameter and U(1) gauge fluctuation dubbed Coulombic AIAO (AIAO*). Phenomenologically we obtain characteristic heat capacities and magnetic responses characterizing phases. Our theory may be directly applied to an insulating pyrochlore system where both A and B sites are magnetically active and one of them forms a U(1) quantum spin liquids.

We present the global phase diagram of the Heisenberg model on the body-centered cubic (BCC) lattice with nearest-neighbor $J_1$, second nearest-neighbor $J_2$ and third nearest-neighbor $J_3$ exchange couplings, for both antiferromagnetic and ferromagnetic $J_1$, $J_2$, and $J_3$. The classical phase diagram is shown to host four commensurate magnetic orders [ferromagnet $q=(0,0,0)$, Néel antiferromagnet $q=(2\pi,0,0)$, $q=(\pi,\pi,0)$, and $q=(\pi,\pi,\pi)$], and three incommensurate helimagnetic orders, namely, a one-, two- and three-dimensional spiral. The corresponding quantum spin-1/2 model is investigated employing the pseudofermion functional renormalization group (PFFRG) method. It is shown that quantum fluctuations (i) stabilize a quantum spin liquid phase over an appreciable region in parameter space centered around tri-critical points, (ii) strongly renormalize the phase boundaries (compared to those of the classical model), (iii) shift the pitch vector of the helimagnetic orders. We obtain the critical ordering temperatures for the $S=1/2$ model from Quantum Monte Carlo in the unfrustrated parameter regime, and compare it with the estimates obtained from one- and two-loop PFFRG. In the frustrated regime of the model, we compare our estimates with results available from other methods.
1:39PM B37.00011: Control of Magnetic and Topological Orders with a DC Electric Field*  
KAZUAKI TAKASAN (Presenter), Department of Physics, Kyoto University, MASAHIRO SATO, Department of Physics, Ibaraki University — In this talk, we present our theoretical proposal which provides a new route to control magnetic and topological orders in a broad class of insulating magnets with a DC electric field [1]. We show from the strong-coupling expansion that magnetic exchange interactions along the electric-field direction are generally enhanced in Mott insulators. It indicates that we can control the spatial structure of the interactions in magnets with a DC electric field. To illustrate this idea, we particularly focus on two kinds of magnets, frustrated magnets and quasi-one-dimensional magnets, and obtain phase diagrams including several magnetic or topological ordered phases such as quantum spin liquids and Haldane-gap states. Our proposal is effective especially for magnets in the vicinity of quantum critical points, and would also be applicable for magnets under low-frequency AC electric fields such as terahertz laser pulses. Our result would pave a promising way to control the exotic states of matter in magnets.

*This work is supported by JSPS KAKENHI (Grant No. JP16J05078, JP17K05513 and JP15H02117) and Grant-in-Aid for Scientific Research on Innovative Area, Nano Spin Conversion Science (Grant No. 17H05174).

1:51PM B37.00012: Construction of matrix product state for the Gutwiller projected variational wavefunctions  
AMIR MOHAMMADAGHAEI (Presenter), University of California, Riverside, BELA BAUER, Station Q, Microsoft Research, KIRILL SHTENGEL, University of California, Riverside, RYAN MISHMASH, University of California, Berkeley — An accurate description of various quantum spin liquid states using tensor network methods remains notoriously challenging. For large quasi-1D systems, the density matrix renormalization group and related methods usually require significant computational resources and sometimes fail to converge to a satisfactory state. On the other hand, variational wavefunctions acquired from the Gutwiller projection of gaussian fermionic theories has long served as both a theoretical starting point for construction of such spin liquid states and as an inspiration for numerical variational Monte Carlo (VMC) to calculate observables of interest. In this work, we examine a different method by exploring the possibility of constructing a matrix product state (MPS) representation for a Gutwiller-projected state from two given MPS representations of gaussian fermionic theories. We investigate the complexity of different approaches to achieve this goal and test the methods on two copies of a single half-filled band of spin-1/2 fermionic spinons. We then apply this method to two MPS of multi-band fermionic spinon theories in an attempt to describe spin liquid states on a quasi-1D strips of triangular and kagome-like lattices and compare to the complexity of the traditional VMC approach.

2:03PM B37.00013: Bridging partons and coupled-wire approaches to quantum spin liquids.*  
EYAL LEVIATAN (Presenter), DAVID MROSS, Weizmann Institute of Science — Quantum spin systems which avoid symmetry-breaking order, e.g., due to geometric frustration, can instead form so-called quantum spin liquids. These phases, characterized by fractional excitations and emergent gauge fields, are thought to be realized in an increasing number of quasi-two-dimensional materials. In my talk, I will show how a wide range of gapped as well as gapless spin liquids can be accessed by a generalization of the ‘coupled-wire’ technique. In particular, I will construct explicit Hamiltonians that realize these phases and show how this method allows transparent access to subtle questions regarding the emergent gauge field, such as confinement. I will compare and contrast this approach to the popular parton-construction, and highlight the respective advantages.

Session B38 GMAG DMP: 2D Magnetism I  
BCEC 206B - Mark Meisel, University of Florida - Tag(s): Focus
11:15AM B38.00001: Criticality in Two-Dimensional Quantum Antiferromagnets (2D QAF) [Invited] CHRISTOPHER LANDEE (Presenter), Clark University — Low Dimensional (LoD) physics has long provided opportunities (both analytical and experimental) for exploring criticality in model systems that are more tractable than the more formidable 3D analogs. In particular, magnetic LoD compounds have provided multiple physical realizations with which theoretical predictions can be tested. The quantum (S = ½) two-dimensional model clearly reveals the influence of exchange anisotropy (Ising, XY, Heisenberg) and quantum fluctuations upon criticality: the Ising model spontaneously orders, the XY system undergoes a topological transition, and the Heisenberg analog (2D QHAF) remains disordered at any finite temperature. There are many crystalline compounds accurately described as 2D quantum Ising antiferromagnets but the equivalent XY and Heisenberg materials remain in development.

In practice, all known crystalline realizations of 2D QHAF magnetically order at low temperatures due to a combination of interlayer exchange (J_{3d}) and/or exchange anisotropy (Δ). Simulations of the ideal (J_{3d}=0) 2D QHAF [1] revealed that a ratio Δ/J < 0.01 will induce either XY or -l-order at low temperatures and also revealed that the ideal 2D QHAF becomes a perfect 2D QXYAF in an applied field [2]. This talk will describe the approaches followed in the Clark University group in pursuit of the ideal 2D QHAF, as illustrated in the compound [Cu(pz)_{2}(2-HO-py)_{2}](PF_{6})_{2}.

11:51AM B38.00002: Single crystal EPR analysis of pyrazine bridged layered complexes‡ JEFFREY MONROE (Presenter), Chemistry, Clark University, CHRISTOPHER LANDEE, Physics, Clark University, FREDRICK T GREENAWAY, Chemistry, Clark University, JAN L WIKAIRA, Chemistry, University of Canterbury, MARK M TURNBULL, Chemistry, Clark University — Over the last three decades our group has endeavored to model the antiferromagnetic interactions of the copper-oxide high-temperature superconductors via crystal engineering of low dimensional copper(II) systems. Our efforts have led us to systems of the type [Cu(pz)_{2}(L)_{2}](A)_{2} which contain well isolated pyrazine-bridged square-lattices with Heisenberg antiferromagnetic superexchange. We report primarily on [Cu(pz)_{2}(2-hydroxypyridine)_{2}](PF_{6})_{2}. The single crystal EPR linewidth as a function of temperature and angle at X-Band are investigated in three orientations where XYZ=abc. The linewidth is investigated in terms of g-anisotropy, dipolar spin-diffusion, antisymmetric and anisotropic exchange. The linewidth in the ac and bc planes follow a cos^{2}(θ) dependence indicating the dominant contributions to the linewidth are the anisotropic and antisymmetric exchange. These results are compared to those from other techniques including NMR and SQUID magnetometry. The effects of these interactions on the 3D ordering temperature are considered.

12:03PM B38.00003: Low-dimensional quantum magnets supported by non-covalent interactions‡ JAMIE MANSON (Presenter), JACQUELINE VILLA, DANIELLE VILLA, Chemistry, Eastern Washington University, WILLIAM BLACKMORE, ROBERT WILLIAMS, JAMIE BRAMBLEBY, PAUL GODDARD, Physics, University of Warwick, JOHN SINGLETON, NHML, Los Alamos Natl Lab, ROGER JOHNSON, Physics, University of Oxford, SAUL H. LAPIKUS, Advanced Photon Source, Argonne Natl Lab, BENJAMIN HUDDART, THOMAS HICKEN, TOM LANCASTER, Physics, Durham University, STEVE BLUNDELL, Physics, University of Oxford, FAN XIAO, Muon-spec Lab, Paul Scherrer Institut, JOHN SCHLUETER, DMR, NSF — At ambient pressure, [Ni(HF_{2})(pyz)_{2}]SbF_{6} contains S = 1 Ni(II) ions arranged in a tetragonal network consisting of 1D Ni-FHF-Ni chains (J) cross-linked by pyrazine (pyz) ligands (J'). Previous work determined D = 13.3 K, J = 10.4 K and J' = 1.4 K [1]. Below T_{N} = 12.2 K, long-range magnetic order sets in and, as revealed by neutron diffraction, is of the XY-type with Ni(II) moments occupying any collinear orientation in the crystallographic ab-plane. Pressure-dependent X-ray powder diffraction data reveal a first-order structural phase transition at 3 GPa which leads to a distorted monoclinic network and kinked magnetic exchange pathways. In this high-pressure regime, the magnetic ground state switches to Ising-like with concomitant reduction in T_{N}. The related quasi-1D chain, NiI_{2}(3,5-lutidine)_{4}, also forms a tetragonal lattice but consis of discrete molecular units. A chain-like motif affords close Ni-I...I-Ni contacts and strong magnetic coupling. Evidence suggests that this material is a rare isotropic Haldane chain with J = 17.5 K and D = 6.3 K [2]. Time permitting, structural and magnetic properties of each material will be presented.

Honeycomb lattice antiferromagnets have been of tremendous research interests due to their complex magnetic structures ranging from Neél, zigzag, stripy, and spin liquid depending on details of competing exchange interactions. To study these interesting magnetic states, we have synthesized single crystals of a novel spin-3 honeycomb lattice antiferromagnet, Tb$_2$Ir$_3$Ga$_9$, which is a member of a large family of compounds with chemical formula R$_2$T$_3$X$_9$ (R = rare-earth element, T = d-element, and X = p-block element). Structural analysis showed the crystals have formed in orthorhombic symmetry with space group 63 ($\text{Cmcm}$). From the magnetization measurements, we find characteristics of low-dimensional magnetism followed by a long range ordering at 12 K. As determined both by magnetometry and powder neutron diffraction, the Tb spins lie strictly along the a-axis, parallel to the Tb-Tb contact. Two spin-flop transitions are observed when the field is applied parallel to this axis, separated by a plateau corresponding to $M=\frac{M_s}{2}$. Magnetoresistance data reflect the anisotropy and contains features that correlate with the spin flop transitions. We propose a model for the magnetic ground state and a phenomenological theory for the magnetic interactions.

Hydroxy halides M$_2$(OH)$_3$X (M = transition metal, X = Cl, Br, I) represent a family to investigate novel quantum phenomena arising from the magnetic frustration. For instance, via doing Zn into Cu sites in the parent cinoactacamite Cu$_2$(OH)$_3$Cl, herbertsmithite ZnCu$_3$(OH)$_6$Cl$_2$ hosts a perfect two-dimensional kagome magnetic lattice and exhibits quantum spin liquid state without long range magnetic ordering. In this paper, we report a comprehensive study of botallackite Cu$_2$(OH)$_3$Br, a compound with distorted quasi-two dimensional triangular magnetic lattice, via magnetic susceptibility, heat capacity, neutron diffraction, and inelastic neutron scattering measurements. Density functional theory calculations to understand the exchange interactions of this system will be briefly discussed as well.

The copper compound Cu$_2$(OH)$_3$Br has relatively few experimental studies, and, to the best of our knowledge, this material has not been approached from first principles before. Previous experimental work on the isostructural compound Cu$_2$(OH)$_3$Cl has demonstrated an interesting frustrated magnetic phase below the Neel temperature. Furthermore, upon substitution of the halogen ion, the Neel temperature was shown to grow with increasing halogen ion size for Cu$_2$(OH)$_3$Cl, Cu$_2$(OH)$_3$Br, and Cu$_2$(OH)$_3$I, possibly providing insight into the superexchange mechanism in this material. In this talk, we present the results of our first principles calculations on the compound Cu$_2$(OH)$_3$Br. We discuss the magnetic phase; in particular, we find the exchange constants and elucidate the interplay between magnetism and orbital configuration.

Finding skyrmions in different kinds of structures has attracted a lot of attention but also remains a challenge. Here we study the adsorption of transition metal atoms (Cr, Mn, Fe, and Co) deposited on top of a monolayer MoS$_2$ where the transition metal atoms form a triangular lattice. First-principles DFT calculations suggest that the magnetic ordering of this triangular lattice corresponds to a 120-degree antiferromagnetic structure. Heisenberg exchange parameters, single-ion anisotropy constants, and Dzyaloshinskii-Moriya vectors are extracted by choosing different spin configurations and calculating the total energy differences. For the considered transition metal atoms, the ground states are found to be spin spirals formed from 120-degree antiferromagnetic states. Our study shows the potential to find skyrmions in such triangular lattices.
Orbital and Charge Participation in the Magnetic Phases of Intercalated Fe$_{1/3}$TaS$_2$, Fe$_{1/3}$NbS$_2$ and Their Alloys

Conrad Stansbury (Presenter), Claudia Fatuzzo, Eran Maniv, Spencer Doyle, Caolan John, James G. Analytis, Alessandra Lanzara, University of California, Berkeley — The Ruderman-Kittel-Kasuya-Yosida (RKKY) interaction has been used to understand the origin of (anti)ferromagnetic behavior in some magnetic transition metal intercalated dichalcogenides (TMDs). Despite the clean picture that RKKY presents, little has been said about the interplay of intercalate magnetism with the low temperature phases in disulfide TMDs. By using angle resolved photoemission spectroscopy (ARPES) and optical spectroscopies we are able to provide a new picture for the onset of magnetic phases over a family of transition metal intercalates on the basis of charge transfer. The interaction between magnetism and other forms of order in 2H-NbS$_2$ and 2H-TaS$_2$ will also be explored.

Controlling and Tuning the Magnetic Ground State in an Intercalated Transition Metal Dichalcogenide

Spencer Doyle (Presenter), Caolan John, Eran Maniv, James G. Analytis, University of California, Berkeley — It is possible to engineer magnetism in layered TMDs X$_2$ (X=transition metal) via intercalation of magnetic transition metals. In particular, iron intercalation (1/3 Fe per X site) introduces a two-dimensional magnetic sublattice between X$_2$ layers. Despite adopting identical crystal structures with near-identical lattice parameters, the magnetic ground states of Fe$_{1/3}$NbS$_2$ and Fe$_{1/3}$TaS$_2$ are antiferromagnetic and ferromagnetic, respectively. Due to their chemical similarity, these two materials can form end members of an alloying series Fe$_{1/3}$Nb$_{1-x}$Ta$_x$S$_2$. Due to the different magnetic orderings of its end members, this alloying series permits the substitutional control of the magnetic ground state of the material system. I will present our thermodynamic measurements and findings.

Anomalous Hall Effect Mechanisms in Quasi-2D van der Waals Ferromagnet Fe$_{0.29}$TaS$_2$

Ranran Cai (Presenter), Wenyu Xing, HuiBing Zhou, YangYang Chen, Yunyan Yao, Yang Ma, Xincheng Xie, Shuang Jia, Wei Han, International Center for Quantum Materials, Peking University — The recent emergence of two-dimensional (2D) van der Waals ferromagnets has provided a new platform for exploring magnetism in the flatland and for designing 2D ferromagnet-based spintronics devices. Despite intensive studies, the anomalous Hall effect (AHE) mechanisms in 2D van der Waals ferromagnets have not been investigated yet. In this talk, I will present the AHE mechanisms in quasi-2D van der Waals ferromagnet Fe$_{0.29}$TaS$_2$ via systematically measuring Fe$_{0.29}$TaS$_2$ devices with thickness from 14 nm to bulk single crystal. The dominant AHE mechanism is found to be skew scattering in bulk single crystal, and the contribution from intrinsic mechanism emerges and become more relevant as the Fe$_{0.29}$TaS$_2$ thickness decrease. Besides, the coercive field in Fe$_{0.29}$TaS$_2$ thin flake decrease as the Fe$_{0.29}$TaS$_2$ thickness decrease.

Ab-initio study of the magnetic interaction between vanadium impurities in ultra-narrow graphene nanoribbons

Romeo de Coss (Presenter), Department Applied Physics, Cinvestav, Juan Hernández-Aacute;NdeZ-Tecoralco, Instituto de Fisica, BUAP, Miguel Eduardo Cifuentes Quintal, Department Applied Physics, Cinvestav, Lilía Méza-Montés, Instituto de Fisica, BUAP — The exchange interaction between two substitutional vanadium atoms in graphene nanoribbons is studied using ab-initio calculations. The exchange coupling was obtained as the energy difference between the ferro- and antiferro-magnetic configurations. In order to evaluate the effects of quantum confinement and edge magnetism on the exchange interaction, we have studied nanoribbons with zigzag and armchair edges. For comparison we also calculated the 2V-impurities in the bulk (graphene) system. In all the studied cases the exchange coupling shows an oscillatory behavior with the distance between the vanadium impurities, but the values depends on the type of edge structure (AC or ZZ). The present results show the relevance of including the quantum confinement effect and the edge structure in modeling the interaction between magnetic impurities in ultra-narrow graphene nanoribbons. The understanding of the exchange interaction between magnetic impurities in graphene nanoribbons plays an important role in the design of possible novel spintronic devices and quantum gates for quantum computing.

1:51PM B38.00012: Local broken symmetry and spin transport in frustrated Heisenberg model in low dimension*  
LEONARDO DOS SANTOS LIMA (Presenter), Física, Centro Federal de Educação Tecnológica de Minas Gerais — The local spontaneous symmetry breaking is a general phenomena in condensed matter physics. It is characterized by the fact that the action has a local symmetry but the quantum theory, instead of having a unique vacuum state which respects this symmetry, has a family of degenerate vacua that transform into each other under the action of the symmetry group. A simple example is given by a ferromagnetic model in which the action governing its microscopic dynamics is invariant under spatial rotations. A kind of local gauge invariance or spontaneous breaking of U(1) gauge symmetry is realized in nature in the phenomenon of superconductivity.

We have proposed a Meissner mechanism for the spin transport in quantum spin systems. Besides, we study the behavior of the AC spin conductivity in the neighborhood of a quantum phase transition in a frustrated spin model such as the antiferromagnet in the compass lattice with single ion anisotropy at $T = 0$.

11:15AM B39.00001: Spin-to-Charge Conversion in Bi Films and Bi/Ag Bilayers*  
[Invited] DI YUE (Presenter), Department of Physics, Fudan University, WEIWEI LIN, Department of Physics and Astronomy, Johns Hopkins University, JIAJIA LI, XIAOFENG JIN, Department of Physics, Fudan University, C. L. CHIEN, Department of Physics and Astronomy, Johns Hopkins University — Recently, there have been reports on the superior prowess of bismuth (Bi) in spin-to-charge conversion, including large spin Hall angle and long spin diffusion length, qualities that are highly favorable for exploring pure spin current phenomena and devices [1]. Bi/Ag bilayers have also been featured prominently in the inverse Rashba-Edelstein effect (IREE), a related effect offering strong spin-to-charge conversion at interfaces [2,3]. One notes that in most cases the spin injection has been accomplished by spin pumping from Py, a process well known to harbor a variety of parasitic effects due to metallic Py that complicate the voltage measurements of the inverse spin Hall effect (ISHE).

In this work [4], we use thermal injection from a ferromagnetic insulator YIG into Bi films and Bi/Ag bilayers, demonstrated to be without the parasitic effects. The Bi layers of various thicknesses have been made by both MBE and sputtering at 77 K with similar results. The contribution of the pure spin current can be unequivocally determined by the insertion of a MgO(3 nm) layer, which blocks the spin current and eliminates the ISHE voltage. In sharp contrast to previous results, we have observed much shorter spin diffusion length in Bi of about 1 nm and negligibly small spin Hall angle. We have also observed no evidence of the IREE in the Bi/Ag bilayers. We note that Bi is a well-known thermoelectric material with low carrier concentration and very large Nernst voltage.

11:51AM B39.00002: Spin Hall Effect in Ni_{x}Cu_{1-x} Alloys  MARK KELLER (Presenter), KATY GERACE, MONIKA ARORA, JUSTIN
SHAW, THOMAS SILVIA, National Institute of Standards and Technology Boulder — We report a large spin Hall conductivity, $\sigma_{SH}$
in, high resistivity, paramagnetic Ni_{60}Cu_{40}. The value is comparable to what we reported for Pt [1]. Broadband FMR
measurements of ferromagnet/nonmagnet bilayers provide an accurate measure of $\sigma_{SH}$, and simultaneously the damping
due to spin pumping, when the various contributions to the inductively detected signal are analyzed as described in [2].
These measurements do not require patterning of the bilayer, nor perpendicular anisotropy of the ferromagnet. In a
series of samples with the layer structure substrate/Ta(3)/Py(3.5)/Ni_{x}Cu_{1-x}(d)/Ta(3) (thickness in nm), we varied Ni fraction $x$
for $d = 10$ nm and varied thickness $d$ for $x = 0.6$, a composition with a magnetic ordering critical temperature $T_C = 140$ K.
Room temperature FMR measurements with a saturating out-of-plane field showed a substantial $\sigma_{SH}$ for all compositions
we deposited, $0.3 \leq x \leq 0.75$, with a maximum at $x = 0.7$ where $T_C = 270$ K. For the thickness series at $x = 0.6$, we use the
approach detailed in [1] to extract a spin diffusion length of $(7.8 \pm 0.5)$ nm and a spin Hall ratio of $0.81 \pm 0.14$. Both values
are about twice as large as we reported for Pt [1].

12:03PM B39.00003: Anomalous and spin Hall effect in tunnel junctions with spin orbit interaction  CHRISTIAN
ORTIZ PAUYAC (Presenter), RIKEN — Considering a tight binding model in Keldysh formalism we describe the anomalous
and spin Hall effect in tunnel junctions with Rashba spin orbit coupling. Two types of structures are
considered, conventional magnetic tunnel junctions (normal metal - insulator - ferromagnet) and spin filter tunnel
junctions (normal metal - magnetic insulator - ferromagnet). We show that the magnitudes of the anomalous and spin Hall
effects are enhanced in the presence of magnetic insulators. In both types of structures the angular dependence exhibit a
cosine and sine behavior.

12:15PM B39.00004: Observation of the nonlinear anomalous Hall effect in 2D WTe2/Pt heterostructures*  MOHAMMED ALGHAMDI
(Presenter), MARK LOHMANN, JUNXUE LI, Department of Physics and Astronomy, University of California, Riverside, TANG SU,
International Center for Quantum Materials, School of Physics, Peking University, KENJI WATANABE, TAKASHI TANIGUCHI, National
Institute for Materials Science, PALANI RAJA JOTHI, BONIFACE FOWKA, Department of Chemistry, University of California, Riverside,
JING SHI, Department of Physics and Astronomy, University of California, Riverside — Van der Waals (vdW) layered ferromagnets
have become a hot topic of research lately within the two-dimensional materials community due to the ability to study
magnetic properties from a single atomic layer. Fe$_3$GeTe$_2$ (FGT) is one of very few known metallic members of the vdW
ferromagnetic materials family. It has strong perpendicular magnetic anisotropy (PMA) and Curie temperature, $T_C \sim 220$ K,
which makes FGT a good candidate material to study the effect of spin-orbit torque (SOT) on the magnetization of 2D
ferromagnet in FGT/heavy metal heterostructures. For this study we fabricated heterostructures of FGT/Pt with 5 nm of Pt
sputtered onto the surface of ~ 15 nm – 50 nm flakes of FGT. We measured the first and second harmonic Hall responses
to an applied magnetic field in the in-plane parallel and perpendicular to current directions. We also measured the angular
dependence of the 2 $\omega$ signal with fixed in-plane fields larger than the field required to saturate the magnetization in the
hard axis direction. Our analysis of the 2 $\omega$ signals show that damping-like SOT is at least an order of magnitude greater
than the negligible field-like SOT and thus it is the dominant mechanism acting on the magnetization of FGT.

12:27PM B39.00005: Observation of the nonlinear anomalous Hall effect in 2D WTe$_2$  KAIFEI KANG (Presenter),
TINGXIN LI, Applied and engineering physics, Cornell University, EGON SOHN, Physics, Cornell University, JIE SHAN, Applied and
engineering physics, Cornell University, KIN FAI MAK, Physics, Cornell University — The Hall effect has been observed in systems
with broken time reversal symmetry, such as the ordinary Hall effect in solids under a magnetic field and the anomalous
Hall effect (AHE) in magnetic materials. Theories have indicated that in nonmagnetic materials with certain low crystal
symmetries, a nonlinear Hall effect can be observed under zero magnetic field, in which the Hall voltage scales
quadratically to the longitudinal current. Here we report an observation of such effect in atomically thin Td WTe$_2$ flakes, a
semimetal with only one mirror plane along the crystal b axis. In our angle-resolved electrical measurements, we observed
a sinusoidal angular dependence of the nonlinear Hall effect, in which the effect maximizes when the driven current is
perpendicular to the mirror plane and minimizes when it aligns to the mirror plane. This effect can be described as an
anomalous Hall effect with a current induced magnetization. We further studied the temperature and doping dependence
of the nonlinear hall conductivity. The result suggests that both intrinsic Berry curvature dipole and extrinsic spin-
dependent scatterings contribute to the observed nonlinear AHE.
12:39PM B39.00006: Anomalous Hall effect in Pt/\text{Cr}_2\text{Ge}_2\text{Te}_6 heterostructures*  MARK LOHMANN (Presenter), University of California, Riverside, TANG SU, International Center for Quantum Materials, School of Physics, Peking University, MOHAMMED ALGHAMDI, BEN NIU, University of California, Riverside, YUSHENG HOU, University of California, Irvine, MOHAMMED ALDOSARY, University of California, Riverside, WENYU XING, JIANGNAN ZHONG, SHUANG JIA, WEI HAN, International Center for Quantum Materials, School of Physics, Peking University, RUQIAN WU, University of California, Irvine, YONGTAO CUI, JING SHI, University of California, Riverside — Understanding the physical properties of 2D ferromagnets such as \text{Cr}_2\text{Ge}_2\text{Te}_6 (CGT), amongst a plethora of others, has accelerated due to their properties in one to few layers as well as their ability to easily form heterostructures with other 2D materials. This feature is extremely attractive due to the possibility of manipulating interfacial interactions via proximity coupling. Here we demonstrate the anomalous Hall effect (AHE) in Pt thin films sputtered onto the surface of thin exfoliated flakes of CGT which must originate in Pt since CGT is essentially an insulator at low temperatures. The AHE loops persist up to T_c ~ 60 K which matches well to the bulk value. Low-temperature magnetic force microscopy of Pt/CGT reveals magnetic field dependent domain structures consistent with the AHE behavior. The origin of the AHE in Pt/CGT heterostructures is explored through density functional theory calculations. The method used in this study is a powerful tool to understand magnetism in 2D ferromagnetic insulators and provides a new platform for the study of magnetic proximity exchange and spin-dependent transport phenomena.

12:51PM B39.00007: Semiclassical theory of the spin transport of Bloch electrons LIANG DONG (Presenter), QIAN NIU, Physics, University of Texas at Austin — The semiclassical wave-packet theory is a powerful method in studying transport properties. Usually, the charge center of the wave-packet is used to denote the position of a semiclassical electron. In fact, wave-packets with finite size can have other centers which gives an additional degree of freedom. We develop a semiclassical theory where different centers (e.g spin center) can be chosen depending on which physical property (e.g spin) we are interested in. We give an example by applying this theory to calculate the spin transport.

1:03PM B39.00008: Two-band magnetoresistance in spin-filter \text{CrVTiAl} GREGORY STEPHEN (Presenter), CHRISTOPHER LANE, IOANA G BUDA, Northeastern University, DAVID E GRAF, National High Magnetic Field Lab, STANISLAW KAPRZYK, AGH University of Science and Technology, BERNARDO BARBIELLINI, Lappeenranta University of Technology, ARUN BANSIL, DONALD E HEIMAN, Northeastern University — Thin films of spin-filter material \text{CrVTiAl} were grown via sputtering, and their magnetotransport properties have been studied up to B=35 T. The resistivity vs T shows 2-channel semiconducting behavior with a disordered gapless channel and an activated gapped channel. Magnetoresistance measurements provide values for the mobilities of the two conducting channels, 900 and 50 cm^2/Vs. This leads to a ratio of 18:1 for the effective masses, which corresponds to that predicted by density functional theory. Hall and magnetization measurements reveal a small moment saturating near 15 T that is assigned to partial non-compensation of the sublattices. These results combined with previous studies [1,2] show \text{CrVTiAl} to be a compensated ferrimagnet with a spin-polarized electronic structure.

1:15PM B39.00009: Intrinsic spin currents in ferromagnets* VIVEK AMIN (Presenter), Physical Measurement Laboratory, National Institute of Standards and Technology, Gaithersburg, JUNWEN LI, Joint Institute for Computational Sciences, University of Tennessee, Knoxville, MARK STILES, PAUL HANEY, Physical Measurement Laboratory, National Institute of Standards and Technology, Gaithersburg — We present first principles calculations showing that an applied electric field generates intrinsic spin currents in ferromagnets that flow perpendicularly to the electric field. Reduced symmetry in ferromagnets with spin-orbit coupling enable a wide variety of such spin currents. However, we find the total spin current is approximately given by the sum of a magnetization-independent spin current with the symmetry of the spin Hall effect and a spin-polarized anomalous Hall current. We also present a simple tight-binding model that captures the relevant physics. Intrinsic spin currents are not subject to dephasing, enabling their spin polarizations to be misaligned with the magnetization, which is crucial to explain the magnetization-independent spin Hall effect. The spin Hall conductivity and spin anomalous Hall conductivities of transition metal ferromagnets can be comparable to Pt, opening new avenues for efficient spin current generation in spintronic devices.

1:27PM B39.00010: ABSTRACT WITHDRAWN
1:39PM B39.00011: Symmetric and anti-symmetric contributions in mixed spin-current effects in a NiO/Pt nanostructure*  
F. L. A. MACHADO (Presenter), P. R. T. RIBEIRO, M. GAMINO, A. AZEVEDO, SERGIO M REZENDE,  
Departamento de Física, Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil. — Spin-currents generated by thermal gradients are efficiently converted into charge-currents by the inverse spin-Hall effect in films of metals presenting strong spin-orbit coupling. The nature of the thermal induced effects depends on the relative orientation among the directions of the spin-current, the applied magnetic field ($H$), the thermal gradient and the electrical contacts in the metallic film. Mixings in the currents generated by different effects are expected to occur. In this work, the $H$-dependent anti-symmetric spin-Seebeck effect (SSE) was generated altogether with the symmetric planar Nernst effect in a NiO(100 nm)/Pt(6 nm) nanostructure grown on a 0.5 mm thick Si substrate. A sample holder adapted to a PPMS was used for measuring the voltage in the Pt-film for $H$ in the range ±85 kOe and for temperatures ($T$) varying from 100 to 300 K. A simple procedure developed for separating the SSE from the planar Nernst effect yielded magnitudes for the SSE in the range ±30 pAcm/K for a temperature different of 10 K across the sample at 300 K. The magnitude of the SSE signal was found to vary with $H$ and $T$ in good agreement with a drift-diffusion magnonic theory.

1:51PM B39.00012: Effects of oxidation on the spin-orbit torques and domain textures in ultrathin Pt/Co/AlOx heterostructures  
JUNXIAO FENG (Presenter), MARVIN MÜLLER, EVA GRIMALDI, PIETRO GAMBARDELLA, Department of Materials, ETH Zurich — We investigated the correlation between structure, oxidation, and magnetic properties of Pt/Co/AlOx, Pt/CoOx/Co/AlOx and PtOx/Co/AlOx heterostructures. We find that the anomalous Hall resistance, magnetoresistance, magnetic anisotropy, and domain texture are affected in a systematic way by the degree of oxidation of the Co/AlOx, CoO/Co and PtOx/Co interfaces. Moreover, we find that oxidation also influences the spin-orbit torques as well as the current-induced domain-wall motion and switching.

2:03PM B39.00013: Modeling electrical detection of current generated spin in topological insulator surface states*  
CONNIE LI (Presenter), OLAF M VAN T ERVE, United States Naval Research Laboratory, CHENHUI YAN, LIAN LI, Physics and Astronomy, West Virginia University, BEREND JONKER, United States Naval Research Laboratory — Current generated spin in topological insulator (TI) surface states due to spin-momentum locking has been detected recently using FM/tunnel barrier contacts, where the projection of the TI spin onto the magnetization of the FM is measured as a voltage. However, opposing signs of the spin voltage have been reported, attributed to the coexistence of trivial 2DEG states on the TI surface that may exhibit opposite current-induced polarization. Models based on electrochemical potential have been presented to determine the sign of the spin voltage expected for the TI surface states, however neglecting critical experimental parameters. Here we present a Mott two-spin current resistor model which takes into account parameters such as spin-dependent interface resistances, and show that such inclusion can lead to a crossing of the voltage profiles for the spin-up and spin-down electrons within the channel, which can lead to measured spin voltages of either sign. These findings offer a resolution of the ongoing controversy regarding opposite signs of spin signal reported in the literature, and highlight the importance of including realistic experimental parameters in the model.

Evidence of antiferromagnetism as the driver of the metal-insulator transition in vanadium sesquioxide (V$_2$O$_3$)°

[Invited] JUAN TRASTOY (Presenter), Department of Physics and Center for Advanced Nanoscience, University of California, San Diego — Metal-insulator transitions (MITs) in strongly-correlated materials result from the interplay of many degrees of freedom, such as electronic, magnetic or structural. Untangling these contributions has remained a longstanding problem in condensed matter physics. In this work, we have investigated V$_2$O$_3$, an archetypal strongly-correlated material with a MIT where electronic, structural and magnetic phase transitions occur simultaneously. By performing magneto-resistance (MR) measurements across the MIT we acted on the magnetic degree of freedom and revealed an anomalous behavior: the MR crosses over to negative values and seemingly diverges as the MIT takes place. To gain physical insight, we study the antiferromagnetic MIT in a Hubbard model in the presence of a magnetic field by high precision dynamical mean-field theory calculations. We find the model results accurately reproduce the unusual experimental behavior. Furthermore, they reveal a simple mechanism where the magnetic field impedes the antiferromagnetic ordering of one sublattice, thus preventing the opening of the gap. Our study provides strong evidence that the origin of the MIT in V$_2$O$_3$ is the opening of an antiferromagnetic gap.

Large linear magnetoresistance in ultraclean SrVO$_3$°

MATTHEW BRAHLEK (Presenter), JONG MOK OK, ELIZABETH SKOROPATA, HO NYUNG LEE, Materials Science and Technology Division, Oak Ridge National Laboratory, JASON LAPANO, ROMAN ENGEL-HERBERT, Pennsylvania State University, PATRICK IRVIN, JEREMY LEVY, physics, University of Pittsburgh — Observations of linear magnetoresistance have a near 100-year history with origins ranging from effects of open Fermi surface in polycrystalline metals, pushing materials like bismuth to the quantum limit, to large scale inhomogeneity/defect clusters in silver chalcogenides—such diversity has long given rise to controversy. This talk will focus on the surprising observation of a non-saturating linear magnetoresistance that appears in ultraclean, molecular beam epitaxy-grown thin films of the correlated metal SrVO$_3$. The unusual nature of this observation is that the linear magnetoresistance appears only when the samples are in the ultraclean limit and sets in far below the quantum limit; this strongly implies that this is an intrinsic feature of the electronic structure. As such both intrinsic effects, coming from the Fermi surface geometry and electron-electron correlations, and extrinsic effects, particularly defect structures common to perovskites, will be discussed.

°Work supported by the Office of Basic Energy Science, U.S. Department of Energy, Divisions of Materials Sciences and Scientific User Facilities

Spin colossal magnetoresistance in an antiferromagnetic insulator°

DAZHI HOU (Presenter), Tohoku University, ZHIYONG QIU, School of Materials Science and Engineering, Dalian University of Technology, JOSEPH BARKER, Tohoku University, KEI YAMAMOTO, Advanced Science Research Center, Japan Atomic Energy Agency, OLENA GOMONAY, Institut für Physik, Johannes Gutenberg Universität Mainz, EIJJI SAITOH, Department of applied physics, University of Tokyo — Colossal magnetoresistance (CMR) refers to a large change in electrical conductivity induced by a magnetic field in the vicinity of a metal–insulator transition and has inspired extensive studies for decades. Here we demonstrate an analogous spin effect near the Néel temperature, $T_N = 296$ K, of the antiferromagnetic insulator Cr$_2$O$_3$. Using a yttrium iron garnet YIG/Cr$_2$O$_3$/Pt trilayer, we injected a spin current from the YIG into the Cr$_2$O$_3$ layer and collected, via the inverse spin Hall effect, the spin signal transmitted into the heavy metal Pt. We observed a two orders of magnitude difference in the transmitted spin current within 14 K of the Néel temperature. This transition between spin conducting and non-conducting states was also modulated by a magnetic field in isothermal conditions. This effect, which we term spin colossal magnetoresistance (SCMR), has the potential to simplify the design of fundamental spintronics components, for instance, by enabling the realization of spin-current switches or spin-current-based memories.

**12:15PM B40.00004: Observation of non-Fermi liquid behaviors on high-mobility LaNiO$_3^*$**

CHANGJIANG LIU (Presenter), TERENCE BRETTZ-SULLIVAN, FRIEDERIKE WROBEL, GENSHENG WANG, DESHUN HONG, JOHN E. PEARSON, J SAMUEL JIANG, JIANJIE ZHANG, CLARENCE CHANG, Argonne National Laboratory, ALEXEY SUSLOV, National High Magnetic Field Lab, MICHAEL NORMAN, ANAND BHATTACHARYA, Argonne National Laboratory — LaNiO$_3$ (LNO) is a special member of the rare-earth perovskite nickelate family, as it does not show metal-insulator or magnetic transitions at low temperatures. Whether or not LNO behaves like a Fermi liquid in the low temperature regime with quadratic temperature dependence of resistivity remains an open question. Recent measurements of the electronic structure and theoretical calculations support the presence of structural and magnetic instabilities in LNO. However, the impact of these instabilities has yet to be clarified in transport measurements, partly because preparing high-quality LNO samples had been challenging due to a propensity towards oxygen vacancy formation. Here, we report on the observation of non-Fermi liquid transport behaviors at sub-Kelvin temperatures in high-mobility LNO thin films grown by ozone-assisted molecular beam epitaxy. The resistivity of these samples can be lower than 4 $\mu\Omega$ cm at $T = 2$ K, with residual resistivity ratios (RRR) [$\rho (300 \text{ K}) / \rho (2 \text{ K})$] > 24.

**12:27PM B40.00005: Direct Imaging Revealing Halved Ferromagnetism in Tensile-Strained LaCoO$_3$ Thin Films**

XIAOFANG ZHAI (Presenter), QIYUAN FENG, DECHAO MENG, QINGYOU LU, YALIN LU, University of Science and Technology of China — The enigma of the emergent ferromagnetic state in tensile-strained LaCoO$_3$ thin films remains to be explored since there is a longstanding controversy between the theory and experiments. It is that all experiments can only find at most half of the magnetic moment predicted by the theory. Here we show the experimental evidence of the rare halved occupation of the ferromagnetic state in tensile-strained LaCoO$_3$ thin films by the direct magnetic imaging technique using a low-temperature magnetic force microscope. The film was grown by the atomic layer-by-layer laser molecular beam epitaxy and exhibits the coherently strained lattice structure and the stoichiometric composition. The direct magnetic imaging revealed that percolated ferromagnetic regions with typical sizes between 100 nm and 200 nm occupy about 50% of the entire film, down to the lowest achievable temperature of 4.5 K and up to the largest magnetic field of 13.4 T. Our study demonstrated the halved occupation of the ferromagnetic phase in the LaCoO$_3$ ultrathin films as the real microscopic state of the emergent ferromagnetism.

**12:39PM B40.00006: Interplay between Strain-Stabilized Ferromagnetism and Charge Transport in Epitaxial LaCoO$_{3-\delta}$ Thin Films**

VIPUL CHATURVEDI (Presenter), JEFFERY J WALTER, ARPITA PAUL, JONG S JEONG, University of Minnesota, ALEXANDER GRUTTER, BRIAN KIRBY, JULIE BORCHERS, National Institute of Standards and Technology, K. ANDRE MKHOYAN, TURAN BIROL, CHRIS LEIGHTON, University of Minnesota — The presence of ferromagnetic (FM) order in epitaxial LaCoO$_3$ (LCO) thin films, in stark contrast to bulk, has gathered substantial recent attention. Due to the insulating nature of this strain-stabilized FM, however, little attention has been paid to electronic transport. Here, we present a systematic study of epitaxial LCO films (8-22 nm thick) grown under both tensile (on SrTiO$_3$ and LSAT) and compressive strain (on LaAlO$_3$ and SrLaAlO$_4$), emphasizing not only magnetism but also transport. Tensile films exhibit ferromagnetism with saturation magnetization 1-1.5 $\mu_B$/Co and Curie temperature ~80 K, consistent with prior work. Polarized neutron reflectometry has also been performed, revealing a uniform magnetization depth profile with thickness. Most notably, transport, which is semiconducting in all cases, reveals an unanticipated correlation between strain-state and majority carrier type, supported by density functional theory calculations suggesting significant changes in conduction band structure under strain. This provides important clues to the origin of FM in this material.

*Supported by DOE Center for Quantum Materials under DOE-SC0016371.
Most multiferroic materials with coexisting ferroelectric and magnetic order exhibit cycloidal antiferromagnetism with wavelength much larger than lattice spacing. The prototypical example is bismuth ferrite (BiFeO3 or BFO), a room-temperature multiferroic considered for a number of technological applications, including magnetic memories with electric-write capability. While most applications require small sizes such as nanoparticles, little is known about the state of these materials when their sizes are comparable to the cycloid wavelength. This work describes a theory of cycloid magnetism in nanoparticles. It is argued that magnetic anisotropy close to the surface has a huge impact on the ground state cycloidal wavevector, leading to several observable consequences. For certain sizes the cycloidal wavevector is bistable, an effect that may be exploited in the design of novel memory devices.

NiO is a Mott insulator that orders antiferromagnetically below 520 K. The transition temperature drops with Li-doping and becomes first ferrimagnetic and later antiferromagnetic with a Néel temperature of 9 K. Despite intense study of NiO and other Mott insulators, the evolution of correlations with charge doping, which give rise to spectacular phenomena (including superconductivity in cuprates), is poorly understood to date. Here, we combine atomic layer-by-layer molecular beam epitaxy growth of charge doped NiO with density functional theory (DFT) and Quantum Monte Carlo (QMC) simulations. We analyze the band gap with spectroscopic ellipsometry as a function of hole (K) and electron (In) doping, and compare the results with DFT and QMC. Moreover, we measure the distortion of the lattice caused by the large K with extended x-ray absorption fine structure and find a distortion much larger than predicted by DFT.

Magnon spin transport through antiferromagnetic NiO GEERT HOOGBOOM (Presenter), BART VAN WEES, Physics of Nanodevices, Zernike Institute for Advanced Materials — Thus far, antiferromagnets (AFMs) played a passive role of pinning in giant magnetoresistance. AFMs hold promise of ultrafast and lossless AFM transport devices when one is able to simultaneously generate and detect spin currents, while having control over the magnetic moment directions. AFMs have no stray fields so we made use of either the magnetic easy-plane character or an attached ferromagnet to manipulate its magnetic moments. Electrical and thermal injection of magnon spins occurs by a charge current through Pt, creating an interface spin accumulation via the Spin Hall Effect (SHE) and a thermally based magnon gradient. Resulting spin currents are detected by the inverse SHE, showing a 90° and 180° shift in the electrical and thermal signal respectively. Moreover, magnons that are detected non-locally revealed that both injection and detection is dependent on the magnetic texture of the NiO layer.

The cation distribution in piezoelectric ferromagnetic GaFeO$_3$(010) thin films*  JAEYOUNG KIM (Presenter), Center for Artificial Low Dimensional Electronic Systems, Institute for Basic Science, DONG-HWAN KIM, Department of Physics, POSTECH — GaFeO$_3$ is well known piezoelectric ferrimagnet where electron and spin degree of freedoms are coupled. There are four different cationic sites and the disorder in the occupation of them makes it ferrimagnet. Therefore, it is very important to study the site disorder in a specific specimen so as to understand a wide variety of ferromagnetic properties found in different GaFeO$_3$’s. Usually the site occupation of cations can be studied with neutron diffraction and Mösbauer spectroscopy. But, mostly they are not available for thin films. In this work, we have developed a new procedure to identify the site occupation of the cations by measuring X-ray absorption spectroscopy and X-ray magnetic circular dichroism and comparing them with cluster calculations. We apply it to undoped and Co-doped (2%) Ga$_{0.6}$Fe$_{1.4}$O$_3$ thin films and successfully explain the role of doped Co ions and why they have far different ferromagnetic properties.

Spin Transport across Antiferromagnetic Cr$_2$O$_3$ Films Grown on Y$_3$Fe$_5$O$_{12}$*  YAWEN LIU (Presenter), WEI YUAN, Department of Physics and Astronomy, University of California, Riverside, QIMING SHAO, KANG WANG, Department of Electrical Engineering, University of California, Los Angeles, JING SHI, Department of Physics and Astronomy, University of California, Riverside — Spin transport in heterostructures containing antiferromagnetic materials has attracted a lot of attention due to the enhanced transmission of the pure spin current and the interesting orientation dependence. Compared with NiO, Cr$_2$O$_3$ is a better-defined antiferromagnet for its uniaxial anisotropy. Here we report a spin transport study of YIG/Cr$_2$O$_3$/Pt heterostructures, in which both YIG and Cr$_2$O$_3$ are grown by PLD. RHEED patterns indicate that Cr$_2$O$_3$ is textured polycrystalline on single crystal YIG with preferred c-axis along the easy axis of the YIG. We perform both magnetoresistance(MR) and spin Seebeck effect (SSE) measurements. When the in-plane magnetic field is applied along or perpendicular to the c-axis of textured Cr$_2$O$_3$, the high-field MR responses in both directions resemble those of the YIG/Pt. When the field is along the c-axis of textured Cr$_2$O$_3$, MR shows an additional peak feature ~1T at 5 K, and the peak position moves to higher fields at higher temperatures, indicative of the spin-flop transition of Cr$_2$O$_3$. The SSE signal shows a sign reversal at low temperature, which does not exist in YIG/Pt and therefore is also attributed to the Cr$_2$O$_3$.

Hexagonal YbFeO$_3$ thin-film heterostructures grown by pulsed laser deposition*  YU YUN (Presenter), YUEWEI YIN, XUANYUAN JIANG, XIAOSHAN XU, University of Nebraska - Lincoln — Multiferroic materials have drawn significant attention because of its potential application in information processing and storage. Hexagonal ferrites (h-RFeO$_3$, R=Y, Dy-Lu), as identified multiferroic materials, have recently been predicted to have a magnetoelectric effect. To verify theoretical predictions, exploring the suitable substrates and bottom electrodes for the growth of hexagonal ferrites is a big challenge. In our study, we have successfully fabricated high-quality YbFeO$_3$ thin films on the STO (111) substrate with La$_{0.3}$Sr$_{0.7}$MnO$_3$ bottom electrode grown by pulsed laser deposition system. The crystal structure is characterized by X-ray diffraction, and the electron transport properties are investigated from 20 K to 300 K. Our experiments in YbFeO$_3$ multiferroic thin films pave the way for the further investigation of magnetoelectric effects in the hexagonal ferrites.

2:03PM B40.00013: The role of disorder and defects in the ferromagnetic resonance of spinel ferrite thin films
JACOB WISSER (Presenter), Applied Physics, Stanford University, SATORU EMORI, Physics, Virginia Tech, LAUREN RIDDIFORD, Applied Physics, Stanford University, PENG LI, Geballe Laboratory for Advanced Materials, Stanford University, KRISHNAMURTHY MAHALINGHAM, BRITTANY T. URWIN, BRANDON HOWE, Air Force Research Laboratory, ALEXANDER GRUTTER, BRIAN KIRBY, NIST Center for Neutron Research, YURI SUZUKI, Applied Physics, Stanford University — Spin current generation in heterostructures requires low magnetic damping spin-current sources. To this end, we seek to minimize disorder and defects in spin-current source materials and improve interface quality. In this work, we find that epitaxial spinel ferrite MgAl0.5Fe1.5O4 (MAFO) films exhibit low damping and coercivity in the 10-15nm thickness range with a Gilbert damping parameter $\alpha \approx 0.001$ and coercive field $H_c < 5$ Oe. Transmission electron microscopy results indicate these films grow coherently strained on MgAl2O4 substrates with minimal defects. Gilbert damping rapidly increases outside of this thickness range, with $\alpha \approx 0.004$ for 5nm films and $\alpha \approx 0.03$ for 40nm films. Dislocations form at the film/substrate interface in 40nm films, indicating that the film relaxes, causing increased damping and coercivity ($H_c > 50$ Oe). A thickness-dependent magnetization study of MAFO films from 1-45nm thick indicates the presence of a 1.6nm magnetically-dead layer, less than half that found in yttrium iron garnet films. This layer is confirmed to exist at the film/substrate interface by depth profiling via polarized beam neutron reflectivity. The nature of this dead layer is crucial to device integration, and we will discuss interfacing this oxide with platinum and copper/platinum overlayers.

Session B41 GMAG DMP: Novel Magnetic Structures and Excitations I
BCEC 209 - Adam Ahmed, Ohio State University - Tag(s): Focus

11:15AM B41.00001: Anatomy of Dzyaloshinskii–Moriya interaction at interfaces: from Fert-Levy type DMI at Co/Pt to Rashba effect induced DMI at Co/graphene* [invited] HONGXIN YANG (Presenter), Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences — The antisymmetric exchange interaction, Dzyaloshinskii-Moriya Interaction (DMI), has gained an intense research effort due to its crucial role in the creation, annihilation and the influence on the dynamics of magnetic Skyrmions and chiral domain wall. Here, we will present a general DMI calculation approach based on DFT total energy calculations and show the calculated DMI at Co/Pt interfaces and the comparison with experiments. We will address the main features and microscopic mechanism of typical Fert-Levy type DMI at Co/Pt interface from first-principles by clearing up several fundamental questions: how does the DMI extend away from the interface? Where is the corresponding electronic energy source located? [1] How to design enhanced DMI systems? [2,3] Moreover, we will go beyond Fert-Levy type DMI systems to avoid using heavy metals but with simple ferromagnet/graphene interfaces. [4] At the end, we will give a perspective on the topic with new systems which may also give large DMI but are different to FM/HM and FM/graphene.

12:03PM B41.00003: Laser-induced ultrafast magneto-optic dynamics on low-dimensional carbon nanostructures*  
CHUN LI (Presenter), RUI HUANG, YIMING ZHANG, Northwestern Polytechnical University, GEORGIOS AL LEFKIDIS, WOLFGANG HUEBNER, University of Kaiserslautern — Carbon nanostructures constitute a family of novel molecular materials, with great potential applications for future nanoscale spintronics devices. Here, the ultrafast magneto-optic dynamics behavior of carbon nanostructures (including graphene and endohedral fullerenes) are investigated by taking advantage of suitable Λ processes[1-3]. For graphene nanoflakes, different attaching locations of the magnetic elements at the graphene boundary are considered. It is shown that the spin density is typically localized on a single magnetic atom, which leads to localized spin switching within subpicosecond time regime. For the endohedral fullerenes, it is found that both spin switching and spin transfer can be achieved on the experimentally synthesized system Sc3N@C80. The spin density, which for the fully relaxed system is equally distributed among the three Sc atoms, becomes strongly localized by the applied strain, leading to fast, clear-cut, spin-transfer processes. In particular, the fastest spin-transfer process can be accomplished within 100 fs.

12:15PM B41.00004: Time-dependent ab initio insight to the ultrafast demagnetization mechanism  
ZHANGHUI CHEN (Presenter), LIN-WANG WANG, Lawrence Berkeley National Laboratory — Laser induced ultrafast demagnetization process has a great potential in future spintronic devices. Ever since its discovery, this subject has been studied intensively. However, the fundamental physics is still not well understood. There are several long-standing problems regarding the demagnetization mechanism. One major issue is the remarkable underestimation in ab initio simulation. At the same intensity of laser, the theoretical demagnetization rate can be ten times smaller than the experimental observation. Here, we present an ultrafast real-time time-dependent density functional theory method, together with atomic Landau-Lifshitz-Gilbert model, to investigate this problem. Our results show that one important reason for the underestimation is the missing of initial spin disorder, which can significantly enhance the demagnetization to the experimentally observed rate. This spin disorder connects the electronic structure theory with the phenomenological three-temperature model. We have also systematically studied the roles of various interactions which are heavily debated. In particular, we found that electron-electron interaction and spin-orbit interaction play extremely important roles, while electron-phonon and light-spin interactions are not essential.

12:27PM B41.00005: Photocontrol of magnetic structure in a metallic ferromagnet*  
ATSUSHI ONO (Presenter), SUMIO ISHIHARA, Department of Physics, Tohoku University — We study theoretically photoinduced phenomena in a metallic ferromagnet described by the double-exchange (DE) model, where conduction electrons mediate the ferromagnetic (FM) DE interaction between localized magnetic moments in equilibrium. We found that the DE interaction acts as the antiferromagnetic (AFM) interaction in highly photoexcited states, which is in sharp contrast to the conventional DE mechanism. Numerical computations of real-time dynamics described by the Schrödinger equation combined with the Landau-Lifshitz-Gilbert equation reveal that the FM metallic initial state is transformed into the AFM steady state through a transient state with emergent topological magnetic defects. We also calculated magnetic excitation spectra in the photoirradiated FM metallic state by using the Floquet Green function method and found that magnon is softened by photoirradiation, which indicates that the AFM instability is induced by the Stoner excitation in the Floquet state.

12:39PM B41.00006: All-Optical Deterministic Switching of Synthetic CoCrPt Ferrimagnets*  
BRADLEE K. BEAUCHAMP (Presenter), School of Materials Engineering, Purdue University, AVEEK DUTTA, ALEXANDRA BOLTASSEVA, VLADIMIR M SHALAEV, School of Electrical and Computer Engineering, Purdue University, ERNESTO MARINERO, School of Materials Engineering, Purdue University — Ultrafast magnetic switching via femtosecond laser pulses is vital for increasing the speed of spintronic devices and has been demonstrated in various ferrimagnetic materials. However, this switching has not yet been demonstrated in synthetic ferrimagnetic hcp CoPtCr alloys. The synthetic ferrimagnetic trilayers consist of two CoCrPt layers antiferromagnetically coupled via a thin Ru spacer. Synthetic ferrimagnetic thin film trilayers have the potential to be switched in the sub-picosecond time regime. CoCrPt is a highly anisotropic magnetic material with low saturation magnetization, making it optimal for magnetic recording. Here we demonstrate all-optical helicity-dependent switching of CoCrPt/Ru/CoCrPt thin film trilayers using circularly polarized, 65 femtosecond, 800 nm KrF laser pulses.

*This work was conducted under the auspice of the Office of Naval Research, Award N00014-18-1-2481.
12:51PM B41.00007: Optical Control of Magnetic Orientation in Epitaxial CoFe$_2$O$_4$ Films  YI-CHUN CHEN (Presenter), YI-DE LIOU, I-TSE TSAI, JAN-CHI YANG, Department of Physics, National Cheng Kung University — Complex oxides have caught significant attention for the development of the next-generation electronic devices due to their versatile functionalities and the tunability via the external stimuli, such as electrical and magnetic fields. To broaden the application of complex oxides, the new pathway to control the physical properties is on demand. Cobalt ferrite (CoFe$_2$O$_4$, CFO), a ferrimagnetic inverse spinel, which has advantages of high magnetization and coercivity for magnetic data storage, is investigated in this study. We introduce the high density laser to illuminate the epitaxial CFO film and control the magnetic orientation of the film at ambient temperature. Effects of various illumination conditions of CW and pulsed lasers are systematically investigated. Magnetic force microscopy (MFM) and X-ray magnetic circular dichroism coupled to photoemission electron microscopy (XMCD-PEEM) are used to investigate the magnetic orientation of the optical-modulated area. The possible mechanism for modulating magnetic structures is thus determined as the thermal effect combined with magnetostatic couplings.

1:03PM B41.00008: Ultrafast transfer of magnetization on magnetic sublattices in half-metallic Co$_2$MnGe heusler alloys  PHOEBE TENGDIN (Presenter), CHRISTIAN GENTRY, DMITRIY ZUSIN, ADAM Z BLONSKY, JILA, University of Colorado, Boulder, JUSTIN SHAW, HANS T. NEMBACH, MONIKA ARORA, THOMAS SILVA, National Institute of Standards and Technology, Boulder CO, YAROSLAV KVASHNIN, ERNA DELCZEZ, OLLE ERIKSSON, Uppsala University, HENRY C KAPTEYN, MARGARET MARY MURNANE, JILA, University of Colorado, Boulder — Heusler alloys are exciting materials for future applications because they display a wide range of tunable electronic and magnetic interactions such as metallicity, ferromagnetism, superconductivity, and giant magneto-resistance. However, laser-induced spin dynamics in heuslers were expected to be slower than in conventional metallic ferromagnets, due to the presence of a blocked spin channel. Here we directly observe ultrafast spin transfer from one magnetic sublattice to another in half-metallic heusler alloy Co$_2$MnGe, that occurs on the timescale of the femtosecond laser excitation. Ultrafast high harmonic pulses make it possible to simultaneously record the element-specific magnetic dynamics of Co and Mn as the material undergoes demagnetization. The magnetization of Co is transiently enhanced by 10% within 60 fs, while that of Mn rapidly quenches. By comparing our data to density functional theory, we show that optical excitation can directly transfer spin from one magnetic sublattice to another, due to spin-polarized optical excitation pathways. The observed transient enhancement of ferromagnetic ordering demonstrates fast manipulation of spin by light, thus providing a path towards spintronics logic devices that can operate on femtosecond or even attosecond timescales.

1:15PM B41.00009: Revisiting half-metallicity of Co-based full Heusler alloys from non-empirical DFT+U method*  KENJI NAWA (Presenter), YOSHIIO MIURA, National Institute for Materials Science — The half-metallic (HM) ferromagnet, which has 100% spin polarization at the Fermi level ($E_F$), is great advantage to enhance efficiency of spin-dependent tunneling property. In particular, Co-based full Heusler alloys have been paid much attention because of the HM and high Curie temperature. The density functional theory (DFT) calculations are expected to play a key role for searching the HM materials and understanding an origin of HM. However, the DFT methods within the local density approximation often fail to predict the HM due to localized $d$ electrons around $E_F$. In this work, we revisit electronic structure of Co$_2$MnSi by the DFT+U method, where +U parameters representing correlation effect are derived from linear response theory. We revealed important atomic orbital hybridizations, which mainly dominate energy gap at $E_F$. Although the Co$_2$MnSi is not HM, our energy diagram provides a new guideline to tune the HM gap. We extended our calculations to quaternary systems Co$_2$(Y,Mn)Si, where Y is $3d$ transition metals. We found the systems with Y of Ti, V, Cr, and Fe show the HM when composition of Y is selected appropriately.

1:27PM B41.00010: Half-metallic surfaces in thin-film Ti$_2$MnAl$_{0.5}$Sn$_{0.5}$  PAVEL LUKASHEV (Presenter), SAM PROPHET, RISHABH DALAL, University of Northern Iowa, PARASHU KHAREL, South Dakota State University — Materials exhibiting a high degree of spin polarization are in demand in spintronics. Room-temperature half-metals are considered ideal candidates, as they behave as an insulator for one spin channel and as a conductor for the other spin channel. In addition, for nano-size devices, one has to take into account possible modification of electronic structure in thin-film geometry, due to the potential presence of surface/interface states. Typically, these states have a detrimental impact on half-metallicity. Here, we employ density functional calculations to explore an inverse Heusler compound, Ti$_2$MnAl$_{0.5}$Sn$_{0.5}$, which exhibits half-metallic electronic structure in bulk geometry. We show that in thin-film geometry, the type of termination surface has a decisive effect on half-metallicity of this material. In particular, we analyze six possible termination configurations, and show that for four of them, energy states emerge in the minority-spin band gap, significantly reducing the spin polarization. At the same time, two termination surfaces preserve half-metallic properties of this material. Thus, our results show that a judicious choice of the termination surface may be a crucial factor in nano-device applications, where highly spin-polarized current is needed.
1:39PM B41.00011: Why is the Curie temperature of Co2FeSi so high?* GUANHUA QIN (Presenter), University of Missouri, WEI REN, Shanghai University, DAVID SINGH, University of Missouri — We have investigated the Curie temperature of Co2FeSi and Co2TiSi by using first principle calculations. The full heusler alloy Co2FeSi has large magnetic moment per f.u. 6μB and very high Curie temperature ~1100K. And the value for Tc is 380K for half-metallic ferromagnetism Co2TiSi. We Compare these two systems using models and calculations of magnon dispersions.

*Work at the University of Missouri is supported by the Department of Energy, Basic Energy Sciences, Award DE-SC0019114.

1:51PM B41.00012: Electronic structure and magnetic properties in T2AlB2 (T = Fe, Mn, Cr, Co, and Ni) and their alloys* BRUCE HARMON, MATTHEW J. KRAMER, LIQIN KE (Presenter), Ames Laboratory, U.S. DOE, Ames, Iowa 50011, USA — Fe2AlB2 is one of the promising candidates for magnetic refrigeration technology and has attracted great attention since the recent discovery of its substantial magnetocaloric effect around room temperature. The electronic structure and intrinsic magnetic properties of Fe2AlB2-related compounds and their alloys have been investigated using density functional theory. For Fe2AlB2, the crystallographic a axis is the easy axis, in agreement with experiment. The magnetic ground state of Mn2AlB2 is found to be ferromagnetic in the basal ab plane, but antiferromagnetic along the c axis. All 3d dopants considered decrease the magnetization and Curie temperature in Fe2AlB2. Electron doping with Co or Ni has a stronger effect on the decreasing of Curie temperature in Fe2AlB2 than hole doping with Mn or Cr. However, a larger amount of Mn doping in Fe2AlB2 promotes a ferromagnetic to antiferromagnetic transition. A very anisotropic magnetoelastic effect is found in Fe2AlB2: the magnetization has a much stronger dependence on the lattice parameter c than on a or b, which is explained by electronic-structure features near the Fermi level. (Ref: PRB 95, 104427)

2:03PM B41.00013: Magnetic and magnetocaloric properties of Co doped Ni-Mn-Sn Heusler alloys at high magnetic field and pressure* SUDIP PANDEY (Presenter), Department of Physics, Southern Illinois University Carbondale, IL 62901, USA, YURY KOSHKID'KO, Institute of Low Temperature and Structural Research PAS, Wroclaw, 53-421 Poland, IGOR DUBENKO, ANIL ARYAL, Department of Physics, Southern Illinois University Carbondale, IL 62901, USA, ALEXANDER B. GRANOFSKY, Faculty of Physics, Lomonosov Moscow State University, Moscow, 119991 Russia, SHANE STADLER, Department of Physics & Astronomy, Louisiana State University, LA 70803 USA, NAUSHAD ALI, Department of Physics, Southern Illinois University Carbondale, IL 62901, USA — The magnetic and magnetocaloric properties of Ni45Mn43CoSn11 have been investigated using direct method for magnetic field changes up to 14 T, heat capacity measurements, and magnetization with hydrostatic pressure applications. A large reversible magnetocaloric effect resulted in a ΔT_{ad} of about ~−11 K and 5 K for a magnetic field change of 14 T in the vicinity of magnetostructural (T_A~260 K) and magnetic (T_C~320K) transition, respectively. The impact of thermomagnetic history on ΔT_{ad} at high magnetic fields has been revealed. Significant changes in the relaxation time of ΔT_{ad} depending on the type of phase transitions, magnetization, and demagnetization cycle are discussed. The density of states and Debye temperature have been estimated from heat capacity measurements. The mixed effects of pressure and magnetic field on the transition temperature is discussed.

Session B42 DQI: Gates in Superconducting Qubits BCEC 210A - Antonio Corcoles, IBM Thomas J. Watson Research Center - Tag(s): Focus
11:15AM B42.00001: Characterization of Single- and Two-qubit Gates between Transmons and Capacitively Shunted Flux Qubits  JASEUNG KU (Presenter), YEBIN LIU, BRITTON L PLOURDE, Syracuse University, XUEXIN XU, MOHAMMAD H. ANSARI, Peter Grünberg Institute, JARED B HERTZBERG, MARKUS BRINK, JERRY M. CHOW, IBM T.J. Watson Research Center — Capacitively shunted flux qubits (CSFQs) with high coherence hold promise for improved single- and two-qubit gate operations due to their relatively large and positive anharmonicity. When paired with transmon qubits, CSFQs may lead to a novel regime for two-qubit gates based on the cross resonance interaction. We fabricated a two-qubit system consisting of a CSFQ and a fixed-frequency transmon coupled via a bus cavity and we characterized the fidelity of single- and two-qubit gate operations. In this talk, we will present experimental results from these measurements.

11:27AM B42.00002: Characterization of Single- and Two-qubit Gates between Transmons and Capacitively Shunted Flux Qubits: Part 2, Theory  XUEXIN XU (Presenter), MOHAMMAD H. ANSARI, Peter Grünberg Institute, Forschungszentrum Jülich, JASEUNG KU, YEBIN LIU, BRITTON L PLOURDE, Syracuse University, JARED B HERTZBERG, MARKUS BRINK, JERRY M. CHOW, IBM T J Watson Res Ctr — We theoretically model an experiment on a superconducting circuit made of a capacitively shunted flux qubit (CSFQ) and a Transmon qubit both capacitively coupled to a bus resonator in dispersive regime. To model this circuit we take into account the contribution of higher excited states in qubits and block-diagonalize the Hamiltonian perturbatively in the regime of small interaction couplings compared to frequency detuning. We apply external driving microwave pulses over all energy levels and consider the transitions they impose effectively within the computational subspace. More specifically we study single qubit gates and cross-resonance gate, and analyze the fidelity of their operations. Our theoretical results are in agreement with experiment, showing a promising approach to controllably improve single- and two-qubit gate operations in such circuits due to the relatively large and positive anharmonicity of CSFQ.

11:39AM B42.00003: Demonstration of a high fidelity entangling gate in a superconducting architecture  SABRINA HONG (Presenter), PRASAHNT SIVARAJAH, ANTHONY POLLORENO, NICOLAS DIDIER, EYOB SETE, JOSHUA COMBES, KYLE GULSHEN, MARCUS DA SILVA, ALEXANDER PAPAGEORGE, Rigetti Computing — We demonstrate a high fidelity entangling gate in an architecture of alternating fixed and tunable qubits by directly modulating the flux of the tunable qubit. We achieve this by parking the DC flux of the tunable gate where the qubit is first-order insensitive to $1/f$ DC flux noise in addition to performing the flux modulated gate at an “AC sweet spot” where the qubit is first-order insensitive to noise under flux modulation, allowing us to leverage a higher ratio of gate time to coherence time. In addition to characterizing the gate using standard protocols, we qualify its performance over long periods of time, self-consistently assessing the gate fidelity and drift therein.

11:51AM B42.00004: Quantum Gates between Multi-modal Quantum Circuits*  SUMERU HAZRA (Presenter), KISHOR SALUNKHE, GAURAV BOTHARA, ANIRBAN BHATTACHARJEE, SUMAN KUNDU, MEGHAN P. PATANKAR, Tata Institute of Fundamental Research, TANAY ROY, Department of Physics, University of Chicago, IL, USA, RAJAMANI VIJAYARAGHAVAN, Tata Institute of Fundamental Research — Maximum interqubit connectivity and ability to do fast multiqubit operation are key ingredients towards building an efficient quantum processor. We have recently demonstrated trimon, a multimodal device[1,2] with all-to-all longitudinal coupling as a three-qubit quantum processor[3]. Always on strong longitudinal coupling and maximum interqubit interactions in such devices lead to simple implementation of fast high fidelity multiqubit gates. In order to scale up, we propose to use the trimon as a building block for a larger quantum processor using cross resonance drive[4] to turn on interaction between two such units. We will first discuss the coupling of a transmon and a longitudinally coupled two-qubit device named dimon, and explain how to construct a two-qubit CNOT gate. We will present preliminary experimental data and discuss extensions to gates between multiple dimon/trimon blocks. Finally, we will discuss the possibility of using dimon to improve connectivity and directionality of gates in transversely coupled multiqubit systems.

12:03PM B42.00005: Fast single qubit gates in a capacitively shunted fluxonium* HELIN ZHANG (Presenter), University of Chicago — A capacitively shunted fluxonium circuit has among the longest lifetimes seen in cQED due to the exponential suppression of the charge transition matrix element from the extra capacitance. The suppressed matrix elements however make it challenging to perform fast fluxon gates via charge coupling, requiring the use of excited fluxonium levels and Raman transitions [1]. Here, we present and characterize new protocols for performing fast single-qubit gates near half flux quantum, using fast flux modulation. The low transition frequencies near half flux quantum allow for adiabatic gates, and direct synthesis of flux pulses. These approaches increase the ease of control of fluxonium circuit at its highest coherence point, and thereby its feasibility as a building block for future quantum information processors.

12:15PM B42.00006: Sub-100ns entangling gates between two strongly coupled transmon qubits* JUNLING LONG (Presenter), HSIANG-SHENG KU, RUSSELL LAKE, XIAN WU, MUSTAFA BAL, COREY RAE MCRAE, DAVID PAPPAS, National Institute of Standards and Technology, Boulder — Superconducting qubits are very promising candidates for realizing a fault-tolerant quantum computer. However, implementing two-qubit entangling gates with short gate operation time and high fidelity is still a challenge with superconducting qubits. In this talk, we demonstrate a new type of two-qubit entangling gate, the SWIPHT gate [1], on a coupled-transmon device. The two-transmon system, strongly coupled through a bus resonator, is tuned into the secondary resonance regime, where the effective $\sigma_1^z\sigma_2^z$ interaction is enhanced due to the coupling to higher levels of the transmons. Unconditional single qubit gates two-transmon systems with strong $\sigma_1^z\sigma_2^z$ interaction were developed. This allows a SWIPHT CNOT gate with roughly 90 ns gate time. The gate fidelity is extracted by quantum process tomography.

12:27PM B42.00007: Black-box optimization of quantum gates for two coupled transmons* ZHAOQI LENG (Presenter), PRANAV MUNDADA, ANDREW HOUCK, Princeton University — As qubit coherence time sets a limit on the total time available for performing quantum gates, realizing high-fidelity, fast quantum gates is critical for enabling long-depth quantum circuits in the non-fault-tolerant regime and represents a path way towards fault tolerant quantum computation. Here, we present simulated and experimental results on using black-box optimization to tune up quantum gates for two transmon qubits coupled via a bus cavity. This optimization procedure does not require any knowledge of gradients derived from the system Hamiltonian, and thus it is ideal for automatic gate optimization on large quantum systems.

*This work is supported by IARPA under contract W911NF-16-1-0114

12:39PM B42.00008: High fidelity fermionic simulation gates with superconducting gmon qubits BROOKS FOXEN (Presenter), BEN CHIARO, MATTHEW MCEWEN, University of California, Santa Barbara, JOHN M MARTINIS, Google Inc. — We present an experimental realization of a high-fidelity 2-qubit continuous fermionic simulation (fSim) gateset using superconducting gmon qubits. Each fSim gate is parameterized by two angles: the $|01\rangle$ to $|10\rangle$ swap angle $\theta$, and the conditional phase angle $\varphi$. The full fSim($\theta$, $\varphi$) gateset covering $\theta$: $[0^\circ, 90^\circ]$ and $\varphi$: $[-180^\circ, 180^\circ]$ includes both the iSwap (fSim$(90^\circ, 0^\circ)$) and controlled-Z (fSim$(0^\circ, 180^\circ)$) gates making it applicable to error correction, quantum supremacy, and pre-error correction applications including quantum chemistry and quantum approximate optimization algorithms.
12:51PM B42.00009: Experimental Realization of non-Adiabatic Shortcut to non-Abelian Geometric Gates

TONGXING YAN (Presenter), BAOJIE LIU, School of Physics, Southern University of Science and Technology of China, KAI XU, CHAO SONG, Department of Physics, Zhejiang University, SONG LIU, ZHENSHENG ZHANG, School of Physics, Southern University of Science and Technology of China, HUI DENG, ZHIQIUAN YAN, HAO RONG, CAS Center for Excellence and Synergetic Innovation Center in Quantum Information and Quantum Physics, University of Science and Technology of China, KEQIANG HUANG, Institute of Physics, Chinese Academy of Sciences, MAN-HONG YUNG, YUANZHEN CHEN, DAPENG YU, School of Physics, Southern University of Science and Technology of China — When a quantum system is driven slowly through a parametric cycle in a degenerate Hilbert space, the state would acquire a non-Abelian geometric phase, which is stable and forms the foundation for holonomic quantum computation (HQC). However, in the adiabatic limit, the environmental decoherence becomes a significant source of errors. Recently, various non-adiabatic holonomic quantum computation (NHQC) schemes have been proposed, but all at the price of increased sensitivity to control errors. Here we propose and experimentally demonstrate that HQC via shortcut to adiabaticity (STA) can be constructed with only three energy levels, using a superconducting qubit. With this scheme, all holonomic single-qubit operations can be realized non-adiabatically through a single cycle evolution. As a result, we are able to experimentally benchmark the stability of STA+HQC against NHQC. The flexibility and simplicity of our scheme makes it also implementable on other quantum systems.

1:03PM B42.00010: High-fidelity parametric entangling gates at AC flux sweet spots [Invited] NICOLAS DIDIER (Presenter), EYOB A SETE, JOSHUA COMBES, MARCUS DA SILVA, Rigetti Computing — Realizing high-fidelity two-qubit gates is one of the main challenges in building quantum processors. A major limitation is often decoherence, in particular dephasing due to the ubiquitous presence of flux noise in tunable qubits. Under static magnetic flux biases, the dephasing time is greatly enhanced when the tunable qubit is parked at flux insensitive operating points, commonly referred to as "sweet spots". We show that under flux bias modulation around such DC flux sweet spots, even though the qubit continuously explores regions sensitive to flux noise, there exists a modulation amplitude where the qubit is insensitive to low-frequency flux fluctuations like 1/f noise - the AC flux sweet spot. We show how this sweet spot is preserved in presence of instrumental white noise by lowpass filtering the flux line. We present how the AC flux sweet spot allows to reach state-of-the-art fidelities in parametrically-activated entangling gates. arXiv:1807.01310.

1:39PM B42.00011: Coherent, Landau-Zener control of a superconducting composite qubit* DANIEL CAMPBELL (Presenter), BHARATH KANNAN, Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, MA 02139, YUN-PIL SHIM, Laboratory for Physical Sciences, Department of Physics, University of Maryland, College Park, MD 20740, RONI WINIK, Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, MA 02139, ALEXANDER MELVILLE, BETHANY M. NIEDZIELSKI, JONILYN L YODER, MIT Lincoln Laboratory, 244 Wood Street, Lexington, MA 02421, CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD 20740, TERRY PHILIP ORLANDO, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, MA 02139, WILLIAM D OLIVER, Research Laboratory of Electronics, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139, MIT Lincoln Laboratory, 244 Wood Street, Lexington, MA — We consider a computational subspace defined by two transmons coupled with a fixed capacitance. Following Ref. 1, we identify the resonantly coupled, hybridized states as a composite qubit (CQB). The CQB architecture has the desirable property that universal single-CQB gates may be implemented using solely coherent, Landau-Zener control methods based on fast, broadband pulses, without need for microwave control signals. The fidelity of these single-CQB gates is comparable to current state-of-the-art implementations.2 We present these experimental demonstrations and discuss the susceptibility of the CQB to various noise channels.

1:51PM B42.00012: Fault-tolerant and Continuous Holonomic Gates for Topologically Protected Qubits.  

ANDREY KLOTS (Presenter), LARA FAORO, ROBERT F MCDERMOTT, LEV B IOFFE, University of Wisconsin-Madison — We present the design of the topologically protected qubit that allows fault tolerant discrete operations together with the continuous holonomic \( \exp(i\theta \sigma_z) \)-gates. Topological protection of qubits is meaningless without ability to perform fault tolerant operations. These transformations should involve at least the generators of the discrete fault tolerant Clifford group and a rotation at an arbitrary angle such as \( \pi/3 \). We propose a superconducting circuit that satisfies these criteria. The proposed qubit allows protected \( \pi/2 \)-rotations in charge (Q)- and flux (\( \Phi \))-channels. Furthermore, by moving the state of the qubit along the closed loop in the \( \{Q, \Phi\} \)-space we can controllably and continuously gain a finite Berry phase difference between 0 and 1 states that is weakly sensitive to the errors in charge and flux biases.

The qubit is based on superconducting 0-\( \pi \) elements which effectively act as \( \pi \)-periodic Josephson junctions. The discrete gate operations are characterized by the exponential suppression of the flux and charge noise. The continuous holonomic operation maintains exponential suppression of the flux noise and has the quadratic suppression of the charge noise.

Session B43 DCMP: Nonlinear Optics in Topological Semimetals

11:15AM B43.00001: Origins of strong and/or quantized nonlinear optical responses in Weyl semimetals  

JOEL MOORE (Presenter), University of California, Berkeley, and Lawrence Berkeley National Laboratory — Weyl semimetals and other topological materials can support unique electromagnetic responses different from ordinary matter. This talk starts with a brief review of the theory of linear and nonlinear optics in crystals, including recent work on how geometric properties of Bloch states such as the Berry curvature can lead to simplified expressions and sum rules. Previous results show that in Weyl semimetals, nonlinear optics is likely to be a more fruitful ground for novel behavior than linear response. In addition to the Weyl semimetal TaAs whose nonlinear optical properties are the subject of intense study, we explain how other Weyl materials lacking mirror symmetry (and certain related compounds) should have an approximately quantized circular photogalvanic effect (CPGE) and discuss the status of experimental searches for this effect in various materials.

The main results described were obtained in collaborative works with F. de Juan, B. M. Fregoso, A. G. Grushin, T. Morimoto, J. W. Orenstein, and D. Parker.

11:51AM B43.00002: Colossal Bulk Photovoltaic Effect in a Weyl Semimetal*  

GAVIN B OSTERHOUDT (Presenter), LAURA KATHARINA DIEBEL, MASON GRAY, XU YANG, JOHN STANCO, Boston College, XIANGWEI HUANG, Max Planck Institute for Chemical Physics of Solid, BING SHEN, NI NI, Univ of California Los Angeles, PHILIP MOLL, Ecole Polytechnique Federale de Lausanne, YING RAN, KENNETH BURCH, Boston College — The bulk photovoltaic effect (BPVE) is a second-order non-linear optical effect which directly converts light into an electrical current. This effect is intimately related to the topological nature of the material, and is in fact directly proportional to the Berry connection. We present photocurrent measurements on the Weyl semimetal TaAs, where the diverging Berry connection leads to the largest observed BPVE, as well as the first observation of BPVE utilizing mid-infrared radiation.

12:27PM B43.00003: Berry Curvature Enhanced Nonlinear Photogalvanic Response of Type-II Weyl Cone* [Invited]
DONG SUN (Presenter), Peking University — In this talk, signatures of the singular topology in a type-II Weyl semimetal TaIrTe$_4$ is revealed in the photo responses, which are shown to be directly related to the divergence of Berry curvature. As a result of the divergence of Berry curvature at the Weyl nodes, TaIrTe$_4$ exhibits unusually large photo responsivity of 130.2 mA/W with 4-mm excitation in an unbiased field effect transistor at room temperature arising from the third-order nonlinear optical response. Furthermore, the circularly polarized galvanic response is also enhanced at 4-mm, possibly due to the same Berry curvature singularity enhancement with the shift current. Considering the optical selection rule of Weyl cones with opposite chirality, it may open new experimental possibilities for studying and controlling the chiral polarization of Weyl Fermions through an in-plane DC electric field in addition to the optical helicities.

1:03PM B43.00004: Nonlinear transport and optical responses in atomically thin WTe$_2$ [Invited] QIONG MA (Presenter), Massachusetts Institute of Technology — Many exotic quantum phenomena of today's forefront materials arise from the interplay among symmetry, topology, quantum geometry and correlations. Therefore, their detection and characterization require one to probe multiple aspects of the materials. We demonstrate nonlinear electrical transport and infrared optoelectronic measurements as symmetry sensitive probes of the low energy electron states in novel metals/semimetals. Using monolayer and bilayer WTe$_2$ as examples, I will show how nonlinear electrical transport and infrared photocurrent can reveal the Berry curvature properties in a highly symmetry sensitive way. In particular, the nonlinear electrical transport in bilayer WTe$_2$ uncovers a new type of Hall effect, the nonlinear Hall effect. Interestingly, this is an electrical Hall effect in a nonmagnetic material and in the absence of external magnetic field. Coupled with the gate tunability of 2D materials, we demonstrate that such nonlinear Hall effect provides a powerful tool to detect the Berry curvature of nonmagnetic quantum materials in an energy-resolved way.

1:39PM B43.00005: Fragile Topological Bands With Stable Index at Half-Filling in Twisted Bilayer Graphene [Invited] B ANDREI BERNEVIG (Presenter), Princeton University — Using an approximate but crucial particle-hole symmetry, we prove that half-filled graphene has bands that exhibit Wannier (Wilson loop) flow, and hence have to be topological. While this Wannier flow can be interrupted by the addition of certain bands, a topological index remains stable, and characterizes the set of bands. We then show that electron-phonon interaction in this set of bands can cause large superconducting temperatures and predict a certain set of angles where superconductivity should be observed.

Session B44 DCMP: Hole Spins in Semiconductor Quantum Dots BCEC 210C - Alex Hamilton, University of New South Wales - Tag(s): Invited

11:15AM B44.00001: High-fidelity single and two-qubit gates in germanium* [Invited] MENNO VELDHORST (Presenter), QuTech, Delft University of Technology — The promise of quantum computation with quantum dots inspired over two decades of intensive research on creating and manipulating single spins in semiconductor structures. The main focus was initially on GaAs, because of device maturity, and later on silicon, that can be isotopically purified to support extremely long quantum coherence times. Here, I will present germanium as a material that can combine these assets to form an excellent quantum material [1]. I will present the first planar germanium quantum dots, hosting single holes. I will show excellent quantum dot behavior with great control [2]. Single qubits can be defined on these holes with fidelities over 99% and can be coupled to execute two-qubit logic gates. Interestingly, these systems can also make contact to superconductors. I will present our latest effort on hybrid structures, including micro meter long supercurrents and supercurrent discretization [2,3]. Germanium bears therefore great promise for fast and coherent quantum hardware.

*Support though a FOM Projectruimte of the Foundation for Fundamental Research on Matter (FOM), associated with the Netherlands Organisation for Scientific Research (NWO) is acknowledged.
11:51AM B44.00002: Hole spins in quantum wires and quantum dots*  [Invited]  ALEX R HAMILTON (Presenter), Univ of New South Wales — The spin states of heavy holes in semiconductor nanostructures are attracting significant attention for quantum information applications, with rapid progress being made by a number of groups over the past few years. In this talk I will discuss our recent progress studying spin properties of holes in silicon and gallium arsenide quantum wires and dots. In GaAs hole quantum wires we observe highly anisotropic spin properties, which can be used to directly probe the spin-orbit interaction in holes [1,2], as well as evidence for an emergeny spin gap. In silicon single quantum dots we are able to study the spin shell filling sequence for the first 8 holes, which is consistent with the Fock-Darwin states of a circular 2D quantum dot. However while the spin filling obeys Hund's first rule, the hole-hole interaction energy is 90% of the orbital energy [3]. In few hole GaAs and Si double quantum dots we observe Pauli spin blockade, and find that the lifting of the spin blockade by an external magnetic field is highly anisotropic. These results highlight the promise, and challenges, of using holes for spin qubits.

*This work was supported by the Australian Research Council.

12:27PM B44.00003: A Ge heavy hole spin qubit  [Invited]  GEORGIOS KATSAROS (Presenter), Institute of Science and Technology Austria — The interest in hole spins as potential qubits has strongly increased in the past few years. Due to the intrinsically large spin orbit coupling, hole spins should be electrically tunable and show high Rabi frequencies. Indeed in 2016, the first electrically tunable hole spin qubit with Rabi frequencies as high as 70MHz was demonstrated [1]. In our group we work with Ge. Results on the first Ge hole spin qubit will be presented. The qubit is formed in a Ge hut wire [2] double quantum dot. Rabi-frequencies of 140 MHz were reached [3] and Ramsey experiments revealed dephasing times T2* exceeding 130 ns. Furthermore, by measuring the spin relaxation time of holes in Ge hut wires an upper bound for the coherence time could be extracted [4]. While these experiments underline the potential of hole spins in Ge, randomly grown nanowires are not very appealing for the creation of more complex qubit devices. Latest results on positioned hut wires which emphasize the potential of this material platform for scalable quantum devices will be presented.

1:03PM B44.00004: Quantum electronics with holes in Si/Ge*  [Invited]  SILVANO DE FRANCESCHI (Presenter), Univ. Grenoble Alpes & CEA — Silicon and germanium form the core materials of the well-established microelectronics industry. Lately, they have enabled remarkable progress also in the rising field of quantum technologies, generating at the same time new fundamental questions and technological challenges. In fact, there is still a lot to know about these well-known semiconducting materials and their potential for quantum electronics. In this talk, I will focus on hole-based systems made from silicon and silicon-germanium nanostructures. I will present recent experiments dealing with spin-related effects in silicon quantum dot devices, and discuss their implications for hole-spin qubits. I will also report the realization of prototypical hybrid superconductor-semiconductor devices exploiting the superconducting proximity effect in a high-mobility two-dimensional hole gas confined to a germanium quantum well.

*This work has received financial support from the EU H2020 research and innovation program, through the “MOS-QUITO” project (grant n. 688539) and through the ERC Synergy project “QuCube” (grant n. 810504), and from the Agence Nationale de la Recherche, through the OH RISQUE "TOPONANO" project.
Hole quantum dots in planar silicon and in GeSi nanowires* [Invited] FLORIS ZWANENBURG (Presenter), University of Twente — Ge/Si core/shell nanowires are suitable candidates for electrically driven spin qubits, and for the creation of Majorana fermions [1]. In highly tuneable hole quantum dots [2, 3], we observe shell filling of new orbitals and corresponding Pauli spin blockade [4]. In nanowires with superconducting Al leads we create a Josephson junction via proximity-induced superconductivity. A gate-tuneable supercurrent is observed with a maximum of ~60 nA [5]. We identify two different regimes: Cooper pair tunnelling via multiple subbands in the open regime the device [6], while near depletion the supercurrent is carried by single-particle levels of a quantum dot operating in the few-hole regime [5].

Secondly, we create ambipolar quantum dots in silicon nanoMOSFETs. We investigate the conformity of Al, Ti and Pd nanoscale gates by means of transmission electron microscopy [7]. We define low-disorder electron quantum dots with Pd gates [8], and depletion-mode hole quantum dots in undoped silicon [9]. For the latter we use fixed charge in a SiO2/Al2O3 dielectric stack to induce a 2DHG at the Si/SiO2 interface. The depletion-mode design avoids complex multilayer architectures requiring precision alignment and allows directly adopting best practices already developed for depletion dots in other material systems.

*This work is supported by the Netherlands Organisation for Scientific Research (NWO).

Session B45 DCMP: Semiconductor Surfaces, Films, and Nanostructures BCEC 211 - Elena Cimpoiasu, United States Naval Academy

Uranium Surface Nitridation and Its Application in Uranium Passivation* KEZHAO LIU (Presenter), QIFA PAN, RUILONG YANG, KANGWEI ZHU, XIAOFANG WANG, JING LIU, YIN HU, Institute of Materials, China Academy of Engineering Physics — Uranium plays a significant role in the nuclear industry. However, it is chemically active and very easy to be oxidized and corroded in the environment. Therefore, it is very important to study the corrosion and oxidation behavior of uranium metal and to find the appropriate anti-corrosion treatment technology. This report briefly introduces our recent progress in surface nitridation of uranium and its application in anti-corrosion. The relationship between the preparation technologies and the composition as well as structure of the surface layer was studied. By using TEM, AES and XPS, it is found that surface nitriding can effectively improve the corrosion resistance of the metal uranium. The nitride with high nitrogen content exhibits better oxidation resistance than the one with low nitrogen content. This may due to the formation of uranium oxynitride in the nitride with high content. It can prevent the occurrence of further oxidation corrosion. These findings will contribute to the development of metal uranium surface corrosion protection technology.

*This work is supported by the National Natural Science Foundation of China (Grant No. U1630250).
11:27 AM B45.00002: The Experimental Research on Oxidation Kinetics of Uranium Surface Treated by Laser Nitriding* YIN HU (Presenter), HAIBO LI, JIANWEI QIN, XIAOFANG WANG, YONGBIN ZHANG, YANZHI ZHANG, KEZHAO LIU, Institute of Materials, China Academy of Engineering Physics — The oxidation kinetics of uranium surface treated by pulsed laser nitriding, which has been proved to be protective during storing at room temperature in the atmosphere, were studied using reflectance spectroscopy and X-ray diffraction (XRD) technique.

The growth of the oxide thickness firstly follows a parabolic growth model for the nitriding uranium with O2, which is coincided with the diffusion barrier model. And the initial regime of slow oxide-film growth is followed by a much faster growth stage of a linear curve, resulting from the cracking of the initial oxide layer. It has been shown that the critical thickness reached at the onset of the transition is about 300 nm in this work.

The activation energy equaling to 98 kJ/mol was obtained by monitoring the oxide growth in the first stage, and 85.9 kJ/mol in the second stage. In comparison, the growth of oxide thickness of untreated uranium was also monitored, indicating that corrosion resistance could be obviously improved after nitriding treatment. It may result from the formation of U-N-O compound after oxidation, which would resist the diffusion of oxygen ions in the oxide layer.

*This work is supported by the National Natural Science Foundation of China (Grant No. U1630250).

11:39 AM B45.00003: Metallic surface states induced perturbation in electron affinity of epitaxial AlN films* MONU MISHRA (Presenter), GOVIND GUPTA, Advanced Materials and Devices, CSIR-National Physical Laboratory — We report the influence of metallic surface states induced alteration in the electron affinity of epitaxial AlN films. A systematic and in-depth photoemission analysis of epitaxial AlN films grown under different conditions by plasma-assisted molecular beam epitaxy system was performed. The presence of remnant metallic aluminium and native oxide (with different contribution) on the surface (and sub-surface) perturbed the surface chemistry and electronic structure of the grown films. However, no significant change in the morphology of the films was witnessed. It was observed that these metallic states pin the Fermi Level (FL) near valence band edge and lead to the reduction of electron affinity (EA). The metallic states initiate charge transfer from surface to bulk which induces change in the surface and interface dipoles strength. Therefore, the EA of the films varied between 0.6 - 1.0 eV due to the variation in contribution of metallic states and native oxide. However, the surface barrier height (SBH) increased (4.2 - 3.5 eV) adversely due to the availability of donor-like surface states in metallic aluminium rich films.

*Monu Mishra acknowledges CSIR for Senior Research Fellowship

11:51 AM B45.00004: Plasma Nitriding and Carbon Assisted Plasma Nitriding of Tantalum* RUILONG YANG (Presenter), KANGWEI ZHU, Institute of Materials, China Academy of Engineering Physics — Plasma nitriding and carbon assisted plasma nitriding of tantalum were carried out. The nitride layer prepared with pure N2 is composed of TaN and Ta2N with hexagonal structure and a nitriding depth of 500 nm. The carbon assisted plasma nitriding process was carried out with the addition of methane into N2 gas (5% and 10% in volume ratio) as carbon source. The carbonitride films were found to be composed of a larger number of micro-crystals nearly 1 um in size, with a uniform and compact surface, as revealed by scanning electron microscopy (SEM). TaC1-xNx with a face-centered-cubic (FCC) and Ta2C1-xNx with hexagonal structure were identified by X-ray diffraction(XRD). The auger electron spectroscopy (AES) depth profiles reveal that the diffusion depth of nitrogen increased from 500 nm in nitride film to 1.5-3 μm in carbonitride films. The high solubility of nitrogen in tantalum carbide might be the main cause that promoted the diffusion of nitrogen during the plasma carbonitriding process.

*This work was supported by Foundation of President of China Academy of Engineering Physics (YZJLX2016006), and partially supported by Key Project of Natural Science Foundation of China (U1630250), National Fund Project (CXTQ 20171631302), Material Fund (TP201402-3).
12:03PM B45.00005: Atomic layer epitaxy of aluminum nitride: Unraveling the connection between hydrogen plasma and carbon contamination  STEVEN ERWIN (Presenter), JOHN LYONS, United States Naval Research Laboratory — Atomistic control over the growth of semiconductor thin films, such as aluminum nitride, is a long-sought goal in materials physics. One promising approach is plasma-assisted atomic layer epitaxy, in which separate reactant precursors are employed to grow the cation and anion layers in alternating deposition steps. The use of a plasma during the growth — most often a hydrogen plasma — is now routine and generally considered critical, but the precise role of the plasma is not well understood. We propose a theoretical atomistic model and elucidate its consequences using analytical rate equations, density-functional theory, and kinetic Monte Carlo statistical simulations. We show that using a plasma has two important consequences, one beneficial and one detrimental. The plasma produces atomic hydrogen in the gas phase, which is important for removing methyl radicals left over from the aluminum precursor molecules. But atomic hydrogen also leads to atomic carbon on the surface and, moreover, opens a channel for trapping these carbon atoms as impurities in the subsurface region, where they remain as unwanted contaminants. Understanding this dual role leads us to propose a solution for the carbon contamination problem which leaves the main benefit of the plasma largely unaffected.

12:15PM B45.00006: The Effect of Embedded Ag versus Au Nanoparticles on the Photovoltaic Conversion Efficiency in CdTe/CdS Thin Films*  OLIVIA RODGERS (Presenter), YUNIS YILMAZ, SELAM WOLDEGERIMA, MEHMET ALPER SAHINER, Seton Hall University — The addition of metal nanoparticles to photovoltaic cells creates the possibility of improving cell efficiency and reducing production costs. Impressive improvements in photovoltaic conversion efficiencies were found in CdTe/CdS/ITO (indium tin oxide) based solar cells with the addition of embedded Ag nanoparticles. Ag nanoparticles were deposited between the CdS and CdTe layers through pulse laser deposition method. Structural and electrical characterizing was achieved using x-ray diffraction ellipsometry, scanning electron microscopy, energy dispersive x-ray diffraction, atomic force microscopy and Keithley source meter photovoltaic measurement set. Previous research revealed that the photovoltaic conversion efficiency exhibits sensitive dependence on the size and the particle density of the embedded Ag nanoparticles. This work focuses on identifying at what amount of Ag deposition time will yield maximum efficiency. A similar study was conducted using Au nanoparticles deposited with the same parameters. An assessment of the differences between Ag and Au nanoparticles size and density was done. More importantly, a comparison on the photovoltaic conversion efficiency in thin films with Au versus Ag nanoparticles will be discussed.

12:27PM B45.00007: Non-classical effects of extrinsic doping on Au quantum wires  ZAMIN MAMIYEV (Presenter), CHRISTOPH TEGENKAMP, HERBERT PFNÜR, Institute for Solid State Physics, Leibniz University of Hannover — Self-assembled atomic wires on vicinal Si(hhk) surfaces are very versatile quasi-1D objects to study their interaction with the embedding environment [1,2]. Here we employ plasmon spectroscopy to study the response of Au-induced quantum wires to extrinsic doping by hydrogen adsorption. Si(553) and Si(557) surfaces are used as templates, which form double and single atomic strands per terrace upon evaporation of 0.48ML and 0.19ML of Au, respectively. The present study shows that the plasmonic excitation on both surfaces is strongly modified upon hydrogenation of the Si environment. These modifications are specific to the structural Au motif on the surface. Although hydrogen adsorption never happens on the Au chains directly, it clearly modifies the band structure of the whole system including the Au chains. The effects range from simple charge donation and changes of band filling, as for Si(553)-Au, to opening of band gaps partly even close to the Fermi energy as for Si(557)-Au, that will be discussed in detail.

12:39PM B45.00008: Kinetics of a Solid-Solid Charge Transfer Reaction*  
YING PAN, Harvard University, DIMOS POULIKAKOS, Mechanical and Process Engineering, ETH, NATE J. CIRA, YE TAO (Presenter), Harvard University — We present an analysis of the kinetics of charge transfer at a solid-solid interface. The study was enabled by measuring the conductance of ultra-thin, fully suspended single-crystalline silicon nanowires across 7 orders of magnitude with a detection sensitivity of order single event over a 10^3 μm^2 reaction area. We find that a classic, first-order process is unable to capture the reaction progress and propose a new kinetic model based on a continuum of reactant geometries inherently present at typical solid-solid interfaces. The new model captures the kinetic manifestation of heterogeneity in a single, global rate constant. Quantitative agreement with data and an analysis of the parameters suggest that this model may be generally applicable to charge transfer at solid-solid interfaces.

12:51PM B45.00009: Growth of CuMnAs by molecular beam epitaxy: Control over structure and properties*  
FILIP KRIZEK (Presenter), ZDENĚK KASPAR, MARTIN BRAJER, JAN ZUBÁČ, Department of Spintronics and Nanoelectronics, Institute of Physics of the Czech Academy of Sciences, ALIKSEI VETUSHKA, Department of Thin Films and Nanostructure, Institute of Physics of the Czech Academy of Sciences, JOÃO GODINHO, DOMINIK KRIEGNER, ZBYNĚK ŠOBÁN, Department of Spintronics and Nanoelectronics, Institute of Physics of the Czech Academy of Sciences, RICHARD CHAMPION, PETER WADLEY, School of Physics and Astronomy, University of Nottingham, KAMIL OLEJNÍK, TOMAS JUNGWIRTH, VÍT NOVÁK, Department of Spintronics and Nanoelectronics, Institute of Physics of the Czech Academy of Sciences — Antiferromagnetic materials have recently attracted significant attention in connection with the discovery of a way to electrically manipulate their magnetic ordering [1]. Especially magnetic reorientation of tetragonal CuMnAs layers by electrical current has potential for future industrial applications of antiferromagnetic materials [2]. We will present a detailed strategy for growth of CuMnAs by molecular beam epitaxy, while focusing on crystallinity of the grown thin films. These typically contain different densities of specific structural defects, which likely influence their electrical and magnetic properties. This, together with ageing in ambient conditions and significant surface roughness complicates practical implementations of CuMnAs thin films. We will show how careful tuning of the growth conditions improves the structural properties of the material and how growth parameters are reflected in conductivity, Hall coefficient and effectivity of Néel vector manipulation.

1:03PM B45.00010: Preparation of epitaxial ScF3 thin films – a negative thermal expansion material  
AMANI JAYAKODY (Presenter), ZHIWEI ZHANG, University of Connecticut, ZHIHAI ZHU, Massachusetts Institute of Technology, HOPE R WHITELOCK, University of Colorado, JOSEPH I BUDNICK, JASON HANCOCK, BARRETT OTIS WELLS, University of Connecticut — Scandium trifluoride (ScF3) is known for a pronounced negative thermal expansion over a wide range of temperature, from 10 K to 1100 K. The structure of ScF3 can be described as an ABX3 perovskite with an empty A-site. Growing films of ScF3 allows for tuning the lattice constant, the thermal expansion, and the construction of devices based upon differential thermal expansion. We have investigated the growth of ScF3 films on oxide and fluoride substrates using pulsed laser deposition (PLD). There are several unique features to this material that pose challenges for PLD growth: poor adhesion of ScF3 pressed powder targets, a narrow stability range, and complex interfaces between fluorides and oxides. Nonetheless, we have found growth routes for producing films with very good epitaxy and narrow mosaic. This report describes the growth and initial characterization of high quality ScF3 films.
Atom-Scale Dynamics in Surface-Catalyzed Nitrogen Incorporation in Epitaxial Growth of Gallium Nitride

KIEU MY BUI (Presenter), IMASS, Nagoya University, MAURO BOERO, IPCMS, University of Strasbourg, KENJI SHIRAISHI, ATSUSHI OSHIYAMA, IMASS, Nagoya University — GaN is a principal material in optoelectronics and now emerging as a key material in power electronics [1]. One of the challenges to the device fabrication is the formation of higher quality thin films of GaN, that is not yet achieved to date. We here report density-functional total-energy electronic-structure calculations [2] and Car-Parrinello Molecular Dynamics simulations [3] that clarify atom-scale mechanisms of N incorporation in GaN bonding network during Metal Organic Vapor Phase Epitaxy (MOVPE). The results obtained for the first time in this work include (i) that Ga atoms on the growing surface are extremely mobile at the growth temperature, forming a liquid-like phase, and (ii) that ammonia NH3 and its related species NHx intervene into the weak Ga-Ga bond on the growing surface spontaneously or with surprisingly small energy barriers. This finding leads to a conclusion that the epitaxial growth is a reaction enhanced by the existence of weak surface Ga-Ga bonds. Computations have been performed with our own real-space code highly tuned and scalable on for massively parallel HPC architectures.

A SCAN+rVV10 study of Thiophene adsorption on Ir, Rh, and Ag (100)*

ABDELKADER KARA (Presenter), WALTER MALONE, University of Central Florida — Using density functional theory we study the adsorption of thiophene on Ir, Rh, and Ag(100) surfaces. Specifically, we employ the meta-GGA SCAN+rVV10 functional. To assess the performance of SCAN+rVV10 we compared our SCAN+rVV10 results to results calculated using the popular van der Waals (vdW) inclusive GGA functional, optB88-vdW. To find the equilibrium adsorption geometry, we explore a variety of adsorption sites with the plane of the molecule both parallel and perpendicular to the surface. Along with the equilibrium adsorption geometry we present various geometric and electronic properties of the adsorbate/substrate systems such as adsorption energy, adsorption height, buckling of the first layer of the substrate, charge transfer to the molecule, change in the width and center of the substrate's d-band, and change in the surface's work function. We find over all surfaces both functionals predict thiophene to adsorb parallel to the surface. Besides the consensus on a flat adsorption site, generally we find SCAN+rVV10 and optB88-vdW to agree very well concerning thiophene adsorption over Ag(100) and moderately well concerning thiophene adsorption over Rh(100) and Ir(100).

*This work was supported by the DOE-BES DE-FG02-11ER16243. This research used resources of NERSC.

A Density Functional Theory Study of the Adsorption of Thiophene on Transition Metal Surfaces

WALTER MALONE (Presenter), ABDELKADER KARA, WILLIAM KADEN, University of Central Florida — Using density functional theory we study the adsorption of thiophene (C4H4S) over a wide variety of transition metal surfaces including V, Cr, Ta, W, Mo, Nb, Co, and Al(100). To account for long range dispersion we utilize the van der Waals (vdW) inclusive optB88-vdW functional. We explore several adsorption sites with the plane of the molecule either parallel or perpendicular to the surface. We find that on all of the surfaces thiophene prefers to bond in a flat configuration. Along with the equilibrium adsorption sites, we present a variety of other properties of the substrate/adsorbate system including adsorption energy, adsorption height, C-S bond lengths, and charge transfer to the molecule. Using the previously mentioned geometric and electronic data we find the thiophene/substrate interaction increases moving from right to left on the periodic table. Focusing specifically on charge transfer to the thiophene molecule, we find a strong correlation between the charge transfer to thiophene's S atom and the thiophene/substrate interaction, which we build into a descriptor for the surfaces' reactivity.

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B46 DMP GMAG: 4d/5d Transition Metal Systems -- Ruthenates and RuCl3
ANDY CHRISTIANSON (Presenter), Materials Science and Technology Division, Oak Ridge National Laboratory — The double perovskite structure type is extremely flexible and accommodates a large fraction of the elements in the periodic table. Of particular interest are double perovskites containing magnetic 4d or 5d transition metal elements. Such materials exhibit novel phenomena including high ferrimagnetic transition temperatures in conjunction with half metallic or insulating behavior. One of the key remaining challenges is to accurately determine effective spin Hamiltonians to achieve a deeper understanding of this class of materials. This talk will focus on our efforts to determine the effective spin Hamiltonians with inelastic neutron scattering in materials including Sr$_2$ScOsO$_6$, Sr$_2$FeOsO$_6$, Sr$_2$MgOsO$_6$, Ca$_3$LiOsO$_6$, Ca$_3$LiRuO$_6$, and Ba$_2$LaRuO$_6$. Interestingly, all of the Osmates in the above list exhibit significant gaps in the magnetic excitation spectrum, despite being nominally in the 5d$^3$ electronic configuration. This provides an indication of strong spin-orbit effects that would not normally be expected for a 5d$^3$ half-filled t$_2g$ multiplet. We will also discuss what can be learned about the nature of the exchange interactions from inelastic neutron scattering on polycrystalline samples and how such experimental studies can be used to constrain models for effective spin Hamiltonians in double perovskites and related transition metal oxides.

*This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

QIANG HAN (Presenter), Physics, Columbia University, RAFAEL M FERNANDES, Physics, University of Minnesota, ANDREW MILLIS, Center for Computational Quantum Physics, Flatiron Institute, Physics Department, Columbia University — A general Ginzburg-Landau free energy is proposed for the metal-insulator transition (MIT) in correlated oxides, which incorporates magnetism, octahedral distortions, strain as well as the electronic transition. The theory is used to elucidate important experimental features observed across thermal-induced and current induced MIT in 2-1-4 and Ti-doped 3-2-7 calcium ruthenate compounds, including the coexistence of metallic and insulating domains, occurrence, orientation and lengths of stripes at the domain boundaries, as well as the impact of uniaxial and biaxial strain on the transition temperatures and elasto-resistance. Generalization to MIT in other systems is presented.

*AJM and QH are supported by the Basic Energy Sciences Program of the US Department of Energy under grant DOE-SC-0012375. RF is supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under award No. DE-SC0012336.

CHRISTOPHER DIETL (Presenter), Institute for Basic Science, JOEL BERTINSHAW, SHYAM KANTA SINHA, GEORG CRISTIANI, GENNADY LOGVENOV, YURY KHAYDUKOV, THOMAS KELLER, KATRIN FURSICH, GIDEOK KIM, DANIEL PUTZKY, Max Planck Institute for Solid State Research, LAURENCE BOUCHENOIRE, XMas, European Synchrotron Radiation Facility, JOERG STREMPFER, Advanced Photon Source, Argonne National Laboratory, SONIA FRANCOUAL, Deutsches Elektronen-Synchrotron, YONGSEONG CHOI, Advanced Photon Source, Argonne National Laboratory, PETER WOCHNER, SHYJUMON IBRAHIMKUTTY, PETER VAN AKEN, Max Planck Institute for Solid State Research, BUMJOON KIM, Institute for Basic Science, BERNHARD KEIMER, Max Planck Institute for Solid State Research — We report a comprehensive study of epitaxial Ca$_2$RuO$_4$ thin films using resonant X-ray scattering at the Ru-L$_2$ and L$_3$ absorption edges, which directly probe the Ru 4d valence states. The strong modification of the electronic properties by biaxial strain is readily seen in transport measurements, which reveal a tuning from an insulator (on NdCaAlO$_4$(110) substrates) to a metal (on LaSrAlO$_3$(001)). Using magnetometry and resonant X-ray scattering, we can identify ferromagnetic phases in films on LaSrAlO$_3$(001), LaSrAlO$_3$(110) and LaAlO$_3$(100) substrates and antiferromagnetic phases in films on NdCaAlO$_4$(110), LaSrAlO$_3$(110) and LaAlO$_3$(100). The antiferromagnetic phases are most compatible with the B-Type magnetic structure found in the pressurized bulk system exhibiting a $T_N$=$150$ K. While the magnetic moment direction is typically along (010) in bulk Ca$_2$RuO$_4$, a polarization analysis of magnetic reflections of the film on NCAO(110) shows an unusual magnetic moment direction towards (-102).

**12:15PM B46.00004: Investigation on the Itinerant/Local Magnetic Nature in SrRuO$_3$ by ARPES**

JI SEOP OH (Presenter), SE YOUNG PARK, Institute for Basic Science, WONSHIK KYUNG, Lawrence Berkeley National Laboratory, NAOKI KIKUGAWA, National Institute for Material Science, YOSHIYUKI YOSHIDA, National Institute of Advanced Industrial Science and Technology, JUNYOUNG KWON, Institute for Basic Science, SIMON K MOSER, ROLAND KOCH, CHRIS JOZWIAK, AARON BOSTWICK, ELI ROTENBERG, Lawrence Berkeley National Laboratory, CHANGYOUNG KIM, TAE WON NOH, Institute for Basic Science — SrRuO$_3$ (SRO), one of the most famous perovskite metallic ferromagnets, has been the center of various research perspectives. One of the key issue with a long-time standing debate is the origin of ferromagnetism with metallicity. We studied the three-dimensional electronic structure of SRO single crystals by angle-resolved photoemission spectroscopy. We determined the inner potential of SRO single crystals for the first time. We also measured band dispersions on high symmetry planes and opened a way to cross-check theoretical electronic structures of SRO, which has not been accomplished during last 20 years. We also obtained temperature dependence of the ferromagnetic exchange splitting. These results implied the existence of short-range magnetic order above the Curie temperature and supported the dual nature of itinerant/local magnetism in SRO. Detailed experimental results and analyses will be presented and discussed.

**12:27PM B46.00005: Magnetic susceptibility in the Hund’s metal Sr$_2$RuO$_4$ from the dynamical two-particle vertex**

HUGO STRAND (Presenter), MANUEL ZINGL, NILS WENTZELL, OLIVIER PARCOLLET, ANTOINE GEORGES, Center for Computational Quantum Physics, Flatiron Institute — Strontium Ruthenate (Sr$_2$RuO$_4$) is a strongly correlated complex oxide for which crystals with exquisite purity can be prepared, allowing for a wealth of experimental studies. It displays unconventional superconductivity, Hund’s metal physics, and an incommensurate anti-ferromagnetic spin response.

To understand the interplay of collective spin excitations and the Fermi liquid quasi particles we have performed density functional theory and dynamical mean field theory calculations of the dynamic magnetic susceptibility using the Bethe-Salpeter equation, comparing to recent inelastic neutron scattering results.

The crucial importance of local quantum fluctuations in the vertex is established by comparison with the static random phase approximation. We also study the spin-orbit driven anisotropy and disentangle the orbital contributions. Our findings confirm that this material is close to a magnetic instability, as revealed by its sensitivity to impurity substitutions. Finally, by comparing the local and momentum dependent response, we pinpoint signatures of Hund’s metal physics in the inelastic neutron spectra.

*The Flatiron Institute is a division of the Simons Foundation.

**12:39PM B46.00006: Hall number sign changes in Sr$_2$RuO$_4$ reveal coherent-to-incoherent and elastic-to-inelastic crossovers**

MANUEL ZINGL (Presenter), CCQ, Flatiron Institute, JERNEJ MRAVLJE, Department of Theoretical Physics, Institute Jozef Stefan, MARKUS AICHHORN, Institute of Theoretical and Computational Physics, Graz University of Technology, OLIVIER PARCOLLET, ANTOINE GEORGES, CCQ, Flatiron Institute — The 4d transition metal oxide Sr$_2$RuO$_4$ exhibits an unusual temperature dependence of its Hall number with two sign reversals: it is negative at low temperature below 30K (Fermi liquid temperature), turns positive, reaches a maximum and turns negative again at ~120K. We show that this non-monotonic behavior is due to the strong temperature-dependence of the ratio of inelastic scattering rates between the xy and xz/yz orbitals. This ratio becomes remarkably large upon cooling into the Fermi liquid regime, but is overshadowed at lower temperatures by impurity scattering. Another pivotal factor to account for the full temperature dependence is the spin-orbit coupling, as it impacts the topography of the Fermi surface sheets and strongly mixes their orbital character. By considering all these effects, we are able to reveal the significance of both sign changes: the one at 30K is a direct consequence of the crossover from elastic to inelastic scattering, while the higher-T one is associated with the coherence-to-incoherence crossover due to electronic correlations. These qualitative conclusions are supported by quantitative calculations using a Boltzmann transport theory in combination with dynamical mean-field theory, taking into account the electronic structure of the material.
Electric field driven octahedral rotation in Sr$_2$RuO$_4$ and its underlying mechanism

WONSHIK KYUNG (Presenter), Lawrence Berkeley National Laboratory, CHOONG HYUN KIM, CCES-IBS, YEONG KWAN KIM, KAIIST, BEOMYOUNG KIM, Lawrence Berkeley National Laboratory, CHUL KIM, Yonsei University, WOOBIN JUNG, JUNYOUNG KWON, MINSOO KIM, CCES-IBS, AARON BOSTWICK, JONATHAN DENLINGER, Lawrence Berkeley National Laboratory, YOSHIYUKI YOSHIDA, AIST, CHANGYOUNG KIM, CCES-IBS — One of the key goals in the research of perovskite transition metal oxides (TMOs) is to design and control their physical properties, for which MO$_6$ (M=transition metal) octahedron rotation (OR) is considered to be one of the key control parameters. We show, through a combined study of angle resolved photoemission, low energy electron diffraction and first-principles calculations, that OR can be induced and thus be tuned with electric field in Sr$_2$RuO$_4$. Originally rotated octahedra in the surface layer of Sr$_2$RuO$_4$ are restored to the bulk structure upon K dosing on the surface. Our theoretical investigation shows that OR in Sr$_2$RuO$_4$ originates from surface electric field which can be controlled via the screening effect of the overlaid K layer and that the variation of Sr-Sr vertical distance is responsible for the coupling between OR and electric field. Our finding raises a possibility for electric field control of physical properties through the variation of the OR angle even for non-piezoelectric materials.

Quantum continuum fluctuations in glassy perovskite Ca(Co$_{0.15}$Ru$_{0.85}$)O$_3$

DEEPAK K SINGH (Presenter), YIYAO CHEN, ASHUTOSH DAHAL, Department of Physics and Astronomy, University of Missouri, JOSE A RODRIGUEZ, GUANGYONG XU, NIST Center for Neutron Research, THOMAS HEITMANN, University of Missouri Research Reactor, University of Missouri, VITALII DUGAEV, Department of Physics and Medical Engineering, Rzeszow University of Technology, ARTHUR ERNST, Max Planck Institute of Microstructure Physics — The quantum spin continuum and classical spin freezing, associated with a glassy state, represent two opposite extremes of a correlated electronic material. Here, we report the coexistence of a quantum spin continuum with a weak spin glass order in Co-doped CaRuO$_3$ perovskite near the chemical doping dependent metal-insulator transition boundary. Inelastic neutron measurements on Ca(Co$_{0.15}$Ru$_{0.85}$)O$_3$ at low temperature, $T = 1.5$ K, reveal a continuum spectrum in the Q-E space due to uncorrelated spin fluctuations. This persists across the glass transition at $T_G \approx 23$ K. Furthermore, scaling of the dynamic susceptibility yields a very small scaling coefficient $\alpha \approx 0.1$, suggesting extreme locality of the dynamic properties. The experimental results indicate the realization of a narrow regime where the distinction between continuum dynamic behavior and glass-like regimes is reduced.

Direct evidence of orbital-selective confinement effect of Ru 4$d$ orbitals in SrRuO$_3$ ultrathin film

SOONMIN KANG (Presenter), Seoul National University, YI TSENG, Swiss Light Source, Paul Scherrer Institut, BEOM HYUN KIM, Korea Institute for Advanced Study, SEOKHWAN YUN, BYUNGMIN SOHN, BONGJU KIM, Seoul National University, DANIEL MCNALLY, EUGENIO PARIS, Swiss Light Source, Paul Scherrer Institut, CHUL KIM, CHANGYOUNG KIM, TAE WON NOH, Seoul National University, SUMIO IŞIHARA, Department of Physics, Tohoku University, SCHMITT THORSTEN, Swiss Light Source, Paul Scherrer Institut, JE-GUEN PARK, Seoul National University — The electronic structure of SrRuO$_3$ thin film with the thickness from 50 to 1 unit cell (u.c.) is investigated via the resonant inelastic x-ray scattering (RIXS) technique at the O K-edge to unravel the intriguing interplay of orbital and charge degrees of freedom. We found that orbital-selective quantum confinement effect (QCE) induces the splitting of peaks in RIXS spectra of thin films, which corresponds to the charge transfer from O 2$p$ to Ru 4$d$ orbitals. At the same time, we observed a spectral weight transfer from electron-hole continuum to intersite $d$-$d$ excitation across the metal-to-insulator transition (MIT) occurring between 5 and 4 u.c. samples. From these two clear observations, we conclude that QCE gives rise to a Mott insulating phase in ultrathin SrRuO$_3$ films. Our interpretation of the RIXS spectra is supported by configuration interaction calculations of RuO$_6$ cluster models.

Substitution of 4d magnetic ions of a Kitaev-Heisenberg magnet by 3d magnetic ions: the case of Ru$_{1-x}$Cr$_x$Cl$_3$* 

GÄEL BASTIEN (Presenter), Leibniz-Institut für Festkörper- und Werkstoffforschung (IFW) Dresden, 01171 Dresden, Germany, MARIA ROSLOVA, Fakultät für Chemie und Lebensmittelchemie, Technische Universität Dresden, 01062 Dresden, Germany, MOHAMMAD HOSSEIN HAGHIGHI, KAVITA MEHLAWAT, KONSTANTIN NENKOV, Leibniz-Institut für Festkörper- und Werkstoffforschung (IFW) Dresden, 01171 Dresden, Germany, JENS HUNGER, ANNA ISAEVA, Fakultät für Chemie und Lebensmittelchemie, Technische Universität Dresden, 01062 Dresden, Germany, MATTHIAS VOJTA, Institut für Theoretische Physik, Technische Universität Dresden, 01062 Dresden, Germany, THOMAS DOERT, Fakultät für Chemie und Lebensmittelchemie, Technische Universität Dresden, 01062 Dresden, Germany, ANJA WOLTER, BERND BÜCHNER, Leibniz-Institut für Festkörper- und Werkstoffforschung (IFW) Dresden, 01171 Dresden, Germany — The Jeff$=1/2$ Mott insulator alpha-RuCl$_3$ is a promising candidate for the realization of the Kitaev-Heisenberg model. It harbors an antiferromagnetic ground state below $T_N=7$K, however, this ordered state can be suppressed by a magnetic field through a quantum critical point toward a possible quantum spin liquid [1]. In this study, the Ru$^{3+}$ ions with Jeff$=1/2$ moments were partially substituted by Cr$^{3+}$ ions with S=3/2. The effect of this substitution on the magnetic interactions, the magnetic ground state and the field-induced quantum spin liquid were studied by means of magnetization, ac susceptibility and specific heat measurements. The ground state of Ru$_{1-x}$Cr$_x$Cl$_3$ was found to be a spin glass on a broad Cr concentration range with a maximum of the freezing temperature around $x=0.5$. Moreover, the evolution of the magnetic anisotropy with the substitution reveals a rather complex nature of the magnetic interaction between the Ru and Cr magnetic moments.

*This research has been supported by the European Union's Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie Grant Agreement No 796048.
1:51PM B46.00012: An effective spin Hamiltonian for α-RuCl₃ and finite temperature properties* PONTUS LAURELL (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, CASEY EICHSTAEDT, Department of Physics and Astronomy, University of Tennessee, Knoxville, YI ZHANG, Department of Physics and Astronomy, Louisiana State University, TOM BERLJIN, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, ADOLFO GERMAN EGUILUZ, Department of Physics and Astronomy, University of Tennessee, Knoxville, YOUHEI YAMAJI, Department of Applied Physics, University of Tokyo, SATOSHI OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory — We study the magnetic interactions in the Kitaev spin-liquid candidate α-RuCl₃ using ab initio, exact diagonalization, and thermal pure quantum state methods. First we derive a new effective Hamiltonian, using an ab initio downfolding scheme based on a density functional theory calculation for the monoclinic crystal structure (space group C2/m). The calculation includes local crystal field splitting, and local and non-local spin-orbit coupling. Both local and nonlocal Coulomb interactions are computed using the constrained RPA method, and the interaction parameters for the effective spin Hamiltonian are determined using second order perturbation theory. We report both zero and finite temperature properties for this and previously proposed models, including dynamical spin structure factors and the specific heat. Our results highlight the importance of further range anisotropic spin-spin interactions, both for producing the zigzag magnetic order and for predictions beyond static properties at zero temperature.

2:03PM B46.00013: Electronic transport in thin crystals of transition metal oxides with Heisenberg-Kitaev physics* JOSUE RODRIGUEZ (Presenter), AMIRARI DIEGO, California State University, Long Beach, NICHOLAS BREZNAY, Harvey Mudd College, ROBERT KEALHOFER, GILBERT LOPEZ, University of California Berkeley, DAVID ROSSER, FRANCISCO RAMIREZ, NAOMY MARRUFO, SAMANTHA CROUCH, California State University, Long Beach, JAMES G. ANALYTIS, University of California Berkeley, CLAUDIA OJEDA-ARISTIZABAL, California State University, Long Beach — Josue Rodriguez, Amirari Diego, Gilbert Lopez, Nicholas P. Breznay, Robert Kealhofer, David Rosser, Francisco Ramirez, Naomy Marrufo, Samantha Crouch, James G. Analytis and Claudia Ojeda-Aristizabal

Sodium Iridate (Na₂IrO₃) and Ruthenium Chloride (RuCl₃) present exciting phenomena thanks to the honeycomb arrangement of their ions and the interplay of electronic correlations and spin-orbit coupling. They constitute a close experimental realization of the the Kitaev-Heisenberg model. Magnetic susceptibility and heat capacity measurements in bulk crystals have shown signature of magnetic ordered states [1]. We have integrated exfoliated thin crystals of Na₂IrO₃ and RuCl₃ into an electronic device and performed electronic transport measurements, finding through temperature dependent resistance measurements anomalies that correspond to the magnetic ordered transition for Na₂IrO₃.

Monday, March 4, 2019 11:15 AM - 2:03 PM

Session B47 GERA: Catalytic Energy Generation BCEC 213 - Filip Podjaski
11:15AM B47.00001: Mechanism of water oxidation catalyzed by cobalt-intercalated layered MnO2: confinement and intercalant local ordering* JINLIANG NING (Presenter), JAMES FURNESS, YUBO ZHANG, Department of Physics and Engineering Physics, Tulane University, AKILA C. THENUWARA, RICHARD C REMSING, MICHAEL L KLEIN, DANIEL R. STRONGIN, Department of Chemistry, Temple University, JIANWEI SUN, Department of Physics and Engineering Physics, Tulane University — To lower the overpotential is a persistent goal for (photo)electrochemistry reactions, which can be facilitated by selectively stabilizing one reaction intermediate over another. In this mechanistic SCAN+rVV101,2 study of the oxygen evolution reaction (OER) catalysed by cobalt-intercalated layered MnO2, we show that confinement effects and local cobalt atomic ordering in the interlayer space can be used to tune the adsorption energies of O, OH, and OOH reaction intermediates and the scaling relationship between them. Interlayer confinement destabilizes the OER intermediates, but clustering Co atoms can selectively stabilize OOH. With considering both effects, our model predicts an overpotential of 0.30 V, in excellent agreement with the experimental result of 0.36 V. In addition to giving mechanistic explanation for experimental findings, these insights illuminate a route for engineering non-toxic precious-metal-free catalysts through designed layered materials.

*Supported by the DOE Energy Frontier Research Centers (DE-SC0012575).

11:27AM B47.00002: Photocatalytic oxygen evolution reactivity at surface edges and corners of anatase TiO2 nanoparticles revealed by coupled quantum mechanical and molecular mechanical simulations* LIXIN SUN (Presenter), BILGE YILDIZ, Nuclear Science and Engineering, Massachusetts Institute of Technology — Coupled quantum mechanical and molecular mechanical (QM/MM) method is applied to investigate the oxygen evolution reactions (OER) on a realistic 9.5-nm long anatase TiO2 nanoparticle. The nanoparticle surface has easier electron and hole localization behavior on some of the corners and edges, compared to flat surfaces. As a result, OER reaction energy can be reduced by 0.1 - 0.5 eV at the corners and edges. However, since some of the structures with low reaction energies are also prone to form electron polarons, its high OER activity can be compromised due to electron-hole recombination. By considering both factors, the (101) facet and the edge between (101) and (011) facets are found to be the most active for OER, while the remaining corners and edges can be active for reduction reactions. Unlike early works where four-fold coordinated Ti4c was attributed to the only reason for active corners and edges, this work shows that Madelung potential, surface relaxation can also be the cause of active surface.

*The authors are grateful for the support of this research by DOE-Basic Energy Sciences, grant number DE-SC0002633, and the for the computational support by the National Science Foundation through the XSEDE Science Gateways programme, grant number TGDMR120025.

11:39AM B47.00003: Operando studies of carbon removal and contaminants in solid oxide fuel cells* JEFFREY OWRUTSKY (Presenter), WILLIAM A. MAZA, United States Naval Research Laboratory, DANIEL STEINHURST, Nova Research, Inc., STANISLOV TSOI, United States Naval Research Laboratory, BRYAN EIGENBRODT, Chemistry, Villanova University, ROBERT WALKER, Chemistry and Biochemistry, Montana State University — Solid oxide fuel cells (SOFCs) are attractive devices for power generation due to their fuel flexibility. These devices present challenges for real time, direct observations because they operate at high temperatures (> 700 °C). We have developed and used several methods for real-time, operando studies, including infrared emission, near infrared thermal imaging and Raman spectroscopy which are combined with ex situ infrared spectroscopy and mass spectrometry of the products and concurrent electrochemical measurements for comprehensive investigations of the effects of contaminants and remediation approaches. We characterized the products, primarily CO and CO2, as well as anode temperature changes to explore the effects of various mixtures of H2 and O2 on carbon removal from Ni-YSZ anodes as well as during partial methane oxidation for SOFC operation. The prevalent processes effectively reduce to steam reforming with hydroxyl as a primary reaction intermediate. We also report initial studies of sulfur effects based on SOFC operation with methane and compare the results to similar studies for chlorine degradation to identify whether there are common themes.

11:51AM B47.00004: Characterization of Platinum Nanoparticles Utilized in Photocatalytic Hydrogen Synthesis*

DANIEL BOYCE (Presenter), JOHN COLTON, MATTHEW RICHARDS, Brigham Young University — Hydrogen (H₂) gas is a possible alternate fuel to help meet increasing worldwide energy needs, but a major obstacle in the use of H₂ for green, environmentally-friendly fuel is the energetic and chemical requirements to synthesize the gas. We are studying the use of photocatalytic reactions to produce H₂, where a light-absorbing substance acts as a catalyst in shuttling electrons from a donor to protons that are reduced into H₂. Previous research conducted at BYU showed that platinum nanoparticles bound to ferritin catalyzed the photoreaction of methyl viologen to reduce protons in an organic acid offered an increase in hydrogen production efficiency by up to 100 times over platinum black (a commonly available platinum-based catalyst). We are reporting on our efforts to optimize the synthesis of the platinum nanoparticles bound to ferritin that are used in this photocatalytic system and how we characterize these nanoparticles, as well as how these characteristics affect H₂ production.

*We'd like to thank the Brigham Young University Physics Department and the National Science Foundation (grant no. 1757998) for their generous funding.

12:03PM B47.00005: First-principles Studies on the Structural and Electronic Modifications of Nitrogen Electrochemical Reduction on Anatase TiO₂(101) Surface*

YANNING ZHANG (Presenter), TONGWEI WU, University of Electronic Science and Technology of China — The conversion of dinitrogen (N₂) to ammonia (NH₃) through an electrochemical reduction process is attracting increasing attentions due to its great importance in both the biosphere and the fertilizer industry. In this work, we performed systematic density functional theory (DFT) studies on the nitrogen reduction reaction (NRR) mechanisms on both clean and O-decorated TiO₂(101) surfaces at an atomic scale. Our calculation results showed that the Ti₄C₂VO₂c site most likely serves as the active site for NRR process, and the V₂O₂c-decorated TiO₂(101) surface exhibits outstanding NRR catalytic activity through a mixed mechanism compared with the clean anatase TiO₂(101) surface. We further studied the effect of structural and electronic features on N₂ fixation and activation on TiO₂(101) surface. The introduction of surface oxygen vacancy should enhance the nitrogen adsorption obviously with an adsorption energy of -0.46 eV, and the tuning of Ti³⁺ concentration further changes the adsorption energy, such as to -0.65 eV if the concentrations of Ti³⁺ can be decreased to 4%. Our calculation results may provide some guidelines in the design of new catalysts for NRR.

12:15PM B47.00006: Optimizing proton conductivity in alkaline-earth zirconates through defect engineering*

ANDREW ROWBERG (Presenter), Materials Department, University of California, Santa Barbara, LEIGH WESTON, Energy Technologies Area, Lawrence Berkeley National Laboratory, CHRIS VAN DE WALLE, Materials Department, University of California, Santa Barbara — The alkaline-earth zirconates (AeZrO₃; Ae = Sr, Ca, Ba) are among the best solid-state proton conductors and as such have energy applications in solid-state hydrogen fuel cells. They crystallize as perovskite oxides of the form ABO₃. Oxygen vacancies form readily in these systems, and upon exposure to water, these vacancies are filled and the materials are populated with protons. To incorporate oxygen vacancies, acceptor dopants such as Sc and Y substituting on the Zr-site are used; however, these dopants can simultaneously incorporate as A-site donors and self-compensate. We study the properties of these dopants using first-principles calculations with a hybrid functional. We characterize the bulk properties and study the formation of native and extrinsic point defects. We examine the propensity for self-compensation of Sc and Y, as well as possible A-site and O-site acceptors. We find that certain alkali metal A-site dopants (Na in CaZrO₃, K in SrZrO₃, and Rb in BaZrO₃) incorporate oxygen vacancies in higher concentrations than Sc and Y, while also circumventing the problem of self-compensation. Furthermore, these acceptors have low proton binding energies, making them good choices to improve proton conductivity in the zirconates.

calculate the charge-voltage response of various reconstructions of a solvated SrTiO3 surface, revealing that interfacial long-range polarization of the semiconductor electrode under electrical bias. Using this comprehensive model, we predict the relation between electrochemical stability, band alignment, and photocatalytic activity taking into account the develop an embedded quantum-mechanical approach using the self-consistent continuum solvation (SCCS) model to to-hydrogen efficiency for these materials is critically dependent on the electrochemical state of their surface. Here, we investigate the role of a different physical property, namely, the diffusivity, in hydrogen evolution reaction. On typical catalytic metal surfaces, the diffusivity of hydrogen is high, and the binding strength is the dominant controlling factor. In contrast, the diffusion barrier on the surfaces or edges of two-dimensional catalytic materials such as MoS2 is found to be inversely proportional to the binding strength. This relatively large diffusion barrier may serve as another important factor on such surfaces. Moreover, the charge density wave of a catalytic surface can also significantly modulate the diffusion barrier. These findings provide important insights into how to design efficient catalysts for enhanced hydrogen evolution reaction.

12:39PM B47.00008: Role of diffusivity in hydrogen evolution reaction  JIANG ZENG (Presenter), LEIQIANG LI, PING CUI, University of Science and Technology of China, JOHN P PERDEW, Temple University, ZHENYU ZHANG, University of Science and Technology of China — The hydrogen binding strength on a catalyst is known to be an important factor in electrochemical hydrogen evolution. Although much effort has been exerted to improve the binding strength to exploit precious-metal-free catalysts, their performance is still inferior to that of platinum. Based on first-principles calculations, here we investigate the role of a different physical property, namely, the diffusivity, in hydrogen evolution reaction. On typical catalytic metal surfaces, the diffusivity of hydrogen is high, and the binding strength is the dominant controlling factor. In contrast, the diffusion barrier on the surfaces or edges of two-dimensional catalytic materials such as MoS2 is found to be inversely proportional to the binding strength. This relatively large diffusion barrier may serve as another important factor on such surfaces. Moreover, the charge density wave of a catalytic surface can also significantly modulate the diffusion barrier. These findings provide important insights into how to design efficient catalysts for enhanced hydrogen evolution reaction.

12:51PM B47.00009: Configuration entropy of protons in doped-BaHfO3 at finite temperature, an ab-initio based cluster expansion study*  LEI ZHANG (Presenter), MEILIN LIU, Georgia Institute of Technology — Doped-BaHfO3 is a promising solid state protonic conducting electrolyte for solid oxide fuel cells. A widely-recognized feature in aliovalent-doped solid state ionic is that the conductivity of charge carriers, is governed by two competing factors, i.e. concentration and mobility. At finite temperature, e.g. 500 Celsius, point defects has non-negligible configurational and vibrational entropies. The interplay between entropic and electronic energetic creates a non-trivial thermodynamic phase diagram, describing defect ordering, segregation and randomization. This also inevitably modulates kinetic properties of protons. By using ab-initio density functional theory calculations as input, a cluster-expansion model was constructed and utilized in this multi-sublattice cubic perovskite system. A comprehensive thermodynamic and kinetic understanding was generated hereafter, with suggestions about optimal doping concentration and heat treatment protocol.

1:03PM B47.00010: Influence of Sr leaching on the catalytic activity of reconstructed SrTiO3 photoelectrodes*  YIHUANG XIONG (Presenter), ISMAILA DABO, Pennsylvania State University — Perovskite photoelectrodes are being extensively studied in the search for photocatalytic materials for hydrogen production through water splitting. The solar-to-hydrogen efficiency for these materials is critically dependent on the electrochemical state of their surface. Here, we develop an embedded quantum-mechanical approach using the self-consistent continuum solvation (SCCS) model to predict the relation between electrochemical stability, band alignment, and photocatalytic activity taking into account the long-range polarization of the semiconductor electrode under electrical bias. Using this comprehensive model, we calculate the charge-voltage response of various reconstructions of a solvated SrTiO3 surface, revealing that interfacial charge trapping exerts primary control on the electrical response, electronic structure, and surface stability of the photoelectrode. Our results provide a detailed molecular-level interpretation of the enhanced photocatalytic activity of SrTiO3 upon the voltage-induced restructuring of the semiconductor-solution interface.

1:15PM B47.0001: Adsorption characteristics of small aromatic molecules on silica/Ru(0001)  MUHAMMAD SAJID (Presenter), WILLIAM KADEN, ABDELKADER KARA, University of Central Florida — Organic molecules are part of future materials for electronic devices. The performance of these devices depends strongly on the atomic and electronic characteristics at the organic-substrate interface, which is necessary to provide support and/or conduction for the device. To develop a catalogue of anchor-group-dependent trends in these characteristics, we have undertaken a joint computational/experimental study of aromatic molecules (benzene, pyridine and thiophene) bound to Ru(0001), both with and without silica sheets inserted between the two. The silica sheets have been chosen to provide an experimentally accomplishable means of varying the separation between the adsorbate molecules and metal by growing them as monolayer or bilayer. Using DFT with vdW corrections, the models of above-mentioned systems will be presented along with their electronic properties (workfunction, charge transfer etc.). Accompanying, XPS measurements will provide complementary experimental data to compare electronic predictions. These will include changes in workfunction, valence-band measurements, and core-level XPS analysis with Auger Parameter analysis for improved deconvolutions of initial and final-state contributions to binding energy shifts.

1:27PM B47.00012: Understanding the role of vacancy-vacancy interaction and hydrogen-hydrogen coupling in hydrogen bonding on MoS2 surfaces*  LIPING YU (Presenter), Department of Physics and Astronomy, University of Maine, ADRIENN RUZSINSZKY, QIMIN YAN, Department of Physics, Temple University — MoS2 is a promising nonprecious electrochemical catalyst for catalyzing hydrogen production from water. It has been found that (i) the catalytic reaction activity depends on the concentration of sulfur vacancies, and (ii) the free energy of hydrogen adsorption varies with the coverage of hydrogen adsorbates. However, microscopically, the physical factors responsible for such finding remain unclear. In this talk, we will present a microscopic model to understand the effects of vacancy-vacancy interaction and hydrogen-hydrogen coupling. We find that the effect of vacancy-vacancy interaction on hydrogen-surface bonding becomes considerable only when they are separated by less than 1.1 nm. When one hydrogen atom is adsorbed at a sulfur vacancy, the interaction between this sulfur vacancy and others nearby will be largely disabled. Such disabling decreases the adsorption energy and hence strengthens the binding. Similarly, the hydrogen-hydrogen interaction also becomes important only when they are close enough. However, instead of being disabled, such interaction is introduced upon hydrogen adsorption, which increases the adsorption energy and weakens the binding. The generation of those results will also be briefly discussed.

1:39PM B47.00013: Defect-mediated charge and mass transport in energy materials  KHANG HOANG (Presenter), North Dakota State University — Conventional solid-oxide fuel cells (SOFCs) based on yttria-stabilized zirconia (YSZ) electrolytes and Ni-YSZ cermet anodes suffer performance degradation due to problems associated with the Ni-based anodes such as redox cycling instability, nickel agglomeration, carbon deposition, and sulfur poisoning. It is thus necessary to search for new, Ni-free materials that may hold potential for overcoming these problems. Recently, Ba3Ti3O6(BO3)2 has been identified as a possible candidate for SOFC anodes or anode composites [1]. The oxyborate material undergoes a change from ionic under oxidizing and soft reducing conditions to mainly electronic transport under an extreme reducing atmosphere typical of anode environment, leading to a drastic enhancement in the electrical conductivity. In this talk, we introduce a theoretical framework, based on defect physics, to understand changes in the electrical transport mechanism caused by changes in the environment and to explore and design new materials for SOFC applications. [1] Doux et al., ACS Appl. Energy Mater. 1, 510 (2018).
In this work, La$_{0.6}$Sr$_{0.4}$FeO$_{3-δ}$ (LSF64) thin films are employed as model systems and the biaxial strain is introduced by growing LSF64 thin films epitaxially on substrates with different lattice constants. Coupling surface chemical information from in-situ ambient pressure X-ray spectroscopy with morphological and structural information from electron microscopy, we found that in-plane biaxial strain can be a powerful tool in optimizing the particle dispersion of the exsolution products. The observed strain dependence of exsolution advances our abilities to control them and enhance the performance of catalysts for clean energy technologies.

Session B48 DFD GSNP: Fluid-Structure Interactions (FSI)

11:15AM B48.00001: Wave interaction with flexible vegetation: connecting individual blade dynamics to meadow scale wave decay* [Invited] JIARUI LEI, HEIDI NEPF (Presenter), Massachusetts Institute of Technology — Flexible plants move in response to wave orbital velocity, which diminishes wave decay relative to rigid plants. The impact of reconfiguration and blade motion on wave decay has been characterized using an effective blade length, $l_e$, which represents the length of a rigid blade that generates the same drag as the flexible blade of length $l$. The effective blade length depends on the Cauchy number, which represents the ratio of hydrodynamic drag to blade stiffness, and on the ratio of blade length to wave orbital excursion. This laboratory study considered how scaling laws determined for individual blades could be used to predict the wave decay over a meadow of multiple plants. First, the drag force on and motion of individual model blades was studied for a range of wave conditions to provide empirical coefficients for the theoretically determined scaling laws for effective blade length, $l_e$. Second, the effective blade length predicted for individual blades was incorporated into a meadow-scale model to predict wave decay over a meadow. Third, wave decay was measured over meadows of different plant density (shoots per bed area), and the measured decay was used to validate the wave-decay model.

11:51AM B48.00002: An Eulerian method for mixed soft and rigid body interactions in incompressible fluids XIAOLIN WANG (Presenter), Harvard University, KEN KAMRIN, MIT, CHRISTOPHER RYCROFT, Harvard University — Fluid-solid interaction problems are encountered in many engineering and biological applications, but are challenging to simulate due to the coupling between the two material phases. Here, we propose a fully Eulerian approach for solving fluid-solid interactions that is simple to implement and capable of simulating complex multi-body interactions. When the solid is rigid, a projection step is formulated as a composite linear system that simultaneously enforces the rigidity and incompressibility constraints. When the solid is soft, a reference map technique is applied to characterize the body deformation in an Eulerian framework. Several examples including a single body, multiple bodies, and soft-rigid combinations will be presented, with potential applications to biological systems.

12:03PM B48.00003: A Method for Deriving Fluid-Structure Interaction Reduced-Order Models for Cerebral Aneurysms SUYUE HAN (Presenter), YAHYA MODARRES-SADEGHI, University of Massachusetts Amherst — A Reduced Order Modeling (ROM) method is discussed for Fluid-Structure Interaction problems in cerebral aneurysm. In this method, we first conduct training CFD simulations with pre-defined structural motion using the fixed mesh method, and then use the snapshot POD method to generate POD modes for both the flow field and the structure. Instead of using traditional topology-changing method, the CFD simulation is enhanced by a fixed mesh method to handle large-amplitude displacements or structural deformation without changing the mesh connectivity, thus consuming much less time. The POD ROM method is also enhanced by the same fixed mesh method, so that the training CFD simulation could be combined with the ROM smoothly. Besides, by implementing a fixed mesh method into the ROM, there is no need for iteratively calculating the forces acting on the structure for every time step. After generating POD modes for both the fluid and the structure using a fixed mesh, we couple these fluid and structure POD modes to create the FSI ROMs.
Flow-induced vibration of an inclined flexible cylinder in tandem arrangement

BANAFSHEH SEYED-AGHAZADEH (Presenter), Miami University — Flow-induced vibration (FIV) of a flexible inclined circular cylinder placed in the wake of a stationary cylinder is studied, experimentally. A highly flexible circular cylinder with an aspect ratio of 47 and a mass ratio of 120 was held fixed at both ends and placed inclined at 45° to the incoming flow in the test-section of a subsonic wind tunnel. The inclined flexible cylinder lied in the wake of an upstream stationary cylinder of equal diameter and inclination. The dynamic response of the downstream cylinder is studied for center-to-center spacing range from 3 to 7 times the cylinder diameter, in the reduced velocity range of $U^*=3.6-48.5$ and the Reynolds number range of $Re = 260-3750$.

The validity of the independence principle, which states that the behavior of an inclined cylinder is essentially driven by the normal component of the incoming flow velocity, has been previously investigated for a single flexible cylinder. The objective of this study is to examine the effects of inclination on FIV response of cylinders in tandem arrangements. Dynamic response of the inclined flexible cylinder in terms of the excited structural modes, frequencies of oscillations, and modal weight contributions is compared to those of a normal incidence flexible cylinder in tandem arrangement.

Numerical study on the flow-induced vibrations of a flexibly-mounted cavity at the rear of a bluff body

José I Jiménez-González (Presenter), Carlos García-Baena, Javier F. Aceituno, Department of Mechanical and Mining Engineering, Universidad de Jaén (Spain) — We carry out a computational study on the flow-induced vibrations (FIV) of a rigid cavity, flexibly mounted at the rear of a D-shaped body of height $H$, subject to a cross-stream of velocity $u_\infty$.

Simulations are performed for laminar Reynolds numbers to characterize the interaction between wake and parallel rotary plates, connected to the rear edges of the body using torsional hinges. The FIV amplitude response and the effect on force coefficients are investigated for several values of hinge's torsional stiffness $k$, which provide with different natural oscillation frequencies $f_n$ and reduced velocities $U^*=u_\infty/f_nH$. A large FIV response is found for $U^*>2$, where plates oscillate in phase at the shedding frequency. Such response increases the mean drag and fluctuating lift, although reductions are found $U^*<2$, where a weaker FIV response is characterized by oscillation of plates in counter-phase. Finally, to validate the results, we develop a multibody model that allows to retrieve the local aerodynamic forces and torque acting on the plates, using the motion obtained from simulations as input. A final analysis is performed in terms of torque's components and phase between wake forcing and plates' response.

Flutter control using nonlinear tuned magnetic vibration absorbers

Xavier Amadolese (Presenter), Arnaud Malher, Laboratoire d'Hydrodynamique — We will talk about the effects of nonlinear tuned magnetic vibration absorbers on the instability threshold and post-critical flutter of two-degrees-of-freedom « pitch-plunge » wing section. Two post-critical scenarios will be examined: a coupled-mode flutter scenario exhibiting limit cycle oscillations characterized by moderate amplitude in plunge and low amplitude in pitch, and a more complex flutter scenario exhibiting a second post-critical bifurcation from coupled-mode flutter to high amplitude symmetric stall flutter. Magnetic vibration absorbers have been used in plunge, in pitch or in both, and tuned as nonlinear vibration absorbers with cubic stiffness. Their efficiency will be examined in the light of wind tunnel tests and simulations. The latter have been obtained using an analytical aeroelastic model, including a nonlinear unsteady aerodynamic formulation, coupled with the vibration absorbers.

Flutter instability of a reconfiguring beam*  MOHAMMAD TARI (Presenter), FREDERICK GOSSELIN, ERIK LAURENDEAU, Mechanical Engineering, Polytechnique Montreal — Reconfiguration refers to static and dynamic aeroelastic deflections of structures to flow that provide benefits, such as reduced aerodynamic drag. Assuming small structural deformations, the linear theory is used predominantly in engineering applications. However, large deformations of the trees and aquatic plants can only be explained through large deformation theory. The aim of this research is to study experimentally and numerically the flutter instability in slender structures which deform with great amplitude. In particular, we extend the reduced order model of Leclercq & de Langre1 to a RANS coupled with a nonlinear beam model handling large displacements. Since the flutter in such flexible structures arises from the strong interaction of the physics of the fluid and the structure domains, we use a partitioned strongly coupled approach with our in-house structural and fluid solvers. This approach enables us to study flutter and provides insights into the drag reduction mechanisms of flexible structures.

*The work benefited from the financial support of the Natural Sciences and Engineering Research Council of Canada. Computations were made on Calcul Quebec clusters.

To leak or not to leak: deformation of perforated elastic strips driven through a viscous fluid
PEDRO REIS (Presenter), MATTEO PEZZULLA, LORENZO SICONOLFI, FRANCOIS GALLAIRE, Institute of Mechanical Engineering, Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland — From dandelions and insect wings to wire fences and parachutes, there are numerous natural and technological instances of porous flexible structures that deform due to fluid loading. Whereas fluid flow through bulk porous media has been studied extensively, the interaction between a perforated, deformable object and a surrounding viscous fluid has received much less attention. Here, we microfabricate flexible, porous, and slender strips containing a precisely designed array of voids that target set permeabilities. We then drive these perforated strips through a fluid, at low Reynolds number conditions, and quantify the extent of deformation due to viscous loading. We use a reduced theoretical model based on Kirchhoff-Euler beam theory coupled with a description of the fluid loading to deduce the drag force from the deflected shape of the strip. In parallel, we perform ad-hoc numerical simulations to capture the details of the fluid-structure interaction, thereby uncovering a nontrivial effect of permeability on the drag experienced by the porous structure. We hope that the gained insight may guide the design of flexible structures that optimize their porosity and permeability to enhance drag, towards light-weight high-drag slender objects.

Monday, March 4, 2019 11:15 AM - 2:03 PM
Session B49 DPOLY GSOFT: Advanced Deposition Methods for Polymers and Soft Materials

Initiated Chemical Vapor Deposition onto Moving Liquid Surfaces*  PRATHAMESH KARANDIKAR (Presenter), MARK M DE LUNA, MALANCHA GUPTA, University of Southern California — In this talk, we will demonstrate that initiated chemical vapor deposition (iCVD) can be used to deposit thin functional films onto low vapor pressure liquids such as silicone oils and ionic liquids. The substrate viscosity, surface tension, monomer solubility and process parameters such as deposition time and deposition rate determine the polymer structure on the liquid. The spreading coefficient of the polymer on the liquid surface can be used to predict the thermodynamically preferred polymer morphology. Films, nanoparticles, and gels can be formed. We demonstrate that modifications to the deposition chamber can enable in situ modulation of the liquids in a vacuum allowing polymer deposition on moving liquids. We demonstrate liquid motion in silicone oils of viscosities ranging from 5 cSt to 50 cSt. We study the deposition of fluorinated polymers on the moving liquids and demonstrate that the mechanical response of the polymer films can be tuned by the use of a crosslinker ethylene glycol diacrylate. Our experimental findings allow for further understanding of nucleation and growth mechanisms of polymer films on liquid surfaces by inducing liquid motion and allows us to probe the mechanical strength of thin films.

11:27 AM B49.00002: Initiated Chemical Vapor Deposition of Copolymer Based Electrolytes for 3D Microbatteries

WENHAO LI (Presenter), LAURA BRADLEY, JAMES J WATKINS, Polymer Science and Engineering, University of Massachusetts at Amherst — Reliable fabrication of nanoscale, solid-state polymer electrolytes (SPEs) with conformal 3D coating capability and good ionic conductivity is one major challenge toward fully assembled 3D microbatteries. Here we utilize initiated chemical vapor deposition (iCVD) to produce sub-micron copolymer thin films comprised of hydroxyethyl methacrylate (HEMA) and ethylene glycol diacrylate (EGDA). These copolymer films are subsequently converted into SPEs via solution-based lithium salt doping and demonstrate ionic conductivity of \((6.1 \pm 2.7) \times 10^{-6} \text{ S cm}^{-1}\) at room temperature, the highest value reported to date for nanoscale SPEs. An investigation of copolymer composition, crosslinking density, polarity, structural relaxation is presented to explain the ion conduction.

11:39 AM B49.00003: Vapor Deposited Polymers: from Fundamentals to Commercialization [Invited]

KAREN GLEASON (Presenter), Department of Chemical Engineering, Massachusetts Institute of Technology — Chemical vapor deposition (CVD), as practiced by the semiconductor industry, typically utilizes high powers and high temperatures to drive non-selective chemistry. However, employing selective chemistry allows deposition rates of CVD organic films to be high, even when energy input is low. The CVD method is ideally suited for insoluble and infusible materials such as fluoropolymers, crosslinked organic networks, and conjugated semiconducting and conducting polymers. To date, a portfolio of >70 CVD homopolymers and copolymers have been demonstrated. The conformal nature of CVD polymerization enables the facile integration of organic thin films into device prototypes onto thermally sensitive and mechanical flexible substrates. Scale up of the process has facilitated the commercialization of CVD polymer technology.

12:15 PM B49.00004: iCVD Solid Nanoadhesives for Precision Assembly at Near Room Temperature*

XAVIER LEPRO (Presenter), Materials Science Division, Lawrence Livermore National Laboratory, JOHN SIMON MILLER, Materials Engineering Division, Lawrence Livermore National Laboratory, GAVIN WINTER, SALMAAN BAXAMUSA, Materials Science Division, Lawrence Livermore National Laboratory — Adhesives are widely used in manufacturing processes to bond components. Due to their ubiquity in consumer goods, adhesives and sealants form a mature $50B industry with decades of investment in formulation chemistry for various applications. However, nearly all adhesives are based on the application of viscous resins which cure based on chemical reaction, solvent evaporation, or cooling of a hot melt. Capillary forces from liquid-like resins both prevent the formation of thin (<1 μm) bondlines and can wick or damage porous materials such as foams, aerogels and other delicate structures at the nano and microscale.

Here we synthesized adhesive solid polymers directly from vapor-phase reagents by initiated chemical vapor deposition (iCVD) avoiding any liquid intermediates while achieving thickness control within tens of nanometers. We formulated thermoplastics that bond physically rather than chemically by inducing polymer chain interdiffusion when the polymer is heated above its glass transition temperature, \(T_g\). Whereas chemical cure near room temperature requires liquid-phase metal catalysts or UV light, this approach allows to engineer \(T_g\) via polymer composition.

12:27 PM B49.00005: Using volatile liquid oxidant in PEDOT synthesis by oxidative Chemical Vapor Deposition (oCVD)*

MEYSAM HEYDARI GHARAHCHESHMEH (Presenter), KAREN GLEASON, Chemical Engineering, Massachusetts Institute of Technology (MIT) — Conducting Polymers (CPs) are desired for next generation flexible, stretchable, wearable, and large-area electronic devices. The oxidative Chemical Vapor Deposition (oCVD) is a versatile deposition technique with the potential for commercial production of CPs in large-scale applications. Here, we report the oCVD poly(3,4-polyethylene dioxythiophene) (PEDOT) synthesis using a volatile liquid oxidant. The flow rate of volatile liquid oxidant to the oCVD reactor is more controllable than its solid oxidants counterparts, which resulted in better control of the oxidant surface concentration. In addition, the main advantage of using volatile liquid oxidant is that the final CPs thin films exploit directly in device fabrication without the need for any post-deposition rinsing step to remove unreacted oxidants and oxidation by-products. The texture and structural properties of deposited oCVD PEDOT films with volatile oxidant as a function of deposition temperature and a fraction of oxidant saturation pressure (P/P_{sat}) were investigated. It was noted that the orientation of oCVD PEDOT films is highly influenced by the process parameters and has a significant impact on electrical conductivity.

Selective spin-on deposition of polymers on heterogeneous surfaces*  
YUANYI ZHANG (Presenter), COLTON D'AMBRA, CRAIG HAWKER, RACHEL SEGALMAN, CHRISTOPHER M BATES, University of California, Santa Barbara — Traditional photolithography relies on the manipulation of spun cast polymer films using a complex sequence of processing steps to generate patterns for device fabrication. Selective deposition holds promise to reduce this economic burden and enable self-aligned fabrication by directly coating material only on desired regions of a heterogeneous surface. Our work introduces a strategy to achieve selective polymer deposition via spin coating without necessitating superfluous processing steps (e.g., thermal annealing, etching). This talk will focus on understanding the interplay between polymer design, spin coating conditions, and consequent thin film characteristics.

*This work was supported in part by Semiconductor Research Corporation (SRC).

Morphology and Thermal Properties of Semi-Crystalline Polymer Films by Slow Deposition

RODNEY PRIESTLEY (Presenter), Princeton University — Thin-film growth via physical vapor deposition (PVD) has been successfully exploited for the delicate control of film structure for molecular and atomic systems. The application of such a high-energetic process for polymeric film growth has been an enduring challenge. However, the recent development of Matrix Assisted Pulsed Laser Evaporation (MAPLE) has provided a new means to deposit a variety of macromolecules in a manner similar to PVD. Here, employing MAPLE for the growth of semi-crystalline polymer thin films, we show the ability to tune film morphology by manipulation of substrate temperature. This is accomplished by exploiting the effects of temperature on polymer crystal nucleation and dynamics. During slow film growth, crystal nucleation can either be permitted or suppressed, and crystal thickness can be tuned by temperature modulation. Finally, by combining MAPLE deposition with flash DSC, we demonstrate the ability to measure the extent of crystallinity and melting temperature of thin films grown over a wide temperature range.

Thin films of ultramonodisperse polystyrene polymers

ADAM RAEGEN (Presenter), JAMES FORREST, Physics and Astronomy, University of Waterloo — We present a study of the aging of thin films composed of ultramonodisperse polymeric/oligomeric samples. Purified polymeric samples of known molecular weight and polydispersity are deposited via thermal evaporation onto actively cooled silicon substrates, forming uniform films. Ellipsometry allows us to investigate the thickness and refractive index of these vapour deposited films. We compare calorimetric glass transitions of these films with different production parameters.

Confined Polymer Crystallization in Vapor-Deposited PE/PMMA Blend Films*

YUCHENG WANG (Presenter), RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — Polymer blends are widely applied in technologies because they can join features from individual components to optimize performance. However, for thin films comprising immiscible polymers, it is challenging to precisely control the film structure because of the spontaneous phase separation, which can influence the resulting properties in an undesirable way. In this work, we utilize a vapor deposition technique termed matrix-assisted pulsed laser evaporation (MAPLE) to process thin films of PE/PMMA and illustrate that the technique can effectively control the size of phase separation. During MAPLE, thin films are formed atop a temperature-controlled substrate by the addition of separate nanoscale polymer droplets at an ultra-slow rate, thereby confining the phase separation within a much smaller scale relative to films processed via other means. Employing a fast scanning calorimeter, we demonstrate the ability to shift the crystallization temperatures of PE by ~20°C as a result of confinement and temperature during deposition. We also show the preservation of film structures beyond melting.

Emulsion Target Process-Structure-Property Relationships in Resonant Infrared Matrix-Assisted Pulsed Laser Evaporation (RIR-MAPLE) for Selective Deposition of Crystalline Phases in Polymer Thin Films

ADRIENNE STIFF-ROBERTS (Presenter), SPENCER FERGUSON, CASSANDRA WILLIAMS, Electrical and Computer Engineering, Duke University, BUANG ZHANG, University Program in Materials Science and Engineering, Duke University — The semi-crystalline phase of polyfluorene (β-PFO) is desirable for blue polymer LEDs because it yields higher carrier mobilities that lower operating voltage and increase device lifetime. However, the use of poor solvents in solution-based deposition to obtain high β-PFO content also degrades surface quality. Previous research on emulsion-based RIR-MAPLE deposition has shown that emulsion characteristics impact β-PFO content in thin films. In contrast to solution-based deposition, RIR-MAPLE increases β-PFO content to 6% without degrading surface morphology.

The goal of the current work is to establish the process-structure-property relationships of RIR-MAPLE emulsion targets to achieve 42% β-PFO content (for phase stability) by controlling emulsion chemistry and deposition rate. The emulsified polymer particle size will be measured by dynamic light scattering, the structure of PFO films will be characterized by atomic force microscopy, and the β-PFO concentration will be measured using photoluminescence and/or UV-absorbance spectroscopy. In addition, basic device performance of PFO-based LEDs will be measured to determine the impact on device performance.

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B50 DPOLY: UKPPG/DPOLY Polymer Lecture Exchange: Advances in Film Formation and Chain Dynamics

IGNACIO MARTIN-FABIANI (Presenter), Loughborough University — Colloidal self-assembly methods, using particles suspended in a solvent as the building blocks, have been recently proposed as a single-step alternative for obtaining surfaces “on demand”.¹ We recently proved experimentally how in blends of polymer colloids of two different sizes, small particles can segregate during drying into a layer on top of the larger particles.² The moving interface causes a density, and hence a pressure, gradient in the drying film, which pushes larger particles away from the moving interface faster than it pushes smaller particles. By using stimuli-responsive particles, which swell with increasing pH, it is possible to switch stratification on and off by just changing the pH of the initial dispersion.³ For a certain size, stratification is suppressed because of the increased solids content, which reduces particle mobility and reduces the osmotic pressure gradient. This type of self-assembly allows the independent control of the properties of the top and the bottom of the final film, dictated by the functionality of the large and small particles. Modelling shows it is a really strong and reliable effect, taking place for a wide range of particle size ratios and evaporation rates. However, agreement with experiments is limited, because of coffee-ring effects and Marangoni flows that are not usually present in models. In this talk, I will discuss the progress we made in this field and how we can harness the Physics of polymer colloid systems to control the final film structure towards a certain application.

References

Programming surface energy driven Marangoni convection to pattern polymer films

CHRISTOPHER ELLISON (Presenter), University of Minnesota — The Marangoni effect describes how fluid flows in response to gradients in surface energy. We recently developed a method for photochemically preprogramming spatial surface energy patterns in glassy polystyrene (PS) thin films. UV irradiation through a mask selectively dehydrogenates the PS, thus increasing surface energy in the UV exposed regions compared to the unexposed regions. After heating the film to the liquid state, transport of polymer occurs from regions of low surface energy to regions of high surface energy. This method can be harnessed to rapidly manufacture polymer films possessing prescribed three-dimensional topographies reflective of the original light exposure pattern without solvent washes or etching procedures. To better understand this phenomenon, a theoretical model will be presented that reveals the physics of this process, its limits and ways to apply it efficiently for various target metrics.
12:03PM B50.00003: Influence of Hydrodynamic Interactions on Stratification in Drying Mixtures

ANTONIA STAT (Presenter), Princeton University, MICHAEL HOWARD, McKetta Department of Chemical Engineering, University of Texas, Austin, ATHANASSIOS PANAGIOTOPoulos, Princeton University — It is desirable to control the structure of dried multicomponent films for many technologies, but there is an incomplete theoretical understanding of how evaporation affects film structure. Recent experiments[^1] showed that mixtures of small and large colloids unexpectedly stratify with the small colloids counterintuitively on top of the large colloids. Stratification can be modeled without hydrodynamic interactions (HIs) using dynamic density functional theory, but it was recently suggested[^2] that HIs cannot be reasonably neglected. We investigated the influence of HIs on stratification using nonequilibrium simulations of polymer films with explicit and implicit solvent models.[^3] The short chains stratified on top of the long chains in the implicit solvent (no HIs) in agreement with previous theoretical models and simulations. However, the explicit solvent model did not stratify at the same drying conditions due to HIs. Our work shows that it is critical to include HIs into models for drying films.

12:15PM B50.00004: Strategies to improve the unconfined melt electrospinning process via incorporation of ionically conductive particles

ELNAZ SHABANI (Presenter), CHENGXI LI, REBECCA J KOMER, LAURA CLARKE, JASON R BOCHINSKI, RUSSELL E GORGA, BRENTON BOLAND, NEELAM SHEORAN, North Carolina State University — By utilizing a sharp-edged flat plate, multiple parallel jets can be electrospun spontaneously from unconfined polymer melts. In this work polyethylene was electrospun from a thin film of the polymer melt heated on an electrically-grounded flat plate. This technique can produce fibers with a throughput rate of about 50 mg/min without the possibility of clogging which frequently happens in traditional single needle electrospinning due to high viscosity of polymer melts. The effect of increased melt conductivity through salt additives on fiber diameter was studied to present a method for fabrication of smaller diameter fibers from highly-insulating polymer thermoplastics. Also, The environmental temperature, specifically in the spin-line shows to have a significant impact on the fiber diameter and the spinning process.

12:27PM B50.00005: Creating thin film compositional polymer libraries using electrospray deposition

KRISTOF TOTH (Presenter), Yale University, GREGORY DOERK, KEVIN G. YAGER, Brookhaven National Lab, CHINEDUM OSUJI, University of Pennsylvania — Electrospray deposition (ESD) enables the growth of polymer thin films in a precise and continuous manner by the delivery of sub-micron droplets of dilute polymer solutions to a heated substrate. By combining ESD with programmable motor control and gradient solution pumping in a first-of-its-kind user tool at the Center for Functional Nanomaterials at Brookhaven National Laboratory, we show the ability to create one or two-dimensional compositional gradient nanoscale films via ESD. These capabilities make it possible to construct thin film multicomponent “libraries” on a single substrate to rapidly and significantly characterize composition-dependent properties, in particular, thin films involving homopolymer and block copolymer (BCP) blends. We report the design, construction, and validation of a gradient ESD tool which allows users to carefully control the jet stability, flow composition, spray position, and substrate temperature. Paired with synchrotron small angle X-ray scattering (SAXS), this tool forms an integral part of a new platform for high-throughput, autonomous characterization and design of self-assembling polymer blends as well as functional soft materials more generally.

12:39PM B50.00006: Understanding the Deformation of Polymer Thin Films Under Hydration  PETER DUDENAS (Presenter), University of California, Berkeley, ADAM Z WEBER, AHMET KUSOGLU, Lawrence Berkeley National Lab — Understanding the impact of interfaces and surfaces on hydrophilic/amphiphilic polymers including ionomers is of increasing interest as functional polymer coatings and thin-film devices become more ubiquitous. In these thin-film systems, confinement and interfacial energy impact a variety of properties including Tg, modulus, and morphology; the degree of hydration will also significantly impact these properties. Because of this, the characterization of mechanical properties for polymer thin films and networks under hydration remains a challenge. Here, we report the swelling-induced deformation of model hydrogel and block copolymer films as a function of thickness, cross-linking, and surface functionalization to understand the effect of confinement and surface interactions on polymer swelling and swelling-induced stresses. A cantilever bending method is used to characterize the mechanical response which is correlated to morphology using in-situ grazing incidence x-ray scattering. The results and techniques are applicable to understand the structure-functionality of a wide variety of polymers, including hydrogels, ion-conducting polymers for energy conversion, and block copolymers.

12:51PM B50.00007: AFM Observation of the Movements of Single Linear Chains in a Precursor Film of a Spreading Polymer Blend Melt  YASUHIRO WATANABE, JIRO KUMAKI (Presenter), Yamagata University — We have successfully visualized the movements of single chains in a precursor film of a spreading polymer melt on a substrate at the molecular level by atomic force microscopy (AFM). A polymer melt spreading on a substrate forms a precursor film with a thickness comparable to a monolayer at the flow front. Previously, Sheiko and coworkers successfully observed the movements of polymer brush molecules in the precursor film of a spreading melt (Phys. Rev. Lett. 2004, 93, 206103), however, those of conventional linear polymers have not yet been observed due to the limited resolution of the present AFM instruments. We observed a mixture of a poly(methyl methacrylate) (PMMA) oligomer with a small amount of a high-molecular-weight isotactic (it) PMMA polymer, and successfully observed the movements of the it-PMMA polymer chains flowing in the precursor film of the spreading melt at the molecular level. The movements of the individual PMMA chains will be discussed in detail.

1:03PM B50.00008: Lattice Self-Consistent Field Calculations of Ring Polymer Brushes*  QIANG WANG (Presenter), Colorado State Univ, WENJUAN QIU, BAOHUI LI, Nankai University, China — We report the first systematic study using lattice self-consistent field (LSCF) calculations of ring homopolymer brushes grafted onto a flat and homogeneous surface and immersed in an explicit and athermal solvent, which are either uncompressed, compressed by a flat and impenetrable surface, or compressed by an identical brush.[1] Our results clearly show that ring brushes are slightly less stretched than, thus nearly but not completely identical to, the “equivalent” linear brushes having half the chain length and double the grafting density. Our LSCF results are consistent with the molecular simulation results reported in the literature[2,3], except the previous finding that the normal pressure of two opposing ring brushes is only half of the “equivalent” linear brushes at melt density.[3]

1:15PM B50.00009: Comprehensive scaling theory for entanglement in melts and solutions of flexible and stiff polymer chains*  SCOTT MILNER (Presenter), Pennsylvania State University — The entanglement length Ne is a key parameter for all entangled polymer fluids, for which no comprehensive scaling theory yet exists. We have pieces of a theory; the Lin-Noolandi (LN) argument predicts Ne scaling for flexible chains that agrees with data on melts. There are arguments for how Ne should depend on polymer volume fraction, but which are not obviously consistent with LN. Morse scaling describes entanglement for stiff chains, consistent with data. Everaers proposed an ansatz that Ne depends only on “arc-length concentration”, as if chains were uncrossable threads. This ansatz is consistent with simulation of bead-spring chains but not with LN, it has no role for packing length, the central parameter in LN scaling. We propose a comprehensive scaling theory which includes LN in one limit, thread ansatz in another, and reduces to Morse scaling for stiff chains. Our new ingredient is the observation that the typical distance of closest approach between two chains is governed by packing length or chain diameter, whichever is larger. If a chain is sufficiently flexible and bulky, the packing length is relevant; but for stiffened bead-spring chains without sidegroups, the packing length is likely smaller than the chain diameter, so thread scaling applies.

**1:27PM B50.00010: Effect of Polymer Architectures on the Entanglement of Combs and Bottlebrushes**

HEYI LIANG, Department of Polymer Science, University of Akron, BENJAMIN J. MORGAN, Department of Chemistry, University of North Carolina at Chapel Hill, GUOJUN XIE, MICHAEL MARTINEZ, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University, SERGEI SHEIKO, Department of Chemistry, University of North Carolina at Chapel Hill, ANDREY DOBRYNIN (Presenter),Department of Polymer Science, University of Akron — We study correlations between the entanglement plateau modulus and architecture of graft polymers in a melt. To distinguish between two types of graft polymers – combs and bottlebrushes – we introduce the crowding parameter Φ, which describes mutual interpenetration of the neighboring macromolecules. In comb systems, both the backbones and sparsely grafted side chains are coiled and allow side chains of neighboring macromolecules to overlap (Φ<1). In bottlebrush systems, however, the steric repulsion between densely grafted side chains results in chain extension and inhibits side chain interpenetration (Φ≥1). The ratio $G_{e,gr}/G_{e,lin} \approx \phi^3(1+(\Phi/0.7)^3)$ of the plateau modulus of a graft polymer melt, $G_{e,gr}$, to that of a linear polymer melt, $G_{e,lin}$, is a universal function of the crowding parameter $\Phi=\phi^{-1}n_{sc}^{-1/2}$ and graft polymer composition $\phi=n_g/(n_g+n_{sc})$, where $n_{sc}$ and $n_g$ are the degrees of polymerization of side chains and a spacer separating consecutive side chains along the backbone, respectively. Such universal behavior is verified by poly(n-butyl acrylate) combs and other graft polymers reported in literatures. For graft polymers with entangled side chains, the $G_{e,gr}/G_{e,lin}$ ratio is proportional to $\phi^2$.

**1:39PM B50.00011: Entanglement in semiflexible polymer melts and solutions from simulations**

SAI VINEETH BOBBILI (Presenter), SCOTT MILNER, Department of Chemical Engineering, Pennsylvania State University — The Lin-Noolandi scaling argument predicts the entanglement molecular weight from chain geometry, and is well supported by experimental results for real polymers. The argument assumes that polymers are flexible within their tubes, which fails at some point as chains become stiffer. Everaers has made a different scaling proposal, which crosses over from semiflexible chains to stiff chains as described by Morse. Everaers’ ansatz is consistent with simulation data for a range of bead-spring melts, but is not consistent with LN. In this work, we use MD simulations to explore a wide range of entangled bead-spring ring chains, to find out how entanglement properties vary with chain stiffness and concentration. To topologically equilibrate ring chains, we soften the short-range repulsive potential to allow chains to cross. We calculate entanglement properties using three techniques: chain shrinking to find the primitive path, measuring the tube diameter by the width of the “cloud” of monomer positions about the primitive path, and directly measuring the plateau modulus. As chain stiffness varies, we observe three distinct scaling regimes, suggestive of LN scaling, semiflexible chains, and stiff chains.

**1:51PM B50.00012: Polymer Structures and Their Glass Transition Temperatures: An Intriguing Relationship**

TIANYU LI, CNMS, Oak Ridge National Laboratory, HUIQUN WANG, JIMMY W MAYS, Department of Chemistry, The University of Tennessee, KUNLUN HONG (Presenter), CNMS, Oak Ridge National Laboratory — Abstract: Polymer structure play an essential role in dictating chain stiffness and glass transition temperature (Tg). The characteristic ratio ($C_w$) is an important parameter to describe chain stiffness. In general, polymers with stiffer chains have higher glass transition temperature and correspondingly higher $C_w$. However, for poly(n-alkyl methacrylates), this is not always true. For example, poly(ethyl methacrylate) has Tg of 65 °C and $C_w$ of 8.2, but poly(n-hexyl methacrylate) has Tg of -5 °C and $C_w$ of 11.1. Furthermore, poly(n-alkyl acrylates) generally have lower Tgs than the corresponding poly(n-alkyl methacrylate) but actually have higher $C_w$ values. We believe other structural characteristics, such as stereoisomerism, might play a role in these discrepancies. In this contribution we discuss the intriguing relationships of polymer structure (chain stiffness) and glass transition temperatures with relation to structural parameters and solution properties of well-characterized poly(meth)acrylates.

*Funding Acknowledgement: This research was conducted at the Center for Nanophase Materials Sciences (CNMS) at Oak Ridge National Lab (ORNL), which is a DOE Office of Science User Facility.
Phase-separating fluid and polymer mixtures provide a flexible platform for the design of functional materials containing multiple segregated domains. External electric fields provide a modality for biasing this behavior and tuning the miscibility of such mixtures; however, fundamental understanding of electric field effects on phase behavior has been limited by disagreement between theoretical predictions and experimental results.

In this talk, we report progress for a study of binary phase separation in dielectric fluids, performed using a recently developed field theory representation for polarizable molecular species. Polarizability contrast in such systems leads to van der Waals (VDW) interactions that favor immiscibility, inducing aggregation of the more strongly polarizable molecular species, and subsequent demixing. In addition to VDW interactions, which arise from local fluctuations in the polarization of the fluid, the mixture also admits a mean-field dielectric response to the applied field, which favors miscibility of the fluid. The effect of molecular architecture is also considered.

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B51 DPOLY: Advanced Scattering Techniques to Inform the Design of Polymeric Systems  BCEC 253A - Gila Stein, Univ of Tennessee, Knoxville - Tag(s): Invited

11:15AM B51.00001: Exploiting the process of thin film printing for structure manipulation tracked by grazing incidence scattering* [Invited]  EVA M. HERZIG (Presenter), Dynamics and Structure Formation - Herzig Group, Universität Bayreuth, STEPHEPN PRÖLLER, OLIVER FILONIK, Munich School of Engineering - Herzig Group, TU München, CHRISTOPHER GREVE, MICHAEL BUCHHORN, Dynamics and Structure Formation - Herzig Group, Universität Bayreuth, MIHAEL CORIC, JENNY LEBERT, Munich School of Engineering - Herzig Group, TU München — Thin films can have intriguing properties that are exploitable for consumer good applications. Such properties are strongly linked to the morphology on the nanoscale within such thin films. X-ray scattering can be a very powerful tool to resolve such structures, and also, to carry out time-resolved measurements to track the actual formation of the final nanostructures.

We have developed a dedicated set-up that allows us to print, manipulate and examine functional thin films [1]. Using X-rays we have previously demonstrated that structure formation is then trackable and can be used to gain insights into the effect of processing parameters on the structure formation process [2]. While continuously improving the processing and characterization capabilities, we are currently starting to systematically investigate different processing parameters like temperature and solvent atmosphere to understand structure formation mechanisms and their control in various thin film solar cell material systems.

11:51AM B51.00002: Packaging Plastics - Structure-Property Relationships [Invited]  DAVID G BUCKNALL (Presenter), Hariot-Watt University — The use of various experimental methods have been widely employed to study polymer deformation. Despite these previous studies, there still remains a disconnect between the molecular architecture, i.e. branch content, molecular weight between branches, etc, and the macroscopic mechanical properties. The nature of the uniaxial deformation behavior of polymers can be explained using continuum models, a surprisingly simple yet effective example of which is the spring and dashpot model of Haward and Thackray. Such models try and interpret the observed behavior in terms of viscous and elastic components associated with the crystalline and amorphous phases within the semi-crystalline polymer regions. However, these continuum models only provide a very indirect correlation between the observed mechanical behavior and the molecular structure. In this talk, the use of in-situ X-ray scattering experiments will be discussed which have enabled development of a more complete molecular interpretation of the deformation processes in polyolefins and polyesters. These results have allowed us to make direct correlations between the molecular architecture and the mechanical properties.
12:27PM B51.00003: Correlating Thermodynamic Assembly to Functional and Structural Performance of Polymeric Systems by Comprehensive Analysis of Neutron Scattering* [Invited]  
MARK DADMUN (Presenter), University of Tennessee — Small angle scattering is often used to determine the size and shape of polymeric materials, but more thorough analysis of the scattering from multi-component polymer systems provides interfacial surface area, average domain size, and importantly, phase composition. For instance, polyimide aerogels (PIA) saturated with ionic liquids are promising materials as robust electrolytes for next generation batteries. Careful analysis of SANS data from PIA/ionic liquid constructs show that the ionic liquid penetrates the polyimide skeleton. This unexpected structure clearly impacts charge transport and therefore performance of the aerogel as a battery component. This mixing behavior must be more fully understood to rationally utilize these promising materials in devices. We will also present examples of how similar analyses of scattering data provide crucial insight into the correlation of thermodynamic structure and performance in energy harvesting nanocomposites, the relationship between structure and dynamics in all-polymer nanocomposites, and the impact of deposition conditions on the lateral and vertical phase separation in polymer blend thin films.

*Portions of this research were supported by the Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division as well as the National Science Foundation (DMR-1409034 and DMR-1808946).

1:03PM B51.00004: Interfacial structure and dynamics in nanoparticle-polymer composites [Invited]  
RANA ASHKAR (Presenter), Virginia Tech — Nanoparticle-polymer hybrids and composites are central to a wide range of advanced multifunctional materials and technological applications. The premise of such systems lies in the myriad of possibilities that they offer in synergistically integrating particle and polymer properties to obtain significantly improved material performance. The past few decades of research on nanoparticle-based materials have remarkably enhanced our understanding of their macroscopic behavior and have resulted in an array of novel technologies. Yet, the demand for increasingly sophisticated applications of nanoparticle-polymer composites requires design rules that allow control of nanoscale interactions between the nanoparticles and their host environment. Such interactions manifest in unique interfacial structural and dynamical properties which ultimately determine the emergent material behavior. In this talk, I highlight the role of neutron scattering in directly observing and resolving interfacial properties that are critical to the design and performance of nanoparticle-polymer hybrids and composites.

1:39PM B51.00005: Polymer electrolytes for battery technology [Invited]  
JANNA MARANAS (Presenter), Pennsylvania State University — Polymer electrolytes have potential for use in next generation lithium and sodium batteries. Replacing the liquid electrolyte currently used has several advantages: it allows use of high energy density solid lithium as the anode, removes toxic solvents, improves safety, and eliminates the need for heavy casings. Despite their advantages, the conductivity of polymer electrolytes is not sufficient for use in batteries. As a result, considerable effort towards improving conductivity and understanding mechanisms of lithium transport has taken place over the last 30 years. This talk considers the interplay of conductivity, crystallinity, local coordination and polymer dynamics in solid polymer electrolytes. Using a combination of experimental and computational technique, we propose the possibility of high charge mobility using ion aggregates and percolated nanofiller networks.

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B52 DPOLY DBIO: Polyelectrolyte Complexation I: Coacervates and More BCEC 253B -
Debra Audus, National Institute of Standards and Technology - Tag(s): Focus

11:15AM B52.00001: Complexation of homologous polymers with variable polarity  
JIAN QIN (Presenter), SEAN FRIEDOWITZ, JUNZHE LOU, YAN XIA, Stanford University — Polyelectrolyte complexation is sensitive to both long-ranged electrostatic interaction and short-ranged effects including solvation and ion association. We synthesized polyanions and polycations with identical backbone, variable length, and controlled solvation environment around charges. Systematic dependences on molecular weight and local environment are revealed by accurate polymer compositions determined using spectroscopic measurements, for nine sets of polymer pairs. Using two fitting parameters, the backbone solubility parameter and the ion-binding strength, the results are quantitatively described by a solution free energy model that incorporates properly charge connectivity and ion-binding equilibrium.
11:27AM B52.00002: Non-stoichiometric Coacervation between Hyaluronic Acid and Chitosan* BASAK KAYITMAZER (Presenter), ALAADDIN FARUK KOKSAL, ELIF KILIC IYILIK, Department of Chemistry, Bogazici University, OZGE KARABIYIK ACAR, GAMZE KOSE, Department of Genetics and Bioengineering, Yeditepe University — Hyaluronic acid and chitosan present a unique non-cognate pair where both polyelectrolytes are semi-flexible and have pH-dependent charges. These oppositely charged polysaccharides go into liquid-liquid phase separation far away from zero-zeta potential, which usually takes place at 1:1 charge ratios for other oppositely charged macroion-pairs. In this presentation, we explore the reasons behind non-stoichiometric coacervation for the HA/CHI pair. We also briefly studied effect of counterions on the coacervation window; i.e. extend of charge ratios where coacervation prevailed. If the counterion was present as a small ion of the solvent solution (Na⁺ or Ca²⁺), then its chaotropic nature had an effect of keeping the polymer hydrated despite the tendency to release the water molecules upon association of the polymers. This effect was enhanced when the polyelectrolyte had glutamate instead of chloride as its counterion. Since glutamate was a large zwitterion where the charge was distributed around different atoms, it served to extend the coacervation window.

11:39AM B52.00003: Lower critical solution temperature in polyelectrolyte complex coacervates VIVEK PRABHU (Presenter), SAMIM ALI, Materials Science and Engineering Division, National Institute of Standards and Technology, MARKUS BLEUEL, Center for Neutron Research, National Institute of Standards and Technology — Measurements on a common linear oppositely-charged polyelectrolyte complex system, potassium-poly(styrene sulfonate) and poly(diallyl dimethyl ammonium bromide), shows liquid-liquid phase separation upon heating, or lower critical solution temperature behavior. The experimental accessibility of the critical temperature occurs for a narrow range of monovalent salt concentration (Cs) with coexistence curves narrowing with increasing Cs that reduces the polymer concentration (Cp) in the polymer-rich phase. We will describe a qualitative comparison of this phase behavior to available mean field models.

11:51AM B52.00004: Coacervate-driven self-assembly with Transfer Matrix Theory and Self-Consistent Field Theory GARY MIN CHIANG ONG (Presenter), CHARLES SING, University of Illinois at Urbana-Champaign — Complex coacervation occurs when two oppositely charged polyelectrolytes phase separate in an aqueous salt solution, resulting in a polymer dense coacervate phase and a polymer-dilute supernatant phase. Block copolyelectrolytes, which consists of both charged and neutral blocks, use this driving force to self-assemble into geometries which include micelles, vesicles and hexagonal rods. Coacervate-based materials provide advantages in (for example) the delivery of biologic materials, as encapsulation can be performed in the absence of organic solvent while maintaining stability of proteins. Recent advances in coacervation theory and simulations are used to understand the thermodynamics of coacervation-driven self-assembly. Transfer matrix theory is incorporated into self-consistent field theory (SCFT) to study how parameters like salt concentration, total polymer concentration and charge fraction of block copolyelectrolyes can affect the phase behavior of assembled structures, which is crucial in assisting in the design of materials. We show assembly that is analogous to uncharged block copolymer assembly in solution, and limits to standard coacervate phase behavior in the limit of long charged blocks.

12:03PM B52.00005: Structure and rheology of polyelectrolytes in length-mismatched coacervates AMANDA MARCIEL (Presenter), Chemical and Biomolecular Engineering, Rice University, MATTHEW TIRRELL, IME, The University of Chicago — Polyelectrolyte complexes are highly tunable materials that span from low-viscosity liquids (coacervates) to high-modulus solids with high water content, making them attractive as surface coating, membrane purification and bioadhesive materials. However, most of their properties and their effects with salt, pH, polymer ratio and temperature have only been qualitatively described. Here, we present an investigation of the structure and chain conformations, and rheological properties of polyelectrolyte complex (PEC) coacervates comprising biomimetic model polyelectrolytes with mismatched lengths. This model system allows the chain length (6 – 800-mer), side-chain functionality and chirality (L, D) to be tuned while keeping the backbone chemistry constant, thus enabling a systematic investigation of polyelectrolyte chain conformation in the liquid coacervate phase.
KEVIN SHEN (Presenter), Chemical Engineering, University of California Santa Barbara, ZHEN-GANG WANG, Chemistry and Chemical Engineering, Caltech — We study electrostatic correlations by quantifying the relative contributions of linear-response ionic atmospheres (as first described by Debye and Huckel) and counterion condensation (CC). Even for aqueous solutions of highly charged polyelectrolytes, CC may contribute less than half of the (electrostatic) osmotic coefficient drop. We further show that after CC sets in, its relative contribution to the osmotic coefficient actually decreases with increasing concentration. We quantify the strength of CC in terms of an electrostatic binding constant that captures both direct interactions between condensing charges as well as non-local effects of screening and chain connectivity. Critically, we retain the discrete nature of the polyelectrolyte backbone and counterions – this preserves "residual" electrostatic fluctuations of condensed charge pairs. Depending on the strength of residual charge fluctuations, CC can either stabilize or destabilize polyelectrolyte solutions against phase separation.

*KS thanks support by the NSF-GRFP fellowship and Jacobs Institute for Molecular Engineering for Medicine (JIMEM).

MICHAEL RUBINSTEIN (Presenter), Mechanical Engineering and Materials Science, Biomedical Engineering, Physics, and Chemistry, Duke University, SERGEY PANYUKOV, P. N. Lebedev Physics Institute, Russian Academy of Sciences, QI LIAO, Institute of Chemistry, Chinese Academy of Sciences, CHRISTIAN APONTE-RIVERA, Mechanical Engineering and Materials Science, Duke University — We develop a scaling theory and perform molecular dynamic simulations of weakly interacting coacervates with electrostatic interaction energy per charge less than thermal energy $kT$. Such liquid coacervates formed by oppositely charged polyelectrolytes can be asymmetric in charge density and number of charges per chain. We predict that these coacervates form interpenetrating solutions with two correlation lengths and two qualitatively different types of conformations of polyelectrolytes with lower and higher charge densities, which are analogous to chain conformations in quasi-neutral and in polyelectrolyte solutions, respectively. Weaker charged chains are attracted to and adsorbed on stronger charged chains forming a screening "coat" around the stronger charged polyelectrolytes. We present scaling prediction for polymeric diffusion coefficient, viscosity and stress relaxation function of these coacervates. Salt added at lower concentrations screens the repulsion between stronger charged chains, thereby reducing the thickness of the screening coat and resulting in the non-zero net polymer charge in the coacervate. At higher salt concentrations salt screens the attraction between oppositely charged chains, decreasing the coacervate concentration and its polymeric charge density. Thus, we predict a non-monotonic salt concentration dependence of polymeric charge density for asymmetric coacervates. Phase diagram for a mixture of oppositely charged polyelectrolytes at various compositions is proposed for different salt concentrations.

*This work was supported by NSF, NIH and CFF.

JEFFREY TING (Presenter), SIQI MENG, LU LI, HAO WU, University of Chicago, AMANDA MARCEL, Chemical and Biomolecular Engineering, Rice University, MATTHEW TIRRELL, University of Chicago — Polyelectrolyte complexes that form solid-like precipitates in water strongly resemble kinetically trapped solid mixtures and present formidable challenges in reproducing reliable properties and functionality. However, salt can be employed to break intermolecular ion pairs and process these nonequilibrium assemblies from a rubbery to a viscous liquid-like state. Here, we explore this transition with a pairing of RAFT-derived poly(styrene sulfonate sodium) (PSS) and poly(vinyl benzyl trimethylammonium chloride) (PVBTMA), using a combination of rheology, small angle X-ray scattering (SAXS), optical imaging, and thermal characterization. PSS and PVBTMA homopolyelectrolytes were synthesized at different molar masses with low dispersity; sodium bromide was chosen to probe individual chain and complex features. With no added salt, solid-like aggregates precipitated from solution. At 2.5 M salt, viscoelastic behavior was observed – shifting of the storage/loss moduli exhibited excellent time-salt superposition. Systematic SAXS studies were in good agreement with morphologies at various combinations of molar mass and salt. Finally, thermogravimetric analysis of the separate complex and supernatant phases enabled us to quantify the partitioning of salt and water.

1:15PM B52.00009: Guanidinium can Break and Form Strongly Associating Ion-Complexes  
KAZI SADMAN (Presenter), QIFENG WANG, KENNETH R SHULL, Northwestern University — Guanidinium is one of nature's strongest denaturants and is also a motif that appears in several interfacial contexts such as the RGD sequence involved in cell adhesion, cell penetrating peptides, and anti-microbial molecules. It is important to quantify the origin of guanidinium's ion-specific interactions, so that its unique behavior may be exploited in synthetic applications. Here we show that guanidinium ions can both break and form strongly associating ion-complexes in a context-dependent way. These insights into guanidinium's behavior are elucidated using polyelectrolyte complexes (PECs), where inter-polymer ion-pairs between oppositely charged polymers play an important role in determining material stability. We demonstrate that guanidinium salts are very effective in dissolving the poly(styrenesulfonate)/poly(allylamine) (PSS:PAH) complex, which has one of the highest measured polycation-polyanion association affinities. We also demonstrate that incorporating guanidinium charges directly into the polyelectrolyte results in a complex that remains stable under highly denaturing conditions. The model system of PSS:PAH is used to glean insights into guanidinium's denaturing activity, and to broadly comment on the nature of ion-specific interactions in charged macromolecules.

1:27PM B52.00010: Thermodynamic Characterization of Complex Coacervates of Oppositely Charged Biopolymers*
FATMA AKCAY OGUR (Presenter), FATMA AHU AKIN, NAYRA KAVAFYAN, BUSRA GUN, BASAK KAYITMAZER, Department of Chemistry, Bogazici University — Complex coacervation occurs between two oppositely charged macromolecules which go into macroscopic phase separation and form two liquid phases: polyelectrolyte-rich (coacervate) and polyelectrolyte-poor (dilute) phase. There are several areas of application for coacervates in food, cosmetics, pharmaceuticals, and medical adhesives industries. Hyaluronic acid (HA) and chitosan (CH), which are semi-flexible biopolymers, are weak polyacids and polybases, respectively. In this study, isothermal titration calorimetry (ITC) and turbidity experiments were employed to understand the thermodynamics of complex formation and phase separation for this non-cognate biopolymer system. Parameters that affect coacervation (charge ratio of polyelectrolytes, pH, ionic strength, molecular weight of polyelectrolytes) were varied to determine binding constants, change in enthalpy, change in entropy, molar heat capacity, and stoichiometry of soluble complex formation and coacervation. By systematically changing these variables, we determined that HA/CH interaction was predominantly entropic as a result of counterion release.

1:39PM B52.00011: The free energy profile of complexation of two oppositely charged polyelectrolyte chains*
SOU MIK MITRA (Presenter), ARINDAM KUNDAGRAMI, Department of Physical Sciences & Centre for Advanced Functional Materials, Indian Institute of Science Education and Research Kolkata — We report a study of the complexation process of two oppositely charged polyelectrolyte (PE) chains in dilute solution interacting through an attractive screened Coulomb potential. The system is modeled using the PE chain free energy within the uniform spherical expansion approximation where the two PE chains as well as the neutral complex are considered to be hypothetical spheres whose radii quantitatively denote the sizes of the respective chains. The two chains start overlapping due to attraction between the monomers, as well as the entropy gain of free counterions. The complexation process ends up in the formation of a neutral coacervate through mutual adsorption of oppositely charged monomers, with associated release of all counterions of both types. The free energy profile that follows this pathway is studied by obtaining the variations of the total free energy, as well as the various individual energy and entropy contributions, as functions of the extent of overlap of the two chains. Also the behavior of the chain size and charge as functions of overlap is presented. These results elucidate the competition of the various driving forces, both enthalpic and entropic in nature, which lead to complexation.

1:51PM B52.00012: Confined Impingement Jet Mixing of Charged Polymers for Functional Structured Colloids and Encapsulation  DOUGLAS SCOTT (Presenter), ROBERT K PRUD’HOMME, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — Confined impingement jet (CIJ) mixing has been demonstrated as a scalable continuous process, thus enabling the mass production of structured nanocolloids consisting of distinct polymer domains as well as the encapsulation of sensitive active ingredients (SAIs) via the technique of flash nanoprecipitation (FNP). Due to the fast mixing in a CIJ mixer, competing timescales of mixing and aggregation dictate final particle size and morphology. Yet, incorporating charged polymers (e.g., ionomers and polyelectrolytes) and their additional timescales of electrostatic interactions has yet to be characterized in detail as a pathway for fabricating functional colloids. Here, we explore the impact of hydrophobic ionomers on traditional FNP for forming complex nanocolloids for use as amphiphilic colloidal surfactants in emulsification studies. The use of ionomers for stabilization of SAIs in a non-traditional medium is also presented. Additionally, the nascent technique of flash nanocomplexation (FNC) is developed as a scalable route for generating polyelectrolyte complexes where process parameters of charge ratio, charge density, and molecular weight disparity are explored in the context of fast mixing times. The application of FNC to the sustainable encapsulation of SAIs is demonstrated.

2:03PM B52.00013: Gradient Nanoporous Poly(ionic liquid) Complex Membrane as Soft Actuators*  JIAYIN YUAN (Presenter), Department of Materials and Environmental Chemistry, Stockholm university — This talk deals with nanoporous polyelectrolyte complex membranes by using poly(ionic liquid)s (PILs).1 PILs are the polymerization products of ionic liquids (ILs) and combine some properties and functions of ILs with polymers. We exploited PILs in the fabrication of nanoporous membranes via electrostatic complexation of PILs with polyacids.2 The porous structure results from phase separation of a hydrophobic PIL in water accompanied by ionic crosslinking between PIL and polyacids. The nanoporous membrane carries a gradient profile in the cross-linking density along the cross-section, triggered by the diffusive penetration of ammonia into the PIL-polyacid blend film. The membrane pore size is tunable from nano- to micrometer scale. The membrane features high actuation speed in response to acetone vapor and serves as environmental sensors to detect solvent quality.3,4

Session B53 GSNP GSOFT: Disordered Networks: From Mechanical Properties to Failure
BCEC 253C - J. M. Schwarz - Tag(s): Invited

11:15AM B53.00001: Experimental study of failure in a granular material [Invited]  DAVID HOUDOUX, THAI BINH NGUYEN, JEROME CRASSOUS, AXELLE AMON (Presenter), University of Rennes 1 — Solid amorphous materials, when submitted to large enough stresses, display localization of the deformation. This localization can take several forms from local plastic events to shear-bands formation. I will present recent experimental results showing how those processes occur in a granular material submitted to a biaxial test.

Our observations show that failure in a sheared granular material is a multi-scale process both on a spatial point of view and on strain increments point of view. When a small strain increment is used to define the deformation field, plasticity occurs in the form of local rearrangements. Those local events can be interpreted as elementary contributions building up in a macroscopic plastic flow on larger strain increments. Correlation between the rearrangements can be evidenced and a transient self-organization of the flow at intermediate strain increments is observed with the formation of intermittent micro-bands. The coupling between the rearrangements is due to the elastic redistribution of the stress when a plastic event takes place. This structuration of the plastic flow corresponds to the fluctuating part of the plastic field and is clearly of a different nature from the final, permanent, shear-band which is a feature of the mean plastic field, defined on large strain increments. We have shown that the shear band emerges through a bifurcation of the mean plastic field. This bifurcation is linked to the emergence of an angle linked to the internal friction of the material which is clearly distinct from the orientation of the anisotropic elastic coupling. I will discuss the interpretation of our observations in the framework of current theoretical models of the plasticity of granular materials.
11:51AM B53.00002: Mechanics of cells in disordered environments [Invited] CHASE BROEDERSZ (Presenter), Physics, LMU Munich — Living cells typically grow and move in a 3D fibrous matrix such as collagen. Macroscopically, these biopolymer matrices exhibit striking nonlinear mechanical responses. At the scale of the cell, the network is highly disordered. The implications of the extreme mechanical response and structural disorder of the matrix for cells embedded in the meshwork remain largely elusive. In fact, it is unknown what the network mechanics looks like from the perspective of such a cell, and it is unclear how the cell interacts with this network at the microscopic scale to sense stiffness and regulate the mechanics of its surrounding matrix. In this talk, I will present our recent theoretical and experimental progress to understand how cells mechanically interface with their environment. Finally, I will discuss how such structured confining environments, which we mimick by using micropatterns, affect cell migration.

12:27PM B53.00003: Towards a virtual bone lab: multiscale interplay between architecture, complexity, and dynamics* [Invited] JEAN CARLSON (Presenter), CHANTAL NGUYEN, AVIK MONDAL, University of California, Santa Barbara, XIAO MA, AHMED ELBANNA, Civil and Environmental Engineering, University of Illinois at Urbana Champaign — Trabecular bone is a flexible, lightweight tissue that exhibits hierarchical mechanisms of fracture resistance across scales. At the mesoscale, it resembles a web of interconnected struts (trabeculae) that erode with age and diseases such as osteoporosis, resulting in increased fracture propensity. Recent ex vivo experiments have indicated that the traditional macroscale diagnostic marker of osteoporosis, bone mineral density (BMD), correlates poorly with bone strength when used as a sole predictor, but that it can explain much of the variation in bone strength when considered in conjunction with architectural features. We introduce a novel approach to modeling trabecular bone that combines network analysis with simulations of mechanical loading and failure, enabling a unique characterization of how bone architecture contributes to robustness and resilience. We generate network models from tomographic images of real human vertebral bone. Weighted edges represent trabeculae and nodes represent branch points where trabeculae meet. We simulate loading and deformation on finite element models in which edges are replaced by beams, resulting in a considerable reduction in computation time in comparison with fine-grained models used for in silico validation. The beam-element analysis facilitates direct comparison of mechanics and topology at multiple scales ranging from that of individual edges (beams) to the network as a whole. In addition, we discuss implications of our work in the context of clinical application, facilitated by advances in data acquisition methods for assessing fine tissue structure, and we highlight future directions for integrating our results into a comprehensive characterization of bone that links its molecular constituents at the nanoscale to its architecture at large.

1:03PM B53.00004: A quasi-continuum approach for modeling fracture in disordered networked materials: Can small world architectures save the day? [Invited] AHMED ELBANNA (Presenter), AHMED N GHAREEB, University of Illinois at Urbana-Champaign — The skeleton of many natural and artificial structures may be abstracted as networks of nonlinearly interacting elements. Examples include rubber, gels, soft tissues, and lattice materials. Understanding the multiscale nature of deformation and failure of networked structures hold key for uncovering origins of fragility in many complex systems including biological tissues and enables designing novel materials. However, these processes are intrinsically multiscale and for large scale structures it is computationally prohibitive to adopt a full discrete approach. Here, we introduce a new adaptive numerical algorithm for solving polymer networks, the building blocks in many biological and engineering systems, using an extended version of the Quasi-Continuum (QC) method. In regions of high interest, for example near defects or cracks, each polymer chain is idealized using the worm like chain model. Away from these imperfections, the network structure is computationally homogenized, using Hill-Mandell's principle, to yield an anisotropic material tensor consistent with the underlying network structure. Dynamic adaptivity provides a seamless transition across the two models. Overall, the proposed method provides a multi-resolution capability by retaining explicit representation of small scale heterogeneities and topological features, where they matter near the crack tips, while still accurately accounting for bulk elasticity and loading. We illustrate the efficiency of the method by applying it to study the fracture of large scale polymer network problems as realized in experiments on hydrogels. We further apply the method to test the influence of network topology on its fracture resistance and demonstrate that networks with small-world architectures, balancing clustering and average path length, may lead to an optimum fracture toughness. We discuss the implications of our findings for the analysis and design of tough networks.
Disordered networks are used widely to study heterogeneous material failure. These structures are inherent to many systems, such as rigid foams or granular materials. In particular, the latter exhibit highly heterogeneous force chain networks that appear to control the response of such media to external perturbations. To characterize these networks, we focus on their mechanical stability. We study the uniaxial response of networks with geometry derived from the force chains observed in granular experiments. We perform experiments on samples created by laser-cutting these networks from acrylic sheets. We find that the mean degree of the network is a control parameter of the failure behavior, which ranges from ductile to brittle. We explain this ductile-brittle transition with rigidity analysis using a frictional (3,3)-pebble game algorithm. We find that the brittle behavior corresponds to the emergence of a percolating rigid cluster occurring at a mean degree close to the isostatic value of a high friction coefficient packing. Moreover, we find that for networks close to the transition point, failure events predominantly occur within the floppy regions between the rigid clusters. To perform an analysis that is not restricted to the networks close to the transition point, we develop a test to study the failure locations. We use a measure taken from network-science tools and capable of identifying likely failure locations in the samples. It consists in comparing the relative importance of the beams of the lattice by studying their geodesic edge betweenness centrality.

Session B54 DPOLY GSOFT DFD DBIO: Extreme Deformation I: Cavitation and Yielding

11:15AM B54.00001: Laser-induced Cavitation Dynamics of Polydimethylsiloxane with Varying Cross-Linking Density and Molecular Weight* SACCHITA TIWARI (Presenter), Mechanical and Industrial Engineering, University of Massachusetts, Amherst, YUE ZHENG, Mechanical and Aerospace Engineering, University of California San Diego, California, AMIR KAZEMI-MORIDANI, Mechanical and Industrial Engineering, University of Massachusetts, Amherst, KELLY MCLEOD, IPEK SACLIGIL, CHRISTOPHER BARNEY, ALFRED CROSBY, GREGORY TEW, Polymer Science and Engineering, University of Massachusetts, Amherst, SHENGQIANG CAI, Mechanical and Aerospace Engineering, University of California San Diego, California, JAE-HWANG LEE, Mechanical and Industrial Engineering, University of Massachusetts, Amherst — High-strain-rate mechanical properties of a cross-linked polymeric model system are relevant to understanding the dynamics and damage mechanisms of various biological tissues under HSR mechanical stimuli. We present the characterization of two material systems: 1) a commercially available polydimethylsiloxane (Sylgard 184) prepared with varying crosslinking times at fixed temperature; 2) a UV-curable polydimethylsiloxane having different controlled molecular weights. For high-strain-rate characterization, we performed laser-induced cavitation with ablation seeds. The ablation seed in a specimen was vaporized without dielectric breakdown, and produced a rapidly expanding cavity. The expansion dynamics of the laser-induced cavity was observed using ultrafast imaging. The dataset obtained from time-dependent radii of cavities was numerically analyzed, and the material's HSR mechanical parameters were identified. This study can lead us to establish a high-strain-rate mechanical characterization method for soft materials including various tissues.

*This research was supported by the Office of Naval Research under contract N00014-17-1-2056.
11:27AM B54.00002: Modeling high-strain-rate microcavitation in soft materials: the role of material response*

ANASTASIA TZOUMAKA (Presenter), DAVID HENANN, Brown University — High-strain-rate inertial microcavitation has been shown to be an effective method for mechanical characterization of soft materials. To model inertial microcavitation Rayleigh-Plesset-based approaches are commonly used to capture the cavitation dynamics; however, these approaches are limited to simple viscoelastic constitutive models for the soft material, such as the Kelvin-Voigt model, since the implementation of more complex viscoelastic models requires the integration of complex mathematical expressions. To circumvent this limitation, we have developed a finite-element-based numerical simulation capability for inertial microcavitation that enables the incorporation of more complex constitutive laws. In this talk, we consider nonlinear elastic and power-law viscous constitutive laws and present a deeper investigation of the role of the elasticity and rheology of the soft material on the consequent cavitation dynamics. We apply our simulation capability by comparing computational results with experimental data from high-strain-rate inertial microcavitation of polyacrylamide and collagen gels in order to mechanically characterize these materials at high strain rates.

11:39AM B54.00003: Crack Geometry Dependence on Kinetic Energy and Loading Rate in High-Speed Cavitation

MATTHEW MILNER (Presenter), SHELBY HUTCHENS, University of Illinois at Urbana-Champaign — Temporary cavitation occurs when a projectile impacts a soft material causing a large radial expansion of the wound tract immediately after the projectile passes. Though cavity size is known to scale with the kinetic energy of the projectile, the fracture-governed damage accompanying this large deformation remains poorly understood. Using a custom designed table-top ballistic cavitation device, we replicate the temporary cavity phenomenon in soft tissue simulants on a small scale by applying a fast, high-pressure pulse of air through a needle. Temporary cavities produced via air pulse (characterized by energy density, loading rate, and needle size) isolate the damage accompanying large and dynamic stretches from that associated with more complicated impact dynamics such as projectile tumble. We find that increasing kinetic energy density and loading rate both result in greater crack area, while transforming the fracture geometry from a single planar crack to multiple radial cracks. As a result, the dependence of accumulated damage, quantified with crack surface area, increases super-linearly with kinetic energy while the temporary cavitation volume is verified to remain approximately linear over the range of energies tested.

11:51AM B54.00004: Inertial Microcavitation in Soft Matter*

JIN YANG, Mechanical Engineering, University of Wisconsin-Madison, JONATHAN ESTRADA, ERIC JOHNSEN, Mechanical Engineering, University of Michigan, DAVID HENANN, Brown University, CHRISTIAN FRANCK (Presenter), Mechanical Engineering, University of Wisconsin-Madison — The last two decades have seen significant advances in the manufacturing and design of soft matter materials with tunable control across orders of magnitude in length scale and elastic modulus. Characterization of the mechanical behavior of this new class of emerging complex soft materials has been challenging, especially in the inertial regime at strain rates beyond 100/s. In this talk I will present an overview of how inertial microcavitation can be exploited to mechanically characterize soft matter at high and ultra-high strain rates (i.e., $10^2 - 10^8$ 1/s) using inertial microcavitation rheometry (IMR). Specifically, I will show how such an approach that features both rigorous experimental and theoretical advances, can be leveraged to inform about the time and length-scale dependent material behavior of complex soft matter.

*We gratefully acknowledge support from the Office of Naval Research (Dr. Timothy Bentley) under grants N000141612872 and N000141712058.

12:27PM B54.00005: The Sound of Light: Using optical breakdown to drive extreme mechanical excitations*

ATHANASIOS ATHANASSIADIS (Presenter), Massachusetts Institute of Technology — When a high-power laser is focused to a small spot in a fluid, nonlinear interactions at the focus can excite a plasma that expands explosively and emits a strong mechanical shock wave into the ambient medium. This phenomenon — called optical breakdown — can generate peak pressures exceeding 1 MPa a centimeter from the source, with pressure pulses typically lasting less than 1 microsecond. In liquids, optical breakdown is accompanied by the growth of a vapor bubble that rapidly expands from micron to millimeter scales. Together, the ultrafast shock and subsequent bubble expansion can be used to probe the dynamic mechanical response of materials at short time scales and large stress scales. In this talk, I will demonstrate how I have leveraged optical breakdown to remotely measure the mechanical properties of submerged solids. I will show how the mechanical excitation can be tuned optically, and discuss how this technique can be adapted to measure the mechanical response of soft media.

12:39PM B54.00006: Molecular Dynamics Simulation of Polymeric Systems Under Shock Deformation∗

JOHN P MIKHAIL (Presenter), GREGORY C RUTLEDGE, Department of Chemical Engineering, Massachusetts Institute of Technology —

Currently, mechanisms by which polymeric systems respond to extreme deformation conditions, in particular deformation due to shock waves, are not fully understood. This work uses molecular dynamics (MD) simulations of atomistically detailed models of both homogeneous and heterogeneous polymeric materials (with structural variations on the nanometer scale) to study the underlying physics of system response to shock waves. Simulations are performed using both equilibrium ("Hugoniostatted") and nonequilibrium MD. Semicrystalline polymers with different configurations and degrees of crystallinity are examined, with shocks applied either isotropically or directionally with respect to the crystalline-amorphous interface. The Hugoniot curves are calculated, along with shock velocity and particle velocity. Analysis of the vibrational state of the systems identifies normal modes, along with changes in the vibrational signature pre- to post-shock. This analysis enables validation against experimental results obtainable via Raman or IR spectroscopy and provides insight into deformation mechanisms.

∗This material is based upon work supported in part by the U. S. Army Research Office through the Institute for Soldier Nanotechnologies at MIT, under Cooperative Agreement Number W911NF-18-2-0048.

12:51PM B54.00007: Rheological properties of small-molecule liquids in elastohydrodynamic lubrication∗

MARK OWEN ROBBINS (Presenter), Department of Physics and Astronomy, Johns Hopkins University, VIKRAM JADHAO, Intelligent Systems Engineering, Indiana University Bloomington — There is an ongoing debate concerning the rheological model that accurately captures the flow of small-molecule liquids in elastohydrodynamic lubrication (EHL). In EHL, liquids experience extreme pressures (>0.5 GPa) and strain rates (>100,000 s^-1). Rheological properties of squalane, a representative EHL fluid, are investigated using nonequilibrium molecular dynamics simulations for pressures up to 1.2 GPa, strain rates between 10^5 – 10^10 s^-1, and temperatures up to 100 C. Simulation results are consistent with experimental data for a broad range of equilibrium and nonequilibrium conditions. At high temperatures and low pressures, where Newtonian viscosity of squalane is low, shear-thinning associated with molecular alignment is observed, which can be described by power-law fluid models. As Newtonian viscosity rises above ~1 Pa-s, shear-thinning is increasingly dominated by thermally-activated flow processes. In these conditions, the stress-strain-rate behavior from simulations and available experimental data is consistent with the Eyring equation for over 10 decades in strain rate. The macroscopic rheological properties are correlated with underlying molecular orientation and dynamics.

∗This work is supported by the Army Research Laboratory through Grant W911NF-12-2-0022.

1:03PM B54.00008: A Molecular View: the Mechanical Behavior of Polymer Networks∗

ZIYU YE (Presenter), ROBERT RIGGLEMAN, University of Pennsylvania — Crosslinked polymer networks swollen in solvent, such as hydrogels, have gained much attention for their unique structural and mechanical properties that mimic natural materials and biological tissues. Since the network structure is linked to material properties, it is important to understand the dynamic behavior of the network during mechanical deformation. As many synthetic and natural soft materials are highly inhomogeneous, an important step is to elucidate how structural heterogeneities, such as network defects and phase boundaries, affect the response of the network to deformation. We use coarse-grained molecular dynamics to investigate the response of swollen polymer networks to deformation and the influence of network heterogeneities on the response. We examine the influence of network structures on soft materials’ bulk mechanical properties using tensile deformation to study both reversible and irreversible responses in gels as a function of polymer concentration, strand length, and network defects. We find that the network formation process will dictate local network structure, which is highly correlated to the dynamic material response under deformation.

∗ONR-40004251
Expansion Instabilities of Tube-Like Defects in Polymer Gels Subjected to Hydrostatic Pressure

CHRISTOPHER BARNEY (Presenter), University of Massachusetts Amherst, YUE ZHENG, SHENGQIANG CAI, Mechanical Engineering, University of California San Diego, ALFRED CROSBY, University of Massachusetts Amherst — Cavitation in soft solids is defined as the unstable expansion of a void within a body subjected to a negative hydrostatic pressure. Classically this expansion has been modeled assuming an initially spherical cavity, but the advent of needle-induced cavitation makes an initially cylindrical geometry experimentally relevant. Tube-like defects of varying aspect ratio are first created at the tip of a needle by incorporating a retraction step to the needle insertion process after puncturing soft polymer gels. Instability-like expansion of the cylindrical defects is then experimentally observed at pressures comparable to those expected of a spherical geometry. Complementary modeling shows that the change in initial geometry has little effect on the critical cavitation pressure. Together these measurements demonstrate that the onset pressure of instability-like expansion of cylindrical voids in soft gels does not deviate considerably from the classical spherical model which enables the confident measurement of local elastic properties in soft gels and biological tissues.

Cavitation to Study Brain Mechanics and Tissue Interface Strength

CAREY DOUGAN (Presenter), Chemical Engineering, University of Massachusetts, YUE ZHENG, Department of Mechanical and Aerospace Engineering, University of California, San Diego, CHRISTOPHER BARNEY, Polymer Science and Engineering, University of Massachusetts, SUALYNETH GALARZA, Chemical Engineering, University of Massachusetts, SHENGQIANG CAI, Department of Mechanical and Aerospace Engineering, University of California, San Diego, ALFRED CROSBY, Polymer Science and Engineering, University of Massachusetts, SHELLY PEYTON, Chemical Engineering, University of Massachusetts — Cavitation is the rapid expansion of an instability within a material. There is a considerable need to study cavitation in biological tissue, as cavitation-related damage has been implicated in explosive blast injuries on military personnel. Post-mortem analysis of human brains exposed to blasts revealed scarring at boundaries between white and gray matter, at the outermost layer, and at blood vessel/tissue interfaces. Our technique introduces a single bubble at the tip of a needle at a specific location and depth to determine localized brain properties and the impact of tissue boundaries on cavitation damage path. Finite element modeling concludes that if a tissue-tissue interface is weaker than the needle injection path, the cavitation damage propagates along the interface. Our data suggests that interfaces synergistically facilitate fracture propagation at critical pressures 5 kPa less than required to cavitate bulk thalamus. When cavitation occurs near the corpus callosum, we observe a fracture propagation along the corpus callosum and cerebral cortex interface. In deeper regions, fracture separates the amygdala from the thalamus region of brain. This approach allows us to study cavitation damage paths to better understand the mechanism for brain injury.

Volume-controlled Cavity Expansion for Probing of Local Elastic Properties in Soft Materials

SHABNAM RAAYAI (Presenter), ZHANTAO CHEN, TAL COHEN, Massachusetts Institute of Technology — Ability to measure the mechanical properties of soft biological materials in vivo can enable physicians in offering more accurate diagnosis of diseases such as cancer. Needle-based cavity expansion techniques are thus capturing the attention of researchers for measurement of the local nonlinear elastic properties in soft materials. Here we introduce a volume-controlled cavity expansion procedure that builds on the Cavitation Rheology technique [1] without relying on the maximum recorded pressure. We show that by employing an effective cavity radius based on our volume measurements we can consistently collapse the experimental results onto the theoretical predictions, regardless of the specific damage or instability mechanism exhibited by the material. We confirm the applicability of this technique by using PDMS samples, presenting good agreement with results obtained via conventional techniques with less than 5% of scatter. Moreover, since this method does not require visual tracking of the cavity, it can be applied to measure the nonlinear elastic response in opaque samples.

The yielding transition of soft colloids

STEFANO AIME (Presenter), John A. Paulson School of Engineering and Applied Science, Harvard University, DOMENICO TRUZZOLILLO, LAURENCE RAMOS, LUCA CIPPELLETTI, Laboratoire Charles Coulomb, Université de Montpellier — We investigate the yielding transition of dense suspensions of colloids interacting via a soft repulsive potential by simultaneously measuring their mechanical response and microscopic dynamics under an oscillating shear deformation.

At low strain amplitude, all systems exhibit ultraslow, ballistic dynamics characterized by a compressed exponential relaxation of correlators, similar to those reported for many jammed soft materials at rest. Upon increasing the strain amplitude, in correspondence to the onset of the non-linear rheological response, we observe a dynamic transition towards a steady state characterized by fast stretched exponential, diffusive-like relaxations, reminiscent of those measured in supercooled liquids at rest.

Although the sharpness of the transition depends on the potential details, this scenario seems to be generic to soft colloids. We show that its main features are captured by an Ising-like model, with dynamic facilitation coupling the relaxation of neighboring sites, and we discuss intriguing analogies with thermodynamic phase transitions.

Plasticity effects in thin film wrinkling: Wrinkling behavior of plastic films bonded to elastomers with large strain mismatch

RAHUL GOPALAN RAMACHANDRAN (Presenter), JUNYU YANG, SAMEER DAMLE, SPANDAN MAITI, SACHIN VELANKAR, University of Pittsburgh — We examine the mechanics of composite films comprising a SEPS elastomer layer sandwiched between two thinner surface layers of plastic (polyethylene). Upon stretching such composite films to over twice their length and then releasing, the plastic surface films develop a highly wrinkled surface texture. The mechanism for this texturing is that during stretching, the plastic layers yield and stretch irreversibly whereas the elastomer stretches reversibly. Thus upon releasing, the plastic layers buckle due to compressive stress imposed by the elastomer. Although the wrinkling process appears somewhat similar to the wrinkling of a stiff elastic film bonded to a soft elastic substrate, our experiments and simulations show that plasticity plays a major role at all stages: (1) during stretching, the plastic layer yields in tension; (2) during recovery, the plastic layer first yields in-plane in compression and then buckles; (3) post-buckling, plastic hinges are formed at high-curvature regions. Homogeneous wrinkles are predicted only within a finite window of material properties: if the yield stress is too low, the plastic layers yield in-plane without wrinkling, whereas if the yield stress is too high, non-homogeneous wrinkles are predicted.

Machine Learning for Modelling Microstructure Evolution in Polymer Mixtures

NIGEL CLARKE (Presenter), University of Sheffield — Our aim is to enhance our modelling capabilities for microstructure evolution with machine learning. In particular, we focus on Gaussian processes (GPs), a popular non-parametric class of models used extensively in ML and uncertainty quantification, which have well documented predictive abilities. In our preliminary studies, we apply existing GP methodology to microstructure evolution to determine the feasibility of generating an emulator to supplement more traditional, computationally intense, approaches. As an exemplar, we focus on the non-linear Cahn-Hilliard equation for describing phase separation in blends. Spatio-temporal problems are particularly challenging for ML due to their high dimensionality, hence we use a method recently proposed for using machine learning to predict video images, based on the idea of light cones, in which the present is only dependent on the past in the immediate spatial neighbourhood, analogous to real-space time-stepping numerical schemes for PDEs. We will present results which highlight the both the strengths and challenges of using ML for modelling microstructure.

*We thank the UK Engineering and Physical Sciences Research Council (EP/S014985/1) for financial support.
11:39AM B55.00003: Impact of Dataset Uncertainties on Machine Learning Model predictions: The Example of Polymer Glass Transition Temperatures*  
ANURAG JHA (Presenter), ANAND CHANDRASEKARAN, CHIHO KIM, RAMAMURTHY RAMPRASAD, Georgia Institute of Technology — Data-driven methods are seeing a revival and are deeply influencing multiple aspects of materials research. Materials property data from computations or experiments, are being utilized to create surrogate models using machine learning (ML) techniques. These models can be utilized to provide rapid predictions of the properties of new materials at a fraction of the cost compared to actual experimentation or computation. Moreover, a variety of techniques are being explored to “invert” the property prediction pipeline to allow for designing materials with desired target set of property values. The quality of the developed surrogate model, depends on the quality (and quantity) of the dataset used in the model training. Often, different experimental studies may report different values for the same property of the same material. This may be due to variations in measurement techniques, conditions, and sample quality among others. How should one treat these variances and what is their impact? This question needs to be answered specifically, since it is paramount to the development of a good prediction model and helps understand its limitations.

*The authors acknowledge support of this work by the Toyota Research Institute through the Accelerated Materials Design and Discovery program.

11:51AM B55.00004: Molecular dynamics and machine learning assisted design of conjugated polymers for improved ionic conductivity*  
CHRISTIAN NOWAK (Presenter), MAYANK MISRA, FERNANDO A ESCOBEDO, Chemical and Biomolecular Engineering, Cornell University — Ionic transport in conjugated polymers is an area of increasing interest for applications involving such devices as sensors, batteries, and electronic ion pumps. In a previous work we used computational models to investigate the effect on ionic conductivity of specific chemistries of side chains attached to a polythiophene (PT) backbone, and made predictions that have been confirmed by experiments. Here we extend our materials design approach such that a chemical group “library” is considered from which polymers can be constructed. We employ two differing machine learning approaches to converge on a general set of high performing chemistries: a genetic algorithm and a neural network. We only consider PT-like molecules and take advantage of the fact that the crystalline arrangements simplify the task of microstructure modeling/prediction. We find some general trends for designing materials with improved ionic conductivity; namely, biasing the ion solvating groups towards the chain ends while still retaining good percolation of the solvation sites. Our ongoing efforts are focused on extending this scheme for optimization ionic conductivity to molecules with more complex morphologies such as Bolaamphiphiles.

12:03PM B55.00005: A charge density prediction model for organic molecules using Deep Neural Networks*  
DEEPAK KAMAL (Presenter), ANAND CHANDRASHEKARAN, RAMAMURTHY RAMPRASAD, Georgia Institute of Technology — In an attempt to accelerate the pace of materials discovery, the community is increasingly using machine learning (ML) based techniques to rapidly map structure property relationships in materials. The Machine Learning methods has the advantage that their computational costs are negligible compared to those of the customary methods like density functional theory (DFT). The simulation properties of polymers is one such example where this limitation is most apparent. Here we propose a method to accurately predict charge densities of large organic systems by learning from pre-calculated examples of smaller systems. We present a novel fingerprint scheme which can numerically represent the local atomic environment. We then use a Neural Networks based models to learn the functional map between the local environments and the charge densities. Further, we introduce a recursive approach to improve these models by selectively incorporating poorly predicted examples. These charge densities are then used to calculate properties which depend on the charge density distribution like the dipole moments, dielectric properties for a host of unseen molecules thus eliminating the need to explicitly solve the laborious Kohn-Sham equations.

Bayesian Optimization for Designing Polymer Electrolytes with a Higher Lithium-ion Conductivity

TIAN XIE (Presenter), YANMING WANG, ARTHUR FRANCE-LANORD, YANG SHAO-HORN, JEFFREY C GROSSMAN, Massachusetts Institute of Technology — Solid polymer electrolytes (SPEs) are candidates for the next generation battery technology due to their safety, stability, and low manufacturing cost. However, the lithium-ion (Li-ion) conductivities of SPEs are still 2-3 orders of magnitudes lower than what is needed for practical applications. In this work, we combine a Bayesian optimization (BO) scheme and coarse-grained molecular dynamics (CGMD) to explore the materials space of SPEs to improve their Li-ion conductivity. The SPEs in the CGMD models are a mixture of polymers and lithium salts in which the salt concentration, polymer/salt interaction strengths, and polymer compositions can be changed continuously and independently. We demonstrate that BO can significantly improve the efficiency of space exploration, which enables us to find the optimum SPE with the highest Li-ion conductivity despite the high computation cost of CGMD simulations. In addition, the Li-ion conductivity predictions from the BO provides a guideline for improving the performance of existing SPEs by changing their components accordingly. Finally, we validate our method by comparing the predictions with fully atomistic molecular dynamics and experimental measurements.

BING CAO, University of Alberta, LAWRENCE A ADUTWUM, Pharmaceutical Chemistry, University of Ghana, ANTON O OLIYNYK, ERIK LUBER (Presenter), BRIAN C OLSEN, ARTHUR MAR, JILLIAN M BURIAK, University of Alberta — Organic solar cells (OSCs) are a potential cost-effective way to transform solar energy into electricity due to their potential for low-cost and high-throughput roll-to-roll production.[1] Improving the power conversion efficiency (PCE) and stability of OSCs are two of the most important tasks on the way toward commercialization. While much effort has been focused on developing new materials, optimization of processing conditions is equally important, where optimization is typically done in a haphazard manner using the experimenter’s “intuition” or through one-variable-at-a-time (Edisonian) manipulation. However, such methods can fail to find the maximum PCE due to the high dimensionality parameter space of processing conditions and correlations between parameters. Moreover, laboratory-scale OSC fabrication is often low-throughput, time-consuming and expensive. Herein, we report an approach that uses Design of Experiments (DOE) along with machine learning (ML) to optimize solar cell efficiency. DoE is used to systematically explore the parameter space of processing conditions and ML is then utilized to estimate the PCE landscape as a function of the processing parameters. This process is then applied recursively to successively smaller regions of parameters space in regions of interest. Utilizing this process allows experimentalists to explore a larger parameter space with fewer experimental trials while obtaining valid and objective conclusions. Specific examples of concrete improvement of the power conversion efficiency of OSCs will be described.

Using Particle Swarm Optimization and SCFT to agnostically identify the stable and low-lying metastable competitive morphologies of block copolymers

CAROL TSAI (Presenter), KRIS T DELANEY, GLENN FREDRICKSON, University of California, Santa Barbara — The unguided search for the stable phase of a block copolymer of a given composition and architecture is a problem of global optimization with important ramifications from a materials discovery perspective. We discuss the development of a reciprocal-space Particle Swarm Optimization (PSO)-SCFT method in which Fourier components of SCFT fields near the principal shell are manipulated. Effectively, PSO-SCFT facilitates the search through a space of reciprocal-space SCFT seeds which yield a variety of morphologies. Using intensive free energy as a fitness metric by which to compare these morphologies, the PSO-SCFT methodology allows us to agnostically identify low-lying competitive and stable morphologies. In this talk, we present results for applying PSO-SCFT to conformationally symmetric diblock copolymers and miktoarm star polymers, and discuss the successes and challenges of the method.

Prediction of suitable solvents and non-solvents for polymers using machine learning techniques

SHRUTI VENKATRAM (Presenter), CHIHO KIM, ANAND CHANDRASEKARAN, RAMAMURTHY RAMPRASAD, Georgia Institute of Technology — Solvent selection is essential for formulations in industrial and research processes like paints, cosmetics and pharmaceuticals. Identifying appropriate solvents for a polymer formulation is usually done by trial-and-error, and therefore, is time-consuming. To mitigate this problem, quantitative measures of solvent-polymer miscibility known as solubility parameters have been developed in the past. In the present study, we first assessed the performance of the Hildebrand solubility parameter to predict solvents for a set of benchmark polymers. Machine learning techniques, trained on a dataset of known polymer Hildebrand solubility parameters, were then used to predict the solubility parameter of a queried polymer. Matching the predicted value with known solvent solubility parameters was then utilized to identify suitable solvents and non-solvents for the queried polymer. This capability has been implemented at www.polymergenome.org.

Applying Machine Learning to Structural Analysis using Pythia

MATTHEW SPELLINGS (Presenter), JULIA DSHEMUCHADSE, SHARON GLOTZER, University of Michigan — The recent explosion of interest and progress in machine learning (ML) methods has driven a proliferation of their application to soft matter systems. ML promises to deliver novel, automatic characterization techniques to solve previously insurmountable problems and it has already been successfully applied in several key areas for both disordered and ordered materials. However, researchers attempting to utilize ML methods often encounter challenges in finding the most appropriate representation of their data. To help alleviate this problem and foster reproducibility in these applications, we present Pythia, an open-source Python library for generating numerical descriptions of particle configurations. Pythia provides a palette of descriptors for users to select from, ranging from the simple to sophisticated. We demonstrate how Pythia can be combined with standard ML methods to quickly identify structures, analyze crystal grains, and study nucleation and growth of complex colloidal crystalline phases—all in a high-throughput manner.

End-to-End Characterization of Colloidal Particles through Holographic Microscopy and Deep Convolutional Neural Networks

LAUREN ALTMAN (Presenter), DAVID GRIER, MARK D HANNEL II, Center for Soft Matter Research, New York University — Analyzing holograms of colloidal particles with Lorenz-Mie theory yields the particles’ sizes, refractive indexes and three-dimensional positions, all with exquisite precision and accuracy. No other technique provides such a wealth of particle-resolved and time-resolved characterization data. The underlying fits to Lorenz-Mie theory, however, require estimates for the particles’ positions and properties that are good enough to ensure convergence to the optimal solution. Here, we demonstrate that this estimation problem can be solved with a single, specially structured deep convolutional neural network. The machine-learning approach to holographic particle characterization is orders of magnitude faster than conventional image-analysis techniques, substantially more robust against image defects, and yields answers that already are sufficiently precise for many applications. We demonstrate the method’s efficacy through experimental measurements of the properties and dynamics of model colloidal systems.

An Anisotropic Langevin Equation for Protein Dynamics

ERIC BEYERLE (Presenter), MARINA GIUSEPPINA GUENZA, University of Oregon — The analysis and description of protein motions is greatly facilitated by reducing the effective dimensionality of the system through coarse-graining and transforming to decoupled normal-mode coordinates. We have developed a coarse-grained, diffusive, Langevin equation to model protein dynamics, the Langevin Equation for Protein Dynamics (LE4PD), which accounts for hydrodynamic effects and mode-dependent free-energy barriers. Here, we extend the LE4PD to describe anisotropic, directional fluctuations of a protein’s residues, projected along the alpha-carbons. We compare the dynamics predicted by the LE4PD to a conventional method to model protein dynamics, principal component analysis (PCA), which does not account for free-energy barriers or possess an associated equation of motion. Testing the formalism on a molecular dynamics simulation of ubiquitin, coarse-grained at the alpha-carbon level, when both free-energy barriers and hydrodynamic effects are neglected, the normal modes predicted by both methods are identical. However, we find that including the barriers and hydrodynamic effects in the mode-dependent description can alter significantly the predicted kinetic and dynamic properties of the protein.

2:03PM B55.00013: Machine-learning solver for modified diffusion equations* QIANSHI WEI (Presenter), University of Waterloo, YING JIANG, Chemistry, Beihang University, JEFF Z. Y. CHEN, University of Waterloo — A feedforward neural network has a remarkable property which allows the network itself to be a universal approximator for any function. Here we present a universal machine-learning based solver for multivariable partial differential equations. The algorithm approximates the target functions by neural networks and adjusts the network parameters to approach the desirable solutions. The idea can be easily adopted for dealing with multivariable coupled integrodifferential equations, such as those in the self-consistent field theory for predicting polymer microphase-separated structures.

Session B56 GSNP DBIO: Network Theory II BCEC 255 - Albert-Laszlo Barabasi

11:15AM B56.00001: Distribution efficiency and structure of complex networks. GEORGIOS GOUNARIS (Presenter), MIGUEL RUIZ GARCIA, ELENI KATIFORI, University of Pennsylvania — Optimized transport networks play a key role in the function of various artificial and natural systems, such as plant or animal vasculature. Part of the function of these flow networks is to efficiently distribute nutrients to the organism. In the case of the animal circulatory system, the oxygen distributed to the tissues is carried by the red blood cells flowing through the capillaries in the blood plasma. The architecture of the network, as defined by its structure and topology controls both the energy dissipated in transferring the viscous fluid (e.g. the blood through the capillaries) and the efficiency of the nutrient transport (e.g. how the oxygen is distributed in the tissue). In this work, we investigate the optimal structure of networks when both energy optimization and transport efficiency are considered. We discuss how the network structure is affected by the trade-offs of different optimization functionals that compete to impose hierarchy and uniformity to the same network.

11:27AM B56.00002: Optimal noise-canceling networks* HENRIK RONELLENFITSCH (Presenter), JORN DUNKEL, Massachusetts Institute of Technology, MICHAEL WILCZEK, Theory of turbulent flows, Max Planck Institute for Dynamics and Self-Organization — From the cerebral cortex to large-scale power grids, natural and engineered networks face the challenge of converting noisy inputs into robust signals. The input fluctuations often exhibit complex yet statistically reproducible correlations that reflect underlying internal or environmental processes such as synaptic noise or atmospheric turbulence. This raises the practically and biophysically relevant question of whether and how noise-filtering can be hard-wired directly into a network's architecture. By considering generic phase oscillator arrays under cost constraints, we explore the design, efficiency and topology of noise-canceling networks. We find that when the input fluctuations become more correlated in space or time, optimal network architectures become sparser and more hierarchically organized, resembling the vasculature in plants or animals. Our results provide concrete guiding principles for designing more robust and efficient power grids and sensor networks.

11:39AM B56.00003: The fundamental advantages of temporal networks AMING LI, Department of Zoology and Oxford Centre for Integrative Systems Biology, University of Oxford, SEAN CORNELIUS (Presenter), Center for Complex Network Research, Northeastern University, YANG-YU LIU, Channing Division of Network Medicine, Harvard Medical School, LONG WANG, Center for Systems and Control, Peking University, ALBERT BARABASI, Center for Complex Network Research, Northeastern University — Most networked systems of scientific interest are characterized by temporal links, meaning the network's structure changes over time. It has been shown that link temporality, by disrupting network paths, can slow down or otherwise hinder many dynamical processes, from information spreading to accessibility. Considering the ubiquity of temporal networks in nature, we ask: Are there any advantages of the networks' temporality? Here we develop an analytical framework to study the critical process of control in temporal networks. We show that temporal networks can, compared to their static counterparts, reach controllability faster, demand orders of magnitude less control energy, and allow control trajectories that are considerably more compact than those characterizing static networks. Thus, temporality ensures a degree of flexibility that would be unattainable in static networks, enhancing our ability to control them.
11:51AM B56.00004: Persistence in Random and Disordered Networks.* OMAR MALIK (Presenter), ALAA M MOUSSAWI, DAVID HUNT, Rensselaer Polytechnic Institute, MELINDA VARGA, ZOLTAN TOROCZKAI, University of Notre Dame, BOLESŁAW SZYMANSKI, GYORGY KORNISS, Rensselaer Polytechnic Institute — To better understand the lifetime and temporal dynamics of activities and trends in social networks, we initiated investigations of diffusive persistence in various graphs. Persistence is defined as the probability that the diffusive field at a given node has not changed sign up to a certain time (or in general, that node remained inactive/active). We investigated disordered networks (characterized by the fraction of removed edges) and found that the behavior of the persistence probability depended on the topology of the network. In 2D networks we have found that above the percolation threshold diffusive persistence scale scales similarly to that of the original two-dimensional regular lattice, i.e., a power law with an exponent of 0.18. At the percolation threshold, the scaling changes to one with 0.12. This new exponent is the result of the interplay of diffusive persistence and the underlying structural transition in the disordered lattice at the percolation threshold. In contrast, we found that in random networks without a regular structure, such as Erdős-Rényi networks, no simple power-law scaling behavior exists above the percolation threshold.

12:03PM B56.00005: Global suppression effect on the infinite-order percolation transitions in growing networks BYUNGNAM KAHNG (Presenter), S. M. OH, Department of Physics and Astronomy, Seoul National University, S.-W. SON, Department of Applied Physics, Hanyang University — The percolation transition in growing networks can be of infinite order, following the Berezinskii-Kosteritz-Thouless (BKT) transition. Examples can be found in diverse systems ranging from socio- to bio-networks such as the coauthorship networks and the protein interaction networks. Here we are interested in how such an infinite-order percolation transition is changed by global suppression (GS) effect. In fact, about a half century ago, Thouless showed that $1/r^2$-type long-range interactions in the one-dimensional Ising model change the phase transition type from second order to first order. One may think that the GS dynamics plays a similar role of changing percolation transitions in complex systems. We show that the BKT transition breaks down, but the features of infinite-order, second-order, and first-order transitions all emerge in a single framework. The critical region below the BKT transition point is extended and the power-law behavior of the cluster size distribution reaches the state with the exponent two, suggesting that the system has the maximum diversity of cluster sizes. We also elucidate the underlying mechanisms and show that those features are universal. Forming such extreme diversity by the GS dynamics may be helpful for establishing stabilized complex systems.

12:15PM B56.00006: Walks in rough energy landscapes: a network model RICCARDO GIUSEPPE MARGIOTTA (Presenter), REIMER KUEHN, PETER SOLLICH, King's College London — A simple way to describe the slow relaxation and ageing of a glass is to consider the system as a point in configuration-space hopping between local energy minima. The associated Markov process is specified by the distribution of these minima and the transition rates between them. Previous studies have explored the analytically tractable mean-field case [Bouchaud et al, 96] where the network of allowed transitions is fully connected. We consider a more elaborate version of the model by introducing the concept of distance among minima: the evolution takes place on sparse networks. This brings the problem into the realm of sparse random matrices. We therefore base our analysis on the spectral properties of the infinitesimal generator of the process - the master operator. We use the cavity method to evaluate the average eigenvalue spectrum and degree of localisation of eigenstates in the thermodynamic limit. These quantities are key in determining the dynamics of the system and can be used to compute time-dependent observables such as the return probability. Our findings show that eigenstates have attributes arising from a non-trivial combination of the corresponding mean field and infinite temperature limits of the model, indicating the existence of three different regimes in time.
12:27PM B56.00007: Disintegration of Different Types of Networks by Overload under Massive Attack† GABRIEL CWILICH (Presenter), Yeshiva University, YOSEF KORNBLUTH, Mechanical Engineering, Massachusetts Institute of Technology, SERGEY BULDYREV, Yeshiva University — We discuss a network which has a fraction of its nodes fail initially, and the redistribution of the betweenness centrality of the remaining nodes leads to subsequent failures, as in the Motter and Lai model; the subsequent change of the betweenness can lead to a cascade of failures that might disintegrate the network. There is a threshold in the size of the initial attack that leads to disintegration. The transition switches from first order to second when the tolerance of the nodes increases for networks with a narrow distribution of the degrees of their nodes (Erdős-Rényi, random regular, small-world). In the case of broader distributions, like a power law with exponent smaller than 3, the destruction of the initial nodes tends to stabilize the network, the value of the threshold goes to zero and the transition remains second order for all tolerances. We present an analytic calculation of the behavior of the betweenness of the different nodes during the disintegration and extensive numerical simulations. We consider the influence of the localized nature of the initial attacks on the disintegration. We show that these type of networks are, surprisingly, much more resilient vis-à-vis localized attacks.

12:39PM B56.00008: Transfractal Stochastic Nets CHRISTOPHER DIGGANS (Presenter), Information Systems Division, Air Force Research Laboratory, DANIEL BEN-AVRAHAM, Physics, Clarkson University, ERIK BOLLT, Mathematics, Clarkson University — A stochastic extension of the (u,v)-flower graph recursion is given for the case where u=1, which produces small-world, transfinite dimensional hierarchical graphs. Inspired by the two equivalent (for the non-stochastic case) means of propagation, two approaches are provided. Both rely on using a list of possible v values and a probability distribution, e.g. v=[v_1, v_2] and p=[p,1-p], and both converge to the same statistics for large graph order. The first, less restrictive case entails choosing a random v value for each edge at each generation; the second, producing a more symmetric result, involves choosing a random value for v at each generation to be consistent across that step. The main contribution of these constructions is the ability to tune desirable network parameters such as assortativity and the exponent of the power law degree distribution. An additional area of interest for the second method is exact eigenvalue propagation, which has been determined for the case of v∈[2,3]. As part of this work, a general result was found for propagating the eigenvalues of recursive quadrangularizations of any simple graph.

12:51PM B56.00009: From the betweenness centrality in street networks to structural invariants in random planar graphs* ALEC KIRKLEY, Physics, University of Michigan, HUGO BARBOSA, Physics & Astronomy, University of Rochester, MARC BARTHELEMY, Institut de Physique Theorique, CEA Saclay, GOURAB GHOSHAL (Presenter), Physics & Astronomy, University of Rochester — The betweenness centrality, a path-based global measure of flow, is a static predictor of congestion and load on networks. Here we demonstrate that its statistical distribution is invariant for planar networks, that are used to model many infrastructural and biological systems. Empirical analysis of street networks from 97 cities worldwide, along with simulations of random planar graph models, indicates the observed invariance to be a consequence of a bimodal regime consisting of an underlying tree structure for high betweenness nodes, and a low betweenness regime corresponding to loops providing local path alternatives. Furthermore, the high betweenness nodes display a non-trivial spatial clustering with increasing spatial correlation as a function of the edge-density. Our results suggest that the spatial distribution of betweenness is a more accurate discriminator than its statistics for comparing static congestion patterns and its evolution across cities as demonstrated by analyzing 200 years of street data for Paris.

*This work was partially supported by the US Army Research Office under Agreement Number W911NF-17-1-0127. M.B. thanks the city of Paris (Paris 2030) for funding and the geohistoricaldata group for discussions and data.

1:03PM B56.00010: Topology of tangledness of network embeddings YANCHEN LIU (Presenter), NIMA DEHMAMY, ALBERT-LASZLO BARABASI, Northeastern University — The force directed layout (FDL; mass and spring model) is a class of layouts in which the position of the nodes are highly correlated with the network structure. In three dimensional space, one can embed any network without link crossings. However, as in glassy systems, the number of low energy configurations in FDL is extremely large, and distinguishing between them is very difficult. Here we introduce a topological measure, which we call the graph linking number, that allows us to classify some of these energy states. We study the relation between graph linking number and the energy of the FDL. We find that the graph linking number for FDL is much lower than random layouts. Also, the distribution of graph linking number in FDL for networks with different topologies can be very different. For some network topologies, e.g. lattices, there is a strong correlation between the graph linking number and energy, while for other network topologies, e.g. Erdős-Renyi and Barabasi-Albert networks we observe less correlation between graph linking number and energy. This shows that the graph linking number is capturing a new interesting aspect of the topology of embeddings not captured by the energy and is therefore useful for classification of graph embeddings.
1:15PM B56.00011: The hidden role of coupled wave network topology on the dynamics of nonlinear lattices

SOPHIA SKLAN (Presenter), Physics and Applied Physics, Nanyang Technological University, BAOWEN LI, Mechanical Engineering, University of Colorado, Boulder — In most systems, its division into interacting constituent elements gives rise to a natural network structure. Analyzing the dynamics of these elements and the topology of these natural graphs gave rise to the fields of (nonlinear) dynamics and network science, respectively. However, just as an object in a potential well can be described as both a particle (real space representation) and a wave (reciprocal or Fourier space representation), the "natural" network structure of these interacting constituent elements is not unique. In particular, in this work we develop a formalism for Fourier Transforming these networks to create a new class of interacting constituent elements - the coupled wave network - and discuss the nontrivial experimental realizations of these structures. This perspective unifies many previously distinct structures, most prominently the set of local nonlinear lattice models, and reveals new forms of order in nonlinear media. Notably, by analyzing the topological characteristics of nonlinear scattering processes, we can control the system's dynamics and isolate the different dynamical regimes that arise from this reciprocal network structure, including the bounding scattering topologies.

1:27PM B56.00012: Structure and Dynamics of Cultured Neuronal Networks*

EMILY S.C. CHING (Presenter), The Chinese University of Hong Kong — We have developed a method that can reconstruct the connectivity structure of a weighted directed network using only time-series measurements of the dynamics of the nodes. Our method is guided by noise-induced mathematical relations. We apply this method to reconstruct cultured neuronal networks using the electrical signals recorded in cultures of cortices of rat embryos by multi-electrode arrays. The reconstructed neuronal networks have 4095 nodes; their connection probability and proportion of the giant strongly connected component are comparable to those of the chemical synapse network of C. Elegans, and both are small-world networks. Our method can further reconstruct the average incoming and outgoing coupling strength of each node and whether the nodes are excitatory or inhibitory. We obtain various interesting results about the distributions of the in-degree and out-degree, and the average incoming and outgoing coupling strength of the nodes. Moreover, we find that the spike rate of the nodes is related to their network properties. Using this relation, we can predict whether a node has high or low spike rate with high accuracy.

*We acknowledge the Hong Kong Research Grants Council (Grant No. CUHK 14304017) for support.

1:39PM B56.00013: Directed aging and memory: Teaching an old foam new tricks

NIDHI PASHINE (Presenter), DANIEL HEXNER, University of Chicago, ANDREA LIU, University of Pennsylvania, SIDNEY ROBERT NAGEL, University of Chicago — As a material ages, its physical properties change. Under an applied stress, it plastically deforms in order to relieve the internal stress in incremental steps. At each instant, it lowers the stress in the most effective way. Thus, over long times, the final state of the material depends on the external stresses it was exposed to during the aging process. A material thus has a memory of the stresses to which it was exposed during the aging process. We exploit this property and direct the aging process with specific protocols in such a way that our material reaches a distinct, final state with a prescribed and desired functionality. In order to demonstrate this behavior, we use sheets of foam that we cut with a laser cutter and place under stress in such a way that the material develops unusual elastic properties. To accelerate the aging process, we apply heat to the sample. We have been able to modify the Poisson's ratio of our system considerably; we can make a sample that was initially nearly incompressible and make it auxetic (negative Poisson's ratio). We can likewise take an auxetic sample and make it incompressible. We have also been able to train local behavior so that a sample responds with a prescribed local deformation in response to a global perturbation.

Session B57 GSNP GSOFT: Physics of Liquids II BCEC 256 - Yang Zhang, University of Illinois at Urbana-Champaign -
Tag(s): Focus
11:15AM B57.00001: Colloidal physics with DNA particles [Invited] FRANCESCO SCIORTINO (Presenter), Sapienza University of Rome — DNA oligomers can nowadays be assembled to produce a large variety of nanometric constructs, via a cascade of self-assembly processes, each one guided by the length of complementary sequences of distinct DNA strands. In the talk I will show that it is possible to build bulk quantities of DNA-made nanoparticles that closely match idealized colloids, transferring modern in-paper and in-silico intuitions into experimental realizations[1-4]. I will show how unconventional collective behaviors, recently explored theoretically, can indeed be reproduced in the lab. Among others I will discuss how the selectivity of the DNA interactions can be exploited to create gels that form both on cooling and on heating [5-6], how to create networks with swappable bonds[7], how to create systems residing on the verge of a percolation transition.

11:51AM B57.00002: Contrasting Dielectric Properties of Electrolyte Solutions with Polar and Polarizable Solvents DOUGLAS GRZETIC (Presenter), KRIS T DELANEY, GLENN FREDRICKSON, University of California, Santa Barbara — We examine the dielectric constant of electrolyte solutions with a polar and/or polarizable small-molecule solvent using a classical field-theoretic approach. We compute corrections to the dielectric constant and screening length due to intra- and inter-molecular correlations via a self-consistent one-loop approximation, accounting for the excluded volume of both solvent and electrolyte. The theory predicts either a non-linear dielectric decrement or increment with increasing salt, depending on whether the fluid correlations are dominated by the dipolar or polarizable nature of the solvent. These contrasting regimes of non-linear dielectric behavior are consistent with those seen experimentally in high- and low-dielectric-constant electrolyte solutions.

12:03PM B57.00003: Ion Solvation at Thermodynamic Extremes from First Principles* VIKTOR ROZSA (Presenter), Institute for Molecular Engineering, Univ. of Chicago, GIULIA GALLI, Institute for Molecular Engineering, Univ. of Chicago; Department of Chemistry, Univ. of Chicago; Materials Science Division, Argonne National Laboratory — The properties of aqueous salt solutions at high pressure and temperature are crucial to understanding geochemically relevant fluids. We report on the properties of aqueous monovalent ions at high pressure and temperature (1 GPa/1000 K, 11 GPa/1000 K), as obtained from first-principles molecular dynamics simulations [1]. In particular, we discuss the effect of ions on the structure and diffusion of water and the effect of water dissociation occurring under pressure, on ion solvation. We further analyze vibrational signatures of solvated ions, by comparing computed infrared and Raman spectra of salty and pure water [2] at the same conditions. Finally we present results for ionic conductivity and dielectric constants.

[1] We acknowledge support from the DOE NNSA Stewardship Science Graduate Fellowship under grant number DE-NA0003864 and MICCoM as part of the Computational Materials Sciences Program funded by the US Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

12:15PM B57.00004: A Universal Equation of State for Hard Polyhedra THI VO (Presenter), SHARON GLOTZER, Chemical Engineering, University of Michigan - Ann Arbor — The empirical formulation of the ideal gas law marked a major turning point in the development of theoretical models aimed at describing fluid behaviors. Its extension to real systems, however, often result in deviations upon comparison with experimental observations due to the presence of both excluded volume and attractive interactions in non-ideal particles. Consideration of particle shape further complicates the development of a universal theoretical framework, although there have been several attempts with varying degrees of accuracy for convex shapes. Here, we introduce a new equation of state for hard polyhedra. The derived expression not only shows excellent agreement with simulations, but also suggests a “corresponding state”-like behavior, allowing for a reduction across shape space onto a single master curve as well as prediction of the order-disorder transition density for polyhedra.
**12:27PM B57.00005: Dynamical Criticality in Higher-Dimensional Equilibrium Glasses Obtained by Swap Monte Carlo**

PATRICK CHARBONNEAU (Presenter), Duke University, LUDOVIC BERTHIER, Université de Montpellier, SILVIO FRANZ, Université Paris-Sud, JOYJIT KUNDU, Duke University — Recent implementation of the swap Monte Carlo algorithm to suitably optimized continuously polydisperse mixtures has been remarkably successful in bypassing the sluggishness associated with glass formation in dimensions, \( d=2 \) to \( 8 \). This advance has renewed the interest in exploring the finite-dimensional echo of the dynamical transition, which leads to a power-law diverging relaxation time in mean-field treatments and in the mode-coupling theory of glasses. Despite competing activated processes, such as hopping and glass nucleation, traces of the dynamics criticality can be observed, especially on the glass-side of the transition. The mean-field-like features of caging and of the dynamical susceptibility are here specifically examined.

*This research was supported by a grant from the Simons Foundation

**12:39PM B57.00006: All-atom Metadynamics Simulations of the Hierarchical Folding Dynamics of Proteins on the Timescale of Seconds**

NATHAN WALTER (Presenter), YANG ZHANG, University of Illinois at Urbana-Champaign — Molecular dynamics simulations have proven instrumental to the understanding of molecular biophysics. However, the temporal constraints of molecular dynamics simulations have limited attempts to capture the protein folding process at the atomic scale. Herein, we circumvent this limitation by using all-atom metadynamics algorithm to directly sample the potential-energy landscape of numerous proteins. Previous applications of the original metadynamics method to proteins penalized select collective variables of the protein assumed to be principle to the folding process. Rather, our method penalizes the full coordinate space of the protein resulting in a 3N-dimensional sampled energy-landscape, unbiased by \textit{a priori} assumptions. With all-atom sampling, over collective variable sampling, a single simulation captures the folding and unfolding process multiple times, enabling the simulation of protein dynamics on scales of seconds, orders of magnitude longer than recorded molecular dynamics simulations. Further, we predict the folded state of the protein, and the activation barrier and the timescale associated with the folding process of the proteins. We will present these findings for several well-studied proteins, to validate our results, and several new proteins, as a novel extension.

ZHIXIA LI (Presenter), LILY ROBERTSON, University of Illinois at Urbana-Champaign, ILYA A SHKROB, Chemical Sciences and Engineering Division, Argonne National Laboratory, JOERG NEUEFEIND, Chemical and Engineering Materials Division, Oak Ridge National Laboratory, KYLE SMITH, University of Illinois at Urbana-Champaign, LU ZHANG, Chemical Sciences and Engineering Division, Argonne National Laboratory, JEFFREY S MOORE, YANG ZHANG, University of Illinois at Urbana-Champaign — Molecular dynamics are promising methods to compute numerous properties of nonaqueous electrolytes, but quantitative predictions depend critically on the prescribed force fields. Here, we show that several quantum-mechanically refined force fields for the lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) - acetonitrile electrolyte yield structures that are in good agreement with the experimental neutron pair distribution function (PDF), while dynamics is dramatically different and inconsistent with NMR measurements. Such glaring discrepancies indicate that inadequate representation of long-range interactions leads to excessive frustration in the free energy landscape. Better agreement is achieved by proportionally scaling down the atomic charges of the ions. This simplification enabled the simulation of concentration dependences of ionic diffusion for 0.2-2 M LiTFSI solutions without sacrificing fit quality of the PDFs. We argue that not only structures but also dynamics constitute important checkpoints on the road to computationally design functional electrolytes.

1:03PM B57.00008: Stabilization of Trp-cage within Confinement by Optimizing the Interface Hydrophobicity*  
YANQIN ZHAI (Presenter), ZHIKUN CAI, YANG ZHANG, Nuclear, Plasma, and Radiological Engineering, University of Illinois at Urbana-Champaign — Understanding the interaction between proteins and confining interfaces is a critical step towards revealing the folding behaviors of protein in cellular context. In particular, the hydrophobicity of the confinement is an important factor that may affect the hydrophobic collapsing of the proteins. Hence, to study the hydrophobic effects of the confinement on the protein behaviors, we performed molecular dynamics simulations of Trp-cage miniprotein sandwiched between two graphene sheets with varying hydrophobicity by tuning the interaction potential. The structural variations of the protein was characterized by the average root-mean-square-displacement, the radius of gyration of the backbone, and the mean contact area between individual residues and the confining interfaces. The results revealed that the confinement tends to stabilize the native state of Trp-cage by reducing its configurational entropy. Specifically, two stabilization mechanisms were identified. The protein may be stabilized by moderately hydrophobic confinement through gentle adsorption and yet without destroying the hydrophobic core of the Trp-cage, or, by highly hydrophilic confinement via volume exclusion caused by dense water layers.

1:15PM B57.00009: Two-step crystallization pathways of hard particle systems via a metastable fluid-fluid phase transition  
SANGMIN LEE (Presenter), Chemical Engineering, University of Michigan, ERIN TEICH, Applied Physics Program, University of Michigan, MICHAEL ENGEL, Institute for Multiscale Simulation, University Erlangen-Nürnberg, SHARON GLOTZER, Chemical Engineering, University of Michigan — Multi-step crystallization pathways are often found in biomineralization, protein crystallization and tetrahedrally coordinated systems, where a single or multiple intermediate state appear during the crystallization process. Despite the importance of those materials, universal characteristics shared by the multi-step crystallization process are not well understood. Here, we report three hard particle systems (truncated tetrahedra, pentagonal bipyramids and triangular bipyramids) exhibiting two-step crystallization via a metastable fluid-fluid phase transition. Monte Carlo simulations reveal that these systems first form a high-density fluid with prenucleation motifs in the form of clusters, fibers, and networks from a low-density fluid. Subsequently, complex crystal structures (cF432, oF244 and cP92) nucleate from the high-density fluid. Our observations demonstrate the existence of diverse crystallization pathways in entropic systems and reveal various dimensionalities of prenucleation motifs.

1:27PM B57.00010: Weak Secondary Relaxation in Molecular Glass Formers*  
SUDIPTA GUPTA (Presenter), Department of Chemistry, Louisiana State University — The physics of glass formers and the glassy dynamics is one of the great mysteries in science. For example, the structural α relaxation, which characterizes the freezing of molecular motions on approaching the glass transition, is well known. However, in recent years in addition to the α relaxation additional secondary dynamic processes were found. Like the so-called excess wing relaxation so far mostly been investigated by dielectric spectroscopy, a method that mainly couples to only one aspect of molecular mobility, namely reorientational motions of molecules carrying a dipolar moment. We present neutron-scattering results, sensitive to density-density fluctuations, on glycerols, in presence of salts and nanoparticles, to identify the nature of this secondary relaxation. New aspects in neutron scattering have been revealed: (i) The first is the unprecedented detection of the excess wing using neutron-scattering experiments, (ii) the systematic comparison between neutron scattering and dielectric measurements, (iii) the characteristic length scale of the secondary relaxation, and (iv) The importance of dynamic heterogeneities in these relaxations.

1:39PM B57.00011: Cluster connectivity and medium-range order in metallic glass*  
XIAOYA WEI, SI LAN, XUN-LI WANG (Presenter), City University of Hong Kong — Bulk metallic glasses were discovered more than 30 years ago. It has been established that, for multicomponent metallic glass alloys, the short-range order or the fundamental building block is characterized by solute-centered clusters. Over longer length scales, the clusters are packed on a fractal network forming the medium-range order. Still, there remain many questions on the structure of metallic glasses, particularly with regard to the development of short- and medium-range orders during structure evolution induced by temperature or mechanical deformation. The experimental results seem to show that during crystallization, mechanical deformation, and liquid-to-liquid phase transformation, the short-range order is enhanced but there are no substantial changes in the structure order. Rather, it is the connectivity between clusters at medium-range scale, that drives the dynamic response. In this paper, we explore the meaning of cluster connectivity and apply the concept to explain our experimental observations.

1:51PM B57.00012: Revisiting the Fragile-to-Strong Crossover in Metallic Glass-Forming Liquids: The Case of the \( \text{Cu}_x\text{Zr}_y\text{Al}_{100-2x} \) Alloy*  
RENÉ ALBERTO ALVAREZ-DONADO, SAMUEL CAJAHUARINGA, ALEX ANTONELLI (Presenter), Universidade Estadual de Campinas — A reliable description of the dynamic properties of metallic glass-forming liquids is highly important for the understanding of the glass forming ability of these materials. To this end, we investigate the behavior of the diffusion coefficient, vibrational spectra, and shear viscosity of the \( \text{Cu}_x\text{Zr}_y\text{Al}_{100-2x} \) alloy (for \( x = 50, 49, 46 \)) through molecular dynamics simulations. The glass transition temperatures (T_g) we obtained for different compositions are in good agreement with both experimental and computational findings, indicating an increase of T_g with the amount of aluminum in the alloy. The inverse of the diffusion coefficient as a function of temperature shows a fragile-to-strong crossover at temperatures (T_fs) in the vicinity of T_g (730 K ≤ T_fs ≤ 797 K), which are significantly lower than previous estimates. These results are corroborated by the development of an excess of vibrational modes at temperatures just below T_fs. Shear viscosity as a function of T_g/T also displays the expected Arrhenius behavior below T_fs. Moreover, our results indicate another dynamic crossover related to the onset of dynamical heterogeneities at a temperature about 1200 K, which much higher than T_fs.

11:27AM B58.00002: Self-assembly of Nematic Liquid Crystals in Drying Drops of Lysozyme Protein Solution
ANUSUYA PAL (Presenter), GERMANO IANNACCHIONE, DEPARTMENT OF PHYSICS, Worcester Polytechnic Institute — In the recent years, an active area of research involves liquid crystals (LCs), e.g. 5CB (4-Cyano-4'-pentylbiphenyl) for sensing biological and chemical analytes. Another active area studies drying protein drops resulting in emergent patterns at the final dried state. In this presentation, these two areas are bridged by adding 5CB, with initial protein solution of lysozyme and de-ionized water. The investigation is done using bright-field and cross-polarizing microscopy, analyzed using ImageJ and Fiji and quantified using statistical tests. It is observed that the crack patterns in the final dried state of the protein is influenced by the presence of small amounts of 5CB. Since the protein lysozyme is not birefringent, cross-polarizing microscopy closely monitors the distribution of the LC, while the bright-field microscopy probes the crack patterns that emerge. The time evolution of the drying dynamics of the drops with and without 5CB are monitored. It is concluded that partial phase separation of LC makes some LC remains mixed and some dispersed into the domains formed by protein cracks. This work demonstrates the utility of using a bulk thermotropic LC as a probe material in a protein solution, revealing new information on the protein self-assembly during the drying process.

11:39AM B58.00003: Towards a Bayesian Interpretation of DNA Self-assembly in Hydrogels
IRIA PANTAZI (Presenter), ERIKA EISER, Physics, University of Cambridge — While widely known as the molecule of life, DNA is also an amazing building block at the nanoscale, since it allows the design and programming of the structure and dynamics of functional nanomaterials. A class of such materials are DNA hydrogels, which exploit elastic or viscous behaviour that is finely regulated by temperature. These functional materials are promising candidates for medical applications, and specifically controlled drug delivery, tissue engineering and biosensing.

In my research I am using computational tools to study the self-assembly of branched-shaped DNA building blocks that form a hydrogel. By using molecular dynamics I am simulating the assembling process, and calculate the equilibrium elastic and viscous moduli of DNA hydrogels. Moreover, I am working towards the design of a model that will employ Bayesian inference in order to associate the hydrogel properties with the different configurations of the DNA building blocks. In my talk I will outline the significance of a model that will describe DNA hydrogels, and how it can lead to the design of novel DNA-based materials.

11:51AM B58.00004: Self-Assembly of DNA origami capsids
STEFAN PAQUAY (Presenter), Brandeis University, CHRISTIAN SIGL, HENDRIK DIETZ, Physics, Technische Universität München, SETH FRADEN, MICHAEL F HAGAN, Brandeis University — DNA origami is an fruitful method to create a wide range of simple and complex objects on the nanometer scale. By folding DNA into truncated tetrahedra (“triangles”) with protrusions and recessions on their outer edges, one can add attractive interaction between these triangles.

With the right design these triangles self-assemble into icosahedra similarly to virus coat proteins but on larger length- and timescales, with potential applications in functional materials.

To guide the design of these building blocks we perform molecular dynamics and kinetic Monte Carlo simulations of coarse-grained, rigid triangles with reactive patches. Specifically, we aim to identify regimes at which the triangles optimally self-assemble into icosahedra of 20 and 60 subunits. Finally, we qualitatively compare the predicted self-assembly kinetics and structures to experiments.

*This project is funded by the Brandeis MRSEC, NIH and the William Keck Foundation
12:03PM B58.00005: The self-assembly of icosahedral shells depends on kinetics and thermodynamics*  
BOTOND TYUKODI (Presenter), FARZANEH MOHAJERANI, Brandeis University, GREGORY GRASON, UMass Amherst, MICHAEL F HAGAN, Brandeis University — We study the out-of-equilibrium self-assembly of subunits whose equilibrium ground state corresponds to an icosahedral shell, in the absence of template. We adapt a method introduced by Rostkoff and Geissler [1], which allows computationally efficient simulation of self-assembly via microscopically reversible dynamics. This allows sampling the non-equilibrium distribution of shell morphologies that arises at long, but finite times, over a wide range of shell sizes. We find that the size and morphology distribution is determined by a competition between kinetic and thermodynamic factors, and can vary significantly from the ground state equilibrium distribution as also seen in dynamical simulations [2]. Our results are general and should be applicable to diverse systems, including the self-assembly of viral capsids, bacterial microcompartments, nano tubules, or DNA origami subunits.

*This work was supported by Award Number R01GM108021 from the National Institute Of General Medical Sciences and the Brandeis Center for Bioinspired Soft Materials, an NSF MRSEC, DMR-1420382.

12:15PM B58.00006: Solvent Effects in Nanocrystal Self-Assembly*  
THOMAS WALTMANN (Presenter), ALEX TRAVESSET, Iowa State University — Materials which are composed of long-range, ordered nanocrystals exhibit many potentially revolutionary properties as compared with traditional materials. There is much to be learned about the dynamics associated with the assembly of these materials. We have previously characterized the equilibrium configuration of arrangements of highly symmetric nanocrystal clusters, and we seek now to determine solvent effects during the process of assembly via computer simulation. We have simulated the process of solvent evaporation using HOOMD and HOODLT and have found that the preferred orientation of the nanocrystals is on the boundary of the liquid solvent. As solvent is evaporated, the nanocrystals are forced to move closer together until the solvent is evaporated out completely, leaving behind nanocrystals in ordered structures.

12:27PM B58.00007: Folding dynamics of colloidal clusters  
SOLOMON BARKLEY (Presenter), ELLEN D KLEIN, VINOTHAN N MANOHARAN, Harvard University — We follow the evolution of colloidal clusters from a well-defined initial configuration towards various stable structures in order to understand how a system traverses a free-energy landscape. We use optical tweezers to assemble individual colloidal particles into an initial extended structure held together by a short-range attraction between particles. Particles diffuse across their neighbours' surfaces, lowering the cluster's free energy when particles come into contact. We precisely track the coordinates of all particles in the rearranging cluster throughout this assembly process with a three-dimensional imaging technique, digital holographic microscopy, and we quantify the various pathways from the initial state to the ground states.

12:39PM B58.00008: Band Gap Optimization of Colloidal MgCu2 Photonic Crystals  
JOHNATHON GALES (Presenter), ETIENNE DUCROT, DAVID J PINE, CSMR, New York University — It was recently shown that a colloidal MgCu2 lattice can be self-assembled using a combination of DNA coated spheres and compressed tetrahedral clusters of spheres. The spheres and compressed clusters form two interpenetrating sublattices, diamond and pyrochlore, respectively. Both sublattices have a photonic band gap. We calculate the photonic band structures of the compressed cluster crystals, which differ from those of the standard pyrochlore lattice that has been considered previously. We find that the compression of the clusters can make the band gap significantly wider than for the typical pyrochlore lattices. We can precisely tune the compression of our synthesized tetrahedral clusters, giving us the opportunity to explore the full range of MgCu2 assembly and optimize their photonic properties.
optically active materials. This work paves the way to exploiting LC interfaces as a means to direct spontaneously formed, reconfigurable, and standing smectic-A films, in which the elasticity arising from the director field distortion and capillary interactions arising from interface deformation compete to direct the assembly of particles. New colloidal assemblies and patterns, ranging from 1D chains to 2D aggregates, sensitive to the initial wetting conditions of particles at the smectic film, are reported. Furthermore, colloidal particles at complex fluid interfaces and within films assemble to form ordered structures via interactions that include capillarity, elasticity, and other fields. Here we study microparticle interactions within free-standing smectic-A films, in which the elasticity arising from the director field distortion and capillary interactions arising from interface deformation compete to direct the assembly of particles. New colloidal assemblies and patterns, ranging from 1D chains to 2D aggregates, sensitive to the initial wetting conditions of particles at the smectic film, are reported. This work paves the way to exploiting LC interfaces as a means to direct spontaneously formed, reconfigurable, and optically active materials.

1:03PM B58.00010: Polymeric Janus Nanoparticles at Water/Oil Interfaces YUFENG JIANG (Presenter), University of California, Berkeley, RAMZI CHAKROUN, ANDRÉ GRÖSCHEL, Physical Chemistry, University of Duisburg-Essen, THOMAS RUSSELL, Polymer Science and Engineering, University of Massachusetts Amherst — We present a study on the assembly of polymeric Janus nanoparticles (pJNPs) at the toluene/water interface. The soft spherical polymeric Janus nanoparticles pJNPs, made by cross-linking polystyrene-block-polybutadiene-block-poly(methyl methacrylate) (PS-PB-PMMA), show a high interfacial activity, even though neither component is soluble in water. The preferential affinity of the PMMA to the aqueous phase causes a spreading of the PMMA block at the interface. Unlike hard NPs where, after the interfacial tension has decreased and stabilized, only a small volume reduction of the pendant droplet is required to induce wrinkling, for soft pJNPs, there must be a significant reduction in the pendant drop volume to induce wrinkling. A series of pJNPs where the molecular weight at constant weight fraction or where the weight fraction at constant molecular weight of the brushes and cores were varied to probe the influence of molecular weight, brush lengths and volume fractions of the component arms on the areal density of the assemblies and the response of the assemblies to a compression. We also investigated the influence of metal ions in the aqueous phase that can complex with the PMMA on the assembly, packing, stability and responsiveness of pJNP assemblies.

1:15PM B58.00011: Rational Design of Anisotropic Colloids to Self-assemble Open Lattices with Omnidirectional Band Gaps YUTAO MA (Presenter), ANDREW L FERGUSON, The Institute for Molecular Engineering, University of Chicago — Patchy colloids possessing anisotropic interactions are versatile building blocks for the self-assembly of complex functional materials. The main challenge in assembling these materials is the rational and efficient discovery of colloidal architectures and chemistries that make the desired aggregate both thermodynamically stable and kinetically accessible. We have previously devised an inverse design strategy termed "landscape engineering" wherein we combine molecular simulations, nonlinear dimensionality reduction, and genetic algorithms to recover and sculpt the low-dimensional free energy landscape governing assembly by rational modulation of building block design. We apply this data-driven design strategy to perform de novo design of patchy colloids that spontaneously assemble into an open pyrochlore lattice with an omnidirectional photonic bandgap. Our particle design assembles the crystal in a two-stage hierarchy where tetrahedral clusters representing the fundamental motif of the crystal are formed at high temperature with >90% yield, and then a gentle ramp to low temperature induces the aggregation of the tetrahedra into the pyrochlore lattice. Our design approach can be extended to other finite-sized and periodic assemblies including Platonic solids and diamond lattices.

1:27PM B58.00012: Interactions and Energy Scales in Self Assembly and Directed Assembly of Nanocrystal Superlattices ALEX TRAVESSET (Presenter), Iowa State University — Long range ordered structures of nanocrystals or nanoparticles are known as superlattices. We, and others, have shown that the cohesive energy of nanocrystals in superlattices is very large, of the order of hundreds of $k_B T$. In this talk we will show theoretical and computational results on nanocrystals capped with hydrocarbons showing how these systems overcome these scales and successfully self-assemble into ordered structures with long range order. Irrespective of the interactions, these systems show a tendency towards local icosahedral order. Time permitting, issues related to polydispersity will be discussed.

*The work is funded by NSF, DMR-CMMT 1606336 `CDS&E: Design Principles for Ordering Nanoparticles into Super-crystals"
Three-dimensional particle-based simulations of fluctuation-stabilized copolymer mesophases

CODY BEZIK (Presenter), Institute for Molecular Engineering, University of Chicago, ABELARDO RAMIREZ-HERNANDEZ, Department of Chemical Engineering, The University of Texas at San Antonio, JUAN DE PABLO, Institute for Molecular Engineering, University of Chicago — Binary blends of $A-(B-b-(B-b-A'))_n$ miktoarm star block copolymers and A homopolymers have been experimentally shown to self-assemble into an aperiodic “bricks-and-mortar” mesophase, which combines a continuous “mortar” phase of the B-type polymer with a discrete “bricks” phase of the A-type polymer. Such materials have been proposed for use as thermoplastic elastomers, combining high mechanical strength and high elastic recovery. It has been demonstrated theoretically that the mesophase is not predicted to exist in the absence of thermal fluctuations, suggesting it is a unique fluctuation-stabilized morphology. A critical feature of this mesophase is that the A-type domains possess a wide range of sizes, from tens to hundreds of nanometers, representing a challenge to simulation-based approaches. Consequently, prior theoretical work has been limited to simulation in two-dimensions. In this work, we use three-dimensional particle-based simulations, which include fluctuations, to extend understanding of the phase diagram of these blends. Our simulations verify that the bricks-and-mortar mesophase emerges in the presence of three-dimensional thermal fluctuations and more accurately capture experimental systems’ phase behavior.

Characterization of Martensitic Phase Transformations in Blue Phase Liquid Crystals Using Resonant Soft X-ray Scattering*

HYEONGMIN JIN, Northwestern Argonne Institute of Science and Engineering, Northwestern University, XIAO LI (Presenter), JAMES DOLAN, Institute for Molecular Engineering, University of Chicago, R. JOSEPH KLINE, National Institute of Standards and Technology, PAUL F NEALEY, Institute for Molecular Engineering, University of Chicago — In this work, we introduce resonant soft X-ray scattering (RSoXS)[1] to study the martensitic transformation of blue phase (BP) liquid crystals (LCs).[2] The combination of RSoXS and single crystal BP LCs—directed and stabilized by the chemically-nanopatterned surfaces—enable to provide a clear picture of how the BP lattice symmetry and molecular orientations change during this transformation. In particular, twin lamellae formation is observed during martensitic transformation to release the residual strain caused by the rapid martensitic transformation. We anticipate that these experiments will provide one of the most comprehensive studies yet of BP and, therefore, soft matter martensitic phase transformations.

*This work was supported by the U.S. Department of Commerce, National Institute of Standards and Technology under the award 70NHNBI4H012 as part of the Center for Hierarchical Materials Design. The Effects of Ligand Concentration on the Mechanical Properties of Nanoparticle Films*

SOPHIE MACFARLAND (Presenter), MORGAN REIK, MELANIE S CALABRO, BINHUA LIN, STUART A RICE, University of Chicago — When dodecanethiol-ligated gold nanoparticles are deposited on an air-water interface, they self-assemble into Langmuir films. Experiments in which the films are compressed uniaxially have demonstrated that as the ligand concentration decreases, the ligand-ligand and ligand-core interactions change and the 2-dimensional compressive and shear moduli of the films increases. However, these experiments were largely done upon films while on an air-water interface – this study focuses on films which are dried and removed from the air-water interface. It is important, since many potential applications of these films are in electronic devices, which require the films to operate in a dry environment. This study examines how variations in the concentrations of ligands in a gold nanoparticle solution and by extension the fractional surface coverage, impact a dried film's mechanical properties. Specifically, the Young's Moduli of the films are measured through contact-mode Atomic Force Microscopy (AFM), which demonstrates that low thiol concentrations are conducive to higher young's moduli.

11:15AM B59.00001: Fragility in shear jamming of dense frictional suspensions* RYOHEI SETO (Presenter), Chemical Engineering, Kyoto University, ABHINENDRA SINGH, James Franck Institute and Institute for Molecular Engineering, University of Chicago, OMER SEDES, MORTON M DENN, Levich Institute, City College of New York, BULBUL CHAKRABORTY, Physics, Brandeis University, JEFFREY MORRIS, Levich Institute, City College of New York — Particulate systems often undergo fluid-solid transition. The packing fraction that corresponds to this particular transition is often found to be protocol dependent. In case of frictional particulate systems, starting from a force-free random configuration at $\phi > \phi_{sj}^{\mu}$ and subjected to shear by constant stress, some rearrangements (i.e., flowing) may occur before getting jammed. Such shear jammed states may flow again by changing the direction of the applied stress; such states are termed "fragile." We quantify this fragility with a stress reversal simulation and identify the point where the fragility vanishes as the isotropic jamming point $\phi_{j}^{\mu}$. We also present a shear-jamming phase diagram of stress-dependent suspension model with a critical-load friction model.

*This study was supported by JSPS KAKENHI Grants No. JP17K05618.

11:27AM B59.00002: Uncovering Instabilities in the Spatiotemporal Dynamics of a Shear-Thickening Cornstarch Suspension* BRICE SAINT-MICHEL, THOMAS GIBAUD, SEBASTIEN MANNEVILLE (Presenter), Physics, Ecole Normale Supérieure de Lyon — We explore unsteady dynamics in a dense cornstarch suspension by coupling long rheological measurements under constant shear stresses to ultrasound imaging. We demonstrate that unsteadiness in DST results from localized bands that travel along the vorticity direction with a specific signature on the global shear rate response. These propagating events coexist with quiescent phases for stresses slightly above DST onset, resulting in intermittent, turbulentlike dynamics. Deeper into DST, events proliferate, leading to simpler, Gaussian dynamics. We interpret our results in terms of unstable vorticity bands as inferred from recent model and numerical simulations.

*This research was supported in part by the National Science Foundation under Grant No. NSF PHY-1748958 through the KITP program on the Physics of Dense Suspensions.

11:39AM B59.00003: Shear jamming, DST and fragile of frictional granular materials under oscillatory shear* MICHIO OTSU, Graduate School of Engineering Science, Osaka University, HISAO HAYAKAWA (Presenter), Yukawa Institute for Theoretical Physics, Kyoto University — The mechanical response of two-dimensional frictional granular materials under an oscillatory shear in a constant volume are numerically investigated. It is confirmed that the shear storage modulus $G'$ depends on the initial amplitude of the oscillation to prepare the system before the measurement. For sufficiently large initial strain amplitude, the shear jammed state satisfying $G' > 0$ is observed even if the packing fraction is below the jamming point. The fragile state is also identified as a long lived metastable state where $G'$ depends on the phase of the oscillatory shear. The dynamic viscosity evaluated from the shear loss modulus $G''$ exhibits a sudden jump similar to the discontinuous shear thickening in the fragile state.[1]

In this talk we also show some preliminary results of hydrodynamic simulation for colloidal suspensions to discuss shear jamming and DST as well as the behavior of dry granular particles under the pressure control protocol.

*This work is partially supported by the Grantin-Aid of MEXT for Scientific Research (Grant No. 16H04025 and No. 17H05420).
11:51AM B59.00004: Using orthogonal shear and acoustic excitation to tune thickening and jamming in suspensions

ITAI COHEN (Presenter), NEIL YC LIN, MEERA RAMASWAMY, RAN NIU, PRATEEK SEHGAL, BRIAN J. KIRBY, Cornell University — Running fast enough over a tub of thickening cornstarch suspension and not sinking is one of the most entertaining science demonstrations garnering millions of viewers every year. As stress is applied to the suspension, the cornstarch particles come close enough to form force chains that are capable of supporting the weight of a person. This thickening, while fun for demonstrations, causes problems for efficient processing of industrial suspensions and garners a high cost. Previously we showed that by applying fast orthogonal perturbations, the viscosity of suspensions under shear can be tuned and decreased by over an order of magnitude. Here, we show that impact driven jamming can be eliminated using a similar technique. Specifically, we conducted a series of impact and extensional flow experiments while cyclically oscillating the bottom plate of our rheometer about the vertical axis. We observe a drastic reduction in the normal forces when the oscillations are turned on. These experiments have the potential to alter suspension processing methods used in numerous industries.

*This work was supported by NSF CBET-PMP Award No. 1232666, NSF CBET-PMP Award No. 1509308 and NSF PHY17-48958.

12:27PM B59.00005: Dynamics of Localized Stresses in Shear-thickening Cornstarch Suspensions

VIKRAM RATHEE (Presenter), DANIEL BLAIR, JEFFREY S URBACH, Georgetown University — Dense colloidal and cornstarch suspensions are common examples of shear thickening suspensions. Spatially resolved surface stresses in a model colloidal suspension using boundary stress microscopy (BSM) revealed dynamic regions of substantially increased local stresses that appear intermittently and move in shear direction. We report BSM of cornstarch suspensions and also find large stress heterogeneities, but with very different dynamics. Above critical stress, the heterogeneous regions propagate along the vorticity direction, perpendicular to shear direction, while at higher applied stresses we do observe propagation in the shear direction similar to the behavior observed in colloidal suspensions.

*NSF Award DMR-1809890

12:39PM B59.00006: Connecting shear jamming and discontinuous shear thickening

IAN MADDEN (Presenter), ERIK LUIJTEN, Northwestern University — Shear stress can induce jamming at packing fractions below the static jamming packing fraction. Here we investigate shear-jamming transitions in a model of two-dimensional shear-jammed discs, observing a transient shear-jamming behavior corresponding to fragile states before the shear-jamming transition. The existence of these states below the onset of shear-jamming was first discovered by Bi et al. (Nature 480, 355–358 (2011)), and further investigation uncovered the related phenomenon of discontinuous shear thickening (Nature 532, 214-217 (2016)). We use molecular dynamics simulations to connect theory to experiment, revealing discontinuous shear thickening and transient shear-jamming to be intimately related. Using this knowledge, we obtain guidance for the design of an experimental system that can reproduce our result.

12:51PM B59.00007: Microscopic signatures of yielding in concentrated nanoemulsions under large-amplitude oscillatory shear

ROBERT LEHENY (Presenter), Johns Hopkins University, MICHAEL C. ROGERS, University of Ottawa, KUI CHEN, Johns Hopkins University, MATTHEW J PAGENKOPP, THOMAS G MASON, UCLA, SURESH NARAYANAN, Argonne National Laboratory, JAMES HARDEN, University of Ottawa — Yielding occurs when a solid is stressed beyond its elastic limit. Signatures of yielding at the nano-to-microscale are irreversible changes to the material's structure. In amorphous solids, the intrinsic disorder makes identifying these microstructural changes difficult. We describe x-ray photon correlation spectroscopy experiments on a series of concentrated oil-in-water nanoemulsions subjected to in situ large-amplitude oscillatory shear in which we characterize the shear-induced droplet dynamics associated with yielding [1]. The dynamics include irreversible rearrangements among the droplets that occur in some regions of the nanoemulsions during a given shear cycle and residual strain-like displacements in those regions that do not re-arrange. We observe a power-law distribution in the size of regions undergoing rearrangement. The values of the onset strains for re-arrangement correlate with the concentration-dependent macroscopic yielding behavior. Specifically, they occur below the strains at which the nanoemulsions become effectively fluidized and, except for the lowest concentration sample in the study, significantly above the threshold strain for nonlinear rheological response.

1:03PM B59.00008: Traction force rheology of colloidal polycrystals and glasses* ZSOLT TERDIK (Presenter), DAVID A WEITZ, FRANS A SPAEPEN, Harvard University — Micron sized colloidal particles in a solution can be assembled and ordered into densely packed polycrystals or disordered glasses. Due to the large size and slow dynamics of colloidal particles, confocal microscopy can be used to directly measure the 3D structure of dynamics of colloidal solids. Measuring the stress response, in addition to visualization, is a challenge because large colloids (which are essential for confocal microscopy) and thermal interaction energies necessarily give rise to solid phases with exceptionally small elastic constants on the order of 10-100 mPa. We introduce a new technique, traction force rheology, to directly measure the mechanical response of colloidal polycrystals and glasses while simultaneously visualizing the microstructure. The method consists of a bilayer of colloidal solid sitting atop a well calibrated soft polymer gel of comparable shear modulus. The composite bilayer is sheared and the shear stresses are inferred from the displacement of embedded tracer particles in the gel. To complement the direct stress measurements, we visualize, in 3D, the time evolution of the complex microstructure including dislocation and grain boundaries in colloidal polycrystals and flow defects in the colloidal glass.

1:15PM B59.00009: Using oscillatory shear to tune the viscosity of shear thickening suspensions* MEERA RAMASWAMY (Presenter), Cornell University, ABHISHEK SHETTY, Anton Paar, ITAI COHEN, Cornell University — When concentrated colloidal suspensions are under stress, their viscosity can increase by over an order of magnitude. These shear thickening suspensions have many interesting technological applications but are also extremely difficult to process in an industrial setting due to the strong dependence of the flow properties on the shear rate. Previous work has shown that the viscosity of these suspensions can be tuned by applying fast orthogonal perturbations to the system. This behavior, however, was only demonstrated for a few values of applied stress and one suspension volume fraction. We are using a custom built attachment to a standard Anton Paar rheometer, to extend these previous measurements to various volume fractions, applied stresses, and system sizes. In this talk, I will describe our results which show that dethickening due to orthogonal shear is volume dependent, and a non-monotonic dependence on the primary applied strain rate. Understanding these trends has consequences for applications involving shear thickening fluids ranging from 3D printing to the processing of cement.

1:27PM B59.00010: Multiparticle finite element model of highly deformed hydrogel assemblies CRAIG MALONEY, AHMED ELGAILANI (Presenter), Mechanical and Industrial Engineering, Northeastern University — Abstract: Packings of hydrogel particles, like any granular material, become rigid when volumetrically confined. At low confinement near the onset of rigidity, linear elastic contact mechanics should provide a good description of the interparticle forces. At higher confinement, the particles become strongly deformed and linear elastic contact mechanics no longer provides a reasonable description of the interparticle forces. Here, we report on simulations using a multiparticle finite element technique, employing the Flory-Rehner constitutive law, to model the full non-linear elastic deformation of all particles in the packing. We show that the shear modulus (μ) of the packing depends strongly on confining pressure (p) with a crossover from a low-pressure regime where μ ~ p^{1/2} to a high-pressure strongly-faceted regime where μ ~ p^{1/4} where interstitial space has essentially vanished and the facet geometry no longer evolves with pressure.

1:39PM B59.00011: Yielding Versus Jamming: Critical Scaling of Sheared Soft-Core Disks JACOB THOMPSON (Presenter), ABE CLARK, Physics, Naval Postgraduate School — Using discrete element simulations, we study critical behavior for yielding of assemblies of soft-core repulsive disks over a range of dimensionless pressures P. We isotropically compress the disks in a shear-periodic (Lees-Edwards) geometry and then perform quasi-static simple shear. After each shear strain step, we relax the potential energy and dilate or compress the grains to maintain fixed pressure P and then evaluate the shear stress τ. We find that the number density of mechanically stable (MS) states and the strain between MS states obey finite-size scaling consistent with a diverging length scale ξ ~ |Σ-Σc|^{-ν}, where Σ=τ/P. We observe two distinct values of ν: one during the initial stress buildup, ν ≈ 1.7, and another characterizing the slips during steady state shear, ν ≈ 1.1. The critical stress Σc increases as P is decreased and approaches a constant in the low-P limit, Σc ≈ 0.1. However, the critical behavior (including the values of scaling exponents) is otherwise independent of P over several orders of magnitude, including well above the jamming transition. Our results show that critical scaling behavior associated with yielding is distinct from jamming, which may explain similarities among nonlocal flows of granular materials, emulsions, and other soft materials.
1:51PM B59.00012: Structural evolution of amorphous systems during large scale deformation* ETHAN STANIFER (Presenter), M. LISA MANNING, Syracuse University — Granular and amorphous materials deform plastically via localized structural rearrangements, although it remains unclear how microscopic structure and material preparation control such events. To address this question, many tools have been developed that use features of the linear response or dynamical matrix to predict the locations of localized rearrangements using structural information alone. However, these methods become less predictive across an avalanche, where stress fluctuations generated by one localized rearrangement can trigger other rearrangements resulting in a large-scale structural change that is not captured by the linear response at the beginning of the avalanche. Therefore, we develop a method to study the linear response of a system during an avalanche. Specifically, we use dimensionality reduction to project the Hessian and forces into the space orthogonal to the minimization direction, and other unstable directions. We extend existing tools for identifying structural defects using this reduced Hessian and study how the population of structural defects evolves during an avalanche with a goal of developing a statistical description of structural evolution during large-scale mechanical instabilities.

2:03PM B59.00013: Colloidal drops under extreme stress SRI SHTI ARORA (Presenter), MICHELLE R DRISCO LL, Northwestern University — We investigate the non-Newtonian behavior of dense colloidal suspensions by impacting a millimetric size droplet onto a solid surface. This method provides a unique platform to gain insight into suspension flow at high stresses and velocity gradients, a regime that is non-trivial to access using conventional rheometric techniques. Here, we present a comprehensive study of colloidal drop impact. We measure the maximal spread of the impacting colloidal drop while varying impact velocity and particle volume fraction. We find that the extent of spreading decreases with increasing volume fraction or decreasing impact velocity. Moreover, there exists a critical volume fraction below which the colloidal drop spreads radially into a flattened disc as commonly observed for Newtonian fluids. Above this critical volume fraction, no inertial spreading is observed, suggesting the onset of a jamming transition inside the colloidal drop. Furthermore, we observe a variety of elastic behaviors which manifest above the critical volume fraction and are controlled by impact velocity.

Session B60 DMP GMAG: DMP Prize Session BCEC 258A - Nitin Samarth, Pennsylvania State University - Tag(s): Invited

11:15AM B60.00001: James C. McGroddy Prize for New Materials Talk: FA Catalogue of Topological Materials Using Topological Quantum Chemistry [Invited] ANDREI B BERNEVIG (Presenter), Princeton University — We will show how, using a new theory called Topological Quantum Chemistry, thousands of new topological materials can be predicted, classified and discovered. The result is that more than 30 percent of all materials in nature are topological.
CLAUDIA FELSER (Presenter), Max Planck Institute for Chemical Physics of Solids — Topology, a mathematical concept, recently became a hot and truly transdisciplinary topic in condensed matter physics, solid state chemistry and materials science. Since there is a direct connection between real space: atoms, valence electrons, bonds and orbitals, and reciprocal space: bands, Fermi surfaces and Berry curvature, a simple classification of topological materials in a single particle picture should be possible [1]. One important criterion for the identification of the topological material is, in the language of chemistry, the inert pair effect of the s-electrons in heavy elements, and the symmetry of the crystal structure. Binary phosphides are an ideal material class for a systematic study of Dirac, Weyl and new Fermion physics, since these compounds can be grown as high-quality single crystals. A new class of topological phases that have Weyl points was also predicted in the family that includes NbP, NbAs, TaP, MoP and WP2 [2-5]. In magnetic materials the Berry curvature and the classical anomalous Hall and spin Hall effect helps to identify potentially interesting candidates. As a consequence, the magnetic Heusler compounds have already been identified as Weyl semimetals: for example, Co2YZ, Mn3Sn and Co5Sn2S2 [6]. The Anomalous Hall angle also helps to identify materials in which a quantum anomalous Hall effect should be possible in thin films. Even beyond this reciprocal Berry curvature, Heusler compounds with non-collinear magnetic structures also possess real-space topological states in the form of magnetic antiskyrmions, which have not yet been observed in other materials [7].

XI DAI (Presenter), Physics, Hong Kong University of Science & Technology — Quasi-particles and collective modes are two fundamental aspects that characterize a quantum mater in additional to its ground state features. For example, the low energy physics for Fermi liquid phase in He-III was featured not only by Fermionic quasi-particles near the chemical potential, but also by fruitful collective modes in the long wave length limit, including several different sound waves that can propagate through it under different circumstances. On the other hand, it is very difficult for sound waves to be carried by the electron liquid in the ordinary metals, due to the fact that long range Coulomb interaction among electrons will generate plasmon gap for ordinary electron density waves and thus prohibits the propagation of sound waves through the electron liquid. In the present paper, we propose an unique type of acoustic collective modes formed by Weyl fermions under the magnetic field, which is called chiral zero sound (CZS). The CZS only exists and propagates along an external magnetic field for Weyl semi-metal systems containing multiple-pairs of Weyl points. The sound velocity of CZS is proportional to the field strength in the weak field limit, whereas oscillates dramatically in the strong field limit generating completely new mechanism for quantum oscillations through the dynamics of neutral Bosonic excitation, which may manifests itself in the thermal conductivity measurements under magnetic field.

JULIA MUNDY (Presenter), Harvard University — Materials systems with many strongly interacting degrees of freedom can host some of the most exotic physical states known. In thin films, the interface between two distinct quantum materials forms a further playground to engineer emergent ground states. Here we demonstrate how we can combine atomically-precise thin film synthesis with picoscale imaging of the resulting structure, to design, construct and probe novel quantum materials at the sub-Angstrom length scales. We will consider a series of complex oxide superlattices where tuning the local distortions of the lattice can lead to dramatic changes in the electronic and magnetic properties of the system. We will demonstrate how this technical approach allows us to stabilize previously metastable “hidden” ground states to construct the first room-temperature strong multiferroic material and a high energy density antiferroelectric system.
11:15AM B61.00001: Excitations in an active smarticle gas*  AKASH VARDHAN (Presenter), ZACHARY JACKSON, WILLIAM C SAVOIE, KURT A WIESENFEILD, DANIEL GOLDMAN, Georgia Institute of Technology — <p style="margin: 0px 0px 10.66px;">Spontaneous stable excitations can arise unexpectedly from homogenous many body systems, e.g. oscillons observed in vibrating granular media, and rotons in superfluid helium. We have observed several such long lived excitations in a gas of active matter particles called “smarticles”. Smarticles are small 3 link planar robots. Each smarticle measures 14X2.5X3 cm<sup>3</sup>, where only the center link is on the ground. In the experiments they are placed on a frictional surface, and change their shape periodically, while interacting with each other via collisions. Although fairly limited in their locomotive capabilities on their own in the considered experimental configuration, interesting behavior is revealed when we allow these smart, active granular materials to mingle. We study the simplest case where two smarticles interact with each other. These two particle excitons demonstrate bouts of coordinated motion synchronized both in their gaits, and spatial orientations. We also witness a unique case of locomotion emerging from their mechanics, wherein the collective executes general planar motion.</p>

11:27AM B61.00002: Attractor symmetry and stability in symmetric self-driven oscillator networks*  IAN HUNTER (Presenter), MICHAEL NORTON, JAMES SHEEHY, Physics, Brandeis University, BOLUN CHEN, Neuroscience, Brandeis University, YOUSSEF FAHMY, Physics, Brandeis University, LANIJAH FLAGG, Physics, Hampton University, CHRIS SIMONETTI, SETH FRADEN, Physics, Brandeis University — The dynamics governing networks of identical oscillators are unchanged by node interchange symmetries, or automorphisms, of the network. Equivariant dynamical system theory predicts such networks consequently must possess steady states, and flow invariant manifolds where particular nodes, exchanged by subgroups of network symmetries, are synchronized. Homogeneous microreactors containing the oscillatory Belousov Zhabotinsky (BZ) reaction, coupled by diffusion, allow the experimental study of symmetric self-driven oscillator networks. A ring of 4 inhibitory-coupled BZ reactors was studied as a model system. This system exhibits symmetric gaits found in quadrupedal animals as its attractors. Experimental invariant manifolds, steady states, and stabilities are compared to those theoretically predicted using methods generalizable to other networks.

11:39AM B61.00003: Domain wall creep and depinning: a scalar field model approach  NIRVANA CABALLERO (Presenter), University of Geneva - Bariloche Atomic Center - CONICET, EZEQUIEL FERRERO, Bariloche Atomic Center - CONICET, ALEJANDRO B. KOLTON, Bariloche Atomic Center - Balseiro Institute - CONICET, JAVIER CURIALE, VINCENT JEUDY, Laboratoire de Physique des Solides, Universite Paris-Sud, SEBASTIAN BUSTINGORRY, Bariloche Atomic Center - CONICET, THIERRY GIAMARCHI, University of Geneva — Domain wall motion is at the heart of new magneto-electronic technologies and hence the need for a deeper understanding of domain wall (DW) dynamics in magnetic systems. In this context, numerical simulations using simple models can capture the main ingredients responsible for the complex observed DW behavior. We present a scalar-field model for the magnetization dynamics of quasi-two-dimensional systems with a perpendicular easy axis of magnetization which allows a direct comparison with typical experimental protocols, used in polar magneto-optical Kerr effect microscopy experiments. We show that the thermally activated creep and depinning regimes of DW motion can be reached, and the effect of different quenched disorder implementations can be assessed with the model. Moreover, our model has material-dependent tunable parameters and allows to reproduce experimental velocity-field curves. In particular, we show how the structural disorder should be modeled to reproduce Pt/Co/Pt velocity-field curves in a broad range of temperatures (ranging from 4K to room temperature). We also use this model to make a connection with DW with defects such as bubbles and overhangs. We examine in particular observables such as the two-dimensional structure factor both numerically and analytically.
11:51AM B61.00004: Modeling the relative dynamics of DNA-coated colloids*  MIRANDA HOLMES-CERFON (Presenter), JAMES LEE-THORP, Courant Institute of Mathematical Sciences — A versatile way to make colloids with programmable interactions is to coat them with strands of sticky DNA. However, the DNA changes the dynamics of the colloids, in ways that can push the system out of equilibrium on experimental timescales. We construct a coarse-grained theoretical model for the relative dynamics of DNA-coated colloids (which is similar to models of molecular motors), and use it to argue that (a) DNA induces friction between the points of contact that can be about 100 times larger than hydrodynamic friction, for relevant experimental parameters, and (b) the friction for particles rolling could be several orders of magnitude smaller than the friction for sliding, when the DNA is very short and stiff. Therefore, we speculate that in certain experimental systems such colloids could act like gears, and assemble into metastable states that would not be observed in their true equilibrium.
