8:00AM X21.00001: Controlling emission and nonlinearity with plasmonic metamaterials* [Invited] VIKTOR PODOLSKIY (Presenter), University of Massachusetts Lowell — Metamaterials encompass a broad class of structures whose electromagnetic response is driven by their geometry in addition to their composition. Plasmonic nanowire metamaterials provide a platform for engineering optical response from dielectric to epsilon-near-zero to strongly anisotropic (hyperbolic) regimes. Importantly, these metamaterials support exotic additional electromagnetic waves. From the effective medium standpoint, these waves can be described by nonlocal (spatially dispersive) permittivity. In this talk we present a theory of nonlocal electromagnetism in nanowire metamaterials and analyze the effect of optical nonlocalities on spontaneous emission and nonlinear optics in these composites. We show that additional electromagnetic modes can drastically increase local density of photonic states, causing significant enhancement of decay rates. We also demonstrate that plasmonic composites can be used to engineer bulk second-order nonlinearities, with amplitude of effective nonlinear polarizability comparable to that in LiNb and KDP. Finally, we show that geometry of nanowire composites can be used as an important parameter to control polarization properties of structural second harmonic generation.

8:36AM X21.00002: Deterministic modal control of second-harmonic generations in a plasmonic two-wire transmission-line* TZU-YU CHEN, National Tsing Hua University, JULIAN OBERMEIER, MARKUS LIPPITZ, University of Bayreuth, CHENBIN HUANG (Presenter), National Tsing Hua University — A plasmonic two-wire transmission-line supports two modes, one with surface plamon fields strongly confined in the gap, the other loosely guided by the wire perimeters. Using the modal asymmetry provided by the loosely guided mode, we demonstrate a new way to allow second-harmonic generation (SHG). Moreover, we demonstrate both experimentally and theoretically the ability to deterministically control the SHG modes.

*Ministry of Science and Technology in Taiwan under grant MoST 106-2112-M-007-004-MY3.

8:48AM X21.00003: Large diffracted transverse magneto-optic Kerr effect in magnetoplasmonic crystals RAFAEL CICHELEIRO, MIKKO KATAJA, MARIANO CAMPOY-QUILES, GERVASI HERRANZ (Presenter), Institute for Materials Science of Barcelona ICMAB-CSIC — Phase-matching conditions are exploited to enable nonreciprocal optical propagation and enhanced magneto-optic responses in magnetoplasmonic systems [1]. Here we show that exploiting diffraction in conjunction with plasmons adds versatility and flexibility in the design of photonic systems. As a testbed we analysed the transverse magneto-optic Kerr effect (TMOKE) in Au/Co magnetoplasmonic gratings that combined magneto-optics, diffraction and plasmonics. Angular resolved measurements revealed narrow line-shape plasmon resonances, enabling large diffracted magneto-optical activity. We show that exploiting diffraction in magnetoplasmonic crystals allows unexpectedly large TMOKE responses that exceed 3% - one of order of magnitude larger than conventional TMOKE. Our results pave the way towards using magneto-optical modulation of SPPs to build non-reciprocal, active photonic components. We anticipate that our results can be used to design more complex diffractive surfaces, such as plasmonic metasurfaces, with the objective to enable creation of novel non-reciprocal photonic devices.

9:00AM X21.00004: Effects of Spatial Confinement on Nonlinear Light Emission from Plasmonic Nanostructures ROBERT LEMASTERS (Presenter), HAYK HARUTYUNYAN, Emory University — Photoluminescence (PL) from plasmonic nanostructures with spatial inhomogeneities have been demonstrated to exhibit an interesting nonlinear character [1,2]. Previous studies on rough metal films have shown the PL signal to have a wavelength dependent nonlinear scaling exponent which increases linearly with emitted photon energy [2]. This result was attributed to recombination of nonequilibrium electrons within the conduction band mediated by the breakdown of momentum restrictions as a consequence of the spatial inhomogeneities of the surface. However, in these experiments the spatial structures under study were random in nature. Thus, the degree of momentum breakdown and its effect on PL are not obvious from these results. To address this, we use a geometry of Au nanowires separated from Au films by nanometric SiO2 layers via ALD to control the degree of spatial confinement of the resonant gap-mode plasmons. Our results indicate that the PL signal from this nanoprecise system has a nonlinear power law exhibiting two distinct linear regimes, differing from that of rough films. This indicates that the physical mechanism of the nonlinear PL signal originating from thermalized hot electron relaxation needs to be revisited.
9:12AM X21.00005: Bistable shallow arches: a new building block for nonlinear mechanical metamaterials
ELEONORA TUBALDI (Presenter), University of Arizona, GABRIELE LIBRANDI, KATIA BERTOLDI, SEAS, Harvard University — Snap-through instability of shallow arches is a well-known phenomenon and it has been extensively investigated in the literature. However, the mechanics of shallow arches has not been exploited yet for engineering nonlinear mechanical metamaterials. In this study, we use shallow arches as building blocks for realizing snapping-through bistable nonlinear structures. By carefully assembling shallow arches in 2D arrangements, we can engineer fully snapping unit cells, which snap between two equally stable energy configurations. These unit cells can tile a 2D space which will have both bistability and snapping-through behavior. In this 2D array, the snapping of a unit cell triggers the snapping of the neighbor cells allowing the propagation of a "snapping wave" in the whole structure. We also show that it is possible to design snapping unit cell showing different configurations accordingly with the specific type of mechanical applied stimulus (i.e. moments, concentrated forces etc.). We successfully prove that a fully reversible nonlinear mechanical metamaterial by harnessing shallow arches snap-through instability is viable. This anticipates being a promising avenue because its versatility in both the 2D space tessellation and the shallow arch design (i.e. bilayer shallow arches).

9:24AM X21.00006: X-ray creation by relativistic electrons in a nanophotonic vacuum*
NICHOLAS RIVERA (Presenter), Massachusetts Institute of Technology, LIANG JIE WONG, Singapore Institute of Manufacturing Technology, JOHN D JOANNOPOULOS, MARIN SOLJACIC, Massachusetts Institute of Technology, IDO KAMINER, Technion Israel Institute of Technology — The vanishingly small response of matter to light beyond ultraviolet (UV) frequencies makes it challenging to leverage concepts from nanophotonics to manipulate the emission and propagation of light at such frequencies. Here, we show that free-electron based two-quanta processes allow tunable light sources from UV to gamma ray frequencies, without the need for any external electromagnetic fields. We find that the intentional design of vacuum fluctuations by tuning the permittivity of a material at IR frequencies allows one to exert direct control over the spectrum and intensity of output X-ray radiation. The per-electron power of such X-ray emission is comparable with that of synchrotrons employing a 0.1-1 T magnetic field. We find that this powerful emission derives its strength from the strong Casimir-Polder forces in the extreme nanoscale of materials. Fundamentally, our results reveal a way to apply the tools of nanophotonics even at frequencies where materials do not respond. They also constitute a new mechanism by which vacuum fluctuations can be used to generate high frequency light, potentially enabling new concepts such as compact and tunable sources of photons from UV-to-gamma-ray energies.

9:36AM X21.00007: Imaging collective behavior in an rf-SQUID metamaterial tuned by DC and RF magnetic fields*
ALEXANDER P. ZHURAVEL, B. Verkin Institute for Low Temperature Physics and Engineering, SEOKJIN BAE, STEVEN ANLAGE (Presenter), Physics Department, University of Maryland, College Park — We examine the collective behavior of two-dimensional nonlinear superconducting metamaterials using a novel imaging technique. The metamaterial is made up of self-resonating microwave oscillators in a strongly coupled 27 x 27 planar array of radio-frequency Superconducting QUantum Interference Devices (rf SQUIDs). By using low-temperature laser scanning microscopy (LSM) we image the photoresponse caused by local heating across the SQUID array, and this corresponds to the strength of oscillation of each meta-atom. Complex collective modes of the metamaterial which are not revealed in global measurements become visible to the LSM. The clustering of active meta-atoms in each collective mode of the metamaterial are imaged. We observe the rearrangement of coherent patterns due to meta-atom resonant frequency tuning as a function of external dc and rf magnetic flux bias. We find that the excited rf SQUID distribution across the metamaterial at zero dc flux and small rf flux reveals a low degree of coherence. By contrast, the spatial coherence heals upon increasing of rf flux amplitude. We discuss possible origins of such coherence variations.

MARC CAHAY, Department of Electrical Engineering and Computer Science, University of Cincinnati, Cincinnati, OH 45221, U.S.A,  
HANS PETER WAGNER, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, U.S.A — We investigated optically pumped lasing from zinc-doped GaAs nanowires (NWs) on a Au film and from NWs comprising a nominally 10 nm thick Au coating at temperatures ranging from 80 to 295 K. The NWs have an average diameter and length of 200 nm and 2.5 µm, respectively, and possess a 7 nm thin Al₂O₃ spacer layer surrounding the NWs. The NWs were optically excited with 150 fs laser pulses with a center wavelength of 770 nm which were provided by a Ti-Sapphire laser. Due to the shortness of the NWs only one longitudinal lasing mode resonates with the gain spectrum which extends from ~1.48 to 1.52 eV at 80 K. At higher temperature the lasing mode slightly shifts towards lower energy and weakens due to band-gap shrinkage and increasing non-radiative losses at surface states. The lasing output versus excitation power (L-L) plot at 80 and 295 K shows the characteristic “S” shape curve for NWs on Au. The L-L plot for Au coated NWs shows lasing at 80 K but suggests amplified spontaneous emission at 295 K due to higher plasmonic losses. A simulation of the experimental data with FDTD calculations reveals that lasing from NWs on Au is predominantly plasmonic while it has a hybrid photonic-plasmonic character in Au coated NWs.

10:00AM X21.00009: Characterization of a Single Quantum Meta-atom for a Superconducting Quantum Transmission Line Metamaterial*  
JINGNAN CAI (Presenter), STEVEN ANLAGE, University of Maryland, College Park — The quantum transmission line (QTL) metamaterial provides a unique opportunity to investigate emergent quantum phenomena, due to the strong coupling between the meta-atoms and the bosonic mode in the resonator as well as the quantum mechanical nature of such interaction. Two designs for QTL are considered in this study: flux and charge qubits embedded in a coplanar waveguide, the latter of which possesses interesting nonlinear coupling between neighboring meta-atoms that depend on the quantum state of the Josephson junction. Here we report the first step towards the realization of QTL metamaterial: the design, fabrication, and characterization of a single flux qubit in the coplanar waveguide. The characterization, which will eventually include vacuum Rabi splitting, Rabi oscillations, and quantum tomography, will be conducted through a microwave transmission measurement.  
*This work is supported by the Department of Energy through grant # DESC0018788

KYOUNGWEON PARK (Presenter), Air Force Research Laboratory, JAKE FONTANA, Naval Research Laboratory, JASON STREIT,  
JAMIE GENGLER, CARL M LIEBIG, RICHARD VAIA, Air Force Research Laboratory — Optical bandpass filters allow or reject a range of wavelengths. Metallic nanorods (NRs) and their assemblies are a promising platform for such components due to their intense light-matter interactions and ability to tune optical cross-section based on the NR’s aspect ratio and volume. Fabrication of arbitrary NR filter design however is challenging due to synthetic limitations on aspect ratio and inherent polydispersity. Herein we demonstrate design and fabrication of arbitrary optical notch filters with a flat top profile using new synthetic strategies combined with wavelength selective particle reshaping. Bandwidth and spectral profile is defined by a collection of NRs with narrow longitudinal plasmon resonances (LSPR) that define absorption and sharp roll-off at the filter edges. Laser irradiation transcribes transmission notches by reshaping a population of NRs in resonance with the LSPR. Furthermore, single or multiple transmission windows across the visible to mid-IR can be fabricated using polydisperse NRs or nanowires. Experimental validation of fabrication models confirm rational design of position, depth, and width of the transmission window, enabling manufacturing of complex optical elements (solutions or solid) not found in natural media.
10:24AM X21.00011: Tailoring Localized Surface Plasmon Resonances in Metallic Nanoarcs for Surface Enhanced Infrared Absorption Spectroscopy*  KUNYI ZHANG (Presenter), ODED RABIN, University of Maryland, College Park — Surface enhanced infrared absorption (SEIRA) takes advantage of the strong localized electromagnetic fields of metallic nanoantennas to amplify the optical absorption of molecules in the infrared region, which provides new opportunities for ultra-sensitive molecule detection. The maximum signal enhancement is predicted when the localized surface plasmon resonance (LSPR) frequency matches with the vibrational band of molecules. In this work, we established an empirical relation between the geometric parameters of gold nanoarcs on silicon wafers and their LSPR frequency. This relation was then utilized to design substrates for SEIRA measurements. The SEIRA signal evolves as the LSPR frequency is scanned from above to below the bond vibrational frequency.

10:36AM X21.00012: Large-scale testing and simulation of nanofabricated thermionic energy converters  PETER SCHERPELZ (Presenter), STEPHEN E CLARK, ARVIND KANNAN, HSIN-I LU, DANIEL MERTHE, Modern Electron — Thermionic energy converters are a potential technology for efficient, direct, and compact heat-to-electricity conversion with no moving parts. We discuss the testing and simulation of devices for thermionic conversion which incorporate a nanofabricated electrostatic lensing system to mitigate space charge. In order to achieve high performance, these devices must minimize loss of the vacuum electrons to the electrostatic grids, which requires precise modeling of electron emission and absorption. We demonstrate the use of a large experimental dataset, encompassing a variety of grid geometries and operating conditions, to validate and improve our model. Specifically, we show that including effects such as dielectric charging provides statistically significant improvements in agreement between experiments and kinetic particle-in-cell simulations. We then use these models to improve device performance, exemplifying the value of experimental validation.

Session X22 DCOMP DMP: Electrons, Phonons, Electron-Phonon Scattering and Phononics VIII  BCEC 157C - David Broido, Boston Coll - Tag(s): Focus
Computational quest for high-mobility 2D materials

Recently, we identified close to 2000 exfoliable 2D materials from first-principles calculations [1]. The next natural step is to explore their properties and look for novel or improved performance. Here, we are searching for electrostatically-doped 2D semiconductors with superior electronic transport properties.

A first goal is then to develop accurate and systematic workflows to compute phonon-limited mobilities [2]. These workflows identify the pockets of electronic states relevant to transport and the phonons needed to describe all possible scattering events within these pockets. Electron-phonon couplings are computed using density-functional perturbation theory with the appropriate 2D boundary conditions and gates to induce doping [3]. Notably, this comprehensive approach to electron-phonon scattering reveals the consistently large intervalley scattering and the subtle impact of doping on electron-phonon interactions. Finally, mobilities are obtained by solving the Boltzmann transport equation using an iterative scheme, combined with an exact integration of the delta functions associated with energy conservation.

Computing the mobility of all the materials in the database remains impractical. Instead, we learn the key features that characterize a high mobility 2D material from a first in-depth study of a small but diverse selection of materials. Density of states, carrier velocities, number of valleys, phonon energetics as well as intra- and inter-valley electron-phonon interactions all play a role. We then translate these observations into computationally affordable and quantifiable descriptors to identify the best candidates in the database.

Lattice dynamics and thermal conductivity in antiferromagnetic semiconductor MnTe

We discuss electronic, magnetic, vibrational and transport properties of the antiferromagnetic semiconductor MnTe. This work derives physically justified Coulomb repulsion, magnetic structure and exchange parameters from density functional theory and the Heisenberg model. Calculated vibrational density of states, magnon and phonon dispersions compare favorably with literature values and our measurements from neutron scattering experiments. First principles Peierls-Boltzmann phonon transport calculations are also presented and show good agreement with measured values. Our work demonstrates that vibrational and magnetic degrees of freedom do not strongly couple in MnTe.

Thermal conductivity of perovskite KTaO3 and PbTiO3 from first principles

The low thermal conductivity of piezoelectric perovskites is a challenge for high power transducer applications. We report first principles calculations of the thermal conductivity of ferroelectric PbTiO3 and the cubic nearly ferroelectric perovskite KTaO3. The calculated thermal conductivity of PbTiO3 is much lower than that of KTaO3 in accord with experiment. Analysis of the results shows that the reason for the low thermal conductivity of PbTiO3 is the presence of low frequency optical phonons associated with the polar modes. These are less dispersive in PbTiO3, leading to a large three phonon scattering phase space. These differences between the two materials are associated with the A-site driven ferroelectricity of PbTiO3 in contrast to the B-site driven near ferroelectricity of KTaO3. The results are discussed in the context of modification of the thermal conductivity of electroactive materials.

Work at the University of Missouri is supported by the Department of Energy, Basic Energy Sciences, Award DE-SC0019114.
In the presence of disorder, it is possible to reach a point where the phonon wave-packets do not propagate far enough to sample the periodicity of the solid, rendering impossible to attribute them a wave vector or a group velocity. This regime is often described by a harmonic theory introduced by Allen and Feldman [4].

We generalize the Peierls and Allen-Feldman approaches with a unified master equation, which enables reliable first-principles predictions of the thermal conductivity of any insulator, ranging from complex crystals to anharmonic glasses. We showcase this approach with an application to a thermoelectric material that displays ultra-low glass-like thermal conductivity and rattling phonon modes.

9:36AM X22.00007: Orbitally driven low thermal conductivity of monolayer gallium nitride (GaN) with planar honeycomb structure: a comparative study  
ZHENVEN QIN (Presenter), Zhengzhou University, GUANGZHAO QIN, RWTH Aachen University, XU ZUO, Nankai University, ZHIHUA XIONG, Jiangxi Science & Technology Normal University, MING HU, University of South Carolina — Monolayer gallium nitride (ML GaN) with honeycomb structure was successfully fabricated recently in experiments, generating enormous research interest for its promising applications in nano- and opto-electronics. By solving the Boltzmann transport equation (BTE) based on first-principles calculations, we performed a comprehensive study of the phonon transport properties of ML GaN, with detailed comparison to bulk GaN, 2D graphene, silicene and ML BN with similar honeycomb structure. We find that the thermal conductivity (κ) of ML GaN (14.93 W/mK) is more than two orders of magnitude lower than that of graphene and is even lower than that of silicene with a buckled structure. Systematic analysis is performed based on the study of the contribution from phonon branches, comparison among the phonon mode levels and phonon anharmonicity. Further deep insight is gained from the electronic structure. Resulting from the special sp orbital hybridization mediated by the Ga-d orbital in ML GaN, the strongly polarized Ga–N bond and its inhomogeneous distribution could lead to the intrinsic low κ of ML GaN. The unraveled orbitally driven low κ of ML GaN offers fundamental understanding of phonon transport and will shed light on further studies of phonon transport in 2D materials.

9:48AM X22.00008: Anomalous phonons in Pb_{0.5}Sn_{0.5}Te*  
AASHISH SAPKOTA (Presenter), JOHN TRANQUADA, IGOR ZALIZNYAK, YANGMU LI, Brookhaven National Laboratory, BARRY L. WINN, Oak Ridge National Laboratory — The (Pb_{0.5}Sn_{0.5})_{1-x}In_{x}Te system is of current interest because of its potential connection to topological superconductivity [1,2]. Recent inelastic neutron scattering (INS) measurements on powder samples of (Pb_{0.5}Sn_{0.5})_{1-x}In_{x}Te, x = 0 and 0.3, reported unexpected low-energy peaks (in the range of 1 to 2.5 meV) in the phonon density of states, which presently lack theoretical explanation [2]. To further determine the nature of these low-energy phonons, we recently performed an INS measurement on a Pb_{0.5}Sn_{0.5}Te (x = 0) crystal. The results reveal that dispersing longitudinal and transverse phonons are not the contributor. Instead, there exist diffusive phonons with spectral weight in the energy range of 1 to 2.5 meV and characteristics deviating from conventional behavior. This suggests that some localized non-dispersive modes are the source for the anomalous low-energy peaks in the density of states. However, a proper understanding of these diffusive excitations will require further study. [1] X.-L. Qi and S.-C. Zhang, Rev. Mod. Phys. 83, 1057 (2011), [2] K. Ran et al., Phys. Rev. B 97, 220502(R) (2018).

10:00AM X22.00009: Unified ab initio thermal transport theory for insulators*  
NAVANEETHA KRISHNAN RAVICHANDRAN (Presenter), DAVID A BROIDO, Boston College — In insulators, heat is carried by phonons. Standard ab initio methods to get the thermal properties of solids rely on the phonon quasiparticles being well-defined, and assume that the lowest order 3-phonon scattering sufficiently describes thermal transport. Here we show that this is not the case for weakly bonded solids, where phonon scattering is so strong that the standard phonon quasiparticle picture can break down, and 3-phonon scattering is insufficient to explain the experiments. To address this issue, we present a novel ab initio method that features an anharmonic many-body renormalization scheme to create well-defined phonon quasiparticles with weakened interactions, and includes both 3-phonon and 4-phonon scattering to obtain thermal transport properties [1]. With this approach, we accurately capture the measured phonon dispersions, thermal expansion and thermal conductivity of both weakly bonded solids like sodium chloride and strongly bonded solids like diamond. Our work presents a unified ab initio framework to accurately predict the thermal properties of solids with varying bond strengths.

*This work was funded by ONR MURI [No. N00014-16-1-2436] & DOE S3TEC-EFRC [No. DE-SC0001299/DE-FG02-09ER46577].
10:12AM X22.00010: First principles investigation of the impact of symmetry and dimensionality on thermal transport* TRIBHUWAN PANDEY (Presenter), CARLOS POLANCO, VALENTINO R. COOPER, DAVID PARKER, LUCAS LINDSEY, Oak Ridge National Laboratory — Symmetry and dimensionality reduction have a profound impact on lattice dynamics, phonon scattering and thermal transport. Here, we will present new insights developed from predictive first principles Boltzmann transport theory in 1D-Ba$_3$N and 2D-InSe and compare them with their bulk counterparts. In particular, for 1D materials new symmetry-based selection rules will be introduced and their effect on thermal conductivity will be assessed. Furthermore, the challenges related to thermal transport modelling in low dimensional materials will be discussed.

10:24AM X22.00011: Characterization of Analytical Thermal Conductivity Models Through Assessment Against Experiment and Simulation RAMYA GURUNATHAN (Presenter), RILEY HANUS, MAXWELL DYLLA, JEFF SNYDER, Materials Science and Engineering, Northwestern University — The Klemens/Callaway equations [Phys Rev 119 (2), 507-509 (1960)] model lattice thermal conductivity ($\kappa_L$) versus temperature and impurity concentration. This framework highlights the dominant phonon scattering mechanisms in a system, and is used for routine interpretation of experimental trends. The model predictions are often regarded as rough estimates due to the assumption of a monatomic lattice and Debye model dispersion. In this study, the Klemens model is applied to both experimental measurements and first-principles simulations of $\kappa_L$, where imperfections are introduced to scatter phonons. We demonstrate the proper application of this model to materials with complex unit cells, and resolve discrepancies over model inputs that can yield a factor of 2-10 difference in the predicted $\kappa_L$ values. Additionally, the model is demonstrated to provide robust predictions of point defect scattering strength in a wide range of materials, whose dispersion relations are known to deviate significantly from the Debye model. We demonstrate how the dispersion relation dependence of the model is, in practice, lifted, allowing for surprising agreement between analytical theory and experiment. Thus, we provide justification for using this model on systems with arbitrary dispersion relations.

10:36AM X22.00012: Thermal conductivity of wide band gap nitrides from first principles calculations* SAHIL DAGLI (Presenter), KELSEY MENGLE, EMMANOUIL KIOUPAKIS, University of Michigan — Wide band gap nitrides are of interest for applications in deep-UV optoelectronics and power electronics. Materials for these devices must be able to dissipate heat generated from operation, making thermal conductivity an important parameter for high-power applications. We have investigated the thermal conductivity of AlN, GaN, Al$_x$Ga$_{1-x}$N and BN polymorphs with first-principles calculations, with a focus on effects from compositional and isotopic disorder. We use density functional theory to calculate the phonon frequencies and interatomic force constants. This information is used to calculate the thermal conductivity using the solution from the full Boltzmann transport equation calculation. Our results provide understanding on the benefits of using isotopically pure compositions in increasing the thermal conductivity of wide band gap nitrides.

*This work was supported by NSF DMREF program (1534221). Computational resources provided by DOE NERSC (DE-AC02-05CH11231).

10:48AM X22.00013: Thermal transport through GaN-AlN interfaces with mass and force variance from first-principles CARLOS POLANCO (Presenter), LUCAS LINDSEY, Oak Ridge National Laboratory — We present thermal conductance calculations of a GaN-AlN interface using a Landauer formalism with all interatomic force constants (IFCs), including those relaxed at the interface, computed from density functional theory. A thorough convergence study of the conductance value is outlined, focusing on the effects of truncating long-range IFCs from polar materials and properly enforcing various symmetries and invariances. For example, enforcing the simple acoustic sum rule instead of using more advanced methods overestimates the conductance by 7% with a 35% overestimation of the optical phonon contributions. We compare our fully first-principles conductance with those using empirical mixing rules to define interfacial IFCs. Moreover, we contrast our calculations with values inferred from thermal conductivity measurements of GaN-AlN superlattices. Our calculations constitute initial steps towards a fully predictive framework of interfacial thermal conductance.

Nanoelectromechanical systems are highly sensitive to adhered particles, and by using frequency shifts caused by particle adhesion on the surface of the resonator, it is possible to obtain stiffness of the adsorbate in addition to its mass and position on the resonator. In order to conduct our experiments, we fabricated NEMS resonators using top-down fabrication techniques. We have measured their multimode resonance response using electrothermal actuation and piezoresistive detection. Matrix Assisted Laser Desorption and Ionization (MALDI) is implemented to deliver particles towards the resonator. We have detected and characterized, in-real time, 20-nm gold nanoparticles using the first four out-of-plane modes. Simultaneous measurements of multiple modes were accomplished using phase-locked loop circuits running in parallel. By using the frequency shifts of resonance frequencies, we propose a method in which we assume the analytes adhered on the beam are hemispherical to obtain mass and stiffness, size and positions of the analytes. The size and position values for individual nanoparticles obtained were verified with independent characterization under SEM. The measurements provided here confirms the utility of multimode NEMS detection technique with analytes down to 20 nm radius.

Mass and Stiffness Spectrometry of 20-nm Gold Nanoparticles by Nanoelectromechanical Systems

Mary Shultz (Presenter), Joam Marmolejos, Patrick Bisson, Tufts University — Soft interfaces are common in biology, the environment, and technological applications. Probing these, particularly when the interface is buried between two condensed phases presents many challenges. The only current method available for probing such interfaces with molecular specificity is the vibrational spectroscopy, sum frequency generation (SFG). SFG attains surface sensitivity due to its nonlinear nature. Due to nonlinearity, separating overlapping signals is difficult, usually leading to nonunique separation. This problem has long been recognized by SFG practitioners and several methods for determining the complex components of the signal have been devised. None produce an absolute measurement of the complex signal. This contribution reports a nonlinear interferometer, that not only addresses this issue but also complex measurement sensitivity due to its nonlinear nature. Project Mjolnir latest status will be presented.

8:24AM X23.00003: Project Mjolnir: High efficiency real time mass spearator and ion trap

Jason Burke (Presenter), Barbara Alan, Aaron Hellingber, Lawrence Livermore Nat Lab — A low energy mass separator and ion trap for the real time separation and trapping of radioactive isotopes has been developed. The apparatus consists of an ultra-high purity helium buffered electrostatic recoil gas stopper and RF carpet to guide ions from a radioactive source to the exit aperture. A natural helium jet created at the exit imparts momentum to the ions. The ions enter a large acceptance radio-frequency quadrupole ion guide which has a DC gradient applied to it. The ions are cooled in the residual helium buffer gas are damped and collimated and continuously injected into a quadrupole mass separator (QMS). Ions are mass and charge selected in the QMS and exit into another RFQ for further beam collimation before being injected into a linear ion trap. The entire apparatus has been designed to be able to continuously load the ion trap. The ion trap is physically small allowing a large solid angle to be covered by detectors to study of short-lived isomers. Project Mjolnir latest status will be presented.

Effective Realtime Data Processing using LabJack T-Series DAQs

Benjamin Montgomery (Presenter), Paul Nakroshis, University of Southern Maine — The ability to accurately collect and computationally process data from sensors in real time is crucial to many scientific experiments. This generally leads to cost-ineffective solutions from well-known manufacturers, usually tied to proprietary analysis software, or oft-crude home-built alternatives. In light of this issue, we have created an open-source python API for the LabJack T-series of DAQs as a powerful, cost-effective alternative that is extensible and accessible to users with varying backgrounds in programming. We demonstrate the efficacy of this interface in the context of gathering and processing data from a quadrant-cell photodiode used to monitor a torsion pendulum in real time, as well as highlighting a few notable advantages found processing data with the LabJack.

*Funding for the equipment used in this project comes from the University of Southern Maine.
8:48AM X23.00005: Measuring Hall Conductivity Using a Cantilever Torque Magnetometer*  Tiffani Paul (Presenter), Samuel Mumford, Stanford University, Amir Yacoby, Harvard University, Aharon Kapitulnik, Stanford University — We present Hall conductivity measurements of Corbino-disk patterned thin film samples on a cantilever-based torque magnetometer. When a voltage is applied across the sample and a magnetic field is applied through the sample plane, the Hall current provides a magnetic moment that interacts with the external magnetic field and yields a torque on the end of the cantilever. The symmetry of this technique eliminates contributions from longitudinal resistance, making Hall conductivity measurements of previously inaccessible materials possible. Following a demonstration of how we determine the elastic properties of the cantilever system, we discuss various realizations of the technique, including for transverse thermoelectric currents, and show preliminary results on simple electronic systems.

9:00AM X23.00006: Increase the sensitivity of magnetoelastic sensors by modifying the sensor geometry  Paula Gonzalez (Presenter), David Gandia, BCMaterials (Basque Center for Materials, Applications & Nanostructures, Andoni Lasheras, University of the Basque Country, Iban Quintana, Ik4-Tekniker, Jon Gutierrez, Maria Isabel Arriortua, University of the Basque Country, Ana Catarina Lopes, BCMaterials (Basque Center for Materials, Applications & Nanostructures — Magnetoelastic sensors have gained a huge interest during the last years. Due to their change on the resonance frequency in response to a mass load, they present the capacity to detect low amounts of different chemical or biological compounds in a precise, cheap, quick and wireless way. In this work, we present a novel approach to increase the sensitivity of that kind of sensors by changing the sensor geometry and by modifying the percentage of coated surface by a mass load. By this new approach, the sensitivity could increases more than a 1000% with respect to the commonly used rectangular shaped magnetoelastic sensors with an uniformly distributed mass load. This work correlates experimental and theoretical results to develop a new model able to quantify the mass attached to the magnetoelastic ribbons. Moreover, the influence of the sample geometry and coating distribution on different magnetic and magnetoelastic parameters such as the delta E effect, the position of the nodal point or the anisotropy field has been studied and significant differences have been observed.

9:12AM X23.00007: Optimal Optical Systems for Collecting Photoluminescence of Point Emitters  Juan Lizarazo Ferro (Presenter), Rashid Zia, Brown University — Many applications that leverage optics, and explorations in fundamental physics, are limited by the experimenter’s ability to collect luminescence from point emitters embedded in solid state hosts. Here we explore the limitations imposed by the common type of optical systems used for this purpose, and we compare them against proposed alternative designs. In addition to comparing their collection efficiency, these new designs are also analyzed for tolerance in the lateral and axial position of the emitters with respect to reference auxiliary surfaces or alignment guides. Ray-optics and FDTD simulations will be used to quantify the proposed alternatives. Both an objective composed of spherical surfaces and a metalens implementation will be presented.

9:24AM X23.00008: Fast Reflective Optic-Based Rotational Anisotropy Nonlinear Harmonic Generation Spectrometer  Jason Dinh Tran (Presenter), Baozhu Lu, Darius Torchinsky, Department of Physics, Temple University — Rotational anisotropy second harmonic generation (RA-SHG) has emerged as effective probe of structural and electronic symmetry of hard condensed phase systems, as well as a spectroscopic tool for investigating the energy-dependent nonlinear electronic properties of solids. A common implementation of this technique has involved sample rotation to obtain the maximal number of nonlinear susceptibility coefficients, leading to significant challenges in experimental alignment which have recently been overcome by diffractive optic-based approaches. However, the same diffractive optics that have opened up this metrology to a variety of new sample configurations have also restricted the RA-SHG spectrometer in both data acquisition speed and broadband spectroscopic capability. We describe the design and application of an RA-SHG spectrometer based almost entirely upon reflective optics that overcomes the wavelength-dependent shortcomings of current state of the art RA-SHG devices and provide examples of the apparatus’ application to a variety of test samples.
9:36AM X23.00009: Fourier Domain Rotational Anisotropy Second Harmonic Generation  BAOZHU LU (Presenter), DARIUS TORCHINSKY, Department of Physics, Temple University — We describe a novel scheme of detecting rotational anisotropy second harmonic generation (RA-SHG) signals using a lock-in amplifier referenced to a fast scanning RA-SHG apparatus. The method directly measures the $n^{th}$ harmonics of the scanning frequency corresponding to SHG signal components of $C_n$ symmetry that appear in a Fourier series expansion of a general RA-SHG signal. We will present measurements on a GaAs test sample to compare point-by-point averaging with the lock-in based method. We will discuss how, when divided by the $C_\infty$ signal component, the lock-in detected data allow for both self-referenced determination of ratios of $C_n$ components of up to 1 part in $10^4$ and significantly more sensitive measurement of the relative amount of different $C_n$ components when compared with conventional methods.

9:48AM X23.00010: High-Pressure Laser Floating Zone Furnace* JULIAN SCHMEHR (Presenter), MICHAEL ALING, ELI ZOGHLIN, STEPHEN WILSON, University of California, Santa Barbara — The floating zone technique is one of the most established methods in growing single crystals for materials research applications, due to its propensity to produce large, extremely high quality specimens. However, limitations in the ultimate pressures of growth atmospheres in standard furnace designs renders many compounds not suitable for crystal growth employing the floating zone technique, either due to excessive volatility or metastability. Here we demonstrate a high pressure laser floating zone system which pushes the envelope of processing pressure for this technique. Focused laser light allows for extremely sharp heating gradients, uniform radial heating profiles and high processing temperatures. In turn this allows for the implementation of a high strength metal growth chamber, allowing for greatly enhanced processing pressures. We demonstrate successful single crystal growths of a range of oxide compounds up to 10 kpsi applied gas pressures, a more than two-fold increase in processing pressures compared to commercially available floating zone systems.

*We gratefully acknowledge funding from the W.M. Keck Foundation.

10:00AM X23.00011: Advancing Silicon Atomic-Scale Applications* ROSHAN ACHAL (Presenter), MOHAMMAD RASHIDI, JEREMIAH CROSHAW, University of Alberta, DAVID CHURCHILL, CS, Memorial University of Newfoundland, MARCO TAUCER, TALEANA HUFF, University of Alberta, MARTIN CLOUTIER, JASON PITTERS, Nanotechnology Research Centre, ROBERT A WOLKOW, University of Alberta — Dangling bonds (DBs) on the surface of hydrogen-terminated silicon present an attractive basis for next generation atomic scale devices as they possess both ideal electronic properties and high thermal stability. One of the ultimate applications of DBs is the creation of atomic scale logic circuitry, where designs may reduce power consumption by several orders of magnitude. We use a Scanning Tunneling Microscope (STM) to fabricate proto-devices and other DB-based structures. Recent developments in the precise fabrication of DBs have enabled significant progress towards this goal. With these developments, new applications of DBs are also emerging. In one such application we demonstrate the use of DBs to store information at the atomic scale, including the ability to read out the information. Further, we demonstrate the potential to advance site selective chemistry on the surface through the reliable creation of reactive sites.

Session X24 DAMOP: Vortices, Rotation, Spin-orbit Coupling and Artificial Gauge Fields

BCEC 159 - David Feder, University of Calgary
So far, lattices of quantum vortices have been observed in axially symmetric, rotating superfluid 4He or rotating Bose-Einstein condensates (BECs). Vortex configurations in rotating superfluids lacking axial symmetry have been discussed theoretically, but experimental observation of such systems proves to be challenging. Here, we present a study of vortices in microscopic free, prolate superfluid 4He droplets rotating around their short axis. The vortices were doped with Xe atoms and studied via coherent x-ray scattering at the LCLS free-electron laser. It was found that the vortices form a distorted lattice within the droplet. We compare the shapes of classical droplets executing rigid body rotation to rotating prolate superfluid droplets, the angular momentum of which has contributions from quantum vortices and potential flow.

*This work was funded under the NSF grant DMR 1701077.

Recent advent of X-ray free electron lasers (XFEL) has enabled the study of rotation in free isolated superfluid 4He droplets. The work presented here extends our study of rotating quantum fluids to non-superfluid 3He droplets. Sub micrometer sized 3He droplets were obtained from free jet expansion of liquid 3He at temperatures less than 3 K and studied via X-ray scattering at the LCLS XFEL. The obtained shapes and sizes of rotating 4He and 3He droplets have been compared. In contrast to superfluid 4He droplets, 3He droplets (T = 0.15 K) are devoid of quantum vortices. Tracing of quantum vortices inside 4He droplets have been previously achieved by doping with large number of Xe atoms. This work presents the first experimental study of the formation dynamics of atomic clusters in a homogenous, vortex-free quantum fluid.

*NSF - DMR 1701077

Superstripe phases in Bose-Einstein condensates, possessing both crystalline structure and superfluidity, opens a new avenue for exploring exotic quantum matters—supersolids. However, complete detection and exploration of superstripes are still challenging in experiments because of the short period, low visibility and external factors such as magnetic field fluctuations or heating issues. Here we propose a scheme in a spin-orbit coupled BEC which overcomes these obstacles and generates a robust magnetic superstripe phase [i.e., only spin (no total) density modulation] with a long period and high visibility, ready for direct real-space observation. In the scheme, two hyperfine spin states are individually Raman coupled with a largely-detuned third state, which induce a momentum-space separation between two lower band dispersions, yielding an effective spin-1/2 system with tunable spin-orbit coupling and Zeeman fields. Without effective Zeeman fields, spin-dependent interaction dominates, yielding a magnetic superstripe phase with a long tunable period and high visibility. Our scheme provides a platform for observing and exploring exotic properties of superstripe phases as well as novel physics with tunable spin-orbit coupling.

Anderson localization in presence of spin-orbit coupling in an atomic Bose gas  
YUCHEN YUE
(Presenter), EMINE ALTUNTAS, FRANCISCO SALCES-CARCoba, ANDiKA PUTRA, CHRIS BILLINGTON, IAN SPIELMAN, Joint Quantum Institute, National Institute of Standards and Technology and the University of Maryland — Anderson localization (AL), describing the absence of diffusion in 1D noninteracting quantum particles in disordered media, is based on multiple scattering processes. Spin-orbit coupling (SOC) is an intrinsic property in many material systems. SOC’s spin-dependent alteration of band structure affects the scattering processes leading to AL. Both disorder and SOC are difficult to tune and control in-situ. Here we describe the interplay of tunable disorder (from optical speckle) and SOC (generated by two-photon Raman coupling) in quasi-1D Bose-Einstein condensates. We show that SOC can significantly decrease the impact of disorder, thereby increasing the conductivity of 1D systems.

Spin-Orbit Coupled Bosons in One Dimension: Entanglement Entropy and Dynamics*  
JUNHYUN LEE (Presenter), WILLIAM COLE, JAY SAU, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park — We study the entanglement and dynamical properties of a spin-orbit coupled Bosons which describe one-dimension ultracold atoms with Raman-induced spin-orbit coupling. The two component spin-orbit coupled Bose liquid was proposed as a platform for studying quantum criticality in itinerant magnets [1]. In the presence of strong spin-independent interactions and spin-orbit coupling, this spinor Bose liquid undergoes an interaction (or density) tuned quantum phase transition similar to those in itinerant magnetic solid state systems. Although the order parameter describes a broken $Z_2$ spin symmetry, the associated phase is qualitatively distinct from the Ising phase transition and has a dynamical critical exponent $z=2$, typical of a Lifshitz transition. We discuss the unusual entanglement and dynamical features of this Lifshitz critical point stemming from its non-integrablility and absence of Lorentz symmetry.

Ground state for trapped two-component Bose-Einstein condensates with synthetic spin-orbit interactions and magnetic fields*  
DAVID FEDER (Presenter), University of Calgary — The experimental realization of synthetic gauge fields in ultracold atomic gases has spurred great interest in the ground state and excitations of multicomponent Bose-Einstein condensates (BECs) in the presence of spin-orbit (SO) interactions and artificial magnetic fields, driven in part by the pursuit of topologically non-trivial states in these systems. While the characteristics of SO-coupled weakly interacting BECs in uniform geometries and in two-dimensional traps are well-understood, for example the existence of stripe phases, little work has been performed for fully three-dimensional harmonic potentials. In this work, the ground state is determined for interacting (effective) two-component BECs in the presence of Raman-induced synthetic SO interactions and magnetic fields, confined in three-dimensional traps. To ensure efficient calculations but also accurate results, the calculations employ a spatial mesh based on a finite element discrete variable representation. The results are compared with previous theory and simulation results and with experimental data where possible.

Rotating sonic black hole from Spin-orbit coupled Bose-Einstein condensate*  
INDERPREET KAUR (Presenter), SANKALPA GHOSH, Department of Physics, Indian Institute of Technology Delhi, New Delhi-110016, India — We show that an analog of rotating black hole namely, BTZ type can be realized in a quasi-2D spin-orbit coupled Bose-Einstein condensate without using any external rotation. In hydrodynamic approximation, the equation for phase fluctuations in the total density modes, that describes the phonon field is similar to the scalar field equation in 2 + 1 dimensions whose space-time metric can be identified with the metric of BTZ black hole. By time evolving the condensate in a suitably created laser-driven potential, we show that the moving condensate forms such rotating black hole in an annular region bounded by inner and outer event horizon as well as elliptical ergo surfaces. We identify the supersonic and subsonic zones and analyze the self-amplifying Hawking radiation that strongly depends on the spin-orbit coupled anisotropy. We calculate the density-density correlation function and show the distribution of the analog Hawking temperature on the event horizon.

Phases and phase transitions of Bose condensed light

VICTOR FLEUROV (Presenter), School of Physics and Astronomy, Tel-Aviv University, ANATOLY KUKLOV, Department of Physics, College of Staten Island — Bose-Einstein condensation of light [1] is characterized by two classical complex fields corresponding to two polarizations of light as well as by the distribution of dye molecules inducing light thermalization through dipolar transition coupled to the thermal bath of molecular vibrations. We emphasize a crucial role of removing the full degeneracy of the dipolar transition in forming algebraic order of the condensate in 2D. The resulting symmetries of the condensate can be characterized by groups $O(2) \times Z_2$, $O(2)$ and $Z_2$ order emerging before $O(2)$. [If the transition is triple degenerate, the symmetry becomes $O(4)$ which excludes the algebraic condensation at any finite temperature]. The main result of this work [2] addresses orientational disorder introduced by local dipolar anisotropy. It can destroy algebraic order in one-photon density matrix while preserving it in the two-photon one. This produces a condensate of photon pairs without any attraction between photons. We call such pairing geometrical.

Fermionic Superfluids in a Ring Trap

YANPING CAI (Presenter), DANIEL ALLMAN, PARTH SABHARWAL, KEVIN WRIGHT, Dartmouth College — Multiply-connected geometries provide a natural setting for studying transport properties of quantum phases of matter. We will report on an all optical approach to create ultracold fermionic superfluids in a ring-shaped trap. The conditions for creating and observing persistent currents in fermionic superfluids are somewhat different than experiments previously conducted with bosonic superfluids. We will report on initial efforts to create and observe persistent flow in a molecular BEC of of $^6$Li atoms. With this new platform for studying transport in dilute fermionic superfluids, we plan to study critical velocities and dissipation mechanisms across the BEC-BCS crossover, and in rings with different dimensionality.

*This research is funded by NSF (1707557)

Linked and knotted synthetic magnetic fields

CALLUM DUNCAN (Presenter), SUPA, Institute of Photonics and Quantum Sciences, Heriot-Watt University, CALUM ROSS, Maxwell Institute for Mathematical Sciences and Department of Mathematics, Heriot-Watt University, NICLAS WESTERBERG, MANUEL VALIENTE, SUPA, Institute of Photonics and Quantum Sciences, Heriot-Watt University, BERND J SCHROERS, Maxwell Institute for Mathematical Sciences and Department of Mathematics, Heriot-Watt University, PATRIK ÖHBERG, SUPA, Institute of Photonics and Quantum Sciences, Heriot-Watt University — We show that the realisation of synthetic magnetic fields via light-matter coupling in the Lambda-scheme implements a natural geometrical construction of magnetic fields, namely as the pullback of the area element of the sphere to Euclidean space via certain maps. For suitable maps, this construction generates linked and knotted magnetic fields, and the synthetic realisation amounts to the identification of the map with the ratio of two Rabi frequencies which represent the coupling of the internal energy levels of an ultracold atom. We consider examples of maps which can be physically realised in terms of Rabi frequencies and which lead to linked and knotted synthetic magnetic fields acting on the neutral atomic gas. We also show that the ground state of the Bose-Einstein condensate may inherit topological properties of the synthetic gauge field, with linked and knotted vortex lines appearing in some cases.

Kaleidoscope vortex lasers possessing orbital angular momentum

TING-HUA LU (Presenter), TENG-DE HUANG, GUAN-YING CHIOU, Department of Physics, National Taiwan Normal University — We propose an efficient and robust method to generate the kaleidoscope vortex beam by employing an astigmatic laser cavity with an extra-cavity cylindrical lens. The kaleidoscope vortex beam is arising from the superposition of Laguerre-Gaussian modes with the longitudinal-transverse coupling effect in the laser cavity. The superposed Laguerre-Gaussian mode leads to the formation of complex phase singularities and implies the participation of different optical orbital angular momentum involved in a single kaleidoscope vortex beam. We experimentally demonstrate that a series of kaleidoscope vortex beams with different symmetry are systematically achieved by using a simple setup. The output power of the laser is dependent on the cavity length. This approach is expected to create high-order optical vortex beams and pave the way for optical entanglement.
10:12AM X24.00012: Imbalanced Fermi gas in antiparallel magnetic fields*  
TAKAAKI ANZAI (Presenter), YUSUKE NISHIDA, Department of Physics, Tokyo Institute of Technology — We study a two-dimensional Fermi gas with the finite density imbalance between two spin components of atoms in antiparallel magnetic fields. The antiparallel magnetic fields act on two different spin components of atoms with same magnitude but opposite directions [1]. It was revealed in the absence of magnetic fields that the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state, where the Cooper pairing takes place with nonzero momentum, emerges in the phase diagram of an imbalanced Fermi gas. Therefore, it is an interesting problem to how the antiparallel magnetic fields compete or cooperate with the FFLO state. We investigate the ground-state phase diagram within the mean-field approximation. At the weak-coupling limit, we find that the FF state is stable with compare to the LO state when the chemical potentials of the two components lie right at Landau levels [2].

10:24AM X24.00013: Unified Spin Electrodynamics of Maxwell Bosons and Dirac Fermions  
FARHAD KHOSRAVI (Presenter), Electrical and Computer Engineering, University of Alberta, TODD VAN MECHelen, ZUBIN JACOB, Electrical and Computer Engineering, Purdue University — Bosons and fermions show similar spin and angular momentum textures. Studies of the spin for the surface plasmon polaritons (SPPs) propagating at the interface of an insulator and a metal, as well as the solutions of the Dirac equation propagating at the interface of a positive and negative fermionic mass media (known as the Jackiw-Rebbi problem (JRP)), show that both photons and fermions in these structures have fully transverse spin and form a momentum-decay-spin triplet. By solving Maxwell equations for bosons and Dirac equation for fermions we have derived these fundamental properties and have shown that they make consistent connection to the experimental results. We have also studied these spin properties in the cylindrical problems of an optical fiber (OF) for bosons, as well as the cylindrical problem of a Dirac wire (DW) for fermions. We have shown that the bosons in OF and fermions in DW show very similar spin and angular momentum textures with longitudinal and transverse spin components that are locked to their respective perpendicular component of the momentum. Our results present an important platform for the study of spin and angular momenta by making accurate predictions about the spin properties of bosons (fermions) by studying the spin of fermions (bosons).

JIN ZHANG (Presenter), University of California, Riverside, JUDAH F UNMUTH-YOCKEY, Syracuse university, JOHANNES ZEIHER, Max-Planck Institute of Quantum Optics, ALEXEi BAZAVOV, Michigan State University, SHAN-WEN TSAI, University of California, Riverside, YANNICK MEURICE, University of Iowa — Analog quantum simulations of lattice gauge theory are a promising direction in understanding high energy physics. We derive a Hamiltonian formulation for the (1+1)-dimensional Abelian Higgs model that is manifestly gauge-invariant. The Hamiltonian formulation of the Polyakov loop can be obtained by the same method, which makes it possible to study this order parameter for the confinement/deconfinement phase transition experimentally. The corresponding quantum simulator is an asymmetric multi-leg ladder of atoms trapped in optical lattices and interacting with Rydberg-dressed interactions, where the required quadratic attractive interactions can be realized. The finite size scaling of the energy gap created by the insertion of a Polyakov loop can be obtained accurately by choosing spin truncations (the number of legs in the ladder) properly, which are cross-checked by tensor renormalization group calculations and Monte Carlo simulations. Phase transitions and quench dynamics also can be studied with this quantum simulator.

*This work was supported in part by the U.S. Department of Energy (DOE) under Award Number DE-SC0010113 (YM) and DE-SC0009998 (JUY) and by the NSF under Grant No. DMR-1411345 (SWT). JZ was supported by MPG and the European Commission (UQUAM).

10:48AM X24.00015: Dynamics of active particles in Bose superfluids  
VISHWANATH SHUKLA (Presenter), Institut de Physique de Nice, Universite Cote d’Azur, France — We investigate the dynamics of active particles in two- and three-dimensional Bose superfluids at finite temperatures. We make use of a minimal model in which particles obey Newtonian dynamics and their equations of motion are self-consistently coupled with the Gross-Pitaevskii equation. We characterize the effective drag force acting on the particles at finite temperatures and study their interaction with vortices in both simple and turbulent environment. In particular, we elucidate the role played by the drag-force, mutual-friction and the Magnus force.

Friday, March 8, 2019 8:00 AM - 10:48 AM
8:00AM X25.00001: Observation of classical dynamical isolation in nonadiabatically modulated photonic cavities*
AVIK DUTT (Presenter), MOMCHIL MINKOV, QIAN LIN, Stanford University, LUQI YUAN, Shanghai Jiao Tong University & Stanford University, DAVID A. B. MILLER, SHANHUI FAN, Stanford University — We experimentally demonstrate the phenomenon of dynamical isolation in harmonically modulated photonic cavities. We achieve this by strongly modulating a fiber ring cavity at a rate much faster than its linewidth. Such a nonadiabatically modulated cavity can show complete suppression of intracavity power even for an on-resonance input, resulting in dynamical isolation of the cavity field from the input light, as predicted in a recent theoretical study by Minkov et al. [APL Photonics 2, 076101 (2017)]. This counterintuitive behavior is strikingly different from the adiabatic regime typically studied in modulated photonic cavities, where the intracavity field is enhanced when the cavity's instantaneous resonance frequency matches the input light's frequency. Our work shows that periodically driven photonic systems can exhibit classical versions of quantum effects such as dynamical decoupling, which rely on modulating an open system at a rate faster than the system-reservoir interaction. Such effects have applications in signal optimization and frequency conversion in integrated photonics.

*Vannevar Bush Faculty Fellowship (Grant No. N00014-17-1-3030) from the U. S. Department of Defense, MURI grant from the U. S. Air Force Office of Scientific Research (Grant No. FA9550-17-1-0002).

8:12AM X25.00002: Floquet quantum critical points in (1+1) dimensions
XUEDA WEN (Presenter), JIE-QIANG WU, Massachusetts Institute of Technology — Given a generic (1+1) dimensional quantum critical points which can be described by conformal field theory (CFT), we propose an analytically solvable setup to study the Floquet dynamics of the CFT, i.e., the dynamics of a CFT subject to a periodic driving. A complete phase diagram in the parameter space can be analytically obtained within our setup. We find two phases: the heating phase and the non-heating phase. In the heating phase, the entanglement entropy keeps growing linearly in time, indicating that the system keeps absorbing energy; in the non-heating phase, the entanglement entropy oscillates periodically in time, i.e., the system is not heated. At the phase transition, the entanglement entropy grows logarithmically in time in a universal way. Furthermore, we can obtain the critical exponent by studying the entanglement evolution near the phase transition. Mathematically, different phases (and phase transition) in a Floquet quantum critical point correspond to different types of Mobius transformations.

8:24AM X25.00003: Entanglement features of Floquet random and fully random unitary quantum circuits
WEI-TING KUO (Presenter), DANIEL AROVAS, YIZHUANG YOU, University of California, San Diego — We study the entanglement dynamics for Floquet random and fully random unitary circuits. The Floquet circuit consists of an on-site Haar random layer alternating with a nearest neighbor interaction layer. In the limit where the local Hilbert space dimension q is large, we show an emergent Ising symmetry and obtain an analytical expression for short time periods via the transfer matrix method. Based on our short time result, we promote the "entanglement feature" to an operator formalism and derive a diffusion equation for the entanglement dynamics at long times. The similar functional form of the corresponding diffusion operators implies a universal thermalization behavior in Floquet random and fully random unitary circuits.

8:36AM X25.00004: Single-photon bound states in atomic ensembles
YIDAN WANG (Presenter), Joint Quantum Institute, MICHAEL GULLANS, Department of Physics, Princeton University, ANTOINE BROWAEYS, Laboratoire Charles Fabry, Institut d'Optique Graduate School, CNRS, Universite Paris-Saclay, JAMES V PORTO, Joint Quantum Institute, DARRICK CHANG, Institut de Ciencies Fotoniques, ALEXEY V GORSHKOV, Joint Quantum Institute — We illustrate the existence of single-excitation bound states for propagating photons interacting with N two-level atoms. These bound states can be calculated from an effective spin model, and their existence relies on dissipation in the system. The appearance of these bound states is in a one-to-one correspondence with zeros in the single-photon transmission and with divergent bunching in the second-order photon-photon correlation function. We also formulate a dissipative version of Levinson's theorem for this system by looking at the relation between the number of bound states and the winding number of the transmission phases. This theorem allows a direct experimental measurement of the number of bound states using the measured transmission phases.
A flow equation approach to periodically driven quantum systems

8:48AM  X25.00005: Semiclassical Phase Reduction Theory for Quantum Dissipative Nonlinear Oscillators

YUZURU KATO (Presenter), HIROYA NAKAO, Department of Systems and Control Engineering School of Engineering, Tokyo Institute of Technology — The phase reduction theory is a framework for analyzing rhythmic dynamics of weakly perturbed classical limit-cycle oscillators. It has been widely used for analyzing synchronization properties of classical dissipative nonlinear oscillators, but it has not been formulated for quantum dissipative nonlinear oscillators in a general way. Thus, we formulate a phase reduction theory for quantum dissipative oscillators. More specifically, we derive a semiclassical multi-dimensional Langevin equation from a general master equation for quantum dissipative systems exhibiting limit-cycle oscillations, and reduce it to an approximate one-dimensional classical stochastic differential equation describing phase dynamics of the oscillator. The density matrix and power spectrum of the oscillator can be explicitly reconstructed from the reduced phase equation. As an example, we analyze synchronization properties of a quantum van der Pol oscillator with harmonic driving and squeezing. The proposed framework allows us to analyze the dynamics of quantum dissipative nonlinear oscillators by using a simple classical stochastic differential equation under semiclassical approximation.

9:00AM  X25.00006: Achieving transitionless quantum driving in a many-particle system via coupling to an auxiliary many-particle system of opposing statistics

RAFAEL HIPOLITO (Presenter), PAUL M. GOLDBART, Physics, The University of Texas at Austin — Transitionless quantum driving (TQD) in a quantum system driven by a time dependent Hamiltonian, \( H_0(t) \), is in principle always possible via the addition of a counterdiabatic term, \( H_1(t) \), as shown by Berry, and where \( H_1(t) \) is in general nonlocal. Time dependence of \( H_0 \) gives rise to a curvature term in the comoving frame, which can be described via a gauge field, that induces transitions between different states, and whose influence is exactly nullified by \( H_1(t) \). We explore an alternative way of achieving TQD in a many-particle quantum system (composed of either bosons or fermions), where all fields are coupled locally. In lieu of \( H_1(t) \), we locally couple the original system A to a second system B (whose particles carry statistics opposite to A's) via a gaugino field. We explore the relationships between the A and B systems and the gauge and gaugino fields necessary to achieve TQD, and show that these relationships have a SUSY-like character. To illustrate, we explore the suppression of the Schwinger effect in a 1+1 D gas of Dirac electrons coupled to a time-dependent electric field that results from the suitable coupling (via gauginos) to its SUSY like partner.

9:12AM  X25.00007: A flow equation approach to periodically driven quantum systems

MICHAEL VOGL (Presenter), Physics, University of Texas at Austin, PONTUS LAURELL, Physics, Oak Ridge National Laboratory, AARON BARR, GREGORY FIETE, Physics, University of Texas at Austin — We present a theoretical method to generate a highly accurate time-independent Hamiltonian governing the finite-time behavior of a time-periodic system. The method exploits infinitesimal unitary transformation steps, from which renormalization group-like flow equations are derived to produce the effective Hamiltonian. The method has a range of validity reaching into frequency regimes that are usually inaccessible via high frequency expansions. Our approach is demonstrated for many-body Hamiltonians where it offers an improvement over the more well-known Magnus expansion. We show how the method relates to the rotating frame approximation and how it can be used to approximately transform to a rotating frame where the exact transformation isn't tractable because infinitely many couplings are generated in an exact treatment. We compare our approximate results to those found via exact diagonalization.

9:24AM  X25.00008: Driven-dissipative coupled Ising models: a new non-equilibrium universality class

MICHAEL FOSS-FEIG, Army Research Lab, ALEXEY V GORSHKOV, Join Quantum Institute, MOHAMMAD MAGHREBI, Michigan State University — Driven-dissipative systems can potentially exhibit non-equilibrium phenomena that are absent in their equilibrium counterparts. However, phase transitions present in these systems generically exhibit an effectively classical, equilibrium behavior in spite of their non-equilibrium origin. In this talk, I investigate an experimentally motivated model where two Ising-like order parameters interact and form a multicritical point. Using perturbative renormalization group techniques, I show that a pair of inherently non-equilibrium multicritical points emerge. These non-equilibrium multicritical points exhibit a variety of exotic phenomena with no counterpart in equilibrium, including spiraling phase boundaries, the emergence of discrete scale invariance rather than the more familiar continuous scale invariance, and the violation of the fluctuation-dissipation theorem at all length scales, resulting in a system which becomes hotter and hotter at longer and longer wavelengths.
**9:36AM X25.00009: Driven-Dissipative Quantum Phase Transitions**  OSCAR VIYUELA GARCIA (Presenter), Department of Physics, Harvard University, JIASEN JIN, Department of Physics, Dalian University of Technology, ALBERTO BIELLA, CRISTIANO CIUTI, Laboratoire Matériaux et Phénomènes Quantiques, Paris Diderot University, ROSARIO FAZIO, Condensed Matter and Statistical Physics, ICTP, DAVIDE ROSSINI, Department of Physics, Universita di Pisa — In this talk, I will explain how quantum simulators can produce novel phases of matter known as driven-dissipative quantum phases. Just like equilibrium phases of matter, systems out-of-equilibrium display critical behavior when transitioning from an ordered to a disordered phase. However, the appearance of different steady-state ordering is of purely dynamical origin and cannot be reduced to the usual equilibrium results. Within this framework, I will show how a combination of powerful numerical and analytical tools beyond mean-field theory unveils novel phases of matter and quantum many-body physics not present under purely equilibrium conditions. I will also discuss how these effects and phases can be found using state-of-the-art quantum simulators.

**9:48AM X25.000010: Scrambling and Floquet in Conformal Field Theory**  RUIHUA FAN (Presenter), Physics Department, Harvard University, XUEDA WEN, Physics Department, Massachusetts Institute of Technology, YINGFEI GU, ASHVIN VISHWANATH, Physics Department, Harvard University — Scrambling and Floquet are two important subjects in the study of quantum dynamics but hard to describe in general. Conformal field theory provides an ideal platform to get more analytical understanding. My talk will be divided into two parts. In the first part, I will discuss scrambling in the unitary minimal models, by analytically calculating out-of-time-order-correlation functions. In particular I will focus on the early-time and late-time behaviors and how they are related to each other. In the second part, I will talk about Floquet physics for general 2D CFTs. The Floquet driving is implemented with the sine-squared deformation. I will discuss the heating features and their stability.

*R.F and Ashvin Vishwanath acknowledge funding from the Simons Foundation through Ashvin Vishwanath's Simons Investigator grant. R. F. was also supported by the Purcell fellowship. Yingfei Gu is supported by the Gordon and Betty Moore Foundation EPiQS Initiative through Grant (GBMF-4306). Xueda Wen is supported by the Gordon and Betty Moore Foundation's EPiQS initiative through Grant (GBMF-4303).

**10:00AM X25.000011: Random Lindblad Dynamics**  TANKUT CAN (Presenter), Initiative for the Theoretical Sciences, CUNY Graduate Center, SARANG GOPALAKRISHNAN, VADIM OGANESYAN, Physics, CUNY College of Staten Island, DROR ORGAD, Racah Institute of Physics, The Hebrew University of Jerusalem — The Lindblad superoperator is the generator of time translation for the quantum Markov master equation. We ask the question: what dynamics follow from a random Lindblad generator? To answer this, we define an ensemble of Lindblad superoperators using random matrix theory, and study the statistical properties its eigenvalues. In particular, we characterize the spectral gap (a.k.a. dissipative gap) which determines the asymptotic decay rate of typical operators in the Hilbert space. We find that the spectral gap is finite in the limit of infinite Hilbert space dimension, and described by a universal non-monotonic scaling function of the dissipative coupling constant.

**10:12AM X25.000012: Drive-dependent dissipation in open quantum systems regularized by thermal fluctuations**  RANGEET BHATTACHARYYA (Presenter), Indian Institute of Science Education and Research, Kolkata — We report an alternate formulation of the quantum master equation (QME) to describe the dynamics of a quantum system weakly coupled to a heat bath, in the presence of weak external drive. A key feature of this approach is the introduction of an explicit Hamiltonian to model the thermal fluctuations in the heat bath. We show that the resulting time coarse-grained dynamical equation for the quantum system has dissipators with a natural regulator, which emerges from an ensemble average over the fluctuations. Importantly, such regularized dissipators arise from the second-order contributions of both the external drive as well as the system-environment coupling. We show that the second-order drive terms, regularized to time-scales set by the fluctuations, result in dynamic drive-induced frequency shifts (such as Bloch-Siegert shifts) as well as drive-dependent relaxation phenomena (the Kramers-Kronig pair of the shift terms). We also present the experimental verification of the drive-induced dissipation terms using Nuclear Magnetic Resonance techniques. It is contemplated that such drive-induced dissipation will play important roles in quantum information processing.

10:24AM X25.00013: Dissipation-induced instabilities of two-component Bose-Einstein condensates in optical cavities  EZEQUIEL RODRIGUEZ CHIACCHIO (Presenter), ANDREAS NUNNENKAMP, University of Cambridge — We investigate the dynamics of a gas of ultra-cold spin-1 atoms inside an optical cavity, which is driven transversely by an external laser whose polarization is not aligned with that of the cavity field. By considering the atom population to be equally distributed between the +1 and -1 spin states, we obtain a two-component Dicke model with complex light-matter couplings. We study the effects of cavity losses on the system by computing the steady-state phase diagram and observe the emergence of dynamical instabilities in the form of limit cycles, induced by the interplay between coherent and dissipative processes. We characterize the physical mechanisms behind the unstable behavior and study the role of cavity fluctuations in the system.

10:36AM X25.00014: Low-cost ultrafast eigenstate transition without undergoing an adiabatic process  FATEMEH MOSTAFAVIKHATAM (Presenter), HAMIDREZA RAMEZANI, physics, university of texas rio grande valley — We introduce a class of non-Hermitian Hamiltonians that offers a dynamical approach to have complete population transfer from the ground state of a system to the ground state of a new system in no time. In particular, in our proposed 2×2 Hamiltonians, one eigenvalue is absolutely real and the other one is complex. This specific form of the eigenvalues helps us to exponentially amplify or decay the population in an undesired eigenfunction while keeping the probability amplitude in the other eigenfunction conserved. This provides us with a powerful method to have a diabatic process with the same outcome as its corresponding adiabatic process. In contrast to standard shortcuts to adiabaticity, our Hamiltonian has a much simpler form with a lower thermodynamic cost. Our proposed Hamiltonians not only have application in rapid population transfer but also can be used for tunable mode selection and filtering in acoustics, electronics, and optics.

Session X26 DQI: Quantum Optimal Control and Machine Learning BCEC 160B - Daniel Egger, IBM Research - Zurich - Tag(s): Focus

8:00AM X26.00001: Universal Quantum Control through Deep Reinforcement Learning*  MURPHY YUEZHEN NIU (Presenter), Massachusetts Institute of Technology, VADIM SMELYANSKIY, SERGIO BOIXO, HARTMUT NEVEN, Quantum A. I. Laboratory, Google — We discover in this work that deep reinforcement learning (RL) techniques are capable of solving complex multi-qubit quantum control problems robustly against control errors. We propose a control framework to jointly optimize over stochastic control errors and facilitates time-dependent controls over all independent single-qubit Hamiltonians and two-qubit Hamiltonians, thus achieving full controllability for any two-qubit gate. As an essential ingredient, we derive an analytic leakage bound for a Hamiltonian control trajectory to account for both on- and off-resonant leakage errors. We utilize a continuous-variable policy-gradient RL agent consisting of two-neural networks to find highest-reward/minimum-cost analog controls for a variety of two-qubit unitary gates crucial for quantum simulation. We achieve up to a one-order-of-magnitude of improvement in gate time over the optimal gate synthesis approach based on the best known experimental gate parameters in superconducting qubits, an order of magnitude reduction in fidelity variance over solutions from both the noise-free RL counterpart and a baseline SGD method, and two orders of magnitude reduction in average infidelity over control solutions from the SGD method.

*Claude Shannon research fellowship from MIT.

8:12AM X26.00002: Reinforcement learning using AlphaZero to optimize entanglement sythesis in circuit QED  FELIX MOTZOI (Presenter), MOGENS DALGAARD, JENS JAKOB SORENSON, JACOB F SHERSON, Aarhus University — We present an implementation of a reinforcement learning algorithm using deep neural networks and Monte Carlo tree search to demonstrate global optimization of the control landscape of superconducting qubits. Our findings show significant improvement in time and best-found fidelity compared to long established local-climbing methods such as GRAPE. Our research suggests that for increasingly complex quantum control problems (as system sizes and architectures grow), sophisticated machine learning may become a preferable tool for calibrating and optimizing high-performance quantum computing experiments.
Applications of machine learning and related techniques to quantum control problems
Sergio Boixo (Presenter), Murphy Niu, Vadim Smelyanskiy, Hartmut Neven, Google Inc. — NISQ quantum computers require precise quantum control to achieve the necessary high fidelity operations. Machine learning offers tools that can be applied to this task. For example, reinforcement learning is a promising paradigm for universal quantum control. In the case of superconducting qubits, this requires explicit bounds on qubit leakage. To achieve high fidelity operations, quantum control parameters are fine tuned experimentally. Machine learning techniques can be applied in the optimization process. Cross entropy benchmarking is a technique to extract the experimental fidelity for generic operations with high precision, providing the cost function for the optimization loop.

Filtering noise through quantum control in high-dimensional systems
Michael Hush, Harrison Ball, Claire Edmunds, Dennis Lucarelli, Michael Jordan Biercuk (Presenter), Q-CTRL — Engineering-inspired filter functions are a powerful heuristic for the development of noise-robust quantum logic operations. We expand on existing single-qubit approaches and present a generalized, computationally efficient framework to calculate filter functions for operations performed on D-dimensional manifolds such as pairs of interacting qubits (including spectator levels), and qudits. We describe the computational approach and illustrate application in both systems. Filter function predictions for noise susceptibility in Molmer-Sorensen entangling gates are experimentally validated via experiments on trapped ions, showing good agreement with no free parameters.

Fast, high-fidelity single-qubit gates in strongly coupled multi-qubit systems
Xiu Hao Deng (Presenter), Shenzhen Institute of Quantum Science and Engineering, SUSTech, Edwin Barnes, Sophia Economou, Virginia Tech — Increasing the coupling strength between qubits can speed up multi-qubit entangling gates, which is essential for implementing more complex algorithms on a quantum processor. However, there is a tradeoff: It becomes challenging to implement single-qubit gates in the strong-coupling regime because the relevant transition frequencies become strongly dependent on the states of other qubits. In a fixed-frequency processor, this leads to significant gate errors and fidelity loss if this effect is not taken into account. To avoid this issue, most works to date have focused on the weakly coupled regime where individual qubits retain their identity, albeit at the price of slow entangling operations. Even in the weak-coupling case though, errors due to inter-qubit coupling can still accumulate over the course of several gates applied in sequence. Here, we present a novel method to mitigate errors in single-qubit gates due to coupling to a second qubit that involves building the coupling-dependent frequency shifts directly into the gate design. This is achieved through a combination of pulse shaping and pulse sequencing. Our techniques provide a way to speed up two-qubit entangling gates without sacrificing the speed and fidelity of single-qubit gates.

Optimal Control for Robust Atomic Fountain Interferometers
Michael Goerz (Presenter), Paul Kunz, U.S. Army Research Laboratory, Mark Kasevich, Physics Department, Stanford University, Vladimir Malinovsky, U.S. Army Research Laboratory — Atomic fountain interferometers provide precision measurements of gravitational fields with unprecedented sensitivity. This provides a wealth of possible applications, from fundamental science such as testing the equivalence principle, to next-generation inertial navigation systems. Fundamentally, the atom interferometer is implemented by laser pulses driving Bragg-transitions between the momentum states of the atomic cloud. Signal contrast is limited by the ability to realize large-momentum-transfer atomic mirrors and beamsplitters with high fidelity and robustness with respect to laser amplitudes and initial velocity distribution of the atoms. Starting from a pulse scheme based on rapid adiabatic passage, we employ Krotov's method of numerical optimal control and ensemble optimization to find shaped laser pulses that yield an increase in fidelity and robustness by roughly two orders of magnitude.

Research was sponsored by the Army Research Laboratory and was accomplished under cooperative Agreement Number W911NF-17-2-0147.
9:36AM X26.00007: Hamiltonian Amplification  CHRISTIAN ARENZ (Presenter), Frick Laboratory, Princeton University, DENYS BONDAR, Department of Physics, Tulane University, DANIEL BURGARTH, Department of Mathematics, Aberystwyth University, CECILIA CORMICK, Universidad Nacional de Cordoba, HERSCHEL A RABITZ, Frick Laboratory, Princeton University — Speeding-up quantum dynamics is of paramount importance for quantum technology. However, in finite dimensions and without full knowledge of the dynamics, it is easily shown to be impossible. In sharp contrast we show that many continuous variable systems can be sped-up without such knowledge, given that the structure of the underlying Hamiltonian is known. We call the resultant procedure Hamiltonian amplification. The method relies on the application of local squeezing operations allowing to amplify even unknown or noisy couplings and frequencies by acting on individual modes. We discuss the performance, physical realisations, robustness and implications of Hamiltonian amplification. Furthermore, we show how to combine amplification with dynamical decoupling to achieve amplifiers that are free from environmental noise. Finally, a significant reduction in gate times of cavity resonator qubits illustrates one potential use of Hamiltonian amplification.

9:48AM X26.00008: Enhanced superconducting qubit gates via accelerated adiabatic evolution  HUGO RIBEIRO (Presenter), Max Planck Institute for the Science of Light, AASHISH CLERK, Institute for Molecular Engineering, University Of Chicago — Qubit gates based on adiabatic evolution are in principle attractive, as they exhibit in-built robustness: they are in principle insensitive to the amplitude, duration and phase of control pulses used to realize the gate. However, the requirement of adiabaticity makes them extremely slow, and hence impractical in many settings. Here, we show how counter-diabatic driving techniques can be used to design one and two qubit gates that have many of the advantages of purely adiabatic gates, but are at the same time fast. We focus on approaches based on accelerated STIRAP (stimulated Raman adiabatic passage) [1, 2], and on specific implementations in various superconducting circuit architectures (both for transmon style qubits, and for fluxonium style qubits).

10:00AM X26.00009: Optimized Single Flux Quantum Pulse Trains for High-fidelity Qubit Control*  KANGBO LI (Presenter), ROBERT F MCDERMOTT, MAXIM VAVILOV, University of Wisconsin - Madison — The hardware overhead associated with microwave control is a major obstacle to scale-up of superconducting quantum computing. An alternative approach to qubit control involves irradiation of the qubits with trains of Single Flux Quantum (SFQ) pulses, pulses of voltage whose time integral is precisely quantized to the magnetic flux quantum. SFQ pulses can be generated and delivered to the qubit via a proximal classical Josephson digital circuit, offering the possibility of a streamlined, low-footprint classical coprocessor for monitoring errors and feeding back to the qubit array. In this talk, we describe an approach for the derivation and validation of complex SFQ pulse sequences in which classical bits are clocked to the qubit at a frequency that is a factor of a few higher than the qubit oscillation frequency, allowing for variable pulse-to-pulse timing in the qubit control sequence. Optimized sequences allow fast, coherent rotations in the qubit 0-1 subspace while suppressing leakage out of the computational manifold. We present simulation results and demonstrate that the performance of optimized SFQ control sequences is comparable to that of microwave-based sequences, with significantly reduced hardware requirements.

*The Hilldale Fellowship.

10:12AM X26.00010: Minimal Time Robust Control for Superconducting Qubit Devices*  ERAN GINOSSAR (Presenter), JOSEPH ALLEN, Advanced Technology Institute, University of Surrey, ROBERT KOSUT, SC Solutions — Fault tolerant quantum computing requires quantum gates with high delity. Given limitations on the lifetime of the qubits two-qubit gate delities can be coherence limited if the gate times are too long, but decreasing the operation time of two-qubit gates is a non-trivial exercise. Optimal control techniques can be used to decrease the operation time in theory, but generally do not take into account the realistic nature of uncertainty within the system when doing so. We apply robust optimal control techniques to demonstrate that it is feasible to reduce the operation time of the cross-resonance gate in superconducting systems to under 100 ns with two-qubit gate delities of F > 0.999, where this gate delity will not be coherence limited and would thus be achievable in experimental operation. This is while ensuring the pulse is robust to some uncertainty in the system, and having chosen a parameterization that aides in experimental feasibility.

*We acknowledge financial support from the EPSRC grants (Grants No. EP/L026082/1 and No. EP/L02263X/1)
10:24AM X26.00011: Error robust quantum logic for superconducting circuits  HARRISON BALL (Presenter), PER J LIEBERMANN, MICHAEL HUSH, MICHAEL JORDAN BIERCUK, Q-CTRL — Superconducting quantum computers differ substantially in the physical implementation of quantum logic operations, and therefore exhibit divergent error processes across hardware systems. In this talk we describe error modeling identifying dominant error channels in superconducting circuits implementing both parametrically activated and cross-resonance two-qubit gates. We use these insights to derive new classes of error-robust controls which combine modulation of both fields mediating the entangling operation and unitary operations applied to individual qubits. We present both analytic and numerically optimized solutions which are designed to reduce sensitivity to time-varying noise in critical system parameters by orders of magnitude.

10:36AM X26.00012: Geometric formalism for constructing arbitrary single-qubit dynamically corrected gates  JUNKAI ZENG (Presenter), EDWIN BARNES, Virginia Tech — Implementing high-fidelity quantum control and reducing the effect of the coupling between a quantum system and environmental noise is a major challenge in developing quantum information technologies. In recent work, a geometrical pulse-shaping method was introduced to facilitate the design of time-optimized pulses that implement gates while suppressing quasistatic noise errors. This method works for resonant pulses that implement a subset of single-qubit gates corresponding to rotations of the qubit about an axis that is orthogonal to the noise fluctuation term in the qubit Hamiltonian. Here, we show that these earlier findings are a special case of a larger geometrical structure hidden within the time-dependent Schroedinger equation. In this framework, any noise-suppressing single-qubit gate corresponds to a closed three-dimensional space curve, where the driving fields that implement the robust gates can be extracted from the curvature and torsion of the space curves. This provides a systematic approach to obtain all possible driving fields that implement an arbitrary dynamically corrected gate in the presence of quasistatic noise. We show that similar geometrical structures exist for quantum systems of arbitrary Hilbert space dimension.

Friday, March 8, 2019 8:00 AM - 10:48 AM

Session X27 DQI: Quantum Foundations II  BCEC 160C - Matthew Pusey, University of Oxford - Tag(s): Focus

8:00AM X27.00001: Quantum theory cannot consistently describe the use of itself* [Invited]  RENATO RENNER (Presenter), DANIELA FRAUCHIGER, ETH Zurich — Can quantum theory be used to consistently describe an agent who herself uses the theory? If quantum theory was a universally valid theory, applicable to arbitrarily complex systems, then this should clearly be the case. To study the question, we consider a setup consisting of four computers that take the role of agents. They are programmed with the rules of quantum theory, which they use to derive statements about the outcome of particular measurements, as well as about the statements that the other computers derived. We then show that the computers sometimes arrive at contradictory statements. This indicates that quantum theory cannot be extrapolated to complex systems, at least not in a straightforward manner.

This talk is based on Frauchiger and Renner, "Quantum theory cannot consistently describe the use of itself," Nature Comm. 9 (2018).

8:36AM X27.00002: Why QBism is immune to no-go theorems [Invited]  RUEDIGER SCHACK (Presenter), Royal Holloway, University of London — In 2012, Pusey, Barrett and Rudolph published a no-go theorem ruling out a class of ontological models for quantum mechanics. In 2015, the first loop-hole free Bell tests confirmed the assumptions of Bell’s theorem, the most famous of all no-go theorems. In 2018, Frauchiger and Renner published a no-go theorem based on the Wigner’s friend thought experiment. Because each of these no-go theorems, and their many variants, rule out a number of competing interpretations, QBism has emerged significantly strengthened from these developments.

What is the reason QBism is immune to these no-go theorems? It is not that QBism is anti-realist; on the contrary, QBism strongly embraces a form of structural realism. The reason lies in the particular way QBism takes the Born rule to be fundamental. This talk will explain the QBist take on the Born rule and how it resolves the apparent contradictions inherent in some recent versions of the Wigner’s friend paradox.
9:12AM X27.00003: An incompleteness theorem for physics  JOHN MYERS (Presenter), Harvard University, F. HADI MADJID, Consultant — We show how Gödel's incompleteness theorems have an analog in quantum theory. Gödel's theorems imply endless opportunities for appending axioms to arithmetic, implicitly showing a role for an entity that writes axioms as logically undetermined strings of symbols. There is an analog of these theorems in physics, to do with the set of explanations of given evidence. We prove that the set of explanations of given evidence is uncountably infinite, thereby showing how contact between theory and experiment depends on activity beyond computation and measurement—a physical activity of logically undetermined symbol handling.

9:24AM X27.00004: Ambiguity in the branching process of Many-Worlds Theories  KATHRIN GERHARD (Presenter), RENATO RENNER, ETH Zurich — Quantum mechanics correctly predicts measurement results and is therefore considered a useful physical theory. However, in a recently proposed thought experiment by D. Frauchiger and R. Renner, agents use quantum theory to describe how other agents use the theory, and contradictory statements appear.

Among the most popular interpretations of quantum theory that try to circumvent such consistency problems are the many-worlds theories. They provide a collapse-free model of the physical world: The wave function of the universe evolves unitarily in time, and every time a measurement happens, the global state splits into branches. Each branch is taken to correspond to an eigenstate of the measured observable, and in that sense, all measurement outcomes happen, but each one in a different world.

In this talk, we present a theorem stating that none of the existing many-worlds theories can give a consistent model of a physical process. Our argument is independent of commonly raised objections to many-worlds theories such as the preferred basis problem or the meaning of probability. In connection with the Frauchiger-Renner thought experiment, we show that the branching process leads to an ambiguity when judging the reality of worlds.

9:36AM X27.00005: Testing Envariance on Quantum Computers*  LUKASZ CINCIIO (Presenter), WOJCIECH ZUREK, Los Alamos National Laboratory — Born's rule does not need to be postulated – it can be derived from entanglement-induced invariance, the symmetry of entangled quantum states [1]. The same envariance can be used as a foundation of quantum statistical physics, to derive microcanonical and canonical ensembles [2]. We discuss logical circuits needed to test these entanglement symmetries on quantum computers and explore the possibility of using envariance to benchmark quantum computers.

*This research was supported in part by DoE via LDRD program at Los Alamos, J. Robert Oppenheimer fellowship and in part by FQXi "Agency in the Physical World".

9:48AM X27.00006: Small violations of Bell inequalities for multipartite pure random states*  CRISTHIANO SILVA (Presenter), Chapman University, RAPHAEL DRUMOND, Federal University of Minas Gerais, ROBERTO OLIVEIRA, Brazilian Institute for Pure And Applied Mathematics — For any finite number of parts, measurements and outcomes in a Bell scenario we estimate the probability of random N-qudit pure states to substantially violate any Bell inequality with uniformly bounded coefficients. We prove that under some conditions on the local dimension the probability to find any significant amount of violation goes to zero exponentially fast as the number of parts goes to infinity. In addition, we also prove that if the number of parts is at least 3, this probability also goes to zero as the local Hilbert space dimension goes to infinity.

*Cristhiano Duarte thanks the International Institute of Physics for its support and hospitality. Cristhiano Duarte and Roberto Oliveira thank CNPq, CAPES and FAPEMIG for financial support during the execution of this project. Raphael Drumond acknowledges the financial support of Bolsa de Produtividade em Pesquisa from CNPq.
Hybrid Computation for Consistent Histories* ANDREW ARRASMITH (Presenter), LUKASZ CINCIO, Theoretical Division, Los Alamos National Lab, ANDREW T SORNBORGER, Information Sciences, Los Alamos National Lab, PATRICK J COLES, WOJCIECH ZUREK, Theoretical Division, Los Alamos National Lab — The consistent histories approach to quantum mechanics can be a valuable tool for studying many physical processes, ranging from the stochastic behavior of molecules to the quantum-to-classical transition. This approach resolves seeming paradoxes and allows us to apply classical logic to sequences of quantum events. Unfortunately, this tool has historically been limited to small systems or simple cases as the computational expense involved exponentially grows with both the system size and with the number of times considered on a classical computer, quickly becoming intractable. To remedy this difficulty, we present a hybrid quantum/classical algorithm suited for noisy intermediate-scale quantum computers that allows us to find and study consistent histories. We demonstrate the performance of this algorithm on the IBM and Rigetti quantum computers, and show a simulated demonstration of what will be possible on larger quantum computers. Finally, we discuss some potential future applications of this algorithm.

Observing a Quantum Measurement WALTER LAWRENCE (Presenter), Dartmouth College, University of Chicago — As a model quantum detector system, place a qubit in each path of a Stern-Gerlach apparatus, so that each qubit registers the passage (or not) of the atom along its path. Now, prepare a spin-1/2 atom with spin-up along X, send it through, and bring the paths back together after passing the quantum detectors. The spin qubit and the two detector qubits are now in a GHZ state. Of course to see this, one must (irreversibly) read out the individual detector states and measure the atomic spin with an ordinary “downstream” Stern-Gerlach system. While these all produce random outcomes, the appropriate products are definite, revealing the state. The products correspond to tensor product observables of which the GHZ state is an eigenstate. We can choose three independent, compatible observables to characterize the state. Two of our choices recover the usual Stern-Gerlach collapse scenario that one would get without the quantum detectors. The third detects the coherent superposition of both scenarios, finding the two detectors in a Bell state conditioned on the X-state of the atom's spin. Thus, when observing the detectors along with the atom, "which path" is compatible with “both paths.” Without the quantum detectors, one loses the option of measuring the third observable.
8:00AM X28.00001: Improved implementation of reflection operators* ANIRBAN NARAYAN CHOWDHURY (Presenter), University of New Mexico, YIGIT SUBASI, ROLANDO D SOMMA, Los Alamos National Laboratory — Quantum algorithms for diverse problems, including search and optimization problems, require the implementation of a reflection operator over a target state. Commonly, such reflections are approximately implemented using phase estimation. We provide a method that uses a linear combination of unitaries and a version of amplitude amplification to approximate reflection operators over eigenvectors of unitary operators using exponentially less ancillary qubits in terms of the precision of implementing the reflection. The gate complexity of our method is comparable to that of the phase estimation approach. We then extend our results to the Hamiltonian case where the target state is an eigenvector of a Hamiltonian whose matrix elements can be queried. Our results are useful in that they reduce the resources required by various quantum algorithms in the literature. Our improvements also rely on an efficient quantum algorithm to prepare a quantum state with Gaussian-like amplitudes that may be of independent interest. We prove a lower bound which shows that the implementation of the reflection operator is optimal in terms of the query complexity.

*ANC was supported partly by a Google Reserarch Award. YS and RS acknowledge support from the LDRD program at Los Alamos National Laboratory.

8:12AM X28.00002: Vibronic Molecular Spectra on a Universal Quantum Computer* NICOLAS SAWAYA (Presenter), Intel Labs — Calculating a molecule's vibronic spectrum is a hard problem in theoretical chemical physics, as any ground-state vibrational mode can couple to any excited-state mode via the Duschinsky transformation. Though this problem scales combinatorially on a classical computer, researchers have previously proposed an $O(M^3)$ scaling algorithm that solves the vibronic problem using a Boson Sampling Device. With a wholly different approach that uses the quantum phase estimation algorithm in the standard circuit model, we present a quantum algorithm that scales as $O(M^2)$ both in parallel classical and quantum operations, with linear circuit depth. Besides the scaling improvement, we also present methods that allow for substantial reductions of the number of samples collected. Additionally, because our measurement procedure does not destroy the vibronic state, the final state can be used in further computational analyses. Finally, we show how one would include finite temperature effects with a small cost. Our results are relevant to chemical/materials discovery and to the simulation of bosonic systems on a universal quantum computer.

*This research is funded by Intel Labs, a division of the Intel Corporation.

8:24AM X28.00003: Quantum Circuit and Algorithm Validation With Prove-It* WAYNE WITZEL (Presenter), KENNETH RUDINGER, Center for Computing Research, Sandia National Laboratories, ROBERT CARR, Computer Science, University of New Mexico, MOHAN SAROVAR, Sandia National Laboratories — Validating algorithm implementations is increasingly important, especially to distinguish implementation mistakes from noise inherent to so-called Noisy Intermediate-Scale Quantum (NISQ) technologies. Debugging a quantum computation is problematic because intermediate states cannot be probed without interfering with the computation. We demonstrate formal quantum algorithm verification using our versatile Python software package called Prove-It [1]. Prove-It is designed to be accessible, convenient, and extensible. It supports unlimited expressivity using LaTeX (including quantum circuit expressions), freedom to add and conveniently track axioms, flexibility to prove theorems independently in any order, and extensible automation capabilities.

8:36AM X28.00004: Hamiltonian and Lindbladian Parameter Estimation STEFAN KRASTANOV (Presenter), SISI ZHOU, Departments of Physics and Applied Physics, Yale University, STEVEN FLAMMIA, School of Physics, University of Sydney, LIANG JIANG, Departments of Physics and Applied Physics, Yale University — Estimating the parameters governing the dynamics of a system is a prerequisite for its control. We present a simple but powerful new method to estimate the Hamiltonian (or Lindbladian) governing a quantum system of a few qubits. Our method makes efficient use of all measurements taken of the system and it saturates the information-theoretic limits for such an estimator. Importantly, it is inherently robust to state preparation and measurement errors. It is not limited to evaluating only a fixed set of possible gates, rather it estimates the complete Hamiltonian of the system. The estimator is applicable to any Hamiltonian that can be written as a piecewise-differentiable function and it can easily include estimators for the non-unitary parameters as well. At the heart of our approach is a stochastic gradient descent over the difference between experimental measurement and model prediction.
8:48AM X28.00005: Quantum Computation with Quantum Schur Circuits* VOJTECH HAVLICEK (Presenter), Computer Science, University of Oxford, SERGI STRELCHUK, Applied Mathematics and Theoretical Physics, University of Cambridge, KRISTAN TEMME, IBM Research — Many quantum algorithms can be given as reversible classical circuits between a pair of quantum Fourier transformations. Here we study quantum circuits where QFT is substituted by the quantum Schur transform. This is motivated by Permutational Quantum Computing, a restricted computational model believed to capture nonclassical features of quantum computing.

A problem supporting this belief was the efficient approximation of matrix elements of the Young orthogonal matrices. While solvable efficiently with PQC, there was no efficient classical algorithm for this task. We give such algorithm by showing that the relevant PQC computation is a quantum Schur circuit and using symmetries of the Schur transformation.

Efficient classical approximation of transition amplitudes however does not mean that the circuits can be also efficiently sampled. We hence prove that quantum Schur sampling circuits with sparse enough output can be sampled from efficiently classically. Numerical study on a small number of qubits shows that a significant fraction of PQC satisfy this condition, allowing for their efficient sampling.

9:00AM X28.00006: Disentangling quantum algorithms using symmetry+ DANIEL GUNLYCKE (Presenter), SEAN A FISCHER, C STEPHEN HELLBERG, STEVEN POLICASTRO, SERGIO TAFUR, United States Naval Research Laboratory — Quantum entanglement is a natural phenomenon in quantum mechanics that has enormous significance in quantum information science, including quantum computing. It enters quantum states in algorithms through the application of multi-qubit quantum logic operations such as the CNOT and Ising gates. While deliberate entanglement adds power and efficiency to algorithms, unintentional entanglement can be undesirable for a variety of reasons. Unintentional entanglement adds complexity, often making the outcome of a given algorithm more difficult to understand, and potentially more sensitive to errors. Furthermore, it can be an indication that an algorithm has not been optimized. If we could transfer entanglement from our algorithms into the bases that define our systems, then we could potentially reduce our algorithms. Such algorithm reductions will be of outmost importance for resource-limited, noisy intermediate-scale quantum (NISQ) computers.

In this presentation, we will demonstrate how such a reduction could be achieved in a small quantum system using symmetry. In addition to reducing the needed resources, our quantum computer calculations show a significant improvement in accuracy.

9:12AM X28.00007: Finding paths with quantum walks MARK HILLERY (Presenter), Physics and Astronomy, Hunter College of CUNY — Quantum walks, which are quantum versions of random walks, have proven useful in the development of quantum algorithms. They have been used to study searches on different graphs. In most cases, the object of the search is a distinguished vertex. However, a quantum walk can find more general objects with a quantum speedup, e.g. extra edges or subgraphs that break the symmetry of the overall graph. They can also find a path from one marked vertex to another, and an example of that will be presented.

9:24AM X28.00008: Machine learning search for quantum algorithms* JIAN LIN (Presenter), ZHONG YUAN LAI, XIAOPENG LI, Department of Physics, Fudan University — Quantum algorithm design lies in the hallmark of applications of quantum computation and quantum simulation. Recent theoretical progress has established complexity-equivalence of circuit and adiabatic quantum algorithms. Here we utilize deep reinforcement learning methods to search for optimal Hamiltonian path in the framework of quantum adiabatic algorithm. We benchmark our approach in Grover search and 3-SAT problems, and find that the adiabatic algorithm obtained by our reinforcement learning approach leads to improved performance in the final state fidelity and significant computational speedups for both moderate and large number of qubits compared to conventional algorithms. Our approach offers a recipe to design quantum algorithms for generic problems through a systematic search. This approach paves a novel way to automated quantum algorithm design by artificial intelligence.

Adiabatic Grover’s Algorithm and Graph Theory

SAMUEL MENDELSON (Presenter), JAKE FARINHOLT, Naval Surface Warfare Center Dahlgren Division — Adiabatic Grover’s Algorithm generally assumes the problem Hamiltonian is diagonal in the computational basis. In this talk, we will show how to reinterpret Grover’s search algorithm as a Graph Theory problem, and conversely, we will show how to build the problem Hamiltonian for various graph search problems directly from the Graph Laplacian. Finally, we analyze the performance of the adiabatic algorithms under various graph constraints and provide evidence to suggest that the performance improves with the number of edges. We rigorously prove that the graph search algorithm is exactly Grover’s algorithm when the graph is complete.

Many-Body-Localization Transition in a Universal Quantum Circuit Model

ADRIAN CHAPMAN (Presenter), School of Physics, University of Sydney, AKIMASA MIYAKE, Physics and Astronomy, University of New Mexico — We develop both exact and approximate methods to compute out-of-time-ordered correlators for arbitrary universal quantum circuits, taking advantage of the mapping of quantum circuits to the dynamics of interacting fermions in one dimension. In this framework, the out-of-time-ordered correlator can be calculated exactly as a superposition of exponentially many Gaussian-fermionic trajectories in the number of interaction gates. We develop a variationally-optimized, Gaussian approximation to the spatial propagation of an initially-local operator by restriction to the fastest-traveling fermionic modes, in a similar spirit as light-front computational methods in quantum field theory. We demonstrate that our method can detect the many-body localization transitions of generally time-dependent dynamics without the need for perturbatively weak interactions.

Intermediate-Scale Full State Quantum Circuit Simulation by Using Lossy Data Compression

XIN-CHUAN WU (Presenter), Department of Computer Science, University of Chicago, SHENG DI, FRANCK CAPPELLO, HAL FINKEL, YURI ALEXEEV, Argonne National Laboratory, FRED CHONG, Department of Computer Science, University of Chicago — To develop, evaluate, and validate new quantum algorithms or quantum computers, we need tools to assess their correctness and fidelity. This requires the capabilities of quantum circuit simulation. However, the number of quantum state amplitudes increases exponentially with the number of qubits, leading to the exponential growth of the memory requirement for the simulations. In this work, we present our quantum circuit simulation by using lossy data compression. We simulate quantum circuits by full-state update technique, and the lossy data compression is applied to the quantum state vector. Our preliminary results suggest that we should be able to significantly increase the size of quantum simulations beyond 50 qubits for certain algorithms.

Low-depth parallelization of k-local gates and applications

BRYAN O’GORMAN (Presenter), WILLIAM HUGGINS, University of California, Berkeley, ELEANOR RIEFFEL, NASA Ames Research Center, BIRGITTA K WHALEY, University of California, Berkeley — Practical use of near-term quantum computers requires taking their limited connectivity into account when realizing quantum circuits. We address this embedding problem for families of quantum circuits defined by a hypergraph where each hyperedge corresponds to a potential gate. We show that any set of k-local gates on n logical qubits can be ordered and parallelized in O(n^{k-1}) depth using a linear arrangement of n physical qubits. The construction is completely general and achieves optimal scaling in the worst case. We demonstrate benefits of this construction for i) sets of mutually commuting gates, as encountered in the Quantum Alternating Operator Ansatz circuits of the generalized QAOA algorithm, and ii) sets of gates that do not commute but for which compilation efficiency is the dominant criterion in their ordering. We find polynomial speedups in cost with number of spin-orbitals and electrons for Trotterized time-evolution of fermionic Hamiltonians under the Jordan-Wigner transformation.

Low-depth parallelization of k-local gates and applications

Stationary Phase Method in Discrete Wigner Functions and Classical Simulation of Quantum Circuits

Lucas Kocia (Presenter), NIST, Peter J Love, Tufts University — We apply the periodized stationary phase method to discrete Wigner functions of systems with odd prime dimension using results from \( p \)-adic number theory. We derive the Wigner-Weyl-Moyal (WWM) formalism with higher order \( h \)-bar corrections representing contextual corrections to non-contextual Clifford operations. We characterize the stationary phase critical points as a quantum resource injecting contextuality and show that this resource allows for the replacement of the \( p^2t \) points that represent \( t \) magic state Wigner functions on \( p \)-dimensional qudits by \( \leq p^t \) points. We find that the \( \pi/8 \) gate introduces the smallest higher order \( h \)-bar correction possible, requiring the lowest number of additional critical points compared to the Clifford gates. We then establish a relationship between the stabilizer rank of states and their number of critical points and exploit the stabilizer rank decomposition of two qutrit \( \pi/8 \) gates to develop a classical strong simulation of a single qutrit marginal on \( t \) qutrit \( \pi/8 \) gates that are followed by Clifford evolution, and show that this only requires calculating \( 3^{t+1} \) critical points corresponding to Gauss sums. This outperforms the best alternative qutrit algorithm for any number of \( \pi/8 \) gates to full precision.

Quantum Simulation and Optimization in Hot Quantum Networks

Martin Schuetz (Presenter), Harvard University, Benoit Vermersch, Gerhard Kirchmair, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences, Lieven Vandersypen, QuTech and Kavli Institute of NanoScience, TU Delft, Juan Ignacio Cirac, Max-Planck-Institut für Quantenoptik, Mikhail Lukin, Harvard University, Peter Zoller, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences — We propose and analyze a setup based on (solid-state) qubits coupled to a common multi-mode transmission line, which allows for coherent spin-spin interactions over macroscopic on-chip distances, without any ground-state cooling requirements for the data bus. Our approach allows for the realization of fast deterministic quantum gates between distant qubits, the simulation of quantum spin models with engineered (long-range) interactions, and provides a flexible architecture for the implementation of quantum approximate optimization algorithms.

Manuel H. Muñoz-Arias, Pablo Poggi (Presenter), Ivan Deutsch, University of New Mexico — We study the implementation of a measurement-based feedback scheme to realize quantum nonlinear dynamics. We specifically study the Quantum Kicked Top (QKT), a standard paradigm of quantum chaos, in the context of an ensemble of spins. The scheme uses a sequence of (not-so) weak measurements of a collective spin variable and global rotations conditioned on the measurement outcome. We show that the resulting dynamics, ensemble averaged over many realizations, is governed by a combination of the QKT Hamiltonian and a non-unitary channel which vanishes in the semiclassical limit, recovering the Classical Kicked Top. We also analyze individual quantum trajectories, where we explore the emergence of chaotic behaviour and revisit the role of the measurement process in the quantum-to-classical transition.

Session X29 DQI: Hybrid Systems: Optomechanics and Microwave-Optical Transduction

BCEC 162A - John Teufel, NIST - Boulder - Tag(s): Focus
Quantum state transfer between microwave and optical frequencies is important in the development of modular quantum computation. Most schemes to realize such a hybrid interface are based on direct quantum transduction, which, nevertheless, has to fulfill stringent requirements such as high conversion efficiency and low added noise. Despite all the recent remarkable efforts, in practice, building a direct microwave-optical quantum transducer still remains a challenge. A possible way out is to generate entanglement between the two modes and use it as a resource for microwave-optical modes transfer through teleportation. In this work, we propose a heralded scheme to entangle microwave and optical modes via parametric down conversion in a generic cavity piezo-optomechanical system. By post-selecting a two-mode squeezed vacuum state, entangled microwave-optical photon pairs can be generated. The entanglement is verified by the Bell inequality violation for a wide range of feasible parameters, showing the potential of the entangled source for realizing quantum state transfer between microwave and optical frequencies.

In Part A: We will propose the experimental scheme for entanglement generation and detection.

*Supported by AFOSR MURI program, UChicago MRSEC (NSF DMR-1420709), NSF award NNCI-1542205, DOE and ARL.
An Optomechanical Transducer for Quantum State Transfer Between Infrared Light and Microwave. Part II: Measurement Results*  
GREGORY A PEAIRS (Presenter), Physics, University of California, Santa Barbara, MING-HAN CHOU, RHYS G POVEY, Institute for Molecular Engineering, University of Chicago, KEVIN SATZINGER, Physics, University of California, Santa Barbara, AUDREY BIENFAIT, HUNG-SHEN CHANG, CHRISTOPHER CONNER, ETIENNE DUMUR, JOEL GREBEL, YOUPENG ZHONG, ANDREW N CLELAND, Institute for Molecular Engineering, University of Chicago — Optomechanical systems provide a very interesting approach to frequency conversion between the microwave and optical domains, and in particular could provide a means to couple superconducting qubits to infrared telecommunications-wavelength signals. This capability would provide a compelling means to long-distance quantum communication. We have combined an aluminum nitride-based interdigital transducer (IDT) with a silicon-based one-dimensional optomechanical resonator, which together promise the necessary optomechanical and electromechanical coupling rates that would allow us to efficiently convert signals between infrared light and microwave electrical signals. We will present recent results using this device, including characterization of the electromechanical and optomechanical elements as well as classical operation using continuous-wave and time-domain signals.

*This work is supported by the Air Force Office of Scientific Research MURI program, the UChicago MRSEC (NSF DMR-1420709), and the Army Research Lab, and made use of the Pritzker Nanofabrication Facility, supported by the National Science Foundation’s award NNCI-1542205. E.D. was supported by LDRD funds from Argonne National Laboratory, and A.N.C. was supported in part by the DOE, Office of Basic Energy Sciences.

Two dimensional optomechanical crystal designs for microwave-optical transduction*  
RHYS G POVEY (Presenter), MING-HAN CHOU, GREGORY A PEAIRS, AUDREY BIENFAIT, HUNG-SHEN CHANG, CHRISTOPHER CONNER, ETIENNE DUMUR, JOEL GREBEL, YOUPENG ZHONG, ANDREW N CLELAND, University of Chicago — Conversion between microwave and optical frequencies via transduction with optomechanical devices is a topic of significant current interest, particularly for applications in quantum communication [1-3]. This process requires cooling the microwave-frequency mechanical resonator to the ground state, typically at mK temperatures. One dimensional optomechanical crystals have been operated in the quantum limit [4], but are limited by laser heating. Two dimensional structures may afford better thermal performance with only a minor reduction in optomechanical coupling strength. In this talk I will discuss ongoing efforts towards a two dimensional optomechanical crystal and cavity design, whilst using piezoelectric materials to convert microwave electrical signals to mechanical motion.

*Supported by the AFOSR MURI program, UChicago MRSEC (NSF DMR-1420709), the DOE, the ARL, and used the Pritzker Nanofabrication Facility supported by NSF NNCl-1542205.

Microwave-mechanical-optical transducer chip design innovations for noise mitigation*  
PETER BURNS (Presenter), BENJAMIN BRUBAKER, MAXWELL URMEY, SARANG MITTAL, ANDREW P HIGGINBOTHAM, CINDY A REGAL, KONRAD LEHNERT, JILA, University of Colorado Boulder — Viewed as resources for quantum information processing, microwave and optical fields offer complementary strengths. We simultaneously couple one mode of a micromechanical oscillator to a resonant microwave circuit and a high-finesse optical cavity, thereby realizing a mechanically mediated electro-optic converter. We have operated this converter at T < 100 mK, and demonstrated conversion efficiency of 47% and added noise of 38 photons [1]. In order to reduce the added noise from mechanical decoherence, we have integrated phononic shielding around the mechanical element. Changing the superconductor to NbTiN further reduces noise in the microwave circuit and conversion process.

9:12AM X29.00007: Low temperature measurement of SiGe properties for superconducting quantum circuits*  
MARTIN SANDBERG (Presenter), MARKUS BRINK, VIVEKANANDA ADIGA, JOSÉ CHAVEZ-GARCIA, JERRY M. CHOW, HANHEE PAIK, JASON ORCUTT, IBM Thomas J. Watson Research Center — Superconducting circuits is a promising technology for building a scalable quantum computer. One of the shortcomings of this technology is that there is at the moment no technology available to transport quantum information in and out of the cryogenic environment that the circuit operates in. In order to transfer quantum information from the chip out to a room temperature environment the signal has to be converted from single microwave photons to something that will not be awash by the thermal noise at 300K. Lately there has been several proposals for how to enable such conversion using microwave to optical transducer. One approach is to exploit the electro-optical effect in strained SiGe. SiGe is a mature technology for on chip optics but is not well explored for superconducting circuits. We have fabricated quantum circuits in the form of transmon style quantum bits (qubits) on a substrate containing SiGe with a thin buffer layer of epitaxial Si. We find that that the introduction of SiGe in the substrate stack does not degrade the coherence properties of the transmon qubit. From the coherence measurements we are able to extract bounds for the loss tangent of SiGe at millikelvin temperatures.

9:24AM X29.00008: Circuit cavity optomechanics approaching the ultrastrong coupling regime  
GABRIEL PETERSON (Presenter), University of Colorado, Boulder, SHLOMI KOTLER, FLORENT LECOCQ, X. Y. JIN, KATARINA CICAK, RAYMOND SIMMONDS, JOSE AUMENTADO, JOHN TEUFEL, National Institute of Standards and Technology — Many of the recent advances in quantum control and measurement of cavity optomechanical systems were enabled by the ability to reach the strong coupling regime, where the parametrically-enhanced optomechanical coupling rate is larger than any decoherence rate in the system. Ideally, the coupling could be further increased to the ultrastrong regime, where it approaches or exceeds the mechanical resonance frequency. In this talk, I will present experimental progress on a new architecture for cavity optomechanics where a mechanically compliant vacuum-gap capacitor resonates with a 3-dimensional microwave cavity. Compared to the planar superconducting microwave resonators used in previous experiments, the cavity resonator provides a similar vacuum coupling rate but superior power handling capability, allowing us to achieve driven optomechanical coupling rates improved by an order of magnitude over previous results. This architecture for microwave cavity optomechanics could therefore enable a new generation of experiments in the ultra-strong coupling regime.

9:36AM X29.00009: Generation of nonclassical states using quantum emitters in the metal-dielectric surface  
KARUN MEHTA, SHUBHRANGSHU DASGUPTA (Presenter), Indian Institute of Technology Ropar — We show that it is possible to generate optical photons in nonclassical states from a metal-dielectric interface using quantum emitters on the interface. The photons thus emitted into the surface plasmon (SP) mode from the initially excited emitters radiate out in free space in a cone-shaped geometry. When detected at two detectors, they exhibit anti-coalescence, a clear signature of nonclassicality. This also indicates that the photons are prepared in the path-entangled N00N-like states. These photons can be used for long-distance communication through free space or fiber. This technique is further scalable to a large number of photons. Such a system can therefore be employed as a building block for a distributed quantum network. We emphasize that our setup is different from the previously reported works in which the emitters get coupled to either propagating SP mode in a nanowire or the guided mode of a nanofiber, instead of the propagating SP mode on the interface. We find that the transmission probability of the photons into the free space is close to 0.7 from a silver-air interface, and therefore it is indeed feasible to implement our model using available technology.

9:48AM X29.00010: A three-dimensional optomechanical system for experiments in the quantum limit*  
BINDU MALINI GUNUPUDI (Presenter), SOUMYA RANJAN DAS, ROHIT NAVARATHNA, SUDHIR KUMAR SAHU, SOURAV MAJUMDER, VIBHOR SINGH, Indian Institute of Science — At low temperatures, microwave cavities are often preferred for the readout and control of a variety of systems. In this work, we present design and measurements of two independent mechanical resonator device coupled to a 3-dimensional rectangular waveguide cavity. We show that with a suitable modification to the electromagnetic field corresponding to the fundamental mode of the cavity, achieved by coupling a mechanical resonator, the circuit parasitic capacitance can be reduced significantly to as low as 13.7 ff. We perform measurements in the optomechanically-induced absorption (OMIA) regime on both the mechanical resonators, and demonstrate a single photon coupling strength of 12.5 Hz and a cooperativity of 40 for each mode. In addition, utilizing a low-impedance environment between the two-halves of the cavity, our design has the flexibility of incorporating a DC bias across the mechanical resonator which is often a desired feature in tunable optomechanical devices. With further improvements in device parameters, this system has the potential to reach the strong-coupling regime, enabling a wide range of quantum optomechanical experiments.

*We acknowledge support by the DAE under the Young Scientist Research Award, and by the UGC under the DSK Fellowship program.
10:00AM X29.00011: Study of coherent microwave-to-optical transduction using on-chip rare-earth ion devices*
JOHN BARTHOLOMEW (Presenter), JAKE ROCHMAN, JONATHAN KINDEM, ANDREI RUSKUC, ANDREI FARAON, Caltech — Quantum transducers will allow application-specific quantum hardware to accelerate the realization of large scale networks of entangled qubits. Rare-earth ions (REIs) in transparent crystals are one system suited to the development of quantum transducer technologies because of their ability to transfer entanglement between their highly coherent optical, electron-spin, and nuclear spin transitions. To harness this appeal, it is important to realize an integrated, on-chip architecture for REI quantum technologies to facilitate network connectivity with other quantum systems.

We will present the fabrication and characterization of on-chip REI devices based on $^{171}$Yb-doped yttrium orthovanadate ($^{171}$Yb:YVO$_4$). The devices combine nanophotonic waveguides or cavities with planar microwave waveguides. Waveguides allow spectroscopic measurements of the optical and spin transitions over broad frequency ranges facilitating studies in a variety of applied magnetic fields. We will report on the potential of this architecture for microwave to optical transduction, including its performance at zero-magnetic field, and suggest avenues for increasing the transduction efficiency.

*This work was supported by the Office of Naval Research and Northrop Grumman.

10:12AM X29.00012: Towards on-chip cavity-enhanced microwave to optical conversion using erbium doped crystals*
JAKE ROCHMAN (Presenter), JOHN BARTHOLOMEW, IOANA CRAICIU, CHUTING WANG, TIAN XIE, JONATHAN KINDEM, KEITH SCHWAB, ANDREI FARAON, Caltech — Generating remote entanglement between distant superconducting circuits via optical photons represents a crucial milestone towards the development of future quantum networks. Ensembles of rare-earth ions (REIs) coupled to optical and microwave cavities offer a promising architecture to achieve bidirectional coherent microwave to optical conversion by harnessing the strong coupling of REI ensembles to microwave and optical fields.

Here, we present an integrated platform composed of a superconducting microwave resonator and an amorphous silicon photonic resonator coupled to an erbium ensemble doped in the yttrium orthosilicate substrate. Our platform enables resonators with high quality factors in both the optical and microwave domain, while maintaining sufficient overlap between the optical and microwave fields required for the magneto-optical converter to achieve high efficiency. We present the fabrication of optical and microwave resonators and characterization of the platform's metrics such as microwave resonator losses due to static magnetic fields and circulating optical photons in the optical resonator.

*Jake Rochman acknowledges support from NSERC. The authors acknowledge support from the ONR Young Investigator Award and ARO/LPS CQTS.

10:24AM X29.00013: Photon super-bunching from a generic tunnel junction  
CHRISTOPHER LEON (Presenter), ANNA ROSLAWSKA, ABHISHEK GREWAL, OLLE GUNNARSSON, KLAUS KUHNKE, KLAUS KERN, Stuttgart, Max Planck Institute for Solid State Research — Generating correlated photon pairs at the nanoscale is a prerequisite to creating highly integrated optoelectronic circuits that perform quantum computing tasks based on heralded single-photons. Here we demonstrate fulfilling this requirement with a generic tip-surface metal junction. When the junction is luminescing under DC bias, inelastic tunneling events of single electrons produce a stream of visible photons of plasmonic origin whose super-bunching index is 17 when measured with a 53 picosecond instrumental resolution limit. The effect is electrically rather than optically driven – absent are pulsed lasers, down-conversions, and four-wave mixing schemes. This discovery has immediate and profound implications for quantum optics and cryptography, notwithstanding its fundamental importance to basic science and its ushering in of heralded photon experiments on the nanometer scale.

Reliable characterization for improving and validating accurate elementary quantum operations*  

TAKANORI SUGIYAMA (Presenter), University of Tokyo, SHINPEI IMORI, Hiroshima University, FUYUHIKO TANAKA, Osaka University — A reliable method for characterizing elementary quantum operations that is suitable for improving and validating their accuracies is indispensable for realizing a practical quantum computer. Current standard methods, e.g., randomized benchmarking, quantum tomography, and gate-set tomography, are not sufficient because they lack reliability or are not suitable for the improvement and validation. A new characterization method, called regularized self-consistent quantum tomography (RSCQT), is an attractive alternative and has superior properties such as (i) the high reliability guaranteed by the asymptotic convergence of predicted probability distributions to the true probability distributions, (ii) applicability of the estimates to conventional validation protocols, and (iii) availability of detailed information of errors on the operations. Here we derive the asymptotic convergence rate, which would be optimal, and show numerical results on 1-qubit system, which confirm the theoretical results and prove that RSCQT is useful in practice.

8:36AM X34.00002: Computer-assisted quantum dot tuning for quantum computation and simulation [Invited]
LIEVEN VANDERSYPEN (Presenter), QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Much progress was made using electrostatically defined semiconductor quantum dots as the basis for quantum computation and simulation. In these experiments, a desired potential landscape is formed in a two-dimensional electron gas by individually adjusting the voltages applied to multiple gate electrodes. As a result, the filling of each dot, its electrochemical potential and its tunnel coupling to neighboring dots or to reservoirs are precisely controlled. Next, control signals for initialization, manipulation and read-out of individual charges and spins are calibrated. Despite this encouraging progress, the field could move faster if tuning and calibration tasks were more extensively assisted or taken over by computer automation. We started work several years ago on automating the initial tuning of coupled quantum dots to the few-electron regime [1] and the subsequent setting of the interdot tunnel coupling [2]. In parallel, we also invested in efficient (fast) measurement methods and the use of virtual gates [3] that allow real-time manual tuning and speed up computer-assisted tuning as well. Currently, our focus is on automating repetitive tasks such as calibration or compensation for background charge switches. I will present our past and present tuning efforts and summarize recent physics experiments on 2x2 and 8x1 quantum dot arrays that are enabled by these tuning methods.

9:12AM X34.00003: Automated Tuning of Tunnel Couplings and Gate Operations for Semiconductor Spin Qubits [Invited]
PASCAL CERFONTAINE (Presenter), JULIAN DAVID TESKE, RENE OTTEN, SIMON HUMPOHL, MICHAEL A WOLFE, PATRICK BETHKE, HENDRIK BLUHM, JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, 52074 Aachen, Germany — Quantum computers require large numbers of qubits with access to high-fidelity initialization, control and readout. While spin qubits in gate-defined quantum dots have demonstrated many of these properties, they need to be individually tuned by adjusting the voltages applied to electrostatic gates. This is a manual and time-consuming process [1] which will become unfeasible for large arrays of qubits. To address this challenge we present an iterative machine-learning algorithm [2] for automated fine-tuning of quantum dots. We estimate the system response by Bayesian updates and thus reduce the number of required measurements. Benchmarks show that the algorithm is able to adjust the tunnel and lead couplings in a singlet-triplet (ST) qubit in GaAs within 5 iterations.

In addition to the calibration of static dot parameters, high-fidelity quantum operations require precise tuning of time-dependent voltage pulses with respect to incoherent and coherent errors. While decoherence can be reduced by numerical pulse engineering, inaccuracies in the qubit model used for pulse engineering can cause coherent errors in the experimental implementation. In order to remove these errors, we present a self-consistent calibration routine for single- and two-qubit gates [2], which can be extended to a larger number of qubits and different sets of quantum gates. We apply this approach to a ST qubit in GaAs, and show experimentally that single qubit gate fidelities of 99.5% can be reached [3]. We use an accurate qubit model to simulate the performance of the calibration routine, and show that two-qubit gate fidelities of 99.9% (99.99%) should be achievable in GaAs (Si).

[2] All our software packages maintaining high software-engineering standards are available open source, see www.quantuminfo.physik.rwth-aachen.de/code

9:48AM X34.00004: Strategies for Automated Tune-up of Quantum Dot Arrays [Invited] SEÁN M MEENEHAN (Presenter), HRL Laboratories, LLC — As quantum dot qubit devices grow beyond two or three dots, computer-aided tools for calibration and control become essential. The first stage in tuning up any quantum dot spin qubit is determining an appropriate set of voltage biases such that all dots are loaded in the desired charge configuration, a task which is already complex at the three-dot level. In this talk we describe an automated process, based on single-dot measurements, simple image analysis, and linear compensation modeling of the device, which enables estimation of arbitrary charge states for a multi-dot system. Crucially, the desired bias state is estimated in a way that keeps all inter-dot tunneling rates within an acceptable range. This ensures relevant charge transitions remain visible, even for dots far away from the electron reservoir, and allows navigation of subsequent charge stability diagrams using image processing techniques. We demonstrate that this method can fully automate tuning of a six dot Si/SiGe device into a configuration appropriate for exchange-only qubit operation, including location of appropriate bias windows for spin preparation and measurement, and a validating demonstration of coherent spin rotations.
Fulfilling the promise of quantum technologies requires to be able to measure and tune several devices; fault-tolerant factorization using a surface code will require ~10^8 physical qubits. A long-term approach, based on the success of integrated circuits, is to use electron spins in semiconducting devices. A major obstacle to creating large circuits in this platform is device variability. It is very time consuming to fully characterize and tune each of these devices and this task will rapidly become intractable for humans without the aid of automation.

I will present efficient measurements on a single quantum dot performed by a machine learning algorithm. This algorithm employs a probabilistic deep-generative model, capable of generating multiple full-resolution reconstructions from scattered partial measurements. Information theory is then used to select the most informative measurements to perform next. The algorithm outperforms standard grid scan techniques in different measurement configurations, reducing the number of measurements required by up to 4 times.

I will also show the use of Bayesian optimisation to tune a single quantum dot device. By generating a score function, we can make the algorithm find the operating regime of a device. We tune the device to the single-electron tunnelling regime searching in a high-dimensionality parameter space in less than a thousandth part of the time that it requires manually.

Friday, March 8, 2019 8:00 AM - 11:00 AM

Session X35 DQI: Characterization and Reduction of Noise in Quantum Computing Architectures I

8:00AM X35.00001: AI for qubits [Invited] LEV BISHOP (Presenter), IBM Thomas J. Watson Research Center — I present theoretical and experimental progress in applying classical AI techniques toward improving transmon-based qubit systems, including readout, hamiltonian estimation and gate calibration.

8:36AM X35.00002: Investigating Crosstalk and Correlated Errors with Randomized Benchmarking on Multiple Qubits* CHRISTIAN KRALFUND ANDERSEN (Presenter), STEFANIA BALASIU, JOHANNES HEINSOO, ANTS REMM, SEBASTIAN KRINNER, JEAN-CLAUDE BESSE, SIMONE GASPARINETTI, CHRISTOPHER EICHLER, ANDREAS WALLRAFF, ETH Zurich — Quantum computing with superconducting circuits has recently shown progress in implementing multi-qubit quantum processors with promising performance. To ensure scalability of these systems for quantum applications, it is critical that any errors remain small, local, and uncorrelated when increasing the number of qubits. In particular, the threshold theorem for quantum error correction is typically derived under the assumption of uncorrelated errors and constant error rates for each qubit. In this talk, we will present characterizations of cross-talk during gate operations using an extended simultaneous randomized benchmarking (RB) protocol. We apply sequences of randomly chosen elements from the single qubit Clifford group simultaneously on up to four qubits and use single-shot readout to measure individual qubits and all $σ_z$-correlators between the qubits. From these measurements, we estimate the multi-qubit error as the average $n$-qubit infidelity per application of $n$ single-qubit Clifford gates. We find the correlated errors to be composed mainly by two-qubit correlations. We also extend this method to analyse the crosstalk and correlated errors induced during two-qubit RB.

*We acknowledge support by ODNI, IARPA, via the US ARO grant W911NF-16-1-0071 and by the NCCR QSIT.

8:48AM X35.00003: Pairwise Perturbative Ansatz for Quantum Process Tomography Part 1: Theory* LUKE GOVIA (Presenter), GUILHEM RIBEILL, MATTHEW WARE, HARI K KROVI, Raytheon BBN Technologies — As candidate quantum processors increase both in size and fidelity, so too does the need for robust verification and validation of their operation. Full characterization of these devices would be highly desirable; however, standard quantum process tomography scales exponentially with the number of qubits. Even for small scale systems, the experimental resource requirements make full tomography very challenging in practice. To circumvent this, we present an ansatz to describe an arbitrary quantum process on a multi-qubit system that only requires characterization of two-qubit processes, such that the number of measurements scales only quadratically with the number of qubits. Our Pairwise Perturbative Ansatz (PAPA) builds a description of the multi-qubit process from tomographic reconstruction of the reduced two-qubit processes on all pairs of qubits in the system. In part 1 of this talk we outline the PAPA approach to multi-qubit process tomography, and show through theoretical simulation how it can be used for excellent characterization of multi-qubit quantum processes.

*This work was funded by the U.S. Army Research Office under Contract No: W911NF-14-C-0048.
In part two of this talk we present a Pairwise Perturbative Ansatz (PAPA) reconstruction of a three qubit process. For this demonstration, we perform GST characterization on neighboring pairs of qubits in a fully connected three qubit system. The local GST reconstructions constrain the global process. As outlined in part one, this data is used to bootstrap a description of a three qubit process from multiple two-qubit reconstructions. Such an ansatz could lead to characterization techniques that scale favorably in the number of qubits while making few assumptions about the structure of system noise.

*This material is based upon work supported by the U.S. Army Research Office under Contract No: W911NF-14-C-0048. Any opinions, findings and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the U.S. Army Research Office.*

Characterization of realistic noise environments is crucial to the design of optimally tailored control methods for error suppression, and to the validation of microscopic models of noise. In particular, spatial correlations between noise afflicting distinct qubits are important in the determination of thresholds for fault-tolerant quantum computation. Recently, spin-locking relaxometry has been implemented to measure the single-qubit spectrum of quantum noise in superconducting circuits. In this talk, we present a generalization of this technique to two-qubit systems, enabling to simultaneously reconstruct the single-qubit and cross-correlation spectra of quantum dephasing noise. We also present simulations showing how this technique can be experimentally benchmarked using two superconducting qubits exposed to engineered photon shot noise from a common microwave cavity mode.

To investigate these assumptions experimentally, there is a need to extend established noise spectroscopy techniques from single- to multi-qubits systems. In this work, we present experiments on correlated dephasing of two superconducting qubits due to photon shot noise in a shared microwave cavity. Utilizing both free and driven evolution protocols, we demonstrate a frequency-selective method to probe the two-qubit correlations, and show how quantum noise spectroscopy techniques can reconstruct both single-qubit and two-qubit cross-spectra.

We illustrate our work with data from both simulation and demonstration of the protocol run through the full stack at Rigetti Computing. By incorporating a model of the experiment that is aware of the controllable parameters, these tools can often help to identify and characterize Fourier-sparse drift in quantum gates, measurements, and state preparation operations. Cumbersome at best, in this talk, we discuss a suite of quantum circuit experiments and data analysis tools that is capable of identifying and characterizing Fourier-sparse drift in quantum gates, measurements, and state preparation operations. Identifying the source of this drift is a critical first step on the path to mitigating it, but techniques to do so have been cumbersome at best. In this talk, we discuss a suite of quantum circuit experiments and data analysis tools that is capable of identifying and characterizing Fourier-sparse drift in quantum gates, measurements, and state preparation operations. Furthermore, the effect of imperfect measurement bases and the resulting projections must be considered. In this work we adapt the framework of RB to MZM qubits with measurement-based gates and expand upon it by offering a protocol to directly characterize the fidelity of the underlying measurements themselves.

Randomized Benchmarking of Majorana Based Qubits

KENNETH RUDINGER, ERIK NIELSEN, ROBIN BLUME-KOHOUT, Sandia National Laboratories — The performance of a quantum computer depends critically on a large number of highly-tuned parameters. Time dependence (drift) in these parameters is generally unheralded, but can have a pernicious and possibly devastating impact on quantum gate fidelities. The effect of impermanent measurement bases and the resulting projections must be considered. In this work we adapt the framework of RB to MZM qubits with measurement-based gates and expand upon it by offering a protocol to directly characterize the fidelity of the underlying measurements themselves.
10:36 AM X35.00012: Calibration for single-qubit gates using robust phase estimation* WILLIAM KIRBY (Presenter), Tufts University, SHELBY KIMMEL, Middlebury College — Constructing single-qubit unitary gates with high accuracy is necessary for most implementations of gate-based quantum computation. A crucial component of this task is gate calibration, which requires methods for measuring the discrepancies between actual, physical gate implementations and ideal gates. In this talk we describe improved practical methods for quantifying such discrepancies using robust phase estimation, which requires only weak assumptions about the initial accuracies of the gate implementations.

*This work is supported by the NSF Graduate Research Fellowship Program under Grant No. DGE-1842474.

10:48 AM X35.00013: Calibrating two-qubit gates via robust phase estimation* KENNETH RUDINGER (Presenter), Center for Computing Research, Sandia National Laboratories, GUILHEM RIBEILL, LUKE GOVIA, MATTHEW WARE, Raytheon BBN Technologies, SHELBY KIMMEL, Department of Computer Science, Middlebury College — Robust phase estimation (RPE) is a Heisenberg-limited characterization protocol for learning the phases of quantum gate operations. Unlike many other similar techniques, RPE requires neither ancillae qubits nor highly accurate state preparation and measurement. Additionally, the computational requirements of RPE are minimal, needing nothing more complex than inverse trigonometric functions. To date, RPE has been used for single-qubit gate characterization and calibration. We extend RPE for two qubits, showing that it may be used to learn the phase for any standard two-qubit gate (e.g., CNOT, CPHASE, Molmer-Sorensen, SWAP, cross-resonance, etc.). We provide both numerical and experimental results.

Session X36 DCMP: Novel f- and d-electron Materials: Skutterudites and Pnictides BCEC 205C
- Tag(s): Invited

8:00 AM X36.00001: Dynamical Mean Field Theory and the Iron Pnictides and Chalcogenides* [Invited] GABRIEL KOTLIAR (Presenter), Rutgers University and Brookhaven National Laboratories — Dynamical mean field theory (DMFT) in its combination with realistic electronic structure methods, now enables the computation of physical properties of materials starting from first principles. It also gives unexpected insights into the physics of strongly correlated systems.

We will illustrate these two aspects of the method, using the theory of Hund metals as an example. These are systems which derive their correlations from the Hund rule coupling rather than the Hubbard U. Primary examples are the iron pnictides and chalcogenides and the ruthenates. In this talk I will describe recent progress in understanding this class of materials using Dynamical Mean Field Theory and advanced quantum impurity solvers. We will stress in which way Hund correlations are different from those of materials near a Mott insulating state and on how the normal state characteristics of Hund metals impact their superconducting states at lower temperatures[2].

We will conclude with current directions to address outstanding challenges in this field[3].

[3] Work on the development of Dynamical Mean Field Theory based electronic structure methods is supported by the DOE DMR Computational Material Science program.
Overview of Experimental Results on Filled Skutterudites with Pt-Ge framework

ROMAN GUMENIUK (Presenter), Institute for Experimental Physics, Freiberg University of Mining and Technology, WALTER SCHNELLE, ANDREAS LEITHE-JASPER, YURI GRIN, MPI CPfS — Filled skutterudites are compounds with the body-centred (space group \textit{Im}-3, \(a = 9\) Å) crystal structure and total chemical formula \(MT_4X_{12}\) (structure type LaFe\(_4\)P\(_{12}\)), where \(M\) = alkaline, alkaline-earth, rare-earth or actinide metal, \(T\) is a transition metal of Fe-subgroup and \(X\) is a pnictogen-atom. Their structural arrangement belongs to the group of the so-called cage-compounds, where positively charged filler-atoms (i.e. \(M\)-component) are situated inside large voids formed by a covalently bonded atomic framework (i.e. \(T_4X_{12}\)). Such a combination of different types of chemical bonding together with vibrational dynamics of the filler results in numerous exciting physical phenomena (e.g. superconductivity, heavy fermion and Kondo behaviours, charge-density wave, thermoelectric properties etc.). In the past decade we succeed in the preparation and study of the physical properties of filled skutterudites with the new Pt-Ge framework and total formula \(MPt_4Ge_{12}\) (\(M\) = Sr, Ba, Ce, Pr, Nd, Eu, Sm). {Sr, Ba, La, Pr}Pt\(_4\)Ge\(_{12}\) are superconductors with high transition temperatures (i.e. up to \(\sim 8\) K). The complete characterization of their properties, which included \(\mu\)SR and penetration depth measurements, revealed LaPt\(_4\)Ge\(_{12}\) to be a multi-gap superconductor, while the PrPt\(_4\)Ge\(_{12}\) is an unconventional superconductor with nodes in the energy gap. CePt\(_4\)Ge\(_{12}\) is found to be a system at the very border between typical intermediate valence and true Kondo lattice behaviour. SmPt\(_4\)Ge\(_{12}\) is a high-pressure phase with the moderate heavy fermion behaviour. Filled skutterudites {Nd, Eu}Pt\(_4\)Ge\(_{12}\) show Curie-Weiss paramagnetism in the temperature range 10-400 K and complicated magnetic structures with multiple orderings below 2 K.

Comprehensive Study of Electronic Structure of Rare-Earth (R) Filled Skutterudites, RPT\(_4\)Ge\(_{12}\)

KHANDKER F. QUADER (Presenter), Kent State University — Materials whose properties are influenced by presence of f-electrons are of current interest. Experiments on rare-earth filled skutterudites demonstrate an intriguing array of thermodynamic, transport and superconducting properties, and bring to fore theoretical challenges posed by f-electron systems. First principle calculations, such as density functional theory (DFT), sparse in the skutterudites, can provide valuable information about electronic structures that can be compared with experiments, and utilized in further theory development. The talk will discuss a comprehensive electronic structure study on a series of rare earth filled skutterudites, RPT\(_4\)Ge\(_{12}\) (\(R\) = La, Ce, Pr), aimed at shedding light on aspects that may be useful for understanding some of their properties: consequences of progressive increase of f-electrons in the series; role of correlation “\(U\)” between the f-electrons and its importance relative to spin-orbit coupling; the nature and variation of 3D Fermi surfaces with the number of f-electrons and “\(U\)”. The calculated Fermi surfaces may be relevant to the currently debated issue of multi-band versus single-band superconductivity; the density of states (DOS) and bands can be compared with resonant photoemission spectroscopy and specific heat measurements, and provide estimates of effective masses; the pseudogaps in DOS may be useful for understanding possible thermoelectric applications. These DFT calculations were cross-checked with VASP and Wien2K programs, and done for different exchange functionals; hence may serve as benchmark calculations for these materials.

*This work is funded in part by a QuantEmX grant from ICAM and the Gordon and Betty Moore Foundation, Grant GBMF5305.
Correlated materials are known to give rise to interesting physical properties such as superconductivity, colossal magnetoresistance, metal to insulator transitions, orbital and charge ordering, etc. In this talk I will present theoretical results for d- and f-systems, obtained with a method based on a combination of density functional theory (DFT) and dynamical mean field theory (DMFT). Due to recent development of forces for structural relaxations in DFT+DMFT method, we are now able to gain further insight into the couplings between electronic and structural degrees of freedom in the vicinity of a Mott transition, thus giving us predictive power for the electronic and structural properties of the correlated materials. Applying this method to AMnO3 (A=Bi,La) oxides, we find unusual electronic states with orbital selectivity, such as Site- and Orbital-Selective Mott state or Orbital-Selective Mott state. I will describe the electronic properties of such states and I will argue that: (1) these switchable novel states are a consequence of a highly sensitive interplay of the lattice with the electronic degrees of freedom of the correlated d-electrons and sp-electrons of the A ions; (2) based on the new understating of these electronic states we can explain the resonant x-ray scattering measurements, which till now could not be explained by other theoretical models. In addition, by comparing the DFT+DMFT structural relaxations at finite temperatures with the experimental crystal structures, we show that DFT+DMFT can capture the fine structural distortions induced by these unusual electronic states much better than DFT, thus confirming the predictive power of the DFT+DMFT method. I will end my talk discussing theoretical correlated electronic structure of filled skutterudites RPt4Ge12 (R=Ce,Pr) and comparison with experimental photoemission spectroscopy data.

*This work is supported by the U.S. Department of Energy as a part of the Computational Materials Science Program.

Soft-modes and electronic topological transitions in p- and d-electron materials

MICHAEL WIDOM (Presenter), Carnegie Mellon University — The Fermi surface of a metal can be altered through the application of isotropic pressure, symmetry-breaking anisotropic strains, or chemical substitution. Changes in Fermi surface topology, such as the opening of a gap, or the creation or disappearance of a pocket, are known as Lifshitz transitions, and can dramatically influence the electronic, magnetic and mechanical properties of a material. This talk will focus on two examples of such transitions: the Burgers distortion that transforms body centered cubic metals to hexagonal close packed is driven by a Jahn-Teller-Peierls transition associated with a pseudogap in d_{xy} orbitals created by symmetry breaking; the collapse transitions in tetragonal AFe2As2 pnictides (A = Ca, Sr, Ba) are driven by the disappearance of a p_z electron pocket upon the application of pressure. These collapse transitions are contrasted with the discontinuous tetragonal to orthorhombic transition in CaFe2As2, which is thermodynamic rather than mechanical in character. Both the Burgers distortion and the collapse transition are connected with soft mode behaviors.

Session X39 GMAG DMP: Magnons, Spin Waves, and Magnetic Dynamics

Topological magnons on a kagome lattice

RANJANI SESHADRI (Presenter), DIPTIMAN SEN, Indian Institute of Science — A system of spins on a kagome lattice interacting via the nearest-neighbor XXZ interaction (anisotropy ratio Δ) and Dzyaloshinskii-Moriya interaction (strength D) is found to have a very rich phase diagram. In the classical limit, five distinct phases with different ground-state spin configurations are found by varying the two interaction parameters. In some of these phases, spin-wave theory using the Holstein-Primakoff transformations is used to find the bulk energy bands of the magnons. In the ferromagnetic phase, where all the spins point along the +z direction, the bulk bands are separated from each other by finite energy gaps. Finding the Chern numbers here, one finds that there are four topologically distinct phases sharing the same ground state spin-configuration. Hence an infinite strip of the system hosts robust edge states which are directly related to the Chern number of the bands. The other phases, however, are found to have gapless magnon bands.
8:12AM X39.00002: Spin waves in doped graphene with in-plane magnetic fields* MATTHEW ANDERSON (Presenter), CARSTEN ULLRICH, University of Missouri — Plasmonics in graphene and related 2D materials has attracted much interest, with many prospects for novel applications. However, the dynamics of collective spin excitations and spin waves in 2D materials has been much less explored. Here, we study the spin-wave excitations of itinerant electrons in doped graphene in the presence of in-plane magnetic fields. We calculate the spin-wave dispersions using time-dependent density-functional methods within a standard tight-binding approach. Dynamical exchange-correlation effects are treated using the Singwi-Tosi-Land-Sjolander (STLS) approach, generalized for systems with noncollinear spins.

*This work was supported by Research Corporation and by DOE Grant No. DE-SC0019109

8:24AM X39.00003: Relation between unidirectional magnetoresistance and magnon generation by spin current* IGOR BORISENKO (Presenter), VLADISLAV DEMIDOV, Physics, University of Muenster, SERGEI URAZHDIN, Emory University, SERGEJ DEMOKRITOV, Physics, University of Muenster — Ferromagnet/spin Hall effect (SHE) material bialayers are central to modern active nanomagnetic devices. The unidirectional magnetoresistance (UMR) observed in such structures – the asymmetry of resistance with respect to the current direction – has been explained in terms of spin-dependent electronic transport [1], or alternatively the effects of SHE-induced magnon generation [2].

We report on electrical measurements of UMR in a Permalloy/Pt bilayer, performed in conjunction with magneto-optical Brillouin light spectroscopy of spin current-driven magnon population. We show that the current dependence of UMR closely follows the dipolar magnon density, and that both dependences exhibit the same scaling over a large temperature range of 80-400 K. These findings demonstrate a close relationship between spin current-driven magnon generation and UMR, and indicate that the latter is likely dominated by the dipolar magnons. Our results may facilitate the development of new magnetoelectronic approaches for the characterization of SHE-induced magnetization dynamics.

*NSF DMR-1504449 and ECCS-1804198

8:36AM X39.00004: How to generate whispering gallery magnons* [Invited] KATRIN SCHULTHEISS (Presenter), Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, ROMAN VERBA, Institute of Magnetism, National Academy of Sciences of Ukraine, FRANZISKA WEHRMANN, KAI WAGNER, LUKAS KÖRBER, TOBIAS HULA, TONI HACHE, ATILIA KÁKAY, Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, AHMAD A AWAD, Department of Physics, University of Gothenburg, VASYL S TYBERKEYCH, ANDREI SLAVIN, Department of Physics, Oakland University, JÜRGEN FASSBENDER, HELMUT SCHULTHEISS, Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf — One of the most fascinating topics in current quantum physics are hybridized systems, in which resonators of different quantum systems are strongly coupled. Prominent examples are circular resonators with high quality factors that allow the coupling of optical whispering gallery modes to microwave cavities or magnon resonances. However, the coupling to magnons with finite wave vectors has not yet been achieved due to the lack of efficient excitation schemes.

Here, we present the generation of whispering gallery magnons with unprecedented high azimuthal wave vectors via nonlinear 3-magnon scattering in a µm-sized magnetic disk exhibiting a vortex state. These modes show a strong localization at the perimeter of the disk and practically zero amplitude in an extended area around the vortex core. They originate from the splitting of the fundamental radial magnon modes, which can be resonantly excited in a vortex state by an out-of-plane microwave field. We will shed light on the basics of this non-linear scattering mechanism from experimental and theoretical point of view. Using Brillouin light scattering (BLS) microscopy, we investigated the frequency and power dependence of this nonlinear mechanism. The spatially resolved mode profiles give evidence for the localization at the boundaries of the disk and allow for a direct determination of the modes’ wavenumbers. Furthermore, time resolved BLS in combination with pulsed microwave excitation revealed the temporal evolution of the 3-magnon splitting and its dependence on the applied microwave power.

*Financial support from the Deutsche Forschungsgemeinschaft within programme SCHU 2922/1-1 is gratefully acknowledged. Samples were prepared at the Nanofabrication Facilities (NanoFaRo) at the Institute of Ion Beam Physics and Materials Research at the Helmholtz-Center Dresden-Rossendorf (HZDR). K.S. acknowledges funding within the Helmholtz PostDoc Programme.
Spin and Charge Pumping and Spin Wave Emission by Magnetic Domain Wall Annihilation:
Quantum-Classical Micromagnetics Approach*  
MARKO PETROVIC (Presenter), PETR PETR PLECHAC, Department of Mathematical Sciences, University of Delaware, BRANISLAV NIKOLIC, Department of Physics and Astronomy, University of Delaware — Recent experiments on magnetic domain wall collisions [1] showed their importance in generating short-lived spin wave bursts, low-power signals which can be used in future spintronics devices. Using a new, time-dependent method to propagate the non-equilibrium density matrix (the TD-NEGF method) combined with the classical Landau-Lifshitz-Gilbert (LLG) equation [2], we analyze spin and charge currents produced by an annihilation of two colliding domain walls in a magnetic material coupled to two electron reservoirs. The advantage of this approach is in its self-consistent coupling between quantum electron spin and classical magnetic moments which gives rise to a dynamical Gilbert damping and allows for calculation of the exact charge current pumped out of the system, in contrast to an approximate solution given by the perturbative spin motive force formula combined with the LLG equation [3]. The pumped currents provide enough information to indirectly determine details of the annihilation event.

*This project was supported by ARO MURI Award and NSF.

Magnon Damping in Yttrium Iron Garnet Films at Millikelvin Temperatures*  
SANDOKO KOSEN (Presenter), ARJAN F. VAN LOO, Department of Physics, University of Oxford, LAURA MIHALCEANU, DMITRY BOZHKO, ALEXANDER SERGA, Department of Physics, Technische Universitaet Kaiserslautern, ALEYX KARENOWSKA, Department of Physics, University of Oxford — Magnon-based quantum devices require low damping materials to maintain coherence. One of the most promising candidates is yttrium iron garnet (YIG). A ferrimagnetic insulator, YIG has the narrowest known linewidth of any practical material at room temperature. Bulk YIG has been shown to have low damping at millikelvin (mK) temperatures. However, there is some debate about whether this is the case in YIG films. Much of the uncertainty centres around the fact that the low-temperature magnetic behaviour of the substrate upon which high-quality samples are grown -- gadolinium gallium garnet (GGG) -- is not fully understood.

In this work, we study magnon damping in YIG films with and without GGG substrates by measuring the resonance linewidth at low temperatures. We observe that GGG contributes to significantly increased damping at low temperatures. Further measurements up to 9K reveal that temperature-peak processes are active above 1K and the presence of additional damping at mK temperatures which we attribute to the two-level fluctuators. Upon saturating the fluctuators, linewidths of 1.4 MHz are achievable in substrate-free YIG films at 20 mK, lower than the measured linewidth in the same films at room temperature.

Non-linear parallel pump FMR studies in magnetic insulators*  
ANEESH VENUGOPAL (Presenter), TAO QU, RANDALL VICTORA, Electrical Engineering, University of Minnesota — Non-linear magnetic response of magnetic insulator materials is often used in the realization of radio-frequency (RF) devices. Although in use, there exists physical aspects that still need investigation for such devices. Here, we use high performance parallel computing based CUDA simulations and a theoretical model for magnon scattering to explore the direct and parametric generation of magnons, excited by microwaves in parallel pumped configurations. The sample is 10-100s of um and the response is largely dominated by the demagnetization fields in the sample. The DC applied magnetic field is in-plane and the RF field is linearly polarized and parallel to the DC field. We first determine the dispersion relation which plays a vital role in the understanding of nonlinear magnons. We then study the effect of ferrimagnet thickness, damping constant, RF frequency and power as well as DC applied magnetic field, on properties like frequency response, operational bandwidth, and power absorption of the material. It is found that the degree of non-linearity can be controlled using parameters like RF power. Analytically, Holstein and Primakoff based analysis is used to arrive at the threshold RF amplitude and dispersion relations.

*We would like to thank DARPA and XSEDE towards this project.
Magnon transport in quasi-two-dimensional van der Waals antiferromagnets* WENYU XING (Presenter), LUYI QIU, XIRUI WANG, YUNYAN YAO, YANG MA, RANRAN CAI, SHUANG JIA, XINCHENG XIE, WEI HAN, International Center for Quantum Materials, Peking University — The recent emergence of 2D van der Waals magnets down to atomic layer thickness provides an exciting platform for exploring quantum magnetism and spintronics applications. However, the potential of 2D van der Waals magnets for magnonics, has not been explored yet. In this talk, we will present the experimental observation of long distance magnon transport over several micrometers in quasi-2D van der Waals antiferromagnet MnPS$_3$. Experimentally, we exfoliated mechanically MnPS$_3$ flakes down to a few nanometers, and then fabricated the devices of non-local geometry where MnPS$_3$ is the transport channel of magnon. Then magnon is injected via thermal method and detected based on inverse spin Hall effect of platinum. As the quasi-2D MnPS$_3$ thickness decreases, a shorter magnon diffusion length is observed, which could be attributed to the surface-impurity-induced magnon scattering.

Spin-wave Confinement and Coupling in Organic-Based Magnetic Nanostructures* MICHAEL CHILCOTE (Presenter), MEGAN HARBERTS, Physics, Ohio State University, BODO FUHRMANN, IZM, Martin-Luther-Universitat Halle-Wittenberg, KATRIN LEHMANN, Institute fur Physik, Martin-Luther-Universitat Halle-Wittenberg, YU LU, Chemistry, Ohio State University, ANDREW FRANSON, HOWARD YU, Physics, Ohio State University, NA ZHU, HONG X TANG, Electrical Engineering, Yale University, GEORG SCHMIDT, Institute fur Physik, Martin-Luther-Universitat Halle-Wittenberg, EZEKIEL JOHNSTON-HALPERIN, Physics, Ohio State University — We present the synthesis of a new class of organic-based magnetic nanostructures consisting of nanowires of V[TCNE]$_x$ that assemble along the ridges of a grooved substrate. These nanowires exhibit uniaxial magnetic anisotropy in direct contrast to the isotropic in-plane response of typical thin-films. When different magnon modes excited in these structures are brought into resonance by varying the orientation of an in-plane magnetic field, we observe anticrossing behavior, indicating strong coherent coupling between excitations. Furthermore, micromagnetic simulations using real nanowire profiles extracted from cross-sectional scanning electron microscopy faithfully reproduce the experimentally measured spectra without any free parameters, including spin-wave and other higher-order modes. These results introduce a new degree of freedom for organic-based magnetism and spintronics, and together with recent demonstration of encapsulation technologies and demonstrated functional microwave devices that exhibit high quality factors across a frequency range, suggest future promising applications in microwave electronics and quantum magnonics.

Revisiting the Einstein-de Haas Effect* MICHAEL G DUNSMORE (Presenter), KAYTE MORI, MIRO BELOV, JOHN THIBAUT, VINCENT T.K. SAUER, JOSEPH E LOSBY, MARK FREEMAN, University of Alberta — The Einstein-de Haas (EdH) effect manifests the intrinsic connection between magnetic moment and mechanical angular momentum. In the original experiment [1], angular momentum changes induced in an iron cylinder by field-driven changes in the net magnetic moment were detected via resonant motion of a torsion pendulum. The miniaturization of torque sensors [2], combined with ultrasensitive optical detection, enables routine measurements of EdH effects. Millimeter to nanometer-scale sensors affixed to yttrium iron garnet structures were fabricated to explore the frequency-dependence of the EdH effect. Described are experimental methods for distinguishing EdH and conventional magnetic torques simultaneously.

*The authors wish to acknowledge support from the Natural Sciences and Engineering Research Council, Canada, the Canada Research Chairs program, and the Faculty of Science, University of Alberta.
10:24AM X39.00011: Observation of Ultrastrong Magnon-Magnon Coupling in YFeO$_3$ in High Magnetic Fields  

GARY NOE (Presenter), Department of Electrical and Computer Engineering, Rice University, MOTOAKI BAMBA, Department of Materials Engineering Science, Osaka University, XINWEI LI, Department of Electrical and Computer Engineering, Rice University, NING YUAN, JIASHU ZHANG, ZUANMING JIN, WEI REN, GUOHONG MA, SHIXUN CAO, Department of Physics, Shanghai University, DMITRY TURCHINOVICH, Fakultät für Physik, Universität Duisburg-Essen, JUNICHIRO KONO, Department of Electrical and Computer Engineering, Rice University — There is currently much interest in exploring resonant light-matter interaction in the ultrastrong-coupling (USC) regime where light and matter mix to an extreme degree and a variety of new phenomena emerge [1]. Recently, we have extended the concept of USC to a magnetic context in the form of matter-matter interaction [2]. Specifically, the exchange interaction of paramagnetic Er$^{3+}$ spins with an Fe$^{3+}$ magnon field in ErFeO$_3$ exhibited a large vacuum Rabi splitting. Here, we report another type of matter-matter USC between two magnon modes in YFeO$_3$. In rare-earth orthoferrite materials, there are ferromagnetic (FM) and antiferromagnetic (AFM) modes of magnons in the terahertz (THz) frequency range. By performing single-shot THz time-domain spectroscopy with a table-top pulsed magnet [3], we have investigated the magnetic field dependent magnon frequency and discovered anticrossing behavior for the FM and AFM magnon modes in high magnetic fields. The magnitude of the vacuum Rabi splitting suggests USC strength between the magnon modes when applying high magnetic fields at certain finite angles with respect to the crystallographic axes of bulk YFeO$_3$.

10:36AM X39.00012: Magnon-photon coupling in orthoferrites  

MARCEL BIALEK (Presenter), ARNAUD MAGREZ, JEAN-PHILIPPE ANSERMET, Institute of Physics, Ecole Polytechnique Fédéral de Lausanne — We study the magnon-photon coupling at THz frequencies [1]. The Purcell effect and magnon-polaritons were shown in ferromagnetic materials [2, 3]. It is interesting to observe these interactions in antiferromagnetic materials due to their high-frequency magnetic resonances. We report on an magnon-photon coupling in high-temperature antiferromagnets, bismuth ferrite BiFeO$_3$ (BFO) and dysprosium ferrite DyFeO$_3$ (DFO). We investigated polycrystalline samples of different thicknesses, thus having different sets of Fabry-Perrot-type cavity modes. We measured transmission spectra in 200-350 GHz frequency band at 300-600 K temperature range using frequency extenders to a vector network analyzer. Magnetic-resonance frequencies soften with rising temperature and cross with cavity modes. In BFO samples, we found that the width of the resonant line broadens at these crossings, consistent with the Purcell effect. In DFO samples, our data show avoided crossings of resonances with cavity modes, which is an indication of magnon-polaritons.

10:48AM X39.00013: Spin Waves Across 3-Dimensional, Close-Packed Nanoparticles*  

KATHRYN KRYCKA (Presenter), JAMES J RHyne, SAMUEl D OBERDICK, National Institute of Standards and Technology, AHMED M ABDELGAWAD, Department of Physics, Carnegie Mellon University, JULIE BORCHERS, National Institute of Standards and Technology, YUMI IJIRI, Department of Physics and Astronomy, Oberlin College, SARA MAJETICH, Department of Physics, Carnegie Mellon University, JEFFREY W LYNN, National Institute of Standards and Technology — While there is much practical and theoretical interest in characterizing magnons within 3-dimensional self-assembled nanoscale systems, few experimental techniques are appropriate. Here inelastic neutron scattering, although intensity limited, is utilized to measure inter-nanoparticle spin waves, or magnons, which arise from coupling between 8.4 nm manganese ferrite nanoparticles that are self-assembled into a close-packed lattice, yet physically separated by oleic acid surfactant. The observed magnons are dispersive, respond to an applied magnetic field, and display the expected temperature-dependent Bose population factor. Moreover, the dispersion yields a non-negative energy gap only when the effective Q is reduced by the inter-particle spacing, confirming that it is a collective excitation between the nanoparticles, rather than originating within individual nanoparticles. The experimental results are well explained by a limited parameter model which treats the 3-dimensional ordered, magnetic nanoparticles as dipolar-coupled superspins.

Friday, March 8, 2019 8:00 AM - 10:48 AM
8:00AM X40.00001: Probing spin correlations using angle resolved photoemission in the coupled metallic/Mott insulator system PdCrO$_2$ [*Invited] VERONIKA SUNKO (Presenter), Max Planck Institute for Chemical Physics of Solids, FEDERICO MAZZOLA, University of St Andrews, SOTA KITAMURA, Max Planck Institute for the Physics of Complex Systems, SEUNGYUN KHIM, PALLAVI KUSWAHA, Max Planck Institute for Chemical Physics of Solids, OLIVER J CLARK, MATTHEW WATSON, IGOR MARKOVIĆ, DEEPNARAYAN BISWAS, University of St Andrews, LEONID POUROVSKII, Collège de France, TIMUR KIM, TIEN-LIN LEE, PARDEEP K. THAKUR, Diamond Light Source, HELGE ROSNER, Max Planck Institute for Chemical Physics of Solids, ANTOINE GEORGES, Collège de France, RODERICH MOESSNER, TAKASHI OKA, Max Planck Institute for the Physics of Complex Systems, ANDREW P. MACKENZIE, Max Planck Institute for Chemical Physics of Solids, PHIL D C KING, University of St Andrews — A nearly free electron metal and a Mott insulating state can be thought of as opposite ends of the range of possibilities for the motion of electrons in a solid. In the magnetic oxide metal PdCrO$_2$, these two coexist as alternating layers. Using angle resolved photoemission, we surprisingly find sharp band-like features in the one-electron removal spectral function of the correlated subsystem. We show that these arise because a hole created in the Mott layer moves to and propagates in the metallic layer while retaining memory of the Mott layer's magnetism. This picture is quantitatively supported by a strong coupling analysis capturing the physics of PdCrO$_2$ in terms of a Kondo lattice Hamiltonian. Our findings open new routes to use the non-magnetic probe of photoemission to gain insights into the spin-susceptibility of correlated electron systems.

8:36AM X40.00002: Magnetic proximity effect in Pt/α-Fe$_2$O$_3$ bilayers [*the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences, Grant No. DE-SC001304]*

SISHENG YU (Presenter), YANG CHENG, ADAM AHMED, FENGYUAN YANG, Ohio State University — Recently antiferromagnetic insulators play an important role in spintronic research including the spin superfluid [1] and long distance spin transport [2]. In this work, we find the magnetic proximity effect (MPE) in non-magnet Pt on antiferromagnetic insulator α-Fe$_2$O$_3$ bilayers. Off-axis sputtering was used to grow the high-quality bilayers as confirmed by atomic force microscopy and X-ray diffraction. Magneto-transport reveals anomalous hall signals at different temperature is observed. To elucidate these features, angle-dependent magnetoresistance (ADMR) measurements at different magnetic fields and temperatures have been conducted to isolate the contributions of anisotropic magnetoresistance (AMR) and spin Hall magnetoresistance (SMR). We also find non-trivial MR signals from field sweeps that reflect novel surface magnetism from the uncompensated moments in α-Fe$_2$O$_3$.

8:48AM X40.00003: Magnetic proximity effect (MPE) in Pt/YIG and Pt/Al:YIG heterojunctions* XIAO LIANG, YUPENG ZHU, ZHENH PENG, LONGJIANG DENG, LEI BI (Presenter), University of Electronic Science and Technology of China — Generation and manipulation of spin current in magnetic insulators, such as yttrium iron garnet (YIG) thin films have attracted great research interest recently. A variety of novel spintronic phenomena have been observed in the example system of Pt/YIG. To correctly interpret these observations, an important question and on-going debate is whether magnetic proximity effect (MPE) exists and its structural origin at this interface.

In this report, we present a joint study of the MPE in Pt/YIG and Pt/Al:YIG interfaces using first-principle calculations and transport characterizations. Theoretically, we demonstrate YIG crystal orientations and interface defects strongly influences MPE in Pt. Experimentally, we used diamagnetic Al$^{3+}$ ions to dope YIG at the tetrahedral site. The anomalous Hall resistance in Pt is found to be linearly proportional to the MPE induced magnetic moments predicted by first-principle calculations. Our findings demonstrate that the interface tetrahedral Fe-Pt exchange coupling is the origin of MPE at Pt/YIG heterojunctions, which can also be controlled by defect engineering at the interface.

9:00AM X40.00004: First-Principles Studies of Influences of Capping Layers on Perpendicular Magnetic Anisotropy (K$_i$) in X/Co$_2$FeAl/MgO (X = 4d/5d transition metals) Structures SICONG JIANG (Presenter), SAFDAR NAZIR, KESONG YANG, University of California, San Diego — The Co$_2$FeAl/MgO based magnetic tunnel junctions (MTJs) with interfacial perpendicular magnetic anisotropy (K$_i$) have attracted extensive interests because of their potential utilization in spin-transfer-torque magnetic random-access memory (STT-MRAM). In this study, we systematically investigated the capping layer impact on the K$_i$ magnitude in Co$_2$FeAl/MgO system with 4d/5d transition metals (TMs) using density functional theory calculations. Our results show that TM capping layers, such as W, Pb, and Bi can effectively increase the K$_i$ values as compared to the uncapped structures. The results are explained in terms of atomic resolved K$_i$ contributions due to different orbital hybridizations. This work shed light on research and development of novel MTJs with high thermal stability during data storage in STT-MRAM in the future.

9:12AM X40.00005: Spin Seebeck Effect in Y3Fe5O12/NiO/Pt Thin Film Heterostructures EGECAN COGULU (Presenter), DEBANGSU ROY, Department of Physics, New York University, TAO LIU, MINGZHONG WU, Department of Physics, Colorado State University, HENDRIK OHLDAG, Advanced Light Source, Berkeley National Lab, ANDREW D KENT, Department of Physics, New York University — The spin Seebeck effect (SSE), where a thermal gradient in a ferromagnet generates spin current, has been in the focus of spintronics studies as it is one of the most efficient ways to generate spin currents. Also, antiferromagnets are gaining attention recently due to their properties like zero net magnetization, low magnetic susceptibility and very fast spin dynamics. In this work, we report SSE measured in Y3Fe5O12(YIG) (20 nm)/NiO(2 nm)/Pt (5 nm) structures as a function of temperature (5 K to 300 K) with the YIG magnetized in-plane, using a lock-in technique that probes the response at the first and second harmonic. By varying the current amplitude, magnetic field direction and temperature we characterize the amplitude of SSE in a comparative study with and without antiferromagnetic layer. Our results show that not only is spin transport possible through thin NiO layers but there is also an increase in the SSE effect magnitude at intermediate temperatures (~150 K). We correlate this increase in the SSE magnitude with an increase in the magnetic susceptibility of NiO shown by our XMLD/XMCD measurements. Our results suggest that the SSE can be used to characterize the response of thin antiferromagnetic materials and optimize their spin-transport characteristics.

9:24AM X40.00006: Spin transport and standing spin waves generation in heavy metal-magnetic insulator-ferromagnet hybrid structures YABIN FAN (Presenter), LUQIAO LIU, Microsystems Technology Laboratories, MIT — Magnons (or spin waves) are collective excitations of electrons' spin angular momenta in magnetic or antiferromagnetic materials. The excitation and tunability of magnons in low-damping magnetic insulators, e.g., the yttrium iron garnet (YIG), is particularly interesting because it could offer much longer magnon propagation length and potential broad spintronics applications.

Here, we study a platinum/YIG/permalloy hybrid structure, where YIG is the magnetic spacer and permalloy (Py) is a low-damping ferromagnetic metal. Through external microwave excitation, the YIG layer and the Py layer can be excited to reach the ferromagnetic resonance modes individually, and we have detected the spin current signal from the Py spin pumping process transmitted through the YIG layer and converted to voltage signals in the platinum (Pt) layer by the inverse spin Hall effect. More importantly, we have detected additional resonance peak and spin pumping voltage signals which are corresponding to the perpendicular standing spin waves (PSSW) in the YIG layer. At specific frequency, this PSSW in YIG could be coupled with the magnon mode in Py, which could possibly facilitate the magnon spin transport from the Py layer to the bottom Pt layer.
Spintronic Properties and Spin-Orbit-Torque Switching Characteristics of Pt/REIG Heterostructures  ETHAN ROSENBERG (Presenter), JACKSON BAUER, Massachusetts Institute of Technology, LUKÁŠ BERAN, Charles University in Prague, CAN AVCI, ETH Zurich, GEOFFREY S BEACH, CAROLINE ANNE ROSS, Massachusetts Institute of Technology — Ferrimagnetic insulator (FMI) thin films with perpendicular magnetic anisotropy (PMA) have recently attracted attention for spin-orbit torque (SOT) switching applications. We report the properties of epitaxial terbium iron garnet (TbIG) and europium iron garnet (EuIG) thin films with PMA. EuIG can be grown with PMA on (100) and (111) GGG substrates, making it ideal for orientation-dependent studies. For instance, Pt/EuIG had similar (001) and (111) Im[\Gamma] in contrast to similar studies on the Pt/CFO system. The TbIG films had a low Ms at room temperature due to their magnetic compensation point of 330K, and AHE measurements of Pt/TbIG showed a sign change at the compensation point. In addition, the (111) Im[\Gamma] of Pt/TbIG was similar to the Pt/EuIG system. Finally, we report the SOT switching characteristics of Pt/TbIG going through its compensation point, as well as the orientation dependence of the SOT switching characteristics of the Pt/EuIG system.

Probing boundary magnetization with spin Hall magnetoresistance in high T_N boron-doped magnetoelectric Cr_2O_3*  WILL ECHTENKAMP (Presenter), ATHER MAHMOOD, CHRISTIAN BINEK, University of Nebraska – Lincoln — Voltage controlled magnetization is a promising route for next-generation low-energy magnetic recording and logic devices. Utilizing magnetoelectric Cr_2O_3 based heterostructures, electric control of ferromagnetic exchange bias has been achieved up to the bulk Néel temperature. Recently spin Hall magnetoresistance has been shown to be present in Cr_2O_3 Pt bilayers, potentially providing a readout mechanism of the antiferromagnetic order parameter which avoids the need for a ferromagnet. In this study we combine this novel readout mechanism with the technique of boron-doping the Cr_2O_3 which increases the Néel temperature up to 400 K. Using a process of magnetoelectric annealing, spin Hall magnetoresistance in boron-doped Cr_2O_3 films is examined for the first time, with significant implications for future spintronic devices.

Interfacial electronic states and correlated magnetic order across BiFeO_3/La_{0.7}Sr_{0.3}MnO_3 complex oxide heterointerfaces*  BO-CHAO HUANG (Presenter), Department of Physics, National Taiwan University, Taipei, Taiwan; and Institute of Physics, Academia Sinica, Taipei, Taiwan; and Institute of Atomic and Molecular Sciences, P. Yu, State Key Laboratory of Low-Dimensional Quantum Physics, Department of Physics, Tsinghua University, and Collaborative Innovation Center of Quantum Matter, Beijing, China; an; YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University, Hsinchu, Taiwan; and Institute of Physics, Academia Sinica, Taipei, Taiwan, CHIA-SENG CHANG, Institute of Physics, Academia Sinica, Taipei, Taiwan, RAMESH, Department of Physics, University of California Berkeley, California, USA, R. E. DUNIN-BORKOWSKI, PH. EBERT, Peter Grünberg Institut, Forschungszentrum Jülich GmbH, Jülich, Germany, YA-PING CHIU, Department of Physics, National Taiwan University, Taipei, Taiwan; and Institute of Physics, Academia Sinica, Taipei, Taiwan, — Atomic-scale electronic states across termination engineered BiFeO_3/La_{0.7}Sr_{0.3}MnO_3 (BFO/LSMO) complex oxide heterointerfaces have been revealed using cross-sectional scanning tunneling microscopy and spectroscopy. The evolution of the Mn, O, and Fe states across MnO_2-BiO and La_{0.7}Sr_{0.3}O-FeO interfaces are demonstrated. Analysis of spectroscopy provides the electronic results of interfacial band gaps and interface bound charges at two kinds of terminations in the BFO/LSMO system. The result exhibits the MnO_2-BiO terminated interface with wide band gaps and dominant Mn^{4+} oxidation state, which can refer to an antiferromagnetic state at the interface. In contrast, the metallic behavior of the La_{0.7}Sr_{0.3}O-FeO terminated interface can be correlated to the ferromagnetism at the interface.

Emergent magnetic textures across SrRuO$_3$/SrMnO$_3$ interfaces

ARIJIT DAS (Presenter), PING ZHANG, ADAM J WATSON, TAMALIKA BANERJEE, Spintronics of functional materials, Zernike Institute for Advanced Materials, University of Groningen — Strongly correlated oxides by virtue of their correlation with lattice, spin and orbital degrees of freedom promote emergent phenomena at heterointerfaces. In SrRuO$_3$, a canonical correlated oxide, ferromagnetism arises due to coupling of oxygen octahedral distortion to hybridization of O 2p and Ru 4d orbitals. Furthermore, tunability of different physical properties at interfaces between thin films of SrRuO$_3$ and SrTiO$_3$ (100), either by tailoring strain or termination plane control can lead to the coexistence of different magnetic states. In this work, we investigate the emergence of an unconventional exchange bias at interfaces between thin SrRuO$_3$ films and SrMnO$_3$ thin films, a G-type antiferromagnet. We find that the competing interfacial exchange coupling between Ru $4^+$ and Mn $3+/4^+$, and the differences in local orbital bonding lead to differences in magnetic interactions at the bilayer interfaces. The magnetic ordering is manifested as an unconventional exchange bias in magnetization studies. We further observe a field dependent magnetic phase around 50 K from the M-T studies while the Tc of SrRuO$_3$ in the bilayer system is found to be $\sim$100 K. We analyze these observations along with unconventional features that is observed in the Hall magnetotransport data.

Unusual Magnetotransport Properties of Epitaxial NiCo$_2$O$_4$ Thin Films at Ultralow Temperatures*

ZHIGANG CHENG (Presenter), Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, XUEGANG CHEN, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln, XIANG ZHANG, LI LU, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska - Lincoln — The inverse spinel NiCo$_2$O$_4$ (NCO) is a room temperature ferrimagnetic material that is promising for developing nanoscale energy and spintronic applications. In this work, we report the unusual thickness-dependent magnetotransport properties of high quality epitaxial NCO thin films. We have characterized the longitudinal magnetoresistance (MR) and Hall effect in NCO films with thickness varying from 5 unit cell (~4.1 nm) to 30 uc (24.6 nm) at ultralow temperatures down to 100 mK. The 10 and 30 uc films exhibit an intrinsic linear negative magnetoresistance, which persists up to 17 T without showing any saturation or upturn, while the 5 uc sample exhibits a positive MR that is possibly due to 2D weak antilocalization (WAL). We also observe robust anomalous Hall effect in the 10 and 30 uc samples, while the switching hystereses are in opposite directions. We discuss the effects of the Berry curvature, disorder scattering, and dimensionality crossover on the observed unusual thickness effect.

Simulation of Hall sign change in ferromagnet SrRuO$_3$*

SHIH-JYE SUN (Presenter), Applied Physics, National University of Kaohsiung, HSIUNG CHOU, Physics, National Sun Yat-Sen University — We employed a modified two-band model to theoretically investigate the mechanism of Hall sign change in SrRuO$_3$, in which an mpurity band couple with conduction and valence bands. Apparently, our theory can interpret the experimental results, which implies the proposed impurity band arising from Ru vacancies is an important factor in Hall sign change. We found that the electron density in the impurity band is getting increase as the impurity band energy approaches the chemical potential resulting in a decrease of Curie temperature of SrRuO$_3$. Besides, the Hall sign change occurs at the Curie temperature only when the band oupling is weak. Further more, the increase of the Ru vacancies makes the impurity band become solid but suppress the Curie temperature. Moreover, from the theoretical prediction a more relatively intrinsic p-type SrRuO$_3$ has higher Curie temperature and opposite for intrinsic n-type SrRuO$_3$.

*We would like to thank the Ministry of Science and Technology of Taiwan for Grant No. MOST 107-2112-M-390-002 (Shih-Jye Sun) and MOST 107-2112-M-110-012 (Hsiung Chou)
8:00AM X41.00001: Stabilizing spin spirals and isolated skyrmions at low magnetic field exploiting vanishing magnetic anisotropy [Invited] MARIE HERVE (Presenter), Physikalisches Institut, karlsruhe institute of technology, BERTRAND DUPÉ, Institut für Physik, Johannes Gutenberg Universität Mainz, RAFAEL LOPES, MAXIMILIANO MARTINS, Serviço de Nanotecnologia Laboratório de Nanoscopia, Centro de Desenvolvimento da Tecnologia Nuclear, TIMOFEY BALASHOV, Physikalisches Institut, karlsruhe institute of technology, LUKAS GERHARD, Institute of Nanotechnology, karlsruhe institute of technology, JAIRO DINIZ, Institut für Physik, Johannes Gutenberg Universität Mainz, WULF WULFHEKEL, Physikalisches Institut, karlsruhe institute of technology — The stabilization of non-collinear chiral magnetic structure is usually attributed to a large Dzyaloshinskii-Moriya interaction (DMI). DMI is enhanced at surfaces and interfaces via the hybridization of the magnetic atoms with 5d elements. Here, we show that a strong DMI is not a necessary condition to obtain a chiral magnetic order in ultra-thin films. Our spin-polarized scanning tunneling microscopy study show that Co/Ru(0001) possesses a spin spiral ground state, although the DMI is weak. Under moderated magnetic field (~150 mT) isolated skyrmion can be stabilized. We attribute the stability of this spin texture to the vanishing of the magnetic anisotropy energy.

8:36AM X41.00002: Correlating Induced Magnetization and the Dyzaloshinskii-Moriya Interaction in Skyrmion-host Metallic Multilayers* RYAN NEED (Presenter), National Institute of Standards and Technology, SABIT KARAYEV, DURGA KHADKA, University of Miami, PATRICK QUARTERMAN, BRIAN KIRBY, National Institute of Standards and Technology, SUNXIANG HUANG, University of Miami — In metallic multilayers, skyrmions can form at interfaces between a 3d elemental ferromagnet (e.g., Co, Fe) and a 5d nonmagnetic element (e.g., Ir, Pd), where broken inversion symmetry and large spin-orbit coupling enable Dzyaloshinskii-Moriya interactions (DMI) to generate chiral magnetic structures. Skyrmions in these systems can be moved through the material by small spin currents and thus present a promising opportunity to realize new, low-energy magnetic storage technologies. Here, we examine prototypical Pt/Co/Pt and Pt/Co/Ir heterostructures to address the question of how the strength of the net DMI of a multilayer structure corresponds to the strength of the proximity-induced magnetism (PIM) that exists in the Stoner-susceptible 5d metals. Specifically, we compare DMI strength, as measured by the spin-orbit torque induced effective field under an in-plane bias magnetic field, to the magnitude of the PIM in Pt and Ir, as determined by X-ray magnetic circular dichroism. We also use resonant reflectometry at the Pt and Ir L3 edges to extract magnetic depth profiles to understand how PIM changes as a function of Pt and Ir layer thickness.

*This research was performed while the author held an NRC Research Associateship award at the National Institute of Standards and Technology.

8:48AM X41.00003: Point-Group Dependence of Dzyaloshinski-Moriya Micromagnetics* AHSAN ULLAH (Presenter), BALAMURUGAN BALASUBRAMANIAN, ANDREI SOKOLOV, LANPING YUE, SHAH VALLOPPILLY, XINGZHONG LI, LI, WENYONG ZHNAG, DAVID SELLMYER, RALPH SKOMSKI, Nebraska Center for Materials and Nanoscience and Department of Physics and Astronomy,, University of Nebraska, Lincoln, Nebraska 68588-0299, USA — The micromagnetic realization of Dzyaloshinski-Moriya interactions (DMI) is investigated, with particular reference to spin spirals and skyrmions in crystals with cubic symmetry. The analysis starts with a group-theoretical analysis and explains the micromagnetism by a magnetic gyration tensor that is loosely related to the vector D of the DMI. In contrast to conventional wisdom, the DMI free-energy term $D \mathbf{M} (\nabla \times \mathbf{M})$ is not caused by broken inversion symmetry but reflects the presence of chiral building blocks (motifs) in the crystal structure. The scalar D includes not only DMI but also magnetocrystalline and magnetostatic contributions. In micromagnetic calculations, this D should never be used for noncubic structures, such as uniaxial tetragonal, rhombohedral, and hexagonal crystals. Furthermore, $D = 0$ for the cubic point groups $T_h$, $O_h$, and $T_d$, which include half- and inverse Heusler alloys ($T_d$), in spite of their broken inversion symmetry and nonzero atomic-scale DMI. The theoretical findings are used to discuss skyrmions in a range of related alloys: MnNiGa and MnNiSn, which crystallize in the centrosymmetric hexagonal Ni2In structure (point group $D_{6h}$), and Heusler-type cubic compounds MnNiIn and MnNiAl.

*This research is supported by DOE/BES (DE-FG02-04ER46152).
9:00AM X41.00004: Magnetic domain texture and Dzyaloshinskii-Moriya interaction in systems with perpendicular exchange bias

RISALAT KHAN (Presenter), School of Physics and Astronomy, University of Leeds, Leeds LS2 9JT, UK, THOMAS FORREST, Diamond Light Source, Didcot, Oxfordshire OX11 0DE, UK, HANS T. NEMBACH, Quantum Electromagnetics Division, National Institute of Standards and Technology, Boulder, Colorado 80305, USA, MANNAN ALI, School of Physics and Astronomy, University of Leeds, Leeds LS2 9JT, UK, JUSTIN SHAW, Quantum Electromagnetics Division, National Institute of Standards and Technology, Boulder, Colorado 80305, USA, CHRISTOPHER HUGH MARROWS, THOMAS MOORE, School of Physics and Astronomy, University of Leeds, Leeds LS2 9JT, UK — We sputter-deposited polycrystalline multilayers of Pt/Co/IrMn and Pt/Co/FeMn exhibiting perpendicular exchange bias (PEB). These multilayers are of interest because of the coincidence of the Dzyaloshinskii-Moriya interaction (DMI) with a vertical exchange field that could remove the need for an externally applied field to stabilise skyrmions [1]. We measured the exchange bias as a function of the layer thickness of Co, IrMn, and FeMn.

Utilising Kerr microscopy and XMCD-PEEM imaging, the domain morphology of the ferromagnetic (FM) layer (Co) was studied when crossing over the paramagnet to antiferromagnet (AFM) phase transition of the coupled AFM layers (IrMn and FeMn). The domain texture is influenced by the FM-AFM exchange coupling. A domain created by nucleation has rough edges, while a domain cooled through the transition maintains its smooth appearance.

The DMI brings about chiral magnetic order, such as Néel domain walls and skyrmions. The DMI was investigated in these systems, particularly how it is affected by the AFM spin order. The DMI was measured at different phases of the AFM layers. We quantified the DMI by Brillouin light spectroscopy [2].

9:12AM X41.00005: Universality of Defect-Skyrmion Interaction Profiles*

IMARA LIMA FERNANDES (Presenter), JUBA BOUAZIZ, STEFAN BLUEGEL, SAMIR LOUNIS, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, 52425, Jülich, Germany — Magnetic skyrmions are prime candidates for future spintronic devices. However, incorporating them as information carriers hinges on their interaction with defects present in any device. We map from full ab initio [1], the energy profile of single magnetic skyrmions interacting with single-atom impurities, establishing a generic shape as function of the defect’s electron filling. Depending on their chemical nature, foreign 3d and 4d transition metal adatoms or surface-implanted defects can either repel or pin skyrmions in Pd/Fe/Ir(111), which we relate to the degree of filling of bonding and anti-bonding electronic states inherent to the proximity of the non-collinear magnetic structure. Similarities with key concepts of bond theories in catalysis and surface sciences imbue the universality of the shape of the interaction profile and the potential of predicting its interaction. The resulting fundamental understanding may give guidance for the design of devices to generate and control skyrmions.

9:24AM X41.00006: Determining the lifetime of metastable skyrmions*

JAMES ROWLAND (Presenter), MOHIT RANDERIA, Ohio State University — The question of the lifetime of metastable skyrmions in a ferromagnetic background is of both fundamental importance and of practical significance for memory applications. We address this question for a chiral magnetic thin film with ferromagnetic exchange \( J \), Dzyaloshinskii-Moriya interaction \( D \), and anisotropy \( K \) in an external field \( B \). We present results for skyrmion lifetimes based on novel numerical and variational approaches for analyzing the saddle-point in configuration-space paths that lead to skyrmion decay. Our results highlight the importance of the ratio of the film thickness \( L \) to the helical pitch length \( L_D = 2\pi J/D \) in understanding skyrmion decay. We show that Bloch point singularities play a crucial role in skyrmion decay even for small \( L/L_D \). The role of anisotropy and external field in determining skyrmion size and stability will also be discussed and comparison with previous results presented.

*JR and MR acknowledge support from DARPA Grant No. D18AP00008.
Quantum Collapse of a Skyrmion

AMEL DERRAS-CHOUK (Presenter), EUGENE M CHUDNOVSKY, DMITRY GARANIN, CUNY Graduate Center and Herbert H. Lehman College — We analytically and numerically investigate the quantum collapse of a small skyrmion in a thin magnetic film with Dzyaloshinskii-Moriya interaction (DMI). The stability threshold determined by the DMI, the external magnetic field, and the underlying atomic lattice has been computed. The Lagrangian describing the coupled dynamics of the skyrmion size and the chirality angle has been derived. An instanton solution of the equations of motion that corresponds to the skyrmion underbarrier contraction via quantum tunneling has been obtained. The tunneling rate has been computed and the conditions needed to observe quantum collapse of a skyrmion in a magnetic film have been elucidated [1].

Interfacial Dzyaloshinskii-Moriya interaction at an epitaxially grown ferromagnetic and heavy metal interface

KEMAL SOBOTKIEWICH (Presenter), University of Texas at Austin, AIDAN J LEE, Ohio State University, XIN MA, KEVIN OLSSON, DAVID LUJAN, University of Texas at Austin, ADAM S AHMED, FENG YUAN YANG, Ohio State University, XIAOQIN (ELAINE) LI, University of Texas at Austin — We study Dzyaloshinskii-Moriya interaction(DMI) in a series of epitaxially grown CoFe/Pt films using momentum-resolved Brillouin light scattering. The symmetry breaking present in the bilayer allows interfacial DMI, which is expected to depend on atomic alignment at the interface. Different CoFe alloys are studied. Co(25)Fe(75) is of particular interest because it exhibits exceptionally low magnetic damping [ref]. By controlling the chemical composition, thickness and growth conditions, one can tune the DMI parameter along with other magnetic properties of the film. We can measure these different properties using a single technique, Brillouin Light Scattering, allowing for a full characterization of the tunable parameters which could allow for engineering materials with the desired combination of properties.

Berry Phase and Exchange Contributions in Antiskyrmion Hosting Heusler Compound Mn1.5XY

JACOB GAYLES (Presenter), YAN SUN, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids — Recently, the Heusler compounds Mn1.4PtSn and Mn1.4Pt0.9Pd0.1Sn were shown to stabilize an antiskyrmion lattice above room temperature. This Heusler compound forms in a superstructure with the D2d symmetry, which allows for an anisotropic Dzyaloshinskii-Moriya interaction (DMI) perpendicular to the tetragonal axis. We use density functional theory calculations of Mn1.5XY to extract the relevant exchange interactions that determine the rich phase diagrams in these materials. The exchange interactions are between the large moments on the Mn atoms ~4 μB, which show magnetic states that are non-collinear ferrimagnetic up to the spin reorientation. The major role of the DMI and anisotropy are due to the X ion, either Rh, Pd, Ir, or Pt which also influence the exchange interactions. The Fermi level can be tuned by the Y ion, either In, Sn or Sb. We last calculate the anomalous Hall effect and topological Hall effects in these regimes, to capture the influence of the electronic structure on the Berry curvature.

Dzyaloshinski-Moriya Interactions and Berry Curvature in Magnetic Nanoparticles

RALPH SKOMSKI (Presenter), BALAMURUGAN BALASUBRAMANIAN, AHSAN ULLAH, RABINDRA PAHARI, DAVID SELLMYER, University of Nebraska - Lincoln — Noncentrosymmetric crystals, such as B20-ordered MnSi, have long been known to exhibit spin spirals in the bulk and skyrmions with quantized topological charge in thin films. We have theoretically and experimentally investigated the skyrmions of magnetic nanoparticles produced by cluster deposition. Our research includes CoSi, which is nonmagnetic in the bulk but magnetically ordered in nanoparticle form. The size confinement imposed by the nanostructuring suppresses the formation of spin spirals and skyrmions but leads top the formation of curling-type spin structures with nonzero Berry curvature and nonzero contribution to the topological Hall effect (THE). Concerning the nanoparticle material, there is an important distinction between centrosymmetric materials and various types of materials without inversion symmetry, especially polar and chiral crystal structures. With respect to the spin states, the former corresponds to broken chirality, whereas the latter imply a violation of chiral symmetry. It is interesting to note that moderately strong Berry curvatures and unquantized THE contributions may also be caused in nanoparticles with inversion symmetry and due to magnetostatic interactions.

10:24AM X41.00011: Signatures of novel spin phases in thermal conductivity of the chiral skyrmion material Cu$_2$OSeO$_3$*  
ARTEM AKOPYAN (Presenter), NARAYAN PRASAI, University of Miami, BENJAMIN TRUMP, GUY G. MARCUS, Johns Hopkins University, SUNXIANG HUANG, University of Miami, TYREL MCQUEEN, Johns Hopkins University, JOSHUA COHN, University of Miami — We report measurements of thermal conductivity ($\kappa$) as a function of magnetic field in single crystals of the chiral skyrmion material Cu$_2$OSeO$_3$ in the temperature range $0.5 \leq T \leq 15$ K. Traversing phase boundaries associated with the low-temperature skyrmion and tilted conical spin phases, recently identified in small-angle neutron scattering studies,$^{a,b}$ gives rise to sharp signatures in $\kappa(H)$ for $H \parallel \langle 100 \rangle$ that are attributed to changes in the magnon thermal conductivity. Different crystallographic orientations for the applied field and heat flow will be discussed.

10:36AM X41.00012: High pressure and magnetic field induced new phase in skyrmion Cu$_2$OSeO$_3$  
LIANGZI DENG (Presenter), HUNG-CHENG WU, RABIN DAHAL, MELISSA GOOCH, ZHENG WU, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston TX 77204, HUNG-DUEN YANG, Department of Physics, National Sun Yat-sen University, Kaohsiung, 804 Taiwan, CHING-WU CHU, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston TX 77204 — In recent years, there has been an enormous experimental research effort on skyrmion materials because of their peculiar topological properties. From a technological perspective, the magnetic skyrmions offer great potentials as information carriers in future robust, high-density, and energy-efficient spintronic devices. Ever since the discovery of skyrmion states in Cu$_2$OSeO$_3$ by Y. Tokura's group in 2012, Cu$_2$OSeO$_3$ has attracted considerable interest due to its complex magnetism, which is very sensitive to external perturbations, such as temperature, magnetic field, and pressure. Earlier high pressure studies on Cu$_2$OSeO$_3$ reveal that the ferrimagnetic transition temperature increases and the skyrmion state in magnetic H-T phase diagram could be enlarged under pressure up to 1.38 GPa. Recently, our group was able to establish the magnetic phase diagram in Cu$_2$OSeO$_3$ under pressure up to 45 GPa. Signatures of high pressure and magnetic field induced new phase in Cu$_2$OSeO$_3$ were detected. Structural analysis under high pressure in Cu$_2$OSeO$_3$ is ongoing to gain greater insight into the complex magnetism. Details of the experimental results will be shared and discussed in the presentation.

Friday, March 8, 2019 8:00 AM - 11:00 AM

Session X43 DCMP: New Developments in Topological Materials BCEC 210B - Ashvin Vishwanath, Harvard Univ - Tag(s): Invited
8:00AM X43.00001: Two-dimensional topological superconductivity in Pb/Co/Si(111)* [Invited] TRISTAN CREN (Presenter), Institut des NanoSciences de Paris, CNRS-Sorbonne University, GERBOLD MÉNARD, SPEC, CEA Saclay, ANDREJ MESAROS, Laboratoire de Physique des Solides, CNRS-University Paris Saclay, CHRISTOPHE BRUN, FRANÇOIS DEBONTRIDDER, Institut des NanoSciences de Paris, CNRS-Sorbonne University, DIMITRI RODITCHEV, LPEM, ESPCI-Sorbonne University, PASCAL SIMON, Laboratoire de Physique des Solides, CNRS-University Paris Saclay — The examination of supposedly well-known condensed matter systems through the prism of topology has led to the discovery of new quantum phenomena that were previously overlooked. Just like insulators can present topological phases characterized by Dirac edge states, superconductors can exhibit topological phases characterized by Majorana edge states. In particular, one-dimensional topological superconductors are predicted to host zero energy Majorana fermions at their extremities. Zero bias anomalies localized at the edge of proximity induced superconducting wires were recently interpreted as fingerprints of the emergence of topological superconductivity [1,2].

By contrast, two-dimensional (2D) superconductors have a one-dimensional boundary which would naturally lead to propagating Majorana edge states characterized by a Dirac-like dispersion. We have recently observed some hint of dispersive Majorana edge states in a single atomic layer Pb superconductor. This material has strong triplet correlations but is not topological by itself [3]. We will show that by applying a Zeeman field with the help of a buried Co-Si nanomagnet one can provoke a transition to a topological state [4].

In addition to their dispersive edge states, 2D topological superconductors are also supposed to support localized Majorana bound states in their vortex cores. We will show that some recent measurements seem to support this theoretical prediction [5].

8:36AM X43.00002: Fractional Excitonic Insulator* [Invited] CHARLES KANE (Presenter), Physics and Astronomy, University of Pennsylvania — We argue that a correlated fluid of electrons and holes can exhibit a fractional quantum Hall effect at zero magnetic field analogous to the Laughlin state at filling 1/m. We introduce a variant of the Laughlin wavefunction for electrons and holes and show that for m=1 it describes a Chern insulator that is the exact ground state of a free fermion model with $p_x + i p_y$ excitonic pairing. For m>1 we develop a composite fermion mean field theory, and we will give several pieces of evidence that our wavefunction correctly describes this phase. We will present physical arguments that the m=3 state can be realized in a system with $C_6$ rotational symmetry in which energy bands with angular momentum that differ by 3 cross at the Fermi energy. This leads to a gapless state with $(p_x + i p_y)^3$ excitonic pairing, which we argue is conducive to forming the fractional excitonic insulator in the presence of interactions. Prospects for numerics on model systems and band structure engineering to realize this phase in real materials will be discussed.

New invariants, complete classification and fast diagnosis for topological crystalline insulators*

CHEN FANG (Presenter), Chinese Academy of Sciences — Topological crystalline insulators have nontrivial band topology jointly protected by onsite symmetries of time reversal and charge conservation, as well as by spatial symmetries of lattice. Different types of lattice symmetries correspond to different topological invariants in the bulk and distinct characteristic surface states. We discuss newly discovered $Z_2$ invariants in 3D protected by rotation (screw) symmetry, inversion symmetry and roto-reflection symmetry, respectively. Each of the new invariants in the bulk is related to the $(d-2)$-dimensional edge states on the boundary. With the new invariants, we establish a complete classification of topological crystalline insulators for each of the 230 space groups in 3D, along with explicit, microscopic constructions for each class. To search for corresponding materials for the topological states in these new classes, we have established quantitative mappings from symmetry eigenvalues of valence bands to topological invariants all space groups. Applying these mappings, we have developed a fully automated diagnosis algorithm for all nonmagnetic crystals. The algorithm is applied to diagnosing 39519 materials, in which 8056 are found topological.

Observation of tunable Dirac interface states in topological crystalline insulator superlattice*

BADIH ASSAF (Presenter), Physics, Ecole Normale Superieure and University of Notre Dame, GAUTHIER KRIZMAN, THANANYAN PHUPHACHONG, Physics, Ecole Normale Superieure, GÜNTHER BAUER, GUNTHER SPRINGHOLZ, Institut für Halbleiter- und Festkörperphysik, Johannes Kepler University, GÉRALD BASTARD, ROBSON FERREIRA, LOUIS-ANNE DE VAULCHIER, YVES GULDNER, Physics, Ecole Normale Superieure — Topological crystalline insulators (TCIs) are unique topological systems. Their Dirac surface band structure - tightly linked to the crystal symmetries - can be tuned using a variety of external knobs. By stacking TCI Pb$_{1-x}$Sn$_x$Se in a superlattice of alternating trivial and non-trivial topology, we dramatically enhance the optical response of its topological Dirac states and succeed in demonstrating the tuning of their energy gap with temperature. We use magneto-optical infrared Landau level spectroscopy to probe the band structure of those topological states in MBE grown high mobility TCI/trivial superlattices for magnetic fields up to 15T and temperatures between 4.2K and 200K. By simply varying the sample temperature, we show that one can tune the penetration depth of surface states into the TCI layer and the inter-surface hybridization across this layer. As a result, we observe a tuning of the Dirac gap over a range extending from 5meV to 60meV. We pave the way for further realization of tunable quantum phases using TCI superlattices.

Wilson Loops, Wyckoff Positions, and Wannier Functions: New Developments in Stable and Fragile Topology

BARRY BRADLYN (Presenter), Department of Physics and Institute for Condensed Matter Theory, University of Illinois at Urbana-Champaign — The interplay of topology and geometry has been -- and continues to be -- a rich area of study for condensed matter physics. Recently, we have realized that spatial symmetries allow for the stabilization of topological phases much more exotic than those that can be found with time-reversal symmetry alone. Examples include topological crystalline insulators, "hourglass Fermion" phases, and Dirac and double-Weyl semimetals. In this talk, I will review recent developments in the theory of band representations which highlight the role of Wannier functions and holonomy in explaining the origins of topological crystalline behavior. I will show how this relates to several new ideas, such as symmetry indicators, topological phases with high co-dimension boundary states, and the "fragile" topology of isolated groups of bands. Finally, I will discuss how non-symmorphic symmetries can protect novel topological surface states, which can be diagnosed through the holonomy of Bloch functions.
Ultrafast electron imaging and diffraction of non-equilibrium structural dynamics in the charge-density wave system 1T-TaS\textsubscript{2}^* [Invited] CLAUS ROPERS (Presenter), University of Göttingen — Time-resolved electron imaging, diffraction and spectroscopy are exceptional laboratory-based tools to trace non-equilibrium phenomena in materials with a sensitivity to structural, electronic and electromagnetic degrees of freedom. The capabilities of these approaches are largely governed by the quality of the beam of electrons used.

This talk will discuss recent advances made by employing high-coherence ultrashort electron pulses from nanoscale field emitters, which substantially enhance the achievable image resolution in both real and reciprocal space. We have recently developed two complementary experimental techniques with ultimate surface sensitivity and spatial resolution, respectively, namely Ultrafast Low-Energy Electron Diffraction (ULEED) [1] and Ultrafast Transmission Electron Microscopy (UTEM) [2].

These methods are applied to study non-equilibrium dynamics in the prominent charge-density wave (CDW) material 1T-TaS\textsubscript{2} after femtosecond optical excitation. Specifically, we study structural phase transitions between different CDW phases and the optical excitation of fluctuation modes. In one set of experiments, ULEED is used to investigate the transient population of phonons and phase modes (phasons). For the transition between the domain-like nearly-commensurate (NC) CDW phase and the incommensurate (IC) phase, we identify the importance of dislocation-type topological defects in the periodic lattice distortion for establishing long-range phase-order. Finally, a new contrast mechanism for UTEM is developed that allows for ultrafast real-space domain imaging upon the structural phase transition.

Ultrafast time-resolved x-ray scattering reveals diffusive charge order dynamics in La$_{2-x}$Ba$_x$CuO$_4$.

Charge order (CO) is ubiquitous in the high-Tc cuprates but its relation to superconductivity is still unclear. While static charge order seems to anticorrelate with superconductivity, charge order fluctuations may favor or enhance Cooper pairing. Here, we investigate the collective CO dynamics in the prototypical cuprate La$_{2-x}$Ba$_x$CuO$_4$ with time-resolved resonant soft x-ray scattering. By suddenly quenching the CO diffraction peak with ultrafast optical pump pulses and probing its recovery in the time domain with resonant soft x-rays, we find that CO excitations in the energy range 0.4-2.0 meV are overdamped and diffusive. At energy scales lower than 0.4 meV, the CO phase exhibits dynamical critical scaling, a universal behavior associated with the propagation of topological defects. Our observations imply that charge order is dynamic and may play a role in establishing superconducting pairing.

Exploring ideal charge-density-wave in superconducting YBCO via innovative uses of X-ray FEL and the pulsed magnet.

Increasingly compelling evidence of various forms of non-superconducting electronic orders, such as charge/spin density waves (CDW/SDW), in the cuprate high-Tc superconductors has fundamentally altered our understanding of the essential physics of these materials. However, it has been difficult to establish the nature of the quantum (zero-temperature) phases that compete and/or coexist with superconductivity. In order to overcome this difficulty, it is necessary to destabilize superconducting long-range order at low temperatures by a high magnetic field. In this context, we performed x-ray scattering at an x-ray free electron laser (FEL) in the presence of pulsed high magnetic fields. This approach provides us with the new insight to understand the intertwined phenomena between CDW and SC in YBa$_2$Cu$_3$O$_x$ (YBCO) cuprates at magnetic fields, as well as an ideal CDW phase. More details will be touched in this presentation.

8:00AM X46.00001: Probing Ultrathin Functional Layers and Buried Interfaces with Advanced X-ray Spectroscopic Techniques [Invited] ALEXANDER GRAY (Presenter), Temple University — Rational design of low-dimensional electronic phenomena at oxide interfaces is considered to be one of the most promising schemes for realizing new energy-efficient logic and memory devices. An atomically-abrupt interface between paramagnetic LaNiO3 and antiferromagnetic CaMnO3 exhibits interfacial ferromagnetism, which can be tuned via a thickness-dependent metal-insulator transition in LaNiO3. A rich cation picture, emerging from the polarity mismatch and electronic reconstruction at the interface, is considered to be the driving factor for this phenomenon. Once fully understood, such emergent functionality could turn this Mott-interface system into a key building block for the above-mentioned future devices. In this talk, I will discuss three recent studies, in which we utilized a combination of x-ray spectroscopic and electron imaging techniques to investigate the electronic-structural origins of this emergent phenomenon. Starting with the building blocks of this heterojunction (CaMnO3 and LaNiO3), we used a combination of hard x-ray photoemission (HAXPES) and x-ray absorption spectroscopy (XAS) to establish a direct link between the in-plane strain and the oxygen-vacancy content in CaMnO3 [1]. Then, by using a combination of XAS and scanning transmission electron microscopy (STEM), we examined the nature of the metal-insulator transition in LaNiO3 in the ultrathin limit (<2 u.c.) [2]. Finally, we utilized a combination of HAXPES and standing-wave photoemission spectroscopy (SW-XPS) to demonstrate a depth-dependent charge reconstruction at the LaNiO3/CaMnO3 interface [3]. Our findings suggest a new strategy for designing functional Mott oxide heterostructures by tuning the interfacial cation characteristics via controlled manipulation of thickness, strain, and ionic defect states.

8:36AM X46.00002: Resistive switching in tunnel junctions with a single-crystal La2NiO4 electrode* SHIDA SHEN (Presenter), MORGAN WILLIAMSON, Department of Physics and Texas Materials Institute, University of Texas at Austin, GANG CAO, Department of Physics, University of Colorado-Boulder, JIANSHI ZHOU, Texas Materials Institute, University of Texas at Austin, MAXIM TSOI, Department of Physics and Texas Materials Institute, University of Texas at Austin — We study the resistive switching in tunnel junctions with single-crystal La2NiO4 electrodes. Such electro-resistive devices are promising candidates for future nonvolatile memory and reconfigurable logic applications thanks to their simple structure, scalability and endurance. Our tunnel junctions were prepared by painting a spot of conductive silver epoxy on the surface of La2NiO4 single crystal. The interface between the silver and the semiconducting single crystal served as a natural barrier forming planar normal metal/insulator/semiconductor (N-I-S) tunnel junctions with resistances ranging from a few tens to tens of thousands of Ohms. The current-voltage measurements performed on such junctions at room temperature demonstrated a bias-driven resistive switching with ratios above 1000% and high endurance. In situ measurements with two junctions (N-I-S-I-N) demonstrate the polarity-dependent resistive switching of the two (N-I-S and S-I-N) junctions and show no contribution from the bulk of the La2NiO4 crystal. Such an interfacial nature of the switching phenomenon is promising for fabrication of thin-film planar devices to be used in nonvolatile memory and logic.

8:48AM X46.00003: Spontaneous epitaxy of VO and stabilization of interface phase of V2O3 during vanadium metal deposition on SrTiO3 in vacuum AGHAM POSADAS (Presenter), University of Texas at Austin, SUNAH KWON, MOON KIM, University of Texas at Dallas, ALEXANDER DEMKOV, University of Texas at Austin — The deposition of vanadium metal on SrTiO3 results in the spontaneous scavenging of oxygen ions from SrTiO3 to oxidize vanadium to VOx, where x = 0.5-1.2, depending on the temperature. At sufficiently high temperature, the VOx forms as an epitaxial film on both SrTiO3 (100) and SrTiO3 (111). Surprisingly, the oxygen scavenging and epitaxy persist for thicknesses over 300 Å with no sign of degradation. Additionally, when vanadium is deposited on SrTiO3 (111), an interfacial phase of hexagonal V2O3 with 2x2 surface reconstruction is formed, which is stable for three monolayers, before rocksalt VO(111) starts to be formed. We describe the growth process and layer by layer characterization of the films using in situ reflection high-energy electron diffraction (RHEED), x-ray and ultraviolet photoelectron spectroscopy (XPS and UPS), and reflective electron energy loss spectroscopy (REELS), as well as ex situ grazing incidence in-plane x-ray diffraction and cross-sectional scanning transmission electron microscopy.
Tunability of the Metal–Insulator Transition in VO₂/TiO₂ Heterostructures*  
GUOXIANG HU (Presenter), Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, QIYANG LU, ILKKA KYLANPAA, JARON KROGEL, Materials Science and Technology Division, Oak Ridge National Laboratory, PAUL KENT, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, OLLE HEINONEN, Materials Science Division, Argonne National Laboratory, HO NYUNG LEE, Materials Science and Technology Division, Oak Ridge National Laboratory, PANCHAPAKESAN GANESH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory —  
The metal–insulator transition in strongly correlated vanadium dioxide (VO₂) has attracted considerable interest. It has been shown that formation of oxygen vacancies (VO) in VO₂ can suppress this MIT completely without any structural transition. Since VO can be introduced via tuning the thickness or type of capping oxide layers, in this work, we studied the control of MIT in VO₂ by interfacing with a TiO₂ capping layer. Using a combined approach with experimental measurements and theoretical calculations, we find that a TiO₂ capping layer on an epitaxial VO₂ thin film suppresses the MIT in VO₂. Density functional theory (DFT) calculations, benchmarked against more accurate many-body quantum Monte Carlo (QMC) calculations, provide information on the VO formation energy profile across the VO₂/TiO₂ interface. It is found that the VO₂/TiO₂ interface can facilitate the VO migration from TiO₂ to VO₂, and it is this migration that is responsible for the suppression of MIT in VO₂. Our study highlights the crucial role of VO introduced by a capping layer in tuning the MIT in epitaxial VO₂ thin films, which is useful for developing advanced electronic and ionic devices.

Origin of Suppression of Metal-Insulator Transition in Non-Stoichiometric VO₂*  
PANCHAPAKESAN GANESH (Presenter), Oak Ridge National Laboratory, FRANK LECHERMANN, University of Hamburg, ILKKA KYLANPAA, JARON KROGEL, PAUL KENT, Oak Ridge National Laboratory, OLLE HEINONEN, Argonne National Laboratory —  
Rutile (R) phase VO₂ is a quintessential example of a strongly correlated bad-metal, which undergoes a metal-insulator transition (MIT) concomitant with a structural transition to a V-V dimerized monoclinic (M) phase below T_{MIT} ~ 340K. In particular, doping vanadia thin-films with oxygen vacancies (VO) has been shown to completely suppress this MIT without any structural transition[1]. We explain this suppression by elucidating the influence of oxygen-vacancies on the electronic-structure of the R phase VO₂, explicitly treating strong electron-electron correlations using dynamical mean-field theory (DMFT) as well as diffusion Monte Carlo (DMC) techniques. We show that VO's tend to change the V-3d filling away from its nominal half-filled value, with the e^{\pi}_{g} orbitals competing with the otherwise dominant a_{1g} orbital. Loss of this near orbital polarization is associated with a weakening of electron correlations, which removes a charge-density wave (CDW) instability along the V-V dimerization direction above a critical doping concentration, thereby suppressing the metal-insulator transition. Our study also suggests that MIT is predominantly driven by a correlation-induced CDW instability. [1] Phys. Rev. Applied 7, 034008 (2017).

Depth-profiling metal-oxygen hybridization and orbital polarization in isovalent perovskite oxide heterostructures*  
PAUL ROGGE (Presenter), Department of Materials Science and Engineering, Drexel University, PADRAIC SHAFER, Advanced Light Source, Lawrence Berkeley National Laboratory, GILBERTO F L FABBRIS, Advanced Photon Source, Argonne National Laboratory, WEN HU, NSLS-II, Brookhaven National Laboratory, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, MARK DEAN, Department of Condensed Matter Physics and Materials Science, Brookhaven National Laboratory, STEVEN J MAY, Department of Materials Science and Engineering, Drexel University —  
Heterostructures of complex oxides have been successfully deployed to realize new electronic properties, with much of this work motivated by interfacial charge transfer effects that change the local charge density. Here, we synthesized superlattices of the isovalent perovskite oxides SrFeO₃ and CaFeO₃ using molecular beam epitaxy to investigate structural-induced changes in the orbital character of carriers across oxide interfaces while retaining the same nominal charge density. Using resonant x-ray reflectivity at the oxygen K-edge, we demonstrate that the Fe-O hybridization in CaFeO₃ and SrFeO₃ differs and is additionally modified at the interface. Further, using linearly polarized photons we find that the reflectivity at the Fe L-edge is polarization-dependent, which is attributed to strain-induced orbital polarization in the Fe 3d electron orbitals. By modeling the resonant reflectivity, we correlate changes in the Fe orbital polarization with changes in the Fe-O hybridization across the SrFeO₃-CaFeO₃ interface and reveal the presence of a hybridization superstructure.  

*P.C.R. and S.J.M. were supported by the Army Research Office, grant number W911NF-15-1-0133.
SUMMAYYA KOUSER (Presenter), Department of Physics and Astronomy, Vanderbilt University, SAURABH GHOSH, Department of Physics and Nanotechnology, SRM University, JOHN BREHM, Department of Physics and Astronomy, Vanderbilt University, ALBINA Y BORISEVICH, Center for Nanophase Materials Sciences, Oak Ridge National Lab, SOKRATES T PANTELIDES, Department of Physics and Astronomy, Vanderbilt University — Structurally designing materials by combining two or more different materials for realizing interesting emergent properties to target a desired functionality reduces the need for serendipity. One of the nascent strategies for pursuing new acentric compounds focuses on layering centrosymmetric materials in a particular fashion that lifts inversion symmetry while retaining other electronic, magnetic or optical functionalities found in the constituent materials, thus enabling new multiferroics or narrow bandgap polar semiconductors. Here, we formulate an approach to functionalize a polar metal i.e., \((Ca_{1-x}Sr_xFeO_3)_m/(SrFeO_3)_n\) into an insulating ferroelectric constructed from metallic oxide components \(CaFeO_3\) and \(SrFeO_3\). We have investigated several odd and even superlattices with different periodicities (e.g. \(m \times n = 1x1, 2x2, 1x3, 3x1\) etc). We find that the trigger for such a metal-to-insulator (M-I) transition is the disproportionation of the oxidation states of the central Fe ions. We find that appropriate periodicity and cation ordering is critical for the desired transition. The present work opens a door for designing ferroelectrics with tunable energy gaps by inducing controlled M-I transitions.

CHENYI GU (Presenter), MIN GU, ZHOUSHEN YUAN, YUEFENG NIE, PENG WANG, College of Engineering and Applied Sciences, Nanjing University, XIAOQING PAN, Department of Physics and Astronomy, University of California, Irvine — Charge transfer at complex oxide interfaces can give rise to a rich variety of exotic two-dimensional phenomena. Recently, an antiferromagnetic to nonmagnetic transition was reported at the LaTiO_3/LaFeO_3 interface based on the observation of Ti and Fe valence change by X-ray photoelectron spectroscopy. Nonetheless, a direct spatially resolved measurement with atomic resolution to support the charge transfer truly happens at the interface is lacking. Here, we investigate the valence variations of Ti and Fe at the LaTiO_3/LaFeO_3 interface by a combination of molecular beam epitaxy and aberration corrected scanning transmission electron microscopy. We demonstrate that the charge transfer from Ti to Fe occurs near the interface accompanied by minor cation intermixing, and the charge transfer depth is two unit cells. Our work provides a spatially resolved observation of charge transfer at this interface, and lends significant credence to charge transfer designs in functional oxide interfaces.

MARTA GIBERT (Presenter), Physik Institut, University of Zurich — Epitaxial heterostructures offer multiple strategies to manipulate the interplay between the different degrees of freedom in transition metal oxides. Interfacial structural and electronic couplings are key to tune the functionalities of these materials and even allow access to novel electronic phases. Perovskite nickelates are interesting materials displaying a metal to insulator transition, with the insulating state characterized by two inequivalent Ni sites. A particular antiferromagnetic order is also stabilized in this low-temperature bond disproportionated state. Through the growth of NdNiO_3/SmNiO_3 superlattices, it will be shown that the existence of a single or double metal-insulator transition temperature can be controlled as function of the layer periodicity. The structural and electronic mechanisms driving this behaviour will be discussed.

Heterostructures also offer large versatility from a synthesis point of view. For example, a double-perovskite heterostructure such as La_2NiMnO_6 can be reproduced as a \((111)_{\text{Lp}}\)-Oriented LaNiO_3/LaMnO_3 superlattices when 1 monolayer-thick layers are considered. The magnetic properties of the high Curie-temperature ferromagnetic La_2NiMnO_6 heterostructure, synthesized both through a thin film and a superlattice approach, will also be presented.
10:36AM X46.00010: Electronic properties of \((001)_{\text{pc}}\) and \((111)_{\text{pc}}\) SmNiO\(_3\)/NdNiO\(_3\) superlattices  
CLARIBEL DOMINGUEZ ORDONEZ (Presenter), University of Geneva, MARTA GIBERT, Physik-Institut, University of Zurich, JENNIFER FOWLIE, SARA CATALANO, University of Geneva, MICHEL VIRET, Service de Physique de l'Etat Condensé, CEA, NICOLAS JAOUEN, Synchrotron SOLEIL, JEAN-MARC TRISCONE, University of Geneva — Rare earth nickelates (R\(\text{NiO}_3\) (RNO), R = rare earth) stand out for their unique metal to insulator transition (MIT) upon reducing temperature (T\(_{\text{MIT}}\)), accompanied by an unusual antiferromagnetic ordering at T\(_{\text{Néel}}\leq T_{\text{MIT}}\). In bulk, NdNiO\(_3\) (NNO) exhibits T\(_{\text{Néel}}\leq T_{\text{MIT}}\), whereas SmNiO\(_3\) (SNO) displays T\(_{\text{Néel}}\leq T_{\text{MIT}}\). It has been shown that the T\(_{\text{MIT}}\) and T\(_{\text{Néel}}\) of the corresponding films can be tuned over a wide temperature range by means of epitaxial strain. Moreover, by growing along the \((111)_{\text{pc}}\) crystallographic direction, one can induce splitting of T\(_{\text{MIT}}\) and T\(_{\text{Néel}}\) over a temperature range never achieved for films grown in the \((001)_{\text{pc}}\)-orientation \([1]\). Here, we adopt a new strategy to study the interfacial matching constraints in R\(\text{NiO}_3\)-based heterostructures and their impact on the electronic properties by growing \((001)_{\text{pc}}\) and \((111)_{\text{pc}}\)-oriented \(\text{m(SNO)/n(NNO)}\)\(_N\) superlattices (SLs). We have found that the T\(_{\text{MIT}}\) and T\(_{\text{Néel}}\) of the whole system depend on the superlattice wavelength (\(\Lambda=m+n\)) with a single T\(_{\text{MIT}}\) for the shortest superlattice period (\(\Lambda\)). In order to understand the evolution of the lattice distortions with the SL periodicities and how interfacial coupling affects T\(_{\text{MIT}}\) and T\(_{\text{Néel}}\), theoretical predictions will be shown.

8:12AM X47.00002: Structural and electronic properties of ferroelectric domain walls in GeTe from first principles* 

DJORDJE DANGIC (Presenter), Tyndall National Institute, Cork, Ireland, ÉAMONN MURRAY, Imperial College London, UK, STEPHEN B FAHY, University College Cork, Ireland, IVANA SAVIC, Tyndall National Institute, Cork, Ireland — Domain walls in ferroelectric oxides can have significantly different properties than their bulk counterparts [1]. This represents a new avenue for the manipulation of material properties for specific purposes. GeTe is a ferroelectric material that is also one of the best performing thermoelectrics, combining beneficial electronic properties with low lattice thermal conductivity [2] and mechanical stability [3]. In this work, we have performed first principles calculations to understand how domain walls affect structural and electronic properties of GeTe. We have identified five different types of domain walls. We find that strong strain-order parameter coupling is present at all of them, which is beneficial for the lattice thermal conductivity reduction. We also show that some of the domain walls are conducting along their planes and insulating out-of-plane. The n- and p-type conduction of these domain walls, discovered in our calculations, presents an opportunity for tuning the electronic transport properties of GeTe for thermoelectric applications.

8:24AM X47.00003: Investigation of the structural, electronic and thermoelectric properties of GeX (X=S, Se, Te) monochalcogenides* 

AIDA SHEIBANI (Presenter), RAAD HALEOOT, BOTHINA HAMAD, University of Arkansas — Electronic band structure calculations were performed using density functional theory (DFT) for the orthorhombic structure of GeS and GeSe compounds, and the trigonal structure of GeTe. These compounds exhibit a semiconductor behavior with band gaps of 1.23, 0.899, and 0.68 eV for GeS, GeSe and GeTe, respectively. Based on these DFT calculations their thermoelectric properties were obtained using Boltzmann transport theory. Different procedures were adopted to increase the thermoelectric properties of these compounds including doping and lowering the dimensionality.

8:36AM X47.00004: First-principles Study of Phonon Drag Effect in SiGe Alloys* 

QIAN XU (Presenter), JIAWEI ZHOU, TEOHUAN LIU, GANG CHEN, Department of Mechanical Engineering, Massachusetts Institute of Technology — Phonon drag is the effect that Seebeck coefficients of semiconductors are often greatly augmented at low temperatures. Recent works have shown that it is important in many materials' thermoelectric (TE) performance even at room temperature, and the major phonons contributing to phonon drag are with longer mean free path (MFP) and lower frequency than those carrying heat. Meanwhile, the point defects in alloys tend to scatter phonons with short MFP and high frequency. Combining phonon drag with alloying might lead to better low-temperature TE materials.

We perform the first-principles calculations on the $zT$ value of n-type SiGe alloys with different doping levels at different temperatures. We found that phonon drag contributes significantly to the Seebeck coefficient, especially at lower temperatures. The Seebeck coefficient peaks around the composition of Si$_{0.15}$Ge$_{0.85}$ due to band convergence, which agrees with reported experimental data. Our first-principles calculations are able to provide guidelines for the design of better low-temperature TE materials.

*This work is supported partially by DOE EFRC (Grant No. DE-SC0001299, for fundamental studies on thermoelectrics), and partially by DARPA MATRIX program (Grant No. HR0011-162-0041 for supporting its thermoelectrics programs).
Thermoelectric properties of ternary chalcogenides and oxides from first principles calculations

HITOSHI MORI (Presenter), MASAYUKI OCHI, HIDETOMO USUI, KAZUHIKO KUROKI, Osaka University — Several ternary chalcogenide compounds have been reported as high-performance or promising thermoelectric materials. Previous works have shown that AgBiSe₂ and TlSbTe₂ have high ZT values of 1.5 and 0.87, respectively [1,2]. Even though there are many other possible candidates of ternary chalcogenides, thermoelectric properties of most of them have not been reported.

In the present study, in order to narrow down promising candidates, we analyze the thermoelectric properties of 20 chalcogenide and oxide compounds represented as ABCh₂ (Ch = O, S, Se, Te) by using first-principles calculation and Boltzmann equation. We find that the power factor of the compounds composed of A = Li, Na, B = Ga, In, and Ch = O are far higher than those of other compounds, which originates from the favorable electronic structure possessing quasi-one-dimensionality and multi valley degeneracy. It is also revealed that we can control the electrical conductivity along the c-axis by the substitution of A atom.

Lone-pair Driven Thermoelectrics at Room Temperature

SAIKAT MUKHOPADHYAY (Presenter), THOMAS REINECKE, United States Naval Research Laboratory — Identifying materials which offer crystal-like charge transport and glass-like phonon transport for improved efficiency (ZT) of thermoelectric materials has been a challenging task. The complex interrelationship between these competing materials properties makes such materials rare. Here we report a series of new materials with promising thermoelectric properties; ZT ~ 0.8, at room temperature. This superior ZT stems from the high electrical conductivity and ultralow thermal conductivity; k ~ 0.3 W/m-K, as obtained from the two-channel model (phonons + oscillators). The calculated k is mainly dominated by the Einstein oscillators, which is similar to the cases with amorphous materials where mean free paths become comparable with the characteristics atomic bond lengths. Very low-group velocities due to weakly bonded atoms and strong anharmonicity associated with S² lone-pair electrons explain such low-k in these systems.

A search for good semi-metallic thermoelectric materials

MONA ZEBARJADI (Presenter), MAXIME MARKOV, SEYED EMAD REZAEI, SAFOURA NAYEB SADEGHI, KEIVAN ESFARJANI, University of Virginia — Heavily doped semiconductors are the most studied class of thermoelectric materials. The presence of the bandgap breaks the symmetry between electrons and holes, allowing large Seebeck coefficient values which are 2-3 orders of magnitude higher than metals. However, the optimal chemical potential in these materials requires a high level of doping usually larger than 10¹⁹ cm⁻³, resulting in low carrier mobility. Semimetals have properties in between semiconductors and metals with Seebeck coefficient values in between. Since there is no bandgap, the Seebeck coefficient values are small for structures where in electron-hole bands are similar. For example, for Dirac semimetals and at the Dirac point, the Seebeck coefficient is zero. However, if there is a large asymmetry between electron-hole bands (that is there is a large effective mass difference), then the Seebeck coefficient of intrinsic semimetals can be as large as those of heavily doped semiconductors. This combined with large intrinsic carrier mobility, makes semimetals potential thermoelectric candidates. In this talk, I will present our search results for semimetals with large Seebeck coefficient values using first principles calculations.

Temperature effects on the thermoelectric properties of PbTe: a first-principles study

JIANG CAO (Presenter), JOSE QUERALES-FLORES, AOIFE R. MURPHY, Tyndall National Institute, STEPHEN B FAHY, University College Cork, IVANA SAVIC, Tyndall National Institute — Thermoelectric materials are of intense interest for energy harvesting applications, because they convert waste heat into electricity. PbTe is one of the most efficient thermoelectric materials. It has a direct narrow gap that increases strongly with temperature [1]. Here we study how the temperature dependence of the electronic bands influences the thermoelectric transport properties of PbTe from first principles. The calculated temperature variation of the direct gap accounts for both thermal expansion and electron-phonon coupling [2]. The temperature dependence of the electronic bands is modeled using a two band Kane model. We also build accurate models of phonon bands and electron-phonon scattering from first principles [3]. By solving the Boltzmann equation, we calculate the thermoelectric transport properties of PbTe in very good agreement with experiments. We find that the temperature variation of the direct gap has substantial effects on these properties, leading to a high figure of merit $zT$ over a broader range of doping concentrations at high temperatures.

Electrical and thermal properties of 2D semimetallic transition metal dichalcogenides TiSe2 and ZrTe2

SEYED EMAD REZAEI, SAFOURA NAYEBSADEGHI, MONA ZEBARJADI, KEIVAN ESFARJANI (Presenter), University of Virginia — 2D materials have manifested a variety of interesting electrical and thermal properties. In this work, we have investigated the electrical and thermal properties of semi-metallic TiSe2 and ZrTe2 using density functional theory calculations. The effect of several exchange-correlation potentials on the band structure and thermoelectric properties has been investigated. We have also shown that tensile strain will open a gap and cause a corresponding non-linear change in electrical transport properties of these materials. Finally phonons and thermal conductivity of ZrTe2 were calculated, and its thermoelectric properties assessed.

Thermal Transport of Part-crystalline Part-liquid Materials

WENQING ZHANG (Presenter), Department of Physics, Southern University of Science and Technology — Multi-component materials usually manifest crystal structure with chemical bond hierarchy, exhibiting the part-crystalline part-liquid (PCPL) or part-crystalline part-amorphous state as the emerging candidates of thermoelectric materials. These materials contain at least two different types of sublattices, one crystalline and another one strongly disordered or liquid-like, leading to extremely low lattice thermal conductivity. This talk presents a survey on the general characteristics of the thermal transport in the part-crystalline materials. We also develop an approach to simulate the complex thermal transport process. We also compare the results in Green-Kubo method and Boltzmann transport theory to elucidate the thermal conductivity of PCPL materials by using empirical interatomic potentials fitting to the liquid-like thermoelectrics like Cu2Se. The contribution to thermal transport from each structural component, i.e. the rigid-crystalline, strongly disordered, and/or liquid-like parts, are respectively analyzed, and the underlying mechanism is elucidated. Based on the observation, a general trend about the thermal transport in a large group of materials is analyzed. Relationship to minimum thermal conductivity is also discussed.

Abstract Withdrawn
10:36AM X47.00012: First principles study on the thermoelectric properties of delafossite compounds

HIDETOMO USUI (Presenter), KAZUHIKO KUROKI, Osaka University — Thermoelectric materials should have the coexistence of large power factor $PF = \sigma S^2$ and low thermal conductivity for the enhancement of thermoelectric efficiency. It is however difficult to obtain good thermoelectric materials because the power factor is maximized at a certain doping level due to the relationship between the Seebeck coefficient and the electrical conductivity. We proposed that the "pudding mold type band", which has a flat portion at a band edge gives rise to large power factor [1,2].

Recently, PtCoO$_2$ has been found to possess extremely small resistivity and high mobility.[3] The electronic band structure of PtCoO$_2$ exhibits the pudding mold type shape, which suggests the possibility to possess large thermoelectric performance. We study the thermoelectric properties of PtCoO$_2$ from first principles calculations within the Boltzmann transport theory and the rigid band approximation. It is found that the power factor can be enhanced due to high mobility by controlling the carrier concentration.

10:48AM X47.00013: First-principles study of LaOBiPbS$_3$ and its analogous compounds as thermoelectric materials

KEIYA KUREMATSU (Presenter), MASAYUKI OCHI, HIDETOMO USUI, KAZUHIKO KUROKI, Department of Physics, Osaka University — LaOBiPbS$_3$ is a kind of pnictgen-dichalcogenide layered compounds, which have recently been investigated as thermoelectric materials owing to their low thermal conductivity and high controllability of constituent elements [1, 2]. However, thermoelectric performance of LaOBiPbS$_3$ is not very high and that of its analogous compounds is still unknown. In this study, we theoretically investigate the thermoelectric property of LaOBiPbS$_3$ and its analogous compounds: LaOPnTtCh$_3$ ($Pn = As, Sb, Bi$; $Tt = Sn, Pb$; $Ch = S, Se$). We find that there are two key factors for increasing thermoelectric performance: one is the spin-orbit coupling, mainly controlled by $Pn$, and the other is the hybridization between $Pn$ in the $PnS_2$ layer and $Ch$ in the rock-salt layer, which determines the gap size. In fact, we find that LaOSbPbSe$_3$, which optimizes these key factors but has not been synthesized yet, can have a power factor that is about 5 times as large as that of the known compound LaOBiPbS$_3$.

Friday, March 8, 2019 8:00 AM - 10:36 AM

Session X48 GSNP: Statistical and Nonlinear Physics I

Focus
8:00AM X48.00001: Interlocking of Sheared Non-convex Hexapods* YUCHEN ZHAO (Presenter), Department of Physics, Duke University, Durham, NC, USA, JONATHAN BARÉS, Laboratoire de Mécanique et Génie Civil, Université de Montpellier, CNRS, Montpellier, France, ROBERT P BEHRINGER, Department of Physics, Duke University, Durham, NC, USA — Packings of non-convex or elongated particles can form free-standing structures like walls or arches, due to particle interlocking effects leading to geometric cohesion. Interlocking effects have been studied for various particle shapes and aspect ratios, but the microscopic origins of the stabilization of rigid structures remains unclear. We report on experiments on hexapods that consist of three orthogonal sphero-cylinders, whose centers are bonded at one origin. The diameter and lengths of the sphero-cylinders are 3, 10, 20 and 30 mm, respectively. We subjected aggregates of spheres or hexapods to quasistatic direct shear and developed novel techniques to measure structural information such as particle positions, orientations, and bending. For spheres and 10 mm hexapods, we observed plasticity phenomena consistent with the Mohr-Coulomb model. For 20 and 30 mm hexapods, however, we observed strain-stiffening during shear. By analyzing X-ray microcomputed tomography data collected during the shearing process, we found that the onset of strain-stiffening is associated with particle bending and that particles that bend significantly tend to be aligned with the compression direction of the shear.

8:12AM X48.00002: Study of Electrical Percolation in CrO$_2$/Cr$_2$O$_3$ nanoparticle composite system SHIVA POKHREL (Presenter), BRENDON WATERS, EHAB H ABDELHAMID, ZHI FENG HUANG, BORIS NADGORNY, Wayne State University — Percolation is a random probabilistic process that triggers a phase transition in disordered systems. In this work we investigate the classical percolation behavior in a CrO$_2$/Cr$_2$O$_3$ half-metal/insulator composite system. Cr$_2$O$_3$ was obtained by annealing of CrO$_2$ powder in air; composite samples with varying volume fraction were prepared by mixing Cr$_2$O$_3$ with CrO$_2$. The percolation threshold and the power law scaling exponent near the threshold were identified by studying the changes in the electrical resistance of the pellets with different volume fractions. Experimental results are compared with theoretical calculations, which were carried out via the combination of mechanical contraction method and Monte Carlo simulations for this binary composite system of non-overlapping hard spherocylinders.

8:24AM X48.00003: Robotic active matter on a deformable surface generates an analog gravity system SHENGKAI LI (Presenter), YASEMIN OZKAN AYDIN, CHARLES XIAO, Georgia Institute of Technology, GABRIELLA H SMALL, Physics and Astronomy Department, Swarthmore College, JENNIFER RIESER, PABLO LAGUNA, DANIEL GOLDMAN, Georgia Institute of Technology — Many analog gravity models of general relativity (GR) have been developed (e.g. in fluids and Bose-Einstein condensates) with goals to probe GR-like phenomena in the laboratory. One common analog is to study the dynamics of freely moving objects (like marbles) on two-dimensional curved or elastic sheets. Such systems have issues which prevent them from functioning as analog gravity models, including dominance of Earth's gravity over metric dynamics, the inability to model time-like curvature effects, and dissipation which limits persistent dynamics. Here, we circumvent these issues by developing an exact analog gravity system based on an active matter system: a robot car driving on a deformable membrane. We observe qualitative GR-like features including circular and precessing orbits around a central depression. We extract a dynamical system that describes our experiments. Remarkably it is the self-propelled aspects of the car that allow a formal mapping to Einstein's equations in 2+1 dimensions, thus creating an accurate GR model whose parameters can be tuned to mimic different astrophysical situations (e.g. Schwarzschild metric around a black hole).

8:36AM X48.00004: Membrane Diffusivity Driven Microtubule-Based Active Nematics* JOSEPH LOPES (Presenter), LINDA S. HIRST, AMANDA TAN, University of California, Merced — Biomimetic systems formed from active nematics provide important insights into how far-from-equilibrium materials can demonstrate assembly, motion, and replication. Active nematics produce collective motion through the interaction between moving particles. Here we couple motor proteins to a lipid membrane and perform gliding assays with dense microtubule populations. We observe the formation of an active nematic phase during gliding, driven by the microtubules propensity to not cross each other when bound to a diffusive surface. In the dilute case microtubules will coalesce into bundles for short term durations, and as density is increased the physical anisotropy of the microtubules forces the formation of the nematic phase. The lipid membrane is a tunable surface that can be deposited on a variety of geometries making this a promising system for the development of more complicated active matter investigations.

Dendritic crystal growth of ammonium nitrate from aqueous solution  ANDREW DOUGHERTY (Presenter), Lafayette College — Dendritic crystal growth is an important example of nonequilibrium pattern formation that involves both nonlinear and noise-driven effects. The resulting large-scale structures are sensitively dependent on relatively small effects, such as surface tension, and on small anisotropies in those quantities. In this work, we report new results for the dendritic growth of ammonium nitrate from supersaturated aqueous solution. This system has been studied previously by van Driel et al.[1] and shown to exhibit several different morphologies, including both steady state dendritic growth and a state with persistent tip-splitting behavior. Specifically, we present new measurements of the tip radius \( r \), growth speed \( v \), and sidebranch spacing \( \lambda \), along with initial estimates of the product \( Dd_0 \), where \( D \) is the chemical diffusion constant and \( d_0 \) is the capillary length. We then compare the resulting estimate of \( \sigma^* = 2 d_0 D / v r^2 \) with the values for other materials and with theoretical expectations.

Twisted states in low-dimensional hypercubic lattices* YOUNG SUL CHO (Presenter), SEUNGJAE LEE, HYUNSUK HONG, Chonbuk National University — Twisted states with non-zero winding numbers have been observed in a ring composed of sinusoidally coupled identical oscillators. In this presentation, we consider finite-sized \( d \)-dimensional hypercubic lattices, namely square \((d=2)\) and cubic \((d=3)\) lattices with periodic boundary conditions. For identical oscillators, we observe new states where the oscillators belonging to each line (plane) for \( d=2 \) (\( d=3 \)) are phase synchronized with non-zero winding numbers along the perpendicular direction. We note that these states can be reduced into twisted states in a ring with the same winding number if we regard each subset of phase-synchronized oscillators as one single oscillator. For nonidentical oscillators, we observe similar patterns with slightly heterogeneous phases in each line \((d=2)\) and plane \((d=3)\) for random configurations.

Drainage through holes drives Arctic sea ice melt ponds to the critical percolation threshold* PREDRAG POPOVIC (Presenter), MARY C SILBER, DORIAN S ABBOT, University of Chicago — During the summer, vast regions of the Arctic sea ice are covered by meltwater ponds that significantly lower the ice reflectivity and accelerate melting. Ponds develop over the summer melt season through an initial stage of rapid growth followed by drainage through macroscopic holes. Recently, we showed that ponds after drainage resemble percolation clusters near a critical percolation threshold. Here, we explore the physical mechanism behind this previously-unrecognized constraint on pond evolution. We show that organization towards the percolation threshold is a consequence of pond drainage through macroscopic holes. The threshold sets the upper limit and scales the pond coverage throughout its evolution after the beginning of drainage. Furthermore, we show that, after rescaling, pond coverage fraction as a function of number of open holes follows a universal curve. This curve governs pond evolution during and after pond drainage, which allows us to formulate an equation for pond coverage evolution that captures the dependence on ice properties.

Disconnectivity graphs in planted spin-glass problems KATJA BISWAS (Presenter), HELMUT KATZGRABER, Physics, Texas A&M University — A disconnectivity graph is a simplified representation of a high-dimensional energy landscape consisting of low-energy pathways between different minima in the landscape. As such, one can use disconnectivity graphs to obtain insights into the accessibility of different minima in the energy landscape, and therefore make predictions for the computational effectiveness of different optimization methods. In this talk different disconnectivity graphs for different planted spin-glass problems are presented, and their similarities and differences discussed.

Floating elastic membrane in rotation : shape of interface and wrinkling instability LUCIE DOMINO (Presenter), Laboratoire PMMH, ESPCI Paris, DOIREANN O’KIELY, DOMINIC VELLA, University of Oxford, ANTONIN EDDI, Laboratoire PMMH, ESPCI Paris — When rotated at constant speed, the surface of a liquid takes the well known shape of a parabola. If the surface of the liquid is covered with a thin elastic membrane, the force balance is modified, which changes the obtained shape. We study the influence of the elastic properties of the membrane on this shape, and compare with experiments. We also report the apparition of a buckling instability at the edges of the floating membrane : radial creases appear and grow closer to the center as rotation speed is increased.
Geometric Stiffening and Softening of an Indented Floating Thin Film

MONICA RIPP (Presenter), Physics, Syracuse University, VINCENT DÉMERY, Physics, Université de Lyon, TENG ZHANG, Mechanical and Aerospace Engineering, Syracuse University, JOEY PAULSEN, Physics, Syracuse University — Thin sheets can behave nonlinearly while the local material response is purely linear. We separate two distinct mechanisms for geometric nonlinearities by studying the normal-force response of an indented polymer film on a liquid bath, using experiments, simulations, and theory. First, we show that the force reaches a plateau at large indentation, causing the effective spring constant of the system to soften, and we use a simple geometric model to capture this behavior at large slopes [1]. Then, we map out the full phase diagram at small slopes, supporting recent predictions [2] that the system stiffens out of the typical linear response for small deflections. Our results provide a prototypical example of how multiple distinct geometric nonlinearities may arise under monotonic driving.

Support from NSF-DMR-CAREER-1654102 and NSF-IGERT-1068780 is gratefully acknowledged.

Simulating the dynamics of actuated thin elastic sheets

SILAS ALBEN (Presenter), ROBERT D. DEEGAN, ALEX A. GORODETSKY, University of Michigan — We develop a method to simulate the dynamics of thin elastic sheets under time-dependent external or internal forces, e.g. contact forces, temperature change, or chemical reactions within the sheet. The dynamics are difficult to simulate efficiently due to numerical stiffness resulting from the in-plane stretching term in the elastic energy. We present a semi-implicit time discretization that allows the dynamics to be simulated stably with essentially no time-step constraint, allowing for fast simulations. We show examples for thin sheets, bilayers, and models of active gel materials, using different spatial geometries and different types of spatial discretizations.

We acknowledge support from the Michigan Institute for Computational Discovery and Engineering (MICDE).

Damage propagation in a model cohesive granular medium

MARIE-JULIE DALBE (Presenter), NICOLAS VANDENBERGHE, EMMANUEL VILLERMAUX, IRPHE, Aix-Marseille University, CÉDRIC BELLIS, LMA, CNRS — Understanding how a crack propagates in a heterogeneous medium is essential in numerous fields, since this process can lead to catastrophic events. The opening of a crack can lead to the emission of an elastic wave, which can interfere with the rest of the material, and provide energy to open new cracks. In particular, in a brittle material, the critical stress leading to rupture is different from one experiment to another. This is usually imputed to the presence of defects, which are weaker points in the material, making crack propagation easier. The interaction of the elastic waves emitted by a crack opening, and existing defects is still not fully understood.

We study a model material made of a monolayer of glass grains attached by individual elastic bridges. Using a high-speed camera, we can follow the propagation of elastic waves in this material as well as the crack opening dynamics. We can in particular observe the interaction of existing cracks and defects.

Mechanism of large-scale flow reversals in turbulent thermal convection

YIN WANG (Presenter), Department of Physics, Hong Kong University of Science and Technology, PIK-YIN LAI, Department of Physics, National Central University, Taiwan, HAO SONG, 3College of Physics and Energy, Shenzhen University, P. R. China, PENGER TONG, Department of Physics, Hong Kong University of Science and Technology — We report a new kind of convective instability for turbulent thermal convection in a closed thin disk cell. It is found that the convective flow stays over a long steady “quiet period” having a minute amount of heat accumulation, followed by a short and intermittent “active period” with a massive eruption of thermal plumes to release the accumulated heat. The rare massive eruption of thermal plumes disrupts the existing large-scale circulation across the cell and resets its rotational direction. The distribution function of the plume eruption amplitude is found to follow the generalized extreme value statistics with an upper bound, which changes with the physical properties of the convecting fluid. The experimental findings have important implications to many closed convection systems of geophysical scale, in which massive eruptions and sudden changes in large-scale flow pattern are often observed.

Friday, March 8, 2019 8:00 AM - 11:00 AM

Session X49 DPOLY: Charged and Ion-Containing Polymers BCEC 252A - Di Jia, Khatcher Margossian, University of Massachusetts, Amherst
The increasing environmental concerns and global warming, attributed to conventional energy production, have motivated researchers to scout for clean energy harvesting (EH) strategy from pollutant-free and natural energy resources. Inspired by naturally occurring mechnano-electroactive materials, flexo-ionic devices consisting of a flexible solid polymer electrolyte membrane (PEM), consisting of an ionic compound and a polymer matrix host, laminated between two compliant carbonaceous electrodes were developed. The laminated flexo-ionic PEMs can generate electrical potential and current via ion diffusion/polarization by subjecting the PEM assembly under mechanical deformation. By varying cation sizes and valencies of ionic compounds in the development of these PEMs, the effects of ion size and valency on flexoelectric properties (i.e. output voltage and current/polarization), ionic conductivity, viscoelastic and mechanical properties were investigated as a function of ion concentration and mode of mechanical stimuli involving intermittent square (low frequency) and dynamic oscillatory (high frequency) displacement. The synergic effect of these factors and their roles in mechano-electrical energy conversion will be discussed.

*Supported by NSF-DMR-Polymers #1502543

The present article describes a novel phenomenon of polarity flipping during mechano-electrical energy conversion subjected to bending deformation of flexible polymer electrolyte membranes (PEM), which were originally developed for polymeric ion conductors in solid Li-ion batteries. This bending induced electrical polarization is analogous to flexoelectricity found in insulators and dielectric materials. However, the basic principle of flexoelectricity in PEMs operates based on electrical energy generation driven by ion polarization/depolarization across the PEM subjected to a pressure (or stress) gradient during bending. The observed flexoelectric coefficient (~323 μC/m), i.e., a measure of the converted mechano-electrical energy, is the highest among all flexoelectric materials hitherto reported. Of particular importance is that the present work is the first to demonstrate the occurrence of polarity switching, i.e., reversal of the polarization direction with increasing succinonitrile (SCN) concentration, attributable to changing ionic size of solvated Li-SCN complexes.

*Supported by NSF-DMR-Polymers #1502543

Coating lithium anode with flowable polymer layer may effectively suppress lithium dendrite growth at high current density.[1] Although the underlying mechanism is poorly explored, the sensitivity on dielectric permittivity and thickness of the polymer layer has been identified.[2] A coarse-grained simulation of lithium deposition in presence of polymer coating, which explicitly incorporates the dielectric heterogeneity, is presented. It was found that the more effective coatings are more adaptable, have modest elasticity, and maintain integrity during deposition. Higher polymer dielectric permittivity and coating thickness inhibit the growth of dendrite, but inevitably sacrifice battery performance.

*This research has been supported by the Assistant Secretary for Energy Efficiency and Renewable Energy, Office of Vehicle Technologies of the U.S. Department of Energy through the Advanced Battery Materials Research (BMR) Program (Battery500 Consortium).
Ion Transport in Well-Aligned Block Copolymer Electrolytes*

PETER BENNINGTON (Presenter), DANIEL SHARON, MOSHE DOLEJSI, PAUL F NEALEY, SHRAYESH PATEL

Institute for Molecular Engineering, University of Chicago — The independently tunable electrical and mechanical properties of block copolymer electrolytes (BCPEs) makes them attractive candidates for ion exchange membranes. However, these materials often show a lower conductivity even after accounting for the reduced volume fraction of the conducting phase. This reduction in conductivity has been ascribed to the tortuosity of the conducting pathways, poorly connected domains, grain boundaries, and low mobility near the BCP interface. It is often difficult to differentiate these nanoscale hinderances to transport in microns-thick membranes due to the inability to fully control the orientation of the BCP domains. Here, we present a new approach to this problem wherein we can fully align the conductive domains of a BCPE along the direction of the electric field produced by interdigitated electrodes (IDEs), thus enabling us to divorce morphological from molecular-level effects. We observe that a low mobility region near the block copolymer interface might explain the lower conductivity of BCPEs compared to an equivalent volume fraction of homopolymer electrolyte.

Phase Behavior of Salt Doped A/B/A-B Ternary Polymer Blends*

SHUYI XIE (Presenter), EN WANG, DANIEL J MEYER, TIMOTHY LODGE

University of Minnesota — The phase prism of a pseudoternary polymer blend system containing low molar mass poly(ethylene oxide) (PEO) and polystyrene (PS) homopolymers, a PS–PEO block copolymer (SEO), and lithium bis(trifluoromethanesulfonamide) (LiTFSI) is constructed. The addition of salt increases the segregation strength, and thus causes both macroscopic and microscopic phase separation. The phase behavior of the ternary system is studied in detail, including isothermal slices at different temperatures and isopleths with different phi_PEO/phi_h ratios. Also, a bicontinuous microemulsion (BμE) channel is located, and the structure as a function of salt concentration and temperature is investigated. Moreover, the congruency condition near the BμE channel will be discussed. This work may serve as a benchmark for experimental design of polyelectrolyte systems with tunable ionic conductivity and high mechanical modulus and help understand the physics underlying the structure and dynamics of ion-containing A/B/A-B ternary blends.

*This work was supported by the Office of Basic Energy Sciences (BES) of the U.S. Department of Energy (DoE), under Contract DE-FOA-0001664.

Detection of the Order-to-Disorder Transition in Block Copolymer Electrolytes Using Quadrupolar 7Li NMR Splitting*

LORENA GRUNDY (Presenter), GURMUKH SETHI, MICHAEL GALLUZZO, NITASH BALSARA

Chemical and Biomolecular Engineering, University of California, Berkeley — Mixtures of block copolymers and salts have been studied for use as safe electrolytes for batteries with energy-dense lithium metal anodes. Locating the order-to-disorder transition (ODT) in these systems is important, because microscopic morphology has a profound impact on bulk properties including ionic conductivity and mechanical rigidity. In this study, the ordered morphologies in a series of mixtures of polystyrene-\(\text{b}\)-poly(ethylene oxide) and lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) salt are shown to be aligned due to exposure to the magnetic field in an NMR instrument, which is confirmed using small-angle X-ray scattering (SAXS). This alignment results in quadrupolar triplet peak splitting in \(^7\text{Li}\) NMR, which disappears above the \(T_{\text{ODT}}\). The \(T_{\text{ODT}}\) identified using this novel NMR method is consistent with that determined using SAXS.

*Funding for this work was provided by the National Science Foundation through Award DMR-1505444. Small Angle X-Ray scattering work at the Advanced Light Source was supported by contract no. DE-AC02-05CH11231. Work at the Stanford Synchrotron Radiation Light Source at SLAC National Accelerator Laboratory was supported by contract no. DE-AC02-76SF00515. NMR work was supported by the UC Berkeley College of Chemistry NMR Facility.
9:12AM X49.00007: Counterion condensation and ionic conductivity in microphase separated block copolymer electrolytes*  CHRISTOPHER ARGES (Presenter), QI LE, KE LE, REVATI KUMAR, Louisiana State University — Ion-conducting polymer electrolytes are central components to many types of electrochemical cells spanning batteries, fuel cells, and water purification units. Ionic conductivity is an important property of these materials as it controls the thermodynamic efficiency of electrochemical systems. Many studies correlate micro-structure attributes of polymer electrolytes to ionic conductivity. However, the impact of counterion condensation, a proxy for the extent and strength of ion-pairing, on ionic conductivity has received less attention and its impact on ionic conductivity is not clearly known. This talk highlights our effort to study counterion condensation in thin film ion-conducting block copolymer electrolytes with precisely defined microstructures. Ionic conductivity and 2D AFM force mapping, combined with all-atomistic molecular simulations, substantiate that microphase separated block copolymer electrolytes are less prone to counterion condensation resulting in lower resistances to ionic charge transport. These findings motivate future studies to probe counterion condensation in precisely defined block copolymer electrolyte microstructures as function of solvation and charge density.

*U.S. Department of Energy Office of Basic Energy Sciences Award #DE-SC0018989

9:24AM X49.00008: Compositionally Asymmetric Block Polyelectrolyte Morphologies*  SEBASTIAN RUSSELL (Presenter), ALAN C WEST, OLEG GANG, Chemical Engineering, Columbia University, MONICA OLVERA DE LA CRUZ, Material Science and Engineering, Northwestern University, LUIS M. CAMPOS, Chemistry, Columbia University, SANAT KUMAR, Chemical Engineering, Columbia University — The delicate balance of (short ranged) enthalpic interactions and entropic factors direct the self-assembly in nonionic diblock copolymers (BCPs) which is exploited in a broad range of applications, e.g., lithography, energy storage, membrane separations, and optics. We demonstrate that such behavior is profoundly altered when one block carries a charged trisaminocyclopropenium (TAC) ion at each monomer. These charged-neutral copolymers (CNBPs) display strongly asymmetric morphology maps with the unique aspect that the minority component, the charged block, has a strong propensity to form the continuous matrix. Such observations, coupled with the unexpectedly low TAC dielectric constant (~2.5) lead us to postulate that the CNBP morphology is strongly modified by long-range electrostatics. This conjecture is verified by detailed geometric calculations and quantitatively captured by a simplistic scaling model derived from surfactant self-assembly principles. This fundamental insight into the role of strong electrostatics on CNBP self-assembly has attractive implications for ion transport in polymeric media while simultaneously improving their mechanical properties.

*LMC thanks the NSF (NSF CAREER DMR-1351293) for funding.

9:36AM X49.00009: Mechanisms of Ion Diffusion as a Function of Microstructure in Ionomer Melts  JONATHAN BOLLINGER (Presenter), MARK STEVENS, AMALIE FRISCHKNECHT, Sandia National Laboratories — Understanding how the mechanisms and relative rates of ion transport depend on melt morphology and polymer architecture is a fundamental issue in ionomers. The low dielectric constant of the polymer backbone drives microscale aggregation of charged-groups and counterions, which can greatly impact ion conductivity. For some melts, aggregates can percolate and provide pathways for free ions to move independent of polymer dynamics; in other cases, isolated aggregates are favored and transport happens through infrequent collision-exchange events. We perform molecular dynamics simulations of coarse-grained ionomer melts that span these morphologies to understand charge mobility as a function of polymer architecture and background dielectric constant. For percolated networks, counterion diffusion depends weakly on these variables and results from discrete step motions along more static pathways of bound charged-groups. In contrast, charge mobility varies widely for systems that form clusters as the probability of ion exchanges is sensitive to the length scale and dielectric nature of the polymer-backbone regions between clusters. We explicitly measure the time scales of these distinct mechanisms and show that they directly underlie diffusion coefficients of the charged species.

9:48AM X49.00010: Structural and Dynamical Properties of Water and Salt ions in Confined Geometries of Block Copolymers  DIPAK ARYAL (Presenter), RITUPARNA SAMANTA, VENKATRAGHAVAN GANESAN, University of Texas at Austin — Understanding the transport properties of water and salt ions in confined geometries of block copolymers is crucial for water purification including others nanotechnology and biotechnology. Here, we investigate the local diffusivities along with supporting structural properties of water and salt (Na⁺ and Cl⁻) ions in the different regions from the pore with varieties of sizes made by morphologies of liner triblock copolymers such as lamella, cylinder, and gyroid using dissipative particle dynamics (DPD) mesoscale simulations. Besides, we extend our study to investigate the water and salt permeability through the membranes. Our results suggest that diffusivities of water and salt ions in the different region of pores are different than in the bulk phases. Under the confined conditions, the mobility of water and salt ions are perturbed by the additional interaction forces that arise from the blocks that have preferable water selectivity, which ultimately reduces the local molecular diffusion. Further, the geometries of block copolymers with different sizes of pore also influence the structural and dynamical properties of water and salt ions.
10:00AM X49.00011: Phase Separation of Polymer Mixtures with Highly Concentrated Ions  ISSEI NAKAMURA (Presenter), Physics, Michigan Technological University — The fluctuation of electrostatic potentials and the dielectric contrast between species often play a crucial role in the liquid-liquid phase separation of electrolytes, but the effect of correlation between the two on the phase behavior remains elusive. Accordingly, we develop a Ginzburg-Landau theory that simultaneously accounts for the two effects for liquid mixtures containing polymer and ionic liquid. Our theory suggests that both effects can be equally important to consider the trend of the phase boundary of the liquid-liquid phase separation involving highly concentrated ions. Moreover, our present results of ionic liquids compare favorably with those calculated by the Gaussian approximation (or the one-loop expansion) of self-consistent field theory. We also show that a comparison between theory and experiment suggests that the fluctuation effect may also be significantly suppressed in ionic liquids. <div class="grammarly-disable-indicator"> </div>

10:12AM X49.00012: Effects of Molecular Polarity and Polymerization on Ion Solvation in Polymer Melts  CAMERON SHOCK (Presenter), ISSEI NAKAMURA, Physics, Michigan Technological University, MARK STEVENS, AMALIE FRISCHKNECHT, Sandia National Labs — We study the solvation energy of ions in polymerized and non-polymerized dipolar solvents using molecular dynamics simulations. We use a coarse-grained Stockmayer fluid model to observe the effects on solvation energy for monovalent, divalent, and trivalent ions due to varying solvent dipole moments. We show that increasing polymer chain lengths leads to significantly more negative solvation energies of ions. This is because in polymerized solvents, chain connectivity leads to higher local packing fraction of solvent dipoles near the ion and hence a stronger dielectric response. Also, there is a substantial difference between simulation results and the predicted Born solvation energy using Onsager theory for dielectrics. We hypothesize that the compressibility of solvents and local dipolar structure are key to understanding the difference between simulated and predicted results.

10:24AM X49.00013: Peering into Phase-Separated Perfluorinated Sulfonic-Acid Ionomers with Energy-Tunable X-rays  GREGORY SU (Presenter), ISVAR CORDOVA, AHMET KUSOGLU, CHENG WANG, Lawrence Berkeley National Laboratory — Ion-containing polymers such as perfluorinated sulfonic-acid (PFSA) ionomers play a critical role as the ion-conducting electrolyte in various electrochemical energy devices such as polymer-electrolyte fuel cells, redox flow batteries, and solar fuel generators. The ion transport properties in PFSA are controlled by the nanoscale phase-separation of hydrophilic and hydrophobic domains. Next-generation membranes leverage new chemistries that enable good conductivity without requiring high relative humidity. As with well-studied PFSA like Nafion, understanding the structure-property relationships in these new materials is critical to optimizing performance. Here, synchrotron X-rays with energies tuned to the sulfonic-acid functional group provide enhanced contrast to reveal the phase separation in dry and wet PFSA membranes with various chemistries. These studies elucidate connections among molecular architecture, morphology and transport properties that can be used as design rules for ionomer membranes and highlight the capabilities of X-rays to understand structure and chemistry in ion-containing polymers in general.

10:36AM X49.00014: Macroion Complexation and Conformation of Neutral Polymer in Solution  MANUELA FERREIRA (Presenter), BENXIN JING, YINGXI ELAINE ZHU, Chemical Engineering, Wayne State University — Unusual electric charging and conformational behavior of neutral polymers, such as poly (ethylene oxide) (PEO), in polar solvents have been reported in the past. To further explore the charging mechanism, we compare the effect of simple small ions and multivalent macroions on the electrical potential and conformation of PEO in solutions of varied polarity. Measured electrical potential indicates that multivalent macroions can effectively bind with PEO to cause significant increase of the effective charges of a PEO chain, which is accompanied with the collapse of PEO chain in polar solvents as determined by single-molecule laser spectroscopy. In contrast, little change of PEO electrical potential and conformation is observed with lithium salt added solutions. More interestingly, as further increasing macroion concentration, unconventional liquid-liquid separating coacervate complexation is observed with macroion-added PEO solution, leading to a facile process of PEO-based ionomers.

10:48AM X49.00015: Diffusion of Charged Macromolecules under Strong Electric Repulsion*  KUO CHEN, JINGFA YANG, JIANG ZHAO (Presenter), Chinese Academy of Sciences — The complicity of diffusive motion of individual charged macromolecules under strong electrostatic interaction has been puzzling for decades. As an effort to explore the mystery, diffusion of polyelectrolyte molecules is investigated at single molecular level. By dual-color fluorescence correlation spectroscopy, the diffusion of different sodium polystyrene sulfonate (NaPSS) molecules is discriminated and their mutual correlation demonstrates the strong coupling of the diffusion of different molecules, leading to the abnormal diffusion of individual NaPSS molecules. After the proper correction of the correlation function, the self-diffusion of NaPSS demonstrates a two-stage feature – a fast and slow diffusion modes. The results have exposed a new species in the multiple diffusion modes in polyelectrolyte solution.

**8:00AM X50.00001: Rapid and non-destructive optical patterning of conjugated polymers for device applications**

[Invited] ADAM MOULE (Presenter), IAN E. JACOBS, JUN LI, ZAIRA I. BEDOLLA VLDEZ, TUCKER L. MURREY, University of California, Davis — A significant obstacle for the industrial development of organic electronic devices is the lack of a patterning technology having the disruptive power that photolithography exerted in traditional microelectronics. Here we present a new scalable patterning technology for organic semiconductors that takes advantage of the existing photolithography infrastructure and is compatible with digital direct-write patterning and sequential roll-to-roll (R2R) solution coating. The Moule group works on a series of solubility control techniques including the use of marginal solvents and polymer doping, that reduce the solubility of polymers at room temperature, but allow patterning at elevated temperatures. Using these techniques, we are able to **vertically stack** and **laterally pattern** mutually soluble polymer layers, which are vital processing steps needed to expand the use of organic semiconductors in device applications. Optimization of these techniques has yielded diffraction limited film patterning with regular features of 200-300 nm with only solution processing steps and direct write laser patterning. We have also recently shown that vertically patterned layers are stable, even with solvent exposure times of hours. This presentation will cover the fundamentals of optical patterning of organic semiconductors and delve into details of how to create doped microdomains, dopant diffusion, and the relationship between polymer crystallinity, dopant diffusion rate, and pattern fidelity.

**8:36AM X50.00002: Branched Side Chains Influence the Efficacy of Doping in Conjugated Polymers**

ELAYNE THOMAS (Presenter), Materials Department, University of California, Santa Barbara, EMILY C DAVIDSON, Department of Materials Science and Mechanical Engineering, Harvard University, REIKA KATSUMATA, Polymer Science and Engineering, University of Massachusetts, Amherst, RACHEL SEGALMAN, Materials Department and Department of Chemical Engineering, University of California, Santa Barbara, MICHAEL L. CHABINYC, Materials Department, University of California, Santa Barbara — The principles that govern effective charge transfer between dopants and semiconducting polymers are poorly understood. It is currently unclear how the position of the dopant in the thin film can affect carrier mobility. Here, we report the evolution in spectroscopic and electrical properties of a model conjugated polymer upon exposure to two types of dopants: a strong oxidant (F₄TCNQ) and a strong acid (HTFSI). The model polymer was poly(3-(2′-ethyl)hexylthiophene) (P3EHT), a branched side chain analogue of the well-characterized polymer P3HT. We find that F₄TCNQ forms a charge transfer complex (CTC) with P3EHT resulting in a maximum electrical conductivity of 3×10⁻⁵ S cm⁻¹. We postulate that the branched side chains of P3EHT constrain the position of F₄TCNQ within the P3EHT crystallites, resulting in partial charge transfer between the donor and acceptor. Conversely, protonation of the polymeric backbone from HTFSI increases the electrical conductivity of P3EHT to 4×10⁻³ S cm⁻¹, two orders of magnitude higher than when F₄TCNQ is used. This work shows that a favorable energetic offset between the donor and acceptor is not sufficient to predict the charge transfer mechanism, but also relies on structural constraints of incorporating a dopant molecule into the polymer film.
Understanding the molecular doping process of semiconducting polymers through in-situ conductivity measurements and structural characterization

MARK DITUSA (Presenter), Physics, University of Chicago, TENGZHOU MA, GARRETT GROCKE, Institute for Molecular Engineering, University of Chicago, JENS NIKLAS, OLEG POLUEKTOV, Chemical Sciences and Engineering, Argonne National Laboratory, SHRAYESH PATEL, Institute for Molecular Engineering, University of Chicago — Polymers with conjugated semiconducting backbones show promise for use in organic electronics, such as thin film transistors, organic photovoltaics and the emerging technology of organic thermoelectrics. Molecular doping is a vital step in the controlling the charge transport of semiconducting polymers. Here, we report on how molecular doping affects the conductivity of polythiophene-based polymers over the course of vapor doping, and how different dopants (fluorinated TCNQs) with variable HOMO-LUMO overlap with our polymers affect the observed conductivity trends. Through in situ conductivity experiments, we show that for all three dopants tested, the conductivity follows a distinct profile that shows rapid increase of conductivity up until an optimal time, after which it falls and then equilibrates between 90% to 50% of the optimal conductivity. In conjunction with our in situ conductivity experiments, we report on scattering and spectroscopy experiments such as GIWAXS, UV-Vis, and EPR spectroscopy on polymer-dopant films at various time-points throughout the doping process. This study shows the potential of these methodologies for use on various polymer-dopant pairings to further advance our understanding of molecular doping dynamics.

Electrical and magnetic characterization of doped conjugated polymers with pendent stable radicals

ALBERT PARK (Presenter), Applied and Engineering Physics, Cornell University, YIREN ZHANG, Materials Science and Engineering, Cornell University, STEPHEN MCMILLAN, NICHOLAS HARMON, MICHAEL FLATTÉ, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa, CHRISTOPHER K OBER, Materials Science and Engineering, Cornell University, GREGORY FUCHS, Applied and Engineering Physics, Cornell University — Conjugated polymers such as poly(3-hexylthiophene-2,5-diyl) (P3HT) are being considered as potential backbone materials for organic radical battery electrodes to increase conductivity over unconjugated backbones, without sacrificing the electrochemical activity of radical groups. This is important for efficient current collection. Although conjugated polymers are among the most conductive organic materials at ambient temperatures, covalent attachment of stable radical such as such as 2,2,6,6-tetramethylpiperidine-1-oxyl (TEMPO) to undoped, regioregular P3HT creates sterically hindrances that result in an exponential decrease of film conductivity as a function of radical content. To recover the conductivity, we dope the conjugated backbone using either iodine or 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F4TCNQ). We characterize electrical properties of the doped conjugated radical polymer by varying both the pendent radical concentration and the doping level. Additionally, we used electron paramagnetic resonance to investigate the interplay between polaron and stable radical electrons. Transport measurements confirm that the conductivity increases by a few to several orders of magnitude, depending on the dopant.

Electronic and Optical Properties of N-doped BBL Polymer

SARBANI GHOSH (Presenter), IGOR ZOZOULENKO, Linkoping University — Since their discovery, conducting polymers have been widely studied over the last few years in many optoelectronic applications. Applying redox chemistry, the intrinsic conductivity of the polymers could be altered by adding/removing an electron to make the polymer as an n-type/p-type material, respectively. The charge transport in electronic devices depends on the performance of both the p-type and n-type materials. P-doped polymers have been extensively studied over n-doped polymers due to lack of stable n-doped polymers. The need of the hour is to study n-type polymer to improve the performance of organic electronic devices. Here we study n-doped poly(benzobisimidazobenzophenanthroline) (BBL) using ground-state and time-dependent (TD) density functional theory (DFT). High electron mobilities (~0.1 cm² V⁻¹ s⁻¹), high structural and thermo-oxidative stability make BBL as an ideal n-doped polymer. To understand the electronic structure and optical spectroscopy of n-doped BBL, a thorough theoretical study is carried out. Formation of polaron and bipolaron due to the reduction of BBL is analyzed by ωB97XD functionals DFT with the 6-31+G(d) basis set. UV visible absorption spectra from TDDFT calculations show the transition from polaron/bipolaron to the conduction band.
High-temperature side-chain dipolar glass polymer, sulfonylated poly(2,6-dimethyl-1,4-phenylene oxide) (SO2-PPO). No advanced dielectric materials for polymer film capacitor and gate dielectric in organic electronics. We design a new class of e.g., amide and sulfone groups. In this work, we explored the opportunity of side-chain dipolar glass polymers as high-k and low-loss dielectric applications because of the enhanced orientational polarization from highly dipolar groups, dipolar polarization and thus high dielectric constant of 6-8 was obtained for these SO2-PPOs. The discharged energy National Institute of Standards and Technology, LEE RICHTER, Materials Science and Engineering Division, National Institute of discuss how these processes relate to the observed Magneto-electroluminescence response.

We will present on key requirements to be able to observe TTA in Rubrene and DiFTES-ADT, in heterojunction-based OLED devices test structures. We will show that a sub-bandgap turn-on does not require higher order recombination processes such as TTA and is thus not a reliable measure. However, if competing interfacial recombination pathways are suppressed, TTA can be reliably observed in the luminescence-current density-voltage characteristics (L-J-V) in mid to high current densities. We will discuss how these processes relate to the observed Magneto-electro-luminescence response.
The Structural, Electronic and Optical Properties of γ-glycine Under Pressure: A First Principles Study

JAEHO SHIN ( Presenter), SEUNGHOOL YANG, CHUL-HO LEE, GUNUK WANG, KU-KIST Graduate School of Converging Science and Technology, Korea University — Since Aviram and Ratner initially proposed the possibility of a molecular-scale rectifier in 1974, diverse type of molecular diodes driven by a specific molecular itself or the asymmetric coupling has been extensively demonstrated [1-2]. In this study, we propose a new class of molecular diode based on a hybrid molecular junction system that is composed with the 2D semiconductor (MoS2 or WSe2) and the standard self-assembled monolayer (SAM) (alkyl- or conjugated molecules). The 2D semiconductor and the SAM are sandwiched between the Au probe tip and Au bottom electrode using conductive atomic force microscopy (CAFM) technique. In the case of the molecular junction with monolayer MoS2 and OPT2, the diode feature with rectification ratio > ~10^3 was observed. Furthermore, the rectification ratio can be programmed according to the number of MoS2 layers, the type of 2D semiconductor, molecular length, and molecular group. Our suggested rectifier architecture can provide potential benefits to simply implement the molecular diode function and propose the idea to improve the diode performance.

Electro-absorption in Metal Nanoparticles within Glass; Comparison with Quantum Dots in Nonconjugated Conductive Polymers

MRINAL THAKUR, JUSTIN VAN CLEAVE (Presenter), Photonic Materials Research Laboratory, Auburn University, AL 36849 — Quadratic electro-optic effect / Kerr coefficient of metal nanoparticles within glass and comparison with iodine doped nonconjugated conductive polymers have been recently reported. In this report, we will discuss results of the measurement of electro-absorption in gold nanoparticles in glass and compare the results with published data on electro-absorption in quantum dots within doped nonconjugated conductive polymers. The electro-absorption was found to increase quadratically with the applied electric field. The magnitude of electro-absorption appears to increase as d^{-3}, where d is diameter of metal nanoparticle. More detailed work on this is in progress. This dependence on d is similar to the recently reported results on Kerr coefficient. This is expected since electro-absorption is proportional to the imaginary part of \chi^{(3)} and Kerr coefficient is proportional to the real part of the same.

Session X51 DPOLY DBIO: Using Polymer Sequence to Control Material Properties

Lisa Hall, Ohio State University - Tag(s): Invited

Using PRISM theory and molecular simulations to understand the complex interplay of copolymer sequence and architecture on assembly in polymer solutions

ARTHII JAYARAMAN (Presenter), University of Delaware — In this talk I will present our recent work using molecular dynamics (MD) simulations and PRISM theory aimed at understanding effects of non-linear polymer architecture and sequence on structure and thermodynamics within polymer solutions. I will focus on amphiphilic copolymer solutions and show how copolymer architecture (linear, bottle brush, cyclic), sequence (diblock, triblock) and composition impact assembled micelle structure (i.e. shape, size, aggregation number) and thermodynamics (i.e. critical micelle concentration, disorder to order transition). I will also discuss how we use PRISM theory and MD simulations in a synergistic and sequential manner to screen through this large polymer design space to achieve our desired structure and thermodynamics in these polymer solutions.
8:36AM X51.00002: Impact of Structural Correlation and Monomer Heterogeneity in the Phase Behavior of Soft Materials and Chromosomal DNA* [Invited] ANDREW SPAKOWITZ (Presenter), Chemical Engineering and Materials Science and Engineering, Stanford University — Polymer self-assembly plays a critical role in a range of soft-material applications and in the organization of chromosomal DNA in living cells. In many cases, the polymer chains are composed of incompatible monomers that are not regularly arranged along the chains. The resulting phase segregation exhibits considerable heterogeneity in the microstructures, and the size scale of these morphologies can be comparable to the statistical correlation that arises from the molecular rigidity of the polymer chains. To establish a predictive understanding of these effects, molecular models must retain sufficient detail to capture molecular elasticity and sequence heterogeneity. This talk highlights efforts to capture these effects using analytical theory and computational modeling. First, we demonstrate the impact of structural rigidity on the phase segregation of copolymer chain in the melt phase, resulting in non-universal phase phenomena due to the interplay of concentration fluctuations and structural correlation. We then demonstrate how these effects impact the phase behavior in statistical random copolymers and in heterogeneous copolymers based on chromosomal DNA properties. With these results, we demonstrate that the spatial segregation of DNA in living cells can be predicted using a heterogeneous copolymer model of microphase segregation.

9:12AM X51.00003: Molecular Engineering Complex Coacervate Materials Using Sequence [Invited] SARAH PERRY (Presenter), Department of Chemical Engineering and Institute for Applied Life Sciences, University of Massachusetts Amherst — Polyelectrolyte complexation can be used in the self-assembly of a wide range of responsive, bioinspired soft materials. Material responses can include swelling and dissolution or liquid-to-solid transitions, which can be harnessed to facilitate encapsulation and the subsequent fabrication of functional materials. Drawing inspiration from proteins as sequence-controlled polymers, we utilize polypeptides as a model platform to study how the patterning or presentation of charges and other chemical functionalities affects the resulting self-assembly and material properties, including the ability to selectively uptake and stabilize globular proteins. Our experimental efforts are supported by the parallel development of computational approaches for modeling and predicting the phase behavior of patterned polymeric materials. The goal of this systematic investigation is the elucidation of molecular engineering design rules to facilitate the tailored creation of materials based on polyelectrolyte complexation that can both illuminate self-assembly phenomena found in nature, and find utility across a wide range of real-world applications.

9:48AM X51.00004: Sequence-controlled polymers: bridging the gap between biotic and abiotic macromolecules [Invited] JEAN-FRANCOIS LUTZ (Presenter), Institut Charles Sadron, CNRS — Over the last decades, synthetic polymers and biological macromolecules have been studied by different scientific communities. Man-made plastics are obtained by simple one-pot polymerization methods and exhibit therefore non-uniform molecular structures. Consequently, molecular polydispersity shall be taken into account in synthetic polymer chemistry and physics. In contrast, biopolymers are produced by precisely-controlled biosynthesis and have perfectly-defined molecular structures. Thus, they exhibit folding and organization properties that are difficult to attain with conventional synthetic materials. Hence, biochemistry and biophysics are disciplines on their own. Yet, in the last few years, the traditional boundaries between biological and non-biological polymers tend to disappear. Due to recent progress in synthetic polymer chemistry, it is today possible to synthesize a wide variety of uniform synthetic polymers. In particular, significant advances have been reported for the synthesis of sequence-controlled polymers, which are man-made macromolecules with perfectly-controlled primary structures. This new class of synthetic polymers open up unprecedented possibilities for tuning structure/property relationships. However, the physical chemistry of these novel materials has been barely investigated to date. In this talk, I will highlight recent approaches developed in my laboratory for the synthesis of uniform sequence-defined polymers. Particular emphasis will be put on the design of abiotic information-containing macromolecules, which are new functional polymers inspired by nucleic acids.
Segmented Ionones: Precision within disperse structures yields interesting microstructures and stimuli-responsive behavior*

MATTHEW GREEN (Presenter), Arizona State University — Ionones are polymers containing a permanent charged group in the polymer backbone and are of interest because of their synthetic versatility, unique morphologies, and ionic nature. The charge placement and the spacing between the charge segments enable the polymer properties to be tuned from glassy solids to rubbery films to viscous liquids. The use of long, soft segment spacers between charges produces a class of polymer called segmented ionones. When segmented ionones are prepared with halide counterions (i.e., strong basicity) they form thermoplastic elastomers and microphase separate into microstructures wherein the ionic domains can form a continuous, percolated network at sufficient volume fractions. This talk will discuss recent efforts to utilize the synthetic versatility of this class of polymer to prepare percolated ionic domains in microphase separated polymers that display a range of thermomechanical properties. Furthermore, the combination of synthetic versatility and electrostatic interactions can be used to influence the dispersion of nanoparticles in a segmented ionene matrix as well as influence the nanoparticle solubility in specific microdomains. Finally, the response to external stimulus (e.g., electrical, mechanical) will be discussed and connected to varying chemistries and microstructural features of the polymers.

Friday, March 8, 2019 8:00 AM - 11:00 AM

Session X52 DPOLY DBIO DFD GSNP: Polymer and Polyelectrolyte Rheology II: Large Deformations

8:00AM X52.00001: Entanglements in strongly strained high molecular weight polymer melts+ HSIAO-PING HSU (Presenter), KURT KREMER, Max Planck Institute for Polymer Research — We study highly entangled, fully equilibrated polymer melts [1] subject to strong isochoric uniaxial deformation in the non-linear viscoelastic regime by extensive molecular dynamics simulations. It is shown that the over-all conformations of the original paths as well as the primitive paths (PPs) affinely follow the deformation, while the distribution of entanglements along the PPs does not [2]. The signature of chain retraction predicted by the tube model right after deformation is verified qualitatively but not quantitatively in all directions [3]. Upon further relaxation an inhomogeneous distribution of topological constraints in the melts due to long-lived clustering of entanglements and the delayed relaxation in chain conformation is observed.

8:12AM X52.00002: Strain Hardening in Extensional Rheology of Polyolefin Multilayer Films ALEX JORDAN, Engineering and Technology Department, University of Wisconsin - Stout, KYUNGTAE KIM (Presenter), BONGJOON LEE, EAN LUDTKE, FRANK BATES, Department of Chemical Engineering & Materials Science, University of Minnesota, OLIVIER LHOST, Total Petrochemicals, CHRIS W MACOSKO, Department of Chemical Engineering & Materials Science, University of Minnesota — The interfacial strength between isotactic polypropylene (iPP) and polyethylene (PE) depends on commercial grades, i.e., detailed molecular structures of the polymers.¹ We utilized extensional rheology to understand molten iPP/PE interfaces. We produced iPP/PE multilayer films prepared from Ziegler-Natta catalyzed high-density PE (zHDPE) and isotactic PP (ziPP) as well as metalloocene catalyzed high-density PE (mHDPE), linear low-density PE (mLLDPE), and iPP (miPP). Films with 2, 160, and 640 alternating layers of ziPP/zHDPE, miPP/mHDPE, and miPP/mLLDPE were fabricated via multilayer coextrusion. Extensional rheology of the 160-layer miPP/mLLDPE system revealed a strain hardening behavior, which became more pronounced when the number of layers increased to 640, effectively quadrupling the interfacial area in multilayer films. The miPP/mHDPE system showed strain hardening only when the number of layers reached to 640. Strain hardening was not observed in individual mHDPE, mLLDPE, and miPP films, nor in their bilayers. We quantitatively model strain hardening in the multilayer films by adding the stress contribution from the equilibrium melt interfacial tension to the measured extensional contribution from the components.

8:24AM X52.00003: Molecular origin of extensional strain hardening in phenyl-containing polymer melts  
CARLOS LOPEZ-BARRON (Presenter), ExxonMobil Chemical Company, WESLEY ROTH BURGHARDT, MU SUNG KWEON, Northwestern University — We recently reported unexpectedly extensional strong strain hardening (SH) in poly(4-vinylbiphenyl) (PVBp) when subjected to uniaxial flow. We postulate that this behavior is due to a molecular rearrangement mechanism (supported by WAXS measurements) that involves flow-induced π-π stacking of the phenyl groups, which results in an enhancement of friction drag between polymer chains [PRL 119, 247801 (2017)]. To further elucidate the molecular mechanism of SH, we measure the time evolution of the molecular alignment using an extensional rheometer housed in a custom-built oven designed to facilitate in-situ synchrotron X-ray experiments. Based on the anisotropic 2D WAXS profiles, we defined two alignment factors, one for the backbone (Abb) and one for the π-π stacking (Aππ). Perfect correlation between Abb and Aππ are observed during extensional flow start-up and flow cessation. Moreover, linear relations between both Abb and Aππ and transient stress (σE+) are observed at stress values below 1 MPa. The resemblance between this behavior and the stress-optical rule observed in many polymeric liquids led us to propose a stress-WAXS rule (SWR): Abb=CbbσE+ and Aππ=CππσE+. Finally, we will discuss the validity of the SWR in PVBp and polystyrene.

8:36AM X52.00004: Macromolecular Dynamics, Extensional Rheology, Pinch-off Dynamics, and Printability of Aqueous Solutions of Flexible and Semi-Flexible Polymers  
JELENA DINIC (Presenter), VIVEK SHARMA, University of Illinois at Chicago — Liquid transfer and drop formation/deposition processes associated with printing, spraying and coating flows involve complex free-surface flows including the formation of columnar necks that undergo spontaneous capillary-driven instability, thinning and pinch-off. For simple Newtonian fluids, the interplay of capillary, inertial and viscous stresses determines the self-similar thinning and pinch-off dynamics. In rheologically complex fluids, extra elastic stresses alter the pinch-off dynamics. Here we show that dripping-onto-substrate (DoS) rheometry protocols that involve visualization and analysis of capillary-driven thinning of a columnar neck can be used for measuring extensional viscosity and extensional relaxation time of polymeric fluids. We investigate the role of chemical structure by contrasting behavior of aqueous solutions of flexible polyethylene oxide (PEO) with solutions of semi-flexible hydroxyethyl cellulose (HEC) and show that both flexibility and extensibility of chains dramatically influence the extensional rheology response and the macromolecular relaxation dynamics. We elucidate how macromolecular stretching and orientation modify excluded volume and hydrodynamic interactions, affecting extensional viscosity response as well as polymer relaxation dynamics.

8:48AM X52.00005: Brownian dynamics simulations of linear and non-linear semidilute polymer solutions in extensional flow*  
CHARLES YOUNG (Presenter), CHARLES E. SING, University of Illinois at Urbana-Champaign — Understanding the relationship between microstructure and bulk properties is an overarching goal in polymer rheology. This is particularly true for non-linear polymer architectures, where topological interactions resulting from chain crossing restrictions lead to flow rates which are locally much higher than the applied flow. Polymers can thus be deformed significantly from their expected conformations, modifying the molecular functionality and the bulk stress. Coarse-grained molecular simulations which satisfy crossing constraints are crucial for developing quantitative models of these phenomena. Using our iterative conformational averaging method for Brownian dynamics simulations, we present an explanation for unexpected dynamics in solutions of non-linear polymers first observed in single molecule imaging experiments. Starting from a solution of linear chains, we introduce trace ring or branched polymers and observe the effect on polymer relaxation and transient stretching in planar extensional flow. We determine the importance of hydrodynamic interactions for polymer solutions ranging from dilute to the entanglement concentration and show that non-linear polymers can exhibit accelerated or hindered relaxation below the overlap concentration.

9:00AM X52.00006: Pinch-off Dynamics, Extensional Rheology and Printability of Polyelectrolyte Solutions  
LEIDY NALLELY JIMENEZ (Presenter), JELENA DINIC, VIVEK SHARMA, University of Illinois at Chicago — Biological macromolecules like proteins, DNA and polysaccharides, and many industrial polymers, are classified together as polyelectrolytes for in solution, the repeat units in their backbone are decorated with disassociated, charge-bearing ionic groups, surrounded by counter-ions. In diverse applications like inkjet printing, sprayable cosmetics and insecticides, paints and coatings that involve the formation of fluid columns or sheets that undergo progressive thinning and pinch-off into drops, the dominant flow within the necking filament is extensional in nature. The extensional rheology response of the charged macromolecular solutions are not as well understood as that of their uncharged counterparts. Here focus on the characterization of capillary thinning and pinch-off dynamics, extensional rheology and printability of two model systems: sodium (polystyrene sulfonate) and poly(acrylic acid) by using dripping-onto-substrate (DoS) rheometry technique. Due to an interplay of hydrodynamics-induced and charged-induced stretching, both the measured extensional relaxation times and the extensional viscosity values show salt- and polymer concentration-dependent behavior that is not expected or anticipated from the typical shear rheology response.
custom-built Taylor-Couette apparatus, operating in the fully turbulent flow regime, at Reynolds numbers between $10^4$ and $10^5$. As a specific example, we characterize the drag reducing properties of the aqueous mucilage extracted from flax seeds (*Linum usitatissimum*), and compare its performance to that of a commonly-used synthetic flexible homopolymer, namely, polyethylene oxide (PEO). The molecular and viscoelastic properties of the principal polysaccharide constituent in flax mucilage is also studied using size exclusion chromatography and extensional rheology techniques (CaBER). Finally, we compare the shear-induced degradation of both polymers under prolonged turbulent flow conditions, and explore the possibility of mitigating chain-scission processes by the use of appropriate ionic and non-ionic surfactant additives to modify the chain flexibility and develop polymer-surfactant complexes. The dilute mucilage solutions are seen to exhibit comparable drag reduction and degradation behavior as aqueous PEO, but on a much cheaper cost-basis, and can potentially serve as an effective, eco-friendly, and economical alternative to synthetic polymers in real-life drag reduction applications.

**9:48AM X52.00008: Rheology and Dynamic Adsorption of Polymer-Surfactant Complexes**  
CARINA MARTINEZ  
(Presenter), VIVEK SHARMA, Chemical Engineering, University of Illinois at Chicago — The rheological properties of polymer-surfactant mixtures play a significant role in applications ranging from enhanced oil recovery, pharmaceutical and biological fluids, cosmetics, food, and coating. Addition of an ionic surfactant to an aqueous solution of neutral polymer like polyethylene oxide is known to result in a shear rheological response with non-monotonic concentration dependent variation, attributed to association complexes formed by hydrophobic interactions between surfactant monomers and polymers chains, as well as charge effects. Furthermore, the formation of association complexes changes both dynamic and equilibrium surface tension. However, due to a lack of suitable techniques, extensional rheology response of polymer-surfactant mixtures has not been characterized in adequate detail, even though most processing flows, especially those involving drop formation or liquid transfer are influenced by extensional rheology and pinch-off dynamics. In this study, we examine how pinch-off dynamics and the extensional rheological response of polymer solutions are modified by the addition of ionic surfactants. We utilize dripping-onto-substrate rheometry protocols and show that shear and extensional rheology response display contrasting concentration-dependent variation.

**10:00AM X52.00009: A Model for Salt Effects on Semidilute Polyelectrolyte Solutions: Equilibrium and Dynamics**  
GUANG CHEN (Presenter), ANTONIO PERAZZO, HOWARD A STONE, Princeton University — Polyelectrolyte (PE) solutions are endowed with both viscous and elastic properties that differ significantly from uncharged polymer solutions. Owing to their universal existence and functionalities in biology and industry, PE solution physics have been widely studied yet are often restricted to specific assumptions, such as the presence of a theta solvent, rod/flexible chain configurations or weakly/strongly charge conditions. Here, we will present a theoretical model based on mean-field theory, which provides new insights and scaling laws for the chain conformation, relaxation time and viscosity of semidilute PE solutions in good solvents. By considering the elastic, excluded volume, and electrostatic energies due to the PE charges and double layer, our theoretical predictions agree well with experiments and offer interpretations for previously unexplained viscoelastic behavior of PE solutions in either high polymer density regimes or conditions with added salt. New criteria for the overlap concentration and other special regimes with varying salt concentrations and polymer density will also be discussed.

**10:12AM X52.00010: Entanglement density and crossovers of polyelectrolyte solutions**  
CARLOS LOPEZ (Presenter), WALTER RICHTERING, RWTH Aachen University — We present steady shear and oscillatory rheology data for flexible sodium polystyrene sulfonate (NaPSS) and semiflexible sodium carboxymethyl cellulose as a function of polymer concentration, degree of polymerisation and added salt. Semidilute non-entangled dynamics are well described by the Rouse model, in agreement with Dobrynin's model for flexible polyelectrolytes. Addition of salt leads to a decrease in chain dimensions and therefore in solution viscosity, the effect being much more pronounced for NaPSS than NaCMC, which can be understood as resulting from the intrinsic rigidity of NaCMC preventing chain collapse at high salt.

The entanglement concentration of NaCMC is found to be only weakly dependent on added salt concentration. This contrasts with the overlap crossover which increases by several orders of magnitude from salt-free conditions to 0.1 M NaCl. Further, we find that the entanglement density remains constant upon addition of salt despite significant changes in polymer conformation. Our results for entangled polyelectrolyte in salt-free and salt solutions strongly contradict several predictions of the current scaling models for polymer entanglement.
10:24AM X52.00011: Coarse grained simulations of migration of polyelectrolytes in a combination of flow fields and electric fields* ANGELO SETARO (Presenter), Rensselaer Polytechnic Institute — Separations can be accomplished by controlling the relative rate at which different molecules travel through a microfluidic device. In a flow, the rate of travel of a molecule is largely determined by its relative position in the flow profile. Thus, if one can control molecules relative positions within a flow profile, one can influence separation. It has been found that the electrophoretic mobility of certain molecules, such as double-stranded DNA, is dependent on their conformation, which is in turn dependent on the local shear rate. This opens the door to using flow rate as a means to modify polymer conformation and by extension polymer mobility. Though this potential method opens the door to a variety of separations, there remain a number of fundamental questions about the underlying mechanism. To address these, we use a combination of theoretical calculations and Brownian dynamics simulations to probe how the combination of velocity gradients and electric field gradients impact particle mobility and migration.

*We acknowledge support from NSF Grant CBET-1826788.

10:36AM X52.00012: Ultralow interfacial tension of polyelectrolyte coacervates using drop retraction method SAMIM ALI (Presenter), ANAND RAHALKAR, VIVEK PRABHU, National Institute of Standards and Technology — The interfacial tension of coacervates can be controlled by a number of physicochemical conditions, such as salt type and concentration, temperature, and polymer molecular mass. An improved understanding of these relationships will help advance applications such as polymer coatings, encapsulation media and wet adhesives. However, interfacial tension measurements are challenging due to the ultra-low magnitudes observed in polyelectrolyte coacervates. This presentation describes the use of shape retraction analysis of a deformed drop of dilute phase generated in situ in the coacervate. Our measurements confirm that the interfacial tension follows the mean field prediction of 3/2 scaling as a function of the difference between salt concentration and the critical salt concentration at which interfacial tension vanishes. The additional effects of temperatures and molecular mass will be described.

10:48AM X52.00013: Bubble dynamics in non-Newtonian fluids MARCOS REYES-MARTINEZ (Presenter), EDWIN CHAN, National Institute of Standards and Technology — Cavitation Rheology (CR) has been investigated as a novel technique for the characterization of the elastic and fracture properties of soft materials. In addition to measuring mechanical properties of solids, the formation and pressurization of a cavity, as dictated by some initial defect size, is an information-rich phenomenon that can illuminate the interfacial properties of fluids undergoing hydrostatic deformation. In this presentation, we explore the use of CR as a probe for the fluid properties of materials that display both Newtonian and non-Newtonian behavior. By tracking the evolution of the pressure inside the bubble and carefully analyzing the geometry of the bubble wall, we gain insight into properties of the fluid such as viscosity, bulk modulus and Poisson's ratio. For the case of a model shear thickening fluid, we observe pressurization rate dependence on the critical cavitation pressure and evidence of transient fracture at sufficiently high pressurization rates. Our observations have deep implications in advancing the study of high-rate deformation of non-Newtonian fluids and soft materials.

Session X53 GSOFT: Geometry and Topology of Active Matter BCEC 253C - Vincenzo Vitelli, Univ of Chicago - Tag(s): Invited

8:00AM X53.00001: Curvature-driven topological protection* [Invited] MARK BOWICK (Presenter), Kavli Institute for Theoretical Physics, University of California, Santa Barbara — Active systems on curved geometries are ubiquitous in the living world. Ordered polar flocks in the presence of spatial curvature are forced to be inhomogeneous and must also exhibit topological defects, even in the steady state, when the curved manifold is topologically non-trivial. I will discuss how dynamical symmetry breaking via spontaneous flow (flocking), together with spatial curvature, are the only ingredients necessary to produce long-wavelength symmetry-protected gapped sound modes. The steady state profile of an active polar flock on a two-sphere and a catenoid will be presented. The topologically-protected sound modes are localized to special geodesics on the surface (the equator or the neck respectively). These modes are the analogue of edge states in electronic quantum Hall systems and provide unidirectional channels for information transport in the flock, robust against disorder and backscattering.

8:36AM X53.00002: Defect ordering and geometrical control in passive and active nematic liquid crystals [Invited]  LUCA GIOMI (Presenter), Leiden University — In this talk, I will discuss some recent theoretical and experimental work on active nematic liquid crystals confined on two-dimensional curved interfaces and highlight how the geometrical and topological structure of the environment can substantially affect collective motion in active materials, leading to spectacular life-like functionalities.

9:12AM X53.00003: Odd Elasticity in Active Metamaterials [Invited]  COLIN SCHEIBNER (Presenter), University of Chicago, ANTON SOUSLOV, Physics Department, University of Bath, DEBARGHYA BANERJEE, Max-Planck-Institute for Dynamics and Self-Organization, PIOTR SUROWKA, Max-Planck-Institute for the Physics of Complex Systems, WILLIAM T. M. IRVINE, VINCENT VITELLI, University of Chicago — The theory of elasticity provides a foundation for describing the mechanics of deformations of continuous media. However, elastic theories of active matter must confront a fundamental challenge: the starting point of elasticity, the elastic energy, is not well defined due to microscopic activity. We introduce Odd Elasticity as a generalized theory of continuum mechanics that breaks key symmetries of the elastic (stiffness) tensor otherwise required by conservation of energy. We show that odd elasticity describes solids in which activity depends on the deformation of microscopic bonds. As a minimal model that produces odd elasticity upon coarse graining, we consider active metamaterials in which internal torques are actuated in response to compression or extension of the beams. Our odd-elastic theory, corroborated by simulations, sheds light on a rich phenomenology, including activity-induced auxetic behavior, active elastic waves and instabilities. Our work revisits the foundations of continuum mechanics and provides a blueprint for the design of active elastic engines, which utilize a strain cycle to convert microscopic activity into useful mechanical work.

Session X54 DPOLY DBIO GSNP: Polymers and Biopolymers in Very Strongly Confined Environments II: Polymers in Nanochannels and Nanopores BCEC 254A - Ining Jou, University of Massachusetts Amherst - Tag(s): Focus

8:00AM X54.00001: Brownian Dynamics studies of a “Tug-of-War” of a DNA translocating through a two-nanopore system  SWARNADEEP SETH (Presenter), ANIKET BHATTACHARYA, Department of Physics, University of Central Florida, WALTER REISNER, Physics, McGill University, WILLIAM B DUNBAR, Two Pore Guys, Inc. — Two nanopore devices show potential for improved translocation control and error reduction through correlation of independent current channels accessed at each pore. We report Brownian dynamics (BD) simulation results for a dsDNA threading through a two-nanopore system using a coarse-grained model for the dsDNA and pore. Specifically, we study “tug-of-war” states, where the DNA is simultaneously present in both pores and the pores exert opposing electrophoretic forces. We extract the life-time of the tug-of-war as a function of biasing conditions, chain stiffness and inter-pore separation and investigate the correlation and cross-correlation functions of the chain translocation velocity through the pores. Our studies are expected to extend the single-pore translocation problem to dual nanopore pore systems and aide in the design of two-pore devices.
Methods for reducing and directly controlling the speed of DNA through a nanopore are needed to enhance sensing performance for direct strand sequencing and mapping of sequence-specific features. We have created a method for reducing and controlling the speed of DNA that uses two independently controllable nanopores operated with an active control logic. The pores are positioned sufficiently close to permit co-capture of a single DNA by both pores. Control logic then turns on constant competing voltages at the pores leading to a "tug-of-war" whereby the molecule is pulled from both ends by opposing forces. These forces exert both conformational and speed control over the co-captured molecule, removing folds and reducing the translocation rate. When the voltages are tuned so that the electrophoretic force applied to both ends of the molecule comes into balance, the life-time of the tug-of-war state is limited purely by diffusive sliding of the DNA between the pores (yielding a two order of magnitude enhancement in translocation time). We quantify the translocation slow-down as a function of voltage tuning and show that the slow-down is well described by a first passage analysis for a one-dimensional sub-diffusive process.

8:24AM X54.00003: Simulations of extension distributions for DNA confined in nanochannels near the persistence length

ADITYA BIKRAM BHANDARI (Presenter), KEVIN DORFMAN, Department of Chemical Engineering and Materials Science, University of Minnesota, Twin Cities — DNA has been used extensively as a model system to study confined polymers. A particularly important application of strongly confined DNA is genome mapping, where DNA molecules labeled at sequence-specific sites along their backbone are stretched by confinement in nanochannels with widths close to the DNA persistence length. The distributions of the fractional extension obtained in genome mapping experiments are skewed-left from a Gaussian distribution. Mehlig and coworkers proposed an explanation for these skewed distributions by obtaining the asymptotic solution for a weakly correlated telegraph model of a channel-confined polymer in the limit of small channels and long chains. We have tested the predictions of this theory using pruned-enriched Rosenbluth method (PERM) simulations. The simulated distributions are in reasonable agreement with theory in the relevant asymptotic limits. However, deviations are observed as we move away from the strict inequalities in the limits of the theory, corresponding to situations that are more representative of experimental systems.

8:36AM X54.00004: Diffusion of DNA in confinement: From nanochannels to cells [Invited]

KEVIN DORFMAN (Presenter), Chemical Engineering and Materials Science, University of Minnesota — The key challenge in understanding the diffusivity of DNA in strongly confined systems is accounting for the hydrodynamic interactions between the polymer and its environment. I will present both experimental and theoretical results on the diffusion of DNA in two highly confined systems that illustrate the complexity of this problem.

In the first case, I will show how combining biased Monte Carlo simulations and confined hydrodynamics calculations leads to a complete picture for the friction of a semiflexible polymer confined to a square nanochannel. The regimes of hydrodynamic friction are closely related to those for the chain extension, including a Rouse-like regime at moderate confinement where the friction is independent of the fractional extension of the chain. Subsequent experimental measurements of DNA diffusion in the so-called “extended de Gennes” regime agree well with the model calculations.

In the second case, I will describe an experimental test of the viscoelastic Rouse model for the segmental motion of DNA within E. coli cells. When the cells are compressed under "Quake" valves, the mean-squared displacement of cytoplasmic particles slows down by over one order of magnitude but the exponent characterizing their subdiffusion is unchanged. In contrast, the corresponding exponent for the subdiffusion of segments of DNA on short time scales (~1 s) undergoes a statistically significantly change when the cells are compressed. These results suggest that factors other than the cytoplasmic viscoelasticity play a role in this non-equilibrium perturbation of the cells.
**Stochastic Resonance Behavior of DNA Translocation with an Oscillatory Electric Field**

JOU (Presenter), RHYS DUFF, MURUGAPPAN MUTHUKUMAR, University of Massachusetts Amherst — Stochastic resonance (SR) describes the synchronization between noise of a system and an applied oscillating field to achieve an optimized response signal. In this work, we use simulations to investigate the phenomenon of SR of a single stranded DNA driven through a nanopore when oscillating electric field (OEF) is added. The system is comprised of a MspA protein nanopore embedded in a membrane and different lengths of DNA are driven from one end of the pore to the other via a constant potential difference. We superimposed an OEF over the existing electric field. The source of noise is due to thermal fluctuations, since the system is immersed in solution at room temperature. Here, the signal optimization we seek is an increase in translocation time ($\tau$) of DNA through the protein pore. Normally, $\tau$ scales linearly with DNA length and inversely with driving force in a drift dominated regime. We found a nonmonotonic dependence of $\tau$ with the frequency of the oscillating field. This nonmonotonic behavior of $\tau$ is observed for all lengths of DNA, but SR occurs only for longer DNA. Furthermore, we also see evidence of DNA extension being influenced by the oscillating field while moving through the nanopore.

**Spontaneous Transport of Single-Stranded DNA through Graphene-MoS2 Heterostructure Nanopores**

BINQUAN LUAN (Presenter), IBM Thomas J. Watson Research Center — The effective transport of a single-stranded DNA (ssDNA) molecule through a solid-state nanopore is essential to the future success of high-throughput and low-cost DNA sequencing. Compatible with current electric sensing technologies, here, I propose and demonstrate by molecular dynamics simulations the ssDNA transport through a quasi-two-dimensional nanopore in a heterostructure stacked together with different 2D materials, such as graphene and molybdenum disulfide (MoS2). Due to different chemical potentials, $U$, of DNA bases on different 2D materials, it is energetically favorable for a ssDNA molecule to move from the low-$U$ MoS2 surface to the high-$U$ graphene surface through a nanopore. With the proper attraction between the negatively charged phosphate group in each nucleotide and the positively charged Mo atoms exposed on the pore surface, the ssDNA molecule can be temporarily seized and released thereafter through a thermal activation, that is, a slow and possible nucleotide-by-nucleotide transport. A theoretical formulation is then developed for the free energy of the ssDNA transiting a heterostructure nanopore to properly characterize the non-equilibrium stick-slip-like motion of a ssDNA molecule.

**Determining the Free Energy and Kinetics of a Translocating Polymer Chain**

ZACHARY DELL (Presenter), MURUGAPPAN MUTHUKUMAR, University of Massachusetts Amherst — Polymer threading or translocation through nanopores is widely studied due to its ubiquity in biology and its recent use as a characterization method. In this work, we explored translocation of a chain from one spherical cavity to another, motivated by viruses and vesicles. The primary theoretical tool for studying a translocating chain is its free energy, which includes the free energy associated with the donor/acceptor compartments, and the polymer-pore interaction energy. In the first stage of the project, we focused on calculating chain free energy under spherical confinement, relevant for donor/acceptor compartments. Due to conflicting theoretical pictures, we implemented Monte Carlo simulations and investigated how the free energy relates to the confinement strength and how it varies when the chain is tethered. With the simulation results and previous translocation theories, we built a center of mass (CM) theory for polymer translocation. This theory establishes a physical interpretation for the translocation coordinate in terms of the CM. Also, our approach allows for the incorporation of hydrodynamics through the CM friction. Both the simulations and theory can be generalized to study other confined environments.

*National Institute of Health (Grant No. R01HG002776-15)

**Using capillaries with varying cross-section to study polymer dynamics and behavior under multiple confining length scales**

DAVID RING (Presenter), ROBERT RIGGLEMAN, DAEYEON LEE, University of Pennsylvania — Infiltrating polymers into cylindrical nanopores to induce confinement has led to the fabrication of a new class of nanostructured polymeric materials. The behavior of polymers during infiltration and under confinement has been elucidated with the help of computational studies, revealing a rich thermodynamic and kinetic landscape. These systems, however, focus on confinement with a single characteristic length scale. There are many situations in which polymers infiltrate into a porous medium with varying dimensions (e.g., a packing of nanoparticles). In this talk, we address the question of what happens when polymers are confined with more than one characteristic length scale. To that end, we have simulated capillaries with varying cross-sections and multiple well-defined points of confinement, including necks and voids. Using umbrella sampling, we can explore the free energy of an infiltrating polymer melt to characterize the impact of confinement on the driving force for infiltration. We also vary the diameter of the capillary mouths to characterize the effect of geometry on the start of infiltration as polymers move from the bulk to the confined pore. Lastly, we also investigate the effect of varying cross-section on the rheological components of the polymer.
10:00AM X54.00009: Polymer-Grafted Nanoparticle Translocation in Strongly Confining Nanochannels*  
MICHAEL HORE (Presenter), WILLIAM R LENART, GABRIELA T JUSTINO, Case Western Reserve University — The process of a particle moving from one region to another through a channel is central to many physical systems, including viral infection and water filtration. In this talk, we discuss the conformation of polymers that are grafted to a spherical nanoparticle surface, and the effect this has on the translocation of the particle through a single, confining nanochannel. Using self-consistent field theory (SCFT) coupled with Poisson-Nernst-Planck (PNP) theory, we investigate the distortion of the grafted polymer layer for nanoparticles undergoing translocation in strongly confining nanochannels, as well as the expected signatures that would be observed experimentally.

*This work was supported by an NSF CAREER Award from the Polymers program (DMR-1651002).

10:12AM X54.00010: Water mediated effects in alpha-helix formation inside nanotubes  
DYLAN SUVLU (Presenter), University of Maine, DAVE THIRUMALAI, Chemistry, University of Texas at Austin, JAYENDRAN C RASAIAH, University of Maine — We present replica exchange molecular dynamics studies of the phase diagram for alpha-helix formation of capped polyalanine in nanotubes (NT) open to a water reservoir as a function of the NT diameter and hydrophobicity. A helix forms only in a narrow range of diameters. Helix formation in polyalanine is driven by a small negative enthalpy and a positive entropy change at 300 K, in contrast to the large negative entropy change that destabilizes the helix and favors the coiled state in bulk water. To understand the sequence dependence of helix formation inside the NT, solvation thermodynamics are determined by forming a thermodynamic cycle with liquid and gas phase MD simulations. Polyalanine forms a more thermodynamically favorable helix in the presence of water inside carbon and boron nitride NT. This is attributed to a favorable solvent reorganization energy and solvation entropy. In contrast, polyserine forms a stable helix in the gas phase but not in the presence of water while inside the CNT. This is attributed to unfavorable water-mediated interactions. However, polyserine forms a helix in a BNNT inside the gas phase but only over a narrow temperature range in the liquid phase. These data have implications for understanding helix formation inside the ribosome tunnel.

10:24AM X54.00011: Free energy cost of localizing an end-monomer of a confined polymer  
JAMES POLSON (Presenter), ZAKARY R. N. MCLURE, University of Prince Edward Island — We develop and employ a simple Monte Carlo simulation method to calculate the free energy cost of localizing an end-monomer of a polymer to the inside surface of a confining cavity. The method is applied to a freely-jointed hard-sphere polymer chain confined to cavities of spherical, rectangular and cylindrical geometries. We consider cases where the other end of the polymer is free and where it is tethered to another point on the surface. We characterize the dependence of the free energy on the cavity size and geometry type, the localization position, the polymer length, and the effects of excluded volume interactions. The relevance of these results to the initial stages of polymer translocation through nanopores is discussed.

10:36AM X54.00012: Polymer Conformation & Diffusion in Symmetric Thin Film Confinement  
JAMES PRESSLY (Presenter), ROBERT RIGGLEMAN, KAREN WINEY, University of Pennsylvania — Polymer conformation and dynamics in thin film nanoconfined controls a variety of properties important for advanced coating technologies and nanoplatelet composites. In this study, we examine the effect of chain length and film thickness on polymer conformation, entanglement density, and center of mass polymer diffusion using coarse grained molecular dynamics simulations. Polymer chain lengths of N = 25-400 and were confined between parallel plates to create polymer film thicknesses of h = 5-40σ. The plates are composed of discrete beads with athermal polymer-plate interactions. The simulations indicate that the diffusion coefficient, D, increases as the film thickness decreases, with longer chains exhibiting a larger increase in D. This increase in the diffusion coefficient correlates with chain disentanglement as confinement increases, similar to previous simulations of polymers confined to cylindrical pores. While we observe slowed diffusion in the most confined cylindrical geometries associated with chain segregation, polymer diffusion confined in thin films increases monotonically with increasing confinement.
In unconfined systems ($H >> P$), we found the dependence of the isotropic-nematic transition volume fraction ($f_{IN}$) follows Onsager theory. For strongly confined polymer solutions, $f_{IN}$ decreases as $H$ decreases due to the increased segmental correlation length, and enhanced segmental alignment is found throughout the solution. For the isotropic to nematic transition, diffusion along the nematic director increased as the density increased while lateral diffusion decreased. Further increase in volume fraction leads to smectic transition. The transition volume fraction ($f_{NS}$) systematically shifts higher for more flexible polymers. Upon transition into the smectic phase, polymer diffusivity decreases sharply by two order of magnitude. For both I-N and N-S transitions, we found evidence of universal critical exponents near the transition density.

Session X55 GSNP GSOFT: Shell Buckling I BCEC 254B - Shmuel Rubinstein, Harvard University - Tag(s): Focus

8:00AM X55.00001: Non-destructive prediction of the buckling load of soda cans and space rockets [Invited]
EMMANUEL VIROT (Presenter), EPFL - Harvard University — What is the critical load required to crush a soda can or a space rocket shell? Surprisingly, there is no good way to estimate it, because of the high defect-sensitivity of the buckling instability. Here we measure the response of (imperfect) soda cans to lateral poking and identify a generic stability landscape, which fully characterizes the stability of real imperfect shells in the case where one single defect dominates. We show that the landscape of stability is independent of the loading protocol and the poker geometry. Our results suggest that the complex stability of shells reduces to a low dimensional description and that tracking the ridge and the valley of the landscape of stability defines natural coordinates for describing the stability of shells. By using this new paradigm, we show that we can accurately and non-destructively predict the buckling load of real imperfect shell structures, thereby promising drastic reductions of the costs of structural engineering experimental tests.

8:36AM X55.00002: How localized imperfections modify the buckling threshold of cylindrical shells* EMILIO LOZANO (Presenter), ECPS, EPFL, SHMUEL RUBINSTEIN, SMRlab, Harvard University, TOBIAS SCHNEIDER, ECPS, EPFL — Shells buckle and collapse at load levels below the thresholds predicted by linear stability analysis. The reduction of the load-carrying capacity has been linked to extreme sensitivity to geometric imperfections. Historically, spatially extended periodic imperfections have been analyzed using linear and weakly nonlinear theory. Recent fully nonlinear approaches suggest however the importance of spatially localized imperfections. We thus characterize experimentally and numerically the effect of spatially localized imperfections in an axially loaded cylindrical shell. For different types of imperfections, the buckling thresholds as a function of its size shows similar behaviour. This suggests a universal failure mechanism due to local buckling.

*Supported by the Swiss National Science Foundation SNSF under grant 200021-165530
8:48AM X55.00003: Localized edge state equilibria control when a soda can buckles*  
EMILIO LOZANO, FLORIAN REETZ, Ecole polytechnique federale de Lausanne, EMMANUEL VIROT, Ecole polytechnique federale de Lausanne / Harvard SEAS, SHMUEL RUBINSTEIN, Harvard SEAS, TOBIAS SCHNEIDER (Presenter), Ecole polytechnique federale de Lausanne — Thin-walled cylindrical shells such as rocket walls (or soda cans) offer exceptional strength-to-weight ratios yet predicting at which load the structure becomes unstable and fails remains an unsolved problem. Shells buckle and collapse at loading conditions much below those predicted by linear stability theory. We thus propose a fully nonlinear approach and show that fully nonlinear equilibrium states located on the boundary of the unbuckled state's basin of attraction define critical perturbation amplitudes and guide the nonlinear initiation of catastrophic buckling. For a clamped thin cylindrical shell under axial compression a fully localized single dimple deformation is identified as the edge state—the attractor for the dynamics restricted to the stability boundary. Under variation of the axial load, the single dimple undergoes homoclinic snaking in the azimuthal direction, creating states with multiple dimples arranged around the central circumference. Once the circumference is completely filled with a ring of dimples, snaking in the axial direction leads to further growth of the dimple pattern. The bifurcation structure of the equilibria closely resembles that observed in the Swift-Hohenberg equation with quadratic-cubic nonlinearity.

*Supported by SNSF grant 200021-165530

9:00AM X55.00004: Interacting defects affect the buckling of imperfect spherical shells  
DONG YAN (Presenter), MATTEO PEZZULLA, PEDRO REIS, Institute of Mechanical Engineering, Ecole Polytechnique Federale de Lausanne (EPFL), Switzerland — The presence, distribution, and interaction of defects dictate the buckling strength of shell structures. Even if the sensitivity of shell buckling to imperfections has long been recognized, to date, the successful prediction of critical loads is restricted to cases with a single defect, of known geometry. However, in reality, shells typically contain a distribution of defects and their interaction has not been well studied. In this talk, we will focus on spherical shells with multiple defects and study the role of defect interactions in dictating the buckling pressure. In the experiments, we fabricate polymeric shells containing two precisely engineered geometric defects through a customizable coating technique. We vary the relative size and location of these two defects and quantify the relationship between buckling pressure and defect distribution. The experimental results are then contrasted against finite element modeling (FEM) simulations. Upon validation of the numerics, we use FEM to perform a broader and more systematic exploration of the parameter space. Our results provide a better understanding of defect interactions, which we hope will put us on a step to better predict the buckling pressure of practical shell structures.

9:12AM X55.00005: On Establishing Buckling Knockdowns for Imperfection-Sensitive Shell Structures*  
SYMEON GERASIMIDIS (Presenter), Civil and Environmental Engineering, University of Massachusetts, Amherst, EMMANUEL VIROT, EPFL/Harvard University, JOHN HUTCHINSON, SHMUEL RUBINSTEIN, School of Engineering and Applied Sciences, Harvard University — This presentation contributes to recent efforts aiming to revise long-standing knock-down factors for elastic shell buckling, which are widely regarded as overly conservative for well-constructed shells. The presented work focuses on cylindrical shells under axial compression with emphasis on the role of local geometric dimple imperfections and the use of lateral force probes as surrogate imperfections. Two buckling thresholds are identified (local and global buckling) and related for the two kinds of imperfections. Four sets of relevant boundary conditions are accounted revealing a strong dependence of the global buckling load on overall end-rotation constraint when local buckling precedes global buckling. A reasonably complete picture emerges, which should be useful for informing decisions on establishing knockdown factors.

*E.V. and S.M.R. acknowledge their involvement in a project directed at new methods for analyzing shell buckling headed by T. M. Schneider at EPFL. E.V. has been supported by this project. Quasi-static experimental path-following*  ROBIN M NEVILLE (Presenter), RAINER GROH, ALBERTO PIRRERA, MARK SCHENK, ACCIS, University of Bristol — Our work aims to exploit structural nonlinearity in engineering, with a particular focus on aerospace applications, to develop well-behaved nonlinear structures [1].

In addition to improved numerical methods, experimental validation of nonlinear structures is critical in ensuring their use in engineering applications, especially in conservative industries such as commercial aviation.

Existing experimental techniques are unable to fully characterise the nonlinear response of even simple nonlinear structures, as they cannot measure structures with force-displacement responses that include limit points and snapping behaviour. An experimental method has been developed to extend our ability to measure the structural response of nonlinear structures [2]. In this presentation we will present our recent developments in experimental path-following on nonlinear structures.

On the role of localised post-buckling equilibria in axially compressed cylinders*  RAINER GROH (Presenter), ALBERTO PIRRERA, University of Bristol — We revisit buckling of axially compressed cylinders by considering fully localised post-buckling states in the form of one or multiple dimples. Using a combination of nonlinear quasi-static finite element methods and numerical continuation algorithms, we trace the evolution of odd and even dimples into one ring of circumferential diamond waves. The growth of the post-buckling pattern with varying compression is driven by a homoclinic snaking sequence, with even and odd dimple solutions intertwined. The initially stable and axially localised ring of circumferential diamonds destabilises at a pitchfork bifurcation to produce a second circumferential snaking sequence that results in the Yoshimura pattern. Localised dimple solutions represent saddle points in the energy landscape providing an exponentially decreasing energy barrier between the stable pre-buckling and re-stabilised post-buckling wells. The significance of the Maxwell load as a measure for quantifying the onset of mountain-pass solutions and the reduced resilience of the pre-buckling state is assessed. Finally, conservative buckling loads for design are inferred by tracing critical boundaries of the snaking set.

Powering the Renaissance: Methods to Reveal the Energy Landscapes in Thin Shell Buckling  JACK PANTER (Presenter), Department of Physics, University of Durham, JUNBO CHEN, TENG ZHANG, Mechanical & Aerospace Engineering, Syracuse University, HALIM KUSUMAATMAJA, Department of Physics, University of Durham — The extreme non-linearity of thin shell buckling introduces significant challenges to studying even the simplest geometries. Here, we develop a new approach by coupling efficient and powerful energy landscape methods to a conceptually simple discretized elastic mesh model. This highly versatile approach can probe the buckling energy landscape of any thin shell, or composite of thin shells, without the need for a priori assumptions about deformation morphologies or symmetries.

As an example, we investigate the landscape of an axially compressed cylinder, revealed to be remarkably rich and highly variable as a function of aspect ratio and compressive strain. Firstly, we observe that a relatively small, discrete set of sub-critical buckled states balloons in size as the aspect ratio is increased. We then use a string method to obtain the minimum energy pathways between any two minima. We show how experimental local probing techniques can access the true initial buckling transition for centrally-located dimples. By recursively connecting the local minima, we reveal the landscape to be dominated by a small number of multiply-dimpled states at small aspect ratios, becoming glassy and highly-connected at large aspect ratios, and featuring many multi-step pathways between minimum pairs.
10:00AM X55.00009: Buckling of thermalized cylindrical shells

ANDREJ KOSMRLJ (Presenter), Princeton University, DAVID R. NELSON, Harvard University — We explore how thermal fluctuations affect the buckling of thin cylindrical shells. It is known that for flat solid sheets thermal fluctuations effectively increase the bending rigidity and reduce the bulk and shear moduli. As a consequence, thermal fluctuations increase the critical buckling load. In cylindrical shells, thermal fluctuations also increase the bending rigidity and reduce the in-plane elastic constants. However, the additional coupling between the shell curvature, the in-plane stretching modes and the out-of-plane undulations leads to novel phenomena. In shells thermal fluctuations effectively generate compressive load. As a consequence, the critical axial buckling load for cylindrical shells is reduced due to thermal fluctuations, which is similar to the reduced buckling pressure for spherical shells, but different from the enhanced buckling load for flat sheets. Similar to spherical shells, we find that for cylindrical shells with a sufficiently large radius the thermally generated compression can be large enough that shells become unstable even in the absence of external load. Furthermore, we find that the critical radius also depends on the aspect ratio (length/perimeter) of cylindrical shells.

10:12AM X55.00010: Imperfection-insensitive thin wavy cylindrical shells under bending: Effect of local radius of curvature on buckling and imperfection-sensitivity.

KSHITIJ YADAV (Presenter), SYMEON GERASIMIDIS, Department of Civil and Environmental Engineering, University of Massachusetts, Amherst — The imperfection-sensitivity of thin cylindrical shells has long been an obstacle for their optimal applications. To nullify this behavior, a conservative knock-down factor method is utilized for the design of thin cylindrical shells. Alternatively, stiffeners are also used to increase their capacity and to reduce the imperfection-sensitivity. We explore wavy cross-sectional thin cylindrical shells under bending to investigate the impact of imperfections on their load carrying capacity. We found that thin wavy cylindrical shells are insensitive to imperfections under bending in contrast to thin circular cylinders. This insensitivity is achieved by reducing the local radius of curvature and consequently, the effective radius of the cylindrical shell is reduced. This way cylindrical shells become less sensitive to imperfections and increase their load carrying capacity.

10:24AM X55.00011: Out-of-plane buckling of architected sheets with non-periodic cut patterns

CONNOR MCMAHAN (Presenter), PAOLO CELLI, Caltech, BASILE AUDOLY, Caltech & LMS, CNRS, Ecole Polytechnique, CHIARA DARAIO, Caltech — We investigate the out-of-plane shape morphing capability of elastic sheets with architected cut patterns. These cuts result in arrays of tiles connected by flexible hinges. We demonstrate that a non-periodic cut pattern can cause a sheet to buckle into three-dimensional shapes, such as domes or patterns of wrinkles, when pulled at specific boundary points. This phenomenon stems from the geometric incompatibilities between regions that are designed to undergo different amounts of strain. Global buckling modes observed in experiments are rationalized by an in-plane kinematic analysis, and are reproduced in simulations of homogenized shell models implemented in the open-source finite-element platform FEniCS. Our work illustrates a scalable route towards the fabrication of three-dimensional objects with nonzero Gaussian curvature from initially-flat sheets.

Session X56 GSNP: Chaos and Nonlinear Dynamics

BCEC 255 - Adolfo Del Campo, University of Massachusetts Boston

8:00AM X56.00001: Renormalization Group for Barrier Escape: Crossover to Intermittency

DAVID HATHCOCK (Presenter), JAMES PATARASP SETHNA, Cornell University — We develop a critical theory of barrier crossing in overdamped systems with low barriers. Traditional calculations in reaction-rate theory typically assume the energy barrier separating two metastable states is much larger than the thermal energy of particles in the system. When the barrier vanishes, however, there is a qualitative change in behavior as the metastable states merge. Instead of escaping over a barrier, particles now slide down a sloping potential. We formulate a simple renormalization group description of this transition and derive the scaling form for the mean escape time with an arbitrary potential and spatially dependent noise. The renormalization group analysis unifies barrier crossing problems with the theory of intermittency, originally used to describe bursts of chaotic dynamics in discrete maps. This correspondence leads to an exact functional expression for the escape time that, in certain limits, recovers the results predicted by reaction-rate theory, intermittency theory, and deterministic dynamics.

**8:12AM X56.00002: Operator Scrambling and Fermi's Golden Rule**  BIN YAN (Presenter), LUKASZ CINCIO, WOJCIECH ZUREK, Los Alamos National Lab — The out-of-time-order correlator (OTOC) qualifies the scrambling of local operators over the entire system. It has been argued that at early times the OTOC exhibits an exponential growth with a rate bounded above by $2\pi/\beta$, where $\beta$ is the inverse temperature.

In this work, we show that for generic (0+1)D systems the OTOC is ultimately related to the thermal average of the Loschmidt echo, with the perturbation given by the coupling between subsystems. It is further argued that the exponential growth and the temperature dependence of the OTOC can be determined by the Fermi's golden rule.

*This research was supported by the DOE under the LDRD program at the Los Alamos National Laboratory. LC also acknowledges support by the DOE through the J. Robert Oppenheimer fellowship.

**8:24AM X56.00003: Universal entanglement spectra in random quantum circuits**  PO-YAO CHANG (Presenter), National Tsing Hua University, XIAO CHEN, Kavli Institute for Theoretical Physics, University of California at Santa Barbara, SARANG GOPALAKRISHNAN, CUNY College of Staten Island, and CUNY Graduate Center, JED PIXLEY, Rutgers University — We will discuss the time evolution of the entanglement spectra in a spin-1/2 chain under random unitary dynamics. We find that the reduced density matrix develops level repulsion on an O(1) time scale while the bandwidth of the entanglement spectrum is rapidly changing, well before the subsystem has fully thermalized. In this locally thermal regime, random matrix theory describes the correlations between nearby entanglement energy levels but fails to capture global level correlations in the entanglement spectral form factor or the entanglement density of states. We find this behavior is universal and holds for a multitude of other quantum circuits. We will provide a heuristic explanation of our results.

**8:36AM X56.00004: Extreme Decoherence and Quantum Chaos**  ZHENYU XU (Presenter), LUIS PEDRO GARCIA-PINTOS, Department of Physics, Umass boston, AURELIA CHENU, Theoretical Division, Los Alamos National Laboratory, ADOLFO DEL CAMPO, Department of Physics, Umass boston — We study the ultimate limits to the decoherence rate associated with dephasing processes. Fluctuating chaotic quantum systems are shown to exhibit extreme decoherence, with a rate that scales exponentially with the particle number, thus exceeding the polynomial dependence of systems with fluctuating k-local interactions. Our findings suggest the use of quantum chaotic systems as a natural test-bed for spontaneous wave function collapse models. We further discuss the implications on the decoherence of AdS/CFT black holes resulting from the unitarity loss associated with energy dephasing.

8:48AM X56.00005: Experimental Study of Quantum Graphs With Symplectic Symmetry*  LEI CHEN (Presenter), Department of Electrical and Computer Engineering, University of Maryland, College Park, EDWARD OTT, THOMAS M ANTONSEN, STEVEN ANLAGE, Department of Physics and Department of Electrical and Computer Engineering, University of Maryland, College Park — Quantum graphs had been introduced as a powerful tool to study quantum chaos. Graphs with time-reversal symmetry (TRS) and broken time-reversal symmetry (BTRS), which correspond to the Gaussian orthogonal ensemble (GOE) and Gaussian unitary ensemble (GUE) respectfully, had been previously explored experimentally. We are introducing a microwave network with special design to study the Gaussian symplectic ensemble (GSE) statistics, which may be useful for research in quantum dots with strong spin-orbit scattering and other quantum chaotic systems. Two geometrically identical subgraphs with GUE symmetry are constructed from coaxial cables connected by T junctions. BTRS properties are realized by making nodes with circulators. The two subgraphs are connected with two bonds, along which one has phase shift of π, and the other one has zero phase shift. The phase shift π and 0 are achieved by putting short and open circuit connector caps into the bonds respectfully. This trick ensures the graph has an antiunitary symmetry T which squares to -1. Statistical analysis of both experimental data and simulations based on the Random Coupling Model (RCM) for this GSE graph will be presented.

*We acknowledge support under contract AFOSR COE Grant FA9550-15-1-0171 and the ONR Grant N000141512134.

9:00AM X56.00006: Nonlinear wave chaos in superconducting billiards  MIN ZHOU (Presenter), THOMAS M ANTONSEN, EDWARD OTT, STEVEN ANLAGE, University of Maryland, College Park — The Random Coupling Model (RCM) has been shown to successfully predict the statistical properties of linear wave chaotic cavities in the highly over-moded regime. It is of interest to extend the RCM to strongly nonlinear systems. We have studied the statistics of harmonics generated in a billiard by a nonlinear circuit [1] and the case of a billiard with a single nonlinear port, both of which have a point-like nonlinearity. In this talk, we discuss measurements of the nonlinear S-parameters in superconducting billiards where the nonlinearity is continuously distributed. By taking advantage of the high power (up to +35 dBm) vector network analyzer (VNA), we observe that the S-parameters are power dependent. One billiard is a cut-circle quasi-2D microwave cavity which is made of Pb-plated copper. The granular Pb material has a dominant nonlinear resistance that manifests in the S-parameters. We find the noise from the measurement setup affects the statistics in such a low loss system. Another billiard which is made of Pb-plated copper. The granular Pb material has a dominant nonlinear resistance that manifests in the S-parameters. We find the noise from the measurement setup affects the statistics in such a low loss system.

9:12AM X56.00007: Enhanced Stability and Exceptional Points in Active Photonic Couplers  VASSILIOS KOVANIS (Presenter), YVERTAY ZHIYENBAYEV, CONSTANTINOS VALAGIANNOPOULOS, Physics Department, Nazarbayev University, YANNIS KOMINIS, Physics Department, NTUA — We consider active photonic couplers consisting of two coupled dissimilar waveguides with gain and loss. We show that under generic conditions, not restricted by parity-time or other types of symmetry, there exist finite-power, constant-intensity Nonlinear Supermodes, resulting from the balance between gain, loss, nonlinearity, coupling, and dissimilarity. These Nonlinear Supermodes are characterized by the amplitude ratio and the phase difference of the two electric wave fields, which can be tuned to have almost any desired value, by appropriate parameter selection. The asymmetry of the system is shown to result in non-reciprocal dynamics enabling directed power transport functionality. In turn, we systematically investigate the dynamical response of such asymmetric coupler in the context of a set of single-mode equations with gain/loss saturation included. Additionally, we point and map, in the parameter and in the solution space of this photonic structure, a rich set of Exceptional Points, corresponding to non-Hermitian degeneracies where two eigenvalues and eigenvectors coalesce. The importance of the Exceptional Points is crucial for the system response under noisy perturbations or other modulations as well as for sensing applications.

9:24AM X56.00008: Unwinding the model manifold: choosing similarity measures to remove local minima in sloppy dynamical systems  BENJAMIN FRANCIS (Presenter), MARK TRANSTRUM, Physics and Astronomy, Brigham Young University — We consider the problem of parameter sensitivity in models of complex dynamical systems through the lens of information geometry. In most cases, models are sloppy, that is, exhibit an exponential hierarchy of parameter sensitivities. We propose a parameter classification based on how sensitivities scale at long observation times. We show that for oscillatory models, sensitivities can become arbitrarily large, which implies a high effective-dimensionality on the model manifold. This translates to multimodal fitting problems and stands in contrast to the low effective-dimensionality previously observed in sloppy models with a single fixed point. We define a measure of curvature on the model manifold which we call the winding frequency that estimates the density of local minima in the model's parameter space. We then show how alternative choices of fitting metrics can “unwind” the model manifold and give low winding frequencies. This prescription translates the model manifold from one of high effective-dimensionality into the “hyper-ribbon” structures observed elsewhere. This translation opens the door for applications of sloppy model analysis and model reduction methods developed for models with low effective-dimensionality.
9:36AM X56.00009: Chaos and High Temperature Pure State Thermalization* YURI LENSKY (Presenter), XIAOLIANG QI, Physics, Stanford University — Classical arguments for thermalization of isolated systems do not apply in a straightforward way to the quantum case. Recently, there has been interest in diagnostics of quantum chaos in many-body systems. In the classical case, chaos is a popular explanation for the legitimacy of the methods of statistical physics. In this work, we relate a previously proposed criteria of quantum chaos in the unitary time evolution operator to the entanglement entropy growth for a far-from-equilibrium initial pure state. By mapping the unitary time evolution operator to a doubled state, chaos can be characterized by suppression of mutual information between subsystems of the past and that of the future. We show that when this mutual information is small, a typical unentangled initial state will evolve to a highly entangled final state. Our result provides a more concrete connection between quantum chaos and thermalization in many-body systems.

9:48AM X56.00010: Nucleation of Defect Turbulence in the Two-dimensional Complex Ginzburg-Landau Equation* WEIGANG LIU (Presenter), UWE CLAUS TAUBER, Virginia Tech — We numerically investigate nucleation processes in the transient dynamics of the two-dimensional complex Ginzburg-Landau equation towards its "frozen" state with stationary spiral structures. We are interested in the transition kinetics between a random initial configuration and the latter frozen state with a well-defined low density of quasi-stationary vortices. Nucleation is monitored using the characteristic length between the emerging shock structures. The average nucleation time for different system sizes is measured over many independent realizations to obtain good statistics. An extrapolation method as well as a phenomenological formula are employed to eliminate finite-size effects. The non-zero barrier for the nucleation of single vortex droplets in the extrapolated infinite-size limit suggests that the transition to the frozen state is discontinuous. We also investigate the nucleation of target waves which emerge if a specific spatial inhomogeneity is introduced. A long "fat" tails exists in the distribution of nucleation times in this case, which suggest that the associated transition may be continuous.

*This research is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering under Award DE-FG02-09ER46613.

10:00AM X56.00011: Thouless and Relaxation Time Scales in Many-Body Quantum Systems* MAURO SCHIULAZ (Presenter), Yeshiva University, E. JONATHAN TORRES-HERRERA, Instituto de Fisica, Benemerita Universidad Autonoma de Puebla, LEA SANTOS, Yeshiva University — We study the time scales involved in the relaxation process of isolated quantum many-body systems. Using experimental observables and a realistic many-body quantum model, we unveil three different time scales: a very short time that characterizes the early fast decay of the initial state, and two much longer times that increase exponentially with system size. These are the Thouless time, $t_{\text{Th}}$, and the relaxation time, $t_{\text{R}}$. The Thouless time refers to the point beyond which the dynamics acquire universal features, and relaxation happens when the evolution reaches a stationary state. We show that in chaotic systems, $t_{\text{Th}}<<t_{\text{R}}$, while for systems approaching a many-body localized phase, $t_{\text{Th}}$ tends to $t_{\text{R}}$. We also compare these results with those for random matrices, and study how self-averaging properties depend on time scales.

10:12AM X56.00012: Capture and chaotic scattering of a charged particle by a magnetic monopole under a uniform electric field KOU MISAKI (Presenter), University of Tokyo, NAOTO NAGAOSA, University of Tokyo, Riken CEMS — Motivated by the realization of magnetic monopole of Berry curvature by the energy crossing point, we theoretically study the effect of magnetic monopole under a uniform electric field in the semiclassical dynamics, which is relevant to many physical situations such as relaxation through the diabatic point. We found that the competition between the backward scattering by the monopole magnetic field and the acceleration by the electric field leads to the bound state, i.e., capture of a particle near the monopole. Furthermore, the nonlinearity induced by the magnetic monopole leads to the chaotic behavior in the transient dynamics, i.e., the transient chaos. We computed characteristic quantities of the strange saddle which gives rise to the transient chaos, and verified that the abrupt bifurcation occurs as we tune the system parameter toward the parameter region in which the system is integrable.
10:24AM X56.00013: PULSEDYN: Open source code for dynamical simulations of strongly nonlinear systems  RAHUL KASHYAP (Presenter), SURAJIT SEN, University at Buffalo, The State University of New York — We present PULSEDYN which is an open source C++ code written with the goal of performing highly accurate and late time simulations on strongly and weakly nonlinear chains while requiring minimal effort on the user's part. PULSEDYN offers a suite of potentials and solvers and simulations and may be set up using a parameter file and running the code provided as an executable. PULSEDYN is also written with an emphasis on modularity, allowing for easy changes to be made to the code. PULSEDYN is available to download from Github and is accompanied by documentation and a detailed user manual [1]. We show standard results reproduced from literature using PULSEDYN for benchmarking purposes. We then use PULSEDYN to demonstrate how a strongly nonlinear Fermi-Pasta-Ulam-Tsingou system transitions from quasi-equilibrium to the equipartitioned state and verify our results by correctly predicting the exact equilibrium specific heat of the system from the simulated equipartitioned state.

10:36AM X56.00014: The dynamics of the musical saw PETUR BRYDE (Presenter), LAKSHMINARAYANAN MAHADEVAN, Harvard University — The musical saw is played by first being bent into an S–curve before it is bowed - this geometry allows for vibration modes that are localized near the point of inflection. To understand this, we consider how the spectrum of a curved plate or beam is controlled by a spatially varying curvature profile. Using a recent geometric interpretation of Anderson-like localization that links the underlying eigenvalue problem and a closely related elliptic problem allows us to determine the conditions for and extent of mode localization and suggests an explanation for the sweet sound of the saw.

10:48AM X56.00015: Thermodynamics of Turing Machines* ARTEMY KOLCHINSKY (Presenter), DAVID WOLPERT, Santa Fe Institute — Turing Machines [TMs] are the canonical model of computation. Using results from thermodynamics of computation, we investigate bounds on the amount of work required to perform calculations using TMs. First, we consider the minimal amount of work required to run a given input program on a TM. We also consider the minimal amount of work required to produce a given string as an output of a TM, in analogy to Kolmogorov complexity (which asks about the length of the shortest program needed to produce a given string on a TM). We analyze two ways of implementing a TM, one of which is shown to require less work than any computable implementation. We also show that unlike the Kolmogorov complexity of a string which can be arbitrarily large, the minimal amount of work required to produce a given string is bounded by a constant.

Session X57 GSNP: Mechanical Metamaterials II BCEC 256 - Johannes Overvelde, AMOLF

8:00AM X57.00001: Bidirectional Folding with Atomic Layer Deposition Bimorphs for Autonomous Micro-Origami* ITAI COHEN (Presenter), BARIS BIRCAN, MARC MISKIN, Physics, Cornell University, ROBERT J LANG, Robert Lang Origami, KYLIE J DORSEY, PAUL L MCEUEN, Physics, Cornell University — We present micron sized self-folding structures that consist of nanometer-thin, atomic layer deposited SiO$_2$-Si$_3$N$_4$ bilayers, built with conventional semiconductor fabrication methods. A bending response originating from strain differentials within these bilayer stacks is used as the fold actuation mechanism. This strain differential induced bending is controlled by ion exchange reactions in our nanoscale sheets, enabling us to produce radii of curvature at the order of microns within fractions of a second. By lithographically patterning these sheets and localizing the bending using flat photoresist panels, we create microscale origami devices that can sense chemical changes in their environment and respond by changing configurations according to prescribed mountain-valley fold patterns. Finally, we show that our fabrication approach offers a range of chemical, electrical and biological functions as well as a path to sequential folding through the programming of stacks.

*This research was performed in part at the Cornell Nanoscale Science and Technology Facility. This research was supported in part by NSF DMR 1435829.
8:12AM X57.00002: Computational design of multistable metamaterials  FERNANDO INIGUEZ-RABAGO (Presenter), YUN LI, JOHANNES OVERVELDE, AMOLF — Metamaterials’ properties arise not only from their chemical composition, but mainly from their periodic structure. While most of these materials are characterized by a fixed geometry, some materials are designed with internal hinging mechanisms. This allows them to be reconfigured with external stimuli, therefore exhibiting tuneable properties. However, these materials become dependent on the stimuli, and once removed the material will relax to the initial configuration. Previously we proposed a design strategy based on space-filling extruded polyhedra to create 3D reconfigurable materials comprising a periodic assembly of rigid plates and elastic hinges. Interestingly, for some of these structures we found additional stable configurations that are spatially admissible, but that cannot be reached without temporarily deforming the rigid faces. Here, we soften this constraint to open up new folding pathways. We introduce a computational approach to scan the energy landscape of these complex 3D structures, and show that our method closely mimics experimental implementations of locally actuated metamaterials. Using this approach, we find a wealth of multistable unit cells that can be assembled to create responsive materials capable of switching between different properties.

8:24AM X57.00003: Programmable Anisotropic Multi-stability in an Origami-inspired Metamaterial* SOROUSH KAMRAVA (Presenter), Northeastern University, RANAJAY GHOSH, University of Central Florida, ZHIHAO WANG, ASHKAN VAZIRI, Northeastern University — In this project, we design, develop, fabricate and study a new class of 3D origami-inspired metamaterials with highly anisotropic mechanical instability and controlled reconfigurability. This metamaterial is constructed by connecting star-shaped units that are formed by folding an array of interconnected Miura-ori patterns, also known as origami string. The origami string is a one degree of freedom slender mechanisms in which we substituted paper and creases with 3D printed faces and revolute hinges, respectively. The star-shaped unit exhibits mechanically rich and strongly nonlinear behavior that includes bi-stability and reconfigurability. In addition, we introduce a 3D combination of star-shaped units with zero effective Poisson's ratio in three orthogonal directions allowing its behavior in each loading direction to be programmed independently. The mechanical instability of this metamaterial in each orthogonal direction directly depends on the characteristics of star-shaped units aligned in that direction. Also, our study provides a framework to program the star units and create the desired properties in each orthogonal direction of the 3D metamaterial.

*United States National Science Foundation, Division of Civil, Mechanical, and Manufacturing Innovation, Grant No.1634560.

8:36AM X57.00004: Topological defects in complex mechanical metamaterials  ANNE MEEUSSEN (Presenter), Designer Matter Department, AMOLF, ERDAL C. OGUZ, YAIR SHOKEF, School of Mechanical Engineering, Tel Aviv University, MARTIN VAN HECKE, Huygens-Kamerlingh Onnes Laboratory, Leiden University — While topological defects play a crucial role in condensed matter, they are not widely explored in mechanical metamaterials. We introduce a systematic strategy to design frustrated metamaterials with local or topological defects. We uncover their distinct mechanical signatures, and show how defects can be harnessed to engineer a desired response. Our work presents a new avenue to systematically introduce frustration and defects with a topological signature in mechanical metamaterials.

8:48AM X57.00005: Propagation of Pop-ups in Kirigami Shells  AHMAD RAFSANJANI, School of Engineering and Applied Sciences, Harvard University, LISHUAI JIN (Presenter), School of Mechanical Engineering, Tianjin University, BOLEI DENG, KATIA BERTOLDI, School of Engineering and Applied Sciences, Harvard University — Kirigami-inspired metamaterials are attracting increasing interest because of their ability to achieve extremely large strains and shape changes via out-of-plane buckling. While in flat kirigami sheets all ligaments buckle simultaneously leading to a continuous phase transition, here we demonstrate that kirigami shells can also support discontinuous phase transitions. Specifically, we show via a combination of experiments, numerical simulations and theoretical analysis that in cylindrical kirigami shells the buckling induced pop-up process initially localizes near an imperfection and then, as the deformation is increased, progressively spreads through the structure. Notably, we find that the width of the transition zone, as well as the stress at which propagation of the instability is triggered, can be controlled by carefully selecting the geometry of the cuts and the curvature of the shell. Our study significantly expands the ability of existing kirigami metamaterials and opens avenues for the design of the next generation of responsive surfaces, as demonstrated by the design of a smart skin that significantly enhance the crawling efficiency of a simple linear actuator.
9:00AM X57.00006: Kirigami surfaces: programmable mechanical response via hierarchical design* NING AN (Presenter), State Key Laboratory for Strength and Vibration of Mechanical Structures and School of Aerospace, Xi’an Jiaotong University, Xi’an 710049, People’s Republic of China, AUGUST G DOMEL, John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA, AHMAD RAFSANJANI, Department of Materials, ETH Zürich, 8093 Zürich, Switzerland, JINXIONG ZHOU, State Key Laboratory for Strength and Vibration of Mechanical Structures and School of Aerospace, Xi’an Jiaotong University, Xi’an 710049, People’s Republic of China, KATIA BERTOLDI, John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, USA — Kirigami - the ancient Japanese art of cutting paper - has recently inspired the design of highly stretchable and morphable mechanical metamaterials that can be easily realized by embedding an array of cuts into a thin sheet. An attractive feature of these systems is that they are manufactured as a simple flat surface with cuts and then exploit elastic instabilities to transform into complex three-dimensional configurations. In this study, we focus on a thin elastic sheet perforated with a hierarchical pattern of cuts and demonstrate that the hierarchy significantly enhances the programmability of the system. In particular, we show that, by tuning the geometric parameters of this hierarchy, not only a variety of different buckling-induced 3D deformation patterns can be triggered, but also the stress-strain response of the surface can be effectively programmed. Finally, we show that when multiple hierarchical surfaces of various geometric patterns are brought together to create one combined heterogenous surface, the mechanical response can be further tuned and complex stress-strain curves can be achieved.

*Ning An was supported by the China Scholarship Council as a visiting scholar at Harvard University.

9:12AM X57.00007: Morphing origami shells: the case of the Miura ori HUSSEIN NASSAR (Presenter), MAE, University of Missouri, Columbia — Origami has become a source of inspiration in design across multiple scales. Its rules stipulate that a 3D shape must be folded from a single flat sheet: cutting and gluing are prohibited. Although seemingly restrictive, these rules have allowed artists, and more recently scientists, to construct surprisingly intricate shapes while guaranteeing an advantageous assembly-free fabrication based on a single process: folding. Origami-inspired structures have a second advantage: their folding/unfolding mechanism can be leveraged to adapt to a changing environment. Indeed, local folds aggregate and bring on large changes in shape, curvature and elongation on a global scale. The talk advocates for a way of describing origami tessellations as a class of morphing, yet kinematically constrained, shell structures rather than a mere discrete assembly of hinged plates. A purely kinematical continuum theory of these shells is suggested and exemplified in the case of the Miura origami tessellation. Various finite deformation modes (large strains, large curvatures) are successfully predicted and explained by the theory and are subsequently numerically constructed under suitable boundary conditions. The results demonstrate the rich morphing abilities of origami shells.

9:24AM X57.00008: Nonlinear elastic response of a topological mechanical metamaterial JOSHUA SOCOLAR (Presenter), Physics Department, Duke University, YUXUAN CHENG, Physics Department, Wuhan University — We consider the static response of a finite 1D lattice of pivoting rigid bars connected end-to-end by harmonic springs of zero equilibrium length. The linearized model is equivalent to the Kane-Lubensky model of rigid rotors and is topologically polarized when the pivot point of each bar is off center. We fix the angular displacement of the leftmost bar and solve the nonlinear torque balance equations for the equilibrium configuration. For the unpolarized case, we find an algebraic decay of the rotation angle θ_n due to nonlinear effects associated with the bulk zero mode. For one sign of the polarization, θ_n decays exponentially and the elastic energy is nearly zero, consistent with the excitation of the zero mode at the left edge. For the other sign, θ_n also decays exponentially with the same decay length as the zero mode, but with a finite energy, and there is a turning point beyond which θ_n grows exponentially toward the free boundary. Numerical solutions are explained in detail by an analysis that necessarily includes terms of up to fifth order in θ_n. The results provide insight into numerical results for the directional response of a 2D mechanical graphene model to an externally applied local strain.

9:36AM X57.00009: Geometric information and rigidity percolation in floppy origami SIHENG CHEN (Presenter), L MAHADEVAN, SEAS, Harvard University — Floppy origami structures have many folded configurations and are thus natural candidates for storing information geometrically. To address how we might harness this idea, we study the effect of folds and constraints in a planar tessellation inspired by the simplest globally coordinated origami pattern known as Miura-ori. Introducing folds randomly along the diagonals of the quads in Miura-ori makes the rigid structure floppy. We show how the number of degrees of freedom in the system varies with the increase in the density of constraints, first linearly, and then nonlinearly. In the nonlinear regime, mechanical cooperativity sets in via an inherent redundancy that depends on the assignment of constraints, and the degrees of freedom in the system depends on the density of constraints in a scale-invariant manner. The redundancy in the constraints shows a percolation transition at a critical constraint density \( \rho_c \). Our work shows how floppy origami can be used to store information in a scale-invariant way, and how we can control its rigidity exquisitely by taking advantage of a percolation transition.
Topological Directional Response in the Continuum Limit of Mechanical Metamaterials

ADRIEN SAREMI (Presenter), D. ZEB ROCKLIN, Georgia Institute of Technology — Flexible mechanical metamaterials display an exciting variety of novel deformation properties, including programmability, nonlinearity and robustness. However, these functionalities, which rely on nonuniform deformations of the microscopic unit cell of which the metamaterial is composed, are not captured by conventional elastic theory, creating a challenge in examining their actual large-scale properties. We address this via micromorphic continuum elasticity, which treats deformations that are nonuniform locally yet vary smoothly over larger lengthscales. We examine in particular topological edge and interface modes and directional response analogous to that observed by Kane and Lubensky in discrete models. We identify a new counting argument between modes of deformation and constraints that ensures mechanical criticality in the continuum, leading to a novel correspondence between a bulk topological invariant and boundary modes. Finally, we explore the lengthscales of deformations governed by this theory for given system geometries, elastic properties and disorder.

Topological edge floppy modes in quasicrystals

DI ZHOU (Presenter), LEYOU ZHANG, XIAOMING MAO, Department of Physics, University of Michigan, Ann Arbor — Quasicrystals (QCs) are fascinating materials that exhibit physics properties not available in crystals, such as rotational symmetries forbidden in lattices, physics of higher dimensions, and self-similarity. The interplay of these unique features with topological states of matter can offer a rich variety of interesting phenomena. In this talk, we discuss topological mechanics in 2-dimensional quasicrystalline parallelogram tilings. We use the Penrose tiling as our example to demonstrate how these boundary modes arise with a small geometric perturbation to the tiling. The same construction can also be applied to disordered parallelogram tilings to generate topological boundary floppy modes. We find that, due to the unusual rotational symmetry of quasicrystals, the resulting topological polarization can exhibit orientations not allowed in periodic lattices. Our result reveals new physics about the interplay between topological states and quasicrystalline order and leads to novel designs of quasicrystalline topological mechanical metamaterials.

The topological basis of function in flow and mechanical networks

JASON W ROCKS (Presenter), ANDREA LIU, ELENI KATIFORI, University of Pennsylvania — Recently, both flow networks and mechanical networks have been shown to be remarkably tunable. By tuning the local node connectivity, it is possible to robustly control the propagation of inputs in order to achieve a wide variety of specific tasks. However, the network architectures used to achieve such tasks demonstrate significant design flexibility, blurring the relationship between structure and function. Here we seek to identify the structural features responsible for function in tuned networks. Using persistent homology, we show that networks develop large-scale topological features when they are tuned, which are similar for different networks with the same function, regardless of the details of the local link topology. These features correlate strongly with the tuned response, providing a clear relationship between structure and function.

Using tunable origami for active energy absorption

ZHONGYUAN WO (Presenter), JULIA RANESES, EVGUENI FILIPOV, University of Michigan — Energy absorption devices are widely used to mitigate damage from collisions and impact loads. Due to the inherent uncertainty of possible impact characteristics, passive energy absorbers with fixed mechanical properties are not capable of serving in different application scenarios. Therefore, origami-inspired structures, which possess the ability to reconfigure and deploy, are a qualified candidate for a novel active design. In this work, we apply the constrained zipper-coupled Miura-ori tubes (deployable and stiff after locking) as the basis to a tubular energy absorber. Numerical and experimental (static and dynamic) studies are performed to quantify the response of these novel structures. This work shows that the reconfigurable origami could change their stiffness and the total amount of energy they absorb. These behaviors are suitable for creating systems with on-demand properties that adapt to different impact scenarios.

10:36AM X57.00014: Atomic layer deposition for membranes, metamaterials, and machines*  KYLE J DORSEY (Presenter), TANNER G PEARSON, School of Applied and Engineering Physics, Cornell University, EDWARD P ESPOSITO, Laboratory of Atomic and Solid State Physics, Cornell University, BARIS BIRCAN, YIMO HAN, School of Applied and Engineering Physics, Cornell University, SIERRA RUSSELL, Nanoscale Engineering, SUNY Polytechnic, DAVID ANTHONY MULLER, School of Applied and Engineering Physics, Cornell University, ITAI COHEN, PAUL L MCEUEN, Laboratory of Atomic and Solid State Physics, Cornell University — Ultra-thin films of inorganic materials are well-suited for fabrication of micron-scale actuators because they can sustain small radii of curvature, are compatible with semiconductor processing, and are chemically robust. We leverage atomic layer deposition (ALD) to produce free-standing mechanical devices with sub-5 nm film thicknesses. We fabricate cantilevers from ALD films to characterize the mechanical properties. We find that ALD films are elastic and exhibit a bending stiffness on the order of $10^{-15}$ J. These measurements enable fabrication of cantilever springs with ultra-low spring constants suitable for micron-scale machinery. ALD mechanical metamaterials are fabricated by patterning of both the film and its substrate. Corrugations transferred into the ALD film enhance its bending stiffness and enable bending anisotropy, while cuts etched into the film soften the in-plane response. We integrate these results to produce magnetically actuated three-dimensional devices with applications in micromachinery.

Session X58 GSOFT: Granules and Glasses BCEC 257A - Wen Zhang, University of Science and Technology of China

8:00AM X58.00001: Structural and topological nature of plasticity in sheared granular materials*  YUJIE WANG, YIXIN CAO, Physics, Shanghai Jiao Tong University, TIQIAO XIAO (Presenter), Shanghai Institute of Applied Physics, WALTER KOB, University of Montpellier and CNRS — Upon mechanical loading, granular materials yield and undergo plastic deformation. The nature of plastic deformation is essential for the development of the macroscopic constitutive models and the understanding of shear band formation. However, we still do not fully understand the microscopic nature of plastic deformation in disordered granular materials. Here we used synchrotron X-ray tomography technique to track the structural evolutions of three-dimensional granular materials under shear. We establish that highly distorted coplanar tetrahedra are the structural defects responsible for microscopic plasticity in disordered granular packings. The elementary plastic events occur through flip events which correspond to a neighbor switching process among these coplanar tetrahedra (or equivalently as the rotation motion of 4-ring disclinations). These events are discrete in space and possess specific orientations with the principal stress direction.

*The work is supported by the National Natural Science Foundation of China (No. 11175121 and 11675110).

8:12AM X58.00002: The Jamming Energy Landscape is Hierarchical and Ultrametric*  ROBERT DENNIS (Presenter), ERIC CORWIN, Physics, University of Oregon — Recent infinite dimensional mean field results have shown that the energy landscape of glasses forms a hierarchically structured ultrametric space. We directly explore this prediction in low dimensional finite size systems. Starting in an energy minima of an over-jammed system, we apply a small random perturbation to the positions of our particles and re-minimize in order to find new minima. By enumerating these minima and calculating the distance between their force networks, we produce a small correlated portion of the overlap matrix. This matrix exhibits a clear hierarchical structure and shows the signature of an ultrametric space. That such a hierarchy exists for the jamming energy landscape provides direct evidence for the existence of a marginal phase created by the Gardner transition.

*We gratefully acknowledge support from the NSF under Career Grant No. DMR-1255370 and a grant from the Simons Foundation No. 454939.
8:24AM X58.00003: Jammed packings behave similarly under random force and shear  PETER MORSE (Presenter), Syracuse University, ELISABETH AGORITSAS, École Normale Supérieure, M. LISA MANNING, Syracuse University, FRANCESCO ZAMONI, École Normale Supérieure, ERIC CORWIN, University of Oregon — Mean-field calculations suggest that in infinite dimensions, the response of a system to global shear and random forces may be equivalent. Whether or not this is true in 2d or 3d systems remains an open question. To address this, we develop a method for driving 2d jammed packings of disks by quasi-static persistent random forces and demonstrate that the response is similar to what is observed in athermal quasi-static shear simulations. We also investigate the gap and small force statistics in these randomly forced packings as well as the spatial organization of vibrational modes and particle rearrangements in order to compare to similar observations under shear. We expect that the results of this work may have interesting applications in understanding emergent behavior in active matter systems.

8:36AM X58.00004: Characteristic temperatures predicted from inherent structures*  JIANHUA ZHANG (Presenter), WEN ZHENG, NING XU, University of Science and Technology of China — We calculate the correlation and linear response to external forces for inherent structures (metastable solid states at zero temperature) of different systems. Borrowing the idea of fluctuation-dissipation relation for thermodynamically equilibrated systems, we obtain a temperature-like quantity purely from the correlation and response of inherent structures. For systems with Lennard-Johns, Weeks-Chandler-Andersen, and harmonic particle interactions, we surprisingly find that the temperature-like quantity agrees well with the crystallization or onset temperature for crystal or glass forming liquids. Our study indicates that some equilibrium information can be obtained just from nonequilibrium metastable solid states, which thus proposes a novel way to calculate characteristic temperatures. Our results also suggest that effective temperatures previously calculated in ageing glasses may be simply the onset temperature of glass forming liquids.

8:48AM X58.00005: ABSTRACT WITHDRAWN —

9:00AM X58.00006: Landau Theory of Complex Spherical Packing Phases*  DUNCAN MCCLENAGAN (Presenter), Department of Physics and Astronomy, McMaster University, KAI JIANG, School of Mathematics and Computational Science, Xiangtan University, ANCHANG SHI, Department of Physics and Astronomy, McMaster University — A large number of complex spherical phases, such as the Frank-Kasper phases (e.g., the \( \sigma \), A15, C14 and C15 phases), have been observed in various soft matter systems. Understanding the formation of these novel ordered structures presents an interesting challenge to the soft matter community. We are developing Landau theories that are capable of describing the occurrence and stability of these phases. Our research indicates that the A15 and \( \sigma \) phases may emerge as stable or metastable phases in systems described by a Landau theory derived from the statistical mechanics of block copolymers. We will discuss our results and their significance to the mechanisms for the formation of complex spherical phases in soft matter systems.

9:12AM X58.00007: Glass Transition in Supercooled Liquids with Medium-Range Crystalline Order.  INDRAJIT TAH (Presenter), Tata Institute of Fundamental Research Hyderabad, SHILADITYA SENGUPTA, University of Tokyo, SRIKANTH SASTRY, Physics, Jawaharlal Nehru Centre for Advanced Scientific Research, CHANDAN DASGUPTA, Physics, Indian Institute of Science, SMARAJIT KARMAKAR, Tata Institute of Fundamental Research Hyderabad — The origin of the rapid dynamical slowdown in glass forming liquids in the growth of static length scales, possibly associated with identifiable structural ordering, is a much debated issue. Growth of medium range crystalline order (MRCO) has been observed in various model systems to be associated with glassy behavior. Such observations raise the question of whether molecular mechanisms for the glass transition in liquids with and without MRCO are the same. In this study we perform extensive molecular dynamics simulations of a number of glass forming liquids and show that the static and dynamic properties of glasses with MRCO are different from those of other glass forming liquids with no predominant local order. We also resolve an important issue regarding the so-called point-to-set method for determining static length scales, and demonstrate it to be a robust method for determining static correlation lengths in glass formers.
9:24AM X58.00008: Softening of rapidly heated nanoscale glassy films of methylbenzene

RINIPAL KAUR (Presenter), VLADISLAV SADTCHENKO, Chemistry, The George Washington University — Using Fast Scanning Calorimetry (FSC), we investigated the impact of thin film confinement on softening and vaporization of glassy films of methylbenzene in the limit of high heating rates. The glassy films of distinct thicknesses ranging from 2 to 1800 nm were grown by vapor deposition and subjected to heating with rates in excess of $10^5$ K/s. For the films with thicknesses above 20 nm, the resulting softening kinetics strongly implied a surface facilitated mechanism: the softening originated at surfaces of a sample and progresses into its bulk via a transformation front. Yet, according to our analysis, the kinetic parameters for the softening front propagation differed significantly for the films with thicknesses below and above 300 nm. For example, the apparent activation energy barrier for the front propagation almost doubled for thicker films. We interpret these results in the framework modified Wilson-Frenkel model of softening front propagation and discuss their implications for past FSC studies of nanoscale vapor-deposited glassy films.

9:36AM X58.00009: Surface facilitated softening of rapidly heated glasses: recent experimental results and the fundamental mechanisms

VLADISLAV SADTCHENKO (Presenter), ULYANA CUBETA, RINIPAL KAUR, Chemistry, The George Washington University — Under certain conditions, e.g., during rapid heating, stable vapor-deposited, ordinary glassy, and even viscous liquid films can undergo softening by surface facilitated mechanism: the softening originates at the surface of a sample and progresses into its bulk via a transformation front. Despite years of research on this phenomenon, no simple theoretical model is currently available for quantitative description of glass softening by a propagating front. Based on our recent fast scanning calorimetry studies of surface facilitated glass softening and melting of superheated molecular crystals, we developed a comprehensive analytical description of the softening front propagation. This description is essentially a modification of well-established Wilson-Frenkel theory of non-equilibrium phase transitions. We present further experimental evidence in support of this analytical approach, and discuss the model's advantages, formalism, limitations, and applicability under a variety of experimental conditions.

9:48AM X58.00010: Stagnant zone formation in a 2D granular bed under penetration*

HONGYI XIAO (Presenter), MATT HARRINGTON, DOUGLAS DURIAN, University of Pennsylvania — Penetration into a granular material is a process that is both rich in physics and important in engineering applications. Here, we present experiments with a rectangular indenter penetrating horizontally into 2D granular beds. The penetration force experienced by the indenter shows a linear increase with the penetration depth, and this force is larger for penetration into elongated particles than that into circular-shaped particles. Particle positions are tracked, and local particle-based strains are calculated, showing a triangular-shaped stagnant zone in front of the indenter, and two shear bands along the edge of the stagnant zone. A structural function, $Q_k$, is used to characterize the local packing anisotropy, which reveals unique structural signatures as well as different structure-dynamic relations for the stagnant zone and the shear bands. The linear force law and the distinct regions observed here agree with a recent continuum model for granular penetration [1], while the structural information extracted here further demonstrates the microscopic difference between shear jammed and shear localized regions.

*Funded by NSF grants MRSEC/DMR-1120901 and MRSEC/DMR-1720530.

10:00AM X58.00011: Intruder spacing induces particle jamming during intrusion into granular media

SWAPNIL PRAVIN (Presenter), Temple University, ENDAO HAN, HEINRICH M JAEGER, The University of Chicago, S. TONIA HSIEH, Temple University — Robotic feet often encounter granular substrates that can display complex behavior ranging from solid to fluid in a single step. The effects of foot morphology on the interaction between feet and granular substrates remain poorly understood. Inspired by the presence of toes on animal feet, the goal of this study was to characterize the effect of spacing between two intruders ("toes") on granular material behavior. To this end, we measured and numerically simulated the force response to intrusion of two parallel square rods into dry poppy seeds while varying the rod gap spacing. Our results show that a peak in total force occurs at a gap of ~3 particle diameters, which was 20 % greater than the force at large separation (>11 particle diameters), beyond which the total produced force plateaued. We propose that this peak in force is the result of particle jamming between the intruders. To quantify the degree of particle jamming, interparticle forces were calculated from simulations. As expected, the total number of strong forces—identified as force chains—indicated greater particle jamming at gap spacings close to those corresponding to the peak force. These findings indicate that intruder separation and particle jamming can significantly affect force response to granular intrusion.
A New Calculation of Stretched Exponential Time Dependence in As2Se3 Structural Glass

CHRIS NELSON (Presenter), Physics and Astronomy, St. Cloud State University — It has been shown by a number of authors that the relaxation times of structural glasses satisfy a stretched exponential dependence with a particular value for the exponent $\beta$ at the glass temperature. Previously, this author used a free energy approach involving frustration in locally preferred structures to calculate the NQR distribution, the correct glass and Kauzzmann temperatures, as well as the spike in the heat capacity for the structural glass As$_2$Se$_3$. Here we calculate the correct relaxation time exponent ($\beta=3/5$) based on a statistical mechanical approach using the same approach. In addition, we show that this time dependence is entirely determined by the cooperative behavior of said structures, and at the glass transition temperature the system + bath is non-equilibrium steady state.

Presenting New Generation Amorphous Glassy Alloys “NGAGA”

DIPTI SHARMA (Presenter), Science, WIT, JOHN MACDONALD, Chemistry and BioChemistry, WPI, NEERAJ MEHTA, Physics, BHU — This work explores the details of “New Generation Amorphous Glassy Alloys (NGAGA)”. Several decades ago, single glassy material was explored, and one single glass transition of a single amorphous glassy material can be seen i.e. Amorphous Selenium. Later, binary glassy alloys appeared where an example of SeTe can be seen and glass transition of binary glassy alloys were explored as single but shifted glass transition. Then tertiary amorphous material came into research field i.e. SeTeAg and showed either shorter or wide and shifted kinetics of glass transition with doped material. But as time advanced, New Generation Amorphous Glassy alloys with four materials in one, appeared i.e. SeTeSnAg those brought very different results in glassy behavior. In this work, we are going to discuss changes occurred in NGAGA and in their kinetic behavior. From 1st generation to 4th generation, glassy alloys were made in our lab and studied and showed significant results in the research area of soft condensed matter and material Physics.

Keywords: Amorphous material, glassy alloys, material, transition, kinetics, Calorimetry, thermal behavior, new generation material.

Rigid clusters versus rigid regions in frictional granular packings and their role in packing mechanics

J. M. SCHWARZ (Presenter), KUANG LIU, Department of Physics, Syracuse University, JONATHAN E KOLLMER, Department of Physics, University of Duisburg-Essen, SILKE HENKES, Department of Mathematics, University of Bristol, KAREN DANIELS, Department of Physics, North Carolina State University — Force-chains are a well-established signature of granular packings yet their role in packing mechanics remains elusive. We explore two new complementary mechanical signatures, namely that of rigid clusters and that of rigid regions. To determine rigid clusters, we implement a frictional version of a (3,3) pebble game on experimental packings of photoelastic disks undergoing a jamming transition. To determine rigid regions, we compute the dynamical matrix in the presence of friction and use a threshold-based criterion to determine which regions are rigid. While the rigid cluster decomposition depends on the topology of the contact network, the latter approach depends both on the topology and forces of the contact network. We find that the rigid clusters correlate well with the rigid regions, particularly near the jamming transition. We also observe “partial rigidity” with both signatures containing holes of floppiness involving groups of disks in the contact network and we look for correlations between rigid clusters/regions and force chains. In some cases we find that spanning force chains can dictate the boundary of a rigid cluster/region, while in other cases there is little correlation, hinting at the complexity of the problem.

Granular drag induced by oblique impact

KAI HUANG (Presenter), VALENTIN DICHTL, FELIX RECH, Experimentalphysik V, University of Bayreuth — Considering granular medium as a complex fluid with a finite yield stress, an object moving inside has to locally unjam and mobilize the surrounding particles in order to step forward. Consequently, granular drag depends strongly on the local rheological behavior. Using a recently developed bi-static radar system capable of tracking a metallic object with a diameter down to a few millimeters, we monitor the trajectory of a projectile penetrating obliquely into a granular medium and characterize the velocity dependent granular drag in both vertical (along gravity) and horizontal directions. Recent advances in this particle tracking technique and the possibility of using it as a local rheometer for granular media will be discussed.

Friday, March 8, 2019 8:00 AM - 10:48 AM

Session X59 GSOFT: Soft Composites: Mechanics and Structure I

University of San Diego - Tag(s): Focus
8:00AM X59.00001: Glassy Dynamics in Composite Biopolymer Networks* [Invited] JOERG SCHNAUSS (Presenter), TOM GOLDE, MARTIN GLASER, TINA HÄNDLER, CARY TUTMARC, IMAN ELBALASY, JOSEF A. KAS, Leipzig University, HARALD HERRMANN, German Cancer Research Center, DAVID M SMITH, Fraunhofer Institute for Cell Therapy and Immunology — The cytoskeleton is a highly interconnected meshwork of strongly coupled subsystems providing mechanical stability as well as dynamic functions to cells. To uncover central biophysical principles, it is essential to investigate not only one distinct functional subsystem but rather their interplay as composite biopolymeric structures. Here, these effects caused by composite structures will be especially addressed with the two key elements of the cytoskeleton actin and vimentin IF. In contrast to previous studies, entangled conformations of these reconstituted composite networks can be described by a superposition of two non-interacting scaffolds. Key elements are the ability to compare different compositions with comparable architectural features as well as to identify polymer-specific interactions, which are typically ignored in most established models. We have experimentally identified inter-filament interactions as a key factor that can overwrite scaling predictions of the classical semiflexible polymer physics by comparing results of networks of actin, vimentin IF, keratin IF and synthetic double-crossover DNA nanotubes. Acquired results of the linear and non-linear bulk mechanics are captured in the frame of an inelastic glassy wormlike chain model allowing to address the diversity of the polymer types based on their specific interactions, which lead to differing relaxation behaviors for the different polymer types. Accounting for this molecular diversity, the composite effects can be expressed as a superposition of the non-interacting scaffolds.

*We acknowledge funding by the Deutsche Forschungsgemeinschaft (DFG) and by the European Research Council (ERC).

8:36AM X59.00002: Actin crosslinker density tunes mesoscale mechanics in actin-microtubule composites* SHEA RICKETTS (Presenter), MADISON FRANCIS, University of San Diego, LEILA FARHADI, University of Massachusetts Amherst, JACOB WALES, Rochester Institute of Technology, MICHAEL RUST, University of Chicago, MOUMITA DAS, Rochester Institute of Technology, JENNIFER ROSS, University of Massachusetts Amherst, RAE ROBERTSON-ANDERSON, University of San Diego — The physical interactions between semiflexible actin filaments, rigid microtubules and the suit of smaller proteins that crosslink both filaments, allows the cytoskeleton to precisely tune its structure and mechanics to enable a vast array of cellular processes such as cytokinesis. Here we use optical tweezers microrheology to determine how steric entanglements versus chemical crosslinking impacts the nonlinear mesoscale mechanics of actin-microtubule composites. We create co-polymerized and co-entangled composites of actin and microtubules with varying concentrations of actin crosslinkers. We optically drive microspheres through the crosslinked composites at speeds much faster than the relaxation rates and distances larger than network mesh size. We simultaneously measure the force the filaments exert on the microspheres during and following the strain. We map network stiffness, relaxation profiles, and spatial heterogeneities to the concentration of actin crosslinkers in composites.

8:48AM X59.00003: Modeling composite cytoskeletal networks using effective medium theory* JACOB WALES (Presenter), Rochester Institute of Technology, SHEA RICKETTS, University of San Diego, LEILA FARHADI, University of Massachusetts, Amherst, MICHAEL RUST, University of Chicago, JENNIFER ROSS, University of Massachusetts, Amherst, RAE ROBERTSON-ANDERSON, University of San Diego, MOUMITA DAS, Rochester Institute of Technology — The mechanical response of most eukaryotic cells is due to their cytoskeleton, a polymeric scaffold made up of two major types of biopolymers, actin filaments (F-actin) and microtubules, which have very different mechanical properties. The cytoskeleton is responsible for a number of cellular functions including maintaining cell shape, rigidity, and facilitating movement. Here we seek to investigate, understand, and predict the structure-function properties of engineered cytoskeletal scaffolds with tunable mechanics. We study composite networks of F-actin and microtubules using an effective medium theory, and characterize their mechanical response using rigidity percolation theory. We obtain the shear rigidity of these networks as a function of the concentrations of F-actin and microtubules, the type of crosslinking, and the concentration of the crosslinkers. Our results may help to elucidate the design principles of smart biopolymer composites with adaptive mechanical properties.

*This work was funded by a W.M. Keck Foundation Research Grant.
The addition of sticky nanoparticles in a physically associated hydrogel matrix is considered. It is shown that the nanoparticles assortatively self-assemble into a percolated nanoparticle network at volume fractions far below the percolation threshold of a pure sticky nanoparticle hydrogel. Concurrently, it is shown that hydrogel undergoes substantial mechanical reinforcement, as manifested by the emergence of a low-frequency plateau in the viscoelastic shear moduli as determined via rheology, and the increased elastic moduli as determined via cavitation. Nanoparticles added beyond the percolation threshold are shown to bolster the connectivity of the percolated nanoparticle network, as revealed by mechanical measurements as well as structure factor calculations. These results provide fundamental insights into the self-assembly, and mechanical consequences therein, of multicomponent reversible hydrogels.

*We acknowledge financial support from the NSF MRSEC DMR-1420382.

9:36AM X59.00007: Mechanical structure function properties and fracture toughness of Articular Cartilage modeled as a biopolymer double network* LEIJA SUTTER (Presenter), ANDREW B SINDERMANN, School of Physics and Astronomy, Rochester Institute of Technology, THOMAS S WYSE JACKSON, LENA BARTELL, Department of Physics, Rochester Institute of Technology — We present results on cracking and fracture toughness of biopolymer double networks, with Articular Cartilage (AC) as our model system. AC is a soft tissue that covers the ends of bones and distributes mechanical loads at the joints in our knees and elbows. Adult AC has very few cells, and its network-like extracellular matrix primarily determines its mechanical response. As a material, AC is remarkable. It is only a few millimeters thick and has minimal regenerative capacity, yet can withstand large forces over our lifetimes during which it undergoes 100-200 million loading cycles without fracturing. The molecular mechanism underlying this exceptional toughness is not well understood. Here we investigate the mechanical structure-function properties underlying the fracture toughness of AC by using a framework that combines a double network model of AC with rigidity percolation theory. We study how the stress relaxation and crack propagation in the double network depend on its composition and on loading conditions. Our results may help to formulate a quantitative criterion for fracture in AC and similar soft and biomaterials akin to the Griffith criterion for fracture of brittle materials.

*The research was funded by the National Science Foundation via the award NSF/DMR- 1808026
On the interplay between two rigidity transitions in disordered semiflexible polymer-tissue networks

AMANDA PARKER (Presenter), Physics, Syracuse University, M. CRISTINA MARCHETTI, Physics, UC Santa Barbara, M. LISA MANNING, J. M. SCHWARZ, Physics, Syracuse University — Low-connectivity semiflexible polymer networks undergo a rigidity transition from floppy to rigid as shear strain is increased beyond some finite value. Collections of cells with no gaps between them (confluent tissues) also undergo a rigidity transition from fluid to solid, as a parameter characterizing the shape of an individual cell is varied. Both transitions are driven by geometric constraints, though in confluent tissue, topology also plays an important role. We present numerical studies of a vertex model of a two-dimensional confluent tissue embedded in a two-dimensional semiflexible polymer network, with mechanosensitive coupling between the two systems. We study how a rigidity transition in one system may or may not induce rigidity in the other, depending on the nature of the coupling. In addition to going beyond studying the onset of rigidity in a single network construct, the semiflexible polymer-tissue network is relevant to cancer in which cancerous tissue (a tumor) is surrounded by and interacts with an extracellular matrix, consisting primarily of cross-linked collagen, a semiflexible polymer.

*This work is supported by NSF-POLS 1607416.

Ensemble dynamics of large DNA molecules within entangled and crosslinked cytoskeleton networks

DEVYNN WULSTEIN (Presenter), KATHRYN REGAN, SHEA RICKETTS, RAE ROBERTSON-ANDERSON, RYAN J. MCGORTY, University of San Diego — The cellular interior is highly crowded. How biological macromolecules, such as DNA, diffuse through these environments has yet to be fully elucidated. We mimic the crowded cellular environment by creating custom-designed co-polymerized networks of actin and microtubules that are crosslinked at various motifs. We study the effect of the co-entangled and co-crosslinked cytoskeleton networks on the ensemble dynamics of large circular and linear DNA molecules using selective-plane illumination differential dynamic microscopy (SPIDDM). As a digital Fourier microscopy technique, SPIDDM measures dynamics over a large range of length and time scales that supplement and expand on the dynamics measured using single-molecule tracking of DNA in the same environments. We find interesting differences between ensemble and single-molecule dynamics over the temporal and spatial scales probed.

Polypelectrolyte composite: hyaluronic acid mixture with DNA

TOMISLAV VULETIC (Presenter), IDA DELAČ MARION, Institut za fiziku, Zagreb, SIGRID BERNSTORFF, Elettra-Sincrotrone Trieste, KREŠIMIR SALAMON, Rudjer Bošković Institute, DANIJEL GRRGICIN, Institut za fiziku, Zagreb — Biomacromolecules are mostly polyelectrolytes (PE), dissociating into polyions and small counterions. Their long-range electrostatic interaction leads to arrangements different than for neutral polymers and generates difficulties in physical understanding. For the last decade we have addressed these by studying the structure and dynamics of two semirigid (bio)PEs, DNA and HA (hyaluronic acid). Here we present a study of mixtures of DNA and HA, as a system of like-charged semi-rigid chains, differing, however, by the respective persistence lengths of 50 and 1 nm. We studied salt-free mixtures across a broad range of concentration ratios c_{HA}/c_{DNA}=0.05-50 (c=5-200 g/L). By polarizing microscopy we established that DNA and HA form clearly separated thread-like domains defined and oriented by solution shear. We applied small angle x-ray scattering (SAXS) and observed a PE correlation peak at q* wave vector, ascribed to DNA subphase and thus reporting on its effective concentration c_{DNA}*. From c_{DNA}* it was possible to infer the c_{HA}* of HA subphase. We found a ratio G= c_{HA}*c_{DNA}*=0.85 across the studied range. As there is the osmotic pressure, P equilibrium between DNA and HA subphases, the constant G indicates that P~c^{9/8} scaling commonly found for DNA and other highly charged PEs is valid also for HA which does not feature counterion condensation – so it's not due to the concentration dependence of the latter. Furthermore, as for HA all counterions contribute to P, the HA osmotic coefficient f_{HA}^* is a measure of f_{DNA}. We found the latter to be 0.28 and corroborated previous workers who found the concentration of counterions controlling the osmotic pressure to be double the Manning-condensation theory value for DNA.

8:00AM X60.00001: Speaking Science to Power: Providing S&T Advice to Governments [Invited] JOHN HOLDREN (Presenter), Harvard University — This presentation discusses the opportunities and challenges for scientists and technologists in advising government policy-makers on science and technology for policy and policy for science and technology. It draws on the author’s five decades of experience as an academic engaging U.S. and non-U.S. governments on science and technology issues, most of it in parallel with an academic career but also, from January 2009 to January 2017, as President Obama’s Science Advisor and the Senate-confirmed Director of the White House Office of Science and Technology Policy. Considerable attention will be given to the contrasts between science and technology policy under Obama versus under Trump, including suggestions for dealing with the particular challenges posed by the latter.

9:12AM X60.00002: Federal Policy Making: Perspectives from Inside and Outside Government [Invited] CELIA MERZBACHER (Presenter), Independent consultant — Federal policy decision making is influenced by many factors and actors, including science and the scientific community. Drivers, incentives, and metrics vary among stakeholders inside and outside of government, which can make it difficult to find a mutually agreeable path. Yet action can be swift when what is made possible by science and technology (S&T) intersects a national need or threat. Policy makers in government must keep abreast of S&T advances relevant to their mission, whereas those outside government who seek to influence policy must be credible and understand how the various parts and agencies of government work. The process of federal policy making will be explored through examples, ranging from microelectronics to nanotechnology to quantum technology.

9:48AM X60.00003: Advice from a Scientist-Policy Maker on Giving Advice to a Policy Maker [Invited] ANDREW ZWICKER (Presenter), Princeton University and NJ State Legislature — As a member of the APS, I have met with and offered advice to federal policy-makers and their staff multiple times. Since 2016, I have also been a member of the NJ Legislature where I am the only scientist, and am the Chair of the Science, Innovation, and Technology Committee. In that role, I meet regularly with scientists and other stakeholders on a multitude of state legislative issues. Based upon my experiences, it is clear to me that effective scientific policy advice must, of course, start with an understanding of the background of the people you are speaking to and a presentation that is clear, jargon-free, and has a specific request. However, the assumption is most often to begin with the "big picture" and put the request at the end, but that is the opposite of what I have found to be effective. In addition, one must understand that while clear science policy advice is important, final policy decisions are most often made based upon a variety of complex factors, from fiscal restraints to competing interests. If these are known and acknowledged in the meeting there is an opportunity to maximize the impact. I will offer examples and practical advice based upon both my scientific and legislative background.

10:24AM X60.00004: Science Legislative Fellow Advisors for State Legislatures* [Invited] NATHAN PHILLIPS (Presenter), Earth and Environment, Boston University — As a science fellow in the California legislature during 2014; in my current work to initiate a science policy fellowship program in Massachusetts; and in working alongside colleagues to bring science fellowships to nine other states, key recurring lessons learned which I will share in this talk are:

1. Science fellows in state legislatures are as valuable for how they think as for what they know.

2. State-level science policy fellowships not only benefit policymakers and policymaking, but powerfully benefit the scientific community and enterprise.

3. Professional rewards and fulfillment are of a different nature for state legislative science fellows than for academic scientists, but are no less rewarding nor fulfilling.

I will draw off my own anecdotes and experiences as a scientist in state legislatures to illustrate these points. I’ll also discuss the vast diversity of potential science fellowship program structures and how they may be appropriately matched to the diversity of states, political geography and legislative structures.

Friday, March 8, 2019 8:00 AM - 11:00 AM
8:00AM X61.00001: Design of graphene-based catalysts for Belousov Zhabotinsky reaction*  
D JAYA PRASANNA KUMAR, SACHIN VERMA, KABEER JASUJA, PRATYUSH DAYAL (Presenter), Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Use of hybrid materials containing structures at different length scales has gained significant traction because of their ability to provide multifunctional characteristics to soft materials. Here, we focus on the Belousov-Zhabotinsky (BZ) reaction, which represents a nonlinear chemical oscillator, and show that its dynamics can be tuned by using hybrid 2D materials, i.e., graphene-based nanosheets decorated with different nanoparticles (NPs). Specifically, we demonstrate that through the careful choice of NP decorations in designing our catalytic mats, frequency of chemical oscillations in the BZ reaction system can be increased four times. Further, we reveal that this observed behavior is attributed to enhanced access to active catalytic sites on NPs, as well as the rapid shuttling of electrons facilitated by the highly conductive graphene platform. We also perform modelling and simulation studies and our results reveal a strong correlation between the rate of charge transfer and the frequency of chemical oscillations. In essence, we showcase the ability of a 2D material, like graphene, to influence the dynamics of an oscillatory chemical reactions and anticipate that our approach will open up new avenues to tune the dynamics of chemical oscillators.

8:12AM X61.00002: Self-moving reaction droplets synergized by graphene-based nanocomposites*  
D JAYA PRASANNA KUMAR (Presenter), PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Chemo-mechanical transduction to perform locomotion is one of the characteristics of biological systems that has inspired the design of self-moving biomimetic systems. Here, we harness self-oscillating Belousov-Zhabotinsky (BZ) reaction, synergized by graphene-based catalytic mats to demonstrate spontaneous motion of the BZ reaction droplet in surrounding oil. Specifically, we synthesize graphene-based catalytic mats by decorating Ce and Ru nanoparticles (NP) on graphene nanosheets, thereby creating a 0D-2D heterostructures, and subsequently, use these mats to catalyze the BZ reaction. Our results demonstrate spontaneous locomotion of BZ droplets in oil bath due to the Marangoni flow that is brought about by the interaction between BZ reaction intermediates and surrounding oil. We further demonstrate that the velocity of the droplet motion is dependent upon the conductivity of the catalytic mats. In particular, we show two-fold increase in the droplet velocity when RuNP decorated graphene sheets are used to catalyze the BZ reaction instead of the traditional solution based BZ catalysts. Our findings can be used to design self-moving synthetic objects and opens up new avenues to control their behaviour through the use of 0D-2D hybrid nanomaterials.

8:24AM X61.00003: Enzyme-coated liposomes as dual-direction self-propulsive motors  
AMBIKA SOMASUNDAR (Presenter), Chemical Engineering, Penn State University, University Park, SUBHADIP GHOSH, Chemistry, Penn State University, University Park, FARZAD MOHAJERANI, Chemical Engineering, Penn State University, University Park, PAUL CREMER, Chemistry, Penn State University, University Park, DARRELL VELEGOL, Chemical Engineering, Penn State University, University Park, AYUSMAN SEN, Chemistry, Penn State University, University Park — Directional migration in response to specific chemical signals is critical for the survival of biological organisms. This enables living cells to move towards food, escape away from toxins, transport cargo and coordinate collective behavior. Controlling the motion of a motor either towards or away from chemical species is the first step in designing adaptive life-like synthetic motors. Model protocells derived from phospholipids and other amphiphiles have been studied and their movement through catalysis has been observed. However, control of directionality based on chemical cues (chemotaxis) has been difficult to achieve. In this talk, I will discuss both positive and negative chemotaxis of autonomous liposomal protocells based on the interplay between positive enzymatic catalysis-induced chemotaxis and solute-phospholipid interaction-based negative chemotaxis. In doing so, I will systematically rule out currently available mechanisms of colloidal transport and propose a potentially new and previously unrecognized mechanism of transport due to the Hofmeister effect. This opens up the possibility of other mechanisms for the transport of biological colloids.

8:36AM X61.00004: Enhanced Diffusion and Chemotaxis of Catalytically Active Enzymes* [Invited] RAMIN GOLESTANIAN (Presenter), Department of Living Matter Physics, Max Planck Institute for Dynamics and Self-Organization, JAIME AGUDO-CANALEJO, TUNRAYO ADELEKE-LARODO, PIERRE ILLIEN, University of Oxford — Enzymes have been recently proposed to have mechanical activity associated with their chemical activity. In a number of recent studies, it has been reported that enzymes undergo enhanced diffusion in the presence of their corresponding substrate, when this substrate is uniformly distributed in solution. Moreover, if the concentration of the substrate is non-uniform, enzymes and other small molecules have been reported to show chemotaxis—biased stochastic movement in the direction of the substrate gradient—typically towards higher concentrations of this substrate, with a few exceptions. The underlying physical mechanisms responsible for enhanced diffusion and chemotaxis at the nanoscale, however, are still not well understood. We will review the available experimental observations of both enhanced diffusion and chemotaxis, and discuss critically the different theories that have been proposed to explain the two. We put particular emphasis on an equilibrium model recently introduced by us, which describes how the diffusion of dumbbell-like modular enzymes can be enhanced in the presence of substrate, thanks to a binding-induced reduction of the internal fluctuations of the enzyme. We then turn to chemotaxis, beginning with an overview of the chemotaxis-like diffusiophoretic behavior of micron-sized colloids in solute gradients, followed by a discussion of why chemotaxis at the nanoscale requires special consideration. Next, we review the experimental evidence of nanoscale chemotaxis, and describe a number of shortcomings and pitfalls in the phenomenological models for chemotaxis introduced in some of those works. Finally, we discuss a microscopic model for chemotaxis including both non-specific interactions and binding between enzyme and substrate recently developed by us, which overcomes many of these shortcomings, and is consistent with the experimental observations of chemotaxis.

9:12AM X61.00005: Single Molecule Imaging of Nanoscale Self-Propelled Active Matter MENGQI XU (Presenter), JENNIFER ROSS, University of Massachusetts Amherst, LYANNE VALDEZ, AYUSMAN SEN, Chemistry, Penn State University — Active matter composed of ensembles of self-propelled particles display exciting emergent properties. When coupled to larger objects, enzymes can act as the propulsion of self-propelled particles displaying exciting emergent properties. When coupled to larger objects, enzymes can act as the propulsion of self-propelled particles, and recent studies have shown that these enzymes have exciting self-propelled properties, as well. Studies using fluorescence correlation spectroscopy (FCS) or macroscopic observation have revealed that enzymes can perform enhanced diffusion depending on the substrate concentration. The mechanism for enhanced diffusion remains unclear. We report new results using single particle tracking with total internal reflection (TIRF) microscopy to observe this emergent activity of active enzymes to test proposed mechanisms that could result in enhanced mobility of active enzymes. Using urease as a model enzyme, we observe that the diffusion of individual enzymes increases three fold as a function of substrate. This diffusion is unaffected by the background concentration of enzymes. Further, we find that the oligomerization state is unchanged by the presence of the substrate, implying that the enzyme does not significantly change size upon binding of substrate. This work effectively eliminates some previously-postulated theories of the mechanism of enzymatically enhanced diffusion.

9:24AM X61.00006: Engineering active matter at the nanoscale with DNA nanotechnology IBON SANTIAGO (Presenter), Physics of Synthetic Biological Systems, Technical University of Munich — Self-generated movement in response to internal or environmental events is a key characteristic of living organisms that distinguishes them from non-living things. Progress in bio and nanotechnology has enabled the creation of active particles that can convert energy into motion. Catalytic self-propelled motors are of fundamental interest in statistical biophysics and are also highly necessary in the context of artificial cellular systems. Although much research has been done on micron-sized motors, progress in catalytic nanomotors of sub-100 nm is still in its infancy.

This talk will present recent work in the synthesis, propulsion mechanism and measurement techniques of self-propelled particles. The chemical synthesis of nanomotors and new electrochemical characterisation tools to assess their motor behaviour will be presented. Finally, I will demonstrate the coupling of enzymatic nanomotors to propel larger structures mediated by DNA hybridization.

Catalytic enzymes are active matter — AH-YOUNG JEE (Presenter), TSVI TLUSTY, STEVE GRANICK, Institute for basic science — Recent studies suggest that the enhanced diffusion of catalytically-active enzymes is promoted by super-diffusive “kicks” generated by the catalytic events. Pursuing this idea, we have explored methods to vary systematically the turnover frequency, $k_{\text{cat}}$, which defines how many substrate molecules are consumed in a given time. Our measurements using fluorescence correlation spectroscopy in super-resolution mode (FCS-STED) enable us to illuminate this matter. The contrast between motions in the presence of inhibitor and of substrate is especially interesting.

Directing Self-Propelled Enzymes and Enzyme-Coated Vesicles Using Chemical Signals* [Invited] AYUSMAN SEN (Presenter), Pennsylvania State University — The ability to move both towards and away from specific chemical signals is a critical survival mechanism in living systems. The motion itself arises from the harnessing of free energy from enzymatic catalysis. A variety of enzymes has been shown to undergo positive chemotaxis, moving up their substrate concentration gradient. We propose a general expression for the active movement of an enzyme in a concentration gradient of its substrate. The proposed model takes into account both the substrate-binding and catalytic turnover step, as well as the enhanced diffusion effect of the enzyme. The model is general, has no adjustable parameters, and only requires three experimentally defined constants to quantify chemotaxis. Model enzyme-functionalized synthetic protocells have also been studied and they exhibit both positive and negative chemotaxis based on the interplay between positive enzymatic catalysis-induced chemotaxis and solute-lipid interaction-based negative chemotaxis. Controlling the extent and direction of chemotaxis holds considerable potential for designing cell mimics and delivery vehicles that can reconfigure their motion in response to environmental conditions.

Exploring, exploiting, and ignoring history dependence in active droplet simulations* JOSEPH ALBERT (Presenter), VINCENT HENRY CRESPI, Pennsylvania State University — Active droplets are an appealing model system for studying self-propelled particles because of their high symmetry and simple composition. Nonetheless, their mechanism of action is complex - they are driven by a self-maintained concentration gradient that results in history-dependent motion.

This talk presents several formulations of this system which can be used to analyze and simulate active droplet systems. From these we establish how spherical droplets can emulate persistent motion of polar swimmers by storing orientation information in their local emission cloud. We show that this simplified picture of a droplet’s dynamics is sufficient to describe its response to an external potential or time-dependent force.

Simulations of interacting droplets suggest that Vicsek-like variables are sufficient to describe the system’s state. However, the pairwise interactions between particles are can be highly anisotropic and asymmetric, reflecting the system's history dependence at higher Péclet numbers.

Sideways self-propulsion of Janus rods* NAVEEN REDDY (Presenter), Hasselt University, DUGYALA VENKATESHWAR RAO, Chemical Engineering, Indian Institute of Science Education and Research (IISER) Bhopal, JAN FRANSAER, Materials Science, KU Leuven, CHRISTIAN CLASEN, Chemical Engineering, KU Leuven — The sideways self-propulsion behaviour of Janus rods will be presented [1-2]. Janus rods are prepared by consecutively sputter-coating platinum and gold on different sides of aligned polystyrene nano/micro-fibers produced via electrospinning. Self-propulsion is induced via the reaction of hydrogen peroxide at the Janus particle interface, and the effect of the particles shape on their self-propulsion trajectories is studied. We show that the self-propulsion trajectories change from straight to circular when the particle shape is changed from a straight to an ‘L’ shaped rod. In order to understand and quantitatively describe the particle shape effects, we have adopted a mathematical model developed by Hagen et al [3] to predict their trajectories. We show that the trajectory of irregularly shaped rods depends only on the particle shape. The predicted trajectories for various particle shapes are in good agreement with the experimental observations. We show that these sideways self-propulsion rods are effective in cargo transportation.

ABHRAJIT LASKAR (Presenter), OLEG SHKLYAEV, ANNA CHRISTINA BALAZS, University of Pittsburgh — Catalyst-coated, hard particles can spontaneously generate fluid flows, which in turn propel the particles through the fluid. If the catalyst-coated object were a deformable sheet, the self-generated flows could affect not only the sheet's motion, but also its shape. By developing models that capture the interrelated chemical, hydrodynamic and mechanical interactions, we uncover novel behavior emerging from the previously-unstudied coupling between active, soft sheets and the surrounding fluid. The chemically-generated flows “sculpt” the sheet into various forms that yield different functionalities, which can be tailored by modifying the sheet's geometry, patterning the sheet's surface with different catalysts and employing cascades of chemical reactions. These studies reveal how to achieve both spatial and temporal control over the position and shape of active sheets and thus, utilize the layers to autonomously and controllably trap soft objects, perform logic operations and execute multi-stage processes in fluid-filled microchambers.

Session X63 GSOFT DBIO: Out-of-Equilibrium Properties of Soft Materials and Biological Systems BCEC 259A - Stephen Whitelam, University of California, Berkeley - Tag(s): Focus

8:00AM X63.00001: Early Career Award for Soft Matter Research [Invited] APARNA BASKARAN (Presenter), Brandeis University — tbd

8:36AM X63.00002: Designing active colloidal architectures from diffusiophoretic interactions* ANTOINE AUBRET (Presenter), JEREMIE PALACCI, University of California, San Diego — In Nature, energy input is needed to develop advanced features, e.g. self-healing or self-regulation. I will show how we can extend this principle to the artificial world, using light to carve non-equilibrium interactions between synthetic microswimmers. Following sequential light-patterns, they autonomously assemble into robust self-spinning structures, or microgears. A rotor constitutes a dissipative building block that creates a repulsive, anisotropic potential of diffusiophoretic origin, which we characterize using Highly Inclined Laminated Optical sheets microscopy (HILO). The results agree with analytical and numerical predictions of a simple model of a rotor forming a hexapolar sink of fuel. We show that gears act as contactless ‘teeth’, synchronizing their motion, and constitute the fundamental components of synchronized micro-machineries that auto-regulate and whose dynamics is tuned by the spins of their internal components. The study demonstrate the potential of non-equilibrium interactions to program self-assembly and control dynamical colloidal architectures beyond static, equilibrium assemblies.

8:48AM X63.00003: "Light driven motion of active microswimmers" POOJA ARYA (Presenter), DAVID FELDMANN, SVETLANA SANTER, Institute of Physics and Astronomy, University of Potsdam, Germany — We report on active colloids which can undergo light-driven self-propelled motion. The mechanism of self-propulsion is based on generation of local hydrodynamic flow at each micro-particle resulting from light-driven diffusioosmosis (LDDO) [1]. At the heart of this process is photosensitive azobenzene containing surfactant which undergoes a reversible trans-cis photo-isomerization with corresponding changes in hydrophobicity of the whole surfactant molecule. Active microparticles consist of porous silica and are negatively charged in water. When porous silica particles are dispersed in the solution of cationic photosensitive surfactant, they absorb partially the surfactant in trans-state, but the more hydrophilic cis-isomers are expelled out of the particles. Under illumination with blue light promoting trans-cis photo-isomerization, a continuous local hydrodynamic flow at a single particle is formed where cis-isomers leave the particle, while trans-isomers flow inside. The particles become active when one side of the porous surface is covered with a metal layer.

9:00AM X63.00004: Transport Processes in Active Fluids  KATHERINE KLYMKO (Presenter), CCSE, Lawrence Berkeley National Laboratory, JEFFREY EPSTEIN, Physics, Univ of California - Berkeley, KRANTHI K MANDADAPU, Chemical Engineering, Univ of California - Berkeley — We perform a coarse-graining analysis of the paradigmatic active matter model, Active Brownian Particles, yielding a continuum description in terms of balance laws for mass, linear and angular momentum, and energy. The derivation of the balance of linear momentum reveals that the active force manifests itself directly as a continuum-level body force proportional to an order parameter-like director field, which therefore requires its own evolution equation to complete the continuum description of the system. We derive this equation, demonstrating in the process that bulk currents may be sustained in homogeneous systems only in the presence of inter-particle aligning interactions. Further, we perform a second coarse-graining of the balance of linear momentum and derive the expression for active or swim pressure in the case of mechanical equilibrium.

9:12AM X63.00005: Competition between chiral self-replicators is mediated by surface growth dynamics  ASHISH B. GEORGE (Presenter), KIRILL KOROLEV, Boston University — Phase separation and self-assembly of chiral components underlie many biological and industrial processes. We study how chirality of the components impacts these processes. Motivated by recent experiments with microbes, we focus on two-dimensional growth of auto-catalytic or self-replicating agents. The dynamics, described by a chiral reaction-diffusion equation, recapitulate experimental findings in homochiral populations. We predict very unusual behavior when there are two distinct chiral components. Depending on the relative chirality of each, the population evolves to a stable mixed state with both components or a homochiral state where one component goes extinct. To explain our results, we derive an effective theory that couples component competition and growth front dynamics. The theory reduces to a chiral extension of the KPZ equation coupled to a Burgers’ equation with multiplicative noise. The solution of these equations exhibits bulges and dips on the surface at boundaries between domains with different chirality. These undulations in turn alter the motion of the domain boundaries and determine composition and spatial structure. Our findings suggest a new class of surface growth phenomena and can explain the rapid evolution of chirality in biological populations.

9:24AM X63.00006: Self-oscillating poroelastic instabilities  DAVID DYKSTRA (Presenter), NIGEL VISSER, CORENTIN COULAIIS, Institute of Physics, University of Amsterdam — Responsive materials changing shape in response to physical stimuli such as light, heat or chemical reactions are ubiquitous in nature and have recently sparked a myriad of applications, e.g. in smart coatings and soft robotics. So far, stimuli-responsive materials are not “active”: they cannot exhibit a perpetual motion unless the environmental conditions change. Here we show experimentally, numerically and theoretically how a simple system - a confined beam at the boundary of a solvent interface - can harness a combination of poroelastic swelling and elastic instabilities to generate perpetual oscillations. These oscillations are realised by rational design and optimisation of the time-dependent hysteretic loop coupling mechanical deformation to solvent transport within the structure. Our work provides general principles for active systems that operate autonomously, harnessing energy from their environment and as such offers new vistas for active metamaterials and soft robots.

9:36AM X63.00007: Dynamic clustering of passive colloids in an active bacterial bath*  SHREYAS GOKHALE (Presenter), JUNANG LI, ALEXANDRE SOLON, NIKTA FAKHRI, JEFFREY GORE, Massachusetts Institute of Technology — Active or self-propelled particles such as motile bacteria often exhibit exotic forms of self-organization on account of their intrinsically nonequilibrium dynamics. Further, it is known that these nonequilibrium dynamics can be harnessed to manipulate passive objects such as microscopic gears and motors. Here, using video microscopy experiments and numerical simulations, we show that the nonequilibrium fluctuations in a bath of motile *Pseudomonas aurantiaca* bacteria can spontaneously drive the self-assembly of suspended passive colloidal silica particles. In contrast to the phase separation between active and passive particles reported in previous computational studies, we observe a dynamic clustering phenomenon with frequent formation and fragmentation events. We demonstrate that the mean cluster size increases with increasing bacterial density. Moreover, we extract an effective attractive interaction energy scale from the distribution of bond lifetimes and show that it correlates well with the mean cluster size. We hypothesize that a local transient circulation of the bacterial velocity field around colloidal particles is responsible for the observed attractive interactions.

*S.G. thanks the Human Frontier Science Program (HFSP) for a cross-disciplinary postdoctoral fellowship.

9:48AM X63.00008: Large Deviation Functions for active Brownian particles  TREVOR GRANDPRE (Presenter), Physics, UC Berkeley, DAVID LIMMER, Chemistry, UC Berkeley, KRANTHI K MANDADAPU, Physics, UC Berkeley, KATIE KLYMKO, Lawrence Berkeley Lab — Large deviation Functions (LDFs) characterize fluctuations of extensive observables away from equilibrium and offer a route to relate those fluctuations to the systems response to external perturbations. LDFs are difficult to calculate analytically and sometimes numerically for complex interacting systems. For a system of interacting active Brownian particles, we show how a weighted many body expansion can be used to calculate LDFs for a wide variety of relevant observables such as the mass current, active work, and activity. These in turn can be used to understand diverse phenomena such as the Motility Induces Phase Separation (MIPS) and active transport.
Solids has brought new light to a multitude of problems - active foam provides a new platform to ask questions both in (phase). Stroboscopic analysis is used when studying cyclic forcing. Just like our understanding of active fluids and active evolution. Next, we study interactions between multiple active voxels with cyclic perturbations (in-phase and out-of-motion. We quantify this response of a single active voxel as a function of energy injected, symmetry and time course of injection triggers rearrangements in the structure involving neighbor swapping (T1), leading to cascades and global programmatically injected and removed from voxels in a 2D liquid soap foam in a Hele-Shaw cell. This cyclic energy such a material, where the activity of a single voxel is driven by volume oscillations. The platform allows air to be feedback. To the best of our knowledge, no abiotic "active" foam experimental systems currently exist. We have developed example include the central channel of the nuclear pore complex and liquid drops formed from multivalent interactions. Some biophysical interactions are typically non-specific and cannot be tuned. In contrast, macromolecular diffusion through networks can be controlled by binding and unbinding events between passing molecules and flexible chains. Some biophysical examples such as binding and unbinding rates, number of binding sites and chain elasticity, on diffusion is still poorly understood. Following a statistical mechanics approach, we have developed a diffusion model which shows that the maximum diffusion occurs for few occupied binding sites independent of other parameter choices. We show the validity of our findings by comparing model predictions with a macroscopic diffusion experiment designed to contain similar driving mechanisms and to allow tuning of key parameters including the number binding sites, activity and kinetic parameters. These findings will drive future research work and understanding of controlled active diffusion in dynamic networks.

Propagating Fronts in Columns of Fire Ants CALEB ANDERSON (Presenter), ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — For the past two decades, the study of active matter has revealed rich physics and universal behaviors, such as collective motion, across a wide variety of biological and synthetic systems with seemingly disparate particle interactions. Here we present our surprise observation and measurements of stable activity fronts propagating through 2 dimensional columns of thousands of fire ants. We then propose a model to explain the origin of these macroscopic non-linear fronts from simplified pairwise interactions between ants, and perform computer simulations that capture the experimental observations. Finally, we finish by comparing the fronts to other instances of collective motion observed in active systems.

Mechanics of Active Foam: Local Energy Injection in Addressable 2D Foam+ LAUREL KROO (Presenter), Department of Mechanical Engineering, Stanford University, MANU PRAKASH, Department of Bioengineering, Stanford University — The study of foam has inspired many insights into cellularized materials, including biological tissue. While cellular sheets superficially resemble passive foam structures, cells incorporate many layers of internal activity and feedback. To the best of our knowledge, no abiotic "active" foam experimental systems currently exist. We have developed such a material, where the activity of a single voxel is driven by volume oscillations. The platform allows air to be programatically injected and removed from voxels in a 2D liquid soap foam in a Hele-Shaw cell. This cyclic energy injection triggers rearrangements in the structure involving neighbor swapping (T1), leading to cascades and global motion. We quantify this response of a single active voxel as a function of energy injected, symmetry and time course of evolution. Next, we study interactions between multiple active voxels with cyclic perturbations (in-phase and out-of-phase). Stroboscopic analysis is used when studying cyclic forcing. Just like our understanding of active fluids and active solids has brought new light to a multitude of problems - active foam provides a new platform to ask questions both in foam physics and, by analogy, in tissue mechanics.

Friday, March 8, 2019 8:00 AM - 11:00 AM
8:00AM X64.00001: Probing the dynamics of individual biomolecules with 1-μs resolution* [Invited] THOMAS PERKINS (Presenter), JILA, NIST & University of Colorado Boulder — Protein folding occurs as a set of transitions between structural states within an energy landscape. An oversimplified view of the folding process emerges when transiently populated states are undetected because of limited instrumental resolution. To achieve state-of-the-art performance, we integrated several recent technical advances that improve the precision, stability, and accuracy of AFM-based single molecule force spectroscopy. Using modified cantilevers optimized for 1-μs resolution, we reexamined the unfolding of individual bacteriorhodopsin (bR) molecules in native lipid bilayers. The experimental data revealed the unfolding pathway in unprecedented detail. Numerous newly detected intermediates—many separated by as few as 2–3 amino acids—exhibited complex dynamics, including frequent refolding and state occupancies of <10 μs. Equilibrium measurements between such states enabled the folding free-energy landscape to be deduced. These results sharpen the picture of the mechanical unfolding of bR. Finally, recent efforts to improve the quantity and quality of AFM studies of diverse biomolecules, including nucleic-acid structures and globular proteins, will be discussed.

8:36AM X64.00002: Destabilization of nucleosomes by HMGB proteins and FACT complexes [Invited] MICAH J MCCAULEY, RAN HUO, EMILY NAVARRETE, Northeastern University, NICOLE BECKER, QI HU, MOLLY NELSON HOLTE, Department of Biochemistry and Molecular Biology, Mayo Clinic College of Medicine and Science, UMA M MUTHURAJAN, Department of Chemistry and Biochemistry, University of Colorado, IOULIA ROUZINA, Department of Chemistry and Biochemistry, Ohio State University, KAROLIN LUGER, Department of Chemistry and Biochemistry, University of Colorado, GEORGES MER, L. JAMES MAHER, Department of Biochemistry and Molecular Biology, Mayo Clinic College of Medicine and Science, NATHAN ISRAELOFF, MARK WILLIAMS (Presenter), Northeastern University — Nucleosome disruption plays a key role in many nuclear processes including transcription, DNA repair and recombination. We combine atomic force microscopy (AFM) and optical tweezers (OT) experiments to probe the effects of various motifs of High Mobility Group B (HMGB) proteins on nucleosome stability. We find that the double box Hmo1 and the single box Nhp6A from \textit{S. cerevisiae} destabilize and unwind DNA from the H2A-H2B dimers that are part of the histone octamer. Unlike Nhp6A, Hmo1 also releases half of the DNA held by the (H3-H4)$_2$ tetramer. Despite this destabilization, the octamers appear intact, and the remaining (H3-H4)$_2$ tetramer interactions with the DNA are also destabilized. We also probe the human histone chaperone protein FACT (facilitates chromatin transcription), which also contains an HMGB box. We find that FACT (including the subunits Spt16 and SSRP1) binds directly to the nucleosome, specifically disrupting the H2A-H2B dimer interaction with DNA. Disruption leads to the release of that DNA from the nucleosome and the ejection of these dimers from the octamer, revealing a mechanism for regulation of chromatin assembly. Differences in nucleosome destabilization point to complementary roles that HMGB proteins play in chromatin remodeling.

9:12AM X64.00003: Single ligand and receptor binding spectroscopy using an atomic force microscopy* LINA ALHALHOOLY (Presenter), Physics, North Dakota State University, MATTHEW CONFELD, Pharmaceutical Sciences, North Dakota State University, YONGKI CHOI, Physics, North Dakota State University — Binding and unbinding between individual ligands and receptors were measured and quantified using an atomic force microscopy (AFM). Initially, the cell stiffness is characterized by force-distance measurements using ligand-free AFM tips and compared to several cancer and non-cancerous cells. Then, we measured the unbinding force with peptide-coated AFM tips, targeting specific cell receptors. The unbinding force between the ligand and receptor was measured to be an order of 100 pN. Such individual, specific interaction measurements were further supported by pre-blocking the cell receptors with the excess, free ligands.

*This research was supported by the NIGIM/NIH R15GM122063 and 1P20GM109024 (Pilot Project).
9:24AM X64.00004: Single Molecule Studies of a Novel Mechanism of Bacterial Transcription Initiation*  
DEBORA TENENBAUM (Presenter), JANE KONDEV, JEFF GELLES, Brandeis University — In bacteria, gene transcription begins with the binding of an RNA polymerase (RNAP) core enzyme to the initiation factor σ, which allows it to recognize promoter sequences on the DNA and initiate RNA synthesis. In the canonical transcription cycle, upon reaching the termination sequence and releasing the transcript, RNAP detaches from the DNA and is free to restart the process. However, previous work in our lab has shown that following termination, bacterial RNAP frequently remains bound to the DNA template, and sometimes exhibits one-dimensional sliding over thousands of basepairs. Moreover, in the presence of free σ factor molecules in solution, the sliding, DNA-bound polymerase is often observed to restart transcription. This mechanism of transcription initiation might have implications for the transcriptional coupling of nearby genes.

In this talk, I will describe single-molecule fluorescence-microscopy experiments we are doing to further characterize this novel mechanism of transcription initiation in vitro, and to evaluate its role in the coupling and coordination of gene expression.

9:36AM X64.00005: Single-molecule orientation mapping in 3D using a novel optical design  
ABHISHEK KUMAR (Presenter), University of Maryland, College Park, JAMES M MARR, Materials Measurement Laboratory, National Institute of Standards and Technology, ANTHONY MAUTINO, University of Maryland, College Park, MARK MCLEAN, JEREMIAH WOODCOCK, JEFFREY GILMAN, STEPHAN STRANICK, Materials Measurement Laboratory, National Institute of Standards and Technology, VERONIKA SZALAI, JAMES LIDDLE, Physical Measurement Laboratory, National Institute of Standards and Technology — Single molecule (SM) localization-based super-resolution techniques have revolutionized the application of optical microscopy because of their ability to image structures below the diffraction limit in widefield. Fluorescent dyes and proteins used for SM imaging absorb and emit photons via an emission dipole, and any restriction on the motion of the dipole creates an asymmetry in the observation of the emission. Mapping this dipolar orientation can be a useful reporter of the local environment of molecules, and help improve localization accuracy for super-resolution imaging. We present a simple and flexible optical design, that can be incorporated into a standard optical microscope, to enable mapping the orientation of single molecules by simultaneously imaging 4 polarization orientations. A single camera is used to acquire all 4 channels, and fine adjustment controls for each channel minimize optical aberrations. We have used nanofabricated aperture arrays, fluorescent beads and single molecules embedded in a polymer matrix to characterize the system.

9:48AM X64.00006: Single molecule study of the stability of G-quadruplex DNA as an anti-cancer drug target  
PARASTOO MALEKI (Presenter), HAMZA BALCI, Kent State University — In targeted therapy, small molecule drugs are utilized to detect specific targets. G-quadruplex (GQ) structures are such a target for targeted cancer therapy. GQ is a physiologically significant secondary structure of DNA or RNA, which is formed by guanine-rich sequences. Studies on cancer cells show that stabilizing the GQ structures in telomeres with small molecules reduces telomerase activity and proliferation of cancer cells. However, the underlying dynamics of small molecule-GQ interactions are not known. In this study, we performed single molecule measurements to study how stability and dynamics of GQ are impacted by its interactions with several different small molecules. Moreover, we investigated the impact of these molecules on folding dynamics of the GQ structure. We observed significant enhancement in GQ stability in the presence of small molecules, as measured by the fraction of GQ molecules that remained folded against Bloom helicase mediated unfolding at the single molecule level. In addition, our measurements showed that folding of GQ takes place faster than our time resolution over all salt concentrations we studied (2-150 mM KCl) with or without small molecules, making it challenging to identify the impact of small molecules.
Single-Molecule Activity of φ29 DNA Polymerase Monitored by Nanoscale Transistors

CALVIN LAU (Presenter), KRISTIN NICHELLE GABRIEL, NAREN德拉 KUMAR, SUDIPTA MAJUMDAR, ARITH RAJAPEAKSE, WONBAE LEE, GREGORY WEISS, PHILIP G COLLINS, University of California, Irvine — Single-molecule techniques are enabling the rapid advancement of next-generation DNA sequencing. Recently, electronic nanocircuits functionalized with DNA polymerases have arisen as a new, potentially high-density and high-throughput platform for single-molecule DNA sequencing and enzyme kinetic studies [1]. Here, we describe single-molecule electronic measurements of φ29 DNA polymerase, an enzyme having extremely high fidelity and processivity. Using φ29 linked to carbon nanotube transistors, base-by-base activity of individual polymerase molecules was continuously monitored for up to 30 min as the enzymes replicated single-stranded templates. Base incorporation rates averaged 20 s⁻¹ but varied widely. Rates up to 200 and 400 s⁻¹ occurred when φ29 encountered homopolymeric sequences of poly(dT) and poly(dC), respectively. On the other hand, the processing of poly(dA) and poly(dG) sequences was dominated by pauses lasting 50 to 300 s. Such observations of sequence-dependent activity demonstrate how single-molecule methods can excel over traditional, ensemble-based techniques like PCR sequencing and gel chromatography assays.

Reliable extraction of energy landscape properties from critical force distributions

SUDEEP ADHIKARI (Presenter), KEVIN BEACH, University of Mississippi — The structural dynamics of biopolymers such as proteins are described in the context of their conformational energy landscapes. In pulling experiments using optical tweezers, features of the energy landscapes are extracted from the probability distribution of the critical force at which the polymer unfolds, and typically the analysis is based on rate equations having Bell-Evans form. We argue that this analysis is inadequate and leads to unreliable landscape parameters in many common situations. We propose a modified closed-form expression for the distribution of critical forces that works better for parameter extraction and is valid even up to fast pulling rates. We present results based on simulated data that confirm the utility of our new formula.

Quantifying Collective Dynamics in the Ribosome

MARIANA LEVI, PAUL WHITFORD (Presenter), Northeastern University — The functional dynamics of molecular assemblies often involve large-scale collective rearrangements. While these motions occur in a high-dimensional space, experiments are typically only able to simultaneously measure a small number of interatomic distances. Accordingly, a major challenge in single-molecule studies is to identify kinetically-relevant degrees of freedom. To address this issue for the ribosome, we use a range of theoretical models and molecular dynamics simulations in order to simulate hundreds of spontaneous large-scale (~30-50 Å) conformational transitions at various points of the elongation cycle. With these large data sets, we are assessing the ability of experimentally-accessible coordinates to capture the rate-limiting free-energy barriers. This analysis suggests design strategies for next-general experiments, as well as helps rationalize controversial/contradictory experimental observations. Finally, these calculations provide a quantitative foundation that is allowing us to study the precise relationship between structure and dynamics in the ribosome.

Relaxation spectrum of a concentration quench of Brownian particles.

AYKUT ERBAS (Presenter), UNAM, Bilkent University, JOHN FREDERICK MARKO, MONICA OLVERA DE LA CRUZ, Northwestern University — Single-molecule or SPR (Surface Plasmon Resonance) experiments rely on the relaxation of concentration quenches of initially surface-bound molecules into confined reservoirs to determine molecular kinetic rates. Similarly, biological processes such as exocytosis, in which small molecules are emitted into the intracellular cleft for cellular communication, can be considered to be a relaxation process of an effective concentration quench. We study a model system closely related to the above cases in which weakly interacting Brownian particles are released from their binding sites into a confined volume by using molecular dynamics simulations and scaling arguments. Our results suggest that the rebinding rate of released particles exhibits various power laws until the confined volume is entirely filled by the particles. Furthermore, the cumulative rebinding rate, which is the time integration of the rebinding rate, exhibits a novel plateau behavior. This plateau is a result of the decreasing number of collisions between sparsely-placed binding sites and dissociated ligands. Our results can have important consequences for molecular signaling as well as for the interpretation of kinetic measurements of ligand-receptor interactions.
10:48AM X64.00011: Incorporating photo-artifacts into the analysis of single molecule FRET measurements

IOANNIS SGOURALIS (Presenter), Arizona State University — Single molecule experiments, such as those measuring FRET, encode precise information on individual molecules free of bulk averaging. Nevertheless, because smFRET assessments employ conventional fluorescence microscopy setups, artifacts such as background photons, shot-noise, cross-talk, and fluorophore blinking are limiting factors that necessitate the use of advanced analysis methods. In our recent work we employ infinite hidden Markov models and propose a novel formulation to model and analyze smFRET measurements that contains nonparametric statistics with an explicit representation of the fluorophore photo-physics. As a result, our method combines the advantages of traditional hidden Markov models while it avoids the associated state-space size restrictions or other model selection assumptions. For this, we carefully formulate the measurement process itself accounting for the photo-physics on the individual donors and acceptors in addition to the other experimental characteristics. As a result, our framework obtains accurate estimates even when recorded intensities are excessively noisy, photo-blinked, and also of short duration. Finally, our estimates remain accurate even when fluorophore photo-states alternate at scales comparable to those of the FRET efficiency itself.

University - Tag(s): Focus

8:00AM X65.00001: The mechanics of epithelial folding* [Invited] ADAM MARTIN (Presenter), HANNAH YEVICK, Biology, MIT — Throughout the lifespan of an organism, tissues are remodeled to shape organs and organisms and to maintain tissue integrity and homeostasis. Apical constriction is a ubiquitous cell shape change of epithelial tissues that promotes epithelia folding and cell/tissue invagination in a variety of contexts. Apical constriction promotes tissue bending by changing the shape of constituent cells from a columnar-shape to a wedge-shape. Drosophila gastrulation is one of the classic examples of apical constriction, where cells constrict to fold the primitive epithelial sheet and internalize cells that will give rise to internal organs. We find that the apical constriction of these cells constrict via repeated contractile pulses of the cytoskeleton, specifically actin filaments and the molecular motor myosin II. Contractility of the cells results in anisotropic tension, which is essential for the proper orientation of the fold. We are investigating mechanisms that pattern contractility across the tissue to ensure robust folding.

8:36AM X65.00002: Lineage and state dynamics in stem cell differentiation* [Invited] ALLON KLEIN (Presenter), Systems Biology, Harvard Medical School — High-dimensional single cell measurements allow capturing snapshots of dynamic transitions in biological systems. Over the past few years, measurements such as single cell RNA-Seq (RNA-Seq) have come to be routinely used in stem cell biology. However, as single cell measurements necessarily destroy cells, they do not definitively reveal long-term dynamic behaviors. Various theoretical models have been invoked to link static snapshots to dynamics, all necessarily making assumptions. I will describe the assumptions underlying one such model of a Fokker-Planck type, and its limitations. I will then show how the combination of lineage data in single cell transcriptomes allows explicitly testing dynamic inference models on single cell RNA-Seq data. Our results show the successes but also failures of dynamic inference, and provide a test demonstrating the existence of "hidden variables" underlying cellular dynamics as measured by RNA-Seq. The results and methods are applied to the lineage hierarchy of hematopoiesis.

AMK additionally acknowledges funding support by the Burroughs-Wellcome Fund CASI award, and by the Edward J Mallinckrodt foundation.
Animals vary more in size than in proportions; a possible quantitative version of this observation would be that organisms exhibit scaling, so that the dimensions of different body segments all vary in proportion to the overall size of the organism. If this were true, pattern formation in biological systems would be qualitatively different from that in the non-biological pattern forming systems that we understand, such as Rayleigh-Benard convection and directional solidification. A relatively pure version of this question is accessible in the early development of insect embryos, where a "blueprint" for the final segmented body plan is visible in striped patterns of gene expression. We measure the positions of these stripes in an ensemble of 100+ embryos from a laboratory strain of *Drosophila melanogaster*, under controlled conditions. These embryos vary in length by only 4% (rms), yet we can resolve the scaling of stripe positions with length. The resulting 1% accuracy of relative positions is so high as to exclude alternatives, such as combinations of unscaled signals from the two ends of the embryo.

The formation of somites is a self-organizing mechanical process that has received little attention so far. In this work, we build a 2D computer model of mesenchymal to epithelial transition process to explore the cellular mechanisms that promote somite organization. We focus on the first stage of somite formation, the establishment of the dorsal layer as an anterior propagating wave of cell maturation. First we explore and discuss the separate and combined contributions of cell polarization, adhesion and elongation to the formation of the dorsal layer. Finally, we explore the process of apical constriction and show how the forming layer is segmented into discrete units.

*NIH Grants R01 GM076992, U01 GM111243 and R01 GM077138

In order to study experimental signatures of the limiting-pool mechanism, we consider a simple model of the self-assembly of two spherical structures from a common pool of building blocks. Using theory and simulations, we analyze the time series of the sizes of the spherical structures and make specific predictions about their autocorrelation functions. We then compare these theoretical results to fluorescence data from experiments that measure nucleoli size as a function of time in late stages of *C. elegans* embryo development. This approach can be used in other experimental systems to quantitatively test for the limiting-pool mechanism, and can be extended to other size-control mechanisms.

ANDREW MUGLER, Purdue University — Morphogen profiles allow cells to determine their position within a developing static disorders in the system due to coupling to other dynamical processes. We developed a deep-learning based live cell imaging and analysis procedure to trace single cell trajectories in high-dimensional morphology space. Using TGF-β induced Epithelial-to-Mesenchymal transition (EMT) in human HK2 cells as a model system, we experimentally depicted the quasi-potential landscape of EMT, identified three distinct morphology states that are correlated with different expression levels of EMT regulators and markers. We further reconstructed an extended state network that depicts coupling between cell cycle and EMT, and quantified the transition matrix from single cell data. In many aspects the single cell studies are analogous to the more established single molecule approaches in molecular biophysics, while the transition process under study is complicated by existence of dynamic and static disorders in the system due to coupling to other dynamical processes.

10:00AM X65.00007: Structural redundancy in supracellular actomyosin network connections enables robust tissue folding  HANNAH YEVICK (Presenter), PEARSON MILLER, JORN DUNKEL, ADAM MARTIN, Massachusetts Institute of Technology — It is essential for the fate of an organism that key morphogenetic processes occur reproducibly. While much is known about how genetic regulation achieves robustness, less is known about how a tissue mechanically ensures reproducibility. Gastrulation is an indispensable stage of development. Drosophila fruit fly gastrulation is driven by myosin-dependent constriction and this robust large-scale movement requires coordinated forces at the tissue level. Yet, how the cytoskeleton is connected across the constricting tissue to realize shape change is unknown. We demonstrate a high degree of robustness in Drosophila gastrulation whereby ablating many cells doesn’t halt shape change. To understand this robustness, we integrated concepts from graph theory to analyze the connectivity of a supracellular network of myosin connections that links cells in the tissue. We found that a dense meshwork of tissue scale connections ensures structural redundancy and that even when large numbers of connections are lost some paths across the tissue persists and folding proceeds. We propose that in the same way that redundancy ensures the large-scale function of telecommunication or transportation networks under localized failures, the organization of myosin activation enables robust morphogenesis.

10:12AM X65.00008: Diffusion vs. direct transport in the precision of morphogen readout  SEAN FANCHER (Presenter), ANDREW MUGLER, Purdue University — Morphogen profiles allow cells to determine their position within a developing organism, but there are multiple mechanisms by which these profiles form, and in some cases the mechanism is still not agreed upon. Here we derive fundamental limits to the precision of morphogen concentration sensing for two canonical mechanisms: the diffusion of morphogen through extracellular space and the direct transport of morphogen from source cell to target cell, e.g. via cytonemes. We find that direct transport establishes a morphogen profile without adding extrinsic noise. Despite this advantage, we find that for sufficiently large values of population size and profile length, the diffusion mechanism is many times more precise due to a higher refresh rate of morphogen molecules. We compare our predictions with data from a wide variety of morphogens in developing organisms.

10:24AM X65.00009: Intracellular crowding as mechanoregulator of intestinal organoid growth via modulating Wnt-receptor complex phase transition*  YIWEI LI (Presenter), JILIANG HU, MING GUO, Mechanical Engineering, Massachusetts Institute of Technology — Enormous amounts of essential intracellular events are crowdedly packed inside picoliter-sized cellular space. However, the significance of the physical properties of cells remains underappreciated due to a lack of evidence of how they impact cellular functionalities. Here, we show that the degree of intracellular crowding serves as a mechanoregulator of intestinal organoid growth via modulating Wnt/β-catenin signaling. Intracellular crowding varies upon stimulation by different types of extracellular physical and mechanical cues, and leads to a significant enhancement of Wnt/β-catenin signaling by promoting phase transition of LRP6 receptor complex. By enhancing intracellular crowding using either osmotic or mechanical compression, we show that expansion of intestinal organoids was facilitated through elevated Wnt/β-catenin signaling and greater intestinal stem cells (ISCs) self-renewal. Our results provide an entry point for understanding how intracellular crowdedness functions as a mechanotransducer linking extracellular physical cues with intracellular signaling, and potentially facilitate the design of engineering approaches for expansion of stem cells and organoids.

Population variation in human pre-implantation embryo development, or: how I learned to stop worrying and love IVF data.  

BRIAN LEAHY (Presenter), HELEN YANG, RONALD ALEXANDER, VINOTHAN MANOHARAN, DANIEL NEEDLEMAN, Harvard University — The early mammalian embryo is the physicist's dream for studying development. Between fertilization and implantation in the uterus, the mammalian embryo undergoes a global reorganization (compaction) followed by a symmetry-breaking differentiation (blastocyst formation), with no external direction from the mother. While studies on mouse embryos illuminate the mechanisms of development, the genetic homogeneity of lab mice obscures the natural variability in mammalian development. Here, we examine thousands of videos of human embryos recorded during IVF procedures to explore the natural variability in mammalian pre-implantation embryo development. We leverage this variability to infer possible regulatory mechanisms in early development. Finally, we will discuss our work on extending non-invasive 3D microscopy to imaging human embryos.

Biophysical studies of metabolic control in mouse oocytes and embryos  

XINGBO YANG (Presenter), TIM SANCHEZ, MARTA VENTURAS, DANIEL NEEDLEMAN, Molecular and Cellular Biology, Harvard University — While a great deal is known about pathways and enzymology of carbohydrate metabolism, it is still poorly understood how metabolic fluxes are modulated during development and in response to environmental factors, or degraded in disease. Mounting evidence suggests that defects in metabolism may cause chromosome segregation errors in eggs and embryos, leading to age related infertility in women, but the possible underlying mechanisms remain unclear. We are developing and testing a coarse-grained biophysical model of enzyme engagement of electron carriers, with the goal of extracting metabolic fluxes from fluorescence lifetime imaging microscopy measurements. We are attempting to construct a theory of the control of mitochondrial respiration and cytoplasmic fermentation in mouse oocytes and embryos by using this approach in conjunction with metabolic manipulations. Our preliminary results argue that the fluxes through these pathways can be redirected in response to perturbations, but this is accompanied by large changes in cell biological features, including disassembly of the spindle, which we speculate might underlie the connection between metabolic defects and chromosome segregation errors.

Systematic mutagenesis of oncocin reveals enhanced activity and insights into the mechanisms of antimicrobial activity*  

PIN-KUANG LAI (Presenter), KATHRYN GELDART, SETH RITTER, YIANNIS KAZNESSIS, BENJAMIN HACKEL, University of Minnesota — Oncocin is a proline-rich antimicrobial peptide that inhibits protein synthesis by binding to the bacterial ribosome. The aim of this work is to improve the antimicrobial activity of oncocin by systematic peptide mutagenesis and activity evaluation. We discovered that a pair of cationic substitutions (P4K and P7K/R) enhanced the activity by 2 to 4 fold (p<0.05) against multiple Gram-negative bacteria. An in vitro transcription / translation assay indicated that the increased activity was not because of stronger ribosome binding. Instead a cellular internalization assay revealed a higher internalization rate for the optimized analogs thereby suggesting a mechanism to increase potency. In addition, we found that the optimized peptides' benefit is dependent upon nutrient-depleted media conditions.

Quantifying the Formation and Dissolution of Multilayer Regions in the Expansion of Twitching Bacterial Colonies

ERIN SHELTON (Presenter), Department of Physics, University of Guelph, LORI BURROWS, Department of Biochemistry and Biomedical Sciences, McMaster University, JOHN DUTCHER, Department of Physics, University of Guelph — Type IV pili (T4P) are very thin (5-8 nm in diameter) protein filaments that can be extended and retracted by certain classes of Gram-negative bacteria including P. aeruginosa [1]. These bacteria use T4P to move across viscous interfaces, referred to as twitching motility. Twitching can occur for isolated cells or in a collective manner [2]. In collective motion, the advancing front of an expanding colony consists of finger-like protrusions consisting of many aligned bacteria, with 5 to 30 cells across the fingers, followed by cells that twitch within a lattice-like pattern. During the outward radial motion of the fingers along an agar-glass interface, cells can vertically displace the agar to form multilayer regions. Using our custom-built, temperature- and humidity-controlled environmental chamber, we have studied the formation and dissolution of multilayer regions within fingers for a range of agar concentrations. We find that there is a minimum finger width required for the stability of multilayer regions.

Magnetotactic bacterial scattering in porous media hinders transport

AMIN DEHKHARGANI (Presenter), NICOLAS WAISBORD, THOMAS COONS, JEFFREY S. GUASTO, Tufts University — Swimming cells exhibit complex surface scattering behaviors in both natural and engineered porous habitats, impairing their persistent random walks. Using microfluidics experiments complemented with Langevin simulations, we study how the scattering of magnetotactic bacteria (MTB) within a lattice of obstacles modifies cell transport, and how guidance by an external field augments their mobility. MTBs are used as a model biological system, because they share motility mechanisms with many other bacterial species, and their swimming direction is easily manipulated via an external magnetic field. We show that both the diffusive and directed mobility of the cells decreases markedly in the presence of porous microstructure compared to bulk fluid. Moreover, the spacing between the obstacles and the degree of the disorder in the lattice play a key role in the magnitude of the observed reduced mobility. These results are an important step toward understanding the physical ecology of swimming cells in quiescent porous media as well as for controlling micro-robots in complex environments.

Cargo carrying capacity of a single bacterium

PRANEET PRAKASH, AMITH ZAFAL ABDULLA, MANOJ M. VARMA (Presenter), Indian Institute of Science — In recent times, several groups have demonstrated bio-hybrid micro-robots where bacteria are attached to “cargo” such as polystyrene beads, which are transported using the power generated by bacterial motility. A system consisting of a single bacterium pulling a load is important for a clear understanding of such bacteria powered devices. Previous reports of cargo delivery by single bacteria have relied on attaching the cells to very small particles (~ 1 micron dia.) so that statistically only one cell can bind due to steric restriction. Such an approach is not effective, as dynamics of a single cell carrying a large load, say ~ 10 micron dia., cannot be studied. Systems describing single bacterium carrying such large size cargo have not been described so far to the best of our knowledge. In this talk, we ask a very general question, namely, what is the maximum load of a spherical cargo which can be transported by a flagellated swimmer at a specified speed. We present a technique to attach single loads as large as 12 micron diameter to micron sized single bacteria. Further, results from our experiments and theoretical analysis suggests the crucial role of tuning the flagellar geometry and the torque-speed characteristics of the flagellar motor to maximize cargo carrying capacity.
Three-dimensional imaging and force mode analysis of microflows induced by swimming *Chlamydomonas reinhardtii* KYLE WELCH, Department of Chemical Engineering and Materials Science, University of Minnesota, SANTOSH KUMAR SANKAR, Department of Mechanical Engineering, University of Minnesota, BO-KAI ZHANG, XINLIANG XU, Complex Systems Division, Beijing Computational Science Research Center, JIARONG HONG, Department of Mechanical Engineering, University of Minnesota, XIANG CHENG (Presenter), Department of Chemical Engineering and Materials Science, University of Minnesota — Understanding the fluid flow induced by microswimmers is paramount to revealing how they interact with each other and their environment. Here, we present a three-dimensional (3D) measurement and characterization of the flow field induced by motile planktonic algal cells, Chlamydomonas reinhardtii. A single alga is captured and held stationary by a micropipette, which beats its flagella in a characteristic breaststroke pattern. We track the 3D flow field around the alga by employing fast holographic imaging on 1 um tracer particles, which leads to a nominal spatial resolution of ~ 54 nm along the optical axis and ~ 44 nm in the imaging plane. The method allows us to image the flow around a single alga continuously over thousands of flagellar beat cycles and show time-averaged and phase-binned 3D flow fields. We analyze these 3D flow fields and determine the dominant force modes of the flagellar motion of C. reinhardtii. Our study demonstrates the power of holography in imaging detailed microscopic flows and provides crucial information for understanding the detailed locomotion of swimming microorganisms.

Length regulation of multiple flagella that self-assemble from a shared pool of components THOMAS FAI (Presenter), LISHIBANYA MOHAPATRA, JANE KONDEV, Brandeis University, ARIEL AMIR, Harvard University — The single cell biflagellate Chlamydomonas reinhardtii has proven to be a very useful model organism for studies of size control. We consider a model of flagellar length control whose key assumption is that proteins responsible for the intraflagellar transport (IFT) of tubulin are present in limiting amounts. We show that this limiting-pool assumption and simple reasoning based on the law of mass action leads to an inverse relationship between the rate at which a flagellum grows and its length, which has been observed experimentally, and has been shown theoretically to provide a mechanism for length control. We extend our length-control model to two flagella by considering different mechanisms of their coupling. Within our theoretical framework we conclude that, if tubulin and IFT proteins are freely exchanged between flagella, simultaneous length control is not possible if the disassembly rate is constant. However, if disassembly depends on the concentration of IFT proteins at the tip of the flagellum, simultaneous length control can be achieved.

Encounter rates between motile bacteria and sinking particles JONASZ SLOMKA (Presenter), VICENTE I. FERNANDEZ, ROMAN STOCKER, ETH Zurich — Many marine microbes rely on sinking particles of organic matter as their food source. Once attached to a particle, bacteria can solubilize its organic matter and convert it into biomass. This process hinders carbon from sinking to the deep ocean (a process known as the ‘biological pump’) and thus affects the magnitude of carbon flux in the ocean. Carbon consumption by bacteria is preceded by their encounter with sinking particles, whose quantification is needed to understand the biological pump. Here, we theoretically predict these encounter rates by combining the Stokes flow around the particle with Jeffrey's equation for a rod in flow. We show that elongated bacteria - unlike spherical particles often used in encounter rate estimates – break the fore-aft symmetry of the flow streamlines, with major consequences on encounter rates. Specifically, for small to intermediate sinking speeds, this symmetry-breaking implies that elongated swimmers are up to hundred times more likely to encounter the sinking particle than spherical bacteria with the same volume. We find that the mechanism for this encounter rate enhancement is the hydrodynamic focusing of elongated swimmers downstream of the sinking particle, which leads to their preferential attachment to the back of the particle.
9:24AM X66.00008: Collective bacterial vision  HARSHITHA SHANKAR KOTIAN (Presenter), Centre for Nanoscience and Engineering, Indian Institute of Science, Bangalore, India, SHALINI HARKAR, Robert Bosch Centre for Cyber Physical Systems, Indian Institute of Science, Bangalore, India, SHUBHAM JOGE, AYUSHI MISHRA, Molecular Reproduction, Development and Genetics, Indian Institute of Science, Bangalore, India, AMITH Z. ABDULLA, Centre for Nanoscience and Engineering, Indian Institute of Science, Bangalore, India, VARSHA SINGH, Molecular Reproduction, Development and Genetics, Indian Institute of Science, Bangalore, India, MANOJ M. VARMA, Centre for Nanoscience and Engineering, Indian Institute of Science, Bangalore, India — Bacteria are well studied primitive organisms and an ideal system for physical scientists to study how simple systems perform complex tasks. Swarming is one such complex collective phenomenon of producing surfactant to ease their motility on a semi solid surface (nutrient supplemented 0.6% agar). We perturbed the swarming pattern of *Pseudomonas aeruginosa* (PA) by incorporating inert obstacles (PDMS) in the agar plate thus creating local depletion of nutrient and water rich agar surface. To our surprise, we noticed that the bacteria as they colonize the surfaces with such obstacles effectively avoid them by changing the course of their path at a distance as far as 5 mm thus ‘seeing’ (sensing) them at \( \sim \) thousand body lengths. We refer to this phenomenon as “collective bacterial vision”. We demonstrate a fluid dynamic model that can guide them around these obstacles. Our model leads to further questions such as, is it possible for a single bacterium to possess “bacterial vision”? What is the grouping cost and ideal group size? Is there a need for information transfer in the group? Is this phenomenon a completely active or completely passive or a delicate balance between them? We will describe our attempts to address some of the above questions though most of them are still open.

9:36AM X66.00009: Bacterial growth curves are predictable from cellular Raman spectra*  KEN-ICHIRO F. KAMEI (Presenter), KOSEKI J. KOBAYASHI-KIRSCHVINK, YUICHI WAKAMOTO, Department of Basic Science, Graduate School of Arts and Sciences, The University of Tokyo — Raman microscopy is an imaging technique that has been applied to cells to obtain Raman spectra that reflect the abundances of various biomolecules. It allows distinguishing cellular states in a label-free and non-destructive manner. Previously, employing spontaneous Raman scattering, we showed that cellular Raman spectra and transcriptomes could be linked in both *S. pombe* and *E. coli*, and that the transcriptomes could be reconstructed from Raman spectra (Kobayashi-Kirschvink et al., *Cell Systems*, 2018). Considering that omics information, which characterizes cellular states with *molecular* resolution, is linked to Raman spectra, we next asked whether Raman spectra could be linked to *macroscopic* quantities of cellular states. Our recent experimental and computational study indicates that different cellular states of single-gene knockout *E. coli* strains were distinguished by Raman spectra, and the entire population growth curves of different strains could be predicted by Raman spectra from cells in exponential phase. These results suggest that cellular Raman spectra have the potential to integrate macroscopic and microscopic characterizations of cellular states.

9:48AM X66.00010: Imaging the emergence of collective swarming in light-controlled bacteria*  YI PENG (Presenter), ZHENGYANG LIU, KECHUN ZHANG, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota — Collective motions of active matter as illustrated by bird flocks, fish schools and bacterial swarms demonstrate the intriguing emergent behaviors of living systems. While moving independently at low density, active entities move collectively with its neighbors at high density, exhibiting orientational order at a scale larger than their individual sizes. Although such a disorder-order nonequilibrium phase transition has been previously studied, detailed kinetics of this transition has not been explored in experiments. Here, using engineered *E. coli*, whose locomotion can be reversibly controlled by light, we experimentally study the kinetic pathway of the swarming transition in 3D bacterial suspensions. We trigger bacterial swarming by tuning light intensity and image the emergence of collective motion. We map the phase diagram of bacterial swarming as functions of bacterial concentration, swimmer velocity and the number fraction of active swimmers. Moreover, we find that the swarming transition occurs in a nucleation manner and characterize the incubation time of the transition. Our results reveal the microscopic dynamics of the emergence of bacterial swarming and provide insights into the nonequilibrium phase transition in active matter.

*NSF CBET-1702352, DARPA YFA-D16AP00120
Myxococcus xanthus is a rod shaped soil bacterium that lives in collectives of many millions of cells. These groups of cells exhibit different collective behaviors which benefit the bacteria depending on the external environment. When \( M. \) xanthus are in favorable conditions, colonies will swarm and spread out to explore new territory, resulting in thin layers only a few cells thick. Our goal is to understand how the motility of individual bacteria along with local interactions can lead to the collective behaviors that exist on length scales significantly larger that of the individuals. Using a confocal laser scanning microscope we image layers of cells with single cell resolution while simultaneously obtaining height maps of the layer thickness across the sample. From these images we are able to extract flow and director fields of the bacteria over time. Topological defects in director fields are connected to pressure fluctuations in active nematic systems which can lead to local changes in layer thickness. By combining height maps with director and flow fields, we are able to examine how the active nematic nature of the system can result in thickness changes in bacteria layers.

**Self-organization of swimmers drives long-range fluid transport in bacterial colonies**

Microbes commonly live in structured communities that affect human health and influence ecological systems. Colony mode of bacterial growth on solid substrates (e.g. food products) is closely related to biofilm development, and it is a main approach to study structured microbial communities. Heterogeneous populations, such as non-motile and motile populations, often coexist in bacteria colonies. Here we discovered that motile cells in sessile colonies of peritrichously flagellated bacteria can self-organize into motile bands that can drive long-range fluid transport at a constant speed of \( \sim 30 \) μm/s, providing a stable high-speed avenue for material transport at the colony scale. These findings present a unique form of large-scale self-organization and active transport in bacterial colonies.

**Bacterial Surface Motility is Modulated by An Abiotic Jamming Transition and is Independent of Chemotaxis and Individual Motility**

Bacillus subtilis is a model organism for the study of directed, collective motion over surfaces with groups exhibiting motility on length scales three orders of magnitude larger than themselves in a few doubling times. While genetic and chemical studies clearly show that surface tension gradients and water availability are required for this 'ultrafast' group motility, the relative importance of chemosensing, exogenous nutrient gradients, and individual motility are largely unknown from an experimental viewpoint. We demonstrate that contrary to simulations of bacterial growth on surfaces, \( B. \) subtilis does not rely on chemotaxis for direction, that the rate of dendritic expansion of the colony is faster when bacteria are motile but that the same type of group motility is possible even with non-motile cells, and that water availability is likely a control parameter modulating an abiotic jamming transition that determines whether the group remains fluidized and therefore motile.

*The University of Oregon
Despite decades of microbiology research, we lack a practical understanding of how bacteria migrate through host tissues in disease and through soils in bioremediation to consume environmental pollutants. Models of bacterial motility neglect how the impact of cells on their microenvironment dynamically influences subsequent motion of cells. We aim to unravel how the multi-scale dynamic feedback between bacterial motility and nutrient consumption gives rise to emergent behaviors. We find that E. coli suspension droplets in two-dimensional confinement spontaneously separate into two populations according to a self-generated oxygen gradient: immotile cells cluster in a droplet center and motile cells congregate near an outer air interface. We show how cluster formation and size depend on the interplay between oxygen consumption, diffusion, and bacterial motility. Understanding the impact of gradient-consumption feedback on population scale dynamics will better inform population level microbial behaviors like biofilm formation and migration.

Session Y01 DCMP: Interactions and Dynamics in Topological Semimetals BCEC 106

11:15AM Y01.00001: Quantum oscillations in Dirac/Weyl semimetals due to strain and external fields  DMITRY PIKULIN (Presenter), Microsoft, RONI ILAN, Tel-Aviv University — I will discuss how strain can cause quantum oscillations in Dirac/Weyl semimetals. In particular, I will concentrate on quasiclassical trajectories formed by strain alone and how they are modified in presence of external field. I will mention both bulk and bulk-boundary quantum oscillations.

11:27AM Y01.00002: Theory of spin torque in Weyl semimetals with magnetic texture*  DAICHI KUREBAYASHI (Presenter), Center for Emergent Matter Science, RIKEN, KENTARO NOMURA, Institute for Materials Research, Tohoku University — We theoretically study the spin-transfer torque, a fundamental physical quantity to understand the electrically-induced dynamics of magnetic texture. We calculate the electrically-induced non-equilibrium spin density of a Weyl semimetal (WSM) and obtain the analytical expression of the spin torque corresponding to a non-adiabatic spin-transfer torque. Importantly, the strength of the obtained spin torque outstrips that of conventional ferromagnetic metals when magnetization varies steeply. Furthermore, due to the suppression of longitudinal conductivity in this regime, the dissipation due to Joule heating for the spin-transfer torque is smaller than that in conventional ferromagnetic metals. We also analyze the dynamics of the domain walls driven using the spin-transfer torque and find that the velocity of the domain wall is one order of magnitude greater than that of a conventional ferromagnetic nanowire. Consequently, the fast-control of domain walls can be achieved with smaller dissipation in the WSM. Therefore, the WSM can be a new candidate for application to spintronics devices such as the racetrack memory.

11:39AM Y01.00003: Counting formula for the pseudo Landau levels visible in an energy spectrum*  TOSHIKAZE KARIYADO (Presenter), International Center for Materials Nanoarchitectonics, National Institute for Materials Science — One interesting feature of Dirac/Weyl systems is that spatial modulation, for instance given by strain, can be regarded as a gauge filed. This “pseudo” gauge field can generate pseudo magnetic field, and enables us to observe magnetic like phenomena such as Landau level formation or quantum oscillations even without external magnetic field. Here, by considering a simplest situation to have finite pseudo magnetic field, we derive a concise formula to count the number of pseudo Landau levels clearly visible in the energy spectrum. The derived formula is numerically verified in a toy model. Equipped with the formula, we also discuss the possible realization of the pseudo Landau levels in existing Dirac materials, particularly in antiperovskite Sr$_3$SnO series.

11:51AM Y01.00004: Topological semimetal coupled to nano-mechanical resonator  KUN WOO KIM (Presenter), Physics of Complex Systems, Institute for Basic Science, JUNHO SUH, Korea Research Institute of Standards and Science — The detection of gapless Dirac point in semimetals is an important issue for the characterization of topological phase. While the direct measurements of spectral functions and magneto-conductance are widely employed, the strength of electronic signal is vanishingly small near Dirac point due to its low density of states. Here, we propose a way to detect the presence of Dirac node through the coupling to a nano mechanical resonator. Playing as a nonlinear circuit element, the quantum capacitance of topological semimetal induces an abnormal frequency shifting in the resonator near Dirac node. This quantum and mechanical setup will be ideal for the characterization of various topological matter and its boundary states.

12:03PM Y01.00005: Dirac cones protected by chiral symmetry in wallpaper groups*  CHING-KAI CHIU (Presenter), Kavli Institute for Theoretical Sciences, YANG ZHESEN, Chinese Academy of Sciences, CONGCONG LE, Kavli Institute for Theoretical Sciences — Dirac cones in 2D Brillouin zone (BZ) can be protected by chiral symmetry. The spinless and spin-1/2 systems preserving chiral symmetry can be realized in time-reversal symmetric superconductors and correspond to symmetry class BDI and DIII respectively. Since the total winding number in the entire BZ is zero, there are at least two Diracs cones in the BZ. Furthermore, crystalline symmetries lead to duplicate Dirac cones and additional constraints. The minimal numbers of the Dirac cones in the BZ under different symmetries might be different. In this talk, we classify the minimal numbers of the Dirac cones protected by chiral symmetry in all 17 wallpaper groups for class AIII, BDI, and DIII.

12:15PM Y01.00006: Stability of the Semimetallic Phase in strongly interacting Weyl semimetals*  JOHAN CARLSTROM (Presenter), EMIL J BERGHOLTZ, Stockholm University — Using a combination of analytical arguments and diagrammatic Monte Carlo simulations, we show that the corrections to the dispersion in interacting Weyl semimetals are determined by the ultraviolet cutoff and the inverse screening length. If both of these are finite, then the diagrammatic series is convergent even in the low-temperature limit, which implies that the semimetallic phase is protected by a symmetry of the self energy. We also find that the frequency dependent part of the self energy gives an extremely small correction to the Greens function of the interacting system, implying that the impact of interactions almost entirely takes the form of a renormalisation of the single particle dispersion.

12:27PM Y01.00007: Strain-induced nonlinear spin Hall effect in topological Dirac semimetal*  YASUFUMI ARAKI (Presenter), Institute for Materials Research, Tohoku University — Topological Dirac semimetals (TDSMs) form a new class of three-dimensional topological semimetals, characterized by pair(s) of doubly-degenerate nodal points (Dirac points) in their momentum(k)-space band structures. They show the intrinsic spin Hall effect (SHE), which comes from the k-space topology around the Dirac points. This spin Hall conductivity is topologically protected, while it cannot be easily tuned or enhanced at linear response. In order to overcome this problem, I theoretically propose that an electric field applied to a lattice-strained TDSM gives rise to an additional "nonlinear spin Hall current", namely the spin current perpendicular to and quadratic in the electric field [1]. The spin current response is obtained by the Boltzmann transport theory, regarding the strain as a pseudomagnetic field for the Dirac electrons. The nonlinear SHE arises as the hybrid of the regular Hall effect driven by the pseudomagnetic field (strain) and the anomalous Hall effect from the k-space topology. This behavior implies that one can obtain a rectified (dc) pure spin current out of an alternating (ac) electric field, which renders the TDSM an efficient spin-current injector.

12:39PM Y01.00008: Enhanced conductance of Weyl semimetals with strain-induced chiral magnetic fields in the ultra-quantum limit  JAN BEHRENDS (Presenter), TCM Group, Cavendish Laboratory, University of Cambridge, JENS BARDARSON, Department of Physics, KTH Royal Institute of Technology, RONI ILAN, Raymond and Beverly Sackler School of Physics and Astronomy, Tel-Aviv University — Magnetotransport is one of the key signatures of Weyl semimetals. It is believed to reveal the chiral anomaly, the nonconservation of chiral charge, by showing a large negative magnetoresistance for longitudinal transport. With the realization of chiral magnetic fields, fields that act with opposite sign on the two chiralities, transport experiments in presence of those fields come in sight. In this work, we show that the conductivity in the ultra-quantum regime of a disordered Weyl semimetal subjected to a chiral magnetic field in transport direction increases with the field strength and width of the sample. We relate this increment to the spatial separation of counterpropagating modes in those samples. Our results are based on tight-binding simulations and supported by analytical arguments. We argue how this effect can be used in devices that need spatial separation of charge carriers.

12:51PM Y01.00009: Ferromagnetic Weyl semimetal phase and anomalous Hall effect in stacked Kagome lattice* AKIHIRO OZAWA (Presenter), KENTARO NOMURA, Institute for Materials Research, Tohoku University — Recently, Weyl semimetals, which have three-dimensional linear dispersions near the Fermi energy have been intensively investigated. Especially, ferromagnetic Weyl semimetals are drawing attentions as a system which implements some novel transport phenomena such as the anomalous Hall effect. It is reported that ferromagnetic Weyl phase is realized in stacked Kagome material Co3Sn2S2 by experiment and first principle calculation. In this presentation, we study the electronic state and the phenomena such as the anomalous Hall effect. Our results are based on tight-binding simulations and supported by analytical arguments. We relate this increment to the spatial separation of counterpropagating modes in those samples. Our results are based on tight-binding simulations and supported by analytical arguments. We argue how this effect can be used in devices that need spatial separation of charge carriers.

1:03PM Y01.00010: Semiclassical transport theory in Weyl semimetals beyond the relaxation time approximation* TOBIAS MENG (Presenter), TU Dresden — In this talk, I will detail new insights into transport in Weyl semimetals based on the semiclassical Boltzmann approach treated beyond the relaxation time approximation. This approach allows us to investigate the impact of various scattering mechanisms, and to make a step towards a more realistic description of transport experiments in Weyl semimetals. In particular, I will discuss Weyl-specific signatures in the low-field magnetotransport beyond the well-known negative quadratic magnetoresistance.

*We acknowledge funding by the Deutsche Forschungsgemeinschaft through the Emmy Noether Programme ME 4844/1-1 and through SFB 1143.

1:15PM Y01.00011: “Hinge” surface states in Weyl semimetals TOBIAS MENG (Presenter), TU Dresden — In this talk, I will detail new insights into transport in Weyl semimetals based on the semiclassical Boltzmann approach treated beyond the relaxation time approximation. This approach allows us to investigate the impact of various scattering mechanisms, and to make a step towards a more realistic description of transport experiments in Weyl semimetals. In particular, I will discuss Weyl-specific signatures in the low-field magnetotransport beyond the well-known negative quadratic magnetoresistance.

1:27PM Y01.00012: Non-local spin-spin coupling in topological semimetals SONU VERMA, DEBASMITA GIRI, KESHAV PAREEK, Physics, Indian Institute of Technology Kanpur, HERBERT FERTIG, Physics, Indiana University Bloomington, ARIJIT KUNDU (Presenter), Physics, Indian Institute of Technology Kanpur — We study the spin-spin coupling in finite-geometry topological semimetals employing the RKKY theory of interaction among impurity spins. The impurity spins can be on the surface of the geometry, where the mediated interaction between them can be through the topological surface states. Alternatively, the impurity spins can be on opposite surface of the system, where the mediated interaction can be through the semimetallic bulk states, giving rise to signatures of possible non-local effects.
Effects of long-range interactions on topological semimetals

SHOUVIK SUR (Presenter), PALLAB GOSWAMI, Physics & Astronomy, Northwestern University — In the presence of long-range interactions the low energy dynamics in a metal usually undergoes significant re-adjustments, leading to a state that qualitatively differs from that in the non-interacting limit. The band structures of many three dimensional systems host topologically protected nodal-points or nodal-lines. In such semimetals long-range interactions play an important role in both the native phase, and upon tuning to a topological or geometric quantum critical point. Here we study the interplay of long-range interactions and topology in a nodal-point semimetal.

Session Y03 DCMP: Transport in Topological Systems: Theory and Experiment BCEC 107B

11:15AM Y03.00001: Configuration-sensitive transport at the domain walls of a magnetic topological insulator*

YANFENG ZHOU (Presenter), ZHE HOU, QING-FENG SUN, School of Physics, Peking University — We report on the transport of a two-terminal device containing a domain wall (DW) in a magnetic topological insulator (TI). In the low-energy case, the transport behaviors of the magnetic TI are dominated by chiral edge states (CESs) at the device edges as well as at the DW. We calculate the band structures of magnetic TIs with both a Bloch wall and a Néel wall. For a Bloch wall, two copropagating CESs at the DW are doubly degenerate, while for a Néel wall a split is present. Consequently, the transport is strongly dependent on the DW configuration. In the Bloch wall case, the incoming electron with zero energy is totally reflected regardless of the system parameters. However, in the Néel case, the device functions as a chirality-based Mach-Zehnder interferometry, so that the transmission coefficient oscillates between zero and unity with changes in system parameters. By constructing the scattering matrix of the device from the effective Hamiltonian, these transport behaviors can be well understood.

11:27AM Y03.00002: Conditions for fully gapped topological superconductivity in topological insulator nanowires*

RONI ILAN, Department of Condensed Matter Physics, Tel Aviv University, FERNANDO DE JUAN (Presenter), Donostia International Physics Center, Spain, JENS BARDARSON, Department of Physics, KTH Royal Institute of Technology — Among the different platforms to engineer Majorana fermions in one-dimensional topological superconductors, topological insulator nanowires remain a promising option. Threading an odd number of flux quanta through these wires induces an odd number of surface channels, which can then be gapped with proximity induced pairing. Because of the flux and depending on energetics, the phase of this surface pairing may or may not wind around the wire in the form of a vortex. We show that for wires with discrete rotational symmetry, a vortex is necessary to produce a fully gapped topological superconductor with localized Majorana end states. Without a vortex the proximitized wire remains gapless, and it is only if the symmetry is broken by disorder that a gap develops, which is much smaller than the one obtained with a vortex. These results are explained with the help of a continuum model and validated numerically with a tight binding model, and highlight the benefit of a vortex for reliable use of Majorana fermions in this platform.

*Marie Curie Programme under EC Grant agreement No. 705968 (F. J.). ERC Starting Grant No. 679722 and the Knut and Alice Wallenberg Foundation 2013-0093 (J. H. B.). Partial support by the National Science Foundation under Grant No. NSF PHY-1748958 (J. H. B.).
11:39AM Y03.00003: Topological Properties of Gapped Graphene Nanoribbons with Spatial Symmetries* KUAN-SEN LIN (Presenter), Department of Physics, University of Illinois, Urbana Champaign, MEI-YIN CHOU, Institute of Atomic and Molecular Sciences, Academia Sinica — To date, almost all of the discussions on topological insulators (TIs) have focused on two- and three-dimensional systems. One-dimensional (1D) TIs manifested in real materials, in which localized spin states may exist at the end or near the junctions, have largely been unexplored. Previous studies have considered the system of gapped graphene nanoribbons (GNRs) possessing spatial symmetries with terminations commensurate with inversion- or mirror-symmetric unit cells. In this work, we prove that a symmetry-protected $Z_2$ topological classification exists for any type of termination. Instead of the Berry phase, only the origin-independent part of it gives the correct bulk-boundary correspondence by the $\pi$-quantized values. The resulting $Z_2$ invariant depends on the 1D unit cell and is connected to the symmetry eigenvalues at the center and boundary of the Brillouin zone. Using cove-edged GNRs, we demonstrate the existence of localized states at the end of GNR segments and at the junction between two GNRs based on a topological analysis. The current results are expected to shed light on the design of electronic devices based on GNRs as well as the understanding of the topological features in 1D systems.

*This work is supported by a Thematic Project (AS-TP-106-M07) at Academia Sinica.

11:51AM Y03.00004: Quasi-one-dimensional first- and second-order topological insulators: Bi$_4$X$_4$ (X = Br, I)* CHIHO YOON (Presenter), Department of Physics and Astronomy, Seoul National University, CHENG-CHENG LIU, Beijing Key Laboratory of Nanophotonics and Ultrane Optoelectronic Systems, School of Physics, Beijing Institute of Technology, HONGKI MIN, Department of Physics and Astronomy, Seoul National University, FAN ZHANG, Department of Physics, The University of Texas at Dallas — Recently, quasi-one-dimensional materials Bi$_4$X$_4$ (X = Br, I) in both $\alpha$ and $\beta$ crystalline phases have been proposed as a promising platform for the realization of various topological insulator (TI) phases [e.g., PRL 116, 066801 (2016)]. This list includes the strong TI, the weak TI, and the second-order TI with helical hinge states. We perform first-principles calculations and construct an effective model for Bi$_4$X$_4$. These results allow us to derive all the aforementioned TI phases and guide future experimental studies.

(F.Z.)

12:03PM Y03.00005: PbSnSe: a model system to study topological phases* GAUTHIER KRIZMAN (Presenter), Department of Physics, Ecole Normale Superieure, BADIH ASSAF, Department of Physics, University of Notre-Dame, MILAN ORLITA, Laboratoire des Champs Magnétiques Intenses, THANYANAN PHUPHACHONG, Department of Physics, Ecole Normale Superieure, GUNTHER BAUER, GUNTHER SPRINGHOLZ, Department of Physics, Johannes Kepler Universität, LOUIS-ANNE DE VAULCHIER, YVES GULDNER, Department of Physics, Ecole Normale Superieure — Pb$_{1-x}$Sn$_x$Se hosts three-dimensional (3D) massive Dirac fermions across the entire composition range for which the crystal structure is cubic. In this talk, we will present a comprehensive experimental mapping of the 3D band structure of Pb$_{1-x}$Sn$_x$Se as a function of chemical composition (0<x<0.3), temperature (1.6<T<200 K), and magnetic field (0<B<34 T). We use magneto-infrared spectroscopy to determine all the Dirac parameters in the trivial and topologically non-trivial regimes.

In 3D Pb$_{1-x}$Sn$_x$Se topological insulators, an effective closure of the bulk energy gap with increasing temperature, magnetic field, or lead content is expected at the critical point of the phase transition. However, in this talk we experimentally demonstrate that such a gap closure consistently does not occur. Avoided-crossing of either bulk bands or N=0 Landau levels are evidenced. These results show that Pb$_{1-x}$Sn$_x$Se is a model system to study topological phases and the nature of the phase transition.

*This work is supported by Agence Nationale de la Recherche LabEx ENS-ICFP Grant No ANR-10-LABX-0010/ANR-10-IDEX-0001-02 PSL and by the Austrian Science Fund, Projects P 28185-N27 and P 29630-N27. It is also partly supported by a PSL scholarship.
12:15PM Y03.00006: Higher-order topology in two-dimensional crystals  FRANK SCHINDLER (Presenter), University of Zurich, WLADIMIR BENALCAZAR, The Pennsylvania State University, MARTA BRZEZINSKA, University of Science and Technology, MIKEL IRAOLA, Donostia International Physics Center, ADRIEN BOUHON, Uppsala University, STEPAN TSIRKIN, University of Zurich, MAIA VERGNIORY, Donostia International Physics Center, TITUS NEUPERT, University of Zurich — We study two-dimensional spinful topological phases of matter protected by time-reversal and crystalline symmetries. To define the topology we employ the concept of corner charge fractionalization: We show that corners in a higher-order topological phase can carry charges that are fractions of even multiples of the electric charge. These charges are quantized and topologically stable as long as all symmetries are preserved. We classify the topologies corresponding to different corner charge configurations for all 80 layer groups, and present their bulk topological indices. These can be calculated from the symmetry data and Brillouin zone Wilson loops. To corroborate our findings, we present tight-binding models and density functional theory calculations for various material realizations.

12:27PM Y03.00007: Exploring electronic properties of topological insulator Bi2Se3 using nuclear magnetic resonance  ROBIN GUEHNE (Presenter), GRANT V. M. WILLIAMS, SHEN V CHONG, MacDiarmid Institute for Advanced Materials and Nanotechnology, School of Chemical and Physical Sciences, Victoria University of Wellington, Wellington, New Zealand, VOJTĚCH CHLAN, Department of Condensed Matter Physics, Charles University, Prague, Czech Republic, JUERGEN HAASE, Felix Bloch Institute for Solid State Physics, Leipzig University, Leipzig, Germany — The investigations of 3-dimensional topological insulators such as Bi2Se3 focus chiefly on the gapless surface states that emerge as a consequence of the special energy band inversion near the Fermi level induced by spin-orbit coupling. Not as much studied are the real-space effects in the bulk. The band inversion, for example, changes the wave function of the free carriers, compared to the topologically trivial counterpart. We will show that nuclear magnetic resonance (NMR) as a local, bulk probe can detect this band inversion through the electric quadrupole interaction that, in addition, measures the concentration of free carriers, e.g. originating from self-doping effects. NMR data in external fields up to 17 T, i.e., shifts, linewidths and quadrupole splittings, in doped single crystalline samples of Bi2Se3 are discussed.

12:39PM Y03.00008: Thermal Hall Effect Measurements on Topological Materials  LUKE PRITCHARD-CAIRNS (Presenter), University of Edinburgh, JEAN PHILIPPE REID, University of St.Andrews, ROBIN S. PERRY, University College London, DHARMALINGAM PRABHAKARAN, University of Oxford, ANDREW HUXLEY, University of Edinburgh — In the past few decades topology has become a central theme in condensed matter physics, allowing a more complete understanding of concepts such as the quantum Hall effect and of the class of materials termed topological insulators. Topological insulators were first predicted in 1987 and have subsequently been experimentally realised in a host of materials. A similar effect has been predicted to occur for SrCu2(BO3)2 (SCBO) but with one crucial difference; unlike those materials previously found, it is the spin waves that have a topological character rather than the conduction bands [3]. SCBO is therefore a bosonic topological material.

Theoretical predictions from [1] suggest that the topological nature of SCBO should be evident from thermal Hall effect measurements. In order to demonstrate the feasibility of these measurements, we have used our setup to reproduce those results from [2], which show a (magnon) Hall effect signal of a similar magnitude to that predicted for SCBO, and under similar conditions. We then present new thermal Hall data on the material SCBO, for which a positive result would be evidence for one of the first known bosonic topological insulators.

Selective Contact and Patterning of Topological Surface States by Interfacing with Trivial and Ferromagnetic Insulators*

ANKITA ANIRBAN (Presenter), Cavendish Laboratory, University of Cambridge, ABDUR REHMAN JALIL, Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, YUNBO OU, MIRKO ROCCI, Dept. Of Physics, Plasma Science and Fusion Center and Francis Bitter Magnet Lab, Massachusetts Institute of Technology, GREGOR MUSSLER, Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, JAGADEESH MOODERA, Dept. Of Physics, Plasma Science and Fusion Center and Francis Bitter Magnet Lab, Massachusetts Institute of Technology, CRISPIN BARNES, CHRISTOPHER J FORD, Cavendish Laboratory, University of Cambridge — Topological insulators (TIs) are a novel class of material which host helical surface states with exciting and unique electronic properties. They can provide insights into new physics and also pave the way for potential spintronic applications. Much work has been done to identify and characterise these surface states, but in order to utilise them towards multifunctional devices, we need a way to control the exchange gap opening in a tailored way and pattern them accordingly. We present results from devices which allow selective contact and patterning of topological surface states. We interface a TI with a ferromagnetic insulator to open up a gap in the Dirac cone, in an effort to have independent contact to the top and bottom surface states of a single TI film, enabling the characterisation and utilisation of the two surface states separately. We also study heterostructures with two TI layers separated by a trivially insulating tunnel barrier, allowing for a way of probing the dispersion relation of TIs using spin and momentum resolved tunnelling.

The effect of lattice termination on the Zeeman gap of topological edge states in the quantum spin Hall insulator WTe2*

ALEXANDER LAU (Presenter), Kavli Institute of Nanoscience, Delft University of Technology, RAJYAVARDHAN RAY, Institute for Theoretical Solid State Physics, IWF Dresden, DANIEL VARJAS, ANTON AKHMEROV, Kavli Institute of Nanoscience, Delft University of Technology — We investigate the effect of the sample termination on the electronic properties of the recently discovered quantum spin Hall insulator WTe2. For this purpose, we have derived a minimal 4-orbital tight-binding model by means of a combination of symmetry considerations, density-functional theory calculations and experimental data. Here, we are going to present the results of our theoretical study including spectra of topological edge states and conductance calculations for various sample geometries with and without magnetic field. We observe that the edge-state dispersion considerably depends on the lattice termination: for some terminations the edge-state spectrum features a Kramers doublet, or Dirac point, of topological states inside the bulk energy gap. For others, this Dirac point is “buried” in the bulk continuum of bands. Here, we will show that this qualitative difference is strongly reflected in the electronic conductance under magnetic field. In particular, we find that the specific behavior is related to the type of Zeeman gap in the corresponding edge-state spectrum.

Bulk-boundary correspondence of non-Hermitian systems*

ZHONG WANG (Presenter), SHUNYU YAO, FEI SONG, Tsinghua University — An intriguing issue of non-Hermitian systems is the fate of bulk-boundary correspondence. We show that a previously overlooked “non-Hermitian skin effect” necessitates a non-Bloch bulk-boundary correspondence, which is based on a complex-valued Brillouin zone. This dramatic generalization of bulk-boundary correspondence is illustrated in the non-Hermitian Su-Schrieffer-Heeger models and Chern insulator models. We analytically obtain their topological phase diagrams, which are remarkably different from those of the Bloch Hamiltonians. As a natural formulation of the non-Bloch bulk-boundary correspondence, we introduce the non-Bloch topological invariants in the complex Brillouin zone (instead of the standard Brillouin zone with real-valued momentum), which faithfully predict the number of topological edge modes. Specifically, the chiral edge modes of two-dimensional non-Hermitian Chern bands are determined by the non-Bloch Chern numbers.

It has been shown that nanoribbon transistors consisting of InAs or GaSb channels can be processed by transferring epitaxial semiconductor layers onto a Si substrate, and further integrated into compound semiconductor CMOS circuits. In our research, we adapt this technique and study transferring epitaxial InAs/InGaSb topological insulator to Si/SiO2 or FM-insulator substrate. We will describe the processing for the QSH devices and present their low temperature transport data.

Magnetic topological insulators are an exciting new platform for the investigation of exciting time-reversal symmetry-breaking physics such as the quantum anomalous hall effect, inverse spin galvanic effect, axion electrodynamics, and spin orbit torque. These materials systems also have great potential for spintronic device applications, but practical development has so far been inhibited by the extremely low (around 30 K) Curie temperature of these materials. Interfacial proximity coupling to other magnetically ordered compounds has been suggested as a mechanism by which this challenge may be addressed. However, separating interfacial exchange coupling from less-desirable effects such as intermixing presents significant challenges. In this work, we use neutron and magnetic X-ray spectroscopy to assemble a depth and element-resolved picture of magnetism within topological insulator/antiferromagnet heterostructures. Our results support true proximity-induced magnetization in (Bi,Sb)2Te3 films interfaced with CrSb and MnTe, with enhanced ordering temperature and chiral magnetic structures. We show that the topology and magnetism of the (Bi,Sb)2Te3 may be readily controlled through exchange coupling with the adjacent antiferromagnet.

Topological insulators (TI) have been widely studied due to their unique band structure. The Dirac cone band dispersion as well as spin-momentum locking at the surface enables the existence of Dirac plasmons with resonance frequencies in the THz range [1]. People have observed localized Dirac plasmons by etching TIs into stripe arrays [2]. There is limited experimental evidence for propagating surface plasmon polaritons in TIs. Due to the nature of TI surface states, the propagating surface plasmon will be both charge density wave and spin density wave. Here we present our work on exciting propagating Dirac plasmons in TIs by lifting off gold gratings on top of the TI surface. We demonstrate the tunability of the plasmon resonance frequency by varying the grating coupler period. Future work may also include other degrees of tunability, and the simulation of plasmon dispersion relation. The research on propagating Dirac plasmons give rise to new dimensions of plasmonic and spintronic applications with TI.

First-Principles Prediction of Room Temperature Quantum Anomalous Hall Effect in 2D Oxalate-Bridged Metal Organic Complexes

LIZHI ZHANG (Presenter), University of Tennessee, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Quantum anomalous Hall (QAH) insulators are a highly promising class of materials for spintronic devices and quantum computations because of their precise quantization nature, robust properties against defects, and relatively low energy consumption for operation. To realize the QAH effect, quantum spin Hall (QSH) insulators must be utilized, which requires transition metal doping or surface functionality control. Here, we propose a new family of high temperature organic QAH insulators of 2D oxalate-bridged metal (M) organic complexes, \( M_2(C_2O_4)_3 \) (M=Re, Pt, Hg). First-principles calculations show the spin–orbit coupling gaps ~160 meV, with Curie temperature, calculated by non-linear spin wave theory based on the XYZ Heisenberg model, of greater than ~380 K, which indicates a room-temperature QAH effect. The first room-temperature organic QAH insulators with computationally proved high thermal stability can be realized experimentally.

11:15AM Y04.00001: First-Principles Study of Perpendicular Magnetic Anisotropy in Multiferroics

XUEZENG LU (Presenter), Northwestern University — Searching for materials with room-temperature electric-field control of magnetism has interested researchers for many years. Electric field assisted changes of perpendicular magnetic anisotropy (PMA) is a flourishing field owing to its application in magnetic random access memories (MRAMs). PMA has typically be explored in heterostructures comprised of ferromagnets and/or ferroelectrics, relying on interfacial effects whereby the strain generated by the substrate or changes in the electronic structures occur at the heterointerface due to the application of an electric field. Here we propose design rules, based on \((ABO_3)_1/(A'BO_3)_1\) superlattices and \(AA'B'B'O_6\) double perovskites exhibiting hybrid improper ferroelectricity (HIF), to realize potential in-plane electric-field control of PMA. Our studies show a change of PMA occurs in some ordered perovskite phases due to a polar-to-nonpolar phase transition driven by strain. Discovery of such phenomena allows us to formulate chemical and energetic design rules to facilitate the selection of other promising multiferroics for the applications in low-energy information storage and logic devices.

11:27AM Y04.00002: Ferromagnetic Resonance in BTO-BFO Films Grown on LSMO

GITI KHODAPARAST (Presenter), HAN-BYUL KANG, Virginia Tech, BENJAMIN MADON, Ecole Polytechnique, MIN GYU KANG, BRENDE N A MAGILL, DEE PAM MAURYA, SHASHANK PRIYA, Virginia Tech, HENRI-JEAN M DROUHIN, JEAN-ERIC WEGROWE, MARUCOS ALVES, Ecole Polytechnique — We synthesized epitaxial BTO-BFO films grown on LSMO with decreased leakage and improved multiferroic properties. This work provides new direction for ferromagnetic resonance studies in high quality BTO-BFO films. We observed small Gilbert damping (\( \alpha=0.004\)) and the absence of large inhomogeneous broadening, in a film with 80 nm thickness of BTO-BFO on LSMO (110). Magnetic insulators, such as BTO-BFO are potentially excellent candidates for pure spin current without the existence of charge current. This new materials system can provide opportunities for spin transfer in multifunctional materials where controlling magnetization or spin current, is crucial toward for developing nanoscale spin-based memory and devices.

11:39 AM Y04.00003: Oxygen exchange kinetics in perovskite oxides: Effects of elastic strain, dislocations, and surfaces [Invited] BILGE YILDIZ (Presenter), Departments of Nuclear Sci. and Eng., and Materials Sci. and Eng., Massachusetts Institute of Technology — Interfaces between dissimilar oxides are attracting significant interest for their potential role in accelerating charge transport and surface reaction kinetics. If well understood and controlled, they can provide a new way to enable high-performance solid-oxide fuel cells, separation membranes as well as fast switching memristive devices. For example, recent studies have demonstrated that cobaltite hetero-interfaces exhibit orders of magnitude faster oxygen reduction kinetics compared with either single phase. The interfacial strain fields and electronic interactions between the two phases as well as the effect of these interactions on the surface chemistry are the likely mediators behind such an unprecedented enhancement. The underlying mechanisms must be understood quantitatively, so that we can go beyond isolated and empirically found interface or surface structures to rationally designing dissimilar oxide interfaces with superior properties. In this talk, I will present our findings on how elastic strains, dislocations, and surface chemistry affect the defect chemistry and the charge transport/transfer kinetics, by using atomistic computations and model experiments using thin films. These recent results are encouraging for an improved understanding of oxide hetero-interfaces and surfaces at elevated temperatures, and could enable the discovery of new interfaces with fast oxygen transport and oxygen reduction kinetics.

12:15 PM Y04.00004: Optical spectroscopic study on the oxygen vacancy formation in SrTiO3 single crystals YUNSANG LEE (Presenter), JUNHWI LIM, Soongsil University, SANG DON BU, Physics, Chonbuk National University — We investigated the changes in the emission characteristics of SrTiO3 (STO) single crystals under control of oxygen vacancies by using gamma-ray irradiation. The photoluminescence spectroscopy is useful in probing oxygen vacancies, since the intensity of the visible emission is nearly proportional to the amount of oxygen vacancies. The STO samples were prepared in the directions of (100), (110) and (111). The unirradiated samples were found to show visible emissions near 500 nm, indicating they should have initially had some oxygen vacancies. With the gamma-ray irradiation increasing up to 100 kGy, the visible emission was found to increase for all three directions of STO samples. Interestingly, the variation in emission was dependent on the surface orientation of the STO: the intensity variation was greatest in the (111) sample. We discussed our results in relation to the surface energy of the STO.

12:27 PM Y04.00005: Prediction and Direct Observation of Apical Oxygen Vacancies in YBCO STEVEN HARTMAN (Presenter), Institute of Materials Science and Engineering, Washington University in St. Louis, BERNAT MUNDET BOLOS, JAUME GAZQUEZ, Consejo Superior de Investigaciones Científicas, Institut de Ciencia de Materials de Barcelona, ROHAN MISHRA, Mechanical Engineering and Materials Science, Washington University in St. Louis — Prior study of the high-temperature superconductor YBa2Cu3O7-x (YBCO) has revealed the fundamental role of oxygen vacancies in controlling the material's superconductivity. At low oxygenation (x > 0.5), the vacancies are ordered in the CuO chains, and nearly all studies of the vacancies in YBCO, even for high oxygenation (x > 0) have focused on the chain vacancy for this reason. However, optimally doped YBCO (x = 0.06) has relatively few vacancies, and these do not form ordered patterns, which are easy to detect using diffraction techniques. In this work, we use first-principles calculations and scanning transmission electron microscopy (STEM) to investigate vacancy formation in optimally doped YBCO. Our calculations show that at optimal doping, vacancy formation at the apical site is equally favorable to chain vacancy formation. To confirm this prediction, we use the atomic resolution of STEM to provide direct observation of these apical vacancies under certain experimental conditions. We also characterize the effects of apical vacancies on YBCO's electronic properties, using the calculated density of electronic states and experimental electron energy loss spectroscopy.

12:39 PM Y04.00006: Coexistence of polar displacements and conduction in doped ferroelectrics: an ab initio comparative study* CHENGLIANG XIA (Presenter), YUE CHEN, The University of Hong Kong, HANGHUI CHEN, New York University Shanghai — Degenerately doped ferroelectrics may create an approximate polar metallic phase. We use first-principle calculations to investigate n-doped LiNbO3-type oxides (LiNbO3 as the prototype) and compare to perovskite oxides (BaTiO3 as the prototype). In rigid-band approximation, substantial polar displacements in n-doped LiNbO3 persist even at 0.3e/f.u., while that in n-doped BaTiO3 quickly get suppressed and completely vanish at 0.1e/f.u. Supercell calculations which use oxygen vacancies as electron donors support results from rigid-band approximation and provide more detailed charge distribution. We find that in n-doped LiNbO3, conduction electrons are not as uniformly distributed as in n-doped BaTiO3. Insulating and conducting Nb sites coexist but substantial cation displacements are observed throughout n-doped LiNbO3. Our work shows that polar distortions and conduction can coexist in a wide range of electron concentration in n-doped LiNbO3, which is a practical approach to create an approximate polar metallic phase. Our results also show that Li displacements are not solely induced by Nb-O displacements, which may shed light on the origin of ferroelectricity in LiNbO3.

12:51PM Y04.00007: Proton-transfer Ferroelectricity of Trans-Unitcell Ion-Displacement and Multiferroic Soliton in Sodium and Potassium Hydroxides  MENGHAO WU (Presenter), Huazhong University of Science and Technology — We show first-principles evidence of robust proton-transfer ferroelectricity with considerable polarization in sodium and potassium hydroxides, which are ready for commercial scale production. Moreover, even a small amount of proton vacancies can completely change the mode of proton-transfer from intra-unitcell to trans-unitcell, giving rise to a hitherto unreported type of multiferroic soliton with “mobile” magnetism and a tremendous polarization that can be two orders of magnitude higher compared with most perovskite ferroelectrics. Their vertical polarizations of thin-film are robust against depolarizing field, rendering various designs of 2D ferroelectric field-transistors with non-destructive readout and ultra-high on/off ratio via sensing the switchable metallic/insulating state.

1:03PM Y04.00008: Imaging current filaments created by the metal-insulator transition in vanadium dioxide* MARK FIELD (Presenter), Rigetti Computing, CHRISTOPHER HILLMAN, PHILIP STUPAR, Teledyne Scientific, EUAN RAMSAY, JAMES VICKERS, Thermo Fisher Scientific — Vanadium dioxide (VO2) undergoes a reversible metal-insulator transition at 67 °C, changing from a semiconductor at low temperatures to a metal at high temperatures. The crystal structure changes from monoclinic to rutile and this structural change is sufficient to modify the bandstructure. Current biasing a thin film of VO2 shows high resistivity Ohmic behavior at low currents, and at higher currents the resistance suddenly drops as the Joule heating is sufficient to trigger the metal - insulator transition. At this point the heating decreases allowing sections of the material to revert to a semiconductor, concentrating the current within a metallic filament. At intermediate currents the metallic filament forms but the low resistance path does not dissipate enough heat to maintain it, and thermal oscillations are observed where the filament repeatedly forms and collapses. In this work we image a metallic filament within a current biased thin film VO2 sample using a laser scanning microscope. We observe the evolution of the filament in time when the device is oscillating, following the formation and collapse of the filament, and measure the time scales for each process.

1:15PM Y04.00009: Magnetism of BiFeO3 Nanoparticles across its ferroelectric phase transition* ALEXANDER CARDONA, EDWIN RAMOS, University of the Andes, ALEX HOJEM, Physics, UC San Diego, ANDREAS REIBER, University of the Andes, IVAN SCHULLER, Physics, UC San Diego, JUAN RAMIREZ (Presenter), University of the Andes — Multiferroics exhibit simultaneous magnetic and ferroelectric ordering. The archetypical multiferroic material, BiFeO3(BFO), has attracted much attention since it has both, high ferroelectric Curie temperature (1103 K) and, high antiferromagnetic Néel temperature (643 K) in bulk. Here we explore a new route of magnetic control via nano-structuration in the form of nanoparticles (NPs). We fabricated BFO NPs by the sol-gel method with different particle sizes. We have found that their magnetic properties at room temperature and down to 2K change drastically by varying the NP size. Here we present magnetometry studies at high temperature up to the ferroelectric phase transition crossing the antiferromagnetic ordering temperature. These measurements were contrasted with XRD at high temperature to map the structural phase transition associate to the ferroelectric distortion. Our results suggest that NP size also modifies the ferroelectric and antiferromagnetic transition, allowing for a full control of the multiferroic ordering.

Session Y05 DCMP: Novel Techniques BCEC 108 - Daniel Arovas, University of California, San Diego

11:15AM Y05.00001: A Multi-Element Microcalorimeter X-ray Detector that processes Pulses in Real Time TERRENCE JACH (Presenter), National Institute of Standards and Technology, STEPHEN M. THURGATE, Murdoch University, ROBIN H CANTOR, Star Cryoelectronics, JOEL ULLOM, National Institute of Standards and Technology — Terrence Jach, NIST, Gaithersburg, MD, Stephen M. Thurgate, Murdoch University, Perth, Australia, Robin Cantor, Star Cryoelectronics, Santa Fe, NM, and Joel Ullom, NIST, Boulder, CO. We describe a microcalorimeter x-ray detector that operates up to 8 detector elements with full digital processing in real time. Each detector element employs a transition-edge sensor and two-stage SQUID electronics. The detector covers an energy range of 200 eV to 10 keV, with 5 eV resolution, at a count rate of 800/s. The processing includes pulse pileup rejection, digital filtering, peak fitting and an energy-calibrated histogram that displays a collective spectrum from all 8 detectors. The computer overhead is sufficiently low that we can envision a considerable expansion of the number of detectors.
11:27AM Y05.00002: Galeras Volcano internal structure characterization using geological and geophysics techniques as input to muon tomography studies* DENIS TORRES (Presenter), Physics, Universidad de Nariño, DAVID MARTINEZ, Physics, South Dakota School of Mines and Technology, ROBERTO TORRES, Servicio Geologico Colombiano, ALEX TAPIA, Physics, Universidad de Medellin, JAIME BETANCOURT, Physics, Universidad de Nariño, JAIRO RODRIGUEZ, Physics, South Dakota School of Mines and Technology, DAVID DUEÑAS, Physics, University of Cincinnati, DANILO ARTURO, Physics, Universidad de Puerto Rico — The Galeras Volcano (GV) activity has been monitored for several years due to it is surrounded by highly populated areas. Many populations have grown and settled in dangerous areas, this has increased the risk levels of these populations taking into account the GV recent history of eruptions and generation of pyroclastic flows. In this work, densities in the GV Complex and its variations were analyzed using geological studies and different geophysical methods, such as the seismic tomography of the P wave velocities and gravimetry. In the first method, layers are used at depths ranging from 4 to -10 km, taking 0 km as the sea level. It was obtained that the greatest density variation is between 2 and 0 Km with values between 2.16 and 2.43 g/cm³. Using the gravimetric method, a distribution map of densities ranging from 2.16 to 2.72 g/cm³ was obtained, the map shows a large number of low densities that can correspond to young bodies with little consolidation. The results obtained in this work will be a key input to enhance the developed GEANT4 simulations of GV within the project that aims to study the GV structure using the muon tomography technique.

*The speaker would like to thank the award received by FIP DS Program. The award will support speaker attendance to APS conference.

11:39AM Y05.00003: Studies in Baseplate-Pixel Sensor Gluing of the Pixel Strip Modules for the Compact Muon Solenoid Experiment Phase-2 Upgrade JEM GUHIT (Presenter), Mount Holyoke College, JAMES KEAVENEY, MARINO MISSIROLI, CMS, DESY — The upgrade program, Phase-2 of the High Luminosity LHC (HL – LHC), is planned to increase instantaneous peak luminosities to 5.0 x 10³⁴ cm⁻² s⁻¹. This study focuses on the Pixel-Sensor (PS) Module which will be installed in the end cap region of the Compact Muon Solenoid (CMS) detector. In order to prolong the lifetime of the modules during operation, an efficient cooling system has to be embedded within the components. The contact between the module and cooling is provided by a glue layer. Therefore, the study outlines the advances and improvements made on the gluing techniques between the baseplate and pixel sensor of the pixel strip (PS) modules to meet specifications. The automated assembly was commissioned by DESY (Deutsches Elektronen Synchrotron) to increase the building efficiency of the modules. Using two types of epoxy glues, a fast curing, and slow curing glue, the specifications were achieved by exploiting the precision of the motion stage to achieve a thin glue layer with excellent coverage. The techniques were tested and produced promising results. Further studies on improving the method and assembly of modules are being done at the Detector Assembly Facility (DAF) at DESY in Hamburg, Germany.

11:51AM Y05.00004: Photoelectric Effect And Mass-Energy Energy Equations Must IncludeRotational And Vibrational Kinetic Energy Factors As Well As Linear Kinetic Factors. Also Mass-Energy Equation Must Also Include Potential Energy Factors. STEWART BREKKE (Presenter), Northeastern Illinois University — Einstein originally proposed in his Special Theory of Relativity that at low speeds \( E_0 = m_0c^2 + \frac{1}{2}mv^2 \). However, the total energy at low speeds must include the rotational and vibrational kinetic energies as well as potential energies. Therefore the proper mass-energy equation at low speeds must be \( E_0 = m_0c^2 + \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2 + kx_0^2 + Gm_1m_2/r + kQ_1Q_2/r \). Originally, Einstein proposed that the ejected electron in the Photoelectric Effect through collisions in the material has lost its original kinetic energy and only the energy from the impacting photon affects the linear kinetic energy of the ejected electron. However, also through collisions in the material the ejected electron all rotational and vibrational kinetic energy is lost and only the energy from the impacting photon is retained by the ejected electron. Therefore, the resulting equation for the Photoelectric must be \( hf = (\frac{1}{2}mv^2 + \frac{1}{2}I\omega^2 + \frac{1}{2}kx_0^2) \max + \phi \) to include the rotational and /or vibrational kinetic energies if present in the final Photoelectric Effect equation.
12:03PM Y05.00005: Ultralow-power nonlinear optics using optical nanofibers in metastable xenon atoms*

HARI LAMSAL (Presenter), JAMES FRANSON, TODD BUTLER PITTMAN, Department of Physics, University of Maryland, Baltimore County — Nonlinear optics (NLO) is a very broad field with applications ranging from frequency conversion and all-optical switching to quantum computing. For many of these applications, the use of low power lasers is desirable. Consequently, there is currently a push for the realization of new physical platforms enabling ultralow-power NLO. We study a promising ultralow-power NLO platform consisting of an optical nanofiber (ONF) suspended in a gas of metastable xenon atoms (Xe*). The origin of strong nonlinearity in this platform is due to the tight confinement of the ONF guided evanescent mode (~1 μm²) over a long distance (~1 cm), and a resonant interaction of the mode with the surrounding atoms. In this talk, I will describe how we develop our experimental “ONF in Xe*” platform, with ONF’s having long life, and no degradation of transmission through them. I then will explain the experimental result of ultralow-power (nWs level) saturation effects using the platform.

*This work is supported by National Science Foundation (NSF) (1402708).

JEFFREY LINDEMUTH (Presenter), Lake Shore Cryotronics (United States) — The Hall effect, discovered in 1879 by E. Hall, is the primary method to measure carrier density, mobility and carrier type in materials. The most common method for measuring the Hall effect in semiconductors uses a DC magnetic field. This method depends are reversing the direction of the magnetic field. For some applications, especially low mobility materials, the use of an AC field instead of a DC field provides better measurements. Using the field reciprocity theorem, it is possible to generate the same hall measurements without the use of an external AC field. The frequency of this “effective AC field” is determined by the rate of interchanging the current and voltage leads attached to the sample and is not limited by the induction of the magnet generating the DC field. The current excitation can also be modulated by switching the direction of the current leads. The frequency of the effective AC field and the AC current do not have to be the same. This provides the opportunity of dual frequency (AC field/AC current) hall measurements over a wide, and independent, frequency range. Measurements of low mobility (< 1 cm²/(V s) materials will be presented.

12:27PM Y05.00007: Morphology of copper using lateral electrodeposition suitable for low-temperature soldering of microelectronic devices*

SABRINA ROSA (Presenter), ARASH TAKSHI, University of South Florida — Lateral copper growth for the development of electroplating technique as a low-temperature soldering procedure allows modification of the morphology and properties of soldering joints. The approach is particularly useful for soldering electronic components to a plastic 3D printed substrate and printed circuit boards(PCBs). Miniaturization of PCBs has shown an improvement in the efficiency and properties of electronic devices leading to new applications. An electrode pattern was used with a separation gap of 1mm. A junction between the two working electrodes was reported to occur in less than 1 minute, this result ensures the participation of the electrolyte. Hydrogen bubbles released after the electrolysis caused the structure of the electroplated layer to be more porous suitable for sensors and other applications. The morphology of copper deposits based on the interaction with hydrogen was examined using Scanning Electron Microscopy (SEM) technique. Further experiments are required to optimize the soldering process for 3D approaches allowing interconnections of microelectronic devices.

12:39PM Y05.00008: Effect of Evaporation Boundary Condition on The Consolidation and Crack Propagation in Drying Colloidal Films*

HAN GAO, School of Mechanical Engineering and Automation, Beihang University, JIAJIA ZHOU, MASAO DOI, Center of Soft Matter Physics and its Applications, Beihang University, YE XU (Presenter), School of Mechanical Engineering and Automation, Beihang University — We investigate the dynamics of consolidation front growth and the subsequent crack propagation during the directional drying of colloidal film. By varying the geometry of the drying boundary, we observe that the shape of the consolidation front evolve from the shape of the boundary to one with smallest curvature. We also find the direction of the crack propagation keeps perpendicular to the consolidation front, resulting curved cracks. A theoretical model is developed to explain the evolution of consolidation front. Our finding allows us to explore other evaporation boundary conditions, such as temperature and humidity gradient, to control the direction of crack propagation in drying colloidal films.

Friday, March 8, 2019 11:15 AM - 1:51 PM
11:15AM Y06.00001: The role of Joule heating in the voltage-triggered insulator-to-metal transition in VO$_2$.\textsuperscript{*}

ALYSON SPITZIG (Presenter), ALEX J FRENZEL, JEEHOON KIM, Physics, Harvard University, CHANGHYUN KO, SEAS, Harvard University, SHRIRAM RAMANATHAN, School of Materials Engineering, Purdue University, JENNIFER HOFFMAN, JASON D HOFFMAN, Physics, Harvard University — VO$_2$ undergoes a conductivity increase of up to five orders of magnitude as the temperature is increased through 341 K. Recently, the insulator-to-metal transition (IMT) has been triggered with an applied voltage, but debate remains as to whether the transition can be due to electric field effects alone, or whether Joule heating is necessary. Here, we use a conductive AFM tip to locally apply a voltage bias and measure the current through a VO$_2$ film. By fitting the $i/v$ curves immediately preceding the IMT to the temperature-dependent Poole-Frenkel conduction mechanism, we determine the local temperature of VO$_2$ in the insulating state. We find that the tip has locally warmed the film to 335 K ± 4 K immediately preceding the transition. Therefore, Joule heating plays a significant role in the voltage-triggered IMT in VO$_2$.

\textsuperscript{*}AS was funded by NSERC CGSM #6563, JDH was funded by Gordon and Betty Moore Foundation EPiQS Initiative Grant No. GBMF4536, NSF Grant No. DMR-1231319, sample fabrication funded by AFOSR Grant No. FA9550-08-1-0203.

11:27AM Y06.00002: Self-consistent GW study of VO$_2$\textsuperscript{*}

ANDREY KUTEPOV (Presenter), Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory — The question of the metal-insulator transition (MIT) in VO$_2$ remains open. Hybrid functionals [1] and non-self-consistent G$_0$W$_0$ [2] studies state that non-local exact exchange (EEX, included in hybrids and GW) is the most important. However, the arbitrariness of the percentage of EEX (hybrids) or of the starting point (G$_0$W$_0$) makes the agreement of the results with experiment not convincing. From the LDA+DMFT studies of VO$_2$ [3,4] it follows that strong on-site correlations are important for MIT. However, LDA+DMFT operates with local parameters (U and J) and the argument in favor of strong correlations might be just a consequence of missing the non-local EEX in LDA+DMFT. The talk will be about the role of self-consistency in GW approach, which eliminates dependence on the starting point. It will be shown that indeed the GW level of theory provide all necessary basis for description of MIT in VO$_2$ quantitatively.

11:39AM Y06.00003: Microstructural Engineering of the UV/Near-UV Photocurrent Production in VO$_2$ Thin Film Based Detectors\textsuperscript{*}

JASON CREEDEN (Presenter), SCOTT MADARAS, DOUG BERINGER, MELISSA R BEEBE, IRINA NOVIKOVA, ROSA ALEJANDRA Lukaszew, Physics, William & Mary — We sought to optimize the photosensitivity of VO$_2$ thin films in the near-UV (NUV) and UV regions after recent reports demonstrating it is possible to push the typical IR photoresponse of VO$_2$ into the visible spectrum via thin film growth on TiO$_2$:Nb substrates. By controlling the microstructure of the films via deposition parameters and substrate doping, we optimize VO$_2$ growth for TiO$_2$ and TiO$_2$:Nb substrates and compare their photocurrent response using 405 nm (NUV) and 254 nm (UV) light. We found that the VO$_2$ on TiO$_2$:Nb heterostructure demonstrates greater photocurrent response. By measuring the external quantum efficiency (EQE), we found a dramatic photosensitivity improvement for the VO$_2$ on TiO$_2$:Nb compared to undoped TiO$_2$ substrates. Notably, we demonstrated greater than 100% EQE for VO$_2$ on TiO$_2$:Nb for both wavelengths and an improvement in the EQE using UV in comparison to the NUV. Finally, we additionally propose a mechanism for this photoresponse which potentially allows for greater than 100% EQE.

\textsuperscript{*}We would like to thank the Defense Threat Reduction Agency (HDTRA 1-16-1-0056) for the continued support and funding for the project.
11:51AM Y06.00004: An infrared investigation of the insulator-to-metal transition in a thin, epitaxially strained VO₂ film* DAVID LAHNEMAN (Presenter), PATRICK MCARDLE, MUHAMMAD M QAZILBASH, Department of Physics, College of William & Mary, TETIANA SLUSAR, HYUN-TAK KIM, Metal-Insulator Transition Laboratory, Electronics and Telecommunications Research Institute — The insulator-to-metal transition temperature of vanadium dioxide (VO₂) can be tuned through epitaxial strain induced by lattice mismatch between a thin VO₂ film and the substrate. Here we report infrared and optical measurements on a very thin (~ 10 nm) VO₂ film on (001) TiO₂ substrate with an insulator-to-metal transition temperature of ~ 305 K, just above room temperature. We map the transition as it evolves in temperature using near-field imaging at a wavelength of ~10μm from a mid-infrared laser. Using our tabletop home-built argon plasma light source, we obtain the broadband near-field infrared spectra on the pristine substrate and the film-substrate system.

12:03PM Y06.00005: Correlation-driven metal-insulator transitions in hydrogenated VO₂* SE YOUNG PARK (Presenter), Center for Correlated Electron Systems (CCES), Institute for Basic Science (IBS), SO YEUN KIM, Department of Physics and Astronomy, Seoul National University, STEFFEN BACKES, Centre de Physique Théorique, Ecole Polytechnique, France, BYUNG CHEOL PARK, Center for Correlated Electron Systems (CCES), Institute for Basic Science (IBS), JUNWOO SON, HYOJIN YOON, Department of Materials Science and Engineering, Pohang University of Science and Technology (POSTECH), TAE WON NOH, Center for Correlated Electron Systems (CCES), Institute for Basic Science (IBS), SILKE BIERMANN, Centre de Physique Théorique, Ecole Polytechnique, France — We investigate the electronic and optical properties of hydrogenated HₓVO₂. We find doping-dependent metal-insulator transitions as increasing hydrogen content from the optical conductivity measured by spectroscopic ellipsometry, showing a gap opening with a structural transition forming V-V dimer as increasing the H doping. The insulating phase is investigated using density functional and dynamical mean-field theory. We identify the orbital-ordered paramagnetic insulating phase as the ground state of HVO₂ in which both the dimer-induced bonding-antibonding splitting and the orbital ordering stabilized by electron correlations play an important role in the metal-insulator transition. We compare the calculated optical conductivity of the metallic and insulating phases with experimental data and discuss the increase in the charge transfer energy with high hydrogen content.

12:15PM Y06.00006: Insights into the anomalous thermal properties of VO₂ from synchrotron spectromicroscopy SUHAS KUMAR, Hewlett Packard Labs, STEPHANIE BOHAICHUK (Presenter), Stanford University, LU CHEN, University of Michigan, ADITYA SOOD, Stanford University, DAVID A SHAPIRO, Lawrence Berkeley National Laboratory, HAIDONG ZHOU, University of Tennessee, AARON M LINDENBERG, Stanford University, LU LI, University of Michigan, STANLEY WILLIAMS, Hewlett Packard Labs, ERIC POP, Stanford University — Within the last year there have been reports on two distinct anomalous behaviors of the thermal conductivity of VO₂ across its insulator-metal transition, namely: (1) a violation of the Wiedemann Franz law and (2) a giant peak in thermal conductivity during the transition. These have not been captured by physical models, and an understanding of their origin requires in situ probing of both the electronic and structural transitions in VO₂ with very high spatial and thermal resolution. Here we performed temperature-controlled scanning X-ray absorption spectromicroscopy (SXASM), using synchrotron radiation with <30 nm spatial resolution, on single crystal VO₂ that exhibited these anomalies in thermal conductivity. SXASM revealed distinct signatures of the Mott electronic transition and the Peierls structural distortion, which occurred at slightly different temperatures, with the electronic transition occurring first. These results are combined with measurements of thermal conductivity, Seebeck coefficient, and electrical conductivity. We juxtapose these multi-dimensional data sets to shine light on possible correlations between the different transitions and the anomalous changes in VO₂ thermal properties.
**12:27PM Y06.00007: Modulating metal-insulator transitions in VOX by tuning oxygen stoichiometry**  
MINHAN LEE (Presenter), YOAV KALCHEIM, JAVIER DEL VALLE, IVAN SCHULLER, Department of Physics and Center for Advanced Nanoscience, University of California - San Diego — Thermally driven metal-insulator transitions (MITs) in vanadium oxides (VOX) have been of special interest in fundamental physics and oxide electronics. The existence of multi-valence states of vanadium leads to a complicated vanadium-oxygen phase diagram. Moreover, for thin films, finite size or strain effects can alter the physical and thermodynamic properties of the V-O system. Therefore, precise oxygen stoichiometry control in these oxide films remains an outstanding issue and a clear phase stability diagram has not yet been found. We demonstrate a gas evolution technique to precisely modify the oxygen stoichiometry in VOX thin films grown on sapphire substrates. By carefully tuning the temperature-oxygen partial pressure-time relationship, controlled phase evolution between VO2, V2O3 and Magnéli phases (VnO2n-1) was achieved, along with the detailed characterization of their electrical transport and structural properties. Moreover, we show that high quality films, with well-defined MITs can be synthesized this way.

**12:39PM Y06.00008: Non-Gaussian resistance noise behavior across the metal-insulator transition in VO2 thin films**  
AHMED ALI (Presenter), DASHARATH ADHIKARI, COLIN P KILCOYNE, SAMBANDAMURTHY GANAPATHY, Physics, University at Buffalo — Vanadium dioxide (VO2) thin films exhibit a sharp metal-insulator transition (MIT) at a critical temperature ~ 330 K. The significance of a Peierls-type instability or a Mott-Hubbard-type transition near Tc has been a topic of discussion for many years. We present results from a resistance noise spectroscopy study of VO2 thin films that show that the power spectral density (PSD) of the fluctuations near Tc show a marked deviation from the metallic and insulating phases. The PSD increases by orders of magnitude and deviates from a typical 1/f behavior near Tc. The probability density function (PDF) of the fluctuation is non-Gaussian in nature in thin films near Tc whereas the fluctuations are Gaussian at all temperatures in single crystal nanobeams. Our results suggest that the transition likely occurs as a single domain phenomenon in nanobeams whereas the nucleation and propagation of multiple domains of opposite phase are significant near Tc in thin films. The influence of the coexistence of phases on electrical transport will be discussed based on our analysis of the 1/f behavior, PSD, PDF and the second spectrum of noise.

**12:51PM Y06.00009: Resonant Hard X-ray Emission Spectroscopy of VO2 Thin Films in Metallic and Insulating Phases**  
SUNG SOO HA (Presenter), SEOKJUN CHOI, MOHD FAIYAZ, Gwangju Institute of Science and Technology, SUYONG LEE, Pohang Accelerator Laboratory, Pohang University of Science and Technology, DO YOUNG NOH, Gwangju Institute of Science and Technology — Resonant X-ray emission spectroscopy (XES) was carried out to study the metal-insulator transition (MIT) of vanadium dioxide. The Vanadium K-beta emission spectra including kβ2,5 and kβ1,3 both in the metallic and insulating phase were monitored with an x-ray energy resolution of about 1.6 eV at the 3rd generation Pohang Accelerator Laboratory using a highly oriented pyrolytic graphite (HOPG) spectrometer in von-Hamos geometry. The K-beta emission intensities were monitored as the excitation x-ray energy was scanned through the Vandium K-edge to obtain the X-ray absorption near edge structure (XANES) profile. In both the emission spectra and the XANES profile, the difference between the insulating and metallic phase was clearly observed. We also observed distinct resonant behavior in the elastic/inelastic scattering intensity. The physical interpretation of the resonant behavior will be discussed in relation with the energy band structure of the insulating and metallic phase of VO2.

Resistance fluctuation of V$_2$O$_3$ films near the metal-insulator transition

LIYANG CHEN

Presenter, PANPAN ZHOU, Rice University, YOAV KALCHEIM, IVAN SCHULLER, University of California San Diego, DOUGLAS NATELSON, Rice University — The metal-insulator transition in the correlated material V$_2$O$_3$ is a highly studied phenomenon. Recent research has shown the nanotextured phase coexistence around the transition temperature ($T_c$) in V$_2$O$_3$ films, but the dynamic electronic properties are still not well resolved. Here, we study resistance fluctuations as a function of time in both low frequency (< 300 kHz) and higher frequency (225MHz-580MHz) ranges, comparing them to show the dynamic properties at both low and high frequency. We performed measurements at temperatures above $T_c$, close to $T_c$, and below $T_c$. We found 1/f type noise close to and below (yet near) $T_c$ as expected at low frequencies, and similar resistance fluctuation noise (mean square voltage fluctuations proportional to the square of the bias current) at higher frequency. However, the integrated noise intensity at high frequency exceeds our expectation based on an extrapolation of the observed low frequency data. More detailed measurements and experiments are ongoing to reveal the mechanism that causes the resistance fluctuations in V$_2$O$_3$ films near the metal-insulator transition.

The authors acknowledge support from the U.S. DOE office of Science/Basic Energy Science Award DE-FG02-06ER46337.

The role of defects on the metal-insulator transition in V$_2$O$_3$ and VO$_2$

DARSHANA WICKRAMARATNE

Presenter, NRC Research Associate residing at, US Naval Research Laboratory, Washington, DC 20375, USA, NOAM BERNSTEIN, IGOR MAZIN, Center for Computational Materials Science, US Naval Research Laboratory, Washington, DC 20375, USA — V$_2$O$_3$ and VO$_2$, are prototypical strongly-correlated materials that undergo a metal-insulator transition (MIT). The MIT in both materials leads to a concomitant structural phase transition and a magnetic phase transition in V$_2$O$_3$. Recent experiments [PRB 91, 205123, 2015] explored the sensitivity of the MIT to defects and demonstrated the MIT phenomenon in V$_2$O$_3$ is sensitive to the presence of defects while it is robust in VO$_2$. To explore the underlying mechanisms for this behavior we performed first-principles calculations to assess the role of defects on the structural, magnetic and electronic properties of V$_2$O$_3$ and VO$_2$. In V$_2$O$_3$ we find defects disrupt the antiferromagnetic (AFM) order in the insulating phase. We also find small polarons form through self-trapping or due to defects. We assess the impact of this phenomenon on the spin-flip energy between the metallic paramagnetic and the insulating AFM state with the goal of understanding how this impacts the MIT temperature. In VO$_2$, we explore the impact of defects on the vanadium dimerization in the insulating phase and the impact on the MIT.

NB and IM were supported by Office of the Undersecretary of Defense for Research and Engineering’s Basic Research Office through the LUCI. DW was supported by a NRC associateship at the US NRL.

NMR and bulk studies on S=1/2 spin chain Bi$_6$V$_3$O$_{16}$

TANMOY CHAKRABARTY

Presenter, IVO HEINMAA, Physics, NICPB, VALERIY YU. VERCHENKO, Chemistry, Lomonosov Moscow State University, P L PAULOSE, DCMPMS, TIIFR, RAIVO STERN, Physics, NICPB — We report the NMR and bulk properties of a vanadium based S=1/2 spin chain compound Bi$_6$V$_3$O$_{16}$ in its low temperature phase where the magnetic V$^{4+}$ ions are arranged in a one-dimensional chain mediated by V$^{5+}$ and oxygen ions. We have carried out magnetic and heat capacity measurements, both static and magic angle spinning (MAS) $^{51}$V NMR measurements and analysis for unaligned powder sample. The magnetic susceptibility $\chi$ shows a broad maximum around 50 K signifying a short-range magnetic order which matches well with the S=1/2 Heisenberg chain model. In the NMR measurements, we only detected the non-magnetic $^{51}$V. The spin susceptibility calculated from the shift of the static $^{51}$V NMR spectra reproduces well the behavior observed in $\chi$. The MAS NMR experiments reproduce the trend observed in $\chi$ and static NMR with unprecedented accuracy, and confirm that there is only one site the V$^{4+}$ ions are occupying. We have also performed and analyzed spin-lattice relaxation measurements of $^{51}$V.

Department of Science and Technology, Government of India, Mobilitas-Plus Estonian fellowships (MOBJD295, MOBJD449), European Regional Development Fund (TK134), Estonian research council (PRG4) and Government of Estonia (IUT23-7)
SCOTT MADARAS (Presenter), JASON CREEDEN, DOUG BERINGER, IRINA NOVIKOVA, ROSA ALEJANDRA LUKASZEW, Physics, William and Mary — We have studied vanadium dioxide (VO2) films grown on titanium dioxide (TiO2) substrates to investigate the properties of the heterojunction that forms at the interface between substrate and film with the purpose of applying it as an UV photodetector. The use of niobium as dopant on TiO2 substrates has been shown to favorably modify the energy levels at the heterojunction thus promoting photocurrent generation when illuminated with UV light. To further investigate this electronic structure modifications we study the ultrafast dynamics of the insulator-metal-transition (IMT) in such samples by using a pump probe configuration. The samples are pumped with ~150 fs pulses of 400nm wavelength light, and the changes in electronic structure of the heterojunction region are detected via change in relative optical reflectance (ΔR/R) of a 800nm probe light. The VO2 on TiO2:Nb doped samples generate distinctive ΔR/R effects compared with the VO2 films deposited on plain TiO2 substrates samples that are undoped.

Session Y08 DCMP DMP: Superconducting Devices and Applications BCEC 150 - Lei Wang, Yale Univ

11:15AM Y08.00001: Ferroelectric control of superconductivity in an oxide interface* PRASANNA KUMAR ROUT, YORAM DAGAN (Presenter), Tel Aviv University — We study the transport properties of two-dimensional (2D) interfaces between a (3D) ferroelectric oxide and a polar one. The interface is superconducting with a transition temperature of 300mK. From the analysis of the anisotropy of the critical fields we find that superconductivity is 2D in nature. The resistance and the Hall conductance of the interface exhibit a hysteretic behavior as a function of gate voltage. The area of the hysteresis loop becomes zero at the ferroelectric transition temperature. A hysteretic dependence on gate voltage is also seen for the superconducting transition temperature and critical fields. We discuss possible interplay between superconductivity and ferroelectricity at this interface.

*Support from the Israeli Science Foundation is acknowledged

11:27AM Y08.00002: Tunable superconducting devices with a reconfigurable artificial-spin-ice* YANGYANG LYU (Presenter), Nanjing University, XIAOYU MA, University of Notre Dame, JING XU, Northern Illinois University, YONGLEI WANG, Nanjing University, ZHILI XIAO, Argonne National Laboratory, HUABING WANG, Nanjing University, RALU DIVAN, JOHN E. PEARSON, Argonne National Laboratory, BOLDIZSAR JANKO, University of Notre Dame, WAI-KWONG KWOK, Argonne National Laboratory — Recent work has shown that the magnetic charges in an artificial spin ice can strongly influence the properties of materials in contact with the spin ice structure [Science 352, 962 (2016) & Nature Nano. 13, 560 (2018)]. Here, we present a novel heterostructure combining a newly-introduced artificial spin ice pattern with a superconducting MoGe film. The reconfigurable magnetic template produced by artificial spin ice strongly couples with the vortices in the superconducting film, which enables us to control its transport properties. We will demonstrate some tunable functions of this artificial-spin-ice and superconductor heterostructure.

*The experiments were supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division and by DOE BES under Contract No. DE-AC02-06CH11357 that also funds Argonne's Center for Nanoscale Materials (CNM) where the nanopatterning was performed. YYL and YLW was supported by NSFC under Contract No. 61771235.

11:39AM Y08.00003: Estimating the effect of grain boundaries on the superconducting superheating field in 2D Ginzburg-Landau Theory* ALDEN PACK (Presenter), MARK TRANSTRUM, JARED CARLSON, Brigham Young University — The Meissner effect is the expulsion of an applied magnetic field by a superconducting material. For large applied fields, a surface effect creates barrier to vortex nucleation so that the Meissner state may persist in a meta-stable state up to a critical, superheating field. We study the role of grain boundaries, including surface morphology and material inhomogeneity, on vortex nucleation within two-dimensional Ginzburg-Landau theory. Our simulations mimic conditions observed in Nb3Sn SRF cavities using in particle accelerators. We show how defects lower the superheating field and discuss implications for SRF cavity performance and development.

**11:51AM Y08.00004: Tunneling spectroscopy of Nb/Al bilayers for superconducting computing**  
ZAC BARCIKOWSKI (Presenter), University of Maryland, College Park, JOSHUA POMEROY, MICHAEL DAVID STEWART, National Institute of Standards and Technology — Niobium and aluminum, and the compounds made from them, are important materials in the superconducting computing community. However, much remains to be explored to understand the interaction of states between Nb based superconductors and Al, and how these properties can be used to improve tunnel junctions and cavities. Tunneling spectra of normal metal (N)/insulator (I)/superconducting bilayer (S) tunnel junctions are found to vary significantly as a function of the thickness of the bilayer elements. We present N/I/S tunnel junctions fabricated with various Al thicknesses in the superconducting bilayer electrode. Tunneling spectra are measured at 4 K and fit using Maki analysis to extract orbital depairing and spin-orbit parameters.

**12:03PM Y08.00005: Proximity effect of Nb/Al superlattice as a superconducting resonator**  
LONG CHENG (Presenter), SANGIL KWON, Institute for Quantum Computing, University of Waterloo, HAMID R. MOHEBBI, High Q Technologies LP, YONGCHAO TANG, DAVID CORY, GUOXING MIAO, Institute for Quantum Computing, University of Waterloo — Superconducting resonator has evoked growing interest due to the wide spectrum of applications, especially in the booming realm of quantum information and quantum computing. How to achieve high-Q resonators as well as the ones maintaining high Q in a modest magnetic field are the long-standing goals and persistently explored issues. Here we systematically study how the proximity effect influence the performance of Nb/Al superlattice resonators. We fabricate a series of Nb/Al superlattice resonators with total thickness of 50 nm, while the number of repetition ranges from 1 (ie, 25nm Nb/25 nm Al) to 20 (ie, (1.25nm Nb/1.25nm Al)20). The DC transport measurement shows the proximity effect becomes stronger with the increasing number of repetition, while microwave measurement shows non-monotonic dependence of Q value, which may be ascribed to the competition between the enhanced proximity effect and the reduced mean free path of electrons. Based on this work, we are able to find the optimal design for proximity enhancement, which may be beneficial for further exploring high performance resonators.

*Natural Sciences and Engineering Research Council of Canada (NSERC) Discovery grant RGPIN-04178, and Ontario Early Researcher Award

**12:15PM Y08.00006: Ternary and higher order classical cryogenic memory cells**  
NIKETH NAIR (Presenter), YEHUDA BRAIMAN, Oak Ridge National Laboratory — For many classical cryogenic computing applications, a key issue in designing powerful and practical systems is the scaling of memory. In particular, the amount of circuitry required to build and access memory units has limited the amount of information that it is possible to store. A possible solution to this problem is to consider designs that store more information in a single memory unit. Therefore, it may be beneficial considering ternary and higher order multivalued memory systems that use the same number of Josephson junctions as binary units.

In this talk we will present a ternary cryogenic memory cell paradigm based on an array of inductively coupled Josephson junctions[1]. We show how reading, writing and resetting are implemented using single flux quantum (SFQ) current pulse inputs and outputs from the circuit. We further show how both destructive readout (DRO) and nondestructive readout (NDRO) can be implemented.

*Support for this work was provided by the US Department of Energy, Office of Science, Advanced Scientific Computing Research. Oak Ridge National Laboratory is managed by UT-Battelle, LLC for the US Department of Energy under Contract No. DE-AC05-00OR22725.
12:27PM Y08.00007: Vortex rectenna powered by environmental fluctuations*  
JANA LUSTIKOVA (Presenter), Institute for Materials Research, Tohoku University, YUKI SHIOMI, Quantum-Phase Electronics Center, University of Tokyo, NAOTO YOKOI, Institute for Materials Research, Tohoku University, NORIYUKI KABEYA, NORIAKI KIMURA, Center for Low Temperature Science, Tohoku University, KOICHIRO IENAGA, SHIN-ICHI KANEGO, SATOSHI OKUMA, Department of Physics, Tokyo Institute of Technology, SABURO TAKAHASHI, Institute for Materials Research, Tohoku University, EJI SAITO, Department of Applied Physics, University of Tokyo — A rectenna, standing for a rectifying antenna, is an apparatus which generates d.c. electricity from electric fluctuations. It is expected to realize wireless power transmission as well as energy harvesting from environmental radio waves. To realize such rectification, devices that are made up of internal atomic asymmetry such as an asymmetric junction have been necessary so far. Here we report a material that spontaneously generates electricity by rectifying environmental fluctuations without using atomic asymmetry [Lustikova et al., Nat Commun (2018)]. The sample is a common superconductor without lowered crystalline symmetry, but, just by putting it in an asymmetric magnetic environment, it turns into a rectifier and starts generating electricity. Superconducting vortex strings only annihilate and nucleate at surfaces, and this allows the bulk electrons to feel surface fluctuations in an asymmetric environment: a vortex rectenna. The rectification and generation can be switched on and off with only a slight change in temperature or external magnetic fields.

12:39PM Y08.00008: Superconducting Microwave Circuits with High Kinetic Inductance Materials in High Magnetic Fields  
AZARIN ZARASSI (Presenter), JEN-FENG HSU, TZU-CHIAO CHIEN, XI CAO, MICHAEL HATRIDGE, SERGEY M FROLOV, University of Pittsburgh — We report our experimental progress towards a semiconducting nanowire Josephson junction fluxonium. We fabricate co-planar waveguide and meander nanowire superconducting resonators from NbTiN and NbN thin films. These resonators exhibit a wide range of intrinsic quality factors based on fabrication methods, including lift off versus etching. They maintain their quality factors in finite magnetic fields. These thin-film resonators provide large kinetic-inductance boosts where they can be used as the large shunting inductor in a fluxonium qubit where the nonlinear element is either a conventional Al/AlOx/Al Josephson junction or a semiconducting nanowire weak link.

12:51PM Y08.00009: Geometric Superinductors for Mesoscopic Physics*  
MATILDA PERUZZO (Presenter), ANDREA TRIONI, MARTIN ZEMLICKA, Institute of Science and Technology Austria, 3400 Klosterneuburg, Austria, LISA ARNDT, FABIAN HASSLER, JARA Institute for Quantum Information, RWTH Aachen University, 52056 Aachen, Germany, JOHANNES FINK, Institute of Science and Technology Austria, 3400 Klosterneuburg, Austria — High impedance has recently risen as a tool for circuit engineering in cQED. For regular microwave circuits the agreed upon impedance is 50Ω, vacuum itself has an impedance of 377Ω. In the quantum realm however there is a threshold above which a superconducting circuit is considered high impedance, the resistance quantum RQ=6kΩ. In fact impedance of the environment affects the quantum fluctuations of phase and charge and when the quantum resistance is surpassed charge fluctuations are suppressed to below 2e. Most interesting is the behavior of the Josephson junction (a key element for superconducting qubits) in this regime. The low charge fluctuations allow for the measurement of Coulomb blockade and Bloch oscillations of charge. This work demonstrates how the use of geometric superconducting inductors can become a new method to achieve high impedance. The inductor consists of a superconducting high density planar coil suspended on a 220nm silicon membrane which can achieve characteristic impedances of 14kΩ while having a self-resonance frequency above 8GHz. We present this new circuit element and it’s applications for the measurement of Josephson junctions in the high impedance regime.

*We aknowledge support from the NOMIS Foundation
Quantum thermodynamics in superconducting circuits

JORDEN SENIOR (Presenter), ALBERTO RONZANI, BAYAN KARIMI, YU-CHENG CHANG, AZAT GUBAYDULLIN, JOonas T PELTONEN, QTF Centre of Excellence, Aalto University, CHIIDONG CHEN, Institute of Physics, Academia Sinica (Taiwan), JUKKA P PEKOLA, QTF Centre of Excellence, Aalto University — Quantum thermodynamics has become a field of increasing importance in recent years, the understanding of heat transport at the quantum limit, having broad ranging applications, for example in circuit QED experiments, and nanoscale physics.

By integrating the tools of ultra-sensitive microwave bolometry with those of superconducting circuits (qubits), we present a platform for investigating fundamental quantum thermodynamics in mesoscopic systems, and our initial experimental realizations.

We will present recent observations of flux-tunable photonic heat transport between thermal baths embedded in both equal (quantum heat valve) and unequal (quantum heat engine) resonant environments interfaced by a transmon qubit. We demonstrate that the coupling to the qubit mediates the interface between the classical and quasi-Hamiltonian regime for this transport in the static-flux limit [1], and present our initial findings for a driven-flux system.

This work was supported by the Centre for Quantum Engineering (CQE) at Aalto University, OtaNano, and VTT Technical Research Center.

Spectroscopy of the two unequal superconducting resonators coupled via transmon qubit for the realization of the quantum heat engine

AZAT GUBAYDULLIN (Presenter), JORDEN SENIOR, BAYAN KARIMI, QTF Centre of Excellence, Department of Applied Physics, Aalto University, YU-CHENG CHANG, Department of Physics, National Taiwan University, JOonas T PELTONEN, QTF Centre of Excellence, Department of Applied Physics, Aalto University, CHIIDONG CHEN, Department of Physics, National Taiwan University, JUKKA P PEKOLA, QTF Centre of Excellence, Department of Applied Physics, Aalto University — Progress in both superconducting circuit QED experiments and ultrasensitive nanoscale bolometry provide a unique platform for studying heat transport in the quantum limit, towards the realization of quantum heat engines and refrigerators [1,2]. Transmon qubits coupled to superconducting resonators have been considered as promising candidates for realizing such quantum systems, such as the recently demonstrated quantum heat valve [3]. This work is devoted to study both theoretically and experimentally the transmission spectrum of the resonator-qubit-resonator assembly, in both the equal (valve) and unequal (engine) resonators regimes. For the realization of the quantum heat engine, we study the flux-tunable photonic heat transport in the resonator-qubit-resonator assembly with unequal resonators terminated by mesoscopic normal-metal reservoirs. Additionally, a means to characterize a superconducting resonator shunted with a highly dissipative normal metal bolometer is presented.

1:27PM Y08.00012: 1D Josephson chains isolated from the environment by superinductors* WEN-SEN LU (Presenter), KONSTANTIN KALASHNIKOV, PLAMEN KAMENOV, WENYUAN ZHANG, MICHAEL GERSHENSON, Rutgers University, New Brunswick — Superinductors offer new types of functionality, including non-dissipative high-impedance isolation of quantum circuits from the environment [i]. In our work we studied the chains of Josephson junctions (JJs) and individual JJs isolated from the environment by the superinductors made of strongly disordered Aluminum [ii]. The superinductors have been fabricated as nanowire meanders with small in-plane dimensions (to reduce parasitics) and the kinetic inductance up to 3 µH. We measured the current-voltage characteristics of JJ circuits with the normal-state resistance of individual JJs varied between 1 kΩ and 100 kΩ, and we observed the transition between thermally activated phase diffusion and macroscopic quantum tunneling regimes. We will also discuss application of superinductors for the observation of Bloch oscillations in Josephson circuits.

1:39PM Y08.00013: Microwave Microscopy of Materials Limitations of Superconducting RF Cavities* BAKHROM ORIPOV (Presenter), STEVEN ANLAGE, University of Maryland, College Park — There are considerable efforts world-wide to improve particle accelerators by using Superconducting Radio Frequency (SRF) cavities which are limited by surface defects which lead to cavity breakdown at high accelerating gradients. A novel near-field magnetic microwave microscope that can study these defects was successfully built using a magnetic writer from a conventional magnetic recording hard-disk drive. We study the 3rd harmonic response-$V_{3f}(T, H_{rf})$ because it is far more sensitive to rf field amplitude $H_{rf}$ and temperature $(T)$ than linear response measurements. In our experiments on Nb surfaces we observed 2 different classes of nonlinearity depending on the location of the probe, which we call Low-field and Periodic. In the low-field case we observe that $V_{3f}$ increases uniformly as a function of applied rf field amplitude, reaches a peak value and decreases back to 0. In the periodic case $V_{3f}$ has periodic dips at $H_{rf} = H_1(T), H_2(T), H_3(T)$... The periodic case nonlinear response can be linked to Josephson effect at or near the surface and is in good agreement with the nonlinear response expected from rf-current-biased Resistively and Capacitively Shunted Junction (RCSJ) model.

1:51PM Y08.00014: Wafer Bonding Approach for Epitaxial Al/GaAs(001)/Al Tri-layers* ANTHONY MCFADDEN (Presenter), University of California, Santa Barbara, COREY RAE MCRAE, RUSSELL LAKE, National Institute of Standards and Technology (NIST), Boulder, MICHAEL A SEAS, University of California, Santa Barbara, JIANGUO WEN, JIE WANG, ILKE ARSLAN, Center for Nanoscale Materials, Argonne National Laboratory, DAVID PAPPAS, National Institute of Standards and Technology (NIST), Boulder, CHRIS PALMSTROM, University of California, Santa Barbara — Superconductor-insulator-superconductor (Josephson) junctions utilizing amorphous oxide barriers have been studied extensively, however relatively little work has been done using single crystal semiconductors in place of amorphous oxide barriers. This is likely due to difficulty in fabrication of such structures including symmetry mismatch of the semiconductor to the superconductor and the reactions and roughening that may occur at the temperatures needed for semiconductor growth. This work focuses on a wafer bonding approach, subsequent substrate removal, and superconductor regrowth for fabrication of Al/GaAs(001)/Al Josephson junctions. AlGaAs/GaAs/Al structures are grown by molecular beam epitaxy and wafer-bonded to Si. The substrate and sacrificial AlGaAs layers were removed by selective wet etching followed by surface cleaning in ultrahigh vacuum and aluminum regrowth. The wafer bond and Al/GaAs interfaces are studied by transmission electron microscopy. X-ray photoelectron microscopy is used to determine GaAs surface cleaning conditions compatible with the wafer bonding process following substrate removal. X-ray and electron diffraction are used to assess crystalline quality and orientation of the epitaxial aluminum.

2:03PM Y08.00015: Quantum Transport in 2DEGs in Epitaxial GaN Quantum Wells on Superconducting NbN
PHILLIP DANG (Presenter), GURU BAHADUR SINGH KHALSA, Cornell University, D. SCOTT KATZER, NEERAJ NEPAL, BRIAN DOWNEY, United States Naval Research Laboratory, ALEXEY SUSLOV, National High Magnetic Field Laboratory, HUILI XING, Cornell University, DAVID J. MEYER, United States Naval Research Laboratory, DEBDEEP JENA, Cornell University — The epitaxial integration of superconducting NbN with III-N semiconductors was previously demonstrated in our report [Yan et al, Nature 555, 183-189 (2018)]. We have investigated the magnetotransport properties in this superconductor/semiconductor heterostructure, of the two-dimensional electron gas (2DEG) in the GaN quantum well in magnetic fields up to 35 Tesla. The 2DEGs exhibited strong Shubnikov-de Haas (SdH) oscillations that showed indications of spin-splitting as well as Hall-effect resistance plateaus that approach the quantum Hall regime. By varying a gate voltage to sweep the Fermi level, we directly observe the change in carrier concentration through SdH measurements. The associated change in occupation of Landau levels allows us clear access down to the 3rd Landau level. We report our observations of electron scattering processes due to dislocations near the gate-induced pinchoff point of the transistor and compare the scattering of N-polar and Ga-polar HEMTs. We comment on possibility of reaching the quantum Hall state in this material system, which would open a path towards realizing proximitized quantum Hall and superconducting states in a superconductor/semiconductor heterostructure.

Session Y10 DMP DCMP: Surface Science of Organic Molecular Solids, Films, and Nanostructures - Materials Synthesis, Deposition, and Device preparation BCEC 151B - Dane McCamey. - Tag(s): Focus

11:15AM Y10.00001: Magnetism of ultra-short one dimensional atomic chains* [Invited] NICOLAS VARGAS (Presenter), Physics, University of California, San Diego, CARLOS MONTON, Physics and Astronomy, University of Texas at San Antonio, FELIPE TORRES, MIGUEL G KIWI, Physics, Universidad de Chile, DORA ALTBIR, Physics, Universidad de Santiago de Chile, VAGSON CARVALHO-SANTOS, Physics, Universidade Federal de Viçosa, ALEXANDER A. BAKER, TREVOR M WILLEY, Condensed Matter and Materials Division, Lawrence Livermore National Laboratory, IVAN SCHULLER, Physics, University of California, San Diego — Driven by almost a century of theoretical work, the physical realization of one dimensional (1D) magnets has become essential to address pressing problems such as quantum criticality, many-body, spin transport, the emergence of new (topological) magnetic phases, and the extent and persistence of short- and long magnetic interactions as a function of length.

We report structural and magnetic properties of one-dimensional Fe chains as a function of length in the 10 to 200 atoms range. These Fe chains are grown using iron phthalocyanine (FePc) thin films and FePc/ metal-free-phthalocyanine (H2Pc) superlattices (SLs). The length of 1D Fe chains is precisely controlled by the deposited thickness of the FePc layers.

Although structurally identical, 1D Fe chains formed in films and superlattices have different magnetic behavior. In films, the coercive field remains almost constant whereas in SLs increases with the length of the chain. This difference can be explained using a semi-classical model, which combines short range direct Exchange and Dzyaloshinskii-Moriya interactions. The increase of the coercive field in SLs is attributed to a magnetization reversal process which is governed by chiral symmetry breaking produced by a weak magnetic anisotropy. This anisotropy originates at the extreme of the Fe chains by proximity with the H2Pc layers and is observable by element selective X-ray absorption spectroscopy (XAS).

11:51AM Y10.00002: Coordination dependence of cooperative effects in spin crossover [Fe(H₂B(pz)₂)(bipy)] thin film GUANHUA HAO (Presenter), XUANYUAN JIANG, Department of Physics and Astronomy, University of Nebraska-Lincoln, AARON MOSEY, Physics Department, Indiana University Purdue University-Indianapolis, ANDREW J YOST, Department of Physics and Astronomy, University of Nebraska-Lincoln, XIN ZHANG, Department of Chemistry, University of Nebraska-Lincoln, ALPHA N’ DIAYE, Advanced Light Source, Lawrence Berkeley National Laboratory, JIAN ZHANG, Department of Chemistry, University of Nebraska-Lincoln, RUIHUA CHENG, Physics Department, Indiana University Purdue University-Indianapolis, XIAOSHAN XU, PETER A DOWBEN, Department of Physics and Astronomy, University of Nebraska-Lincoln — The electronic state of Fe(II) spin crossover complex [Fe(H₂B(pz)₂)(bipy)] (pz = pyrazol-1-yl, bipy = 2,2'-bipyridine) thin film on Al₂O₃ has been investigated by magnetometry (SQUID) and X-ray absorption spectroscopy (XAS) in both the total electronic yield mode and the photo-luminescence yield mode. The transition temperature of the spin crossover transition has a 20 K difference between the cooling and heating sequence in magnetometry and X-ray absorption spectroscopy taken in both the total electronic yield and photo-luminescence yield modes, indicating cooperative effects in the Fe(II) spin crossover complex. The differences in the hysteresis loop for the spin crossover transition for this Fe(II) spin crossover complex at the surface of the molecular film, extracted from X-ray absorption taken in the total electronic yield mode, differs from the bulk, as obtained from magnetometry and photo-luminescence yield mode X-ray absorption. This indicates the intermolecular interactions between the spin crossover molecules, at the surface of the Fe(II) spin crossover complex thin film, differs from bulk.

12:03PM Y10.00003: Local charge accumulation at a trinuclear metal-organic nanostructure on a surface AGUSTIN SCHIFFRIN (Presenter), CORNELIUS KRULL, MARINA CASTELLI, School of Physics and Astronomy, Monash University, PROKOP HAPALA, Institute of Physics, Czech Academy of Sciences, ANTON TADICH, Australian Synchrotron, MARTINA CAPSONI, Department of Physics and Astronomy, University of British Columbia, MARK T EDMONDS, JOHN HELLERSTEDT, School of Physics and Astronomy, Monash University, SARAH A. BURKE, Department of Physics and Astronomy, University of British Columbia, PAVEL JELINEK, Institute of Physics, Czech Academy of Sciences, DHANEESH KUMAR, School of Physics and Astronomy, Monash University — Coordination chemistry relies on harnessing active metal sites within organic matrices. Polynuclear complexes — consisting of organic ligands bound to several metal atoms — are relevant due to their electronic and magnetic properties, and to their potential for functional reactivity pathways. However, their synthesis remains challenging, with few geometries and configurations that have been achieved. Here, we synthesize — via supramolecular chemistry on a noble metal surface — one-dimensional metal-organic nanostructures composed of terpyridine-based molecules coordinated with well-defined polynuclear iron clusters. Combining low-temperature scanning probe microscopy techniques, density functional theory and x-ray absorption spectroscopy, we demonstrate that the coordination motif consists of coplanar terpyridine groups linked via a quasi-linear tri-iron node with mixed positive valence and a metal–metal bond configuration. This unusual linkage is stabilized by local accumulation of electrons between cations, ligands and metal surface. This morphology, enabled by the bottom-up on-surface synthesis, yields an electronic structure that hints at a chemically active polynuclear metal center, paving the way for nanomaterials with novel catalytic and magnetic functionalities.

12:15PM Y10.00004: Electron Induced Disordering and Decomposition of Alkanethiol Self-assembled Monolayers on Au(111) JODI GRZESKOWIAK (Presenter), University at Albany, CARL VENTRICE, SUNY Polytechnic Institute — Self-assembled monolayers (SAMs) are used for applications such as molecular electronics, selective deposition, and other forms of surface modification. Lithography within the semiconductor industry is adopting shorter wavelengths of light such that the interaction of secondary electrons with the organic resist is becoming the primary mechanism for photo-initiated electro-chemical reactions. To study the interaction of low energy electrons with thin organic films, measurements have been performed on electron induced disordering and decomposition of 1-decanethiol molecules grown via vapor phase deposition on Au(111). These monolayers arrange into two phases commonly referred to as lying down and standing up. The lying down phase is a physisorbed layer that is only weakly interacting with the substrate via Van der Waals forces. Conversely, the standing up phase is a chemisorbed species that is more strongly bound to the substrate. Surface analysis techniques were used to characterize the monolayers before and after electron exposure. LEED was used to determine the structure of the SAM and the rate of disordering and decomposition. TPD was used to evaluate the thermal stability of the attached SAMs and the resulting desorption products after electron exposure.
Assessing Monomer and Aggregate Populations in Squaraine-Based Organic Solar Cells
Catherine Ryczek (Presenter), Adriana Cruz, Physics Department, Hamilton College, Zhila Hooshangi, Chemistry Department, Rochester Institute of Technology, Kristen Burson, Physics Department, Hamilton College, Christopher Collison, Chemistry Department, Rochester Institute of Technology — Higher efficiencies of organic photovoltaic (OPV) devices have often been correlated with structural order within the solid state active layer of the device. Structural order is thought to improve charge mobility and energy transfer since both rely on effective orbital overlap between molecules. Nevertheless, questions remain about the role of electronic aggregates since they may act as energy traps for excited state species after photoexcitation, thereby leading to reduced overall efficiency. We aim to demonstrate how OPV efficiency is indeed related to aggregate (vs. monomer) populations through quantitative measurement. Population can be measured through absorption measurements and with a knowledge of the extinction coefficient of the species in question, along with the path length for the light through the sample. Experimentally, we will focus on the thickness measurements for a set of squaraine films. Squaraines are interesting because their efficiencies are significantly impacted by the exact geometry of aggregation, which can be controlled through chemical tuning. We will therefore use AFM thickness measurements coupled with spectroscopic techniques to confirm the importance of aggregation for molecular design strategy and fully optimized OPV devices.

Tuning the tunneling decay coefficient in self-assembled monolayer junctions
Xiaoping Chen, Harshini Annadata, National University of Singapore, Bernhard Kretz (Presenter), David Egger, University of Regensburg, Christian Nijhuis, National University of Singapore — Having insight into charge transport across organic-inorganic interfaces is important for the development and improvement of molecular electronic devices. Within the regime of quantum tunneling transport, the charge transfer rate strongly depends on the tunneling decay coefficient $\beta$, which determines the decline of the current across the junction as a function of the length and the barrier height. For self-assembled monolayer (SAM) junctions, it is well-known that the value of $\beta$ depends on the specific electronic structure of the molecular backbone. In our combined experimental and computational study, we demonstrate that $\beta$ of a non-conjugated SAM junction can be lowered significantly by using different halogens as termination on one side of the molecular backbone. With our experiments we can also show that this lowering of the tunneling coefficient is correlated with a change in the dielectric constant. Furthermore, our calculations allow for understanding how the frontier orbitals and transmission channels are effected by the change of the end-group.

Coherent X-ray measurement of local step-flow propagation during growth on polycrystalline C$_{60}$ thin film surfaces
Randall Headrick (Presenter), Jeffrey Ulbrandt, Department of Physics and Materials Science Program, University of Vermont, Peco Myint, Division of Materials Science and Engineering, Boston University, Jing Wan, Yang Li, Department of Physics and Materials Science Program, University of Vermont, Andrei Fleurasu, Yugang Zhang, Lutz Wiegart, National Synchrotron Light Source II, Brookhaven National Laboratory, Karl Ludwig, Department of Physics, Boston University — Vacuum deposition of C$_{60}$ on a graphene-coated surface is investigated with X-ray Photon Correlation Spectroscopy in surface-sensitive conditions. Local step-flow is observed through the observation of oscillatory correlations in the later stages of growth after crystalline mounds have formed. An important aspect of the work is that coherent X-rays do not average over complex structures, and this allows us to monitor the growth on polycrystalline surfaces without loss of information. The experimental results show that the step-flow velocity must be nonuniform, and we model the velocity of each step-edge as being a simple function of the lengths of the terraces above and below it. This model predicts that the steps become almost stationary near the edges of the mounds where the local terrace length is very small, and the average slope of the surface is large. It was not previously known that such nonuniform and disordered step arrays as we have observed would follow such a simple growth law. This work shows that the use of coherent X-ray scattering provides an approach to better understand surface dynamics and fluctuations during crystal growth.

Differences in Self-Assembly of Spherical C₆₀ and Planar PTCDA on Rippled Graphene Surfaces*

YANLONG LI (Presenter), Physics, Virginia Tech, XIAOYANG LIU, Chemistry, Virginia Tech, CHUANHUI CHEN, Physics, Virginia Tech, JAMES DUCHAMP, RONG HUANG, Chemistry, Virginia Tech, TING-FUNG CHUNG, Physics, Purdue University, MAXWELL YOUNG, TAREK CHALAL, Physics, Virginia Tech, YONG CHEN, Physics, Purdue University, JAMES R HEFLIN, Physics, Virginia Tech, HARRY DORN, Chemistry, Virginia Tech, CHENGGANG TAO, Physics, Virginia Tech — It was recently recognized that two-dimensional (2D) graphene exhibits nonplanar aberrations such as a rippled surface. Understanding the self-assembly of organic semiconductor molecules on monolayer 2D curved graphene surfaces is a paramount issue for ultimate application. Herein, we report on the preparation of fullerene, C₆₀ and perylenetetracarboxylic dihydride (PTCDA) molecules adsorbed on a rippled graphene surface. We find that the C₆₀ form a quasi-hexagonal close packed (hcp) structure, while the PTCDA form a disordered herringbone structure. These 2D layer systems have been characterized by STM imaging and DFT approaches. The DFT results exhibit interaction energies for adsorbed molecule/rippled graphene complexes located in the 2D graphene valley sites that are significantly larger in comparison with adsorbed planar/molecule graphene 2D complexes. In addition, we report that the adsorbed PTCDA prefer different orientations when the rippled graphene peak regions are compared to the valley regions. This difference in orientations causes the PTCDA molecules to form a disordered herringbone structure on the rippled graphene surface.

Effect of Admixture on Domain Morphology Transitions in Phase Separation of PCBM:tn-ZnPc from CCl₃ Solution

RAYMOND PHANEUF (Presenter), MIRIAM CEZZA, University of Maryland, College Park — We present results of investigations aimed at understanding how small mutually immiscible organic molecules self-assemble into domains during phase separation from liquid solutions. As a prototypical system we investigated molecular mixtures consisting of tetrano zinc-phthalocyanine (tn-ZnPc), an electron donor, and [6,6]-phenyl-C₆₁-butyric acid methyl ester (PCBM), an electron acceptor, in chloroform and deposited on native oxide-covered Si(111) substrates. Previously we showed that for a 1:1 mixture PCBM:tn-ZnPc which has much higher solubility, precipitates onto the silicon substrate with domain morphologies which vary widely over the range of supersaturation rates investigated. For the highest rates the domains are isotropic, and apparently amorphous – with a mesoscale near-periodicity. Slowing the supersaturation rate causes an abrupt change in the domain size and shape, to micron-scale faceted domains; we speculated that either (1) a transition from spontaneous decomposition kinetics to nucleation and growth of crystalline domains or (2) a "cascade" series of transitions through increasingly stable structures was responsible for this. Here we present results in which the admixture of PCBM:tn-ZnPc is varied systematically to distinguish between these two mechanisms.

Abnormal ionic conductance switching under sub-3nm fluid confinement*

SYLVIA XIN LI (Presenter), Chemical Engineering, Massachusetts Institute of Technology, NAM S KIM, Chemistry, University of Maryland, College Park, GARY W RUBLOFF, Materials Science and Engineering, University of Maryland, College Park, SANG BOK LEE, Chemistry, University of Maryland, College Park, MARK A REED, Electrical Engineering, Yale University — Nanoscale protein ion channels are essential to bridge chemical and electrical signals in biological systems. When the confinement length of fluids is below a few nanometers, new transport behavior is expected and continuum-theory might no longer be valid. However, characterization and understanding of ion transport under such extreme confinement is limited. Here we construct solid-state nanofluidic devices with accurate confinement lengths ranging from sub-3nm to 10nm via precise nanofabrication techniques. We perform diverse electrical measurements under both quasi-equilibrium and perturbed states. We observe abnormal ionic conductance switching and propose that these intriguing phenomena result from a complex interplay between ion-surface interaction and confinement effect. These new transport behaviors have potential implications in a wide of applications, such as water treatment, bio-sensing and energy storage and conversion.

Competing on-surface reaction pathways of bifunctional anthracene precursors to obtain organometallic networks

AMELIA DOMINGUEZ-CELORRIO (Presenter), Instituto de Nanociencia de Aragón, Universidad de Zaragoza, Spain, DIEGO PEÑA, Centro Singular de Investigación en Química Química Biológica e Materiais Moleculares (CIQUS) and Departamento de Química Orgánica, Universidad de Santiago de Compostela, Spain, VERONIQUE LANGLAIS, Centre d'Elaboration de Matériaux et d'Etudes Structurelles - Centre National de la Recherche Scientifique, Toulouse, France, DAVID SERRATE, Instituto de Ciencia de Materiales de Aragón, CSIC-Universidad de Zaragoza, Spain — On surface synthesis is a versatile bottom up fabrication approach to create covalent nanostructures with atomic precision. Several organic covalent structures have been created by this approach, such as graphene based structures or organometallic networks. Aiming at the synthesis of a porous network, we study the hierarchy of chemical reactions of 10-bromoanthracene-9-yl-boronic-acid (BABA) precursors that are vapour sublimated onto crystalline surfaces under ultra-high-vacuum conditions. Our scanning tunnelling microscopy and spectroscopy characterization unveils that BABA dehydration to produce boroxine rings and metal substitution of the halogen group take place simultaneously leading to the formation of an organometallic honeycomb network, similarly to the case of using a simple phenyl core instead of anthracene [1]. In our case, however, the competition between these two reactions is extremely dependent on the catalytic role of the substrate, its surface termination and its temperature during the deposition of the precursor. As a consequence, the reaction pathway can be readily controlled by the choice of the catalytic surface (Ag(001), Ag(111) or Ag(111)).

We acknowledge FEDER funds from Interreg POCTEFA program (grant TNSI/EFA194/16)

Session Y19 DMP: Computational Materials Design and Discovery -- Synthesizability and Stability

Networks of materials: a complexity approach to material synthesizability

MURATAHAN AYKOL (Presenter), Toyota Research Institute, VINAY I HEGDE, Northwestern University, SANTOSH SURAM, LINDA HUNG, PATRICK HERRING, Toyota Research Institute, CHRISTOPHER WOLVERTON, Northwestern University, JENS HUMMELSHØJ, Toyota Research Institute — Network science can provide a new arsenal of methods for materials informatics to address some of the daunting challenges in the field of materials. [1,2] One such challenge we address in this talk is the laboratory synthesis of computationally designed materials. The art of synthesis itself is too complex to be treated with an all-encompassing, quantitative approach as yet, because it involves not only the modeling of the energy landscape of competing phases or the kinetics of transformations, but also abstract factors, such as experience of scientists, state-of-the-art in experimental methods, resources and more. We present one of the first examples of “networks of materials” in the form of thermodynamic equilibria derived from high-throughput computational phase diagrams and analyze the local and global properties of this network. [1] We discuss how synthesis probabilities of yet-to-be-made, novel inorganic materials can be predicted from the dynamics of this network via machine-learning, connecting high-throughput computational design and experiments.

Roadmap for the Synthesis of Exotic 2D Metastable Carbon using Topologically Assembled Precursors

PURUSOTTAM JENA (Presenter), HONG FANG, Virginia Commonwealth University — Metastable structures of matter often possess properties superior to those of their ground state. A case in point is diamond vs. graphite. Yet, many predicted metastable structures are dismissed as hard-to-realize in practice as their basins of attraction are either too shallow or too narrow or both. There is no available theoretical approach that can deliberately enhance the realizability of these structures and directly guide their experimental synthesis. Here, we introduce a new approach to create potential energy surfaces in which the volumes of the basin of attraction of targeted metastable structures are increased by design, while simultaneously suppressing the accessibility of the ground state as well as other isomers. This approach is based on topologically assembled precursors, followed by density functional theory relaxations, and is applied to realize high-energy carbon allotropes such as penta-graphene comprised entirely of pentagon rings, O-graphene comprised of five- and eight-membered rings and R-graphene comprised of four-, six- and eight-membered rings.
11:39AM Y19.00003: Disorder drives synthesizability of multi-component systems*  CORMAC TOHER (Presenter), COREY OSES, STEFANO CURTAROLO, Mechanical Engineering and Materials Science, Duke University — The factorial increase in the number of potential compositions with increasing number of elemental components is not reflected in the number of synthesized ordered chemical compounds [1]. We show that this is due to formation-entropy-gain exceeding formation-enthalpy-gain as more species are added to the mixture. An analysis of the dependence of formation enthalpy on the number of species [2] using data extracted from the AFLOW data repository [3] shows interesting trends about the interplay between entropic and enthalpic effects on the synthesizability of multi-component materials.

*The authors acknowledge support by DOD-ONR (N00014-15-1-2863, N00014-17-1-2090, N00014-16-1-2583, N00014-17-1-2876). S.C. acknowledges support from the Alexander von Humboldt Foundation. C.O. acknowledges support from NSF (DGF1106401).

11:51AM Y19.00004: Retrosynthetic Planning with Generative Models  SHINTARO FUKUSHIMA (Presenter), TOYOTA InfoTechnology Center, Co.Ltd., YUICHI MOTOYAMA, KAZUYOSHI YOSHIMI, Univ of Tokyo-Kashiwanoha — Recently, retrosynthetic planning with machine learning and deep learning has been studied actively. One of the powerful approach was the retrosynthesis based on the molecular similarity proposed by Coley et al. In this approach, similarities between the target product and products in the reaction database were calculated to find similar products. Next, candidate reactions were generated by modifying reactions of the similar targets. This method by Coley et al. is more accurate than other methods. However, its search space is limited because it is based on the matching with the existing reactions. In this presentation, we propose a method with generative models, such as GAN(generative adversarial network) or VAE(variational autoencoder ) in order to expand the search space. The idea of the proposed method is to learn a generative model with GAN or VAE, generate reactants with the generative model, and then a reaction with reaction prediction. We got new reactants with the proposed method. We applied our proposed method to US patent dataset. As a result, reactants which did not exist in the reaction database were produced. Besides, the accuracy of retrosynthesis was higher than the previous methods.

12:03PM Y19.00005: Fantastic Metastable States and Where to Find Them: A Computational Search for Superlattices with Enhanced Functional Properties*  JOHN BONINI (Presenter), KARIN RABE, Rutgers University, New Brunswick — Superlattice systems continue to be of great interest in the development of new or enhanced material functionalities. One exciting prospect is that the conditions of the superlattice allow for the stabilization of novel states not accessible in bulk materials. To find such states, and the conditions under which they are stabilized, we construct a database of first principles calculations which describe not only the ground state of each constituent material, but a number of local minima and how these states change with mechanical, electrical, and other conditions. A data-driven approach is used in structure determination where the most probable local minima are systematically identified through analysis of existing materials databases. The resulting data set can be used as input to the "bulk-layer model" [1] to rapidly identify superlattice combinations with desirable functional properties, as well as the superlattice "stacking method" [2] to carefully compute the ground state of a particular superlattice. Examples applying the method to perovskite oxide compounds and superlattices will be presented.

Evaluating Species Stability with First Principles Calculations

LAUREN WALTERS (Presenter), LIANG-FENG HUANG, JAMES M RONDINELLI, Northwestern University — Novel multicomponent materials such as BiCuOS and BiCuOSe are used in a wide variety of applications like structural materials, semiconductors, and catalysis; however, the complex chemistry of having multiple anions makes reliable synthesis of these products challenging. Here we describe an ab-initio approach to evaluate the thermodynamic stabilities of multicomponent solids in aqueous environments with variable environmental conditions. The approach allows us to generate electrochemical Pourbaix diagrams that can be used to guide hydrothermal synthesis of these complex phases. Furthermore, we utilize a revised Helgeson-Kirkham-Flowers model to incorporate nonstandard state conditions for aqueous ions as functions of temperature and pressure. Our work identifies the main factors needed for the informed synthesis of new complex transition metal compounds and routes to deliver long-term stability of copper-based alloys.

The authors were supported by the ONR MURI under Grant No. N00014-16-1-2280. Calculations were performed using the QUEST HPC Facility at Northwestern University.

Formation enthalpies for automated computational materials design

RICO FRIEDRICH (Presenter), DEMET USANMAZ, COREY OSES, Department of Mechanical Engineering and Materials Science, Duke University, ANDREW R SUPKA, MARCO FORNARI, Department of Physics and Science of Advanced Materials Program, Central Michigan University, MARCO BUONGIORNO NARDELLI, Department of Physics and Department of Chemistry, University of North Texas, CORMAC TOHER, Department of Mechanical Engineering and Materials Science, Duke University, STEFANO CURTAROLO, Materials Science, Electrical Engineering, Physics and Chemistry, Duke University — The accurate calculation of formation enthalpies is crucial for computational materials design. For compounds chemically similar to their reference phases such as metal alloys, standard semi-local approximations to density functional theory (DFT) lead to accurate results [1]. When the phases are chemically dissimilar as in the case of oxides, DFT suffers from a lack of error cancellation leading to deviations of several hundred meV/atom compared to experimental values [2]. We use the automated computational materials design framework AFLOW [3] to benchmark correction schemes for ab initio formation enthalpies [2, 4]. These empirical methods can improve DFT predictions by a factor of 4 to 7. Zero-point vibrational and thermal contributions to the formation enthalpy are found to largely cancel each other.

We acknowledge support by DOD-ONR (N00014-15-1-2266, N00014-17-1-2090, N00014-16-1-2326, N00014-17-1-2876). R.F. and S.C. acknowledge support from the Alexander von Humboldt foundation. C.O. acknowledges support from the NSF under Grant No. DGF-1106401.

The Phase Stability Network of All Inorganic Materials

VINAY ISHWAR HEGDE (Presenter), NORTHWESTERN UNIVERSITY, MURATAHAN AYKOL, TOYOTA RESEARCH INSTITUTE, CHRISTOPHER WOLVERTON, Northwestern University — In the pursuit of unlocking structure-property relationships, a dominant paradigm in materials science has been the bottom-up investigation of how the arrangement of atoms and interatomic bonding in a material determine its macroscopic behavior. Here we consider a complementary approach, a top-down study of the organizational structure of networks of materials, based on the interaction between materials themselves. We unravel the phase stability network of all inorganic materials as a dense complex network of 21,000 thermodynamically stable compounds (nodes) connected with 41 million tie-lines (edges) defining their two-phase equilibria as computed by high-throughput density functional theory. The connectivity of nodes in the materials network shows a lognormal distribution, while the network itself shows small-world behavior, with a number of compounds acting as “hubs” having connections to nearly all other compounds. Analyzing the structure and topology of the materials network has the potential to uncover new knowledge inaccessible from the traditional atoms-to-materials approaches. We use the connectedness of materials in the network to derive a general, data-driven metric for reactivity, the “nobility index”, and quantitatively identify the noblest materials in nature.
12:51PM Y19.00009: Instabilities during solid-solid structural phase transformations provide guidance for the high-throughput materials discovery* NIKOLAI A ZARKEVICH (Presenter), Ames Laboratory, HAO CHEN, VALERY LEVITAS, Iowa State University, VITALIJ K PECHARSKY, DUANE D JOHNSON, Ames Laboratory — Electronic and lattice instabilities are studied during the solid-solid phase transformations in materials subjected to a general stress. The elastic instability criterion is proposed. The instability criteria are useful for the high-throughput discovery of novel materials. Our findings reveal novel, more practical synthesis routes for new or known high-pressure phases under predictable nonhydrostatic loading, where competition of instabilities can serve for phase selection.

*New methods were developed at Ames Laboratory, supported by the U.S. Department of Energy (DOE), Office of Science, Basic Energy Sciences, Materials Science and Engineering Division. Ames Laboratory is operated for the U.S. DOE by Iowa State University of Science and Technology under contract DE-AC02-07CH11358. Solid-solid phase transformations in materials exhibiting caloric effects were considered under auspices of CaloriCool(TM), which is supported by the Advanced Manufacturing Office of the Office of Energy Efficiency and Renewable Energy of the U.S. DOE. Non-linear mechanics was supported by NSF (CMMI-1536925), ARO (W911NF-17-1-0225), and Extreme Science and Engineering Discovery Environment (XSEDE) (high-performance computational resources allocation MSS170015).

1:03PM Y19.00010: Exploring the landscape of nonlinear mechanical metamaterials EDER MEDINA (Presenter), SEAS, Harvard University, PATRICK FARRELL, Mathematical Institute, Oxford University, CHRISTOPHER RYCROFT, KATIA BERTOLDI, SEAS, Harvard University — Nonlinearities have recently emerged as a powerful tool for designing mechanical metamaterials, as they lead to systems with a complex and programmable response. Currently, nonlinear responses have primarily been explored through traditional experimental techniques and standard single-solution numerical solvers. Here, we use an in silico continuation method to discover multiple configurations with associated different properties for a single loading parameter. We test the method on simple porous structures under compressive loading; as the load increases, we discover bifurcating families of stable and metastable states. Using this method we find structures that can switch between energy-releasing and energy-harvesting configurations, and structures that are geometrically hysteretic. Physical experiments are conducted to validate the results.

1:15PM Y19.00011: Expanding the elemental space of atomic laminates by a theoretical/experimental approach MARTIN DAHLQVIST (Presenter), JOHANNA ROSEN, IFM, Linkoping University — More than 50 years ago a family of atomically laminated compounds were discovered, being comprised of a transition metal M, an A-group element, and carbon and/or nitrogen X, and therefore being referred to as MAX phases. The exploration of the taxonomy of these can be accelerated by theoretical design on the atomic level combined with combinatorial experimental synthesis. Here, we use predictive phase stability calculations to probe transition metal (M) alloying in MAX phases and identify several chemically ordered structures. Subsequent materials synthesis of these indicates a potentially large family of thermodynamically stable phases, with Kagomé-like and in-plane chemical ordering, and with incorporation of elements previously not used for MAX phases, including Y and W. In extension, we suggest a matching set of novel two-dimensional MXenes, from selective etching of the A-element and, when so required, the alloying metal. The here demonstrated structural design on both 3D and 2D atomic levels expands the property tuning potential of functional ceramics.

1:27PM Y19.00012: Symmetry induced stability in alkali doped calcium-silicate-hydrate* ONGUN OZCELIK (Presenter), NISHANT GARG, CLAIRE WHITE, Princeton University — CO₂ emissions originating from the construction industry have a significant impact on global warming where the production of ordinary Portland cement clinker is responsible for approximately 8% of all human-made CO₂. Alkali doped calcium-silicate-hydrate (C-S-H) is a critical silicate material since the use of blended cements and alkali-activated materials in construction industry can substantially reduce human-made CO₂ emissions. However, the effect of alkali doping (Na and K) on the long-term stability and associated durability of C-S-H remains an open question. Here, using first principles quantum chemistry calculations on the model crystalline phase clinotobermorite, we show that there is a strong interplay between the thermodynamic stability of alkali doped C-S-H and the symmetry of the alkali atoms in the structure. We investigate the associated structural mechanisms by calculating the migration barriers of alkali atoms within the material, the electronic charge distribution in the material and the variation of basal spacing by using both computational methods and X-ray diffraction analysis.

IVOR LONCARIC (Presenter), PREDRAG LAZIC, Division of Theoretical Physics, Rudjer Boskovic Institute, Zagreb, Croatia — Sulfosalts form a vast mineral group which may be imagined as chemically analogous to oxides, with O replaced by S. However, the metal cations in sulfosalts generally have tetrahedral S coordination, and the chemical variety is much greater than in oxides, owing to the several possible oxidation states of sulfur. Structurally they range from the very simple to the very complex, and also span the whole range of anisotropies, from chainlike to fully 3D. They are less ionic than oxides, thus they display surprising crystallochemical flexibility and superior tunability of the valence of the transition metal ions. This results in a large variety of interesting electronic, magnetic and mechanical properties. Here we present an initial study of a particular class of sulfosalts, based on murunskite. The electronic structure is discussed with respect to possible signatures of thermoelectricity and superconductivity.

Session Y20 DMP: Hybrid Perovskites -- Lattice Vibrations BCEC 157A - Yan Li, University of Utah - Tag(s): Focus

11:15AM Y20.00001: The Impact of Lattice and Charge Fluctuations on Carrier Dynamics in Halide Perovskites
MATTHEW Z. MAYERS, Department of Chemistry, Columbia University, LIANG TAN, Department of Chemistry, University of Pennsylvania, DAVID EGGER (Presenter), Institute of Theoretical Physics, University of Regensburg, ANDREW RAPPE, Department of Chemistry, University of Pennsylvania, DAVID REICHMAN, Department of Chemistry, Columbia University — While halide perovskites (HaPs) have shown great technological promise for use as materials in energy devices, several of their unique optoelectronic properties remain incompletely understood. We develop a microscopic theory that is aimed at describing pertinent physical effects related to the carrier transport and optical properties of HaPs. It captures the nuclear displacements to all orders and goes beyond assuming linear electron-phonon coupling in calculating the dynamics of carriers and band gap characteristics. We combine the theory with first-principles calculations and apply it to the paradigm HaP compound MAPbI3. Our results explain intriguing experimental findings related to the charge-carrier mobility and optical properties, including their temperature dependencies. The findings of our work demonstrate that orbital overlap fluctuations in the lead-halide structure play a leading role in determining the optoelectronic features of HaPs.

ALI KACHMAR (Presenter), Qatar Environment and Energy Research Institute (QEERI), Hamad Bin Khalifa University (HBKU), WISSAM SAIDI, Mechanical Engineering and Materials Science, University of Pittsburgh — Temperature can have a dramatic effect on the solar efficiency of methylammonium lead iodide (CH3NH3PbI3) absorbers due to changes in the electronic structure of the system even within the range of stability of a single phase. Herein using first principles density functional theory, we investigate the electron band structure of the tetragonal and orthorhombic phases of CH3NH3PbI3 as a function of temperature due to electron-phonon coupling and thermal expansion. Our results show that the band gap increases with temperature for the two CH3NH3PbI3 phases in excellent agreement with experimental results. We also found that temperature have a significant effect on the effective masses and Rashba coupling especially in the tetragonal phase. At room temperature, electron-phonon coupling is found to enhance the effective mass by a factor of two, and to diminish the Rashba coupling by the same factor compared to T=0 K values.

*WAS acknowledges a start-up fund from the Department of Mechanical Engineering and Materials Science at the University of Pittsburgh.

AYALA COHEN (Presenter), Weizmann Institute of Science, DAVID EGGER, University of Regensburg, ANDREW RAPPE, University of Pennsylvania, LEEOR KRONIK, Weizmann Institute of Science — We consider the Br vacancy in CsPbBr3 as a prototype for the impact of lattice dynamics on defect energetics in halide perovskites (HaPs). Using first-principles molecular dynamics based on density functional theory, we find that the static picture of defect energetics breaks down; the energy of the VBr level is found to be dynamic, oscillating by as much as 1 eV on the ps time scale at room temperature. These significant energy fluctuations are correlated with the distance between the neighboring Pb atoms across the vacancy and with the electrostatic potential at their atomic sites. The unusually strong coupling of lattice dynamics and defect energetics bears important implications for both experimental and theoretical analysis of defect characteristics in HaPs and may hold significant ramifications for carrier transport and defect tolerance in this class of photovoltaics.
Lattice dynamical properties of halide-perovskites from infra-red spectroscopy and first-principles calculations
CHRISTIAN GEHRMANN (Presenter), Institute of Theoretical Physics, University of Regensburg, MICHAEL SENDNER, SEBASTIAN BECK, Kirchhoff Institute for Physics, Heidelberg University, ROBERT LOVRINCIC, Institute for High Frequency Technology, TU Braunschweig, DAVID EGGER, Institute of Theoretical Physics, University of Regensburg — Halide perovskites (HaPs) are intriguing optoelectronic materials. It is of particular interest to understand how the outstanding optoelectronic properties of HaPs are related to their vibrational properties, especially in light of the possibility that phonons might be the dominant source of scattering for charge carriers at room temperature. Studying the lattice dynamics of the all-inorganic CsPbBr₃ as well as the hybrid MAPbBr₃, we here present our findings on how the A-site cation as well as its potential orientation effects influence the vibrational properties of HaPs. To this end, we show results from first-principles calculations, based on density functional theory, and compare these with experimental data obtained from far infra-red spectroscopy. Finally, we present results related to the LO phonons that are not infra-red active, but inherently contained in our calculations and experimentally accessible through reflectance measurements.

Vibrational Dynamics of Hybrid Organic-Inorganic Perovskites
DEPEI ZHANG (Presenter), Department of Physics, University of Virginia, TIANRAN CHEN, NIST Center for Neutron Research, National Institute of Standards and Technology, ALEXANDER CHEN, Department of Chemical Engineering, University of Virginia, MAIKO KOFU, Material and Life Science Experimental Facility, Japan Proton Accelerator Research Complex, WEI-LIANG CHEN, Center for Condensed Matter Sciences, National Taiwan University, DOUGLAS L ABERNATHY, Spallation Neutron Source, Oak Ridge National Laboratory, MINA YOON, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, CRAIG BROWN, LELAND HARRIGER, GUANGYONG XU, NIST Center for Neutron Research, National Institute of Standards and Technology, RYOICHI KAJIMOTO, Material and Life Science Experimental Facility, Japan Proton Accelerator Research Complex, YU-MING CHANG, Center for Condensed Matter Sciences, National Taiwan University, JOSHUA CHOI, Department of Chemical Engineering, University of Virginia, SEUNGHUN LEE, Department of Physics, University of Virginia — Vibrational modes, which are connected to the electronic properties of hybrid organic-inorganic perovskites (HOIPs) through the structural transition, electron-phonon coupling, and hot-phonon bottleneck effect, is an important topic for perovskite solar cells. This talk focuses on the phonon modes of two perovskite materials, MAPbI₃ (MA = CH₃NH₃) and FAPbI₃ (FA = HC(NH₂)₂). We have performed inelastic neutron scattering, Raman scattering, and density-functional theory (DFT) calculations on both systems. Our analysis well reproduces the low-temperature inelastic neutron scattering spectra for MAPbI₃ and FAPbI₃, and illuminates the connection between the vibrational dynamics and the organic molecules.

Rotational Dynamics of Organic Cations in the [CH₃(CH₂)₇NH₃]₂PbI₄ Perovskite
XIAO HU (Presenter), DEPEI ZHANG, TIANRAN CHEN, ALEXANDER CHEN, University of Virginia, DANIEL PAJEROWSKI, Oak Ridge National Laboratory, GUANGYONG XU, National Institute of Standards and Technology, WEI-LIANG CHEN, National Taiwan University, MINA YOON, Oak Ridge National Laboratory, YU-MING CHANG, National Taiwan University, JOSHUA CHOI, SEUNGHUN LEE, University of Virginia — The biggest challenge of the 3D high-efficiency perovskite solar cells, such as CH₃NH₃PbI₃ and CH(NH₂)₂PbI₃, is their device instability. 2D perovskite compounds such as butylammonium methylammonium lead iodide perovskite, [CH₃(CH₂)₃NH₃]₂(CH₃NH₃)₁Pb₃I₁₇, present a solution to this problem. Here we present our recent quasi-elastic neutron scattering on a powder sample of the 2D 1-layer system ([CH₃(CH₂)₇NH₃]₂PbI₄) as a function of temperature. Upon cooling, this system undergoes an orthorhombic phase(ACam) to another orthorhombic phase(Pbca) and further to a monoclinic phase(P2₁/a). Our group theory and density functional theory analysis show that the rotational dynamics is dominated by C₃ rotation of NH₃ and CH₃ groups. The relaxation rate of the C₃ modes decreases with decreasing temperature through the orthorhombic-to-orthorhombic transition. On the other hand, in the low-temperature monoclinic phase, the C₃ rotation becomes very slow to detect. The relevance of this finding to electronic properties will also be discussed.

The work is supported by the US Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences, under Award DE-SC0016144.
Lead halide perovskites are polaronic materials

XIAOYANG ZHU (Presenter), Columbia University — Lead halide perovskites have been demonstrated as high performance materials in solar cells and light-emitting devices. These materials are characterized by coherent band transport expected from crystalline semiconductors, but dielectric responses and phonon dynamics typical of liquids. Here we explain the essential physics in this class of materials based their dielectric functions or dynamic symmetry breaking on microscopic level. We show that the dielectric function of a hybrid organic-inorganic lead halide perovskite (LHP) possesses combined characteristics of a polar liquid and a ferroelectric material. The latter response in the THz region may lead to dynamic and local ordering of polar nano domains by an extra electron or hole, resulting a quasiparticle which we call a ferroelectric large polaron, a concept similar to solvation in chemistry. Compared to a conventional large polaron, the collective nature of polarization in a ferroelectric large polaron may give rise to order(s)-of-magnitude larger reduction in the Coulomb potential and introduce potential barriers to charge carrier scattering. The ferroelectric large polaron may explain the defect tolerance and low recombination rates of charge carriers in lead halide perovskites, as well as providing a design principle for high performance semiconductors from nano, molecular, and hybrid materials. [Science, 2016, 353, 1409; Science Adv. 2017, 3, e1701217; Nature Mat. 2018, 17, 379].

Large Polaron Formation and its Effect on Electron Transport in Hybrid Perovskite

FAN ZHENG (Presenter), LIN-WANG WANG, Lawrence Berkeley National Laboratory — Many experiments have indicated that large polaron may be formed in hybrid perovskite, and its existence is proposed to screen the carrier-carrier and carrier-defect scattering. However, detailed theoretical study of the large polaron and its effect on carrier transport at the atomic level is still lacking. In this work, using CH$_3$NH$_3$PbI$_3$ as an example, we implement tight-binding model fitted from the density-functional theory to describe the electron large polaron ground state and to understand the large polaron formation and transport at its strong-coupling limit. We find that the formation energy of the large polaron is around -12 meV for the case without dynamic disorder, and -55 meV by including dynamic disorder. By performing the explicit time-dependent wavefunction evolution, together with the rotations of CH$_3$NH$_3^+$ and vibrations of PbI$_3^-$ sublattice, we studied the diffusion constant and mobility of the large polaron state. On one hand, the vibration of the sublattice provides additional driving force for carrier mobility, on the other hand, the large polaron polarization further localizes the electron, reducing its mobility.

Impact of the exchange-correlation functional on the analysis of static and dynamical structural properties of MAPbI$_3$

HUBERT BECK (Presenter), CHRISTIAN GEHRMANN, DAVID EGGER, Institute of Theoretical Physics, University of Regensburg — Hybrid organic-inorganic halide perovskites (HaPs) have shown many properties that are advantageous for efficient renewable energy applications. Several of the open questions for these systems can be addressed by first-principles calculations applying density functional theory (DFT). However, in order to achieve reliable insight from such calculations, it is important to understand which of the various microscopic effects in the different DFT-related approximations play an important role in the calculations. Here, we present an investigation on the importance of various theoretical aspects in the DFT calculations of the structural properties for MAPbI$_3$. We focus on a comparison of calculations varying the DFT functional, the account of van-der-Waals interactions as well as the inclusion of spin-orbit coupling. Our computed unit-cell volumes and bulk moduli are compared to results of experiments, addressing the relative importance of these effects on calculations of structural properties of MAPbI$_3$. Finally, we also present results on the impact of temperature-induced structural fluctuations on calculating the structural properties of MAPbI$_3$.

Magneto-Raman Spectroscopy on multiferroic metal-organic framework 

[(CH$_3$)$_2$NH$_2$]Co(HCOO)$_3$$^\ast$ RACHAEL RICHARDSON (Presenter), DAMIOLA OLOGUNAGBA, Florida A&M University, ZHENG-GUANG LUI, National High Magnetic Field Laboratory, NAN HUANG, University of Tennessee-Knoxville, DMITRY SMIRNOV, National High Magnetic Field Laboratory, DAVID GEORGE MANDRUS, University of Tennessee-Knoxville, KOMALAVALLI THIRUNAVUKKARASU, Florida A&M University — Metal-organic frameworks (MOFs) are a class of nanoporous compounds where organic groups are used in combination with transition metal ions to obtain multifunctional materials. The family of MOFs perovskites ABX$_3$ comprised of methylammonium (A= (CH$_3$)$_2$NH$_2$) and metal (B=Co, Cu, Fe, Mn, Ni) cations with a formate (X=HCOO$_3$) anion are studied because of their multiferroic properties [1]. Therefore, several efforts have been made to understand the nature and strength of exchange interactions in these materials including magnetization at high magnetic fields up to 60 T and infrared spectroscopy at magnetic fields up to 35 T [2,3]. Concurrently, we performed magneto-Raman spectroscopy on [(CH$_3$)$_2$NH$_2$]Co(HCOO)$_3$ at magnetic fields up to 31T to probe the magneto-elastic coupling, the results of our investigations and its implications will be discussed.

$^\ast$Work at NHMFL was supported by NSF DMR-1157490, DMR-1644779 and the state of Florida. The project is also funded by DoN HBCU/MI program.

Acoustic phonon instabilities and central peaks at the Brillouin zone boundary in the organic-inorganic perovskite CH$_3$NH$_3$PbCl$_3$$^\ast$ MANILA SONGVILAY (Presenter), University of Edinburgh, MARYAM BARI, YE ZUO-GUANG, Department of Chemistry and 4D labs, Simon Fraser University, GUANGYONG XU, PETER M GEHRING, WILLIAM RATCLIFF, NIST Center for Neutron Research, National Institute of Standards and Technology, KARIN SCHMALZL, Forschungszentrum Jülich GmbH, Jülich Centre for Neutron Science at ILL, FRÉDÉRIC BOURDAROT, INAC, MEM/MDN, Université Grenoble Alpes, CEA, BERTAND ROESSLI, Laboratory for Neutron Scattering and Imaging (LNS), Paul Scherrer Institut (PSI), CHRIS STOCK, University of Edinburgh — Lead halide hybrid perovskites consist of an inorganic framework hosting a molecular cation located in the interstitial space. These compounds have been extensively studied as they have been identified as promising materials for photovoltaic applications. In particular, the interaction between the molecular cation and the inorganic framework has been suggested to influence the electronic properties. CH$_3$NH$_3$PbCl$_3$ undergoes several structural transitions associated with both distortion of the octahedra and orientational ordering of the CH$_3$NH$_3$ cation. We have measured the low-frequency lattice dynamics using neutron spectroscopy. We report an anomaly in the acoustic phonon linewidth towards the high-symmetry point Q$_{X}$=(2, 1/2, 0) when approaching the transitions, and a hardening of the entire phonon branch with decreasing temperature. Measurements at the Brillouin zone edges Q$_{X}$=(2, 1/2, 0), Q$_{M}$=(3/2, 1/2, 0) and Q$_{R}$=(3/2, 3/2, 5/2) show central peaks appearing at the lower temperature transition. We discuss the presence of both central peaks and acoustic phonon instabilities as evidence of a strong coupling between the inorganic framework and the molecular cation.

$^\ast$We acknowledge funding from the EPSRC and the STFC

Diffuse Neutron and X-ray Scattering from Cesium Lead Bromide$^\ast$ MATTHEW KROGSTAD (Presenter), ALEX RETTIE, STEPHAN ROSENKRANZ, DUCK YOUNG CHUNG, Materials Science Division, Argonne National Laboratory, MERCOURI KANATZIDIS, Department of Chemistry, Northwestern University, FENG YE, Quantum Condensed Matter Division, Oak Ridge National Laboratory, XING HE, OLIVIER DELAIRE, Department of Mechanical Engineering and Materials Science, Duke University, RAYMOND OSBORN, Materials Science Division, Argonne National Laboratory — Cesium lead bromide has attracted recent attention, along with other lead halide perovskites, due to its optoelectronic properties. It has been proposed that the long carrier life supporting these properties is due to local polar fluctuations. To investigate the short-range lattice distortions that such fluctuations would imply, diffuse neutron and x-ray scattering experiments were performed on single crystals of CsPbBr$_3$ across range of temperatures spanning two structural phase transitions. Significant diffuse scattering indicating short-range displacement correlations was found in all three structural phases. In particular, diffuse neutron scattering from CsPbBr$_3$ shows distinct elastic and inelastic features, distinguishing between static and dynamic forms of local displacement correlations.

$^\ast$This work was funded by DOE, BES, DMSE.

Session Y23 GIMS: X-rays 8CEC 158 - Tag(s): Focus
Effectively Pin-hole Collimated USAXS as a Premier Tool to Quantitatively Analyze Anisotropic Hierarchical Porous Microstructures*  
TABBETHA DOBBINS (Presenter), AARON HOPKINS, Rowan University, JAN ILAVSKY, Advanced Photon Source, Argonne National Laboratory, MILAD MILAD AZAMI-GHADKOLAI, RAJENDRA BORDIA, Dept. of Materials Science & Engineering, Clemson University — The 2D collimated Bonse-Hart USAXS instrument was used to study the anisotropic and hierarchical pore microstructures in freeze-cast lithium titanate (Li₄Ti₅O₁₂). USAXS data with scattering vector q=0.0001Å⁻¹ to 0.02Å⁻¹ were collected at sample orientations from -10° to 190°. I vs. azimuthal angle polar data at q values of 0.0003Å⁻¹, 0.0006Å⁻¹, 0.001Å⁻¹, and 0.005Å⁻¹ were also collected. Six Li₄Ti₅O₁₂ samples differing by salt and gel additives and lithium titanate particle size were measured. Samples are strongly anisotropic at low q (aspect ratio of 0.3 to 0.4) for intercolumnar porosity and mildly anisotropic at high q (aspect ratio of 0.8) for interparticle pores. Models suggests the pore microstructures are comprised of two large anisotropic populations: 1μm (Φ=0.77; SA=2.88m²/cm³) and 0.5μm (Φ=0.05; SA=0.35m²/cm³) and two small, relatively isotropic populations: 38nm (Φ=0.02; SA=1.38m²/cm³) and 14nm (Φ=0.16; SA=35.3m²/cm³).

*The Clemson University portion of this work was supported in part by the National Science Foundation EPSCoR Program under NSF Award # OIA-1655740. This research used resources of the Advanced Photon Source, a U.S. Department of Energy (DOE) Office of Science User Facility operated by Argonne National Laboratory under Contract No. DE-AC02-06CH11357.

High Magnetic Field X-ray Diffraction at the National High Magnetic Field Laboratory (NHMFL)*  
DREW REBAR (Presenter), ALEXEY E KOVALEV, National High Magnetic Field Laboratory, DALLAS MANN, MICHAEL SHATRUK, Chemistry and Biochemistry, Florida State University, YAROSLAV MUDRYK, VITALIJ K PECHARSKY, Ames Laboratory, Iowa State University, KAYA WEI, JULIA H. SMITH, ALEXEY SUSLOV, THEO SIEGRIST, National High Magnetic Field Laboratory — We develop a custom high magnetic field x-ray diffraction system for measurements in the 25 T Florida split coil magnet at the DC Field Facility of NHMFL, Tallahassee, FL, to probe spin-lattice coupling at extreme steady-state magnetic fields. This allows thermal cycling of materials with first order transitions and thermal relaxation of highly conductive or magnetocaloric materials. The system utilizes a Mo rotating anode X-ray source and PILATUS 300K-W X hybrid pixel array detector customized to tolerate the fringe fields of the split coil magnet. We plan to further modify the diffractometer with an elliptical mirror system which will enhance intensity and create a convergent x-ray beam configuration. We present a study of the magnetocaloric material, AlFe₂B₂, highlighting the evolution of the unit cell volume in field and a study of the magnetostrictive material, GdNi, highlighting the evolution of the crystal axes at high field.

*This research is supported by NSF-DMR grant MRI-1625780. NHMFL is supported by the National Science Foundation Cooperative Agreement No. DMR-1644779 and the State of Florida. The Ames Laboratory is operated for the U. S. Department of Energy by Iowa State University of Science and Technology under contract No. DE-AC02-07CH11358.

High Resolution Digital X-Ray Detection via Optical Interrogation of Electro-Optic Materials  
GEORGE HERRING (Presenter), LAMBERTUS HESSELINK, Stanford University — We report on the development of a high resolution (greater than 30 lp/mm), high quantum efficiency x-ray detector in the 40 to 60 keV range using non-linear optics. Typical indirect x-ray detectors use a scintillation material to convert high energy x-ray photons into a larger number of lower energy visible photons. Indirect x-ray detectors with the previously stated specifications have a low quantum efficiency due to the combination of a thin scintillation material, which has little x-ray stopping power, and a limited ability of the optical train and CMOS sensor to collect the visible photons. Instead of using a scintillator to convert incident x-rays into lower energy visible photons, we explore the use of non-linear optics to convert incident x-rays into a localized change in the index of refraction, which can be measured with optical interferometry. The non-linear optic consists of a biased Pockels Cell. When x-rays interact with the cell they release space charges which modify the electric field within the cell and thus changes its index. With this new design of x-ray detector, we explore the tradeoffs between x-ray stopping power, transverse spatial resolution, temporal resolution, and signal to noise ratio.
Bulk metallic ribbons have inherent rough surfaces. The non-trivial surface scatterings could mislead USANS data as the scattering of the Cu50Zr50 alloy disappeared under the surface neutron contrast-matched environment, indicating that the scattering originated not from its internal structure but from the surface. This confirms the homogeneity at the atomic level sustains to a micrometer. On the other hand, the crystallized alloy showed a strong scattering under the matching environment due to the structural heterogeneity inside the alloy. This technique can apply to the bulk samples when the transmission is high enough, not causing multiple scattering.

*We acknowledge partial financial support from KAERI and KIST (KIST funding number: 2G10480, 2V06030).
12:27PM Y23.00007: A high quality multilayer x-ray monochromator for third generation synchrotron sources
MATTHEW DECAMP (Presenter), KARL UNRUH, University of Delaware, ANTHONY DICHIARA, RAY CONLEY, Argonne National Labs — The ability to provide high spectral resolution with high dynamic photon flux is a hallmark of third generation synchrotron sources. However, under most circumstances, only two modes of operation are currently available for user studies, monochromatic and polychromatic modes. In polychromatic operation, the spectral bandwidth can exceed 1keV, which is often too large for accurate structural reconstruction in solid-state systems. In contrast, monochromatic operation comes at significant cost to photon flux, making the study of transient structural changes difficult to measure.

In this work we describe the design and performance of a new multilayer monochromator for use at hard x-ray synchrotrons. This monochromator can provide users with both a tuneable bandwidth and increased photon flux sufficient for rapid structural determination. Our results demonstrate that this multilayer monochromator can provide widely tunable hard x-ray, possessing energy bandwidth of 20-100eV, and photon fluxes that significantly exceed standard double crystal monochromators. This capability not only has implications for time-domain materials research, but could be utilized on a variety of x-ray scattering/spectroscopic techniques.

12:39PM Y23.00008: Critical-Dimension Grazing-Incidence Small Angle X-Ray Scattering: Enhancing the latent signal using Bragg scattering*
DINESH KUMAR (Presenter), Computational Research, Lawrence Berkeley National Laboratory, GUILLAUME FREYCHET, ISVAR CORDOVA, Advanced Light Source, Lawrence Berkeley National Laboratory, JOSEPH WALTER STRZALKA, X-ray Science Division, Argonne National Laboratory, PATRICK NAULLEAU, Center for X-ray Optics, Lawrence Berkeley National Laboratory, RONALD J PANDOLFI, Computational Research, Lawrence Berkeley National Laboratory, PETER ERCUUS, CHENGYU SONG, Molecular Foundry, Lawrence Berkeley National Laboratory, ALEXANDER HEXEMER, Advanced Light Source, Lawrence Berkeley National Laboratory — The semiconductor industry is continuously pushing the limits of photolithography, with feature sizes now under 10 nm. X-ray scattering\(^1\) has emerged as a possible contender to determine the average shape of a line grating with a sub-nanometer precision. However, to fulfill its promise, faster algorithms must also be developed to interpret and extract metrics from reciprocal space scattering data. We are presenting a novel, fast, and accurate X-ray technique and analysis algorithm: Critical Dimension Grazing Incidence X-ray Scattering, CD-GISAXS

The CD-GISAXS technique operates in grazing incidence configuration with a continuous azimuthal rotation of the sample, thus does not require high-energy X-rays to penetrate the wafer and greatly reduces the data acquisition times, permitting analysis within the framework of the DWBA. The Bragg rods coming from the line gratings, intersect with the momentum transfer vector of the elastic X-ray scattering at a single point above the horizon. The Bragg rods can be scanned by rotating the momentum transfer vector, and therefore the sample.

12:51PM Y23.00009: Applications of Thin Film Atomic Layer Deposition Superconducting Titanium Nitride to Astronomical Measurements*
CALDER SHEAGREN (Presenter), PETER BARRY, RITOBAN BASU THAKUR, RONG NIE, Kavli Institute for Cosmological Physics, University of Chicago, ERIK SHIROKOFF, QING YANG TANG, Department of Astronomy and Astrophysics, University of Chicago — Microwave Kinetic Inductance Detectors (MKIDs) are an appealing option for conducting millimeter-wave astronomy and measuring the Cosmic Microwave Background due to their ease of fabrication and multiplexing. MKIDs make detections when a microwave photon breaks Cooper pairs in the superconducting metal, modifying the kinetic inductance of the metal and the resonant frequency of the on-chip resonator. A material of interest for fabricating MKIDs is Atomic Layer Deposition titanium nitride (ALD TiN) due to its high kinetic inductance and low critical temperature. We can precisely control these characteristics of the TiN by tuning deposition parameters such as thickness, stage temperature, and nitrogen flow. This method also admits high quality factors, allowing for increased multiplexing, and wafer-level uniformity with film thicknesses in the range of 4-18 nm. We present measurements of the critical temperature and internal quality factor of ALD TiN resonators under the variation of various ALD parameters as it relates to fabricating MKIDs.

*This work was supported by NSF grant no. AST-1554565, the Kavli Institute for Cosmological Physics, and the Pritzker Nanofabrication Facility at the University of Chicago, which receives support from SHyNE under NSF grant no. NNCI-1542205.
1:03PM Y23.00010: The status of the ultra-high resolution spectroscopy at the HFIR* FANKANG LI (Presenter), Neutron Sciences Directorate, Oak Ridge National Laboratory, HAO FENG, JIAZHOU SHEN, Physics Department, Indiana University Bloomington, MORRIS LOWELL CROW, MASAAKI MATSUDA, Neutron Sciences Directorate, Oak Ridge National Laboratory, STEVEN PARNELL, Faculty of Applied Sciences, Delft University of Technology, ROGER PYNN, Physics Department, Indiana University Bloomington, JAIME FERNANDEZ-BACA, Neutron Sciences Directorate, Oak Ridge National Laboratory — To measure the crystal lattice distortion or the lifetime of weak interactions among quasiparticles, such as phonons, electrons and magnons, with high resolution, the key is to break the inverse relationship between the resolution and useable flux. By using the Larmor precession of the neutron spin inside a given magnetic field, its momentum or energy change during the interactions with sample can be measured with ultra-high resolution. Therefore, this unique property of neutron provides us with another approach to overcome some of the limitations of conventional neutron scattering instruments. Also, it can make the best use of all the available neutrons by allowing the use of large divergent beams. The progress on upgrading the HB-1 polarized triple axis spectrometer at the High Flux Isotope Reactor of ORNL with superconducting magnetic Wollaston prisms will be presented. For neutron diffraction, the achievable resolution of the absolute peak splitting and relative lattice distortion (Δd/d) can be 2×10⁻⁴ and 1×10⁻⁶ relatively. While for inelastic scattering, for example phonon linewidth measurements, the resolution can be <10µeV.

*This research is sponsored by the Laboratory Directed Research and Development Program of Oak Ridge National Laboratory.

1:15PM Y23.00011: Oxidation state sensitive 3D atomic mapping of oxide-supported catalysts through X-ray Standing Wave (XSW) excited X-ray photoelectron spectroscopy (XPS)* ANUSHEELA DAS (Presenter), NARAYANACHARI KVVL, BO-HONG LIU, DENIS T KEANE, MICHAEL J BEDZYK, Northwestern University — XSW excited XPS was used to study the hydroxylated surface of rutile TiO₂ (110) single crystal, where the excess unpaired electrons of the hydroxyls play a critical role in surface chemistry and photocatalytic processes. The experiments were performed at APS DND-CAT 5IDC using a 7 keV incident beam. The hydroxylated O 1s binding energy was 2.4 eV higher than that of the bulk-like O atoms and was found to have a different XSW coherent fraction and position. Summation of these Fourier components for 3 symmetry inequivalent hkl Bragg peaks generate a chemical state sensitive 3D atomic map of oxygen. We also studied monolayer coverages of vanadium oxide (catalytic material) supported on the same surface. Collecting V, O and Ti 1s XPS signals as we scanned across a Bragg peak at different stages of a redox reaction allowed tracking of surface sites for chemically distinct V atoms, important for understanding their catalytic behaviour. These results coupled with DFT calculations will give unique insights into this as well as other related oxide supported catalysts.

*Northwestern University (NU) Institute for Catalysis in Energy Processes under DOE Grant DE-FG02-03ER15457, NU MRSEC program (NSF DMR-1121262), NU Center for Hierarchical Materials Design program under NIST Grant 70NANB14H01

1:27PM Y23.00012: Testing for the Continuous Spectrum of X-Rays Predicted to Accompany the Photoejection of an Atomic Inner Shell Electron* PHILIP JACOBSON (Presenter), ANDRIJA RASOVIC, SONGQI JIA, YUE LI, ARTHUR CAMPELLO, CHASE GODDARD, STANISLAV STOUPIN, J. Y. PETER KO, YUCHAO CHEN, JUSTIN OH, GWEN GARDNER, CARL FRANCK, Cornell University — For decades, experimental evidence for an elegant prediction of quantum electrodynamics has been sought: the detection of a broad spectrum of X-rays at low energies expected upon sudden ejection of an inner shell electron following absorption of an incident high energy photon. We report here on a recent attempt that provides a significantly reduced upper limit on the process that is consistent with contemporary theory and contradicts earlier observations. The Cornell High Energy Synchrotron Radiation Source (CHESS) was employed to deliver a 46 keV incident beam on solid copper film targets. To suppress extraneous events detection of scattered photons was performed in coincidence with the fluorescent decay of the K shell hole produced by photoejection. Through variable thickness targets we assessed secondary processes.

*This work is based upon research conducted at the Cornell High Energy Synchrotron Source (CHESS) which is supported by the National Science Foundation under award DMR-1332208. Session Y24 DAMOP DCMP: Topological States in AMO Systems II BCEC 159 - Chuanwei Zhang, University of Texas at Dallas - Tag(s): Focus
In this talk we present a new class of phases of matter called higher-order topological phases. Such systems exhibit gapped boundaries that are themselves lower-dimensional topological phases. Furthermore, they manifest topologically protected states at intersections between multiple surfaces. These states can, e.g., carry fractional charge, or be chiral propagating modes. We show that some of the simplest examples of these phases are connected to materials with quantized electric quadrupole moments, and illustrate how they can be realized in a variety of meta-material systems. We will also review the first experimental evidence for these phases in meta-material contexts. To characterize these new insulating phases of matter, we introduce a new type of invariant that had been previously overlooked, and we show how these invariants can predict a collection of new phenomena.

**Topologically Protected Photonic Modes in Composite Quantum Hall/Quantum Spin Hall Waveguides**

SHUKAI MA (Presenter), Department of Physics, University of Maryland, College Park, BO XIAO, Department of Electrical and Computer Engineering, University of Maryland, YANG XU, KUEIFU LAI, GENNADY SHVETS, Cornell University, STEVEN ANLAGE, Department of Physics, University of Maryland, College Park — Photonic topological insulators (PTI) are a new class of structures that can support backscattering-free propagating waves at an interface between topologically non-trivial structures. In the bi-anisotropic meta-waveguide (BMW) PTI designs, by carefully tuning the geometrical and electromagnetic properties, we can emulate the electronic quantum spin Hall (QSH) effect using its electromagnetic analog. A magneto-optical material added to the structure will introduce a quantum Hall (QH) photonic bulk insulator on the BMW basis. The combined photonic systems with multiple topological phases supporting reflection-free edgemodes are proposed and experimentally demonstrated. The spin degree of freedom of such topologically protected edgemodes determines their unique pathways through these systems, free from backscattering and able to travel around sharp corners. As an example of their novel properties, we demonstrate a full 4-port circulator based on composite QH and QSH back-scattering free waveguides.

**Interacting Hall Response in Quantum Gas Experiments**

SEBASTIAN GRESCHNER (Presenter), MICHELE FILIPPONE, THIERRY GIAMARCHI, Department of Quantum Matter Physics, University of Geneva — Recent experiments with ultracold quantum gases in artificial magnetic fields have shown the possibility to study the Hall effect in quasi one-dimensional highly tunable ladder systems. In this context we theoretically analyze the properties of the reactive Hall response on ladder models with strongly interacting bosons and fermions. We compare different methods for the computation of the static Hall coefficient and discuss its dependence on the various methods or limits considered. In the cases relevant for recent experiments in synthetic dimensions, we find a surprising universal behavior of the weak field Hall coefficient of single component phases in the case of an SU(M) symmetric interaction. For strong magnetic fields we study the interesting properties of the quantum-Hall effect in various quantum phases on ladder geometries including vortex-lattice, biased ladder or Laughlin like states.

**Higher Order Floquet Topological Insulators with Anomalous Corner States**

BIAO HUANG (Presenter), University of Pittsburgh, W.VINCENT LIU, University of Pittsburgh and Shanghai Jiaotong University — The theoretical and experimental discovery of topological insulators of higher multipole nature, dubbed “higher order topological insulators” (HOTI), has triggered heated discussions in recent studies. But so far, all researches have been limited to static systems due to the lack of higher order topological invariants constructed for a genuine dynamical system. Here, we report a Floquet-driven model showing the anomalous corner states and a construction of dynamical topological invariant built upon evolution operators $U(t)$. We show that the bulk static nested quadrupoles, constructed by eigenstates of the static Floquet operator $U_F = U(T)$, vanish identically, while corner states emerge in all energy gaps with quantized charges due to the dynamical topology. The signature of such an anomalous Floquet phase in cold atom experiments is also discussed via corner particle dynamics and a band tomography. Our work paves the way to the systematic study of HOTI in regimes far away from equilibrium.

*U.S. ARO (W911NF-11-1-0230), AFOSR (FA9550-16-1-0006), and MURI-ARO (W911NF-17-1- 0323)
Here we focus on recent results challenging the usual viewpoint, the occurrence of higher-order exceptional points where a macroscopic fraction of the states coalesce at a single point with a geometrical multiplicity of one [2] and where the system becomes devoid of extended states [2].

A scheme to generate such higher-order exceptional points in lattices will be presented together with an argument [3] regarding the separation of the spectrum into topological states and localized states originated by higher-order exceptional points.

*We thank FondeCyT 1170917.

12:39PM Y24.00006: Non-Hermitian adiabatic transport in the space of exceptional points*  
JUDITH HOELLER  
(Presenter), NICHOLAS READ, JACK HARRIS, Yale Univ — An $n \times n$ non-Hermitian Hamiltonian matrix $H$ can describe a dissipative system, such as $n$ coupled weakly dissipative classical harmonic oscillators. Under full parametric control over $H$, the parameter space contains a connected -- but not simply-connected -- subspace of $n$th order exceptional points, at each of which $H$ is equivalent to an $n \times n$ Jordan block. We show that smooth variations of parameters during time $T$, along a loop within that space, can single out one state that is least dissipative and evolves adiabatically. Its complex adiabatic phase is $T$ times a Puiseux series in powers of $T^{-1/n}$; the coefficient at order $T^0$ is the Berry phase, which is a multiple of $2\pi/n$ (modulo $2\pi$) and only depends on the homotopy class of the loop within the space of $n$th order exceptional points.

*We acknowledge support from Yale University (JH) and from AFOSR grant FA9550-15-1-0270 and ONR MURI N00014-15-1-2761 (JGEH).

12:51PM Y24.00007: Topological symmetry classes for non-Hermitian models and connections to the bosonic Bogoliubov–de Gennes equation*  
SIMON LIEU  
(Presenter), Imperial College London — The Bernard-LeClair (BL) symmetry classes generalize the Altland-Zirnbauer classes in the absence of Hermiticity. Within the BL scheme, time-reversal and particle-hole symmetry come in two flavors, and “pseudo-Hermiticity” generalizes Hermiticity. We propose that these symmetries are relevant for the topological classification of non-Hermitian single-particle Hamiltonians and Hermitian bosonic Bogoliubov–de Gennes (BdG) models. We show that the spectrum of any Hermitian bosonic BdG Hamiltonian is found by solving for the eigenvalues of a non-Hermitian matrix which belongs to one of the BL classes. We therefore suggest that bosonic BdG Hamiltonians inherit the topological properties of a non-Hermitian symmetry class and explore the consequences by studying symmetry-protected edge instabilities in a one-dimensional system.

1:03PM Y24.00008: Stability of Non-Hermitian Phases  
DAN BORGNIA  
(Presenter), Harvard University — Recent work on non-Hermitian physics in condensed matter systems has focused on the classification of new topological phases. The notion of a gap usually used to describe the stability of Hermitian phases is not sufficient in the presence of loss and gain terms. This work uses known results in the theory of pseudo-spectra and Jordan Normal Forms to detail the stability of novel non-Hermitian phases under different disorder profiles in 1D with some generalizations into higher dimensions. We find agreement with previous work in simple chiral models and single parameter disorder distributions of our generalized stability arguments.
Topological charge pumping in the interacting bosonic Rice-Mele model*  ANDREW HAYWARD
(Presenter), Institute for Theoretical Physics, Georg-August-Universität Göttingen, CHRISTIAN SCHWEIZER, MICHAEL LOHSE,
MONIKA AIDELSBURGER, Fakultät für Physik, Ludwig-Maximilians-Universität München, FABIAN HEIDRICH-MEISNER, Institute for Theoretical Physics, Georg-August-Universität Göttingen — In recent years, demonstrations of topological Thouless charge pumping have been performed with ultra-cold atoms. We discuss our recent work [1] investigating charge pumping in the Bosonic Rice-Mele model and verify that the charge pumping remains quantized as long as the pump cycle avoids the superfluid phase. In the limit of hardcore bosons, the quantized pumped charge can be understood from single-particle properties such as the integrated Berry curvature constructed from Bloch states, while this picture breaks down at finite interaction strengths. These two properties -- robust quantized charge transport in an interacting system of bosons and the breakdown of a single-particle invariant -- could both be measured with ultracold quantum gases extending a previous experiment [2]. We also relate the structure of the spectral flow of the entanglement spectrum to the properties of the charge pump.

Topologically robust defect states in two-fold PT-symmetric systems  SANG-JUN CHOI
(Presenter), JUNG-WAN RYU, HEE CHUL PARK, Center for Theoretical PCS, Institute for Basic Science — The emergence of topologically robust states has been understood in terms of the bulk-edge correspondence; they appear at the boundary between two insulating systems whose topology cannot be continuously deformed into another. However, is its converse true? Here, we find that at the boundary where two topologically trivial insulating system meets, a robust localized state can appear. We provide a new topological identification where two-fold PT-symmetry of the system protects the emergence of such a state against continuous deformations. Moreover, we show the localization length of the topological defect state is insensitive to a wide range of parameters, and the defect states in the known systems fall into our topological identification.

Topological insulators in synthetic dimensions  DAVID LONG (Presenter), PHILIP CROWLEY, Boston University, IVAR MARTIN, Materials Science Division, Argonne National Laboratory, ANUSHYA CHANDRAN, Boston University — Few level quantum systems driven by multiple incommensurate external tones exhibit temporal analogs of many real-space topological phenomena. I will discuss how a qubit driven by two tones realizes a topological insulator in frequency space and identify the symmetry protecting the insulator. The edge modes of the topological insulator can robustly transfer a large amount of energy between the drives for symmetry-broken initial states.

Interaction-induced multivaluedness and topological change between quantum current and its variance  CHIH-CHUN CHIEN (Presenter), University of California, Merced, MEKENA METCALF, Sandia National Lab, CHEN-YEN LAI, Los Alamos National Lab, MASSIMILIANO DI VENTRA, University of California, San Diego — The variance of a quantum observable has been an important quantity in quantum mechanics, and it can reveal additional information beyond the average. By analyzing the parametric curves of the quantum current versus its variance, we found a general change of topology due to the interactions. We consider a benzene-like lattice with fermions driven by a magnetic flux for the isolated system and a three-site lattice connected driven by two particle reservoirs for the open system. In both systems, there is a one-to-one correspondence between the current and its variance in absence of interactions. When the interactions are introduced, the parametric curves exhibit loop structures and show multivalued correspondence between the current and its variance. The phenomena could be realizable using available cold-atom technology.

Order-from-disorder effects and Zeeman field tuned quantum phase transitions in a bosonic quantum anomalous Hall system

FADI SUN (Presenter), JINWU YE, Mississippi State University — We study possible many body phenomena in the recent experimentally realized weakly interacting quantum anomalous Hall system of spinor bosons by Wu, et.al, Science 354, 83-88 (2016). At a zero Zeeman field $h = 0$, by incorporating order from disorder effects, we determine the quantum ground state to be a $N = 2$ XY-antiferromagnetic superfluid state and also evaluate its excitation spectra. At a finite small $h$, the competition between the Zeeman energy and the effective potential generated by the order-from-disorder leads to a canted antiferromagnetic superfluid state, then drives a second order transition to a spin-polarized superfluid state along the z direction. The transition is in the same universality class as the zero density superfluid to Mott transition. Scaling behaviours of various physical quantities are derived. The ongoing experimental efforts to detect these novel phenomena are discussed.

Session Y27 DQI: Quantum Foundations III BCEC 160C - John DeBrota, University of Massachusetts Boston - Tag(s): Focus

11:15AM Y27.00001: Reconstructing quantum space-time from agents' subjective experiences* [Invited] LIDIA DEL RIO (Presenter), ETH Zurich — Within a global physical theory, a notion of locality allows us to find and justify information-processing primitives, like non-signalling between distant agents. Here, we propose exploring the opposite direction: to take agents as the basic building blocks through which we test a physical theory, and recover operational notions of locality from signalling conditions.

For example, in quantum theory, the tensor product rule allows us to describe independent systems jointly, and imposes a notion of locality of actions. However, if one is given a global system, there is no prior reason for considering some factorization of the system's state space as 'the only physical one.' Thus, if multiple agents observe the same system, their individual factorizations of the state space do not necessarily coincide, but can be related by an isomorphism. We may then explore how a group of agents could find out the relation between their individual factorizations of a global space, given only the operational experimental data for each agent, together with communication, under different constraints.

This factorization problem is a generalization of the marginal problem and of self-testing, both of which assume a fixed tensor factorization behind the different local descriptions. It can be applied to derive conditions for a common space coordinate set shared by a group of agents, and as such it is a first step towards operational quantum relativistic theories.

*FQXi Large Grant "Physics of the Observer"

11:51AM Y27.00002: Locally Causal Quantum Mechanics in Space-Time MORDECAI WAEGELL (Presenter), Chapman University — I introduce a reformulation of quantum mechanics as a theory of physical fields in space-time which obey the constraints of special relativity. Instead of being described by a single de-localized wavefunction in configuration space, the fundamental subsystems within a composite system are each described by a continuum of local relative wavefunctions in space. Each relative wavefunction is defined on a particular world-line through space-time, using only the past states and coupling unitaries of the systems within the past-interaction-cone, and thus obeying explicit local causality. As a result, the narrative and causal structures of this reformulation are Lorentz covariant - unlike single-wavefunction descriptions. This model explains violations of Bell inequalities while obeying local causality, but entanglement correlations are not physically obeyed until Alice's and Bob's measurement results are compared locally in space-time. Explaining their experiences in this experiment then necessitates the existence of multiple Alices and multiple Bobs who got different measurement outcomes, and thus we arrive at a locally-branching many-worlds interpretation of quantum mechanics in space-time which obeys local causality - unlike global-branching many-worlds models.
12:03PM Y27.00003: Quantum Clocks: Gravitation and Relativity* ALEXANDER R. H. SMITH (Presenter), Dartmouth College, MEHDI AHMADI, Santa Clara University — Time enters quantum theory through its appearance as an external classical parameter in the Schrödinger equation. In general relativity, time is defined operationally as what is indicated by a clock and the spacetime metric encodes the relationship between different clocks. Reconciling these two different notions of time in a quantum theory of gravity leads to the problem of time, one aspect of which is the disappearance of time in the Wheeler-DeWitt equation.

Motivated by this problem, the conditional probability interpretation (CPI) posits that time evolution emerges from entanglement shared between a clock and system of interest, the joint state of which does not evolve with respect to a background time and satisfies a Wheeler-DeWitt equation. After reviewing the CPI, I will present a generalization in which the clock and system interact — we should expect such a coupling when the gravitational interaction between the clock and system is taken into account. I will demonstrate how such clock-system interactions result in a time-nonlocal modification to the Schrödinger equation. Furthermore, I will demonstrate how time dilation becomes probabilistic within the CPI framework and recover on average the special relativistic result.

12:15PM Y27.00004: Quantized Electromagnetic-Field Propagation in General Non-Local and Non-Stationary Dispersive and Absorbing Media* VERNE JACOBS (Presenter), United States Naval Research Laboratory — We develop dynamical descriptions for the propagation of quantized electromagnetic fields, in the presence of environmental interactions. These descriptions are systematically and self-consistently developed in the complimentary Schrödinger and Heisenberg pictures. An open-systems (non-equilibrium) quantum-electrodynamics and quantum-statistical description is thereby provided for electromagnetic-field propagation in general non-local and non-stationary dispersive and absorbing optical media, including a fundamental microscopic treatment of decoherence and relaxation processes due to environmental collisional and electromagnetic interactions. Particular interest is centered on entangled states and other non-classical states of electromagnetic fields, which may be created by non-linear electromagnetic interactions and detected by the measurement of various electromagnetic-field correlation functions. Accordingly, we develop dynamical descriptions based on general forms of electromagnetic-field correlation functions involving both the electric-field and the magnetic-field components of the electromagnetic field, which are treated on an equal footing.

12:27PM Y27.00005: Spacetime formulation for time crystals and continuous variables TIAN ZHANG (Presenter), University of Oxford, OSCAR DAHLSTEN, Department of Physics, Southern University of Science and Technology — In ordinary, non-relativistic quantum theory, especially in quantum information, space and time are treated differently. For example, time is a parameter rather than an operator; states are defined across the whole space but only at one time. These go against our intuition from relativity as well as classical probability theory. Thus, space-time density matrices have been introduced and here we discuss one of these formulations called pseudo-density matrix (PDM) which treats space and time indiscriminately. As a first application, we use this formulation to analyse time crystals via quantum error correction, which is the first time to discuss time crystals in the language of quantum information. We achieve the same result as the absence of continuous time crystals and formulate discrete time crystals in terms of quantum error correction. NMR experiments have been conducted to verify the results. We also extend this space-time formulation to the continuous variables via a generalisation for Wigner function, and discuss Gaussian case in particular. This is the first step we take to understand temporal vs spatial modes in quantum fields and black holes. We want to analyse temporal correlations in black hole information paradox.
12:39PM Y27.00006: Using Fisher Information to Analyse Inter-measurement Quantum Particles*  DAVID ARVIDSSON SHUKUR (Presenter), University of Cambridge and MIT, CRISPIN BARNES, University of Cambridge, NICOLE YUNGER HALPERN, Harvard-Smithsonian Center for Astrophysics and Harvard University — A debated question in quantum mechanics is how to describe and interpret a quantum particle between observations. Previous discussions have mainly been centred on controversial and interpretation-dependent weak values. In this talk we provide an operational methodology for the analysis of inter-measurement quantum particles. We assume that absolutely perfect quantum evolutions are impossible, and that all interactions include some disturbances. By calculating the quantum Fisher information with respect to these disturbances we obtain a quantitative tool to map out the past path of quantum particles and to investigate the “quantumness” of post-selected experiments. We relate the Fisher information to the Kirkwood-Dirac quasiprobability distribution by decomposing the density matrix of the quantum state in terms of the projectors of the final measurement and the generator eigenbasis of the relevant interaction. We then show that when the Fisher information of a post-selected experiment exceeds its standard maximum, there exist negative quasiprobabilities in the representation, revealing violations of noncontextuality. Our methodology provides a new approach to investigating the foundations of quantum mechanics.

The Sweden-America Foundation

12:51PM Y27.00007: Noninformative prior of the quantum statistical model in the qubit system*  FUYUHIKO TANAKA (Presenter), Osaka University — In quantum process tomography, we often encounter a parametric family of qubits with less symmetry and estimate the parameter from experimental data. If we use Bayes estimates, then we have to choose a default probability distribution over the parameter space, which is called a noninformative prior. While the effect of the prior becomes smaller with the large amount of data, the choice of the noninformative prior based on a certain criterion has been of theoretical interest. In this talk, we consider a suitable definition of a noninformative prior in a general parametric family of qubits.

In the classical Bayesian statistics, there is no universal criterion and still there are many works on the choice of a noninformative prior like the famous Jeffreys prior. The most famous one is Bernardo's criterion, which deals with the maximization of the mutual information. However, its formal extension is troublesome because the quantum relative entropy between two pure states diverges.

Recently the author proposed another way based on the quantum detection game, which is well-defined in pure-states model. In this talk, as further development, we extend the argument to general qubit models, which yields Bures geometry.

*This work was supported by JSPS KAKENHI Grant Numbers 16H04382.

1:03PM Y27.00008: Uncertainty relations for time averaged weak values*  ELI POLLAK (Presenter), Chemical and Biological Physics, Weizmann Institute of Science — Time averaging of weak values using the quantum transition path time probability distribution leads to the establishment of a general uncertainty principle for the weak values of two not necessarily Hermitian operators. This new principle is a weak value analog of the Heisenberg-Robertson strong value uncertainty principle. It shows that complementarity does not prevent the simultaneous determination of weak values of non-commuting operators. When the time fluctuations of the weak values of the two operators under consideration are proportional to each other there is no uncertainty limitation on their variances and, in principle, their means can be determined with arbitrary precision. This will be exemplified by considering weak value uncertainty relations for the time-energy, coordinate-momentum and coordinate-kinetic energy pairs, and an analysis of spin operators and the Stern-Gerlach experiment in weak and strong inhomogeneous magnetic fields. We find that anomalous spin values are associated with large variances implying that their measurement demands increased signal averaging. These examples establish the importance of considering the time dependence of weak values in scattering experiments.

*Israel Science Foundation
1:15PM Y27.00009: Three-Particles Aharonov-Bohm Effect* YUTAKA SHIKANO (Presenter), Quantum Computing Center, Keio University — Recently, we showed the successful experiment on the three-particles Aharonov-Bohm effect using the tapped ion [A. Noguchi, YS, K. Toyoda, S. Urabe, Nature Communications 5, 3868 (2014)]. In this experiment, there still remain several fundamental questions on the identical particles. Inspired by our experiment setup, we can discuss the properties of the identical particles from the Aharonov-Bohm effect perspectives. The phase shift by changing the particle status leads to give an answer to the following question when the Aharonov-Bohm phase can be acquired. As the minimum setup, three particle setting is considered. Maybe, it is possible to be generalized to the N-body particles. Furthermore, the dynamical non-locality aspects will be discussed if possible.

*This work is financially supported by a grant from The Precise Measurement Technology Promotion Foundation, JSPS KAKENHI (Grant Nos. 16K05492, 16K05410, 17H02797, 17K05082) and Collaborative Research Project of Laboratory of Materials and Structures.

1:27PM Y27.00010: Topological barriers for charged quantum systems* ISMAEL PAIVA (Presenter), YAKIR AHARONOV, MORDECAI WAEGELL, JEFF M TOLLAKSEN, Chapman University — The Aharonov-Bohm effect introduced a surprising influence of topology on the dynamics of quantum systems. The discovery of such a phenomenon unveiled that the evolution of a quantum system with charge traveling around a solenoid is affected by the magnetic flux on it, even though the solenoid only produces electromagnetic field on its interior. Here, making use of the concept of modular variables, which evidence the dynamical nonlocality presented in quantum mechanics, we argue that this effect allows solenoids to be used as barriers of energy for charged quantum systems. Moreover, we present and discuss a thought experiment, as well as its numerical simulation, where a configuration of solenoids inside a cavity can trap some quantum states in a certain subregion of it.

*Ismael L. Paiva acknowledges financial support from the Science without Borders Program (CNPq/Brazil).

1:39PM Y27.00011: Quantum simulation of a general PT-symmetric two-level system* CHAO ZHENG (Presenter), Department of Physics, North China University of Technology — The evolution of a two-level quantum system with a general PT-symmetric Hamiltonian is simulated as a subsystem in a four-dimensional Hilbert space, which makes it possible to simulate any two-level PT-symmetric quantum system using a conventional quantum mechanics system. We studied the ability to simulate and investigate novel quantum systems and phenomena using a conventional Hermitian quantum computer. The quantum circuits are given for a qubit and two qudit systems.

1:51PM Y27.00012: Computing with a single qubit faster than the computation quantum speed limit* NIKOLAI SINITSYN (Presenter), Theoretical Division, Los Alamos National Laboratory — The possibility to save and process information in fundamentally indistinguishable states is the quantum mechanical resource that is not encountered in classical computing. I demonstrate that, if energy constraints are imposed, this resource can be used to accelerate information-processing without relying on entanglement or any other type of quantum correlations. In fact, there are computational problems that can be solved much faster, in comparison to currently used classical schemes, by saving intermediate information in nonorthogonal states of just a single qubit. There are also error correction strategies that protect such computations.

*the LDRD program at LANL
2:03PM Y27.00013: Problems with Decoherence in Quantum Geometrodynamics* MAANELI DERAKHSHANI (Presenter), Utrecht University — I illustrate some severe conceptual and technical problems that arise in attempts to apply quantum decoherence concepts to "quantum geometrodynamics" (i.e. Dirac constraint quantization of classical general relativity in the Hamiltonian formulation). In particular, I show that the Problem of Time, the Hilbert Space Problem, and the conceptual dependence of decoherence on time evolution and Hilbert space structure implies: 1) suppression of interference cannot take place between components of a superposition of quantum-gravitational (i.e. Wheeler-DeWitt) wave functionals; 2) approximate diagonalization of the reduced density matrix (associated with said superposition) in the 3-geometry basis cannot take place, and such a reduced density matrix is mathematically ill-defined; 3) time-dependent functional Schroedinger equations for the matter components of said superposition cannot be derived in a semiclassical approximation. I conclude, contrary to extant claims in the quantum gravity literature, that quantum decoherence concepts cannot be consistently applied to quantum geometrodynamics. I then suggest that quantum decoherence concepts can only be sensibly applied to quantum gravity theories that posit classical time parameters or matter-clock variables at a fundamental level.

Friday, March 8, 2019 11:15 AM - 2:15 PM

Session Y29 DQI: Semiconducting Qubits: Automation of Tune-up BCEC 162A - Natalia Ares

11:15AM Y29.00001: Silicon MOSFET quantum dots with simplified metal-gate geometry* EDUARDO BARRERA (Presenter), FRANCOIS SFIGAKIS, FERHAT AYDINOGLU, JONATHAN D BAUGH, Institute for Quantum Computing, University of Waterloo, Waterloo, Canada — Silicon (Si) CMOS spin qubits have become a promising platform for a future quantum information processor due to recent demonstrations of high fidelity single and two qubit gates [Veldhorst et. al., Nature 526.7573 (2015)], compatibility with industrial CMOS process and promising prospects for scalability. Typical Si spin qubits devices consist of gate-defined quantum dots, each defined by several metal gates, which pose a challenge to scaling the technology up. Hence, future designs of Si spin qubits will need to reduce the fabrication complexity and adopt a scalable design.

Here, we introduce a two metal-layer MOSFET quantum dot device that reduces the number of metal gates and simplifies the dot tune-up procedure. By performing electron counting measurements with a charge sensor, we determine that the accumulation gate defining the electron reservoir can tune the dot-reservoir tunnel rate by about 10 decades/V. Magnetospectroscopy measurements up to 6 T reveal electron spin filling in the few electron regime from which we estimate a valley splitting of about 290 μeV.

*The authors would like to thank NSERC, the Waterloo Institute for Nanotechnology, the Canada First Research Excellent Fund, and the University of Waterloo's Quantum NanoFab facility.

11:27AM Y29.00002: Single electron charge shuttling in a linear quantum dot array* ADAM MILLS (Presenter), DAVID ZAJAC, MICHAEL GULLANS, FELIX SCHUPP, THOMAS HAZARD, JASON R PETTA, Princeton University — Recent advances in silicon spin qubits have pushed single qubit fidelities beyond 99.9% [1,2] and have lead to the realization of two-qubit gates based on exchange coupling [3-6]. In order to advance spin qubits to the next level of technological complexity, it is important to start investigating how to scale up to larger multi-component architectures. These architectures must allow for arbitrary coupling of spatially separated qubits, demanding the development of inter-qubit quantum state transfer procedures. Here we demonstrate shuttling of a single electron across a linear array of 9 series-coupled Si quantum dots in ~50 ns with an approach that is extendable to larger quantum dot arrays.

*Research sponsored by ARO grant No. W911NF-15-1-0149 and the Gordon and Betty Moore Foundation's EPIQS Initiative through grant GBMF4535. Devices were fabricated in the Princeton University Quantum Device Nanofabrication Laboratory.
11:39AM Y29.00003: Electron shuttling based error-correction architectures using quantum dot qubits* VEIT LANGROCK (Presenter), DAVID PETER DIVINCENZO, Institute for Theoretical Nanoelectronics (PGI-2), JARA-FIT Institute for Quantum Information, FZ Jülich, Germany — Spin-qubits based on electrons in gate-defined quantum dots [1] are currently one of the major candidates for quantum computers realized in semiconductor hosts. The inherent dot mobility provided by the conceptual ease of electron shuttling in such gate-defined systems is a powerful resource which has been incorporated as a vital component in proposals for fault-tolerant spin-qubit architectures [2,3], with the assumption that such operations can be realized with very high fidelity and on relatively short time scales. We address the issue of decoherence for such shuttling devices and present a possible realization of a scalable fault-tolerant quantum memory based on more realistic device models.

*VL acknowledges support from Helmholtz IVF grant 'Scalable solid state quantum computing'.

11:51AM Y29.00004: Simulating coherent electron shuttling in quantum dots BRANDON BUONACORSI (Presenter), BENJAMIN D SHAW, JONATHAN D BAUGH, Institute for Quantum Computing, University of Waterloo, Canada — Coherent transport of electron spins is required for several proposed large-scale architectures based on quantum dot spin qubits [1,2]. In [1], spin singlets are distributed across neighboring computational nodes by sequential single-electron tunneling through a linear array of quantum dots. We adopt a simplified metal-gate geometry for silicon MOS dots and use the Nextnano software to determine the potential landscape as a function of varying gate voltages, subsequently solving the time-dependent Schrodinger equation in 1D to simulate coherent shuttling. An algorithm is presented that calculates time-dependent voltages that maintain a desired fidelity with the ground state orbital wavefunction. These tools are used to vary the geometrical device parameters to maximize the electron shuttling velocity. We further show that the essential physics can be captured in an effective Hamiltonian model, which allows us to explore how spin-orbit and valley states affect the shuttling fidelity and maximum velocity.

12:03PM Y29.00005: Algorithm for automated tuning of a quantum dot to the single electron regime.* MAXIME LAPOINTE-MAJOR (Presenter), JULIEN CAMIRAND LEMYRE, DANY LACHANCE-QUIRION, SOPHIE ROCHELLE, MICHEL PIORO-LADRIERE, Institut quantique and Département de Physique, Université de Sherbrooke, Sherbrooke, Québec, J1K 2R1, Canada — Tuning quantum dot devices to an operational target is a time-consuming process. In this work, we have developed an algorithm adapted to quantum dots measured by charge detection with a single electron transistor (SET). The program uses a computer-controlled visual approach, where the tuning of the quantum dot is performed with an intuitive heuristic approach. Small size stability diagrams of the dot and reservoir gates are measured in an adaptive sequence until the last electronic transition of the quantum dot is found. For each stability diagram, the charge detector background is removed and the electron occupancy transitions are identified. From these transition points, lines are reconstructed using a modified Hough transform and other image detection tools. Preliminary tests on previously measured stability diagrams show reliable performances of the algorithm for different samples. This work is a step towards fast automatized initialization of quantum dots arrays.

12:15PM Y29.00006: Control of a GaAs “QuByte” in the single electron regime – adding dots one-by-one  
CHRISTIAN VOLK (Presenter), ANNE-MARIJE ZWERVER, QuTech, TU Delft, PIETER EENDEBAK, Netherlands Organization for Applied Scientific Research (TNO), SJAAK VAN DIEPEN, QuTech, TU Delft, FLOOR VAN RIGGELEN, Netherlands Organization for Applied Scientific Research (TNO), UDITENDU MUKHOPADHYAY, JUAN PABLO DEHOLLAIN, TOIVO HENSGENS, QuTech, TU Delft, CHRISTIAN REICHL, WERNER WEGSCHEIDER, Solid State Physics, ETH Zürich, LIEVEN VANDERSYPEN, QuTech, TU Delft — Spin qubits based on semiconductor quantum dots (QDs) are promising building blocks for quantum computation. So far, research mainly focused on devices with up to four QDs. However, quantum algorithms, quantum simulations and mediators to exchange quantum information require larger and scalable systems. Though, controlled filling becomes challenging with an increasing number of QDs due to cross-capacitances and electron latching effects.

We develop a scalable technique, the ‘n+1 strategy’ where, starting from a double QD, subsequent QDs will be added one-by-one. We measure the capacitive coupling between all relevant gates and the QDs in order to create a parameter set of virtual gates. That allows individual control of chemical potentials and thus the number of electrons on each QD and furthermore the adjustment of tunnel rates.

We successfully use this technique to tune up a linear array of eight QDs ‘QuByte’ in GaAs so they are occupied by one electron each.

12:27PM Y29.00007: Towards Autonomous Tuning of Double Quantum Dots  
JANA DARULOVA (Presenter), Institute for Theoretical Physics, ETH Zurich, SEBASTIAN PAUKA, ALICE MAHONEY, School of Physics, The University of Sydney, JOHN HORNIBROOK, Microsoft Corporation Sydney, NATHAN WIEBE, CHRISTOPHER GRANADE, Microsoft Corporation Redmond, WA, MAJA C CASSIDY, DAVID REILLY, Microsoft Corporation Sydney, MATTHIAS TROYER, Microsoft Corporation Redmond, WA — Defining quantum dots in semiconductor or semiconductor/superconductor heterostructures is an essential step in initializing solid-state qubits. To date, the majority of the repetitive procedure of finding suitable gate voltages defining a quantum dot is done manually. However, as the complexity of devices as well as the number of devices per chip grows, this approach becomes unfeasible.

Current approaches either require significant, manually measured input, or address specific parts of the tune-up only. In both cases, only one well known device has been addressed.

In this talk we present an alternative autonomous automated solution for the tuning of gate-defined quantum dots which requires as input only the device layout. Our approach is able to characterize unknown devices and determine suitable gate voltages defining either a single or double quantum dot. We also discuss the extraction of the full capacitance matrix and performance of different classifiers when applied to both theoretical and experimental data.

JULIAN DAVID TESKE (Presenter), SIMON HUMPOHL, RENE OTTEN, PATRICK BETHKE, PASCAL CERFONTAINE, HENDRIK BLUHM, JARA-FIT Institute Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, 52074 Aachen, Germany — In the search for a technology best suited for quantum computation, spin qubits based on gate-defined quantum dots have demonstrated very favorable properties, one remaining challenge is their tuning into a suitable operating regime. Since this requires accurate tuning of the voltages applied to all electrostatic gates, this is a time-consuming procedure [1]. Thus, the automation of these tuning procedures is a necessary requirement for the operation of a quantum processor based on gate-defined quantum dots, which is yet to be fully addressed.

We present an algorithm for the automated fine-tuning of quantum dots, and benchmark its performance by tuning tunnel and lead coupling on a GaAs singlet triplet qubit. We employ a Bayesian approach called Kalman filter to estimate the gradients of the parameters of interest as function of gate voltages. Our benchmarks demonstrate the ability of reaching the operation regime within 3 to 5 iterations, corresponding to 10 to 15 minutes of lab-time.

ANDREW MOUNCE (Presenter), PHILLIP J LEWIS, CARA MONICAL, N. TOBIAS JACOBSON, ALBERT GRINE, MARTIN RUDOLPH, JOHN ANDERSON, JOEL R. WENDT, TAMMY PLUYM, DAN R WARD, KURT W. LARSON, MICHAEL P LILLY, MALCOLM S. CARROLL, Sandia National Laboratories — Tune-up and analysis of quantum dots (QD) is an arduous manual task consisting of a sequence of steps that builds upon one another. The tuning and analysis complexity is increasing as designs extend from QDs to multi-objects (e.g., donor-QD coupling and multi-QDs). The process can be simplified by utilizing image recognition techniques and automation. In this talk, I will present image analysis techniques which extract information from transport and charge sensing stability plots. These analysis modules can determine parameters such as tunnel rates and charge configurations in the QD systems. We identify the necessary combination of tune-up steps and feedback from analysis modules (i.e., output parameters for the next scan) that can automate tuning to few-electron charge sensing. This talk presents some of the proof-of-concepts, details and key future challenges.

1:03PM Y29.00010: A Flexible Control System for Quantum Dot Qubits*  
NIZAR MESSAOUDI (Presenter), Keysight Technologies, AZFAR BADAROUDINE, LARISSA NJEJIMANA, Département de Génie Électrique et Informatique, Université de Sherbrooke, GIDGET HEINTZ, Keysight Technologies, MARC-ANTOINE GENEST, MICHEL PIORO-LADRIERE, Institut quantique et Département de physique, Université de Sherbrooke — The advancement of Quantum Dot qubit technology is paving the way to fault-tolerant quantum computing systems. Although spin qubits are still at a relatively early stage, their strong robustness against noise makes them extremely attractive. However, quantum architectures still rely on classical electronics for control and readout. While traditional instrumentation has been used to manipulate and detect qubit spins, they lack the scalability necessary to move from single qubit to multi-qubit experiments. Even if the instruments can be synchronized for signal phase coherence, they lack the flexibility that is required for researchers to explore new control techniques and qubit architectures. This flexibility can be achieved through Digital Signal Processing (DSP) realized on Field Programmable Gate Arrays (FPGA). FPGAs allow the implementation of a range of DSP algorithms while also providing absolute time determinism. This paper discusses the use of commercial FPGA based instruments to implement a spin-qubit control system. A lock-in amplifier is implemented in the FPGA of the digitizer and quantum dot Coulomb blockade measurements are compared to when using a dedicated lock-in amplifier.

1:15PM Y29.00011: Scalable tuning of InAs quantum dots embedded in photonic structures  
JOEL GRIM (Presenter), ALLAN S BRACKER, MAXIM ZALALUTDINOV, SAMUEL CARTER, U.S. Naval Research Laboratory, ALEXANDER C. KOZEN, ASEE postdoctoral research fellow at the U.S. Naval Research Lab, MIJIN KIM, KeyW corporation, CHUL SOO KIM, U.S. Naval Research Laboratory, JEROME THOMAS MLACK, NRC Research Associate residing at the Naval Research Laboratory, MICHAEL K YAKES, U.S. Naval Research Laboratory, BUMSU LEE, NRC Research Associate residing at the Naval Research Laboratory, DANIEL G GAMMON, U.S. Naval Research Laboratory — The prospect of integrated quantum optics platforms based on semiconductor quantum dots (QDs) has driven quantum semiconductor research for decades. This has resulted in advanced demonstrations of single photon emission and switching, quantum transistors, and qubit-photon interfaces. However, the variation in QD emission energies – which prevents interfacing QDs with each other and photonic elements such as cavities and waveguides – has thus far limited these demonstrations to one or two QDs. We have developed an approach that addresses this challenge by laser-patterning strain via local phase transitions of a conformal thin film deposited on the surface of photonic architectures. Using this approach, InAs QDs can be tuned across the entire inhomogeneous distribution, with a spectral resolution down to the homogeneous linewidth, and sub-micron spatial resolution. We show that a scalable number of QDs embedded in the same bridge waveguide can be tuned into resonance. We also demonstrate that the emission energies of QDs embedded in photonic crystal cavities and waveguides can be tuned with this approach.

Deep Reinforcement Learning Based Control of Coherent Transport by Adiabatic Passage of Spin Qubits

RICCARDO POROTTI (Presenter), DARIO TAMASCELLI, Dipartimento di Fisica, Università degli Studi di Milano, MARCELLO RESTELLI, Dipartimento di Elettronica, Informazione e Bioingegneria, Politecnico di Milano, ENRICO PRATI, Istituto di Fotonica e Nanotecnologie, Consiglio Nazionale delle Ricerche — Several tasks, involving the temporal evolution of a system of qubits, require stochastic methods to identify the best sequence of gates and the interaction time among qubits. The great success of deep reinforcement learning (DRL) methods to identify the best strategy in problems involving a competition between short and long-term rewards, has suggested its application to quantum information (QI) as well.

To extend the application of DRL to the transfer of QI, we focus on Coherent Transport by Adiabatic Passage (CTAP) on a chain of three semiconductor quantum dots (QDs). This task is usually performed by the so-called counter-intuitive sequence of gate pulses, which can coherently transfer an electronic population from the first to the last site of an odd chain of QDs, leaving the central depopulated.

We apply a technique to find a near-optimal gate pulse sequence without explicitly providing any preliminary knowledge of the underlying physical system to the DRL agent. Using the advantage actor-critic algorithm, with a small neural network as a function approximator, we trained a DRL agent to select the best action during the evolution to achieve the same results previously found only by ansatz solutions. The method naturally extends to systems affected by dephasing and loss.

Controllable Approximations for Spin Qubit Design - Jacob's Ladder of Device Modelling*

ANDRE SARAIVA (Presenter), CHRISTOPHER ESCOTT, Silicon Quantum Computing, UNSW, ANDERSON WEST, ROSS LEON, RUICHEN ZHAO, Univ of New South Wales, HENRY YANG, Silicon Quantum Computing, UNSW, ANDREW STEVEN DZURAK, Univ of New South Wales — Some key quantities for spin qubits - tunnel rates, exchange coupling and electronic correlations in general - are hard to describe within the most commonly adopted approximations. Tunnel rates and the exchange coupling are small corrections to the total electronic energy, so that variational methods often fail to predict these quantities. Electronic correlations can be accurately calculated for few electrons through full CI, for example, but are difficult for many electrons. We discuss some of the limitations of these approaches and how to overcome these with state-of-the-art methods that are controllable. We review two methods to improve the accuracy of these quantities: the Path Integral Monte Carlo method for tunnel rates and exchange coupling; and the Density Functional Theory applied to the effective mass Hamiltonian for the many electron problem. Both methods have controllable approximations that may be systematically improved by enhancing the computational effort.

GPU-Accelerated Simulations of Single and Two Electron-Spin Qubit Operations in Semiconductor Devices.*

HUGO LEPAGE (Presenter), ALEKSANDER LASEK, DAVID ARVIDSSON SHUKUR, CRISPIN BARNES, University of Cambridge — Although experimental physicists can control the output of electron-spin setups in the lab, it is hard to know exactly what happened to the particles during the manipulation. We present GPU-accelerated simulations that provide valuable insights into how a particle behaves while in the metaphorical “black box” that is the experimental device. In particular, we show how the most general measurements can be implemented for dynamic qubits via a POVM protocol. We provide high fidelity simulations of entanglement distillation for electrons carried by surface acoustic waves. Furthermore, we compare two methods for generating entanglement between electron-spin qubits using the power-of-SWAP operation. By using realistic experimental parameters, we show that entanglement generation via electron-electron collisions in a harmonic channel cannot be implemented for multidimensional systems. We provide an alternative by demonstrating that a method based on the exchange energy across a tunnel barrier is more viable than previously thought. These findings pave the way to designing efficient entangling quantum logic gates.

*This project has received funding from the European Union's Horizon 2020 research and innovation programme under the Marie Skłodowska-Curie grant agreement No 642688.
Controlling spatial entanglement in interacting two electrons trapped in superlattices

DUNG PHAM (Presenter), SATHWIK BHARADWAJ, YUCHEN WANG, Department of Physics, Worcester Polytechnic Institute, Worcester, MA 01609, L RAMDAS RAM-MOHAN, Department of Physics, Electrical and Computer Engineering and, mechanical engineering, Worcester Polytechnic Institute, Worcester, MA 01609 — Entanglement properties of two-electron systems have been the subject of considerable interest in recent years. Solutions to the Hamiltonian in few-electron systems require special techniques to evaluate computationally demanding Coulomb integrals. Here we develop a fully variational action integral formalism to obtain the coordinate space wavefunctions for two electrons trapped in semiconductor superlattices. The entanglement in such systems have contributions from not only the spin part but also from the spatial correlations of the confining potential. The latter contribution has been neglected in most considerations. We show that the probability distributions of electrons largely deviate from those of the widely-used slater-determinant representation. We demonstrate that the entanglement in such systems can be controlled by varying physical parameters, and by applying external fields. The entanglement resonances associated with anti-crossings of eigenstates are displayed for the first time, and these can be manipulated through geometric changes and by the applied electric field.

Friday, March 8, 2019 11:15 AM - 2:15 PM

Session Y34 DCMP: The Physics of Computing and Computing with Physics

11:15AM Y34.00001: Digital-Analog Quantum Computing [Invited] MIKEL SANZ (Presenter), University of the Basque Country, Bilbao, Spain — Purely digital classical computers are rather recent devices which are a consequence of the impressive technological development in miniaturization of electronics and microchips. However, until only few decades ago, digital computers had not sufficient computational power for most applications, so they usually employed analog parts for specific hard calculations. The situation nowadays in quantum computing is similar due to the small number of coherent controllable qubits allowed by current platforms. Even doubling the number of qubits yearly, a purely digital approach with error correction will not allow us to solve relevant problems in the following decades. Here, we will explore in detail a universal digital-analog approach employing the ubiquitous Ising Hamiltonian as the resource. We use this global Hamiltonian, together with local rotations, to generate an arbitrary unitary and we find efficient protocols, polynomial in the number of single-qubit rotations, to produce relevant families of Hamiltonian, such as arbitrary two-body Hamiltonians or, in general, k-body Hamiltonians. We introduce the concept of banged digital-analog quantum computing, in opposition to the stepwise, when single-qubit rotations are much faster than the natural time-scale of the Hamiltonian, which allows us to compute without switching on/off the global interaction. Employing natural models of errors, we compare the performance of digital against both stepwise and banged digital-analog protocols showing that, in general, digital-analog approaches perform better both in time and fidelity. Finally, we will also show that this emerging digital-analog approach can be applied not only to quantum simulations, but also to quantum algorithms. Indeed, we provide an efficient digital-analog description of the Quantum Fourier transform, comparing its performance against the pure digital approach in the presence of errors.

11:51AM Y34.00002: The physics and challenges of neuromorphic computing with spintronic nanooscillators [Invited] JULIE GROLLIER (Presenter), CNRS/Thales lab — TBD
12:27PM Y34.00003: MemComputing: leveraging memory and physics to compute efficiently* [Invited] MASSIMILIANO DI VENTRA (Presenter), University of California, San Diego — In this talk I will discuss how to employ memory (time non-locality), in a novel physics-based approach to computation: Memcomputing [1, 2, 3]. As examples, I will show the polynomial-time solution of prime factorization, the search version of the subset-sum problem [4], and approximations to the Max-SAT beyond the inapproximability gap [5], using polynomial resources and self-organizing logic gates, namely gates that self-organize to satisfy their logical proposition [4]. I will also show that these machines are described by a Witten-type topological field theory, and they compute via an instantonic phase, implying that they are robust against noise and disorder [6]. The digital memcomputing machines we propose can be efficiently simulated, are scalable and can be easily realized with available nanotechnology components.

*Work supported in part by MemComputing, Inc. (http://memcpu.com/) and CMRR.

1:03PM Y34.00004: Benchmarking NISQ-era quantum processors [Invited] JAY GAMBETTA (Presenter), IBM Thomas J. Watson Research Center — As the field marches towards quantum advantage with near-term quantum processors, it becomes imperative to characterize, verify, and validate performance. An outstanding scientific challenge in the community is a scalable set of metrics or experiments which can shed light on the usability of a device for near-term algorithms. Moreover, it becomes critical to explore techniques to extend the computational reach of noisy systems, be it through understanding underlying non-idealities, or more efficient circuit compilation. In this talk I will review the work we are doing at IBM to develop a NISQ device and our recent results.

1:39PM Y34.00005: Accelerating Deep Neural Networks with Analog Memory Devices [Invited] CHARLES MACKIN (Presenter), PRITISH NARAYANAN, HSINYU TSAI, STEFANO AMBROGIO, AN CHEN, GEOFFREY W. BURR, IBM Research--Almaden — Over the next few years, special-purpose hardware accelerators based on conventional digital-design techniques will optimize the GPU framework for Deep Neural Network (DNN) computations, increasing speed and reducing power for both “training” and “forward-inference.” During training, DNN weights are adjusted to improve network performance through repeated exposure to the labelled data-examples of a large dataset. During forward-inference, already trained networks are used to analyze new data-examples.

Even after the improved computational performance and efficiency that is expected from these special-purpose digital accelerators, there would still be an opportunity for even higher performance and even better energy-efficiency from neuromorphic computation based on analog memories (including both memristors and Phase-Change Memory).

In this presentation, we discuss the origin of this opportunity as well as the challenges inherent in delivering on it, with some focus on materials and devices for analog volatile and non-volatile memory. We review our group’s work towards neuromorphic chips for the hardware acceleration of training and inference of Fully-Connected DNNs [1-4]. The presentation will discuss the impact of real device characteristics – such as non-linearity, variability, asymmetry, and stochasticity – on performance, and describe how these effects determine the desired specifications for the analog resistive memories needed for this application. We present some novel solutions to finesse some of these issues in the near-term, and describe some challenges in designing and implementing the CMOS circuitry around the NVM array. The talk will end with an outlook on the prospects for analog memory-based DNN hardware accelerators.

11:15AM Y36.00001: Engineering Quantum States of Matter for Atomic Clocks [Invited] JUN YE (Presenter), National Institute of Standards and Technology Boulder — Precise engineering of quantum states of matter and advanced laser technology are elevating the performance of optical atomic clocks to new levels. These increasingly powerful measurement capabilities are promising greater opportunities for probing fundamental and emerging phenomena.

11:51AM Y36.00002: Geodesy and metrology with a transportable optical clock* [Invited] CHRISTIAN LISDAT (Presenter), Physikalisch-Technische Bundesanstalt — The development of optical clocks that can be transported and operated outside metrology laboratories promises exciting new and competitive measurement methods for geodesy, where chronometric levelling is considered as a complementary method to measure height differences [1-4].

To perform such tasks in a competitive way, it is not sufficient to demonstrate the clock performance in the laboratory, but transportable clocks need to show reproducibility of their frequency at the level of few parts in $10^{17}$ and better in the various locations to which they are transported and where they are used.

At Physikalisch-Technische Bundesanstalt (PTB), we have developed such a transportable optical clock [5] that has been tested for the applications described above by measurement campaigns outside the laboratory. I will present results of the measurement campaigns we have performed so far and discuss the perspective of our apparatus for chronometric levelling.

*We acknowledge support by the German Research Foundation (DFG) within CRC 1128 geo-Q, the Marie-Curie Action ITN FACT, and the EMRP project ITOC. The EMRP is jointly funded by the EMRP participating countries within EURAMET and the European Union.

12:27PM Y36.00003: Geopotential measurements with synchronously linked optical lattice clocks [Invited] MASAO TAKAMOTO (Presenter), RIKEN — The recent progress of optical lattice clocks has improved the accuracies to $10^{-18}$, which outperforms the realization of the SI second. We will present the development of the optical lattice clocks and their applications in geodetic measurements.

1:03PM Y36.00004: Atomic clock performance beyond the geodetic limit* [Invited] ANDREW LUDLOW (Presenter), National Institute of Standards and Technology Boulder — We present recent updates in the development of optical lattice clocks, with particular emphasis on systems using ultracold ytterbium. Over the last several years, the intersection of quantum control, optical coherence, and precision measurement has afforded substantial progress in the development of these clock systems. Measurements can now reach $10^{-18}$ precision or better, at a level capable of beyond state-of-the-art geodesy through determination of the gravitational redshift. We will highlight a variety of Yb clock measurement campaigns that have recently been carried out, including optical frequency ratio measurements with other optical clocks. These measurements are analyzed in the context of beyond-Standard-Model physics, such as fundamental constant variation and dark matter searches. Finally, we will discuss prospects for continued improvements and future measurement applications.

*NIST, DoD, NASA, DARPA
Two clock transitions in neutral Yb for the highest sensitivity to variations of the fine-structure constant

Invited: MARIANNA SAFRONOVA (Presenter), SERGEY G PORSEV, University of Delaware, CHRISTIAN SANNER, JUN YE, JILA, NIST and University of Colorado, Boulder — We propose a new frequency standard based on a $4f^{14} \, 6s6p \, ^3P_0 \rightarrow 4f^{13} \, 6s2 \, 5d \, (j=2)$ transition in neutral Yb [1]. This transition has a potential for high stability and accuracy and the advantage of the highest sensitivity among atomic clocks to variation of the fine-structure constant $\alpha$. We find its dimensionless $\alpha$-variation enhancement factor to be $K=-15$, in comparison to the most sensitive current clock (Yb$^+$ E3, $K=-6$), and it is 18 times larger than in any neutral-atomic clocks (Hg, $K=0.8$). Combined with the unprecedented stability of an optical lattice clock for neutral atoms, this high sensitivity opens new perspectives for searches for ultralight dark matter and for tests of theories beyond the standard model of elementary particles. Moreover, together with the well-established $^1S_0 \rightarrow ^3P_0$ transition one will have two clock transitions operating in neutral Yb, whose interleaved interrogations may further reduce systematic uncertainties of such clock-comparison experiments.

Friday, March 8, 2019 11:15 AM - 1:51 PM

Session Y39 GMAG DMP: Magnetic Sensors, Devices, and Applications  

11:15AM Y39.00001: PicoTesla Magnetic Sensors based on Magnetic Tunneling Junctions with Double-staged Flux Concentrators*  
GUANYANG HE (Presenter), YIOU ZHANG, LIJUAN QIAN, GANG XIAO, Brown University, QIANG ZHANG, J. CARLOS SANTAMARINA, TADEUSZ W. PATZEK, XIXIANG ZHANG, King Abdullah University of Science and Technology — Highly sensitive magnetic tunneling junction (MTJ) sensors have shown great potential as the best miniaturized, low-cost, solid-state magnetic sensors, strongly needed in different applications. We have fabricated high performance MTJ sensors and pushed the magnetic sensing limit to a high level, mainly by incorporating double-staged magnetic flux concentrators (MFC), one on the MTJ chip level and the other on a macroscopic level, to amplify the external field. After multiple optimizations on MFC fabrication conditions, it has increased the sensitivity of the MTJ sensor by a large factor of 517 to 775.4%/Oe in terms of magnetoresistance response. The sensor coercivity is only 0.12 Oe which is desired for sensing application, as we will show that the low-field detectability of magnetic sensor have direct relations with its coercivity. By integrating such MTJ sensors from wafers to integrated circuits, our sensor prototype has achieved detectable field limit of 30pT per root hertz at 10 kHz. We will also present the noise spectrum and the sensitivity spectrum of it and discuss its detectabilities based on these information.

*The work was supported by National Science Foundation through Grants No. DMR-1307056, and by King Abdullah University of Science and Technology (KAUST).

11:27AM Y39.00002: Circumventing Magnetostatic Reciprocity: a Diode for Magnetic Fields*  
JORDI PRAT-CAMPS (Presenter), University of Sussex, PATRICK MAURER, GERHARD KIRCHMAIR, ORIOL ROMERO-ISART, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences — Lorentz reciprocity establishes a stringent relation between electromagnetic fields and their sources. For static magnetic fields, a relation between magnetic sources and fields can be drawn in analogy to Green's reciprocity for electrostatics. So far, the magnetostatic reciprocity principle remains unchallenged and the magnetostatic interaction is assumed to be symmetric (reciprocal). Here we show that a linear and isotropic electrically conductive material moving with constant velocity is able to circumvent the magnetostatic reciprocity principle and realize a diode for magnetic fields. This result is demonstrated by measuring an extremely asymmetric magnetic coupling between two coils that are located near a moving conductor. The possibility to generate controlled unidirectional magnetic couplings implies that the mutual inductances between magnetic elements or circuits can be made extremely asymmetric. Other strategies to break magnetic reciprocity based on novel kinds of magnetic metamaterials will be also discussed.

*This work is supported by the European Research Council (ERC-2013-StG 335489 QSuperMag), the Austrian Federal Ministry of Science, Research, and Economy (BMWF) and the European Union’s Horizon 2020 research and innovation programme (grant agreement No 737087).
11:39AM Y39.00003: picoTesla Magnetoelectric Sensors with Low-Curvature Nano-Plate Resonators  ALEXEI
MATYUSHOV (Presenter), Physics/Electrical and Computer Engineering, Northeastern University, ZHENYUN QIAN, MOHSEN
ZAEIMBASHI, CHENG TU, HUAIHAO CHEN, MENGHUI LI, MATTEO RINALDI, NIAN XIANG SUN, Electrical and Computer
Engineering, Northeastern University — Prior studies have shown the effectiveness of piezoelectric/magnetostrictive MEMS
magnetometers featuring a nano plate resonator and using the ΔE effect for highly sensitive detection of DC magnetic
fields. By monitoring changes in resonance frequency from applied magnetic fields, a sensitivity of a few Hz/nT has been
achieved in unshielded lab environments. With dimensions of ≤ 200 μm across, and < 1 μm thick, these devices offer the
advantages of small scale, including portability and low power consumption, as well as high spatial resolution in sensor
arrays. However, a thorough understanding of magnetic properties and other performance aspects in these
magnetometers has not been developed. In this study we report on the strong effects of resonator plate curvature on
sensor performance. It was found that the total resonance frequency shift dropped off exponentially with increasing
curvature by as much as two orders of magnitude. By fabricating a ΔE effect magnetometer with low curvature in the nano
plate resonator, we achieved maximum magnetic field sensitivity of 4.98 Hz/nT. High frequency stability was also
observed: an Allan deviation measurement yielded a minimum of 0.0245 Hz at 100 ms averaging time. This results in a
theoretical limit of detection of 1.56 pT/Hz1/2.

11:51AM Y39.00004: Brain MRI at ultra-low field: new multifunction instrument  KOOS C J ZEVENHOVEN (Presenter),
Aalto University — While conventional MRI uses increasingly high magnetic fields, another approach has emerged, where
the signal is detected in an ultra-low field (ULF) on the order of Earth’s field. Despite similarities, ULF-MRI differs from high-
field MRI in interesting ways. At ULF, the magnetic pulses can be applied silently and with an open-geometry coil system,
and the signal can be modeled from theory with high accuracy. The unique possibilities of ULF-MRI also include the
combination of MRI and magnetoencephalography (MEG), the measurement of the weak magnetic fields generated by
brain activity. ULF-MRI and associated methods such as current-density imaging (CDI) improve the localization of brain
activity.

Superconducting quantum-interference devices (SQUIDs) configured as pulse-tolerant sensors for ULF-MRI can also be
used for MEG. Compared to our first hybrid prototype, our current-generation system uses more robust techniques and
new software. Our dedicated amplifiers allow switching off even \( B_0 \) even during an imaging sequence, enabling the
encoding of 3D information for current-density imaging (CDI). We demonstrate the state of the art of ULF-MRI and
describe Dynamical Coupling for Additional dimensioNs (DynaCAN) – designing pulse waveforms to couple to a dynamical
system with memory.

12:03PM Y39.00005: Finite element study on magnetomechanical properties of magnetorheological elastomer
used in advanced mechanical systems.  WINNIE KIARIE (Presenter), NEELAM PRABHU GAUNKAR, DAVID C JILES, Iowa State
University, EDWARD BARRON, Dept., of Materials Science and Engineering, Iowa State University, MICHAEL D. BARTLETT, Dept. of
Electrical and Computer Engineering, Iowa State University — Magnetorheological Elastomers (MREs) constitutes a group of
materials referred to as ‘smart’ materials. These materials exhibit field-dependent material property which include change
in damping and stiffness properties of the material when subjected to an external magnetic field. This paper presents a
simulation study of magnetomechanical and thermal properties for a MRE used as a semi-active automotive suspension
bushing. Such suspension bushings isolate passengers from the undesirable effects of the surface over which the vehicle
is being driven on. It also enhances handling and driving comfort of the driver. The performance of semi-active suspension
bushing is highly dependent on the magnetic properties of the MRE. Therefore, electromagnetic simulation using finite
element analysis software is used to design and optimize on the MRE suspension bushing's response to magnetic field.
From the finite element analysis, the magnetic flux density developed within the MRE is observed to depend on the
permeability, thickness and magnetic shielding of the MRE.
Highly Sensitive Magnetic Sensor based on Magnetoelcetric Effect and Cross-Modulation Technique  
CUNZHENG DONG (Presenter), YIFAN HE, XIANFENG LIANG, HUAIHAO CHEN, YUYI WEI, NIAN XIANG SUN, Northeastern University — State of the art bulk magnetoelastic (ME) sensors composed of Metglas/PMN-PT fiber structures have been demonstrated to exhibit a low limit of detection (LOD) of 10 pT at 1 Hz. Because of the low cost and compact size, the ME magnetic field sensor has become competitive to other sensing technologies for applications demanding high sensitivity. The magnetic noise of ME sensors is the key parameter that results from the internal and external noise sources. To reduce the noise level, an active operation mode has been proposed. However, active ME sensors usually show a high magnetic noise over 200 pT/Hz at 1 Hz in the reports. Here, we demonstrate an ultra-sensitive ME sensors based on Metglas/PZT fiber heterostructures operating at the complete demagnetized state of Metglas. A strong correlation was observed between the limit of detection and the degree of demagnetization of Metglas in the ME sensors, which points to a new way of improving the magnetic field sensitivity of ultra-sensitive ME sensors. Our demonstrated ME sensors based on PZT/Metglas has shown LOD below 2pT and magnetic noise level of 9.1pT/Hz^{1/2} in the detection of magnetic field at 1Hz, which is one order of magnitude better than other best reported values for PZT/Metglas heterostructures.

Fabrication and characterization of ultra-soft PDMS based magnetorheological elastomers*  
ANDY CLARK (Presenter), JIAJIA LI, LILA HERNANDEZ, VIDYA RAMASWAMY, Bryn Mawr College, ELISE CORBIN, Cardiovascular Institute, Perelman School of Medicine, University of Pennsylvania, ALEXANDER BENNET, Department of Mechanical Engineering and Applied Mechanics, University of Pennsylvania, XUEMEI CHENG, Bryn Mawr College — Magnetorheological elastomers (MREs) are composite materials consisting of an elastomer matrix with embedded micro- or nano- sized ferromagnetic entities. Ultra-soft PDMS based MREs are promising candidates for dynamic cell culture substrata. In this work, we report the fabrication and magnetic characterization of PDMS based MREs. Sylgard 527 and carbonyl iron powder were mixed together at various ratios and cured at 60°C for 24 hours without applied magnetic field and with applied magnetic field of various field strength. Angular dependent magnetic hysteresis loops of MREs were measured using a vibrating sample magnetometer. MREs cured without magnetic field show no angular dependence in the major hysteresis loop, consistent with the isotropic distribution of iron particles in the MREs. Instead, hysteresis loops for MREs cured in magnetic field clearly display anisotropy as expected. The different first order reversal curve (FORC) distribution characteristics of the isotropic and anisotropic MREs agree with the structural difference of these two types of MREs.

A one-dimensional magnetoelectric sensor array for magnetic sketching*  
ZHAOQIANG CHU (Presenter), WEILIANG SHI, Peking University, XIANFENG LIANG, NIAN XIANG SUN, College of Engineering, Northeastern University, SHUXIANG DONG, Peking University — Although various magnetic sensors have been developed, it is still a challenge to get the imaging of magnetic objects safely and instantaneously, for example, magnetic imaging for capsule positioning, endoscope navigation, and detection of magnetic weapon that is hidden in/on human body. In this paper, a magnetic detecting and sketching system utilizing a one-dimensional magnetic sensor array with 56 magnetoelectric (ME) sensing units is proposed. The ME sensors used in this system are based on a (1-1) connectivity Metglas/piezo-fiber composite operating in longitudinally magnetized and transversely poled (L-T) mode. Simulation and experiment results show that the proposed magnetic detecting system not only can find the 2-D position of a running magnetic metal object, but also can identify its posture and length-diameter ratio. The proposed magnetic detecting method promises an outlook for medical magnetic positioning and security checking.

12:51PM Y39.00009: Superparamagnetic Fe₃O₄ magnetic nanoparticles and their potential for hyperthermia treatment for cancer* BIANCA PAOLA MENESES BRASSEA (Presenter), CAMILLE CYR, ISRAEL MARTINEZ, CRISTIAN BOTEZ, AHMED EL-GENDY, Physics Department, University of Texas at El Paso — The heating efficiency of Fe₃O₄ nanoparticles of different sizes synthesized using supercritical conditions of liquids, under different applied magnetic field intensities and frequencies, was investigated through experimental measurements of specific absorption rate (SAR). The synthesis conditions have been varied in order to obtain different sizes and shapes of Fe₃O₄ nanoparticles and to examine their effect on the SAR values. The morphology and crystal structure characterization of three samples revealed cubic-like shapes with average sizes of 63, 128, and 91 nm and formation of FCC Fe₃O₄ phase structure. The magnetic properties were characterized using magnetization dependent of magnetic field and temperature up to 3 T and 400 K respectively. The samples exhibit superparamagnetic-like behavior at room temperature with saturation magnetization Ms of 108, 74, and 77 emu/g and blocking temperatures Tₜ of 320, 235, and 192 K, respectively. SAR values at 400 Oe and 304 kHz were measured using D5 hyperthermia system to be 126, 33 and 73 W/g for sizes of 63, 91, and 128 nm, respectively. The results yield efficient heating and the nanoparticles perfect feasibility for magnetic hyperthermia treatment of cancer.

1:03PM Y39.00010: Preparation and Investigation of Carbon Coated (Fe-Fe₃C) Nanocomposites for Medical Applications* ARAM MANUKYAN, HARUT GYULASARYAN, EDUARD SHAROYAN, Laboratory of Solid State Physics, Institute for Physical Research, NAS of Armenia, Ashtarak-2, JENNIFER GRAY LYNN, Materials Characterization Lab, The Pennsylvania State University, Materials Research Institute, OSCAR BERNAL, ARMEN KOCHARIAN (Presenter), Physics Department, California State University, Los Angeles 90032 — Carbon-coated ferromagnetic (Fe-Fe₃C) nanocomposites have been synthesized via solid-phase pyrolysis of metal-organic compounds. Structure, morphology and magnetic characteristics of the nanocomposites were investigated by electron microscopy, X-ray diffraction, Raman spectroscopy, STEM-TEM images, EDX line-scan profiles and magnetometry. The magnetic characteristics such as saturation magnetization, coercivity and heating saturation as well as the specific absorption rate (SAR) make these materials attractive for magnetic hyperthermia applications. Hysteresis loop of the (Fe-Fe₃C)@C nanocomposites is of special interest as it shows almost square-like behaviour, where Mₛ/M(200 Oe) = 0.75. The limitation of the magnetic field amplitude and - frequency (H x f) ≤ 10.625x10⁶ Oe/s makes this factor important that provides a high energy absorption even in case of low magnetic fields.

*This work was supported by a grant from the Russian-Armenian (Slavonic) University at the expense of the Ministry of Education and Science of the Russian Federation. The work at CSULA was supported by the National Science Foundation-Partnerships for Research and Education in Materials under Grant DMR-1523588.

1:15PM Y39.00011: Ultrathin cobalt nanowires with high energy product MEIYING XING (Presenter), JEOTIKANTA MOHAPATRA, JACOB ELKINS, JULIAN BEATTY, J PING LIU, physics, university of texas at arlington — Uniform and single crystalline hexagonal close-packed (hcp) Co nanowires (NWs) have been synthesized by optimizing the precursor concentration and cleaning process in a hydrothermal process. The TEM image indicates that the prepared Co NWs have uniform size distribution with a mean diameter and length of 8 nm and 150 nm, respectively. As the radius of the Co NWs is smaller than coherent radius $R_{coh} = 3.65 l_{ex}$, where $l_{ex}$ is the exchange length, the ultrathin Co NWs exhibit the coherent magnetization reversal based on the Stoner-Wohlfarth mode. As a result, a pronounced coercivity of 11.4 kOe is achieved in the aligned Co NW assemblies. The high aspect-ratio, good crystallinity, uniform morphology and desired orientation of Co NW assemblies result in a record high energy product of 56.1 MGOe which is close to the theoretical value. The compaction of the prealigned NWs assemblies at various pressure results in packing density in the range from 5.3 to 7.3 g/cm³ and energy product as high as 20 MGOe. The obtained nanowire based permanent magnets with well controlled aspect ratios exhibited energy products in the intermediate range between Alnico and rare-earth containing magnets.

1:27PM Y39.00012: Search for the new rare-earth free iron-based permanent magnets*  OLGA VEKILOVA (Presenter), OLLE ERIKSSON, HEIKE C. HERPER, Uppsala University — Permanent magnets are irreplaceable for many technological applications. Therefore new magnetic materials, that are cheap and abundant, are vital for the modern society. A good permanent magnet must have a high Curie temperature, high saturation magnetization and uniaxial magnetocrystalline anisotropy. Rare-earth free Fe-rich systems like the hexagonal close-packed Fe3Sn compound are promising candidates. However, its magnetocrystalline anisotropy is planar. Alloying is a possibility for changing the easy axis of magnetization. We have calculated from first principles the electronic structure and magnetic properties of ferromagnetic Fe3Sn doped with Si, P, Ga, Ge, As, Se, In, Sb, Te, Pb, and Bi on the Sn sublattice as well as with the Mn phase-stabilizer on the iron sublattice. We discuss the influence of the different dopants on the magnetocrystalline anisotropies and Curie temperatures of Fe3Sn and suggest new stable/metastable ferromagnetic phases with uniaxial anisotropy suitable for the development of advanced permanent magnets.

*Authors acknowledge support from NOVAMAG project, under Grant Agreement No. 686056, EU Horizon 2020 Framework Programme.

1:39PM Y39.00013: High-Performance Thick On-chip Hard Magnets for MEMS Applications  YIFAN HE (Presenter), CHENGJU YU, Electrical and Computer Engineering, Northeastern University, SAMER HAIDER, Analog Devices, Inc., MOHSEN ZAEIMBASHI, Electrical and Computer Engineering, Northeastern University, GREGORY STEPHEN, Department of Physics, Northeastern University, JIAWEI WANG, YUIYI WEI, HUAIHAO CHEN, XIANFENG LIANG, CHENG TU, CUNZHENG DONG, Electrical and Computer Engineering, Northeastern University, DON HEIMAN, Department of Physics, Northeastern University, BAOXING CHEN, Analog Devices, Inc., NIAN XIANG SUN, Electrical and Computer Engineering, Northeastern University — We adopted two methods for thick on-chip hard magnets fabrication for MEMS application. (1) Dry packing of Nd2Fe14B powders. Nd2Fe14B powders were mixed with binder wax powders, then dry-packed into pre-etched trenches on silicon wafers under 10 MPa pressure and 100°C heating. An out-of-plane, in-situ magnetic field of 1000 Oe was applied during the process. (2) High pressure compression of Nd2Fe14B powders. Nd2Fe14B powders were packed into a metal mould and heated to 300°C with 850 MPa pressure applied. The sample was bonded onto the silicon chip with polyimide. The dry-packed Nd2Fe14B magnets showed a remanent out-of-plane magnetization of 330 emu/cc (Br = 0.42 T), a coercive field of 8.6 kOe (690 kA/m) and an energy product of 2.4~2.6 MGOe (19-21 kJ/m^3). It is also found that the out-of-plane magnetic field can boost the remanent magnetization in that direction. For high pressure compressed Nd2Fe14B magnets, a remanent out-of-plane magnetization of 446 emu/cc (Br = 0.56 T), a coercive field of 9.6 kOe (770 kA/m) and an energy product of 6.4 MGOe (50.5 kJ/m^3) were observed. Our demonstrated Nd2Fe14B on-chip hard magnets are compatible to MEMS fabrication process with a larger thickness of over 1mm and higher achieved energy product over published results for on-chip magnets.

Session Y41 GMAG DMP: Magnetic Materials, Not Oxides  BCEC 209 - Patrick Quarterman, National Institute of Standards and Technology - Tag(s): Focus

11:15AM Y41.00001: Exploring the Magnetic Properties of the Iron-Nitrogen System+  TODD MONSON (Presenter), TYLER STEVENS, STAN ATCITTY, Sandia National Laboratories, BAOLONG ZHENG, YIZHANG ZHOU, ENRIQUE Lavernia, University of California, Irvine — The magnetic properties of the iron-nitrogen system have only been explored on a very limited basis. Theoretical predictions of the magnetic behavior of the different phases of iron nitride are limited and experimental data is quite sparse. By employing several different techniques which include solution based nanoparticle nitridation, electrochemical methods, and metathesis based reactions we have synthesized several different phases of iron nitride: FeN, Fe3N, Fe2N, Fe8N, and Fe24N10. Additionally, we have demonstrated a path for consolidating raw powders of iron nitride into bulk material, enabling additional characterization and application in macroscopic devices. Our difficulties and successes in synthesizing and processing these different phases of iron nitride will be described. Additionally, the magnetic properties of these seldom explored iron-nitrogen compounds will be summarized.

+Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.
11:27AM Y41.00002: Mn-based Heusler Compounds with Low Magnetization* WENYONG ZHNAG, BALAMURUGAN BALASUBRAMANIAN, RABINDRA PAHARI, AHSAN ULLAH, SHAH VALLOPPILLY, RALPH SKOMSKI, DAVID SELLMYER (Presenter), Nebraska Center for Materials and Nanoscience and Department of Physics and Astronomy, University of Nebraska, Lincoln, Nebraska 68588-0299, USA — Heusler compounds with small or zero magnetization are of interest for spintronics applications, because they cause little or no fringing fields and may exhibit ultrafast dynamics and high spin polarization [1-3]. We find virtually zero room-temperature magnetizations in stoichiometric Ru$_2$MnSn and Pt$_2$MnGa Heusler alloys fabricated by rapid quenching from the melt. X-ray diffraction patterns show the formation of a $L_2_1$ structures with $a = 6.22$ Å and a tetragonal structure with $a = 4.02$ Å and $c = 7.24$ Å in Ru$_2$MnSn and Pt$_2$MnGa, respectively. Both systems show nearly linear $M(H)$ curves for intermediate field strengths of several T, and the slopes $dM/dH$ are used to characterize the spin structure. In Pt$_2$MnGa, which shows a helical spins structure with an ordering temperature of about 350 K [4], $dM/dH$ increases with decreasing spiral wave vector $q$. The complex spin structures of Ru$_2$MnSn and Pt$_2$MnGa are used to explain the electron-transport properties of the alloys.

11:39AM Y41.00003: First principles study on alkali-metal-based half-Heusler XCrZ ([X = Li, Na, K, Rb]; [Z = As, Sb]) THU THUY HOANG (Presenter), SUNG-HYON RHIM, SOON CHEOL HONG, Physics, The university of Ulsan — In this works, we present systematic study of strain effects on half-metallicity (HM) of alkali-metal-based half-Heusler XCrZ ([X=Na, K, Rb]; [Z=As,Sb]) using first-principles calculations. Among three structural phases α, β and γ, we focus on the β-phase, which is energetically most stable and compatible with zinc-blende (zb) structured CrAs and CrSb. Except LiCrZ, all compounds are HM, where the total magnetic moments per unit cell are 4 µB, obeying the modified Slater-Pauling rules ($M = N_v - 8$) [1]. In LiCrZ, on the other hand, HM emerges under tensile strain. Furthermore, HM and direct vs indirect band gap of XCrZ are investigated for different cation [X]$^+$, for strains. While uniform strain, hydrostatic limit, impacts little on the band gap, tetragonal distortion associated with sin-plane tensile strain influences valence band maximum of LiCrZ. In particular, indirect to direct gap transition occurs for tensile strain larger than 2% in LiCrSb, where the role of p-d hybridization is discussed.

11:51AM Y41.00004: Disorder and electron correlation effects in the ground state of Ni-Co-Mn-Sn alloys with Heusler structures* AKI PULKKINEN (Presenter), Physics, LUT (Finland), BERNARDO BARBIELLINI, Physics, LUT and Northeastern Univ., JOHANNES NOKELAINEN, Physics, LUT (Finland), VLADIMIR SOKOLOVSKIY, VASILIY D. BUCELNIKOV, MIKHAIL ZAGREBIN, Chelyabinsk State University, Chelyabinsk, Russian Federation, KATARIINA PUSSI, ERKKI LAHDERANTA, Physics, LUT (Finland), ALEXANDER GRANOVKY, Physics, Moscow State University, Moscow, Russian Federation — We consider ab-initio calculations of Co-doped Ni-Mn-Sn shape memory alloy. The Co doping leads to a decrease in both the martensitic transformation temperature and the Curie temperature of martensite and to an increase in the Curie temperature of austenite. Besides, large magnetisation changes occur in the vicinity of structural transformation. As a result, the tuning of Co and Mn contents can lead to favorable magnetocaloric properties . In this work, we focus on the effect of atomic disorder and electron correlation on the structural, magnetic and electronic properties of Ni-Co-Mn-Sn systems by using the Density Functional Theory (DFT) implemented in the VASP and SPR-KKR packages within a 32-atom supercell and the coherent potential approximation, respectively. The optimized atomic positions for compositions studied are obtained by the USPEX package. To study the effect of exchange-correlation, a series of ground state calculations were performed using both the GGA-PBE functional and Meta-GGA with SCAN functional of DFT.

12:03PM Y41.00005: Tuning magnetic anisotropy in the layered mixed halide series CrCl$_{3-x}$Br$_{x}$*  
FAZEL FALLAH TAFTI (Presenter), MYKOLA ABRAMCHUK, SAMANTHA JASZEWSKI, KENNETH METZ, GAVIN B OSTERHOUDT, YIPING WANG, KENNETH BURCH, Boston College — Magnetic anisotropy is the tendency of spins to align in a certain crystallographic direction - the easy axis. Without anisotropy, thermal fluctuations prevent magnetic ordering in two dimensions according to the Mermin-Wagner theorem. In layered materials, the two limits of the easy axis are in-plane (XY) and out-of-plane (Ising). Recent advances in exfoliation and device fabrication have led to the discovery of ferromagnetic ordering with Ising anisotropy in CrI$_3$ monolayers. It is theoretically conjectured that spin-orbit coupling (SOC) provided by halide atoms on the super-exchange path yields the magnetic anisotropy. Here, we design a unique experiment to probe this idea by growing a series of CrCl$_{3-x}$Br$_{x}$ crystals where SOC is tuned between CrCl$_3$ with XY and CrBr$_3$ with Ising anisotropy. We discover a continuous rotation of the easy-axis from XY to Ising with increasing x. Remarkably, the magnetic ordering temperature, optical gap, and inter-layer spacing are also tuned linearly with x. This is the first observation of a continuous rotation of the easy axis and the effect of SOC on the super-exchange path. Methods presented here can be extended to produce other metal mixed halides to fabricate tunable heterostructures and spintronic devices.

12:15PM Y41.00006: Tuning the magnetic properties of NiBr$_2$ with cobalt doping*  
HASITHA SURIYA ARACHCHIGE (Presenter), Department of Physics & Astronomy, University of Tennessee, Knoxville, TN 37996, USA, BINOD RAI, Materials Science & Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, GANESH POKHAREL, Department of Physics & Astronomy, University of Tennessee, Knoxville, TN 37996, USA, ANDREW MAY, Materials Science & Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, ADAM ACZEL, TRAVIS J WILLIAMS, MATTHIAS D FRONTZEK, Neutron Scattering Science Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, CRISTIAN BATISTA, Department of Physics & Astronomy, University of Tennessee, Knoxville, TN 37996, USA, DAVID GEORGE MANDRUS, Department of Materials Science and Engineering, University of Tennessee, Knoxville, Tennessee 37996, USA, ANDREW D CHRISTIANSON, Materials Science & Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — The compound NiBr$_2$ crystallizes in the trigonal space group R-3m. Below $T_N$= 44 K, NiBr$_2$ exhibits antiferromagnetic order characterized by antiferromagnetically stacked sheets of ferromagnetically aligned Ni spins. A transition to a helical magnetic structure occurs below $T_C$=22.8 K with a propagation vector of at 4.2 K. Here we use neutron diffraction to study the tuning of the magnetic properties with cobalt substitution in single crystals for several compositions of Ni$_{1-x}$Co$_x$Br$_2$, where x = 0, 0.2, 0.25, 0.3, and 0.45. Our measurements show that the $T_N$ decreases with doping while changes in $T_C$ are more subtle. The neutron scattering studies further reveal that the 6 incommensurate spots in the parent compound give way to a ring of magnetic scattering reminiscent of that observed previously for Ni$_{0.92}$Zn$_{0.08}$Br$_2$.

12:27PM Y41.00007: Eu-Si nanowires formation on Si(100) studied by scanning tunneling microscopy and spectroscopy*  
AARON WANG (Presenter), TE-YU CHIEN, University of Wyoming — By depositing Eu onto a cleaned Si(100) surface at 400 °C, patterned nanowires are formed and visualized by scanning tunneling microscopy(STM). The nanowires are measured to be ~1.5 nm in diameter, ~1 Å in height and hundreds of nm or more in length. The spacing between the nanowires are found to be mostly 2.2 nm, 2.8 nm and 3.4 nm, i.e. with 0.6 nm increment. Interestingly, the topography images taken at positive and negative bias show single-wire and double-wire morphologies, respectively. Same observations are made in the $dI/dV$ mapping with positive and negative bias. Furthermore, $dI/dV$ spectra taken at the double-wire features (found while scanning at negative bias) exhibit peak-valley features in the valence band - a peak at -3.2 V and valley at -3.4 V. Similar peak-valley $dI/dV$ spectra were reported for the Pt/Si nanowires, which showed signs of strong Rashba spin splitting [1]. Further studies are underway in determining the possibility of strong Rashba effect in this Eu/Si nanowire systems.

Effect of Bi addition on the magnetic and structural properties of chemically synthesized Fe-Pt-Ni alloy

VIMAL DEEPCHAND (Presenter), FRANK M ABEL, University of Delaware, VASILEIOS TZITZIOS, Department of Chemical Engineering, Khalifa University of Science and Technology, GEORGE C HADJIPANAYIS, University of Delaware — L10 FePt has been chosen as the ideal candidate for heat assisted magnetic recording media due to its high magnetocrystalline anisotropy of ~70 Merg/cc, and thermal stability down to 3 nm [1]. Producing L10 alloys with high thermal stability, while reducing the Curie temperature is critical for the development of heat assisted magnetic recording media, and has led to the exploration of third element doping into the L10 FePt [2]. In this work, we studied the effect of bismuth addition on chemically synthesized FePt1-xNiₓ alloys, with x=0.2 – 0.4. The as-made particles showed an fcc structure, but after annealing at 700°C for 30 minutes a transformation to the L10 phase occurred. The addition of Bi appears to enhance the ordering of the L10 alloy relative to the ternary Fe-Pt-Ni but leads to the formation of a secondary phase. Thermomagnetic measurements show a reduction in Curie temperature compared to the Fe-Pt-Ni ternary alloy in the x=0.3 case, which suggests that Bi enters the structure of the L10 alloy. Current efforts are focused on varying the Bi content to optimize the magnetic and structural properties of Fe-Pt-Ni.

Concentration tuned tetragonal strain in alloys: application to magnetic anisotropy of FeNi1-xCox

ALEX WYSOCKI (Presenter), MANH CUONG NGUYEN, Ames Laboratory, Ames, USA, ANDREY POSTNIKOV, Universite de Lorraine, Metz, France, VLADIMIR ANTOPROV, Ames Laboratory, Ames, USA — We explore an opportunity to induce and control tetragonal distortion in materials using the ideas of Bain transformation path for multatomic systems with body- and face-centered symmetries. The concept is illustrated in the case of FeNi1-xCox magnetic alloy formed by substitutional doping of the L10 FeNi magnet with Co. Using electronic structure calculations we demonstrate that the tetragonal strain in this system can be controlled by concentration and it reaches maximum around x = 0.5. This finding is then applied to create a large magnetocrystalline anisotropy in FeNi1-xCox system. We demonstrate that this anisotropy can be significantly improved by delicate tuning the tetragonal distortion, electronic concentration and chemical anisotropy. We discuss possible experimental ways to create such magnet.

Magnetic and Structural Properties of Melt-Spun Co-Ge Ribbons

ONUR TOSUN (Presenter), FRANK M ABEL, Physics and Astronomy, University of Delaware, BALAMURUGAN BALASUBRAMANIAN, RALPH SKOMSKI, DAVID SELLMYER, Physics & Astronomy, University of Nebraska, Lincoln, GEORGE C HADJIPANAYIS, Physics and Astronomy, University of Delaware — The Co-Ge materials is a key subsystem of Heusler alloys and have attracted much interest because they play an important role in the field of integrated circuits [1, 2]. In this work, we have investigated the magnetic and structural properties of Co-Ge melt-spun ribbons in an attempt to understand better the behavior of our Co2Ge nanoparticles prepared by the cluster-beam deposition technique. Melt-spun ribbons with different compositions and different wheel speeds were prepared. Our data showed that small variations in the Co content and wheel speed lead to different structures and magnetic properties. The ribbons with 65% Co composition are ferromagnetic at room temperature with Curie temperatures larger than 800 K in contrast to previous reports that claimed to be ferromagnetic at cryogenic temperatures [3]. The contradiction with the literature could be attributed to the difference in grain size in the ribbons and can explain the effect of size on the magnetic properties of our nanoparticles.

This work was supported by DOE Grants DE-FG02-90ER45413 and DE-FG02-04ER4612
magnetization is observed, but is consistent with a NixPy or spin-canted shell ~1 nm thick.

CHRIS LEIGHTON, Chemical Engineering and Materials Science, University of Minnesota — Recent advances in colloidal synthesis pathways have shown very similar kinetics, unless the intermediate substrate was consumed by an additional biocatalytic intermediate substrates or presence of an external magnetic field. The biocatalytic reactions proceeded through bulk solution performing biocatalytic cascades in two different states, solute suspension or aggregated, produced in the absence or functionalized with various enzymes (amyloglucosidase, glucose oxidase and horseradish peroxidase) were used to reconcile differences between the true mean blocking temperature, \( T_B \), and the zero field cooled magnetization peak. The resulting \( T_B \) vs. \( D \) yields an effective anisotropy surprisingly close to that of bulk Ni. Reduced saturation magnetization is observed, but is consistent with a Ni_{33}\% type or spin-canted shell ~1 nm thick.

*We acknowledge support from NSF-DMR#1809800 and NIH-NIBIB Trailblazer#1R21EB027405-01.  

1:27PM Y41.00012: Quantitative size-structure-magnetic property relationships in thoroughly-characterized metallic Ni nanoparticle assemblies* 

JOSEPH BATLEY (Presenter), MY NGUYEN, ISHITA KAMBOJ, Chemical Engineering and Materials Science, University of Minnesota, ERAY S. AYDIL, Chemical and Biomolecular Engineering, NYU Tandon School of Engineering, CHRIS LEIGHTON, Chemical Engineering and Materials Science, University of Minnesota — Recent advances in colloidal synthesis and other approaches have realized nanoparticles(NPs) with controlled structure, size, functionalization, and self-assembly. In magnetism, the focus on hard ferromagnetic(FM) NPs and oxides has left relatively little research on metallic soft FM NPs. Here, Ni NPs have been synthesized via injection of a Ni-oleylamine(OAm) complex into 200°C trioctylphosphine(TOP). Size control was obtained by varying TOP/OAm ratio, reaction time, and by differential centrifugation. Characterization was performed with X-ray diffraction, transmission electron microscopy, Raman and Fourier-transform infrared spectroscopy, and SQUID magnetometry. Polycrystalline FCC NPs are obtained, with mean diameter, \( D \), tunable from 4—22 nm, and dispersion, \( \sigma/D \approx 10-30\% \). Superparamagnetic blocking can thus be tuned between 15 and >300 K. Size distributions and inter-particle interactions are explicitly accounted for, quantitatively reconciling differences between the true mean blocking temperature, \( T_B \), and the zero field cooled magnetization peak. The resulting \( T_B \) vs. \( D \) yields an effective anisotropy surprisingly close to that of bulk Ni. Reduced saturation magnetization is observed, but is consistent with a Ni_{33}\% type or spin-canted shell ~1 nm thick.

1:39PM Y41.00013: Magneto-Controlled Biocatalytic Cascades with Logically Processed Input Signals – Substrate Channeling versus Free Diffusion* 

YAROSLAV FILIPOV (Presenter), Clarkson University, ANDREY ZAKHARCHENKO, SERGIY MINKO, Nanostructured Materials Lab, University of Georgia, EVGENY KATZ, Clarkson University — Magnetic nanoparticles (MNPs) functionalized with various enzymes (amyloglucosidase, glucose oxidase and horseradish peroxidase) were used to perform biocatalytic cascades in two different states, solute suspension or aggregated, produced in the absence or presence of an external magnetic field. The biocatalytic reactions proceeded through bulk solution diffusion of intermediate substrates or substrate channeling, when the systems were dispersed or aggregated, respectively. The both pathways have shown very similar kinetics, unless the intermediate substrate was consumed by an additional biocatalytic process called “filter” for brevity. In the presence of the “filter” process, the diffusional process in the bulk solution was significantly inhibited, while the process based on the substrate channeling was still active. The systems were switched reversibly between the inhibited dispersed state and the active aggregated state by removing and applying the external magnetic field, respectively. The signal-controlled biocatalytic cascades were considered as Boolean logic circuits with the inputs consisting of biomolecules and the magnetic filed on-off.

Session Y43 DCMP: Advances in the Quantum Control of Single Spins in Semiconductors

BCEC 210B - David Awschalom, University of Chicago - Tag(s): Invited

11:15AM Y43.00001: Multi-node quantum networks based on spins and photons [Invited] RONALD HANSON (Presenter), Delft University of Technology — TBD

11:51AM Y43.00002: Spin and Orbital Resonance Driven by a Mechanical Resonator* [Invited] GREGORY FUCHS (Presenter), Cornell University — I describe our experiments to drive spin and orbital resonance of single diamond nitrogen-vacancy (NV) centers using the gigahertz-frequency strain oscillations produced within a diamond acoustic resonator. Strain-based coupling between a resonator and a defect center takes advantage of intrinsic and reproducible coupling mechanisms while maintaining compatibility with conventional magnetic and optical techniques, thus providing new functionality for quantum-enhanced sensing and quantum information processing. Using a spin-strain interaction at room temperature, we demonstrate coherent spin control [1] and spin coherence protection [2]. At cryogenic temperatures, we use orbital-strain interactions driven by a diamond acoustic resonator to examine multi-phonon orbital resonance of a single NV center [3]. We drive a strong mechanical modulation of the orbital state energies in the side-band resolved limit and produce nine orders of coherent sidebands. When we match the resonator frequency to half of the orbital splitting, we demonstrate resonance between the orbital states using a transverse orbital-strain interaction. The resulting dressed orbital states display Autler-Townes splitting as a function of resonator amplitude that is well-described by a 2-phonon resonance process. Finally, we discuss orbital decoherence protection as means of engineering NV centers to be a better spin-photon interface as a potential application of these techniques.

*We gratefully acknowledge support from the Office of Naval Research (N000141712290).

12:27PM Y43.00003: Probing spin-phonon interactions in semiconductors with x-rays and Gaussian acoustics* [Invited] SAMUEL WHITELEY (Presenter), University of Chicago — Coupling defect spins to phonons provides routes to new quantum control methods, coherence protection, and integrating spin qubits with quantum transducers. Silicon carbide (SiC) substrates host optically addressable point defects with long-lived electronic spin registers. Additionally, SiC is a low loss acoustic material and supports wafer-scale fabrication techniques, making SiC an ideal material for hybrid spin-mechanical systems. We fabricate surface acoustic wave (SAW) resonators taking advantage of isotropic acoustic propagation properties to construct simple Gaussian geometries, which focus strain and minimize diffraction losses. We directly image the mechanical mode with nanometer-scale spatial resolution by using hard x-ray diffraction microscopy and frequency matching a SAW to the timing structure of a synchrotron [1]. The SAW resonators are then utilized for coherent manipulation of divacancy electron spin ensembles in the SiC. We demonstrate all-optical detection of acoustic paramagnetic resonance, which enables quantum sensing of phonons without magnetic microwaves. In addition, we measure coherent magnetically forbidden spin transitions with Autler-Townes splittings and Rabi oscillations on the divacancy spins, as well as show spatial mapping of spin driving which reveals spin coupling to shear [2]. Our model, comprising of ab initio calculations for the spin-strain coupling parameters, captures the salient features of the physics. These results offer a basis for three-level spin system control with phonons and paths to combining spin registers with nanomechanical devices.

1:03PM Y43.00004: Quantum nano-photonics with rare-earth-doped materials* [Invited] ANDREI FARAON (Presenter), Applied Physics, Kavli Nanoscience Institute, Institute for Quantum Information and Matter, California Institute of Technology — I present quantum nano-photonics devices based on nanophotonic resonators coupled to rare-earth-ions in crystals. The rare-earth ions exhibit long coherence times on optical and microwave transitions, which makes them suitable for various quantum light-matter interfaces like quantum memories, single quantum bits and optical to microwave quantum transducers. We demonstrate on-chip optical quantum memories based on atomic frequency combs and optically addressable quantum bits based on single rare-earth ions where the quantum state can be mapped on Zeeman or hyperfine levels with long coherence time. Our solid-state nano-photonics quantum light-matter interfaces can be integrated with other chip-scale photon source and detector devices for multiplexed quantum and classical information processing at the nodes of quantum networks.

1:39PM Y43.00005: Theory of electrical readout of deep defect qubits in solids* [Invited] ADAM GALI (Presenter), Hungarian Academy of Sciences — Paramagnetic color centers with deep levels in the gap are candidates to realize qubits in solids, in particular, those color centers that show spin-dependent fluorescence that can be employed to initialize and readout the electron spin of single color centers, first demonstrated for the nitrogen-vacancy (NV) center in diamond [1]. It has been shown [2] that optical excitation can also lead to ionization of NV center that is also spin dependent. The resultant carriers, i.e., the photocurrent can be collected that is the ground of photocurrent detected magnetic resonance (PDMR).
In my talk, I will show the power and significance of ab initio atomistic simulation techniques that can provide deep insight into the microscopic mechanisms behind the observed phenomena, and how it can be applied to optimize the conditions of qubit measurements. In particular, I will show how ab initio theory can explain the two-photon ionization of NV centre [3] that is the base of PDMR measurements. Intricate details of back ionization reveal the optical spinpolarization process in NV centre [4] under continuous green laser excitation. Theory predicted that two-color excitation will increase the signal-to-noise ratio of PDMR signal of NV center in diamond that was confirmed in experiment [5]. We will discuss very prospective deep color centers, divacancies in silicon carbide [6,7], what could be the experimental conditions to realize PDMR signal from these qubits in this technologically mature semiconductor.

Session Y44 DCMP: Exotic Majorana Physics and Beyond BCEC 210C - Maissam Barkeshli, University of Maryland, College Park - Tag(s): Invited
11:15AM Y44.00001: Solid state realizations of Sachdev-Ye-Kitaev models* [invited] MARCEL FRANZ (Presenter), University of British Columbia — An intriguing connection, pointed out by Kitaev in 2015, exists between a simple model of Majorana fermions with random all-to-all interactions – the Sachdev-Ye-Kitaev (SYK) model – and the horizons of extremal black holes in two-dimensional anti-de Sitter space. This connection furnishes a rare example of holographic duality between a solvable quantum-mechanical model and Einstein gravity. It also opens up a possibility to study quantum black holes, realized holographically in a quantum mechanical model, in a tabletop experiment. In this talk I will review some of these developments and describe the recent efforts to bring the family of SYK models closer to experimental reality. The proposed experimental realizations employ both complex and Majorana fermions in various atomic and solid state systems. These include some of the standard platforms for Majorana zero modes (proximitized quantum wires and topological insulator - superconductor interfaces) as well as electrons in the lowest Landau level in a graphene flake with an irregular boundary.

*The work was supported by NSERC and CIfAR.

11:51AM Y44.00002: Approximating the Sachdev-Ye-Kitaev model with Majorana wires* [invited] AARON CHEW, Caltech, ANDREW ESSIN, UC Davis, JASON ALICEA (Presenter), Caltech — The Sachdev-Ye-Kitaev (SYK) model describes a collection of randomly interacting Majorana fermions that exhibits profound connections to quantum chaos and black holes. I will discuss a potential solid-state implementation based on a quantum dot coupled to an array of topological superconducting wires hosting Majorana zero modes. Interactions and disorder intrinsic to the dot mediate the desired random Majorana couplings, while an approximate symmetry suppresses additional unwanted terms. Random matrix theory and numerics show that this setup indeed emulates the SYK model (with certain corrections). Tunneling measurements provide an appealing first experimental test of this scenario.

*Research supported by the National Science Foundation through grant DMR-1341822; the Caltech Institute for Quantum Information and Matter, an NSF Physics Frontiers Center with support of the Gordon and Betty Moore Foundation through Grant GBMF1250; and the Walter Burke Institute for Theoretical Physics at Caltech.

12:27PM Y44.00003: Majorana Multiplexing [invited] YANG PENG (Presenter), California Institute of Technology — TBD

1:03PM Y44.00004: Quantum Engineering of Majorana Fermions* [invited] DIRK MORR (Presenter), University of Illinois at Chicago — The experimental observation of Majorana states in topological superconductors represents a major breakthrough in realizing their applications in topological quantum computing. This has stimulated the search for new possibilities to engineer Majorana states at the nanoscale, in particular using magnetic-superconducting hybrid (MSH) structures in which islands of magnetic adatoms are placed on the surface of s-wave superconductors.

In this talk, I provide several examples for the quantum engineering of Majorana fermions in MSH systems [1,2]. First, I will report the results of a theory-experiment collaboration demonstrating the ability to tune between a topological phase exhibiting chiral Majorana edge modes and a trivial phase in Fe-Re MSH structures using interface engineering [1]. Second, I will show that one can create a topological switch in MSH systems by imprinting magnetic skyrmions, allowing one to write and delete topological phases. Similarly, it is possible to engineer chiral Majorana states of arbitrary shape through the creation of magnetic domain walls. Third, I show that it is possible to continuously tune MSH systems between 2D and 1D topological phases using atomic manipulation, and thus to change the character of the associated Majorana modes. Finally, I will demonstrate that Josephson scanning tunneling spectroscopy is a crucial tool in identifying topological phases [3].

*This work was supported by the U. S. Department of Energy, Office of Science, Basic Energy Sciences, under Award No. DE-FG02-05ER46225
1:39PM Y44.00005: The Majorana-Hubbard Model* [Invited] IAN AFFLECK (Presenter), University of British Columbia — When a vortex lattice forms in a superconducting layer on a topological insulator a Majorana fermion is predicted to appear in each vortex core. Hopping and interaction terms between the Majorana fermions lead to a novel generalization of the Hubbard model. Furthermore, the hopping amplitude is predicted to vanish at a special value of the chemical potential in the topological insulator, allowing the phase diagram to be studied as a function of the ratio of interaction strength to hopping amplitude. I will present results on the interesting phase diagrams, which includes supersymmetric critical points, in both one and two dimensions.

Friday, March 8, 2019 11:15 AM - 1:51 PM

Session Y48 GSNP: Statistical and Nonlinear Physics II BCEC 251 - Daniel Lathrop, University of Maryland, College Park

11:15AM Y48.00001: The Ising Model in Curved Geometries* NIKOLAS BREUCKMANN (Presenter), University College London, ANANDA ROY, Institut de Physique Theorique, CEA Saclay, BENEDIKT ANDREAS PLACKE, IQI, RWTH Aachen — The study of statistical mechanics in curved geometries has recently gained an increasing amount of attention. Particularly the Ising model in negatively curved spaces has been studied as a mean to understand exotic crystals, soft-matter and field theories in Anti-de Sitter spaces.

We analyze the Ising model on in the hyperbolic plane as well as 2+1-Anti-de Sitter (AdS) space using high temperature series-expansion and Monte-Carlo simulations. While series expansions have been performed on the hyperbolic plane before, we study a wider class of hyperbolic lattices and go to much higher order, allowing us to analyze the dependency of critical phenomena on the magnitude of curvature.

In the past Monte Carlo methods have been difficult to use as the curvature lead to severe boundary effects which persist even for large system sizes. We overcome this problem by constructing families of closed 2D surfaces of increasing area and compactified AdS spaces of increasing volume, akin to periodic boundaries in euclidean space.

It has been discussed into which universality class the Ising model in hyperbolic space falls. Our results strongly support that it falls into the mean-field universality class.

11:27AM Y48.00002: Strong randomness criticality in the scratched-XY model ZHIYUAN YAO (Presenter), Institute for Advanced Study, Tsinghua University, TOBIAS PFEFFER, LODE POLLET, Department of Physics, University of Munich — We study the finite-temperature superfluid−normal-liquid classical phase transitions in a disordered two-dimensional XY model with power law distributed "scratch"-like bond disorder. While for weak disorder the transition is of Berezinskii-Kosterlitz-Thouless type, the transition in the strong disorder regime is in a different universality class with a non-universal jump of the superfluid stiffness. We show this new criticality can be described by the asymptotically exact theory of superfluid-insulator quantum phase transition in one-dimensional disordered boson systems and discuss possible experimental realizations.

11:39AM Y48.00003: Violation of a universal changeover in two-dimensional Potts models NIR SCHREIBER (Presenter), REUVEN COHEN, SIMI HABER, GIDEON AMIR, Mathematics, Bar Ilan University — We present a novel combinatorial approach which allows the determination of the critical temperature and the phase transition order of Potts models with multi-site interaction. Applying this approach to the hexagonal lattice, it is demonstrated that Potts models with local, range independent interaction may changeover from a continuous to a discontinuous phase transition, at a marginal value \( q_c \leq 3 \). Our theory is substantiated by Monte-Carlo simulations. In particular, it is numerically indicated that the system undergoes a first order transition for \( q=3 \). The latter is in agreement with a further prediction of \( q_c \leq 2 \), established under a mild assumption related to the asymptotic growth of hexagonal lattice animals. Our findings are in contrast to known cases where \( q_c=4 \) which were believed to represent a universal phenomenon. Thus, the universality of \( q_c=4 \) is violated.
11:51AM Y48.00004: Non-universal Dynamics of Three-Dimensional Magnetic Systems With Heisenberg Interaction
RIYA NANDI (Presenter), UWE CLAUS TAUBER, Virginia Tech — We numerically investigate the non-equilibrium critical dynamics in three-dimensional isotropic Heisenberg antiferromagnets. To account for the reversible terms arising from the microscopic dynamics of the system, we employ a hybrid simulation algorithm that combines reversible spin precession with relaxational Kawasaki spin exchange processes. We verify the dynamic exponent, and obtain a suitable aging scaling window. We observe and thus validate an older renormalization group prediction that, while the critical aging collapse exponent assumes universal value, the temporal decay exponent is found to be non-universal and dependent on the initial distribution of the spins.

12:03PM Y48.00005: Exact many-body quantum scar states with topological properties in dimensions 1, 2, and 3
SEULGI OK (Presenter), KENNY CHOO, University of Zurich, CHRISTOPHER M MUDRY, Paul Scherrer Institute, CLAUDIO CASTELNOVO, Cavendish Laboratory, University of Cambridge, CLAUDIO CHAMON, Physics Department, Boston University, TITUS NEUPERT, University of Zurich — We provide a general construction of exact excited states in a class of certain non-integrable conserved quantum many-body Hamiltonians. These states have area law entanglement entropy, while they are spectrally embedded in states with volume law scaling. Our construction applies to models in arbitrary dimensions, and we exemplify it for scar states with properties usually associated to gapped ground states of symmetry protected topological phases or topologically ordered phases of matter, including the respective degeneracies.

12:15PM Y48.00006: Stability of quantum statistical ensembles with respect to random local measurements
BORIS FINE (Presenter), Skolkovo Institute of Science and Technology, WALTER HAHN, QuTech, Delft University of Technology — We define a quantum statistical ensemble as 'stable', if a small number of local measurements cannot significantly modify the total-energy distribution representing the ensemble. This stability criterion is applied to lattices of spins-1/2, for which different measures of the quantum ensemble stability are investigated. In the context of the foundations of quantum statistical physics, our results justify the use of statistical ensembles with narrow energy distributions such as canonical or microcanonical ensembles.

12:27PM Y48.00007: Quantum Heat Machines with Trapped Ions
SUMAN CHAND (Presenter), Physics, Indian Institute of Technology Ropar, ASOKA BISWAS — Quantum heat machines (QHM) are those quantum systems that convert heat into the useful form of work. Specific kinds of QHMs, namely the heat engines and the refrigerators, among others have been studied in quantum regimes, using discrete strokes or continuous strokes. Heat engines take the heat from a hot bath, deliver a certain amount of work, and release heat to the cold bath. In most of the proposals of QHMs it is assumed that the hot bath and the cold bath are physically separated and can be switched on or off in a controlled way, just as in the case of their classical counterpart. In quantum regime, however, the interaction between the system and the bath is never switched off. Therefore, newer strategies are required for a QHM that can be implemented in a realistic scenario, and also within the quantum framework. Here, we show how one can implement different strokes of an Otto engine, using a single trapped ion. Using two ions, one can even build a refrigerator. Further, we study how a QHM performs across the critical value of an external parameter, pertaining to the quantum phase transition

Reference
CHRIS KOSCHENZ (Presenter), CARSTEN TIMM, Technische Universität Dresden, Institute of Theoretical Physics / Condensed Matter Theory Group — We present a generalized Bogoliubov-Hartree-Fock theory, which allows to study magnetic ordering, charge ordering, and superconductivity on the same footing and gives additional information about the so-called mixed phases [1]. These phases emerge in parameter ranges where the system is potentially strongly affected by fluctuations and cannot be described by any set of usual Hartree-Fock states (Slater determinants) [1,2]. Furthermore, we show how to obtain the self-consistent set of order parameters in the normal and BCS states by straightforward unrestricted global minimization of the appropriate Landau functional [3]. This method allows us to study the coexistence and competition of various magnetic and superconducting order and can be used to study the possibility of additional phase transitions in the coexistence regime.

NATHANIEL RUPPRECHT (Presenter), DERVIS CAN VURAL, University of Notre Dame — Scientific inference involves obtaining the unknown properties or behavior of a system in the light of what is known, typically, without changing the system. Here we propose an alternative to this approach: a system can be modified in a targeted way, preferably by a small amount, so that its properties and behavior can be inferred more successfully. For the sake of concreteness we focus on inferring the future and past of Markov processes and illustrate our method on two classes of processes: diffusion on random spatial networks, and thermalizing quantum systems.

MATT WALKER (Presenter), MARIJA VUCELJA, University of Virginia — The Mpemba effect is an anomalous relaxation process in which a system starting at a hot temperature cools down faster than an identical system starting at an initially lower temperature when both are coupled to an even colder bath. The effect has been observed in water, clathrate hydrates, magnetic alloys, and driven granular gases. We search for an analogous to Mpemba phenomenon for the case of a Langevin particle diffusing and advecting on a potential energy landscape. The particle is diffusing with a diffusion constant, that corresponds to a temperature that is lower than specified by the initial condition. We study the Mpemba effect, or non-monotonic thermal relaxation, as a function of parameters specifying the potential landscape.

VIDUSHI ADLAKHA (Presenter), Department of Physics, University of Houston, PHILIPP G. MEYER, HOLGER KANTZ, Max Planck Institute for the Physics of Complex Systems, KEVIN E BASSLER, Department of Physics, University of Houston — We show that the anomalous diffusive behavior found in an aging system can be decomposed into three fundamental constitutive causes. A model process that is a sum of increments that are iterates of a chaotic dynamical system, the Pomeau-Manneville map, is examined. The increments can have long-time correlations, fat-tailed distributions and be non-stationary. Each of these properties can cause anomalous diffusion through what is known as the Joseph, Noah and Moses effects, respectively. The model can have either sub- or super-diffusive behavior, which we find is generally due to the combination of the three effects. Scaling exponents quantifying each of the three constitutive effects are calculated using analytic methods and confirmed with numerical simulations. They are then related to the scaling of the distribution of the process through a scaling relation. The work also discusses the importance of Moses effect in the anomalous diffusion of experimental systems.

Universal First-Passage-Time Distribution of Non-Gaussian Currents

SHILPI SINGH (Presenter), PAUL MENCZEL, DMITRY S GOLUBEV, Aalto University, IVAN KHAYMOVICH, Max Planck Institute for the Physics of Complex Systems, JOONAS T PELTONEN, CHRISTIAN FLINDT, Aalto University, KEIJI SAITO, Keio University, ÉDGAR ROLDÁN, The Abdus Salam International Centre for Theoretical Physics, JUKKA P PEKOLA, Aalto University — I present our recent work on the fluctuations of the time elapsed until the electric charge transferred through a conductor reaches a given threshold value. For this purpose, we measure the distribution of the first-passage times for the net number of electrons transferred between two metallic islands in the Coulomb blockade regime. Our experimental results are in excellent agreement with numerical calculations based on a recent theory describing the exact first-passage-time distributions for any non-equilibrium stationary Markov process.

We present a simple analytical approximation for the first-passage-time distribution, which takes into account the non-Gaussian statistics of the electron transport, and show that it describes the experimental distributions with high accuracy. This universal approximation describes a wide class of stochastic processes and can be used beyond the context of mesoscopic charge transport. In addition, we verify experimentally a fluctuation relation between the first-passage-time distributions for positive and negative thresholds.

Electromagnetic properties of random materials

POUYAN KARIMI (Presenter), MARTIN OSTOJA-Starzewski, Mechanical Science and Engineering, University of Illinois at Urbana-Champaign — Scale dependence bounds on the electromagnetic properties are studied in the setting of spatially random linear materials with statistically homogeneous and spatially ergodic random microstructures. First, from the Hill-Mandel homogenization conditions adapted to electric and magnetic fields, uniform boundary conditions are formulated for a statistical volume element (SVE). From these conditions, rigorous bounds are obtained on the macroscale (effective) electrical permittivity and magnetic permeability. Using computational electromagnetism methods, these bounds are obtained through numerical simulations for composites of two types: (i) 2D random checkerboard (two-phase) microstructures and (ii) 2D Gaussian correlated microstructure. The simulation results demonstrate a convergence of these bounds to the effective properties with increasing length scales.

The authors gratefully acknowledge the partial support from the NSF IIP-1362146 (M.O.-S) as well as the Computational Science and Engineering (CSE) Fellowship (P.K.) at NCSA and the use of the campus cluster resources provided under the CSE program at the University of Illinois at Urbana-Champaign.

Session Y51 DBIO: Physical Mechanisms of Cell Fate Decision Making and Stem Cell Differentiation/Reprogramming

BCEC 253A - Wei Wang, Nanjing University - Tag(s): Invited

Trigger waves in cell signaling [Invited] JAMES FERRELL (Presenter), Stanford University — Untethered cytosolic proteins can move 10 µm or so in a few seconds by simple random walk diffusion. In a typical eukaryotic cell (with a radius of ~10 µm), this is fast enough to allow a cell to respond in a spatially coordinated fashion to many stimuli. Over larger distance scales, regulators are often spread via flow. For example, hormones like insulin and epinephrine make their way around the body via the circulatory system on a time scale of a minute or so, whereas random walk diffusion would take about 500 years. An alternative to flow for long-range biological communication is the trigger wave. Action potentials are trigger waves; so are calcium waves in neurons and fertilized eggs; and so are cAMP waves in aggregating slime molds.

Here we will show that mitosis spreads through Xenopus egg cytoplasm via a trigger wave of Cdk1 activation, and apoptosis spreads via a trigger wave of caspase activation. These findings explain how a large cell like a frog egg (~1.2 mm diameter) and function in a spatially coordinated fashion, and they show that trigger waves are a recurring theme in cell signaling.
transdifferentiation*  

12:27PM Y51.00003: Waddington landscape and pathways for stem cell differentiation, reprogramming and transdifferentiation* [Invited]  
JIN WANG (Presenter), Stony Brook University — Waddington landscape in biology gives a qualitative picture for understanding differentiation and development. However, the original Waddington landscape picture lacks physical foundations and quantifications. We developed a nonequilibrium landscape and flux theory for quantifying the Waddington landscape for differentiation, reprogramming and transdifferentiation. We found that the landscape for differentiation and development emerges from the underlying gene regulatory interactions with distinct stem cell and differentiated cell state attractors. Furthermore, the pathways for differentiation, reprogramming, and transdifferentiation among the stem cell and differentiation cell state attractors can be quantified. In addition, the kinetic speed of differentiation, reprogramming, and transdifferentiation can be quantified and associated with the landscape topography. We also show that the dynamics of the differentiation, reprogramming, and transdifferentiation processes are determined by both the landscape gradient and the rotational flux. We show that the flux can influence significantly the pathways and the kinetics of these processes. Importantly, flux may also provide a nonequilibrium driving force for the formation of different cell state attractors as the new active matter phases. We apply the landscape and flux theory to several biological differentiation processes including human stem cell development. We also identified the key genes and regulations for the differentiation and reprogramming based on the landscape topography and pathways. The relationship between development and cancer is also explored with the emergence of cancer stem cell state attractor. This study may provide useful clues for the practice of tissue engineering and cancer treatment.

1:03PM Y51.00004: Setting the epigenetic stage for differentiation: a collective phenomenon [Invited]  
FABRIZIO OLMEDA, Max Planck Institute for the Physics of Complex Systems, STEPHEN CLARK, TIM LOHOFF, The Babraham Institute, HEATHER LEE, The University of Newcastle, WOLF REIK, The Babraham Institute, STEFFEN RULANDS (Presenter), Max Planck Institute for the Physics of Complex Systems — The self-organisation of cells during embryonic development is one of the most intriguing non-equilibrium processes in nature. How do cells coordinate their behaviour in order to build a living organism? Recent technological advances, for example in genomics, for the first time allow us to probe microscopic states of these processes with unprecedented detail. But how can detailed quantitative information on the microscopic scale be translated into a mechanistic understanding of the collective degrees of freedom that determine biological function at the cellular scale? In this talk, I will give the example of epigenetic patterning in early embryonic development to demonstrate how core concepts from non-equilibrium physics can help gain understanding of the collective processes underlying cell fate regulation.  

During early development, when the first cell fate decisions are made, the genome undergoes large-scale changes in epigenetic DNA modifications (DNA methylation) and chromatin structure. As a result of these processes cells carry distinct epigenetic marks that assign their fate during later stages of development and adulthood. But how are these epigenetic marks so robustly established? Combining novel methods from single-cell multi-genomics with non-equilibrium physics we find universal scaling behaviour in the processes leading to the establishment of epigenetic marks. We show that these phenomena result from long-range interactions mediated by the interplay between chemical and topological modifications of the DNA. Our work sheds new light on epigenetic mechanisms involved in cellular decision making. It also highlights how mechanistic insights into the molecular processes governing cell-fate decisions can be gained by the combination of methods from genomics and non-equilibrium physics.
Intracellular noise level determines ratio control strategy confined by speed-accuracy tradeoff

Robust and precise ratio control of heterogeneous phenotypes within an isogenic population is essential in the development and differentiation. However, the mechanisms of such ratio control are poorly understood. Here, we employ experimental and mathematical techniques to understand the combined effects of signal induction and gene expression stochasticity on phenotypic multimodality. We identify two strategies to control phenotypic ratios from an initially homogenous population, suitable roughly to high-noise and low-noise intracellular environments, and we show that both can be used to generate precise fractional differentiation. In noisy gene expression contexts, such as those found in bacteria, induction within the circuit's bistable region is enough to cause noise-induced bimodality within a feasible timeframe. However, in less noisy contexts, such as tightly controlled eukaryotic systems, spontaneous state transitions are rare and hence bimodality needs to be induced with a controlled pulse of induction that falls outside the bistable region. Finally, we show that noise levels, system response time, and ratio tuning accuracy impose tradeoff and limitations on both ratio control strategies, which guides the selection of strategy alternatives.

Friday, March 8, 2019 11:15 AM - 2:15 PM

Session Y53 GSOFT: Towards Soft Active Metamaterials

Soft Active Metamaterials by Programing Ferromagnetic Domains*

Robust and precise ratio control of heterogeneous phenotypes within an isogenic population is essential in the development and differentiation. However, the mechanisms of such ratio control are poorly understood. Here, we employ experimental and mathematical techniques to understand the combined effects of signal induction and gene expression stochasticity on phenotypic multimodality. We identify two strategies to control phenotypic ratios from an initially homogenous population, suitable roughly to high-noise and low-noise intracellular environments, and we show that both can be used to generate precise fractional differentiation. In noisy gene expression contexts, such as those found in bacteria, induction within the circuit's bistable region is enough to cause noise-induced bimodality within a feasible timeframe. However, in less noisy contexts, such as tightly controlled eukaryotic systems, spontaneous state transitions are rare and hence bimodality needs to be induced with a controlled pulse of induction that falls outside the bistable region. Finally, we show that noise levels, system response time, and ratio tuning accuracy impose tradeoff and limitations on both ratio control strategies, which guides the selection of strategy alternatives.

This is an invited talk for Session Towards Soft Active Metamaterials.

Bifurcations in mechanical structures: from smart folding to folding smarts*

Self-folding structures (also known as 4D printing) have emerged as a potential technique for the fabrication of complex structures in three dimensions, much as origami artists fold an intricate shape from flat sheets of paper. Recently, it has become clear self-folding origami exhibits a complex, bifurcated configuration space with exponentially many branches - making self-folding difficult. I will describe recent work extending this analysis to more complex origami having 2 or more degrees of freedom and explore, in detail, how to program a structure to fold robustly despite the proliferation of misfolding pathways. Finally, I will describe how to use the bifurcations and nonlinearities in origami and other mechanical structures to design “smart materials” - metamaterials that can perform logical operations.

Putting stubborn flocks to work

Building on spontaneously flowing liquids assembled from colloidal rollers, I will show that (French) active colloids collectively protest and resist when one tries to waive their privilege to freely choose their direction of motion. I will show that the flows emerging from flocking transitions are intrinsically bistable and can proceed against external pressure gradients. I will theoretically explain this collective stubbornness showing that orientational elasticity and confinement conspire to protect the direction of spontaneous flows. Finally, I will show how to exploit the intrinsic bistability of confined polar liquids introducing a generic design principle for self-sustained microfluidic oscillators.
1:03PM Y53.00004: Manipulating the dynamics of active emulsions* [Invited] CHENYU JIN (Presenter), BABAK VAJDI HOKMABAD, KYLE A BALDWIN, CORINNA MAASS, Max Planck Institute for Dynamics and Self-Organization — Precise control and manipulation are crucial to various applications of active matter. For example, in guidance applications as in active microsensors, microreactors with targeted release or microfluidic droplet logic, we need to know and control the rules by which such entities can be guided, follow external stimuli and control their stability.

Nematic and isotropic oil droplets in aqueous surfactant solutions are well-controlled artificial active system with easily accessible tuning parameters such as temperature, liquid crystalline order or bulk viscosity. These active emulsions exhibit many properties such as wall guidance, chemotaxis, autochemotaxis, as well as tunable swimming dynamics. We demonstrate how the motion of the droplets can be controlled by topographical guidance, droplet topology and chemical gradients, and show avenues for technical application by adding internal compartments.

*supported by the DFG SPP 1726 “Microswimmers” and the Max Planck Society

1:39PM Y53.00005: Designing active topological networks [Invited] HENRIK RONELLENFITSCH (Presenter), Massachusetts Institute of Technology — Mechanical and phononic metamaterials with exotic characteristics, including negative elastic moduli or negative effective mass density, allow for precise control of mechanical functionality. Materials possessing spectral bandgaps are particularly interesting due to their ability to host topological edge modes that enable robust signal transmission even in the presence of defects. Active matter can induce and carry such topological modes through its inherent breaking of time-reversal symmetry. Here, I will present recent work by our group that aims at harnessing interactions between activity and topology to realize autonomously acting metamaterials. Specifically, we show how one can program desired spectral properties such as bandgaps directly into mechanical networks, and thus control topological excitations when time-reversal symmetry is broken. Furthermore, we demonstrate how these ideas can be generalized to design active electronic circuits that can self-select and sustain topological modes and how topology can be used to construct other precisely controllable current patterns.

Friday, March 8, 2019 11:15 AM - 1:15 PM

Session Y55 GSNP GSOFT: Shell Buckling II BCEC 254B - Pedro Reis, Ecole polytechnique federale de Lausanne - Tag(s): Focus

11:15AM Y55.00001: Mechanics of turning a page JIHYE MYEONG (Presenter), Seoul National University, ANNA LEE, POSTECH, HO-YOUNG KIM, Seoul National University — A mundane activity of turning a page arises not only in reading, but also in production of paper and textile. Here we analyze the shape and stability of a thin sheet of paper, bound to a book in one side and compressed from the other side, to gain mechanical understanding of the page turning. We start with describing the shape of a sheet that is buckled between the bound end and gripping fingers, using the Euler elastica. Then we predict the fate of the bent page when the external load is removed, to determine the condition for the page to turn to the other side. Upon corroborating our theory with experiments of various geometry and materials of thin sheets, we suggest the shortest path of fingers to turn pages for both lazy readers and efficient manufacturing robots.
**11:27AM Y55.00002: Swimming through shell buckling**  
ADEL DJELLOULI (Presenter), Harvard University, PHILIPPE MARMOTTANT, GWENNOU COUPIER, CNRS/Grenoble University, CATHERINE QUILLIET, HENDA DJERIDI, Grenoble University — Under pressure, a hollow elastic sphere becomes unstable and collapses. It reinflates back when the pressure is decreased. The hysteresis in shape sequence and in deformation velocity associated to this cycle makes this simple object a good candidate for becoming a swimmer able to move at low or high Reynolds number.

We explore this possibility through a macroscopic experiment in fluids of varying viscosities so as to explore different flow regimes. We show that not only the shape hysteresis leads to swimming but the fast buckling phase is an efficient mechanism for propulsion that implies inertial effects and subtle coupling between shape post-buckling oscillations and fluid flow patterns. Our modeling shows that such an inertial regime could even be reached at microscopic scale.

We anticipate that a conveyor made of a few of microbubbles with different shell thicknesses, would constitute a microrobot whose 3D displacement can be remotely controlled by ultrasonic waves.

*This research was made possible by ERC Grant No. 614655 Bubbleboost.

**11:39AM Y55.00003: Buckled Bundles and Beyond**  
ISAAC BRUSS (Presenter), Harvard University, GREGORY GRASON, Polymer Science and Engineering, University of Massachusetts - Amherst — Defects can elastically buckle 2D crystalline membranes (like graphene) into 3D shapes. Using a combination of numerical simulations and continuum elasticity theory, we show how the same is true for columnar structures (like nanotubes or protein fibers). This discovery builds upon the recently uncovered mapping between the inter-filament spacing in bundles and the metric properties of a curved surface. We show that shape instabilities are controlled by a single material-dependent parameter that characterizes the ratio of bending to cohesion energies. Along with a host of previously unknown shape equilibria—the filamentous analogs to the conical and saddlelike shapes of defective membranes—we find a profoundly asymmetric response to positive and negative disclinations in the infinite length limit that is without parallel to the membrane analog.

*This work was supported by the National Science Foundation through Grant No. DMR 1608862.

**11:51AM Y55.00004: Dynamic buckling of rings and annuli**  
OUSMANE KODIO (Presenter), FINN BOX, DOIREANN O’KIELY, VINCENT CANTELLI, ALAIN GORIELY, DOMINIC VELLA, University of Oxford — When an elastic ring is subject to an external pressure, it is known to buckle as a ‘figure of 8’; similarly an annulus subject to a strong internal tension is known to form two folds. Here we explore how these examples of mode-2 buckling change under dynamic loading. In particular, we show that the presence of inertia means that higher modes are observed at the onset of instability, and present results for the observed mode number as a function of the driving pressure. Our results are in accord with experiments in which an elastic ring is rapidly pulled inwards by surface tension. Surprisingly, we find that while inertia is required to observe higher modes, the actual selected mode does not depend on inertia. We explain this, and reconcile our observation of higher modes with earlier experiments that exhibited mode 2, by understanding the growth rate of instability.

*ERC Grant Agreement No. 637334*
12:03PM Y55.00005: Membrane morphology beyond polyhedra*  
HANG YUAN (Presenter), MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University — Conventional homogeneous or heterogeneous elastic crystalline membrane exhibits buckling transition from sphere to polyhedra. However, their morphologies do not go beyond polyhedra and cannot be externally controlled. We study the morphology of a closed crystalline membrane co-assembled with super-paramagnetic particles which is called magnetoelastic membrane. With additional competition from magnetic dipole-dipole interaction on top of elasticity, magnetoelastic membrane shows novel morphology beyond polyhedra. By systematically changing two dimensionless control parameters, we find a rich class of membrane morphologies. The morphology of magnetoelastic membrane can be manipulated by external magnetic field, providing promising applications for membrane shape control, design of micro-containers and targeted drug delivery systems.

12:15PM Y55.00006: Swelling and warpage of orthotropic plates  
HARRISON WOOD (Presenter), JAMES HANNA, Virginia Tech — While isotropic in-plane swelling problems for elastic sheets have been studied extensively in recent years, many shape-programmable materials, including nematic solids and 3d-printed structures, are anisotropic. Inspired by the warpage of engineered wood panels, we examine plates in which both the in-plane swelling and the material stiffness are highly orthotropic, leading to multiple separations in energy scales. For these orthotropic plates, in-plane swelling can produce configurations that approximate cylindrical shapes and twisted ruled surfaces.

12:27PM Y55.00007: Transverse edge extension underlies compression, buckling and wrinkling in thin solids  
MENG XIN (Presenter), BENJAMIN DAVIDOVITCH, University of Massachusetts Amherst — When a rectangular sheet whose short edges are clamped is stretched, elongated wrinkles appear, indicating the presence of transverse compression. So far, the mechanism by which longitudinal tension and edge clamping act jointly to generate transverse compression has not been clarified. Here we employ analytic tools and numerical simulations to compare this problem with a new variant, where instead of stretching and edge clamping one only imposes edge-localized transverse strain, pulling the corners outward. We find that, despite the absence of longitudinal tension in the new variant, both models exhibit similar transverse stress profile in planar state, thus revealing that the generic origin of compression is the transverse extension of edges relative to the bulk. This similarity in planar stress profiles underlies similarity in the near-threshold buckling patterns exhibited by the two models. In contrast, the two models are sharply distinct in their respective far-from-threshold regime: the deflection of the stretched sheet consists of small wavelength wrinkles whereas the edge-extended sheet does not develop wrinkles. This indicates the role of longitudinal tension in providing an effective substrate resistance, which is crucial for the emergence of wrinkle patterns.

12:39PM Y55.00008: A geometric theory of wrinkling for confined shells: Part 1*  
YOUSRA TIMOUNAY (Presenter), IAN TOBASCO, Department of Mathematics, University of Michigan, DESISLAVA V TODOROVA, ELENI KATIFORI, Department of Physics and Astronomy, University of Pennsylvania, JOSEPH D PAULSEN, Department of Physics, Syracuse University — The problem of joining a planar sheet to a surface with a different metric is a familiar frustration. Flat bandages don't stick as well to curved knuckles or elbows, and maps of the earth exaggerate areas near the poles. We study the deformations of ultrathin (~100 nm) elastic shells, which we manufacture on spherically-curved substrates and then transfer to a flat water bath. The sheets respond by forming distinct domains filled by smooth parallel wrinkles or by disordered buckled patterns. We show that the selection of these domains and the orientation of wrinkles within them depends sensitively on the shape of the boundary of the film. Remarkably, these complex patterns may be predicted by a theoretical model wherein the exposed surface area of the water bath is minimized. The derivation and solution of this model will be presented in the next talk. (This is part 1 in a 3-talk series).

*Support from NSF-DMR-CAREER-1654102 is gratefully acknowledged.
12:51PM Y55.00009: A geometric theory of wrinkling for confined shells: Part 2*  
IAN TOBASCO (Presenter), Department of Mathematics, University of Michigan, YOUSRA TIMOUNAY, Department of Physics, Syracuse University, DESISLAVA V Todorova, Department of Physics and Astronomy, University of Pennsylvania, JOSEPH D PAULSEN, Department of Physics, Syracuse University, ELENI KATIFORI, Department of Physics and Astronomy, University of Pennsylvania — Thin elastic shells readily take on shapes wildly different from their own. Motivated by the puzzle of determining the wrinkle patterns exhibited by shallow shells floating on a water bath, we obtain a fully rigorous asymptotic expansion of the energy (elastic and otherwise) valid in the high-frequency limit. After renormalizing by the typical energy of wrinkling, we derive a coarse-grained model in which an elastically compatible pattern is assigned energy proportional to the difference between its intrinsic undeformed area and its projected area in the plane. Energetically optimal patterns therefore maximize their projected area. Surprisingly, this limiting model turns out to be explicitly solvable in a large variety of cases, including for shells whose (possibly non-constant) curvature is of a known sign. We demonstrate our methods in many cases of interest, offering an ansatz-free explanation for the geometry of wrinkle patterns seen in confined elastic shells. (This is part 2 in a 3-talk series.)

1:03PM Y55.00010: A geometric theory of wrinkling for confined shells: Part 3*  
DESISLAVA V Todorova (Presenter), Department of Physics and Astronomy, University of Pennsylvania, IAN TOBASCO, Department of Mathematics, University of Michigan, YOUSRA TIMOUNAY, JOSEPH D PAULSEN, Department of Physics, Syracuse University, ELENI KATIFORI, Department of Physics and Astronomy, University of Pennsylvania — Materials engineered through surface patterning are used for a broad array of applications, including flexible electronic and microfluidic devices, electronic skin, and many others. Microfabrication techniques based on elastic instabilities have attracted much attention because of their relative simplicity and potential for technological innovation. We employ Gaussian curvature as a mechanism for pattern formation: when a shallow curved shell is placed upon a liquid surface, well-defined domains of unidirectional wrinkles are formed. In the third part of this series of talks, we use finite element simulations and a theoretical approach based on the minimization of the elastic energy, to probe how the global arrangement of the patterns and wrinkling amplitude depends on the shape and curvature of the shell. We finally consider cases of shells with highly non-trivial boundary geometries and we demonstrate how this setup can be employed to harness surface structures with complex, yet predictable and controllable, topography. (This is part 3 in a 3-talk series).

Session Y56 GSNP GSOFT: Machine Learning Approaches to Understanding Bulk Metallic Glasses and Other Amorphous Materials BCEC 255 - Corey O’Hern, Yale Univ - Tag(s): Focus

11:15AM Y56.00001: Machine Learning Stress Overshoot of Amorphous Solids*  
SHIYUN ZHANG (Presenter), WEN ZHENG, NING XU, Department of Physics, University of Science and Technology of China — When undergoing quasistatic shear, slow-quenched glasses exhibit an overshoot in shear stress, which decreases with the increase of quench rate and eventually evolves into a smooth crossover. However, the structure of glasses does not exhibit significant quench rate dependence. It thus remains unclear what determines the emergence of stress overshoot. Here, inspired by image recognition, we propose that stress overshoot of amorphous solids can be predicted from structures of solids using machine learning methods. Our results show that pure geometrical quantities such as local coordination number, bond orientational order and voronoi cell volume, which seem to weakly correlate with soft spots, have displayed very high predictive power of stabilities of amorphous solids, when combined with coarse-grain and machine learning methods. Besides, the stress overshoot in pinned systems suggests that our recently defined order parameter from the normal modes of vibration is a more general structure descriptor to identify stress overshoot. The high accuracy in identifying stress overshoot may imply that machine learning methods successfully capture the spatial correlation of the descriptor in some complicated way.

*National Natural Science Foundation of China (Grants No. 11734014)
11:27AM Y56.00002: Interplay of softness and rearrangements during avalanche propagation* GE ZHANG (Presenter), SEAN RIDOUT, ANDREA LIU, University of Pennsylvania — Disordered solids yield at a common shear strain of about 3%, but the behavior beyond yield is different for different systems and for systems with different histories. Foams can deform indefinitely without fracturing, many systems exhibit crackling noise or avalanche behavior, and still others exhibit shear banding and brittle fracture. Here we study an athermal, jammed packing of Hertzian particles that are sheared quasistatically. We identify the stress drops associated with rearrangements and then use steepest descent dynamics to study the evolution of the avalanches. We find that the avalanches consist of localized events that appear sequentially in well-separated locations of the sample. To understand this behavior, we exploit a machine-learning approach that has been developed to correlate local structure with dynamics in glassy systems. Following earlier work, we define a quantity softness that correlates with dynamical events during the avalanche process. We study the interplay of softness and dynamics: particles with higher softness are more likely to shift, while dynamical events affect local structure and hence softness. This interplay gives insight into the avalanche process.

*DOE DE-FG02-05ER46199/Simons327939

11:39AM Y56.00003: A Structural Measure of Effective- (Fictive-) Temperature and its Basis in Statistical Mechanics* MICHAEL FALK (Presenter), DARIUS D ALIX-WILLIAMS, Johns Hopkins University — The concept of fictive-temperature has long been utilized to characterize the processing dependence of glass structure, and has recently been shown to be predictive of metallic glass ductility. Some theories have hypothesized that it is actually a real temperature related to the configurational degrees of freedom of the glass, i.e. an ”effective-temperature,” notably the shear-transformation-zone (STZ) and soft-glassy-rheology (SGR) theories. Here we derive a thermodynamic integration scheme for calculating effective-temperature based on a 2-temperature hypothesis. To test this scheme we simulate a binary Cu-Zr metallic glass modeled with an EAM potential. Measures of the energy fluctuations associated with both the fast and slow degrees of freedom are measured during the glass quench. The resulting effective-temperature is consistent with estimates of fictive-temperature obtained from simulation in more heuristic ways. The results indicate that effective-temperature can be understood as a purely structural quantity. The method provides a means to measure the effective-temperature in the absence of fluctuations induced by shear and without resorting computationally expensive and impractical methods for explicitly measuring the configurational entropy.

*NSF DMR 1408685/1409560

11:51AM Y56.00004: Interaction potentials for bulk metallic glasses that can generate both brittle and ductile mechanical response* AYA NAWANO (Presenter), JAN SCHROERS, Department of Mechanical Engineering and Materials Science, Yale University, MARK SHATTUCK, Department of Physics and Benjamin Levich Institute, The City College of the City, University of New York, COREY SHANE O’HERN, Department of Mechanical Engineering and Materials Science, Yale University — Bulk metallic glasses (BMGs) have desirable mechanical properties such as high yield strength and elasticity compared to conventional alloys. However, BMGs are typically brittle, which limits their viability for structural applications. We perform molecular dynamics simulations to understand the ductility of model glass formers that interact via the Lennard-Jones, Stillinger-Weber, and embedded atom method potentials. We prepare binary BMGs over a range of cooling rates and perform athermal quasi-static uniaxial tension tests. We correlate the ductility with the fictive temperature, depth in the potential energy landscape, and measures of local structural order. We show that we can prepare samples that span a wide range of mechanical responses for all of the interaction potentials that we study. We also present a phenomenological spring network model that describes brittle and ductile response in terms of the number of springs that have broken and reformed in response to applied strain. We identify the parameters in the model that control the behavior of the stress versus strain curve, which allows us to achieve quantitative agreement with the results from the simulation of uniaxial tension.

12:03PM Y56.00005: Correlations in the shear flow of athermal amorphous solids: A principal component analysis
CELINE RUSCHER (Presenter), JOERG G ROTTLER, Stewart Blusson Quantum Matter Institute — Machine learning methods are increasingly being applied to problems in statistical physics, because they unveil aspects that would generally be neglected by traditional approaches. Here we apply principal component analysis, a method frequently used in image processing and unsupervised machine learning, to study the passage from the elastic to plastic flow regime in amorphous materials. Sets of particle displacements are obtained from simulations of a 2D amorphous model system in steady shear flow at different shear rates in the athermal limit. PCA produces a low-dimensional representation of the data, in which the principal directions clearly identify distinct differences between elastic (i.e. reversible) and plastic deformation. When deformation is accumulated over larger strains, shear localizes along bands, and PCA provides a quantitative measure of the increased degree of anisotropy in the flow patterns. We suggest that PCA can be a useful analysis technique that complements a traditional statistical description via correlation functions.

12:15PM Y56.00006: Analyzing the Internal Structure of Metallic Glasses through X-ray Absorption Fine Structure (XAFS) Spectroscopy*
HANYU ZHANG (Presenter), Case Western Reserve University, JENNIFER CARTER, Materials Science and Engineering, Case Western Reserve University, HAROLD CONNAMACHER, Electrical Engineering & Computer Science, Case Western Reserve University — This project aims to independently find the structure of metallic glasses through theoretical and experimental measures to see if current theoretical simulations yield the same structures as measured through experimental techniques. This is achieved by analyzing the accuracy of current molecular dynamics (MD) simulations to predict the amorphous structure of metallic glasses as characterized by x-ray absorption fine structure (XAFS) spectroscopy experiments. The influence of composition and processing techniques on the final structure is being explored on metallic glasses made from Ni, Co, Ta, and Nb. This project utilizes Large-scale Atomic/Molecular Massively Parallel Simulator (http://lammps.sandia.gov/), a MD software, to build the structures and Larch (Matthew Newville 2013) for data analysis. Used as a Python package, Larch gives us full control of the usage and implementation of our code. We are analyzing how closely the computer-generated structures matches with experimentally measured XAFS spectra. The validity of the computational approach has been tested using the pure crystalline solids.

12:27PM Y56.00007: Local Yield Stress Analysis in Simulated 3D Glasses
DIHUI RUAN (Presenter), Johns Hopkins University, SYLVAIN PATINET, ESPCI, MICHAEL FALK, Johns Hopkins University — The ‘Local Yield Stress’ (LYS) method was developed to characterize the local structure of a atomistic model of a glass in a way that provides insight into its plastic response. The local yield stress is characterized as the incremental stress needed to induce a structural instability when an outer shell surrounding of a patch of atoms is deformed affinely along various shear orientations, while allowing the structure at the core to rearrange via athermal quasi-static (AQS) simulation. Here we generalize the LYS method to three-dimensional systems. We describe a method to democratically sample local shear orientations and triaxialities. By applying the LYS analysis to as-quenched glasses, we are able to identify the statistics of the local yield stress distribution. In order to assess to predictability and persistence of this measure, a correlation is computed between these local yield stresses and the observed plastic events when the glasses are undergoing shear deformation within in AQS simulations.
Bulk metallic glass design: What properties determine the glass-forming ability of multi-component alloys?

Yuanchao Hu (Presenter), Jan Schroers, Department of Mechanical Engineering & Materials Science, Yale University, Mark Shattuck, Benjamin Levich Institute and Physics Department, The City College of the City University of New York, Corey Shane O’Hern, Department of Mechanical Engineering & Materials Science, Yale University — Bulk metallic glasses (BMGs) possess a number of important properties, such as high strength and thermoplastic formability, which stem from the fact that they are structurally disordered in contrast to crystalline metals. Materials scientists have identified several features that are correlated with the glass-forming ability (GFA) of alloys. For example, good glass-formers are typically multi-component alloys composed of elements with atomic radii that differ by more than 10%. Most BMGs also possess a negative heat of mixing, which disfavors clustering of like atoms and hinders phase separation. However, researchers have not been able to a priori predict a new BMG-forming alloy. In this work, we perform computational studies of binary alloys to understand the relative contributions of geometric frustration and energetic frustration in determining the GFA. From a database of the heats of mixing and cohesive energies of binary atomic systems with atoms A and B, we show that most binary alloys follow a Berthelot combining rule, \( \varepsilon_{AB} = \left( \varepsilon_{AA} \varepsilon_{BB} \right)^{1/2} \), where \( \varepsilon_{AB} \), \( \varepsilon_{AA} \), and \( \varepsilon_{BB} \) are the depths of the attractive energy for pair interactions between AB, AA, and BB. We employ this mixing rule in molecular dynamics simulations of binary Lennard-Jones mixtures of atoms with equal sizes, but different cohesive energies. We measure the critical cooling rates of binary systems over the full range of cohesive energies and number fraction \( f_A \) of A and \( 1-f_A \) of B atoms. We show that good glass formers satisfy \( \varepsilon_{AA} > \varepsilon_{AB} > \varepsilon_{BB} \) when \( f_A < f_B \). We find that good glass-forming ability is determined by the conditions \( \varepsilon_{BB} << \varepsilon_{AA} \) and \( f_A < f_B \), and not correlated with the magnitude of the heat of mixing. In future studies, we will identify the variables that control the glass-forming ability in ternary alloys with atoms of different sizes and cohesive energies.

We acknowledge funding from Yale’s Center for Interface Structures and Phenomena (Y.H.) and the National Science Foundation Grant No. CBET-1605178 (C.O.).

Friday, March 8, 2019 11:15 AM - 1:51 PM

Session Y57 GSNP: Mechanical Metamaterials III BCEC 256 - Martin van Hecke, AMOLF

Non-reciprocal Dynamic Response of a Bilinear Lattice — Behrooz Yousefzadeh (Presenter), Brian J Ramirez, Chiara Daraio, Caltech — We report on the non-reciprocal dynamics of a one-dimensional bilinear lattice subject to continuous harmonic excitation. The bilinear nature of the lattice is due to elements within the unit cell that have different elastic moduli in compression and extension. We investigate the asymmetric wave propagation characteristics of bilinear lattices, and explain the results based on the nonlinear dynamics of the unit cell. We show that we can obtain different responses for the forward and backward configurations relying on either (i) the harmonic (frequency-preserving) operating range, or (ii) different onsets of instability. We discuss experimental realization of the unit cell based on 3D-printed macroscale structures.

This material is based upon work supported by the National Science Foundation under EFRI Grant No. 1741565.

Anomalous Collisions of Elastic Vector Solitons in Mechanical Metamaterials — Bolei Deng (Presenter), Harvard University, Vincent Tournat, Le Mans University, Pai Wang, Katia Bertoldi, Harvard University — We investigate via a combination of experiments and numerical analyses the collision of elastic vector solitons in a chain of rigid units connected by flexible hinges. Due to the vectorial nature of these solitons, very unusual behaviors are observed: while, as expected, the solitons emerge unaltered from the collision if they excite rotations of the same direction, they do not penetrate each other and instead repel one another if they induce rotations of opposite direction. Our analysis reveals that such anomalous collisions are a consequence of the large-amplitude characteristics of the solitons, which locally modify the properties of the underlying media. Specifically, their large rotations create a significant barrier for pulses that excite rotations of opposite direction and this may block their propagation. Our findings provide new insights into the collision dynamics of elastic solitary waves. Furthermore, the observed anomalous collisions pave new ways towards the advanced control of large amplitude mechanical pulses, as they provide opportunities to remotely detect, change or destruct high-amplitude signals and impacts.

*This work was supported by the National Science Foundation under Grant No. DMR-1420570 and EFMA-1741685 and from the Army Research Office under Grant No. W911NF-17-1-0147.
DOMINIC ROBE (Presenter), JUSTIN BURTON, Emory University — Amorphous materials show surprising and potentially useful acoustic properties at low frequencies. A notable example are the low-temperature acoustic properties of dielectric glasses, where quasi-localized, resonant states absorb energy and form memories of past excitations. To probe these phenomena at low-frequencies and over long times, we study the vibrational modes of quasi-2D networks of coupled oscillators using parallelized, GPU computing. We vary the degree of pre-stretching (tension) in the network, disorder in site masses, and disorder in the network connectivity. Even with a crystalline network structure, disorder in the site masses gives rise to low-frequency, quasi-localized modes, similar to those studied in glasses and jammed systems. The anharmonic properties of these modes become exceedingly important over thousands of cycles of oscillations. In addition, in order to realize some of these properties in the laboratory, we have developed a mechanical metamaterial fabricated from a silicon nitride layer on a silicon wafer using standard photolithography. The degree and type of disorder can be tuned prior to fabrication, leading to a high-Q, constituent-level visualization of vibrational modes in disordered materials.

*National Science Foundation DMR Grant No. 1455086

KOJI SATO (Presenter), RYOKICHI TANAKA, Tohoku University — It has been shown by Kane and Lubensky that certain classical chains admit topologically protected zero-energy modes that are localized on the boundaries. Although the static features of the localized modes are well captured by linearized equations of motion, the description of their dynamics requires fully nonlinear treatment. We study quasi-periodic solutions of the nonlinear equations of motion of one-dimensional classical chains. Such quasi-periodic solutions correspond to periodic trajectories in the configuration space of the discrete systems, which allows us to define solitons without relying on a continuum theory. Furthermore, we study the dynamics of solitons in inhomogeneous systems by connecting two chains with distinct parameter sets, where solitons show intriguing transmission/reflection properties at the boundary of the two chains.

SERGIO LEIVA (Presenter), CLAUDIO FALCON, ALVARO S NUNEZ, University of Chile — The interaction between phonons and an external elastic deformation within an elastic material can produce various controllable effects. It is known that these external elastic deformations endow the phononic dynamics (their wave equations) with a gauge structure similar to the one of electromagnetism, even though phonons are electrically neutral. An appropriately chosen deformation can generate an acoustic Hall effect among other experimental signals. We set out to study the elastic wave-dislocation interaction and then extend it to an interaction with a distribution of dislocations. Our formalism is based on finding an equation of motion for a wave in a medium with a static deformation in the regime in which the wave does not alter the deformation but its propagation is affected by the presence of this dislocation. With the above, we find an analogy between the Aharonov-Bohm effect and a dislocation. Our study provides a powerful tool to export topological properties to the context of elasticity and, with this, to produce more and better materials for nanoscience. The periodic case of the problem is also studied, and the new topological mechanical material arising from such periodic structure is discussed.

*Millenium Nucleus for Soft Smart Mechanical Metamaterials

MARTIN BRANDENBOURGER (Presenter), XANDER LOCSIN, CORENTIN COULAIS, University of Amsterdam — Over the last few years, there has been an explosion of activity on non-reciprocal metamaterials, namely, which transmit motion in one direction, but block it in the other. However, to date, non-reciprocal transmission has only been achieved for a limited range of frequencies and input magnitudes. Here, we introduce a novel robotic mechanical metamaterial that overcomes these limits. Each building block is a minimal robot that is able to sense the behavior of its neighbor and act consequently, which opens the way to new types of interactions. We leverage this platform to program asymmetric non-equilibrium interactions and show that the system as a whole supports first-of-their-kind unidirectionally amplified waves. As a result, the system achieves unprecedented broadband and attenuation-free unidirectional transport of mechanical energy.
Thermally-triggered tunable vibration attenuation in 3D-printed mono-material lattice metamaterials  

YANGBO LI (Presenter), SIYU CAO, YAN SHEN, China Three Gorges University — Phononic crystals, capable to tailor mechanical wave propagation and displaying omnidirectional band gaps, are vital for numerous potential applications such as wave filtering, waveguiding, acoustic cloaking, and energy harvesting. In raw materials, vibration mitigation depending on intrinsic damping feature usually cannot be adjusted easily and broad attenuation frequency ranges is still scarce in these materials. Here, we propose a novel approach and metamaterial design with the ability of thermally-triggered tunable vibration mitigation in multiple frequency ranges, which arise from the local resonance mechanism. The proposed method utilizes reversible Young's Modulus-temperature relationship of glassy polymer and non-uniformity of steady temperature field in solid structures. Through numerical simulations and low amplitude transmission testing, we demonstrate that the proposed method and metamaterials can exhibit broad and multiple omnidirectional band gaps. The finding reported here provides a new routine to design phononic metamaterial systems with tunable band gaps, offering a wide range of potential applications in harsh environmental conditions and being extended to baseline lattices with other topologies.

Electric-field-triggered instabilities in dielectric elastomer composites: application to tunable phononic crystals*  

MICHAEL JANDRON (Presenter), Naval Undersea Warfare Center, Newport, RI 02841, USA, DAVID HENANN, School of Engineering, Brown University, Providence, RI 02906, USA — Tunable phononic crystals offer promising directions for elastic wave control. When phononic crystals are composed of soft dielectric elastomers, their band-gaps may be manipulated through an applied electric field. In addition, the rich electromechanical instability landscape in these materials offers opportunities for enhanced tunability. In this work, we report on our numerical simulation capability and show how electrically triggered instabilities provide a new route to tunability in phononic crystals composed of dielectric elastomers. The result is a comprehensive view of the instability landscape in dielectric elastomer composites, the suggestion of favorable actuation arrangements, as well a general strategy for exploring enhanced band-gap tunability.

*This work is supported through the Naval Undersea Warfare Center In-house Laboratory Independent Research (ILIR) Program and Brown University School of Engineering.

Non-Abelian sound in mechanical metamaterials  

MICHEL FRUCHART (Presenter), VINCENZO VITELLI, University of Chicago — The propagation of mechanical waves in a medium is shaped by the microscopic arrangement of the oscillating elements. Here, we consider a material where the propagation of sound can be ruled by a band structure with a non-Abelian Berry connection stemming from the presence of an emerging non-crystallographic symmetry. This has dramatic consequences on the wave propagation inside an inhomogeneous medium and at interfaces.

Acoustic Bianisotropic Impedance and Hyperbolic Propagation in Metasurfaces  

LI QUAN (Presenter), Department of Electrical and Computer Engineering, The University of Texas at Austin, ANDREA ALU, Advanced Science Research Center, City University of New York — The strong analogies between electromagnetic and acoustic wave propagation have led to the discoveries of various forms of electromagnetic metamaterials and of their acoustic counterparts. However, the longitudinal properties of acoustics waves in fluid make the effective bulk modulus and effective impedance in acoustics inherently isotropic, which marks a strong difference, and a limitation of acoustic metamaterials and metasurfaces, compared to electromagnetics. Several important concepts in electromagnetics inherently require anisotropic impedance profiles, such as hyperbolic wave propagation, and therefore cannot find a direct counterpart in acoustics. Motivated by this limitation, in this talk we discuss a way to realize acoustic bianisotropy metasurfaces, relying on strong nonlocalities over the surface. Based on this approach, we introduce a design for hyperbolic acoustic metasurfaces with enhanced local density of states for sound, and inherent imaging and canalization properties. These design approaches based on strong nonlocality may also be extended to electromagnetics, offering a new path towards hyperbolic wave propagation.
1:15PM Y57.00011: Vortex Phase Singularities in Multiple Slit Interference Patterns in Chaotic Metamaterial Billiards  JORGE JOSE (Presenter), Indiana University Bloomington, NATALIA M LITCHINITSER, Electrical and Computer Engineering, Duke University — A wide range of diffractive wave interference patterns have been produced by using different planar slit configurations. In particular, situations have been recently studied having more than two slits to test the validity of the superposition principle in wave and quantum mechanics. Here we study the presence of vortex or phase singular fluctuations produced by interference patterns in chaotic billiards with a variable number of diffraction slits. We report numerical wave simulation results of integrable and non-integrable D-shape billiards, having a variable number of slit type configurations. Embedded in this D-shaped chaotic billiards we consider different combinations of positive (PIM) and negative index of refraction (NIM) materials. We compare the topological charge in the phase singularities and their correlations in the different interference pattern configurations produced. We studied closed and open billiards. We found different types of topological charge properties directly related on the geometry, the number of slits as well as the different embedded PIM and NIM configurations. The properties of the vortex pattern configurations and their correlations change dramatically as a function of the geometry of the cavity and the number of slit configurations.

1:27PM Y57.00012: Liquid crystal elastomer based mechanical metamaterials for lightweight extreme impact energy absorption*  SEUNG-YEOL JEON (Presenter), ZEYU ZHU, Mechanical Engineering, Johns Hopkins University, NICHOLAS TRAUGUTT, Mechanical Engineering, University of Colorado Denver, CRISTINA MARTIN LINARES, Mechanical Engineering, Johns Hopkins University, CHRISTOPHER YAKACKI, Mechanical Engineering, University of Colorado Denver, THAO NGUYEN, SUNG KANG, Mechanical Engineering, Johns Hopkins University — Liquid crystal elastomers (LCEs) are one of the most promising materials in the field of impact energy absorption, due to their exceptional energy dissipation behavior arising from the coupling of the relaxation dynamics of liquid crystal (LC) molecules and polymer chains. In this study, we report snapping-based metamaterials composed of LCEs for lightweight extreme impact energy absorption. We synthesized LCEs based on a two-stage thiol–acrylate reaction to program the order of LC molecules and chain alignment within beam elements. We characterized the energy absorption behaviors of the programmed LCE beams with bistability at various strain rates. We found that our LCE-based metamaterials show orders of magnitudes better specific energy absorption compared with previous works and their absorption capability is further enhanced as the strain rate increases. We could also tune the metastable energy states by controlling the strain rates. The combination of the inherent enhanced dissipation of LCEs with snapping-based architectures allows a new class of mechanical metamaterials with excellent energy absorbing capabilities.

1:39PM Y57.00013: Anisotropic Toughness and Crack Growth on Cubic SiC  FAZLE ELAHI (Presenter), MD Z HOSSAIN, University of Delaware — Molecular dynamics calculation is executed applying the Stillinger-Weber atomic interaction to explore the anisotropic properties of cubic SiC. A solid 3C-SiC with predefined edge crack is subjected to uniaxial tensile load along its crystallographic axis. Three major directions (100), (110) and (111) are studied in this work. The crack propagation path is noticeably different in three directions which in return bring variation in critical energy absorption rate. In (100) plane toughness is 70% higher than in (111) plane. The reason behind this variation is the crack propagation path through the atomic system. In (100) direction, Crack starts growing at 7% strain when the stress is 21.9 GPa. The crack face atoms rather than bonds which hinder the growth and require more energy to break. The sole criterion for growth is bond breaking which drive the crack to branch out and propagate through (110) crystallographic plane. At the point of bifurcation, the solid absorb some energy which increase the fracture toughness. However, in other two planes, (111) and (110), crack sees no obstacle and bonds are parallel to the loading direction. They require lower critical energy release rate for crack growth. So, the crack evolve through the straight path and contain lower toughness.
BRANKO BIJELJIC (Presenter), MARTIN BLUNT, QINGYANG LIN, ALI RAEINI, AHMED ALRATROUT, YOUSEF AL-KHULAIFI, AMER ALHAMMADI, YING GAO, Earth Science and Engineering, Imperial College London — Understanding of multiphase flow, transport and reaction phenomena in disordered porous media has recently been transformed by the advances in X-ray and NMR imaging, which inspired new concepts in pore-scale modeling. More accurate static and dynamic experimental description of solid and fluid(s) distributions in the pore space enabled simplifications in descriptions of spatio-temporal complexities through introduction of the intrinsic functions characterizing flow, transport and reaction in the form of distributions, rather than average values.

This concept is illustrated by the predictive modeling of flow and transport on micro-CT images of subsurface porous media validated against NMR experiments. Furthermore, a novel set of ideas used for characterising physical and chemical heterogeneity and their coupled impact on the effective reaction rates and dissolution patterns in multi-mineral porous media will be discussed.

One of the key breakthroughs was achieved by devising differential imaging tomography which provides full information of connectivity at sub-micron scale. Examples will be provided for multi-modal function description of single phase flow and transport, characterisation of initial and recovered oil from micro-porosity in steady-state two-phase flow, and determination of capillary-number dependent flow intermittency.

Furthermore, advances in in-situ characterisation of pore morphology and wettability will be presented, where a distinct pore-morphology signature is identified for unconsolidated and consolidated media. Both pore morphology and wettability have a large impact on the potential for layer flow. A distinct mixed-wet state can be identified where two fluid phases remain connected over a wide range of saturation. This state can be designed to improve oil recovery, the performance of batteries, fuel cells, catalysts, and other disordered porous materials.

11:51AM Y58.00002: Disorder-mediated wetting transitions in unstable imbibition  
AMIR PAHLAVAN (Presenter), Princeton University, LUIS CUETO-FELGUEROSO, Universidad Politécnica de Madrid, GARETH MCKINLEY, RUBEN JUANES, Massachusetts Institute of Technology — An archetypical example of pattern formation is the front instability that emerges when a less viscous fluid displaces a more viscous fluid in a Hele-Shaw cell. This instability, however, has been studied only in drainage—when the invading fluid is nonwetting. Here we show that the interplay between wettability and disorder leads to novel instability regimes. We inject a more wetting liquid into a rough Hele-Shaw cell filled with a less wetting, more viscous liquid. At low injection rates, the displacement is full across the cell gap. Above a critical injection rate, however, a wetting transition occurs and thin films of the invading liquid become entrained on the rough surfaces. This wetting transition is accompanied by a drastic change of the front instability, leading to a dendritic pattern. Our observations point to the crucial role of disorder in pattern formation during fluid-fluid displacement, and its important implications for multiphase flows in porous media.

12:03PM Y58.00003: Suppressing fingering instabilities using gradients in porous media  
NANCY B LU (Presenter), Chemical and Biological Engineering, Princeton University, JANINE NUNES, Mechanical and Aerospace Engineering, Princeton University, SUJIT DATTA, Chemical and Biological Engineering, Princeton University — Drainage, the displacement of a wetting fluid from a porous medium by an immiscible non-wetting fluid, arises in key technological problems including oil recovery, groundwater contamination, and waste CO2 sequestration. When the displacing non-wetting fluid is less viscous than the displaced fluid, Viscous Fingering occurs. By contrast, when the displacing fluid is more viscous than the displaced fluid, Capillary Fingering occurs. These two processes lead to disordered finger-like displacement pathways. For both cases, we find that a pore size gradient stabilizes the flow—the fluid flows uniformly without fingering. For Viscous Fingering, this stabilization only occurs below a threshold flow rate [1], while for Capillary Fingering, it only occurs when the gradient exceeds a static geometric criterion. Knowing these two suppression criteria provides a new way to control fingering instabilities in porous media.

Cooperative mobilization of emulsion droplets in porous media

SHIMA PARSA MOGHADDAM (Presenter), Harvard University, MOHAMAD ALI BJIARCHI, Sharif University of Technology, Iran, MARIA JIMENEZ, University of Granada, Spain, DAVID A WEITZ, Harvard University — We study the cooperative dynamics of monodisperse droplets in 2D porous media using confocal microscopy and particle tracking. The size of the droplets are of the same order of the pore sizes of the medium and are generated on demand and injected into the porous media. We measure the dynamics of the carrier fluid at pore level and track the mobilization of droplets simultaneously. We find that upon arrival or mobilization of one droplet, large pressure fluctuations emerge across neighboring pores. The pressure fluctuations result in cooperative mobilization of droplets. The behavior of emulsions within porous media is an important issue in industry and environmental studies such as water remediation.

Transport of Microgels in a Microfluidic Constrictive Channel*

SHUAIJUN LI (Presenter), JING FAN, City College of New York — The transport of soft bodies in narrow channels are remarkably common in biological systems and industrial processes. During the transport process, the soft body deforms and blocks the channel, and thus induces a pressure drop across the channel. In this work, we study the motion and deformation of microgels in a constrictive channel with a circular cross-section. Employing elasticity theory with small deformation assumption, we find the correlation among the built-up pressure, the mechanical properties of microgels, and the geometry of the channel. An approximate method is applied to estimate stress distribution at the contact surface between the deformable microgel and the channel. We then conduct experiments in constrictive micro-channels using microgels with well controlled sizes and mechanical properties to validate the effectiveness of our analysis. Compared to previous studies on microgel transport through constrictive channels, our result features an optimal balance between simplicity and accuracy. The methodology can be easily extended to various natural and engineered processes involving transport of soft bodies in narrow channels.

Fluid-solute-colloid interactions in porous media and its implications for enhanced oil recovery

SANGWOO SHIN (Presenter), University of Hawaii at Manoa — Flows of colloidal suspensions containing a variety of solutes in porous media are widely found in nature as well as artificial settings such as hydrocarbon recovery, blood flow, water purification, and coastal habitats. Such environments often exhibit spatiotemporal inhomogeneity in the solute and colloid distribution. While it is naively expected that the colloidal particles advect with the flow, non-equilibrium interactions between the fluid, solute, and the colloids may lead to unique colloidal dynamics. We present a number of scenarios in which the colloidal particles can be captured and accumulate continuously in localized regions in porous media despite the presence of strong pore flow due to the fluid-solute-colloid interactions. We link our findings to the chemical flooding process to provide useful insights into the enhanced oil recovery.

Phase change in disordered media: intermolecular forces control simultaneous evaporation and condensation

KE XU (Presenter), Massachusetts Institute of Technology, AMIR PAHLAVAN, Princeton University, RUBEN JUANES, Massachusetts Institute of Technology — We investigate phase change and fluid-fluid redistribution in porous media using micromodel experiments, in which air is injected to displace water. At late times, long after injection stops, we expect the system to arrive at a steady-state equilibrium configuration. Instead, we observe the condensation and growth of liquid droplets at the expense of the evaporation of liquid bridges. This is surprising, given that the liquid bridges are at lower pressure than the liquid droplets. We show that this counterintuitive behavior emerges from the influence of intermolecular forces on the instability of condensing thin liquid films. Our observations therefore point to a new physical mechanism for phase change in disordered media, which drives fluid organization at the pore scale, and has important implications for multiphase-flow properties at the macroscale.
this structure will be integral in robustly applying polymer solutions to groundwater remediation and EOR. We understand this switching as a dynamic coupling between single-polymer conformations and pore-scale flow. We directly observe the flow of polymer solutions in model porous media using confocal microscopy. However, we find that the flow is not purely chaotic, as is commonly assumed: it can adopt two distinct structures, which switch stochastically.

Enhanced oil recovery (EOR); in some cases, the modified flow allows the flooding fluid to sweep a greater portion of the aquifer or reservoir. This enhanced sweep is believed to be linked to unstable flow observed above a threshold flowrate.

Utilizing microfluidics, we flow a purely elastic fluid through a hexagonal array of cylindrical pillars at a range of flow speeds, where the transition to chaotic flow occurs at a critical ratio of the polymer relaxation time to flow time scale (Deborah number). We introduce finite disorder to the system – corresponding to a random perturbation of the pillars by 10% of the lattice spacing – delays the transition to Deborah number, De ~ 1, and reduces the magnitude of the chaotic velocity fluctuations. Larger disorders appear to completely suppress the transition within the tested flow range up to De ~ 5. Examination of the Lagrangian strain rate correlations reveal that disorder broadens the distribution of excitation frequencies in the system, suggesting a potential mechanism for stabilizing the elastic flow.

Disorder Suppresses Chaotic Viscoelastic Flow

Challenges associated with highly confined systems arise beyond critical flow conditions, but little is known about the implications of geometric order/disorder for this transition. 1:51PM Y58.00012: Hydrogels dehydrate liposomes: the structural fate of lipid nanoparticles in the extracellular matrix*  
SARITH BANDARA (Presenter), THOMAS MOLLEY, HOJUN KIM, PRIYALINI BHARATH, University of Illinois at Urbana-Champaign, KRISTOPHER KILIAN, University of New South Wales, CECILIA LEAL, University of Illinois at Urbana-Champaign — Drug-loaded liposomes are the most successful nanomedicine to date, with multiple FDA-approved systems for a myriad of diseases. While liposome circulation time in blood and retention in tissues have been studied in detail, the structural fate of liposomes—and nanoparticles in general—in the body has not been extensively investigated. This presentation explores the structural fate of liposomes in a synthetic hydrogel system with the aim of understanding the possible restructuring effects that liposomes experience in the natural extracellular matrix. Small angle X-ray scattering, confocal microscopy, and cryogenic transmission electron microscopy data demonstrate that poly(ethylene glycol) (PEG), gelatin, and alginate hydrogels cause 200-nm liposomes of 1,2-dioleoyl-sn-glycero-3-phosphocholine (DOPC) to transform into micrometer-sized aggregates. These aggregates are composed of multilamellar vesicles around 100 nm in diameter with a mean interlamellar separation of 5.5 nm. Protecting the liposomes with a corona of PEG damps this restructuring effect, making the multilamellar vesicles formed less stable. We attribute this unilamellar to multilamellar transition to an osmotic driving force from the hydrogel environment.

Session Y59 GSOFT: Soft Composites: Mechanics and Structure II  
BCEC 257B - Moumita Das, Rochester Institute of Technology - Tag(s): Focus

11:15AM Y59.00001: Dynamics of interacting nanoparticles in complex polymeric solutions* [Invited]  
JACINTA CONRAD (Presenter), University of Houston — The nanoscale mechanisms underlying the unusual mechanical properties of polymer nanocomposites and other soft composites remain elusive. Because nanoparticles are of comparable size to heterogeneities present in many complex fluids, their dynamics cannot be described through the framework of micro rheology but rather decouple from the bulk fluid properties. Indeed, nanoparticles diffuse many orders of magnitude faster than expected when coupled to complex fluid relaxations on similar length scales, or much more slowly than expected when physically obstructed. Interactions between the nanoparticles, arising from high particle densities and/or chemical surface modifications, can further modify their dynamics. To understand the underlying physics of transport in this size regime, we measure the dynamics of nanoparticles and polymers in solution, which are simple models of polymer nanocomposites with well-controlled and tunable heterogeneities, using x-ray photon correlation spectroscopy and neutron spin-echo spectroscopy. Electrostatic charges lead to long-range interactions between the particles in organic solvents without disrupting the structure or dynamics of the surrounding polymer solution. The long-range interparticle interactions slow nanoparticle dynamics across the interparticle distance, even though the nanoparticle dynamics are subdiffusive and coupled to the polymer relaxations. Grafted polymers help to stabilize the nanoparticles in complex fluids and lead to soft physical interactions between the grafted particles and the surrounding polymer chains that alter their transport. Our work illustrates that the particle surface chemistry sensitively modifies the transport of nanoparticles through complex media.

11:51AM Y59.00002: Deformation in polymer nanoparticle composites (PNC) at ultra high loading: interplay of jammed solids and glassy mechanics  
EMILY LIN (Presenter), ROBERT RIGGLEMAN, University of Pennsylvania — Polymer nanoparticle composites (PNC) with ultra high loading of nanoparticles (NP) (>50%) have been shown to exhibit simultaneously improved strength and stiffness without compromising, and sometimes even improving, the toughness compared to the neat systems. As a result, these composites have become an interesting class of material for a variety of applications. Furthermore, when the particle volume fraction approaches random-close-pack, these composite systems become a combination of a jammed solid (the random-close-packed NPs) filled with a glass-forming polymer in its interstices. In our study, we aim to understand the origin of these performance enhancements by examining the dynamics of both polymer and NPs during active deformation. We performed molecular dynamics simulation of coarse-grained, glass forming polymers equilibrated in the voids of a random-close-packed NP packing and subsequently applied uniaxial tensile strain to the bulk system. We examined the mechanical characteristics of the PNC systems with different polymer fill fractions at temperatures below the glass transition temperature. We also compared the NP rearrangement behavior in the presence of polymer to the neat NP systems to provide a molecular view of the toughening mechanism in these materials.
Visualization and Mechanical Study of a Transparent Filled Rubber

ZACH GAULT (Presenter), ZSOLT TERDIK, JOERG WERNER, FRANS A SPAEPEN, DAVID A WEITZ, Harvard University — Filled rubbers are composite materials containing two interpenetrating phases: crosslinked elastomers, and a ‘filler’ consisting of colloidal particle aggregates. Above a critical volume fraction, the colloidal aggregates form a system-spanning subnetwork that reinforces the elastomer network and introduces a new energy loss mechanism at low strains of only 1-5%. This loss mechanism, known as the Payne Effect, is one of the mechanical hallmarks of filled rubbers and is a major contributor to rolling friction in tires. We create a transparent model filled rubber which exhibits the mechanical hallmarks of traditional filled rubbers, but can be optically imaged. Fluorescent silica nanoparticles provide optical contrast needed to distinguish the two phases. With this system we can directly observe microstructural changes of filler particle aggregates during in situ shear deformation. We complement these observations with bulk rheological tests to gain new insight into the microscopic deformations underlying the Payne effect. By controlling filler loading and crosslink density, we can tune the microstructure of our composite to better understand the relation between its structure and mechanical properties.

Mechanical response of composite biopolymer networks in the vitreous gel in our eyes*

PANCY LWIN (Presenter), SCOTT FRANKLIN, DAVID ROSS, GEORGE THURSTON, MOUMITA DAS, Rochester Institute of Technology — The vitreous gel in the human eye is a viscoelastic composite network of stiff collagen fibers and softer hyaluronic acid (HA) polymers. Its material properties are critical to vitreous function, and ultimately to that of the eye, and depend on applied stresses, concentrations, and constituent filament stiffnesses. Although it has long been known to undergo dramatic changes with aging and disease, the key vitreous gel phase transitions and their mechanical consequences are not well understood. We mathematically model and investigate the mechanical response of the vitreous gel by modeling it as a composite network made of (i) a stiff network of collagen fibers, and (ii) a flexible polyelectrolyte network of HA. Our results relate the linear and nonlinear mechanical response of this composite network to the structure, micromechanics, and concentrations of the constituents, and may provide insights into mechanical changes associated with vitreous disorders.

In situ mechanical reinforcement of polymer hydrogels via metal-coordinated mineralization

NIELS HOLTEN-ANDERSEN (Presenter), Massachusetts Institute of Technology — Over millions of years, various types of organisms have evolved the ability to synthesize exceptionally strong and tough organic-inorganic composites through cell regulated in situ mineralization of macromolecular material scaffolds. Borrowing inspiration from such complex biomimetic material processing, we have found that metal-coordinate polymer networks can be utilized as model macromolecular scaffolds for controlled in situ hydrogel mineralization. Starting with a monodisperse metal-coordinate polymer hydrogel network, we show that metal-ion coordination crosslinks can serve as nucleation sites for mineral growth, thereby allowing significant mechanical reinforcement upon limited mineralization of the polymer hydrogel scaffold. By targeting nanoscale mineral particle growth directly at the metal-coordinate network crosslink sites, we observe simultaneous significant increases in stiffness and magnetization of the resulting hydrogels with less than 0.1% volume of minerals. We demonstrate that the method of controlling mineralization of polymer hydrogel networks through metal-coordination is general, and therefore potentially offers a broad platform for the development of new bio-inspired organic-inorganic composite materials processing systems.

Confocal Microrheology of biopolymer Hyaluronan*

JARED WELCH (Presenter), SCOTT FRANKLIN, GEORGE THURSTON, MOUMITA DAS, DAVID ROSS, Rochester Institute of Technology — Hyaluronan is a biopolymer that is found throughout the human body in connective tissue. To investigate the viscoelastic properties of this material the diffusion of carboxylate spheres in buffered solutions containing varying concentrations of 60 kDa Hyaluronan was monitored using a confocal microscope. The solutions contained a mix of D2O/H2O to match the density of the spheres. The trajectories of the spheres were analyzed using one- and two-point microrheology analysis methods. At low concentrations of hyaluronan the dynamic viscosity was extracted using the Stokes-Einstein relation. We compare these viscosities with theoretical models and use them to estimate the overlap concentration. At high concentrations, the spheres move in a way that does not correspond to normal diffusion, and the mean-squared displacement vs. lag time displays an interesting concentration-dependent inflection point. We compare results from one- and two-point particle tracking analysis.

A continuum model of the viscoelastic response of the vitreous gel
LOGAN MELICAN (Presenter), School of Mathematical Sciences, Rochester Institute of Technology, SCOTT FRANKLIN, GEORGE THURSTON, School of Physics and Astronomy, Rochester Institute of Technology, DAVID ROSS, School of Mathematical Sciences, Rochester Institute of Technology, MOUMITA DAS, School of Physics and Astronomy, Rochester Institute of Technology — The vitreous gel is a transparent, hydrated extracellular matrix filling the posterior cavity of the eye behind the lens and is surrounded by and attached to the retina. More specifically it is a composite material primarily made of a dilute network of stiff collagen fibrils and flexible polysaccharide (Hyaluronic Acid) chains within an aqueous solution. It has complex viscoelastic properties but becomes progressively fluid-like with age, leading to a number of pathologies. Here we develop a continuum mathematical model of the vitreous gel by drawing from two-fluid models of semi dilute polymer solutions. We solve a system of coupled partial differential equations for the soft and flexible networks, and the fluid via a combination of spectral and Runge-Kutta methods, and obtain the frequency dependent viscoelastic properties of the system as a function of polymer stiffness and density, and fluid viscosity. Our results will help to better understand rheological experiments on the vitreous, and provide new insights into the origin of vitreous liquefaction.

*This research is funded by the National Science Foundation via the award NSF/CBET-1604712.

Optical tweezers microrheology reveals the viscoelastic properties of entangled ring-linear DNA blends
KARTHIK REDDY PEDDIREDDY (Presenter), MEGAN LEE, RAE ROBERTSON-ANDERSON, University of San Diego — Solutions of entangled polymers display complex and intriguing viscoelastic properties that are still poorly understood. While the reptation model can describe the viscoelastic properties of entangled melts of linear polymers, the model is ill-equipped to deal with circular or ring polymers, blends of polymers of varying topologies, or solutions of polymers at concentrations near the critical entanglement concentration. DNA is an excellent model system for resolving this issue as it occurs naturally in linear and circular forms. Here, we use optical tweezers microrheology to measure the linear and nonlinear viscoelastic response of semidilute and entangled blends of circular and linear DNA. We characterize the dependence of viscoelastic properties on the ratio of circular and linear chains in the blend as well as the overall solution concentration. Our results show intriguing properties of blends compared to single-component systems including increased stiffness coupled with faster relaxation rates.

Phase behavior and morphology of multicomponent mixtures
SHENG MAO (Presenter), Princeton University, DEREK KULDINOW, Yale University, MIKKO HAATAJA, ANDREJ KOSMRLJ, Princeton University — Multicomponent systems are ubiquitous in nature and industry. While the physics of binary and ternary liquid mixtures is well-understood, the thermodynamic and kinetic properties of N-component mixtures (N>3) have remained relatively unexplored. Inspired by recent examples of intracellular phase separation, we investigate equilibrium phase behavior and morphology of N-component mixtures within the Flory-Huggins theory of regular solutions. In order to determine the number of coexisting phases and their compositions, we developed a new algorithm to construct complete phase diagrams, based on numerical convexification of the discretized free energy. Together with a Cahn-Hilliard approach for kinetics, we employ this method to study mixtures with N=4 and 5. We report on both the coarsening behavior of such systems and the resulting morphologies in 3D. The number of coexisting phases and their compositions can also be extracted with Principal Component Analysis (PCA) and K-Means algorithms. Finally, we discuss how to reverse engineer the interaction parameters and volume fractions of components in order to achieve a range of desired packing structures, such as nested "Russian dolls" and encapsulated Janus droplets.

Anisotropic self-assembly of polarizable colloidal mixtures
ZIWEI WANG (Presenter), ERIK LUIJTEN, Northwestern University — Particles with directional interactions represent promising building blocks for new functional materials and are often realized by particles with anisotropic shape or with patchy directional bonds. Here we demonstrate that binary suspensions of oppositely charged size-asymmetric colloids robustly self-assemble into a variety of anisotropic superstructures, resulting from the many-body dielectric effects which impart effective directionality to the inter-particle interactions. Via simulations, we illustrate how both local coordination number (connectivity) and fractal dimension can be well controlled through variation of the size ratio and the mismatch in relative permittivity. The mechanism we have identified offers a potential avenue to designing materials with controllable structural properties.
Beyond Bi-disperse: A study of propensity in a Kob-Andersen Quartet*
CORDELL DONOFRIO (Presenter), ERIC WEEKS, Emory University — We simulate the Kob-Andersen bidisperse glassformer system to study dynamics near the glass transition. As the name implies, the standard KA system is composed of two different sized particles. In our system we split the population of large particles into its own binary where half are increased in size and the other half decreased by the same (small) percentage. A similar binary is created for the small particles. Isoconfigurational ensemble runs are then made to understand the influence of slight “errors” in particle size. An isoconfigurational ensemble is a series of simulations, each with the same starting positions but with randomized velocities consistent with the temperature (following Widmer-Cooper et al, 2004). The “propensity” of each particle is defined as the average motion of that particle, averaged over this ensemble. While normally this is done with the exact same particles in the starting positions, having multiple variants of each particle size allows for slight changes to be made to the structure at the start of each run in the isoconfigurational ensemble. We seek to find how large of a change in structure is needed to remove propensity from the system.

Plant Inspired Soft Material Composite with Liquid Encapsulations
AMRITA KATARUKA (Presenter), Civil and Environmental Engineering, University of Illinois at Urbana Champaign, SHELBY HUTCHENS, Mechanical Science and Engineering, University of Illinois at Urbana Champaign — Plants are unique mechanical structures that combine high water content with structural elements. Unlike common soft material and liquid composites (ex: hydrogel), plants compartmentalize their water using semi-permeable membranes. We synthesize plant tissue analogs, idealized as closely packed water droplets surrounded by thin walls of PDMS, to understand their mechanical response. The analogs are created by high internal phase emulsion templating. We choose PDMS because it is highly stretchable and semipermeable yet does not swell in water. It also has a tunable modulus that allows us to capture the varied range of stiffness in flora. However, due to the high viscosity of PDMS prepolymer, adding large quantities of water to the emulsion demands very high shear force. Using microfluidics is also difficult because high pressure – required to make PDMS flow through the channels – easily ruptures device assembly. To overcome these challenges, we combine shear-mixing with centrifugation. The influence of viscosity ratio, amount of stabilizer, and fabrication specifics on droplet generation and structure are investigated. We find that with careful manipulation of the above governing parameters, the micromorphology of the composite can be designed to within plant-cell relevant ranges.

Programming shape changes in tri-stable bilayer structure*
SHICHENG HUANG (Presenter), LIN WANG, DONG WANG, XING GUO, GUANGCHAO WAN, Dartmouth College, JING FAN, Mechanical Engineering, City College of New York, ZI CHEN, Dartmouth College — The programmable shape transition in response to external stimuli has attracted increasing attention. Multi-stable structures represent a stimuli-responsive structure that features more than one stable shape and transition from one to another, appropriate for applications such as in micro-robotics. Although bi-stable structures have been extensively investigated, very few studies have been focusing on tri-stability of such structures. Here we design a partially bonded bilayer structure composed of a SMP layer and a rubber strip. When subjected to changes in temperature, this structure exhibits tri-stability and transits between hemihelical, left-handed and right handed-helical shapes. Theoretical analysis, experiments, and finite element simulations are conducted to identify the mechanism of the tri-stability and used to predict the deformed configuration given geometric and material parameters. Our work provides a facile strategy for fabricating smart reconfigurable structures for a broad range of applications in intelligent materials.

Session Y60 FPS: Iran, North Korea, and Nuclear Proliferation
BCEC 258A - Joel Primack, University of California, Santa Cruz - Tag(s): Invited, Undergraduate
11:15AM Y60.00001: 2019 Szilard Lectureship Award recipient - Scientists and Today's Struggles Against Nuclear Weapons: What Would Szilard Do? [Invited] ZIA MIAN (Presenter), Princeton University — Long standing arms control and nonproliferation arrangements intended to forestall, halt, reverse and eventually eliminate nuclear weapons programs are unraveling and prospects for near-term progress on this critical issue appear bleak. Alongside ambitious plans for modernization and further development of nuclear arsenals and production complexes, for some states the conditions for nuclear weapons use seem to be broadening rather than shrinking. One potentially hopeful development, the 2017 United Nations Treaty on the Prohibition of Nuclear Weapons, has elicited opposition rather than support from most nuclear-armed states. The turn away from restraint towards retrenchment of nuclear weapons and warfighting postures exposes some of the inherent contradictions in the project of arms control as a way to end the threat of nuclear war. This talk will look at what role scientists can play in the current conjuncture with a focus on lessons that might usefully be learned from the organizing initiatives involving Leo Szilard, a pioneer in efforts by physicists as citizen-scientists to transcend nationalism and to bring science and democracy to bear on the challenge of reducing and eliminating the risks from nuclear weapons.

11:51AM Y60.00002: Iran, North Korea, and the Renewed Challenge of Proliferation [Invited] R KEMP (Presenter), Massachusetts Institute of Technology — Nuclear weapons are now a 70-year-old technology. Since that time, progress in science and technology has made access to nuclear weapons easier for all who might seek them—yet, interestingly, there has been less nuclear proliferation in the last four decades than in the first three; and the nuclear proliferation of recent years has occurred has a different character than the proliferation seen in the first half of the nuclear age. This puzzle can be largely explained by the politics of the international system; but technology has also played an important role. Technologies have shaping the actual and perceived capabilities of states; and has provided justifications and means for circumventing different systems of control. This talk examines the cases of Iran and North Korea as archetypes for understanding how technological change might impact proliferation in the future. Particular focus will be given to the impact of the gas centrifuge, which has enabled proliferation; detection of clandestine programs; and to emerging technologies and policies that might help limit, control, or reverse proliferation.

12:27PM Y60.00003: Verification of Denuclearization [Invited] ALEXANDER GLASER (Presenter), Princeton University — A possible denuclearization of North Korea presents a historic opportunity to eliminate a nuclear weapons program. A viable process is likely to proceed in several phases and depend on verification approaches that are considered adequate and effective by all parties. Even in the best case, however, North Korea will retain an arsenal of nuclear weapons for an extended period of time, possibly for many years or even a decade, which will pose additional unique verification challenges. In particular, North Korea may initially not want to reveal the storage locations of its nuclear warheads, warhead components, and long-range missiles because this could provide a target list for an attack. This talk discusses possible concepts and required technologies that would allow monitoring a residual nuclear arsenal while addressing North Korea's security concerns and meeting the requirements of effective verification.

1:03PM Y60.00004: Can Neutrino Detectors Strengthen the Nonproliferation Regime? [Invited] RACHEL CARR (Presenter), Massachusetts Institute of Technology — For 40 years, physicists have explored the idea using neutrino detectors to monitor nuclear activities, especially reactor operations. The challenge is detecting these weakly interacting particles in detectors of reasonable size and cost in cases where their signals would add value to existing monitoring techniques. This talk surveys hypothetical neutrino use cases, including roles in verifying a nuclear test ban treaty, discovering undeclared reactors, monitoring fissile material production in known reactors, and providing information about nuclear waste products. Even with recent advances in neutrino detection, most of the applications remain strongly limited by basic physical or practical constraints. In a few cases, existing or foreseeable neutrino technology has potential to complement more conventional approaches.
1:39PM Y60.00005: Strengthening the Nonproliferation Regime*  [Invited]  FRANK VON HIPPEL (Presenter), Princeton University — In the US State Department’s 1946 Acheson-Lilienthal Report, the first official proposal for a nuclear-weapon-free world, three activities were identified as “dangerous”: uranium mining, plutonium separation and uranium enrichment. They are dual-use; they could be used to produce fuel for either nuclear reactors or nuclear weapons. The report therefore recommended that these activities be placed under ownership of an international Atomic Development Authority (ADA). The US and Soviet Union could not agree, however, on which would come first: US nuclear disarmament or verification that the Soviet Union did not have a nuclear-weapon program. Seven decades later, many countries mine uranium but only one non-nuclear-weapon state separates plutonium (Japan) and three (Brazil, Iran and Japan) have national enrichment plants while, as an alternative model, Germany, the Netherlands and the UK co-own a multinational enrichment company, URENCO, which owns the only enrichment plant in the United States. It may be too late for the ADA but perhaps it is not too late to phase out plutonium separation and national enrichment plants.

Session Y61 GSOFT FIAP: Multiphase Physics: Soft Matter Research at the Interface of Industrial and Academic Interests 8CEC 258B - Joshua Dijksman, Wageningen University & Research - Tag(s): Careers, Focus, Industrial, Undergraduate

11:15AM Y61.00001: Moisture and density measurements in powders: from geophysics to pharmacy  [Invited]  MICHEL LOUGE (Presenter), Merck Sharp & Dohme — The quality of pharmaceutical powders depends on fine control of their density and moisture content. Meanwhile, their processing requires availability of non-invasive instrumentation. We exploit recent advances in quantitative measurements of complex dielectric permittivity in hyper-arid desert sands to design capacitance instruments that can detect subtle changes in density and moisture in pharmaceutical processes and storage. We illustrate the technique with measurements of non-linear moisture diffusion through an excipient powder.

11:51AM Y61.00002: Antigravity static frictional force on the walls of confined granular columns*  PAYMAN JALALI (Presenter), School of Energy Systems, Lappeenranta University of Technology, Lappeenranta, Finland, YUCHEN ZHAO, JOSHUA SOCOLAR, ROBERT P BEHRINGER, Department of Physics, Duke University, Durham, NC, USA — We measure the static frictional force exerted by a granular material on the side wall of a vertical tube as a function of the filling height. We consider a cylindrical tube of diameter \( D \) = 5.2 cm filled to heights up to 6\( D \), which is smaller than the Janssen screening length. We use either glass beads (4 mm monodisperse spherical beads) or sand (0.5 mm polydisperse quasi-spherical particles). The grains are added in discrete steps in such a way that the top of the column remains flat, with a fixed mass per step and a fixed waiting time between steps. For sand, the vertical force on the tube remains zero up to a height of approximately 2\( D \), then increases linearly in the downward direction. Surprisingly, for glass beads the force on the container rises in the upward direction up to a turning height \( h \sim 2D \), above which it declines linearly. The variation in frictional force during a waiting period between steps becomes large for heights near \( h \). Discrete element method simulations of frictional spheres show qualitative agreement with experiments.

12:03PM Y61.00003: Particle formation in spray drying of Amorphous Solid Dispersions: a challenge for soft matter physics  PEDRO VALENTE (Presenter), Hovione FarmaCiencia S.A. — In this presentation we discuss the mathematical modeling of the various concurrent physical phenomena that a polymer solution with an Active Pharmaceutical Ingredient (API) undergo prior to forming an amorphous solid dispersion particle, such as atomization, co-solvent evaporative dynamics, propensity for phase separation and shell formation. We show a set of case studies comparing computational predictions against data from spray drying experiments. The motivation of the work is to support the development of Amorphous Solid Dispersion powders of poorly water soluble APIs in hydrophilic polymeric matrices which is a commonly used strategy to increase the solubility and dissolution rate of oral-dosage forms. However, successful development of amorphous solid dispersions for optimal performance and stability depends on both the formulation (e.g. drug load, polymer system and surfactants) and on the manufacturing technology/process conditions. Optimizing the formulation and the process requires extensive laboratory work, which is often compromised by time and cost constraints. Therefore the ability to perform virtual experiments is highly advantageous and cost-effective.
Novel stratification phenomena have recently been discovered in drying suspensions of polydisperse mixtures of particles. In this process, molecular dynamics (MD) modeling has played an important role. One challenge faced by the MD approach is how to treat the solvent in a computational model. We use large scale MD simulations to study drying suspensions of a binary mixture of large and small particles. The solvent is first modeled explicitly and then mapped to a uniform viscous medium by matching the diffusion coefficients of the particles while keeping all the interactions unchanged. “Small-on-top” stratification of the particles, with an enrichment of the smaller ones at the liquid/vapor interface during drying, is observed in both models under the same drying conditions. Using the implicit solvent model, we study the effect of the initial film thickness and show that the degree of stratification is controlled by the Péclet number defined with the initial film thickness as the characteristic length scale. When the Péclet numbers of large and small particles are much larger than 1, the degree of “small-on-top” stratification is first enhanced and then diminished as the Péclet numbers are increased.

---

Control Stratification in Drying Particle Suspensions via Temperature Gradients

*Supported by American Chemical Society Petroleum Research Fund (#56103-DNI6).

The drying of polydisperse particle suspensions has recently attracted great attention as the particles may stratify according to sizes after drying, which may lead to new fabrication methods of multilayered films. We use molecular dynamics simulations to study a drying suspension of bidisperse nanoparticles and demonstrate a strategy of controlling stratification. When the suspension is kept isothermal during fast drying, it can exhibit “small-on-top” stratification with the smaller particles accumulated in the top region of the drying film. However, when only the region near the substrate is thermalized, a negative thermal gradient develops in the suspension because of evaporative cooling. Since the associated thermophoresis is stronger for larger nanoparticles, relatively more larger nanoparticles migrate into the top region of the drying film. The net result is either diminished “small-on-top” or converted “large-on-top”. By imposing a positive thermal gradient in the drying suspension via thermalizing the vapor at a higher temperature than the solvent, we observe very strong “small-on-top” stratification. Possible experimental approaches to realize various thermal gradients are suggested.

---

Cement cohesion from the structuring of ions and water

*Supported by American Chemical Society Petroleum Research Fund (#56103-DNI6).

The solvent itself can also exhibit a great deal of structure due to confinement and strong electrostatic forces. To investigate these effects, we combine a primitive model for ions and surfaces with an explicit representation of water. We find that the presence of water proves to have a strong impact on the ordering of ions and greatly enhances the strength of attraction between two surfaces. By identifying quantitatively the link between chemistry and cohesive forces in cement, these results may open new paths for designing stronger cements, more durable and more sustainable.

---

Characterization of Multiphase Fluid Transport and Relative Permeability in Microporous Media with Low-Field NMR

Recent advances in low-field nuclear magnetic resonance (NMR) enable the studies of interfacial interactions at micro/nano scales. In this work, relative permeability for decane/water in a carbonate rock is measured with an unsteady-state method. NMR T2 relaxation time distributions of fluids help to distinguish the in-situ water/decane flow in rock while capturing transport behaviors of water displacing decane into pores at different sizes. Furthermore, the permeabilities of water and decane are predicted by the correlation between respective NMR T2 signal strength and mass, and they matches previous results achieved with the unsteady-state method. Additionally, thermal effects on fluid interactions are investigated experimentally for both water and decane. Our findings reveal the physics of multilayer flows in complicated porous media for subsurface energy applications.
Lattice Boltzmann simulations of complex flows in fibrous porous media*  
FANG WANG, ULF SCHILLER (Presenter), Clemson University — Flow phenomena in porous media are relevant in many industrial applications including filters, membranes, and biomedical implants. For instance, nonwoven membranes can be used as filtration media with tailored permeability range and controllable pore size distribution. Predicting the structure-property relations that arise from specific porous microstructures remains a challenging task, and theoretical approaches have been limited to simple geometries. Computer simulations are a cost-effective way of validating semi-empirical relations and predicting the precise relations between macroscopic transport properties and microscopic pore structure. In this contribution, we discuss lattice-based modeling approaches for multiphase flow in porous media and demonstrate their application to nonwoven fibrous membranes and coalescence filtration.

New Class of Model Porous Materials Prepared by Colloidal Self-assembly Methods  
HONGYU GUO (Presenter), China Spallation Neutron Source, Institute of High Energy Physics, CAS, YUN LIU, National Institute of Standards and Technology — Understanding the properties of complex fluids (both liquid and gas) in porous media is crucial for both fundamental science and application, especially for many industrial problems, such as water filtration, protein chromatography, reservoir capacity estimation and productivity of shale gas. Confinement, at the scale observed in many porous media, can lead to dramatic shifts in physical properties such as gas density, phase transitions, and diffusivity. With the development of many nanoscale processing techniques it has become increasingly urgent that detailed structural and phase behavior of materials be probed with the confinement length scales from 1 nm- 10 µm. For this purpose, a model porous material with well controlled pore properties (size, shape and surface chemistry) need be developed. We herein introduce a new class of model porous materials prepared by self-assembly of colloidal particles. The essential of NPs assembly is the controlling of interactions. We have used silica NPs as building blocks suspended in a lutidine/water mixture. This method can be scaled up to synthesize monolithic solid porous materials with almost any designed shape on the scale of a few millimeters to centimeters. They are glass-like solids and have enough mechanical strength.

Atmospheric Pressure Plasma - Soft Matter interactions for controlled Materials Synthesis*  
SHOMEEK MUKHOPADHYAY (Presenter), ZACHARY FISHMAN, MICHAEL LOEWENBERG, Chemical Engineering, Yale University — Atmospheric pressure plasmas are a unique system which has been recently harnessed by engineers in a large number of industrial applications like water treatment to medical applications. Obsidian Advanced Manufacturing (Yale university spinoff) has been pioneering an approach to directly print complex materials for applications like flexible electronics using the interaction of atmospheric pressure plasmas with liquid drops carrying suitable reactants. In this talk we will present some key results of the ongoing collaboration to understand and control the reaction diffusion dynamics in these complex non-equilibrium systems. The interactions of atmospheric pressure plasmas which are essentially non-equilibrium allows us to synthesize materials ( semiconductors and metals) with properties and shapes which are usually difficult using conventional techniques.

Session Y62 DCMP: Interfaces and Mixing - Non-equilibrium Transport Across the Scales  
BCEC 2S8C - Snezhana Abarzhi, Univ of Western Australia - Tag(s): Invited
11:15AM Y62.00001: First Principles Based Multiscale Atomistic Methods for Non-Equilibrium Transport Across Interfaces* [Invited] WILLIAM GODDARD (Presenter), chemistry, materials science, applied physics, california institute of technology
— This symposium is focused on Non-equilibrium transport and mixing across interfaces, with papers describing non-equilibrium coupling of transport at interfaces, including mesoscopic and macroscopic dynamics in fluids, plasmas, and other materials over scales from microns to celestial. Most such descriptions deal with the materials in terms of density and equations of state rather than specific atomistic structures and chemical processes. At interfacial boundaries, such atomistic information can be quite relevant, but it is not yet practical to couple phenomena at celestial scales with the atomistic descriptions of chemistry. The starting point for including such information is quantum mechanics (QM). But practical QM calculations are limited to 100's of atoms for 10's of picoseconds, far from the scales required to properly inform the continuum level about the atomistics. To bridge this enormous gap, we are developing practical methods to extend the scale of the atomistic simulation by several orders of magnitude while retaining QM accuracy for describing chemical processes. These developments are aimed toward including the relevant chemistry for systems with millions of atoms. We will describe the progress in accomplishing these extensions of first-principles-based atomistic simulations to larger scales while dramatically decreasing computational efforts.

11:51AM Y62.00002: Interface dynamics: New mechanisms of stabilization and destabilization and structure of flow fields* [Invited] SNEZHANA ABARZHI (Presenter), Univ of Western Australia — Interfacial mixing and transport are nonequilibrium processes coupling kinetic to macroscopic scales. They occur in fluids, plasmas, and materials over celestial events to atoms. Grasping their fundamentals can advance a broad range of disciplines in science, mathematics, and engineering. This work focuses on the long-standing classic problem of stability of a phase boundary—a fluid interface that has a mass flow across it. We briefly review the recent advances and challenges in theoretical and experimental studies, develop the general theoretical framework directly linking the microscopic interfacial transport to the macroscopic flow fields, discover the new mechanisms of interface stabilization and destabilization that have not been discussed before for both inertial and accelerated dynamics, and chart perspectives for future research.

12:27PM Y62.00003: Nanoscale view of assisted ion transport through the liquid-liquid interface* [Invited] MARK SCHLOSSMAN (Presenter), University of Illinois at Chicago — During solvent extraction, amphiphilic extractants assist the transport of metal ions across the liquid–liquid interface between an aqueous ionic solution and an organic solvent. Investigations of the role of the interface in ion transport challenge our ability to probe fast molecular processes at liquid–liquid interfaces on nanometer-length scales. Recent development of a thermal switch for solvent extraction has addressed this challenge, which has led to the characterization by X-ray surface scattering of interfacial intermediate states in the extraction process. We find that trivalent rare earth ions, Y(III) and Er(III), combine with bis(hexadecyl)phosphoric acid (DHDP) extractants to form inverted bilayer structures at the interface; these appear to be condensed phases of small ion–extractant complexes. The stability of this unconventional interfacial structure is verified by molecular dynamics simulations. The ion–extractant complexes at the interface are an intermediate state in the extraction process, characterizing the moment at which ions have been transported across the aqueous–organic interface, but have not yet been dispersed in the organic phase. In contrast, divalent Sr(II) forms an ion–extractant complex with DHDP that leaves it exposed to the water phase; this result implies that a second process that transports Sr(II) across the interface has yet to be observed. Calculations demonstrate that the budding of reverse micelles formed from interfacial Sr(II) ion–extractant complexes could transport Sr(II) across the interface. Our results suggest a connection between the observed interfacial structures and the extraction mechanism, which ultimately affects the extraction selectivity and kinetics.

1:03PM Y62.00004: Spiky Electric and Magnetic Field Structures in Flux Rope Experiments* [Invited] WALTER GEKELMAN (Presenter), SHAWN TANG, STEPHEN T VINCENA, Dept. of Physics, University of California, Los Angeles — Magnetic flux ropes are bundles of twisted magnetic fields and their associated currents. They are common on the surface of the sun (and presumably all other stars) and are observed to have a large range of sizes and lifetimes. One or more flux ropes are routinely generated in the Large Plasma Device at UCLA. The ropes are kink unstable and when they collide fully 3D magnetic reconnection occurs. The time dependent magnetic field, plasma flow, electron temperature, plasma density, and the space charge and inductive electric fields were measured at over 42,000 spatial positions throughout the plasma volume over several million rope collisions. Magnetic field lines are followed and used to derive quasi-seperatrix layers, locations where reconnection occurs. The complete data set was used to evaluate all the terms in Ohm's law, which resulted in unphysical plasma resistivity. It was then determined that in this situation Ohm's law is non-local. The resistivity was properly evaluated using the fluctuation dissipation theorem (Kubo resistivity). Time domain structures (TDS), sharp pulses in potential and magnetic field are generated during reconnection events and subsequent move from the reconnection region into the rope currents. The probability distribution function of the spike amplitudes is log-normal, the same as the fold of crumpled paper. A amplitude counting method is used to create a vector map of the magnetic field of the spikes. TDS observed by satellites are ubiquitous in the plasma surrounding the earth.

*This work is funded by DOE Office of Fusion Energy Science and the Physics division of the NSF. The work was done at the Basic Plasma Science Facility which is also funded by these agencies

1:39PM Y62.00005: Subdiffusive and superdiffusive transport in plane steady viscous flows* [Invited] MICHAEL ZAKS, Institute of Physics, Humboldt University of Berlin, ALEXANDER NEPOMNYASHCHY (Presenter), Technion - Israel Institute of Technology — Dispersion of particles in chaotic, turbulent or random flows has been studied for a long time. It is known that the action of advection on large spatial and temporal sales typically can be described as an (anisotropic) normal diffusion process. However, as found by Kraichnan in 1970, that is not the case for steady two-dimensional flows of incompressible viscous fluids. We show that the deterministic transport of particles through lattices of solid bodies or arrays of steady vortices can be anomalous. Motion along regular patterns of streamlines is typically aperiodic. Repeated slow passages near stagnation points and/or solid surfaces serve for eventual decorrelation. Singularities of passage times near the obstacles, determined by the boundary conditions, affect the character of transport anomalies. Flows past regular arrays of vorticies are subdiffusive; the temporal evolution of MSD displays some nontrivial similarity properties. Tracers advected through lattices of solid obstacles can feature superdiffusion. The particle transport in spatially irregular flows is also considered. The analytical predictions match the results of numerical simulations.

*The research was supported by Grant I-1271-303.7/2014 from the German-Israeli Foundation for Scientific Research and Development.

Friday, March 8, 2019 11:15 AM - 2:03 PM

Session Y63 GSOFT DBIO: Phase Separation in Biological Processes BCEC 259A - Daphne Klotsa, University of North Carolina at Chapel Hill - Tag(s): Focus

11:15AM Y63.00001: Protein phase separation and emergent material properties* [Invited] SHANA ELBAUM-GARFINKLE (Presenter), Advanced Science Research Center at GC/CUNY — Phase separation has emerged as a new paradigm currently revolutionizing our understanding of cell biology and intracellular organization. The assembly of biomolecules into condensed liquid phases (i.e condensates) appears to underlie the formation of membraneless organelles and other liquid compartments with roles in cell signaling, transcriptional regulation and cytoskeletal organization. Understanding the role of liquid material properties in condensate function and dysfunction requires new tools and approaches. We employ model in vitro systems and a combination of quantitative imaging and rheological tools to interrogate the nature of liquid material properties and their contribution to molecular processes and functions. We find that protein-protein and protein-RNA interactions can tune the material properties of condensates; Conversely, the viscous network of condensates can in turn modulate the molecular diffusion within droplets in a length scale dependent manner. This work provides important insight into the physicochemical rules that govern the regulation of protein/RNA liquid phases, from the cellular functions of membraneless organelles, to the potential misregulation of liquid phase separation in disease.

*NIH-NINDS
Controlling biological droplets with chemical reactions

David Zwick (Presenter), Max Planck Institute for Dynamics and Self-Organization — Phase separation has recently emerged as an important concept to understand the spatial organization of biological matter. In this talk, I will demonstrate that such biological droplets can be controlled by non-equilibrium chemical reactions that affect the droplet material. Such chemical reactions generate compositional fluxes, which control droplet sizes, counteract the effects of surface tension, and can position solid-like particles inside the droplet. I thus show that combining phase separation of proteins with post-translational modifications provides cells with a toolset to build and control compartments without membranes.

Stiffness gradients control phase separation in gels and cells

Kathryn Rosowski (Presenter), Robert Style, Tianqi Sai, Thomas Boddeker, Eric Dufresne, ETH Zurich — Living cells compartmentalize various processes using phase separation. The physical mechanisms which control this phase separation are not fully understood. However, the interior of the cell can be simply viewed as a closely packed elastic network, with well-regulated regions of lower or higher stiffness. Using droplet formation in a polymer gel as a model system, we found that phase separation can be controlled by the elasticity of the network, and that droplet size and location evolve over time under a stiffness gradient. Our findings further suggest that elasticity differences in cells may similarly regulate phase separation and could be used by cells to control droplet location.

How yeast harness 2D liquid-liquid phase separation to organize proteins and lipids in vacuole membranes

Sarah Keller (Presenter), Scott P Rayermann, Glennis E Rayermann, Alex J Merz, University of Washington — For decades, scientists have argued about how living cell membranes acquire and maintain liquid regions enriched in specific lipid and protein types. Physicists have long observed liquid-liquid demixing in artificial membranes. Clear identification of the same phase transition in a living biological membrane has heretofore been elusive. By directly imaging micron-scale membrane domains of yeast organelles both in vivo and cell-free, we show that the domains reversibly appear and disappear at a distinct miscibility transition temperature and that the domains merge quickly, consistent with fluid phases. Interesting physical phenomena underlie membrane domains. For example, domains are strongly coupled across both membrane faces (with a coupling parameter of ~0.02 kT/nm²). Similarly, liquid-liquid phase separation can occur near a critical point. Membranes behave as 2-dimensional Ising systems with conserved order parameter; and we have measured the membrane's effective critical dynamic exponent. A third example is that liquid domains coarsen. As expected, domain radius grows as time¹/³. These results have appeared in PRL (2012) and BJ (2013, 2015, and 2017) and Physics Today (2018).

Physics of non-equilibrium phase separation: Implications for stress granule formation in the cell cytoplasm

Chiu Fan Lee (Presenter), Imperial College London — Phase separation is exploited by biological cells to organize their cytoplasm. Although equilibrium phase separation is a well understood phenomenon, the cell cytoplasm is fundamentally different from a thermal system, with driven chemical reactions and directed movement being two hallmarks of its non-equilibrium nature. In this presentation, I will describe some of the universal features in non-equilibrium phase separation relevant to the cell cytoplasm. I will then discuss their implications for stress granules, which form in the cell cytoplasm when the cell is under stress.

DNA Local Flexibility Dependent Formation of Liquid-like Droplets

Anisha Shakya (Presenter), John King, Center for Soft and Living Matter, Institute for Basic Science — Associative phase separation of biomacromolecules like proteins and nucleic acids into liquid-like droplets, termed liquid-liquid phase separation (LLPS), has been linked to lipid-membrane intracellular organization as well as aggregation mediated diseases. In this work, we have studied the role of sequence-dependent DNA flexibility in LLPS of multiple interacting components. We find that DNA local flexibility, encoded by the DNA sequence, not simply the overall charge density, determines the phase behavior in such systems.

1:15PM Y63.00007: Azobenzene-doped, lipid-bilayer vesicles with light-responsive permeability: measuring mechanical response to photochemical excitation by micropipette aspiration* ARASH MANAFIRAD (Presenter), Physics, University of Massachusetts Amherst, LUCAS ANTONY, JUAN DE PABLO, Chemical Eng., University of Chicago, SANKARAN THAYUMANAVAN, University of Massachusetts Amherst, ANTHONY DINSMORE, Physics, University of Massachusetts Amherst — Inspired by the ability of cell membranes to control the permeability of selected solutes across the lipid bilayer membrane, we report on a synthetic system that switches permeability in response to light. We use experiments and simulations to study giant unilamellar lipid vesicles that contain a photoisomerizing unit (azobenzene) that channels photochemical excitation into mechanical energy within the membrane. In experiments with micropipette aspiration, we hold the vesicles at a constant tension and expose them to UV light with controlled dosage. The membrane surface area, interior volume, and stretching modulus are all measured in situ. We find a threshold molar fraction of azobenzene, below which there is no UV-stimulated response. Above that threshold, we find an extension of the aspirated projection length within seconds of exposure. Together with a prior study of glassy membranes, our experiments and simulations show the basic principles by which the injection of photochemical energy drives the membrane away from equilibrium switching membrane properties in a reversible manner. These results will allow us to mimic cell function and to design smart, responsive artificial systems.

1:27PM Y63.00008: Microfluidic Fabrication of Asymmetric Lipid Vesicles* YUTING HUANG (Presenter), Physics and Applied Physics, Harvard University, LAURA ARRIAGA, Complutense University of Madrid, DAVID A WEITZ, Physics and Applied Physics, Harvard University — Lipid vesicles are aqueous volumes surrounded by a bilayer of lipid molecules, which are amphiphilic molecules with their head groups facing water and tail groups facing oil. These vesicles are simple models that mimic cell membranes and can be used for drug delivery. One interesting type of lipid vesicle is the asymmetric vesicle, in which its bilayer is composed of two dissimilar lipid monolayers. Importantly, all eukaryotic cell membranes exhibit this type of asymmetry and asymmetry is also proposed to enhance mechanical properties of the membrane. Here, we use microfluidics to fabricate mono disperse and highly controllable asymmetric lipid vesicles, which unlike the conventional methods that often end up with highly poly disperse samples. To achieve this, asymmetric vesicles are produced using water/oil1/oil2/water emulsions in a glass capillary device, with different lipids immersed in two different volatile oil phases. Using the asymmetric vesicles, we are trying to measure how mechanical properties are affected by this asymmetry and also how to improve the degree of asymmetry in our vesicles even more. In future, we envision asymmetric lipid vesicles could open a new door in the field lipid based drug delivery systems.

1:39PM Y63.00009: Molecular dynamics of hydrophobic transport using monolayer-protected nanoparticles* MUKARRAM TAHIR, ALFREDO ALEXANDER-KATZ (Presenter), Massachusetts Institute of Technology — Proteins such as serum albumin contain apolar pockets in their three-dimensional structure that facilitate the transport of hydrophobic small molecules in biological settings. Nanoscale carriers that can similarly solubilize therapeutic compounds without requiring chemical modification have immense value as drug delivery systems. Here, we use molecular dynamics simulations to demonstrate that gold nanoparticles functionalized with alkanethiol ligands can passively encapsulate hydrophobic molecules. We focus on the encapsulation of long-chain fatty acids and study the thermodynamics and kinetics of incorporation into the nanoparticle’s surface monolayer as a function of chain length and unsaturation. We also characterize the structure of the nanoparticle and organization of the encapsulated molecules as a function of loading density and demonstrate that loaded nanoparticles release their cargo into lipid membranes upon contact with fluctuations such as lipid tail protrusions. These observations suggest the possibility of designing nanomaterials that can function as synthetic mimics of transport proteins and have applications in solubilizing apolar pharmaceutical compounds in the aqueous environment of biological systems.

*US DOE CSGF contract DE-FG02-97ER25308
Multivalent gene regulatory elements localize condensation of transcription machinery

KRISHNA SHRINIVAS (Presenter), Massachusetts Institute of Technology, BENJAMIN SABARI, Whitehead Institute, PHILLIP SHARP, Massachusetts Institute of Technology, RICHARD YOUNG, Whitehead Institute, ARUP K CHAKRABORTY, Massachusetts Institute of Technology — Enhancers are regulatory elements that cooperatively assemble the transcriptional machinery upon binding by sequence-specific transcription factors. Recently, we and others have hypothesized and demonstrated that the transcriptional apparatus forms liquid-like condensates, particularly at cell-type specific enhancer elements called super-enhancers. Many transcription factors (TFs) and coactivators phase separate \textit{in vitro}, but only at supra-physiological concentrations. A unified mechanism to describe how and why these condensates form around specific genomic loci at physiological conditions is unknown. Here, using a combination of simulation, and complementary \textit{in vitro} experiments, we propose that specific and multivalent enhancers nucleate localized condensation of TFs and coactivators at physiologic-like conditions. Using thermodynamic guiding principles, we predict key interactions that regulate condensate formation, as well as motif features encoded in DNA that drive phase separation and higher-order organization of the 3-D genome. Experiments validate our predictions, and many of these features are encoded and leveraged by mammalian genomes to assemble high amounts of transcription machinery, implicating phase separation in shaping the gene regulatory landscape.

Session Y64 DBIO DPOLY: Physics of Proteins and Nucleic Acids II: Structures, Dynamics, Interactions, and Energetics BCEC 259B - Aihua Xie, Oklahoma State Univ - Tag(s): Focus

11:15AM Y64.00001: The physical basis of computer-aided drug design: assessing and advancing the accuracy of binding affinity calculations* [Invited] MICHAEL GILSON (Presenter), University of California San Diego — Predicting the binding thermodynamics of proteins and small organic molecules is a key aim in computer-aided drug design. I will provide an introduction to this problem in physical chemistry, the statistical mechanical framework for models of binding, and computational approaches based on this framework. I will then describe some interesting and unexpected outcomes of blinded prediction challenges in this field and what they indicate about steps required to improve accuracy, notably the need for improve potential functions, also known as force fields. Finally, I'll present the approaches we are taking, in coordination with the Open Force Field Initiative, to improve the accuracy of force fields and thus speed the discovery of new medications.

*I thank the National Institutes of Health for support of this work (grants R01GM061300 and U01GM111528). These findings are solely of the authors and do not necessarily represent the views of the NIH. MKG has an equity interest in and is a co-founder of and scientific advisor of VeraChem LLC.

11:51AM Y64.00002: New strategies to predict protein-peptide interactions* [Invited] XIAOQIN ZOU (Presenter), Department of Physics and Astronomy, Dalton Cardiovascular Research Center, Department of Biochemistry, and Informatics Institute, University of Missouri - Columbia — Peptides are short polymer chains consisting of amino acids. They are flexible and often change conformations when they bind to proteins. Protein-peptide interactions play an important role in many cellular processes. In silico prediction of protein-peptide complex structure is highly desirable for mechanistic investigation of these processes and for therapeutic design. However, it is challenging to predict all-atom structures of protein-peptide complexes without any knowledge about the binding site and the bound peptide conformation, because of the large degrees of freedom involved in the system. In this talk, I will present our recent development of new strategies for predicting protein-peptide complex structures, based on the integration of information-driven modeling and physics/chemistry-based computational modeling of the interaction modes. The peptide is treated as a flexible structure during modeling, and the search space includes the whole surface of the protein. The methods have been systematically and extensively tested, and the results will be presented. The methods are computationally efficient. They can be used either as a standing-alone tool for large-scale protein-peptide docking or as an initial-stage sampling tool for protein-peptide structure refinement programs.

12:27PM Y64.00003: Effects of Small Compounds on Structure of Amyloid-β1-42 Monomer
FARBOD MAHMOUDINOBAR (Presenter), Physics, New Jersey Institute of Technology, ZHAOQIAN SU, Systems and Computational Biology, Albert Einstein College of Medicine, CRISTIANO DIAS, Physics, New Jersey Institute of Technology — Alzheimer’s disease is associated with deposits of Amyloid-β, an intrinsically disordered peptide. Molecular structure and aggregation rate of Aβ are observed to be significantly dependent on the properties of its aqueous environment. For example, NaCl is shown to accelerate Aβ fibril formation whereas 4-Aminophenol (4AP) and Inositol have been shown to reduce its aggregation rate. Despite many studies to investigate the effects of small molecules on aggregation of Aβ, its atomic interactions with small molecules that mediate various structures and behavior of this peptide are not well understood. To investigate Aβ molecular structures and to understand how Aβ properties are affected by compounds, we performed extensive Replica Exchange Molecular Dynamics (REMD) simulations on Aβ1-42 monomer with explicit solvent and small molecules. Our research reveals that each molecule affects different regions of Aβ1-42 and the peptide adopts distinguished structures compared to control system. Specifically, we observe that NaCl increases contact among residues K16-E22 and V38-I41 while 4AP increases K16-E22 and N27-G37 contacts and Inositol mainly disrupts the intrapeptide contacts. Effects of compounds on structural and physical properties of Aβ1-42 monomer will also be discussed.

12:39PM Y64.00004: Cluster-expansion theory for sequence-specific “fuzzy” interaction between a pair of intrinsically disordered proteins
ALAN AMIN, YI-HSUAN LIN (Presenter), SUMAN DAS, HUE SUN CHAN, University of Toronto — Intrinsically disordered proteins (IDPs) do not fold into a unique tertiary structure in isolation, likely because they are depleted in hydrophobic but enriched in polar, charged, and aromatic amino acids. While many IDPs become ordered upon binding to folded proteins, several IDPs have been recently discovered to retain their structural disorder when binding with each other via a so-called “fuzzy” mechanism. Just like interactions between folded proteins, such a fuzzy mechanism must be determined by the amino acid sequences of the IDPs. Here, we implement the cluster expansion method in statistical mechanics to develop an analytical theory for calculating the sequence-specific IDP-IDP binding affinity. We apply the theory to various IDP pairs selected from a set of 30 polyampholytic IDP sequences with the same amino acid composition but different charge patterns. The sequence-specific correlation between the double-chain binding affinities and single-chain conformations are systematically investigated. Our analytical theory provides a concise and powerful tool for high-throughput proteomic analysis of IDP-IDP interaction.

12:51PM Y64.00005: Conformation-Induced Conductivity Switching in Bacterial Protein Nanowires
SIBEL EBRU YALCIN (Presenter), J. PATRICK O’BRIEN, ATANU ACHARYA, YANGQI GU, PETER DAHL, SOPHIA YI, WINSTON HUYNH, SUBHAJYOTI CHAUDHURI, VICTOR BATISTA, NIHIL MALVANKAR, Yale Univ — Large-scale conformational changes in molecules are attractive because they can serve as information carriers for switches in memory and logic devices. Here we report the ability to control molecular conductivity via conformational switching at an unprecedented scale. Atomic force microscopy showed that individual Geobacter sulfurreducens protein nanowires undergo > 20 Å conformational change that propagates over their micrometer-lengths upon changing the environment. This increases the mechanical stiffness of nanowires by 4-fold and dc conductivity by 15,000-fold. Infrared nanospectroscopy revealed that this conformational change is driven by an internal structural transition. A suite of complementary experimental and computational methods such as X-ray diffraction, Raman, UV-Vis, fluorescence emission spectroscopy and circular dichroism further demonstrated this structural transition. Our studies thus establish nanoscopic approaches to visualize and quantify large-scale conformational changes in biomolecules and present novel strategies for tuning their structure and conductivity. Our work will guide the creation of a new class of programmable biomaterials with precisely controlled electronic and mechanical properties.

1:03PM Y64.00006: Computational Protein Redesign and Decoy Discrimination*  
ZHE MEI (Presenter), JOHN TREADO, ZACHARY LEVINE, COREY SHANE O'HERN, Yale Univ, LYNNE REGAN, The University of Edinburgh — A key aim of computational protein design is to understand how amino acid mutations affect the structure and stability of proteins. Recent studies have used molecular dynamics (MD) simulations to predict the response of wildtype proteins to mutations. However, MD structures can be trapped in local free energy basins, resulting in configurations that diverge significantly from experimental crystal structures. In this work, we construct a mutation dataset, which contains 32 pairs of single-core-residue mutated crystal structures and their corresponding wildtype structures. We perform replica-exchange MD (REMD) simulations on wildtype and mutant structures to obtain a series of possible protein conformations before and after the core mutations. We then perform residue repacking to determine whether the side chain conformations match those in the crystal structures. We also evaluate the local packing fraction and void geometry of the protein structures from REMD simulations to distinguish decoys from the crystal structures. The ability to distinguish experimental structures from decoys will enable unprecedented validation of MD simulations, and provide insight into novel structures that have not yet been experimentally characterized.

1:15PM Y64.00007: Weighted ensemble simulations of biomolecules: Applications to peptides and proteins*  
HIROSHI FUJISAKI (Presenter), Physics, Nippon Medical School, KEI MORITSUGU, Yokohama City University, AYORI MITSUTAKE, Physics, Meiji University, HIROMICHI SUETANI, Oita University — Weighted ensemble (WE) method is an efficient way to numerically sample rare event trajectories generated by random dynamical systems, first introduced by Huber and Kim [1] and further extended by Zuckerman and coworkers [2].

We apply this method to a small peptide called chignolin, which only has 10 amino acids but is known to have at least two stable states, a folded and misfolded states. The main focus is to study the transitions between these two states of chignolin, and to extract the kinetic properties of chignolin at high temperature [3]. While applying the WE method, we use the diffusion map (a manifold learning technique) coordinates as order parameters and compare the result with those using more chemically intuitive coordinates (hydrogen bond distances). Furthermore, we also apply the WE method to proline isomerization of PIN1 enzyme and the global conformational change of adenylate kinase.

1:27PM Y64.00008: Identifying Trimerization Mechanisms of Human Islet Amyloid Polypeptide through Molecular Simulation  
ASHLEY GUO (Presenter), JUAN DE PABLO, University of Chicago — Human islet amyloid polypeptide (hIAPP, or human amylin) is implicated in the development of type II diabetes and is known to aggregate into amyloid fibrils. Early-stage aggregates have been shown to be cytotoxic, prompting study of prefibrillar oligomeric species and their aggregation mechanisms. Here, we build upon recent work that studied formation of the hIAPP dimer, which identified a dimerization pathway and its corresponding free energy profile, by studying and comparing hIAPP trimerization mechanisms. We use atomistic molecular dynamics simulations combined with the finite-temperature string method to identify favorable pathways for trimer formation, relevant intermediate structures, and free energy changes during trimerization. Specifically, we compare and contrast two trimerization scenarios: (1) formation of a trimer from three disordered hIAPP molecules, and (2) formation of a trimer from a single disordered hIAPP molecule added to an hIAPP dimer.
1:39PM Y64.00009: Direct experimental characterization of contributions from self-motion of hydrogen and from interatomic motion of heavy atoms to protein anharmonicity  ZHUO LIU, CHENXING YANG, School of Physics and Astronomy, Shanghai Jiao Tong University, JUAN HUANG, School of Life Sciences and Biotechnology, Shanghai Jiao Tong University, JUN LI (Presenter), School of Physics and Astronomy, Shanghai Jiao Tong University — One of challenges in biophysics is to understand the connection between protein dynamics and its function. The challenge partially arises from the fact that protein present a variety of local atomic motions and collective dynamics on the same time scales, and this has rendered difficult the experimental identification and quantification of different dynamic modes. Here, taking lyophilized protein as examples, we combined the deuteration technique and the neutron scattering experiment to separate the self-motion and the collective interatomic motion of heavy atoms in proteins. We found that the self-motions of protein hydrogen atoms present a resolution-time-dependent anharmonic onset, with the onset temperature increasing when decreasing the resolution time. This can be ascribed to the thermal activation of local side-group motions, mostly the methyl rotations. In contrast, the collective dynamics of protein heavy atoms exhibit a resolution-time-independent anharmonicity around 200 K. Further dielectric spectroscopy and Brillouin light scattering results suggest that the anharmonicity of the heavy atoms results from unfreezing of the relaxation of the protein structures on the laboratory equilibrium time (100-1000 s), which softens the entire bio-macromolecules.

1:51PM Y64.00010: ABSTRACT WITHDRAWN —

2:03PM Y64.00011: Topological analysis of morphological changes of proteins due to the differences of experimental conditions of X-ray structural analysis  HARU NEGAMI (Presenter), Graduate school of engineering, The University of Tokyo — In structural biology, it is an important problem how tiny local mutation of the protein affect its global structure. To understand the mechanism, we focus on a topological method called “Fatgraph models of proteins” [1]. The model is a topological two-manifold with boundary components (surface) which have one to one correspondence with three-dimensional protein structures listed on Protein Data Bank (PDB) [2] with several exceptions. The traits of each surface for each protein are described by invariants.

Although the model enables us to grasp the global structure of each protein, it is still unclear if the method is useful for comparison between several structures because there was no research on the effect of the differences of experimental conditions on protein structure.

Here, we investigated the effect of experimental conditions of X-ray analysis and the fatgraph invariants of proteins which share identical sequences. We found that the invariants are sensitive to the differences of the conditions and proposed a method to analyse the morphological changes due to the mutation.

11:15AM Y65.00001: Interaction of spermatozoa with micro structured surfaces*  ANTON BUKATIN (Presenter), St. Petersburg Academic University, PETR DENISSENKO, VASILY KANTSLER, University of Warwick — Spermatozoa navigation plays crucial role in the process of mammalian fertilization. Mechanical interactions in the heterogenous environment of the fertility such as surface scattering and rheotaxis are the key mechanisms in determining the sperm journey towards the ovum. Here we report an experimental study of interaction mechanisms for single human sperm cells scattering off solid surface boundaries of different curvature. The investigation is based on measuring the trajectories of the cells near curved surfaces of cylindrical pillars with diameters 50 – 500 um in a microfluidic device. By analysing several thousands of cells trajectories we built the scattering functions of interaction process. The results reveal the dependence of the scattering functions on the pillar size. We deduce that for the smaller pillars, 50 – 200 um in diameter, the scattering is primarily determined by the steric interactions, while the hydrodynamics starts playing a role for the larger pillar sizes. The results of the spermatozoa scattering dynamics can be used in designing new types of microfluidic devices for rapid selection of motile cells in-vitro.

11:27AM Y65.00002: Measured effect of boundary distance on flagellar motor torque*  BRUCE RODENBORN (Presenter), MACKENZIE CONKLING, CESAR ROMERO, PHILIP LOCKETT, Centre College — Darnton et al. (2007) used resistive force theory to derive experimental measurements of the torque generated by bacterial motors in free swimming *Escherichia coli*. Recent reports have found similar torque values using both boundary element methods and slender body theory to model flagella swimming near a boundary (Das et al. 2018). Such numerical methods have also been used to model constrained bacteria swimming near a boundary, where their flagella act as micropumps (Dauparas et al., 2018). We use scaled macroscopic experiments to directly measure the torque on constrained, pumping flagella as a function of boundary distance. The helical flagella have a diameter ≈12 mm and are immersed in a fluid with viscosity 10^5 times that of water to ensure the Reynolds number in the experiments is much less than unity, just as in the bacterial experiments. We compare our nondimensionalized values to the numerical data and find good agreement, particularly in the dependence of motor torque on boundary distance. We also report a similar functional dependence of propulsive force measurements as a function of boundary distance.

11:39AM Y65.00003: Bacteria push the limits of sensory precision to navigate dynamic chemical gradients*  DOUGLAS BRUMLEY (Presenter), University of Melbourne, FRANCESCO CARRARA, ETH Zurich, ANDREW HEIN, University of California, Santa Cruz, YUTAKA YAWATA, University of Tsukuba, SIMON LEVIN, Princeton University, ROMAN STOCKER, ETH Zurich — The limited precision of sensory organs places fundamental constraints on organismal performance. An open question, however, is whether organisms are routinely pushed to these limits, and how limits might influence interactions between populations of organisms and their environment. By combining a method to generate dynamic, replicable resource landscapes, high-speed tracking of freely moving bacteria, a new mathematical theory, and agent-based simulations, we show that sensory noise ultimately limits when and where bacteria can detect and climb chemical gradients. Our results suggest the typical chemical landscapes bacteria inhabit are dominated by noise that masks shallow gradients, and that the spatiotemporal dynamics of bacterial aggregations can be predicted by mapping the region where gradient signal rises above noise.

11:51AM Y65.00004: A theory of searching for a target with partial information  GAUTAM REDDY (Presenter), MASSIMO VERGASSOLA, University of California, San Diego — Animals often need to find and navigate to distant targets, such as food, mates or prey, using partial information about their location. Search algorithms that deal with such scenarios have been proposed, but there is no theoretical framework that offers a standard baseline to compare the search efficiency of different algorithms. In this work, we propose a general theoretical framework to describe the task of a decision-making agent searching for a distant target emitting noisy cues. Within this framework, we define a notion of an `asymptotically optimal' search algorithm and show how its performance produces a lower bound to the expected cost of any other algorithm. We demonstrate how the optimal decision boundaries and the corresponding PDFs of search times can be computed in a simplified one-dimensional search task, and compare them to those of a previously proposed `Infotaxis' algorithm. Generic features of searching in higher dimensions are discussed.

12:03PM Y65.00005: Cell decision making at a microfluidic fork  VAMSI SPANDAN (Presenter), CHON U. CHAN, L MAHADEVAN, Harvard University — Many cell types, such as white blood cells, undergo directed migration during wound healing, development and immune response. A simple paradigm for this is related to the aphorism attributed to Yogi Berra "When you come to a fork, take it" - so that one can ask what happens when an active cell comes to a junction in a vasculature? Since the paths may have different mechanical resistance and/or chemokine concentrations, how does the cell respond by integrating multiple signals across different spatial-temporal scales and reject transient noise? We use a combination of numerical simulations and microfluidic experiments to understand the mechanochemistry of cellular decision-making at a confined bifurcation junction. The cell is modelled as a deformable, active acto-myosin cortex surrounding a fluid volume, with active stresses which are a function of the local hydrodynamic and chemical cues. We show how the system shows a range of phenomena reminiscent of critical slowing down, and noise-induced tipping, and compare the results with experiments on single cells moving through a confined microfluidic fork.
12:15PM Y65.00006: Variance Adaptation in Navigational Decision Making*  
JASON WOLK (Presenter), RUBEN GEPNER, DIGVIJAY S WADEKAR, SOPHIE DVALI, MARC H GERSHOW, New York University — Sensory systems relay information about the world to the brain, which enacts behaviors through motor outputs. To maximize information transmission, sensory systems discard redundant information through adaptation to the statistics of the environment. The behavioral consequences of sensory adaptation to environmental variance have been largely unexplored. We study how larval Drosophila adapt sensory-motor computations underlying navigation to changes in the variance of visual and olfactory inputs. We show that variance adaptation can be characterized by rescaling of the sensory input and that for both visual and olfactory inputs, the temporal dynamics of adaptation are consistent with optimal variance estimation. In multisensory contexts, larvae adapt independently to variance in each sense, and portions of the navigational pathway encoding mixed odor and light signals are also capable of variance adaptation. Our results suggest multiplication as a mechanism for odor-light integration.

NSF 1455015

12:27PM Y65.00007: Individual and Automatic Training and Assay of Learned Navigational Behaviors in Drosophila larva*  
AMANDA LESAR (Presenter), JAVAN MF TAHIR, MARC H GERSHOW, New York University — Previous studies of olfactory learning in Drosophila larva show larva can learn through classical conditioning. While behavioral responses of trained larva have been studied, neural responses of freely moving, trained larva are unexplored. Previous training experiments present larva population with an odor and reinforcer in a small number of training trials, then allow larvae to make a decision in the presence of odor without reinforcer once. We develop a chamber which involves rigorous training and testing. The Y maze training chamber allows larva to make a decision, turn around, and go back to Y intersection to quickly make another decision, allowing us to study large number of decisions in short times in individual larva. We will study neural responses of trained versus untrained larva, while larva is making decisions, which can help us to connect stimulus, behavioral responses, and neural activity. We will present initial results for olfactory training of individual larva.

*NSF Award 1455015, NIH Award 1DP2EB022359

12:39PM Y65.00008: Internal bias vs. external sensory cues: the role of "handedness" in navigation decisions of invertebrate model systems  
MASON KLEIN (Presenter), ANGGIE FERRER, ROWANNE ALI, JOSHUA FORER, JOSEPH SHOMAR, Physics, University of Miami, KYOBI SKUTT-KAKARIA, ZACHARY WERKOVEN, BENJAMIN DE BIVORT, Organismic and Evolutionary Biology, Harvard University — How do the internal properties of individual animals combine with external environmental stimuli to produce a physical output? Answering this is important for understanding how the brain functions, and we examine the question using simple invertebrate animals, the Drosophila larva and C. elegans. Both animals have well-mapped brain circuits and limited behavioral repertoires, and exhibit exploratory behavior as they search for food, while at the same time responding to external stimuli. We focus on one specific internal property, the tendency of an animal to turn leftward or rightward (“handedness”). We find statistically significant bias in individual turning and drifting directions, but that turn and drift handedness are uncorrelated. This lack of correlation explains why even strongly left- or right-turning crawlers on average have similar diffusion rates as unbiased turners. Both handedness types are also weakly persistent, with frequent shifts to new biases.

We show that the internal bias (handedness) strongly affects, and in fact dominates, individual turning decisions in the presence of a temperature gradient, suggesting that inherent traits of individuals must be considered to achieve a more complete understanding of navigation and brain processing.
1:27PM Y65.00012: Motility Characteristics of Maze Navigating Fibroblasts

N. G. HALLFORS, Z. HUSAIN, KUST, J. TEO, NYU, G. ALHUSEIN, D. RUTA, A. F. ISAKOVIC (Presenter), KUST — Micropatterned substrates, in the form of mazes, are utilized to study cell migration. Highly motile cells such as fibroblasts rely on complex combination of forces exerted by the surrounding environment and neighboring cells to achieve motion. Substrate stiffness and topology of the patterned maze, together with the cell-cell neighbor interaction are shown to enhance or inhibit cells' self-propulsive behavior. Fluorescence imaging was used to quantify kinematics of the contractile motion of fibroblasts. It is shown that the density of cell population is a critical variable, and that, for sufficiently high densities, cells appear to self-organize into groups that move around (that is “solve the maze”) in qualitatively different manner we termed “rule following” and “cheating”. The motility analysis shows that Hurst exponent of cell dynamics shows a spread of values, indicating that only a fraction of cells follows near-diffusive dynamics, with other, non-diffusive modes of motion being clearly present as well. Similarly, the motility index and chemotactic index analysis show qualitatively more than one mode of cells.

We acknowledge support from Cornell CNF (NSF) and BNL CFN (US DoE).

Development of flow-less linear gradient microfluidic devices

DRAGOS AMARIE (Presenter), ARTURO RUBEN DIAZ, ILEENE ASHLEY DIAZ, Physics and Astronomy, Georgia Southern University, DWAYNE G. STUPACK, Moores Cancer Center, University of California San Diego — Our previous work showed that by splitting and recombining the input flows through a combination of bifurcated and trifurcated channels one can generate a linear chemical gradient across a microfluidics chamber. However, when such devices are meant to study cell migration one must consider that physical factors of the microenvironment have influences in regulating cell fate. Such biomechanical cues have gained significant attention in recent years for their roles in defining fundamental cell properties, including motility, chemotaxis and migration. One such factor is the mechanical stress introduced by the flow in the gradient chamber that induces shear stress thus impacting the migration patterns. In this work we present a microfluidics device that generates highly linear chemical gradients into a cell culture chamber that is separated, flow-wise, from the gradient chamber and any investigated live cells will not experience any confounding fluid flows. The slope and the offset of the gradient can be manipulated with respect to experimental needs to enhance migration.

Session Y66 DBIO: Physics of Microbes II BCEC 261 - Katherine Copenhagen, Princeton University

11:15AM Y66.00001: Geometric localization of cell wall growth and shape determining proteins in *Helicobacter pylori*

BENJAMIN P BRATTON (Presenter), Princeton University, JENNIFER A TAYLOR, NINA R SALAMA, Fred Hutchinson Cancer Research Center, JOSHUA SHAEVITZ, Princeton University — The bacterial kingdom exhibits a wide variety of cell shapes. Our computational imaging framework allows us to extract 3D shapes of individual bacterial cells from fluorescence microscopy images. From these shapes we calculate geometric parameters such as local curvature, surface area, and the enrichment of fluorescent signals. The helical-rod shape of *Helicobacter pylori*, a human stomach pathogen, is important for its pathogenesis and is an ideal model system for studying complex bacterial cell shapes. In *H. pylori*, we have been investigating the geometric localization of the proteins and metabolic probes of cell wall growth. To propagate its helical shape, a cell must grow its longer, outer helical axis more than its inner one. Fluorescent, metabolic probes incorporated into the cell wall show enrichment of growth at both the outer and inner axes. Consistent with these labels, two of the proteins associated with cell wall homeostasis show geometric localization. MreB is enriched at regions of small and negative Gaussian curvature and CcmA is enriched at Gaussians curvatures of about 5 μm\(^{-2}\), similar to the curvature of the outer axis. These data are consistent with a model of helical-rod like growth that takes the simple rod and elaborates it by defining a outer helical axis.

11:27AM Y66.00002: Mechanical Forces to Trigger Morphological Changes in Motile Bacteria

RAVI CHAWLA (Presenter), RACHIT GUPTA, KATIE FORD, PUSHKAR LELE, Texas A&M University — Bacterial swarming is an important mechanism for flagellated bacteria to effectively cover large distances on soft surfaces, such as tissues. Swarming is likely initiated when the flagella sense higher viscous loads such as those experienced near solid boundaries. However, the underlying assumption that soft and porous surfaces cause significantly high loads on the flagella remains untested. Here, we developed an approach to estimate the hydrodynamic drag as a function of separation from soft interfaces. In one type of testing, optical trapping experiments were employed to estimate the diffusivities of tiny objects close to soft interfaces, using a novel flow-geometry. The method was validated by comparing results for transverse diffusion coefficients for single spherical particles near a no-slip solid boundary with predictions from Faxen's law. The data were in good agreement with published models. In a second type of testing, the surface-induced load on the flagellar motor was interpreted from the rates of swarming in two different strains that developed differential hydrodynamic thrust. These results are anticipated to help estimate the magnitude of mechanical forces necessary to initiate the transition of a bacterial cell to the swarmer state.

*NIH R01 Award (NIGMS), TEES
11:39AM Y66.00003: Bacterial Motors and Surface Sensing*  
PUSHKAR LELE (Presenter), Texas A&M University — Surface-sensing precedes the establishment of many types of bacterial colonies on surfaces. Evidence suggests that surface-sensing triggers transcriptional regulation as well as post-translational signaling that promote a variety of interesting cell phenotypes. The molecular mechanisms continue to remain unclear. I will discuss how motile cells discriminate between random forces arising due to Brownian motion and those arising due to surface contact. Our recent measurements that highlight the role of the flagella (otherwise known to be involved in motility) in surface-sensing and signaling will be discussed. Single molecule experiments that explain how flagella tune the sensitivities of modules involved in well-known signaling pathways will be presented. Data indicate an indirect link between the intracellular events and the external hydrodynamic drag acting on individual flagellum, and also hint at the regulation of certain surface-dependent phenotypes by these sensitive modules. I will conclude with a brief note on how mechanically-stimulated regulatory events influence a host of important processes such as bacterial competence, which regulates the uptake of extracellular DNA.

*R01GM123085

11:51AM Y66.00004: Determining the Metabolic Activity and Flow Boundary Conditions of Bacteria from Diffusion Measurements*  
LEVENT ASLANBAS (Presenter), AHMET C KIRLIOGLU, VURAL KARA, KAMIL EKINCI, Mechanical Engineering, Boston University — When live bacteria are adhered onto a microcantilever, the nanomechanical displacements of the microcantilever increase noticeably, suggesting that bacteria fluctuations drive the microcantilever to a higher amplitude than thermal fluctuations. Here, we have performed similar measurements by adhering various bacteria onto the surface of 8-μm-diameter microbeads. After bacteria adhesion, we image the Brownian motion of these single microbeads suspended in liquid by high-resolution optical microscopy. We then calculate the mean square displacements and diffusion constants from the trajectories of the microbeads. Interestingly, microbeads with non-motile bacteria show an unexpected diffusion profile: in a given interval, microbeads with dead bacteria on them tend to diffuse farther compared to those with live bacteria. We will discuss possible sources of this unexpected behavior, including modifications to the no-slip boundary condition on the surface of bacteria.

*We acknowledge support from NIH (R03AI126168).

RENATA GARCES (Presenter), University of Gottingen, SAMANTHA MILLER, The Institute of Medical Sciences, The University of Aberdeen, CHRISTOPH F. SCHMIDT, Department of Physics, Duke University — The ability to maintain a positive turgor pressure, by means of higher osmolarity of the cell interior than the exterior, is a requirement for proper metabolism in walled microbial cells. Turgor pressure is sensitive to changes in external osmotic conditions, and is drastically increased upon osmotic downshock, together with cell volume. Bacteria prevent lysis caused by excessive osmotic pressure through mechanosensitive (MS) channels: membrane proteins that release solutes (ions) in response to mechanical stress. The exact mechanism of channel gating in the natural setting, however, has been elusive due to the lack of experimental methods appropriate for the small dimensions of prokaryotes. We here present experimental data on the gating of MS channels of E. coli subjected to compressive force under iso-osmotic conditions. We indent living cells with micron-sized beads attached to the cantilever of an atomic force microscope (AFM) and characterize the mechanical response. We show that turgor pressure can be monitored through the measured response and quantify its value and fluctuations for individual single cells before and after MS channel gating.

12:15PM Y66.00006: Theoretical investigation of stochastic clearance of bacteria*  
HAMID TEIMOURI (Presenter), ANATOLY BORIS KOLOMEISKY, Chemistry, Rice University — Understanding mechanisms of bacterial eradication is critically important for overcoming the failures of antibiotic treatments. Current studies suggest that the clearance of large bacterial populations proceeds deterministically, while for smaller populations the stochastic effects become more relevant. We developed a theoretical approach to investigate the bacterial population dynamics under the effect of antibiotic drugs using a method of first-passage processes. It allows us to explicitly evaluate the most relevant characteristics of the bacterial clearance dynamics such as extinction probabilities and extinction times. In addition, we investigate the effect of fluctuations in the population growth rates on dynamics of bacterial eradication. It is found that fluctuations for some range of parameters increase the extinction probability and the extinction times, indicating slowing the bacterial clearance. We speculate that this might be a first step in developing of antibiotic resistance.

Mechanotransduction in bacteria: how *Pseudomonas aeruginosa* actively probes and responds to substrate mechanics  MATTHIAS D KOCH (Presenter), ZEMER GITAI, JOSHUA SHAEVITZ, Princeton University — A growing body of evidence suggests that bacteria respond to mechanical cues such as shear flow or surface material properties, yet clear evidence that such mechanical features of the environment are integrated in a cell’s active decision making is lacking. Here, we demonstrate that the pathogen *Pseudomonas aeruginosa* employs arm-like, retractable appendages called pili to actively deform a substrate and probe its mechanical properties. We use a transcriptional fluorescence reporter to show that *Pseudomonas* tunes the expression of virulence factors based on substrate stiffness in the range of 0.1 – 1000 kPa. Using optical tweezers, traction force microscopy, and molecular modeling of the active motor components, we probe the mechanism of pilus-based mechanosensation. These results provide unique insights into the molecular functioning and control of pilus extension and retraction and how this is linked to twitching motility. We find evidence of an active bacterial mechanotransduction pathway that connects substrate mechanical properties to a genetic response via active surface deformation, similar to the mechanogenetic regulation found in stem cell differentiation.

Strength and longevity of non-genetic memory in sister bacterial cells.  HARSH VASHISTHA (Presenter), MARYAM KOHRAM, HANNA SALMAN, University of Pittsburgh — Phenotypic heterogeneity is a vital aspect of isogenic bacterial population related to the survival of the species. The focus of this study is to understand the origin of non-genetic phenotypic heterogeneity by observing the inheritance pattern of different cellular traits in the lineage of single bacterial cells using microfluidics and time-lapse microscopy. We aim to reveal the cellular factors responsible for this variability and estimate the timescale over which new phenotypes emerge. We have developed a unique microfluidic device that allows us to trap and follow E. coli sister cells for hundreds of generations in the same environment, and thus separating cellular effects from environmental ones. Our results reveal strong correlation of several measurable properties like cell size, cell-cycle duration and growth rate between E. coli sister cells for many generations while non-related cells growing in the same environment show almost zero correlation over the same period. These results allow us to quantitatively determine the strength and longevity of non-genetic memory in sister bacterial cells.

Mechanics and dynamics of filaments on curved membranes  FELIX WONG (Presenter), ETHAN GARNER, ARIEL AMIR, Harvard University — Protein filaments that bind to curved membranes exhibit rich behavior, as shown in previous studies of bacterial morphogenesis. Here we model the direct binding of protein filaments to membranes and show that it is typically energetically favorable for filaments to orient along the direction of largest curvature. We then model the dynamics of an ensemble of filaments, each translocating along the direction of largest curvature and subject to noise. We show that their macroscopic properties, such as localization, can vary significantly depending on membrane geometry. Finally, we discuss the implications of our study to bacterial morphogenesis and regulation of bacterial rod shape. Our work shows, from a physical perspective, how cellular-scale dynamics which dictates growth may arise from nanometer-scale properties.

Modes of Bacterial Aging and Death  MARYAM KOHRAM (Presenter), HARSH VASHISTHA, ZOLTAN NAGY OLTVAI, HANNA SALMAN, University of Pittsburgh — Currently, “biological aging” is well defined in human beings and multicellular organisms, and is one of the largest risk factors for most diseases. However, in single cell organisms there has been a sequence of various definitions. My research focuses on understanding the cellular processes responsible for senescence and death in *E. coli* bacteria as well as identifying cellular characteristics of aging. We employed an experimental setup consisting of a microfluidic device designed to trap single-cells while continuously supplying them with nutrients, allowing us to acquire images of the trapped cells. Analysis of these images provides long-term single-cell measurements of cell-size and protein content, which are then used to uncover aging effects and determine modes of cell death. Our data acquired thus far reveal two different phenotypes of cell death: 1. Part of the cells maintain their bacterial chromosome and enter a non-dividing phase. 2. A subset of the population loses its chromosome and so all cellular functions are obstructed. Our results indicate aging in all strains, which is marked by the increase in death rate with time. In addition, by comparing wild type and an ATP synthase *E. coli* mutant, we found different average lifetimes prior to undergoing these transitions.
**1:15PM Y66.00011: Rolling motion of uni-flagellated bacteria near a solid surface**  
GEORGE BARBOSA ARAUJO (Presenter), ZHAOYI ZHENG, JAY TANG, Brown University — Bacterial interaction with surfaces is ubiquitous in nature and is essential to many biological processes such as infection and biofilm formation. Here we study the tethering of uni-flagellated *Caulobacter crescentus* to a solid surface. In particular, we focus on weak reversible adhesion, which allows subsequent detachment. By applying an electrical field parallel to the surface, we observe that some initially tethered bacteria detach from the surface, but remain close to it. The detached cells perform rolling motion, a mixture of translation and rotation, different from the almost exclusive translation observed for nonmotile bacteria or swimming cells that are not previously attached. Our analysis of the rolling motion accounts for electrophoretic force, flagellar rotation, and the cell’s close proximity to the solid surface.

**1:27PM Y66.00012: E. coli in Mazes**  
TRUNG PHAN (Presenter), ROBERT AUSTIN, Princeton University, RYAN MORRIS, University of Edinburgh, MATTHEW BLACK, Princeton University, JULIA BOS, Pasteur Institute — Bacteria often live in topologically complex environments. The path from a colony of bacteria which has exhausted its local supply of food to a source can have many branch points with false, dead-end leads. While chemotaxis can easily navigate bacteria to a food source in the presence of a food gradient, in a sufficiently complex and large maze chemotaxis will fail, leading to bacterial collapse at dead ends. Here, using nano and microfabrication, we made physical puzzles to study the collective behaviors of *E. coli* bacteria. We constructed mazes for bacteria to solve in order to get food and probed for their searching algorithms, with and without the presence of hydro flows.

**1:39PM Y66.00013: High Throughput 3D Tracking of Bacterial Chemotaxis in Complex Environments**  
MARIANNE GROGNOT (Presenter), KATJA M. TAUTE, Rowland Institute at Harvard — Bacterial chemotaxis is an important survival mechanism by which motile bacteria bias their random walk trajectory to navigate chemical gradients. While chemotaxis has been studied extensively in *E. coli*, much less attention has been devoted to the diversity of bacteria with different flagellar architectures, or to motility in viscous or porous environments that more closely mimic the complexity of natural habitats. Current approaches for characterizing and comparing chemotaxis strategies are hampered by being either limited to the population scale, qualitative, low throughput, 2D, and/or dependent on theoretical models.

Here we present a simple yet powerful chemotaxis assay combining a recent high-throughput 3D tracking method with microfluidically created chemical gradients. With a typical throughput of above 3,000 individual trajectories in 5 minutes, we demonstrate that we can directly determine chemotactic drift velocities in diverse environments while simultaneously resolving 3D motility behavior, enabling unprecedented access to a mechanistic understanding and quantitative comparison of chemotactic strategies. We highlight the power of our assay by revealing the role of lateral flagella in the opportunistic pathogen *V. alginolyticus* for motility and chemotaxis in hydrogels.

**1:51PM Y66.00014: Bacterial Scattering from Convex Surfaces and its Effects on Motility and Chemotaxis**  
KENTARO HOEGER (Presenter), TRISTAN URSELL, University of Oregon — For many organisms across length scales, self-propulsion is a key mechanism for survival and nutrient acquisition in changing environments. The model microorganism *Escherichia coli* explores low Reynolds number environments executing ‘run-and-tumble’ chemotaxis in its search for resources. While many studies of chemotaxis and motility take place in open environments, typical real-world environments – like soils, sediments, or the mammalian gut – have physical structure across multiple length-scales which can alter or impede cellular trajectories. To understand how physical structure in the environment alters trajectories and attendant persistence lengths, we built microfluidic devices containing arrays of microscopic circular pillars and studied bacterial interactions with these structures through the lens of probabilistic scattering functions. We find that attractive interactions with the pillars and stochastic noise produce a complex set of probability distributions that characterize bacterial motion in structured environments. Thus, understanding how cells navigate chemical gradients and acquire resources in such complex environments is crucial to our understanding of microbial ecology and may enable design of devices for controlling bacterial motility.

Run-and-tumble motility enables equatorial magnetoaerotaxis

NICOLAS WAISBORD, MICHAEL STEHNACH (Presenter), Tufts University, CHRISTOPHER T LEFEVRE, CEA Cadarache/ CNRS/ Aix-Marseille Université, JEFFREY GUASTO, Tufts University — Guided by Earth’s magnetic field, magnetotactic bacteria (MTB) seek out microoxic environments in the sediments of swamps, lakes, and oceans for survival. To accomplish this, MTB synthesize magnetic nanoparticles that mechanically orient the cells along Earth’s magnetic field, which is mostly parallel to the water column over a broad range of latitudes. In the current paradigm, magnetotaxis provides a global orientation for the cells and facilitates a one-dimensional aerotactic search along naturally occurring, parallel oxygen gradients through ‘run-and-reverse’ motility. However, a variety of MTB species thrive at the equator, in spite of the orthogonal magnetic field and oxygen gradients. Using a microfluidic device and Helmholtz coil, we independently control an oxygen gradient and an orthogonal magnetic field, enabling precise measurements of MTB motility under equatorial conditions. In contrast to the current paradigm, we show that *Magnetococcus marinus* (MC-1) achieves ‘run-and-tumble’ motility, which facilitates exploration and aerotaxis perpendicular to the magnetic field. These results establish a new survival mechanism for equatorial magnetoaerotaxis in bacteria.
