12:03PM B61.00005: Driving Frustrated Lattices of Active Droplets*  ANTON MOLINA (Presenter), Stanford University, STEFAN KARPITSCHKA, Dynamics and Self-Organization, Max Planck Institute, MANU PRAKASH, Stanford University — Self-organization is the process by which interacting building blocks arrange themselves into an ordered structure. While there are many examples of self organization, there are no examples which explore the use of external fields to drive self-organizing particles in a geometrically frustrated environment. Here, we explore frustrated self-organization in a novel system comprised of self-propelled droplets. Ensembles of these droplets interact with one another, via a vapor-mediated and long-ranged potential, displaying dynamic behavior that resembles chemotaxis. We present an experiment that confines droplets to hexagonal lattice sites, using gravity to drive the system away from equilibrium. Hence, we study the relationship between single particle dynamics and the statistics of ensemble organization. In this geometrically frustrated environment we observe a phase transition of droplet self-assembly as a function of the driving from equilibrium. Comparison to simulation allows us to connect our experimental results to statistically relevant distributions, thereby connecting observations of single particle dynamics and local accommodation of frustration to statistical physics.

12:15PM B61.00006: Self-assembly of nanoscale braided structures  EDVIN MEMET (Presenter), MOHAMMAD SHAHJAMALI, CHENG ZENG, ISAAC BRUSS, VINOTHAN N MANOHARAN, LAKSHMINARAYANAN MAHADEVAN, Harvard University — Capillarity, along with bending and cohesive forces, can induce assembly of nanopillar/micropillar arrays into a wide variety of structures. Experiments we performed involving seven hexagonally arranged pillars reveal a surprising transition from straight to twisted conformations. Separately, we also found that large arrays (e.g. 30x30, 10x40) of high-aspect ratio pillars can assemble into various structures, including chiral, globally twisted morphologies. Here we use numerical and scaling methods to understand how the rate of drying, capillarity, bending, and cohesion control the physics of elastocapillary-driven self-assembly.

12:27PM B61.00007: Simulations on encapsulation of multiple cargoes in bacterial microcompartments*  LEV TSIDILKOVSKI (Presenter), FARZANEH MOHAJERANI, MICHAEL F HAGAN, Brandeis University — Bacterial microcompartments are self-assembling protein shells that encapsulate enzymes or other proteins, similar to eukaryotic organelles. Bacteria use them to sequester toxic intermediates from the cytoplasm, or to accelerate the rates of chemical reactions through co-localization of reagents. In this talk I will describe coarse-grained computational models that allow Brownian dynamics simulations of self-assembly of microcompartments around multiple cargo species (e.g. enzymes). Based on these simulations, we have identified multiple factors that control encapsulation. In particular, the simulations show that the relative interaction strengths among the different cargo species play a key role in determining the amount and spatial organization of each species, as well as the nature of assembly pathways. I will also describe the effects of other control parameters (e.g. interactions between cargo and shell), thus providing a basis for utilizing bacterial microcompartments as customizable nanoreactors.

12:39PM B61.00008: Driven Widom-Rowlinson lattice gas

RONALD DICKMAN (Presenter), Physics, UFMG, ROYCE ZIA, Physics, Virginia Tech. — In the Widom-Rowlinson lattice gas, two particle species (A, B) diffuse freely via particle-hole exchange, subject to both on-site exclusion and prohibition of A-B nearest-neighbor pairs. As an athermal system, the overall densities are the only control parameters. As the density increases, a phase transition occurs, leading to ordered states with A- and B-rich domains separated by hole-rich interfaces. Using Monte Carlo simulations, we analyze the effect of imposing a drive on this system, biasing particle moves along one direction. Novel features emerge, including structure factors with kink singularities (best fitted to $|q|$), maxima at non-vanishing wavevector values, oscillating correlation functions, and ordering into multiple striped domains perpendicular to the drive, with a preferred wavelength depending on density and drive intensity. Interfaces between the domains are statistically rough, in sharp contrast with those in the Katz-Lebowitz-Spohn model, in which the drive suppresses interfacial roughness. Defining an order parameter (to account for the emergence of multistripe states), we map out the phase diagram in the density-drive plane.

12:51PM B61.00009: Self-assembly, aggregation, and phase behavior of driven and active colloids

ERIK LUIJTEN (Presenter), Northwestern University — Colloidal suspensions are a prototypical example of systems that can be either passive or active. I will demonstrate how various forms of dynamics and different types of interactions result in unexpected and until now largely unexplored aggregation and phase behavior. These observations, obtained through a combination of experiments and computer simulations, reveal striking connections between colloidal self-assembly and collective dynamics, and between dynamic behavior and equilibrium thermodynamics. Moreover, a remarkable variety of collective dynamics can be realized through simple variation of external electric fields. These observations provoke new thoughts on the nature of "soft" materials and our ability to manipulate them.

1:27PM B61.00010: Feasibility of prediction in driven-dissipative system displaying effective ergodicity breaking

CHONKIT PUN (Presenter), W. KLEIN, Department of Physics, Boston University, HARVEY GOULD, Department of Physics, Clark University — Using machine learning techniques we forecast the size of avalanches in the Olami-Feder-Christensen model using spatial information at different values of noise. We use the convolutional neural network and find that prediction is possible at low noise effective non-ergodic phase and not possible at the high noise effective ergodic phase. By looking at the higher level structures learned from the convolutional neural network, we can identify precursors of large events. Our goal is to understand the theoretical limitations of forecasting extreme events in complex systems.

DEBASHISH CHOWDHURY (Presenter), BHAVYA MISHRA, Indian Institute of Technology Kanpur — The totally asymmetric simple exclusion process (TASEP) was originally introduced fifty years ago as a model for the synthesis of biopolymers, called protein, by macromolecular machines called ribosome. In that formulation, the mRNA template for protein synthesis, that also serves as the track for the motor-like movement of the ribosomes, is represented by a lattice. We introduce a 3-species exclusion model that captures some of the hitherto neglected, but crucially important, details of the initiation of protein synthesis. We study the interference of the synthesis of two different proteins, the templates for which are encoded on two different, but overlapping, segments of the same lattice. We formulate the process of search for the start sites for protein synthesis as first-passage problems and calculate the mean initiation times for the synthesis of the two species of proteins. We show how the mean initiation times get affected by "leaky scanning" and the interference of the three exclusion processes.

1:51PM B61.00012: Pressure exerted by confined active particles

MICHA KORNREICH (Presenter), PAUL M CHAIKIN, New York University — Mechanical pressure, defined as the force applied perpendicular to the surface of an object per unit area, takes dramatically different forms in and out of equilibrium [1]. To experimentally measure the pressure exerted by an out of equilibrium system, we confine self-propelled particles in a negative dielectrophoretic trap. Knowing the potential profile, the density profile reveals the pressure. In equilibrium, pressure is exclusively governed by bulk properties such as density and temperature. In contrast, when the particles are activated, using either an in-plane rotating magnetic field or light-activated self-phoretic particles, we find that the force exerted on the confining trap boundaries depends on the shape of the boundary dielectrophoretic force fields.

2:03PM B61.00013: Surfing on protein waves: proteophoresis as a mechanism for bacterial genome partitioning*
JEAN-CHARLES WALTER (Presenter), CNRS, JÉRÔME DORIGNAC, VLADIMIR LORMAN, Université de Montpellier, JÉRÔME RECH, JEAN-YVES BOJET, MARCELO NOLLMANN, JOHN PALMERI, CNRS, ANDREA PARMEGGIANI, FRÉDÉRIC GENIET, Université de Montpellier — Efficient bacterial chromosome segregation typically requires the coordinated action of a three-component, fueled by adenosine triphosphate machinery called the partition complex. We present a phenomenological model accounting for the dynamic activity of this system that is also relevant for the physics of catalytic particles in active environments. The model is obtained by coupling simple linear reaction-diffusion equations with a proteophoresis, or “volumetric” chemophoresis, force field that arises from protein-protein interactions and provides a physically viable mechanism for complex translocation. This minimal description captures most known experimental observations: dynamic oscillations of complex components, complex separation and subsequent symmetrical positioning. The predictions of our model are in phenomenological agreement with and provide substantial insight into recent experiments. From a non-linear physics view point, this system explores the active separation of matter at micrometric scales with a dynamical instability between static positioning and travelling wave regimes triggered by the dynamical spontaneous breaking of rotational symmetry.

Session B62 GPC: Detecting Signals in a Noisy Climate System

11:15AM B62.00001: Insights Regarding Observational Requirements For Climate Change Signal Detection [Invited]
BRUCE WIELICKI (Presenter), Science Directorate, NASA Langley Research Center — Climate change signals must be detected against both the noise of internal natural variability as well as a wide range of uncertainties in the observing system. Observing system uncertainties include SI traceable accuracy, instrument stability over a decade or longer, calibration across data gaps, changing instrument designs, changing sampling of the earth, and changing data analysis methods. Most current observations used for climate change signals were not designed with climate change uncertainties in mind (National Academy of Sciences Continuity Report for NASA, Nov. 2015). Examples are given of how to set requirements for climate change observations relative to anticipated climate change signals and climate system natural variability. Given that we currently lack an observing system designed specifically for climate change, what would such a system look like? Design principles are provided, and examples are given of how more accurate observations can narrow key scientific uncertainties in climate change. Examples will also be presented of observations that can meet these much more challenging climate change requirements. The lack of a designed climate observing system naturally raises the question of the societal return on investment of providing such a system. Recent published estimates using state of the art economic integrated assessment models (IAMS) suggest a return of ~ 50 per1 invested. Society will be managing the Earth's Climate System actively or passively, wisely or unwisely, for the indefinite future. The world has had an internationally designed, committed, and shared weather observing system for many decades. It is time to begin an equivalent international climate change observing system. The motivation for such systems are the same: a better future for society.
ENS0 Change in Climate Projections: Forced Response or Internal Variability?* [Invited]  NICOLA MAHER (Presenter), DANIELA MATEI, SEBASTIAN MILINSKI, JOCHEM MAROTZKE, Ocean in the Earth System, Max Planck Institute for Meteorology — The El Niño-Southern Oscillation (ENSO) is the dominant driver of interannual variability globally and has effects which are felt in many remote regions of the world. As such it is vital to assess the potential future changes of ENSO. However, there is little consensus on how ENSO sea surface temperature (SST) may change in a future with increasing greenhouse gas emissions and underlying warming (Bellenger et al., 2014; Collins et al., 2010; Guilyardi et al., 2012; Ham & Kug, 2016), with large differences found between different Coupled Model Intercomparison Project 5 (CMIP5) model projections (Collins et al., 2010; Guilyardi et al., 2012). The range of projections of ENSO in the future could be due to differences in model physics, resulting in different projections from different models. However, the role of internal variability must also be considered. Such internal variations can result in different projections from single ensemble members of the same climate model. A large ensemble of a single model can be used to estimate this internal variability, and together with other model ensembles can be used to address uncertainties in model physics.

Two large ensembles are used to quantify the extent to which internal variability can contribute to long-term changes in ENSO characteristics. The range of simulated ENSO amplitude changes in the large ensemble historical simulations encompasses 90% of the Coupled Model Intercomparison Project 5 historical simulations and 80% of moderate (RCP4.5) and strong (RCP8.5) warming scenarios. When considering projected ENSO pattern changes, model differences are also important. We find that ENSO has high internal variability and that single realizations of a model can produce very different results to the ensemble mean response. Due to this variability, 30-40 ensemble members of a single model are needed to robustly compute absolute ENSO variance to a 10% error when 30-year analysis periods are used.

12:27PM B62.00003: From months to Milankovitch: how timescale-dependent interactions in the coupled Earth system determine the spectrum of climate variability and response.* [Invited]  CRISTIAN PROISTOESCU (Presenter), JISAO, University of Washington — Acting as both signal and noise, stochastic internal variability dominates the observational record of Earth's energy budget. While variability confounds estimates of anthropogenic climate change, it can also be leveraged for insight into the underlying physics, provided one understands both the governing stochastic processes, and the ways in which they are encoded in the statistics of observable quantities.

I will show how the frequency spectrum of Earth's temperature variability is determined by - and informs on - the climate system's radiative damping efficiency. This damping efficiency determines how much radiation the system sheds to space for a given change in surface temperature, and it is set by how the different components of the climate system - atmosphere, ocean, cryosphere, and the carbon cycle, interact across a range of timescales. The theoretical model for a timescale-dependent radiative damping efficiency is constrained by a combination of observations of broad-band variability drawn from both instrumental records as well as proxies of past climate change.

1:03PM B62.00004: The climate change signal in hurricanes [Invited]  CHIA-YING LEE (Presenter), ADAM SOBEL, MICHAEL TIPPETT, SUZANA CAMARGO, Columbia University — In this presentation, I will discuss results from our ongoing research on detecting climate change signal in hurricane activity in the recent history. A question that is frequently asked during or after an extreme hurricane season like 2017 is whether such extreme season becomes more frequent or is simply one of the statistical flukes. Such question is hard to answer by using observational data alone as the length of high-quality hurricane record is too short. Therefore, we study this question by a combination of observations, statistical-dynamical downscaling modeling and high-resolution global dynamical modeling approaches. Simulations driven by reanalysis data will be used to estimate historical trends. Simulations driven by outputs from global climate models as well as those directly output from high-resolution global models are used to estimate the roles of radiative forcing, natural variability, and their combination. I will show the comparison of various climatological measures of TC activity from observations and model-based estimates for the current, pre-industrial, and near future periods. In addition to our work, I will also discuss other recent studies on detecting climate change signal on hurricanes.
Detecting changes in marine ecosystems and ocean colour* [Invited] STEPHANIE DUTKIEWICZ (Presenter), OLIVER JAHN, EAPS, Massachusetts Institute of Technology, ANNA HICKMAN, University of Southampton, STEPHANIE HENSON, National Oceanography Centre Southampton, CLAUDIE BEAULIEU, University of California, Santa Cruz, ERWAN MONIER, University of California, Davis — Monitoring changes in marine phytoplankton is important as they form the foundation of the marine food web and are crucial in the carbon cycle. Climate change is affecting marine phytoplankton by altering their nutrient, temperature, light and chemical environments. Often Chlorophyll-a (Chl-a) is used to track changes in phytoplankton, since there are global, regular satellite-derived estimates, and such studies suggesting complex, but as yet limited, patterns of long-term change over the last two decades. However, satellite sensors do not measure Chl-a directly. Instead, Chl-a is estimated from remote sensing reflectance (RRS): the ratio of upwelling radiance to the downwelling irradiance at the ocean's surface. We use a unique ocean physics, biogeochemistry and ecosystem model that explicitly includes a representation of the ocean's optical properties to explore how climate change signals are manifested in Chl-a, phytoplankton communities, and ocean colour over the course of the 21st century. We show that RRS in the blue-green spectrum is likely to have a stronger and earlier climate change-driven signal than Chl-a. This is because RRS integrates not only changes to Chl-a, but also alterations in other optically important constituents. Phytoplankton community structure, which strongly affects ocean optics, is likely to show one of the clearest and most rapid signatures of changes to the base of the marine ecosystem.

Session B63 DBIO GSNP: Evolutionary and Ecological Dynamics II: Eco-evolutionary Feedback

Infect, replicate, and diffuse on: how bacteriophage grows and evolves during a spatial range expansion* [Invited] DIANA FUSCO (Presenter), University of Cambridge — Spatially growing populations are ubiquitous across scales, ranging from the human migration out of Africa to the spreading of diseases. In contrast to well-mixed populations where an individual's chance of survival is only determined by its fitness, in spatially growing populations the physical location of an individual plays a crucial role: the individuals at the edge of the expanding front benefit from having access to virgin territory and giving their offspring the same advantage. The emerging population dynamic results in an evolutionary dynamic dominated by noise, with extreme consequences such as the accumulation of deleterious mutations at the population's front.

To investigate how spatial range expansion affects the evolutionary dynamic of a population, we employ the bacteriophage T7-E. coli system. In an evolutionary experiment lasting only 7 days, we were able to evolve a T7 strain that more than doubled its spreading speed on a bacterial lawn compared to its ancestor. The seeming lack of accumulation of deleterious mutations at the front raised questions regarding the physical nature of the traveling wave describing the expansion front of T7, which was traditionally assumed to behave like a pulled wave at long time scales. In contrast to the assumptions used in the FKPP reaction-diffusion equation generating pulled waves, diffusion rate measurements show that phage dispersal is non-uniform along the range expansion since it depends on the local bacterial density. Using stochastic simulations, we find that this effect can have dramatic consequences on the phage genetic diversity at the front and on the adaptation potential of the population. The underlying physical origin of the effect broadens the relevance of our findings to a wide range of host-pathogen systems that share this feature.

Mitochondria are organelles found in almost all eukaryotic cells. They are highly dynamic and once formed, they can undergo changes in size and content via the processes of fusion, fission, and mitophagy. Mitochondria are famously known as the powerhouse of the cell for their role in cellular energy production. They are also essential for cell signaling and apoptosis, and have their own DNA, called mtDNA, which is maternally inherited. The same cell can have multiple variants of mtDNA, and harmful alterations in mtDNA can accumulate over time resulting in pathological changes in mitochondrial function and disease states. We develop and study a mathematical model to understand and predict the population dynamics of mtDNA and how it is correlated to changes in mitochondrial bioenergetics. We examine the spatiotemporal evolution of populations of healthy and dysfunctional mitochondria subject to mitochondrial biogenesis, fission, fusion, mitophagy, and changes in the mitochondrial membrane potential, and determine their relative impact on mtDNA population dynamics. Our results may provide insights into how different mtDNA populations survive and evolve under different selection pressures and the origins of mtDNA disorders.

11:51AM B63.00002: Dynamics of mtDNA populations in mammalian cells: role of mitochondrial dynamics and its interplay with mitochondrial membrane potential†  BRANDON BOGNER (Presenter), KELLIANNE E KORNICK, LEO SUTTER, School of Physics and Astronomy, Rochester Institute of Technology, REBECCA ZATHANG, School of Chemical Sciences, Rochester Institute of Technology, MOUMITA DAS, School of Physics and Astronomy, Rochester Institute of Technology — Mitochondria are organelles found in almost all eukaryotic cells. They are highly dynamic and once formed, they can undergo changes in size and content via the processes of fusion, fission, and mitophagy. Mitochondria are famously known as the powerhouse of the cell for their role in cellular energy production. They are also essential for cell signaling and apoptosis, and have their own DNA, called mtDNA, which is maternally inherited. The same cell can have multiple variants of mtDNA, and harmful alterations in mtDNA can accumulate over time resulting in pathological changes in mitochondrial function and disease states. We develop and study a mathematical model to understand and predict the population dynamics of mtDNA and how it is correlated to changes in mitochondrial bioenergetics. We examine the spatiotemporal evolution of populations of healthy and dysfunctional mitochondria subject to mitochondrial biogenesis, fission, fusion, mitophagy, and changes in the mitochondrial membrane potential, and determine their relative impact on mtDNA population dynamics. Our results may provide insights into how different mtDNA populations survive and evolve under different selection pressures and the origins of mtDNA disorders.

12:03PM B63.00003: Frequency- and Amplitude-Dependent Microbial Population Dynamics during Cycles of Feast and Famine† JASON RYAN MERRITT, SEPPE KUEHN (Presenter), University of Illinois at Urbana-Champaign — In nature microbial populations are subject to fluctuating nutrient levels. Nutrient fluctuations are important for evolutionary and ecological dynamics in microbial communities since they impact growth rates, population sizes, and biofilm formation. Here we show that when populations of *Escherichia coli* are subjected to cycles of nutrient excess (feasts) and scarcity (famine) their abundance dynamics during famines depend on the frequency and amplitude of feasts. We show that frequency and amplitude dependent dynamics in planktonic populations arise from nutrient and history dependent rates of aggregation and dispersal. These conclusions are enabled by precision measurements performed with automated continuous culture devices coupled to custom fluorescence microscopes. The instruments automatically sample, image and count single-cells drawn from continuously-cultured populations on a timescale of minutes for periods of weeks. The quality of the data enable us to construct a concise phenomenological model that recapitulates our experimental observations. Our results show that the statistical properties of environmental fluctuations have substantial impacts on spatial structure in bacterial populations driving large changes in abundance dynamics.

*NSF (PHY 0822613 and PHY 1430124)

12:15PM B63.00004: Evolutionarily stable coexistence in a single nutrient: optimization and cross-feeding ZHIYUAN LI (Presenter), Princeton University, BO LIU, Peking University, NED WINGREEN, Princeton University — Two questions on coexistence have perplexed community ecologists for nearly a century: first, the “paradox of the plankton”, that nature world possess tremendous diversity while theoretical models suggested the number of species can hardly exceeds the number of nutrients. Second, evolution has been shown to exacerbate this paradox. As species are constantly evolving towards optimality, which may produce a supreme winner that takes over the habitat. To investigate these questions, we utilized and extended the graphical tools of resource-competition theory to relate and unify multiple models for microbial diversity, and quantified the optimal metabolic strategies in resource competition models in general. This framework was then applied to metabolic models that allows species to increase dimension in nutrient space by secreting metabolites. With this simple model, we explored the possibilities of coexistence though cross-feeding on a single supply nutrient, and investigated general criteria for such co-existence to be evolutionarily stable.

12:27PM B63.00005: Diversification of investment strategies in an ecological public goods game driven by the spatial structure of the population JOSEPH RAUCH (Presenter), JANE KONDEV, Brandeis University, ALVARO SANCHEZ, Yale University — Ecology and evolution work in tandem to create biodiversity, especially when they act on similar timescales, as can happen in microbial populations. Frequency and density dependent ecological models, like the public goods game, are known to be capable of supporting diverse populations. Recent experiments have shown diversification of gene expression in a bacterial population for a gene expressing a public good. Motivated by these observations we study an ecological public goods model and compare the extent to which mutations can fix in a population and generate diversity in a well-mixed situation and one with spatial structure. We show that rapid diversification within an ecological public goods game can drastically vary depending on the time scale of evolution and the time scale of ecological dynamics. While populations in a well-mixed model quickly come to equilibrium, limiting the amount of diversity typically to two dominant investment strategies; models with spatial structure prolong the time to equilibrium and allow multiple mutants to fix themselves in the population. Our theoretical studies agree with the experimental observations and point to a general principle how ecological public good games in spatially extended microbial population can lead to rapid diversification.
The evolution of multicellular life from single-celled ancestors is one of the most radical shifts in the history of life on earth, and sets the stage for evolution of more complex life forms. Despite the significance of this transition, we know little about the process by which cells first assemble groups and form multicellular organisms. We study this problem experimentally; a single mutation in the ACE2 gene of Baker’s yeast S. cerevisiae prevents mother and daughter cells from separating after cellular division. These yeast clusters, called ‘snowflake’ yeast, comprise a few hundred cells and grow to a maximum diameter of 200 microns. To evolve larger multicellular size, snowflake yeast clusters must mitigate forces strong enough to fracture cell-cell bonds. After a year of artificial selection for larger multicellular size, five populations of snowflake yeast surprisingly evolved to grow to a maximum diameter of 1 mm. In this work we investigate how nascent multicellular clusters evolve to overcome substantial mechanical constraints and dramatically increase their size.

Avalanche critical fluctuations are an important dynamic feature of many systems including earthquakes and magnet polarization. They are caused by sudden release of potential built up by frustration in energy dissipation. Here, we introduce the concept of resource frustration in ecological systems to describe transient buildup of resources within a community which are then dissipated via avalanche-like events of individual species growth. We developed a general model to predict the conditions under which this type of fluctuations emerge in ecological systems and identified scaling laws and critical exponents of these avalanche events. We also demonstrated that these scaling laws are universal across multiple model microbial communities, (e.g., siderophore dependence and auxotrophic mutualism) using consumer-resource models. Our results reveal a novel class of transient phenomena in ecology and provide mechanisms by which stochastic fluctuations in individual components amplify and propagate throughout the ecological system.

1:15PM B63.00009: What do metabolic constraints inform us about the emergence of early stable bacterial communities? GA CHING LUI (Presenter), SIDHARTHA GOYAL, Physics, University of Toronto — Stability of an ecosystem is determined by its composition. As a system gains stability, one of the major trends observed during ecological succession, which refers to the development of a community, is an increase in compositional diversity [1]. It has been shown that multispecies systems can support a larger community with more surviving species at steady state when the variability across pairwise coupling strengths between species is smaller [2]. But how a small system with one species and no foreign invaders develops into a large diverse system remains an open question. Here, we consider the stability of a system under constant nutrient flux [3] when a species is competing with its closely related mutants to understand how early diversity is established. Using adiabatic approximation and discarding higher order terms, we recover the reduced dynamics for chemostats similar to Lotka-Volterra systems. By introducing small perturbations to the growth rates of the otherwise identical species constrained by rates of metabolic regulations, the rules for obtaining stable multispecies communities are obtained.

1:27PM B63.00010: Eco-evolutionary hysteresis in bacterial genomes driven by horizontal gene transfer  
AKSHIT GOYAL (Presenter), Simons Centre for the Study of Living Machines, National Centre for Biological Sciences (NCBS-TIFR) — Many naturally-occurring bacteria lead a lifestyle of metabolic dependency, i.e. they depend on others for crucial resources. We do not understand what factors drive bacteria towards this lifestyle, and how. Here, we systematically explain the role of horizontal gene transfer (HGT) in metabolic dependency evolution. Across 835 bacterial species, we mapped gene dynamics on a deep evolutionary tree, and assessed the impact of HGT and gene loss on bacterial metabolic networks. Our analyses suggest that genes acquired by HGT can affect which genes are later lost. Dependency evolution by gene loss is contingent on earlier HGT via two steps. First, we find that HGT and gene loss act on contrasting regions of metabolic networks—losses remove existing anabolic routes; HGT adds new catabolic routes. This increases the chance of new metabolic interactions between bacteria, which is a prerequisite for dependency evolution. Second, we show how gaining new routes can promote the loss of specific ancestral routes (termed "eco-evolutionary hysteresis", EEH). Phylogenetic patterns indicate that both types of dependencies—those mediated by EEH and pure gene loss—are equally likely. Our results highlight HGT as an important driver of metabolic dependency evolution in bacteria.

1:39PM B63.00011: Species Packing with Generalized Resource Dynamics*  
WENPING CUI (Presenter), Department of Physics, Boston College, Boston University, ROBERT MARSLAND, PANKAJ MEHTA, Department of Physics, Boston University — An important question in ecology is to understand how species assemble under different resource dynamics. Here we explored generalized MacArthur’s resource models with two different resource dynamics: self-renewing(original MacArthur’s) and external-supplied resource dynamics. A statistical physics inspired cavity method is used to solve two resource dynamics analytically. Surprisingly, we find that two resource dynamics have different upper bounds of species packing. We show that external-supplied resource dynamics can introduce higher order competition between species and affect coexistence patterns dramatically.

1:51PM B63.00012: Resource utilization determines growth rates and evolution in simple multi-species evolutionary model.  
JOSHUA DIJKSMAN (Presenter), Wageningen University & Research — Species proliferate in an ecosystem if resources are abundant. Populous species at the same time deplete resources, which undermines their expansion. This suggests that resource utilization, appropriately quantified, should set their growth rate. By defining a species by the amount of different resources it consumes, and using the alignment of this vector with the vector of available resources as species growth rate, we can implement growth but also drift in species composition, and hence entire ecosystem evolution through speciation and adaptation. Our approach displays all the salient features of ecosystem evolution. We can evolve ecosystems even by initiating dynamics out of a single primordial ancestor. Despite the nonlinear and stochastic nature of this MacArthur-style approach, the modeling approach yields a robust, universal solution for the mean ecosystem fitness dynamics that is resilient against resource shocks. More generally, ecosystem fitness depends in an intuitive way on model parameters such as resource influx, reproduction rate and evolutionary noise. Our resource utilization approach to growth modeling so provides a general but simple starting point to evolutionary ecosystem dynamics.

2:03PM B63.00013: MEST-SPACETIME STRUCTURE, MASSENERGY STRUCTURE, AND ORIGIN of LIFE  
DAYONG CAO (Presenter), Avoid Earth Extinction Association — MEST is a balance systemic model of mass, energy, space, and time.

According to Einstein field equation and negative Einstein equation, there are massenergy center with massenergy structure and spacetime center with spacetime structure which has gravity of the spacetime (as negative gravity).

The spacetime center structure can explain of dark matter and dark energy. A balance structure between massenergy and spacetime can explain of the homogeneous, isotropic, and flat structure of the universe. It can suppose a balance system between the sun and a dark sun as a spacetime center of Oort cloud which is dark matter-dark energy.

Beginning of the solar system, there have dark matter around baby sun. The dark matter with ring structure (of spacetime center structure) impacted on the stellar matter with open structure, and create organic macromolecule of the life's system with open system and closed system together. The impactions also could cause mass extinction, and could make natural gas, oil, and coals.

The period of the mass extinction has relationship with orbit of revolution of solar system, Galactic Spiral Arm, and balance system between sun and dark sun.
http://meetings.aps.org/Meeting/APR16/Session/M13.8
11:15AM B64.00001: Inferring the helix-helix electrostatic interaction strength from the structure of dense DNA toroids*  Luca Barberi (Presenter), LPTMS, CNRS, Univ. Paris-Sud, Université Paris-Saclay, Amélie Leforestier, Françoise Livolant, LPS, CNRS, Univ. Paris-Sud, Université Paris-Saclay, Martin Lenz, LPTMS, CNRS, Univ. Paris-Sud, Université Paris-Saclay — DNA is often condensed to remarkably dense phases, where one or more chains are curved at scales comparable to their persistence length. This can happen in the presence of highly valent cations, like in the capsids of some bacteriophage viruses, where a long DNA chain is rolled up to nearly crystalline densities with spermidine(3+) and putrescine(2+). Despite their biological relevance, cation-mediated helix-helix electrostatic interactions remain poorly understood and their experimental measurement limited to arrays of locally parallel DNA helices. These forces relying on strong spatial correlations between charges on neighbouring helices, straight DNA chains may interact differently than curved ones. We are able to infer the strength of helix-helix electrostatic forces in a spermine(4+)-condensed DNA toroid, predicting with a minimal model the inter-helical spacing spatial inhomogeneities observed in our recent cryo-electron microscopy experiments. Our results suggest that electrostatic cohesion may be one order of magnitude weaker in toroids than in other DNA condensates with less local curvature. Curvature-reduced electrostatic interactions may facilitate DNA ejection dynamics in bacteriophages.

11:27AM B64.00002: The Nanomechanics of Cellulose Synthesis*  Lori Goldner (Presenter), Nina Zehfroosh, Tobias I. Baskin, University of Massachusetts Amherst — Despite its ubiquity and technological importance, cellulose is synthesized in plants by a process that is poorly understood. Cellulose is a crystalline fiber made up of glucan chains synthesized by a large enzymatic complex that resides in the plant cell membrane. Decisive progress was made more than a decade ago when fluorescently-tagged complexes were first observed moving in the cell membranes of living plants. Complexes move with a speed between 100 and 400 nm/min and this motion is presumed to be related to the rate of cellulose synthesis. We present the results of a careful study of CESA motion in two different plant species over a wide range of timescales. We show several surprising aspects of this motion and discuss models to explain it. After accounting for localization error, the mean squared displacement (MSD) of the moving cellulose synthase complexes shows subdiffusive timescales below 10 seconds suggesting short-range trapping. Over longer timescales, an extant model and particle MSDs support a Brownian ratchet mechanism. However, initial indications are that step-size distributions are non-Gaussian, indicating that a Brownian ratchet alone may not be sufficient to explain CESA mechanics.

11:39AM B64.00003: On the behavior of random RNA secondary structures near the glass transition*  William Baez, Department of Physics, Ohio State University, Kay J. Wiese, CNRS-Laboratoire de Physique Théorique, Ecole Normale Supérieure, Ralf Bundschuh (Presenter), Department of Physics, Ohio State University — RNA forms elaborate secondary structures through intramolecular base pairing. These structures perform critical biological functions within each cell. Due to the availability of a polynomial algorithm to calculate the partition function over these structures, they are also a suitable system for the statistical physics of disordered systems. In this model, below the denaturation temperature, random RNA secondary structures exist in one of two phases: a strongly disordered, low-temperature glass phase, and a weakly disordered, high-temperature molten phase. The probability of two bases to pair decays with their distance with an exponent 3/2 in the molten phase, and about 4/3 in the glass phase. Inspired by previous results from a renormalized field theory of the glass transition separating the two phases, we numerically study this transition. We introduce distinct order parameters for each phase, that both vanish at the critical point. We finally explore the driving mechanism behind this transition.

11:51AM B64.00004: Salivary mucin glycopolymers reduce virulence traits of cavity-causing *Streptococcus mutans*

CAROLINE WERLANG (Presenter), WESLEY CHEN, KATHARINA RIBBECK, Massachusetts Institute of Technology — Dry mouth is a condition characterized by an underproduction of saliva that affects one in five American adults. This reduction in salivary mucus is associated with higher incidences of cavities, oral ulcers, and microbial infections in the mouth. Saliva's protective effects are derived from mucins, gel-forming proteins. These natural brush polymers display over two-hundred unique glycan motifs. Reconstituted salivary mucin gels have been shown to prevent biofilm formation of *Streptococcus mutans*, bacteria whose adherence to teeth causes cavities. Here, we show that mucin affects other virulence behaviors of these bacteria, reducing population-level signaling and gene transfer, which can spread antibiotic resistance. This evidence points to mucin gels' unique ability to regulate the phenotypes of potentially pathogenic microbes. We also present our continuing efforts to design synthetic mucin-mimetic glycopolymers and test their efficacy at reducing microbial virulence. We hope that these principles can be used to develop mucin-inspired therapeutic polymers that could potentially alleviate the severity of dry mouth related symptoms based off of saliva's natural protection mechanisms.

12:03PM B64.00005: Molecular characterization of mucus binding

JACOB WITTEN (Presenter), TAHOURA SAMAD, KATHARINA RIBBECK, Biological Engineering, Massachusetts Institute of Technology — Mucus coats all wet epithelial surfaces of the body. Binding of small molecules to mucus has an important role in human health, as it may affect the diffusivity and activity of drugs and toxins that act in a mucosal environment. Despite the importance of mucus-small molecule binding, there is a lack of data revealing the precise physicochemical features of small molecules that lead to mucus binding. We developed a novel equilibrium dialysis assay to measure the binding of small molecules to mucin and other mucus components at unprecedented throughput, and combined this assay with a small molecule microarray to identify a novel mucin binding motif. Furthermore, we showed that for molecules with this motif, binding to mucins and the mucus-associated biopolymers DNA and alginate is modulated by differences in hydrophobicity and charge. Finally, we showed that molecules without the motif exhibited different trends from molecules with the motif, suggesting a complex dependence of mucin binding on molecular physicochemical properties.

12:15PM B64.00006: Microfluidic delivery of cutting enzymes for fragmentation of surface-adsorbed DNA molecules

JULIA BUDASSI (Presenter), Stony Brook University, ALAN GAN, East Brunswick High School, East Brunswick, NJ 08816, ALBERT TIAN, Ward Melville High School, E. Setauket, NY 11733, JONATHAN SOKOLOV, Stony Brook University — We describe a method for fragmenting DNA molecules surface-adsorbed and immobilized onto a polymethyl methacrylate (PMMA) coated silicon substrate by ‘molecular combing’ [1]. Microfluidic channels were formed into polydimethylsiloxane (PDMS) stamps using the soft lithography technique. The channel widths varied from 3.5 to 7 microns. The channels were pre-filled with a buffer solution by the channel outgas method [2]. Bovine serum albumin was diffused into the channels to coat the PDMS surfaces (which would otherwise strongly adsorb the DNase I cutting enzyme). DNase I was allowed to diffuse into the channel for 1 hour, resulting in efficient and precise fragmentation of the DNAs over the full channel length of 10mm. Applications to DNA sequencing will be discussed.

12:27PM B64.00007: Anomalous, non-Gaussian, viscoelastic and age-dependent dynamics of histone-like nucleoid structuring proteins in live Escherichia coli*  
YONG WANG (Presenter), ASMAA SADOON, Department of Physics, University of Arkansas — We report our measurements of the dynamics of H-NS proteins, which interact with both proteins and DNA simultaneously, in live E. coli bacteria. The dynamics turn out to differ significantly from other molecules reported previously. A new power-law distribution was observed for the diffusion coefficients of individual H-NS proteins. In addition, we observed a new distribution of displacements, which does not follow the Gaussian, Cauchy, or Laplace distributions, but the Pearson Type VII distribution. Furthermore, we experimentally measured, for the first time, the time/frequency dependence of the complex modulus of the bacterial cytoplasm, which deviates from the viscoelasticity of homogeneous protein solutions and shows a glass-liquid transition. Lastly, we observed that the dynamics of H-NS protein is cell-length/cell-age dependent. The findings are expected to fundamentally change the current views on bacterial cytoplasm and diffusional dynamics of molecules in bacteria.

12:39PM B64.00008: Spatially-defined active matter using DNA strands  
ANIS SENOUSSI (Presenter), JEAN-CHRISTOPHE GALAS, ANDRÉ ESTEVEZ-TORRES, Sorbonne Universite and CNRS, Laboratoire Jean Perrin, Paris, France — Living systems have the incredible ability to organize themselves from molecules to the macroscopic scale. To understand the complex processes involved, we are reproducing some features of morphogenesis by rationally designing spatiotemporal patterns in artificial active materials. Taking advantages of the predictable interactions between their sequences, we use nucleic acids as elementary bricks to build complex active systems.

We designed a minimal system composed of protein filaments and modified molecular motors that can convert chemical energy into large-scale mechanical work upon the addition of a specific DNA strand. We expressed and purified each molecular components and rationally-assembled them to create a DNA-responsive material. This material undergoes macroscopic changes resulting in global or local contractions. This approach can be used to create original out-of-equilibrium systems that link a DNA-based chemical reaction network capable of generating a concentration landscape, as previously demonstrated [1], with a force-generating system.

12:51PM B64.00009: Selective response of DNA sequences at THz frequencies from numerical simulation*  
ALEXANDER SHVONSKI (Presenter), VICTORIA GABRIELE, KRZYSZTOF KEMPA, Boston College — We numerically simulate the response of DNA sequences to driving with THz radiation using the dynamical model of Ref. [1]. Homogeneous sequences of AT base-pairs experience an amplitude response that is distinct from homogeneous GC sequences in the parameter space of driving amplitude and frequency. Heterogeneous sequences with the same number of AT and GC pairs, but different ordering, also exhibit distinct responses in some regions of parameter space. Results indicate that THz driving is selective between different DNA sequences. [1] R. Tapia-Rojo, J. J. Mazo, and F. Falo, “Thermal and mechanical properties of a DNA model with solvation barrier,” Physical Review E 82, 031916 (2010).

1:03PM B64.00010: Surprising Charge Transport in DNA  
ROMAN ZHURAVEL (Presenter), Hebrew University of Jerusalem — The field of Nano-electronics concentrates a lot of interest from technological and scientific points of view. While charge transport in the solid state has been widely researched, for large single molecules many fundamental questions remain unsolved.

DNA is a good model molecule for many polymeric systems. Charge transport along DNA molecules has attracted scientific interest for over half a century. However, due to the many free parameters concerning these experiments, a variety of results were achieved, triggering an ongoing scientific debate on the DNA molecule conductivity. Our goal in this research is to reveal the charge transport mechanisms by controlled elucidation of the affecting parameters.

We have developed an experimental system for measurements of individual DNA molecules in a very precise and well defined manner with minimum number of experimental uncertainties. Preliminary measurements of 100bp dsDNA molecules with random and ordered sequences show unusually high currents and complex temperatures dependence, leading to new insights regarding the transport mechanism, which will be presented here.
RNA structure and kinetics including pseudoknots through complete landscape enumeration

OFER KIMCHI (Presenter), Harvard University; TRISTAN CRAGNOLINI, Chemistry, University of Cambridge; REES F GARMANN, VINOTHAN N MANOHARAN, MICHAEL PHILLIP BRENNER, Harvard University; LUCY COLWELL, Chemistry, University of Cambridge — Kinetic barriers as well as non-nested loops (pseudoknots) still pose challenges in the accurate prediction of RNA secondary structure. We will (1) develop a physical model to estimate the entropies of complex pseudoknots; and (2) demonstrate that their NP-complete enumeration need not impede their study. Our novel polymer physics model can address arbitrarily complex pseudoknots using only two free parameters corresponding to concrete physical quantities — over an order of magnitude fewer than the sparsest state-of-the-art phenomenological methods. By coupling this model to exhaustive enumeration of the set of possible structures, we compute the entire free energy landscape of secondary structures resulting from a primary RNA sequence. Despite our model’s parametric sparsity, it performs on par or better than previously published methods in predicting both pseudoknotted and non-pseudoknotted structures on a benchmark dataset of RNA structures of ≤ 80 nucleotides. We discuss the implications of the complete enumeration procedure employed for the study of kinetics.

Protamine progressively folds DNA before looping

OBINNA UKOGU, ADAM SMITH, LUKA DEVENICA, HILARY BEDIAKO, ASHLEY CARTER (Presenter), Amherst College — In sperm, protamine proteins cause a rapid condensation of the DNA to almost crystalline packing levels. Understanding the physical mechanism for this dramatic process is an important limiting case in biophysics. In addition, protamine condensation of DNA may be useful in biomaterials research to assemble or fold DNA nanostructures. Here our goal is to understand the first step in the pathway, the folding of the DNA into a single loop by protamine. To answer this question, we image single molecules of DNA with bound protamine using an atomic force microscope (AFM). We also directly measure DNA folding dynamics in real time using tethered particle motion (TPM) assays. We expected our measurements to show a single folding event as the loop forms, but both measurements showed the presence of multiple, long-lived (100 s) intermediates. Structurally, these intermediates are half-loops or “c-shapes” that become more folded over as the protamine concentration increases. This data suggests a new model for DNA looping whereby small molecules coat the DNA and progressively fold it before forming a loop.

DNA Base-Pairing Visualized by Liquid-Cell Transmission Electron Microscopy

HUAN WANG (Presenter), BO LI, YE-JIN KIM, OH-HOON KWON, STEVE GRANICK, IBS Center for Soft and Living Matter — We show that fragile biological samples including DNA can be imaged using in situ transmission electron microscopy (TEM) without metal staining. Reporting statistical analysis of large datasets concerning single-strand and double-stranded aqueous DNA trapped in creases between paired graphene sheets, we visualize individual molecules with ~1 nm spatial resolution and ~100 ms time resolution for up to ~3 min, apparently without significant perturbation from the electron beam. Inspecting the time-dependent base-pairing of single-stranded DNA base-pairing, some pathways are as anticipated while others are surprising.

1:51PM B64.00014: Zippering dynamics of an RNA hairpin: Role of helicity*  
HUAPING LI, ALKAN KABAKCIOGLU (Presenter), Koc University — Despite several computational studies on hairpin folding and some supporting experimental data, role of the helical geometry on hairpin folding dynamics remains mostly unexplored. We here address this question by means of extensive molecular dynamics simulations on helical and (non-helical) "ladder-like" coarse-grained models. It is known that the folding time (t) of a thermally quenched RNA hairpin depends on the number of base pairs (N) as $t \sim N^\alpha$, where $\alpha=1+\nu$ is found to fit the experimental data with $\nu \approx 0.6$ (Flory exponent in three dimensions). We find that $\alpha$ changes from 1.6 to 1.2 ($=2\nu$) in three dimensions when duplex helicity is removed. Simulations in two dimensions ($\nu = 0.75$) and with a ghost chain ($\nu = 0.5$) further support the hypothesis $\alpha=2\nu$ for a "ladder-like" hairpin. The contrast between the two models which have identical single-strand properties suggests that duplex dynamics is a relevant component of the folding process, hence contradicting the theoretical models focusing on the non-equilibrium behavior of the unpaired segments alone. We propose a new scaling argument for $\alpha=1+\nu$ in helical chains and an energy argument for $\alpha \geq 2\nu$.

11:15AM B65.00001: Collective mechanical adaptation of honeybee swarms* [Invited]  
ORIT PELEG (Presenter), University of Colorado, Boulder, JACOB PETERS, MARY SALCEDO, L MAHADEVAN, Harvard University — Honeybee swarms form large congested tree-hanging clusters made solely of bees attached to each other. How these structures are maintained under the influence of dynamic mechanical forcing is unknown. To address this, we created pendant clusters and subject them to dynamic loads of varying orientation, amplitude, frequency and duration. We find that horizontally shaken clusters adapt by spreading out to form wider, flatter cones that recover their original shape when unloaded. Measuring the response of a cluster to an impulsive pendular excitation shows that flattened cones deform less and relax faster than the elongated ones. Particle-based simulations of a passive assemblage suggest a behavioural hypothesis: individual bees respond to local variations in strain by moving up the strain gradient, which is qualitatively consistent with our observations of individual bee movement during dynamic loading. Together, our findings highlight how a super-organismal structure responds to dynamic loading by actively changing its morphology to improve the collective stability of the cluster at the expense of increasing the average mechanical burden of an individual.

11:51AM B65.00002: Unsupervised Classification of Behavior for Open Field Mouse Recordings*  
UGNE KLIBAITE (Presenter), JESSICA VERPEUT, MIKHAIL KISLIN, SAMUEL S WANG, JOSHUA SHAEVITZ, Princeton University — Advances in computer vision and deep learning have made it possible to explore animal behavior at fine temporal and spatial scales. In particular, new advances in automated pose detection make it possible to track fine-scale movements in mice, a model system for the study of many aspects of neural function, from locomotion and coordination to complex neurodevelopmental disorders such as autism. We combine the use of a deep-learning-based approach called LEAP (LEAP Estimates Animal Pose), which produces estimates of joint coordinates, with unsupervised classification in order to discover distinct behavioral bouts in 72 wild-type mice in an open field arena over five subsequent days. We use the resulting behavioral phenotypes to explore the evolution of behavior in individuals over time, as well as identify behavioral differences between wild-type individuals and genetic models of neurodegenerative disease. These differences elucidate complex phenotypes that arise from neuropathology, and capture greater complexity with fewer experimental constraints than simpler high-throughput behavioral assays.

*This work was supported by the National Institutes of Health (R01MH115750) and the National Science Foundation, through the Center for the Physics of Biological Function (PHY-1734030)
Experimental testing of the model both analytically and through computer simulation. This model makes robust predictions that can be applied to various scenarios. The ratio of the rates of creation and evaporation of the pheromones is crucial. Here we map the phase diagram for the extended model to forage from both food sources equally. We extend this model to include indirect recruitment of ants forage bistably from the different food sources, but as the population size is increased over a certain critical population size, they will start to forage from one of two food sources, the ants exhibit this type of bistability. At small population sizes, the ants will forage from one of two food sources, but as the population size is increased over a certain critical population size, they will start to forage from both food sources equally. We extend this model to include indirect recruitment of ants to a food source via a pheromone laid out by other ants. The critical population size of this extended model depends on the ratio of the rates of creation and evaporation of the pheromones. Here we map the phase diagram for the extended model both analytically and through computer simulation. This model makes robust predictions that can be experimentally tested.

12:51PM B65.00007: Decompositions of Behavioral Modulations and Run Shapes in Drosophila Larvae  JOSEPH SHOMAR (Presenter), ANGGIE FERRER, JOSHUA FORER, TOM ZHANG, MASON KLEIN, University of Miami — With its small size and limited motor tool set, the Drosophila larva is a good system for studying how animals alter their behavior to reach optimal conditions. We aim to distinguish behavioral modulations caused by the physical effects of temperature from those due to sensory input and to decompose curved runs (bouts of forward crawling) into run-shape eigenvectors.

To decouple the causes of behavioral modulation, we use temperature-insensitive mutants and 3 different spatiotemporal stimulus environments; PID controllers maintain the different spatial and temporal gradients. Many larvae are recorded during free navigation and computer vision software segments trajectories into alternating sequences of runs and turns, analogous to classic 2D random walks. The turn rate is the dominant characteristic of diffusive processes and larvae primarily achieve navigation by modulating it. Monte-Carlo simulations allow for comparison with experimental data and for analysis of otherwise unfeasible experiments.

Our results suggest that larvae exhibit different average speeds due to physical changes, and exhibit different turn rates because of both physical changes and sensory input. Computational methods are currently being explored for use in decomposing runs into run-shape eigenvectors.

1:03PM B65.00008: Slingshot Spider: Ultrafast kinematics, biological function and physical models of an extreme arachnid  SYMONE ALEXANDER (Presenter), SAAD BHAMLA, Georgia Institute of Technology — The natural evolution of ultrafast motion in living systems has inspired physicists, biologists, and engineers to design biomimetic materials and fast-moving robots. In this work, we quantify kinematics of a tiny ‘slingshot spider’ native to the Peruvian Amazon Rainforest. This spider exploits a conical 3D web structure to slingshot itself at extreme speeds and achieve accelerations exceeding 600 m/s², an order of magnitude faster than a cheetah (13 m/s²). To the best of our knowledge, this is the fastest movement by an arachnid ever recorded. In this talk, we will discuss how slingshot spiders achieve ultrafast motion, and share insight about the biological function of this extraordinary prey capture strategy. We reveal how the motion is actuated by a trigger mechanism that happens under a millionth of a second (0.8 μs). Lastly, we extract the underlying physics of this motion and the role of the 3D web in power amplification using simple physical models constructed from elastic rubber bands. The physical models further shed insight into built-in safety structures in the web that rapidly dissipate excess energy and protect the spider against the large stresses generated during this extreme motion.

1:15PM B65.00009: Testing a thermodynamic approach to collective animal behavior in laboratory fish schools  JULIA A GIANNINI (Presenter), Physics, Syracuse University, JAMES PUCKETT, Physics, Gettysburg College — Social animals including insects, fish, birds, and even humans exhibit self-organized collective behavior. Macroscopic properties arise not only from interactions between individuals, but also from environmental cues. Here, we present results from a series of experiments that utilize high speed footage of 2D schooling events, particle-tracking, and projected static and dynamic light fields to observe and control the behavior of negatively phototaxic laboratory fish schools (Hemigrammus bleheri). First, we use static light fields consisting of dark circular regions to produce visual stimuli that confine the schools to a range of areas. Next, we use dynamic light fields where the radius of the dark region shrinks linearly with time to compress the schools. Through measuring global quantities analogous to density, temperature, and pressure in statistical mechanics, we find that the temperature-like parameter depends on the speed of the compression. We discuss the implications of our results on current models.

1:27PM B65.00010: Mechanics of Snow-diving Animals  LEENA PARK (Presenter), Department of Biological and Environmental Engineering, Cornell University, EMMANUEL VIROT, Harvard University, SUNGHWAN JUNG, Department of Biological and Environmental Engineering, Cornell University — Some fox species plunge-dive to catch prey (e.g. rodents) underneath a pile of snow. This hunting behavior is known as “mousing.” In this behavior, the diving speed can range between 2 and 4 m/s. Here, we investigate how foxes dive into snow without alerting prey. An important factor to consider in this mousing process is the impact on snow. Snow is a compressible fluid consisting of 1~10% ice and the rest of air. When a tapered object (in this case, a fox’s head) compresses or dives into the snow, the pressure/information front does not propagate fast enough for the prey to detect and escape. Animals that portray this mousing behavior, such as red foxes, arctic foxes, and even servals and other feline species, all generally share a slim, narrow facial structure. In this study, 3D printed fox heads and similar funnel-shaped objects are dropped into a pile of snow to understand the propagation of the pressure in snow and the drag on the object.
1:39PM B65.00011: How to jump without spinning  MADHUSUDHAN VENKADESAN (Presenter), ALEXANDER LEE, ERIC CHAN, Department of Mechanical Engineering and Materials Science, Yale University — The remarkable displays of jumping in animals like frogs have inspired many studies on how their muscles generate power. However, in their natural habitats, these animals typically push off against muddy and unpredictably compliant terrains that induce the feet to apply unequal forces on the ground. This may result in substantial angular momentum at take-off, and have dire consequences such as the animal's mouth pointing away from an intended prey, or landing in ways that prevent escaping a predator. We investigated whether morphological features of jumping animals may alleviate this critical problem and help them to jump without spinning. Our analyses and experiments with a brainless passive mechanical jumper focus on the dynamics within the frontal plane as it pushes off unequally using two legs. We find that a flexible pelvis is sufficient to reduce the angular momentum due to unequal leg forces by several orders of magnitude in both our experiments and mathematical analyses. A flexible pelvis acts like a whiffletree mechanism that can balance loads between the legs. Our scaling analyses of these jumpers suggest passive mechanical designs for robotic jumpers and point to the critical role of pelvis morphology in jumping animals for stability.

1:51PM B65.00012: Geckos reconfigure control modules to self-right on diverse substrates  BENJAMIN MCINROE (Presenter), University of California, Berkeley, THOMAS LIBBY, University of Washington, DANIEL E KODITSCHEK, University of Pennsylvania, ROBERT FULL, University of California, Berkeley — Animals synergistically employ multiple appendages and body segments to perform behaviors. We hypothesize that these controllable components can be represented by sets of simple models (templates), recruited in series or parallel to provide multiple strategies for executing a maneuver. As the physics of substrate-body interaction changes, these control modules may be reconfigured for new functions, enabling task completion in new environments. To further define our conjecture, we measured terrestrial self-righting in geckos. On flat, rigid surfaces, geckos self-righted with average righting times of 0.22 ± 0.03 s using dynamic motions including body torsion and tail-ground contact. When placed on a partially excavated surface where the tail could not make ground contact, average righting time increased by 40%. However, righting time decreased to 0.19 ± 0.02 s if the geckos used a new strategy, swinging the tail in a way similar to inertial air righting. Body-level behavior was invariant to the dichotomy in tail control. From our experiments, we begin to develop composable templates for terrestrial righting. Our results suggest that geckos employ the tail as a multifunctional control module in parallel with a body torsion template to increase robustness to challenging substrates.

2:03PM B65.00013: Tuning impulsive mechanisms to their environment*  SATHVIK DIVI (Presenter), Mechanical Engineering Department, Carnegie Mellon University, MARK ILTON, Department of Physics, Harvey Mudd College, XIAOTIAN MA, SARAH BERGBREITER, Mechanical Engineering Department, Carnegie Mellon University — Organisms like fleas and froghoppers achieve fast repeatable motions due to the presence of highly tuned impulsive mechanisms; a motor slowly loads a spring, and this stored energy is quickly released by a latch. In this work, we explore how the latch and spring parameters are tuned to their environments to maximize performance. An analytical model is constructed to include both impulsive system parameters (e.g., mass, spring, latch) as well as the compliance and inertia of the environment. Simulations are then performed across the design space to understand the tuning relationship between the latch, spring and substrate (environment) parameters. These results are validated experimentally using an 8-gram robot for which latch and spring parameters can be changed. This robot is then tested on multiple compliant substrates. Results demonstrate that the latch and spring parameters can be tuned to their environment to maximize take-off velocity. Certain combinations of latch/spring/environment parameters result in recovery of energy from the compliant substrate thereby resulting in higher performance, and ultimately efficient, fast, and repeatable motions.

11:15 AM B66.00001: Self-repairing symmetry in jellyfish* [invited] LEA GOENTORO (Presenter), MENGSHA GONG, Division of Biology and Biological Engineering, California Institute of Technology, CHIN LIN GUO, Institute of Physics, Academia Sinica, Taiwan — Standing on a British shore a century ago, D’Arcy Thompson wondered whether the shape of a medusa can be likened to the equilibrium form of a gelatinous drop. While many study how animals get their shapes during development, less is understood about how or whether animal shape is regulated in adulthood. We pursue this question of animal shape regulation in the moon jellyfish, Aurelia aurita. Using grafting and mechanical modulations, we found that Aurelia shape is governed by a morphogenetic system with multiple equilibria – such that we can make jellyfish with various stable shapes, including oval, rectangular, and triangular. Further, combining experimental and mathematical analyses, we found evidence that the shape of a medusa is governed as a dynamic equilibrium of the underlying tissue mechanics. Thus, as Thompson envisioned, belying its calm majesty, the shape of jellyfish is not statically encoded, but rather a continual balancing act.

11:51 AM B66.00002: On “irreversible” torsion in early chick embryonic brain development* HAO ZHANG (Presenter), HANNAH GROVER, SHICHENG HUANG, GUANGCHAO WAN, ZI CHEN, Thayer Engineering, Dartmouth College — The rightward torsion of the chick embryonic brain tube is one of the earliest organ-level left-right asymmetry developmental events. Previous studies have shown that vitelline membrane (VM) exerts the necessary force on the chicken embryo brain that drives the torsion, and surface tension can replace the mechanical role of VM resulting in a similar degree of torsion at a comparable stage. However, recent experiments show that when the surface tension is removed the torsion does not fully reverse suggesting that there are other overlooked mechanical factors in this process. Here, we show through a combination of in vivo experiments and a physical model of the embryonic morphology that the twisting of the chick embryonic brain tube is partially reversed when the surface tension is removed and the deformation of the early brain can be path dependent. We also studied the effect of embryonic curvature and shape on the degree of torsion, and identified how buoyancy may play a mechanical role in in this “irreversible” brain torsion process.

12:03 PM B66.00003: Motility and adhesion gradient induced vertebrate body axis elongation and somite formation ANUPAM GUPTA (Presenter), LAKSHMINARAYANAN MAHADEVAN, Harvard University — The body of vertebrate embryos forms by posterior elongation from a terminal growth zone called the Tail Bud (TB). The TB produces highly motile cells that eventually constitute the presomatic mesoderm (PSM), a tissue playing an important role in elongation movements. PSM cells establish an anterior-posterior cell motility gradient which parallels a gradient associated with the degradation of a specific cellular signal (Fgf8) known to be implicated in cell motility. As Fgf8 degrades over time, anteriorly positioned cells move less, before eventually coming to a rest as they aggregate into epithelial somites. We show that simple microscopic and macroscopic mechano-chemical models for tissue extension that couple Fgf activity, cell motility, cell density and tissue rheology at both the cellular and continuum levels suffice to capture the speed and extent of elongation. These model qualitatively capture the condensation of cells into somites due to the effect of adhesion in the anterior region. These observations explain how the continuous addition of cells that exhibit an increase in cell density and a gradual reduction in motility combined with lateral confinement can be converted into somite formation in the anterior region and an oriented movement and drive body elongation.

12:15 PM B66.00004: Biomechanics of anteroposterior axis elongation in the chicken embryo ARTHUR MICHAUT (Presenter), Genetics, Harvard Medical School, KARINE GUEVORKIAN, PCC, Institut Curie, OLIVIER POURQUIE, Genetics, Harvard Medical School — In vertebrate embryos, anteroposterior axis elongation is a crucial developmental process resulting in the establishment of the basic body plan and the growth of the embryo from the tail region. In chicken, it has been proposed that a gradient of random cell motility along the presomitic mesoderm (PSM), rather than directed cell movements, drives axis elongation (Bénazéraf et al, Nature 2010). In order to access the physical mechanisms that could explain this process, we study the rheological properties of the PSM and the forces produced due to posterior PSM expansion. Both micropipette aspiration, as well as rounding experiments, show a liquid-like behavior for the PSM, and allow us to measure its viscoelastic properties. In addition, we have developed a novel cantilever-based system to measure the force of axis elongation and we relate it to the cell movements along the axis. We demonstrate that an isolated PSM explant elongates autonomously and contributes to the total elongation force of the embryo, highlighting its role in axis elongation. Taken together, our results provide a first quantitative description of the mechanics of the tail region in the chicken embryo, which will be essential for future modeling of axis elongation.
12:27 PM B66.00005: Actomyosin-mediated cytoplasmic flows synchronize the cell cycle in *Drosophila* embryos

AVANEESH NARLA (Presenter), University of California, San Diego, VICTORIA E. DENEKE, Department of Cell Biology, Duke University, ALBERTO PULIAFITO, Laboratory of Cell Migration, IRCCS (Istituto di Ricerca e Cura a Carattere Scientifico), STEFANO DI TALIA, Department of Cell Biology, Duke University, MASSIMO VERGASSOLA, University of California, San Diego — The synchronous cleavage divisions of early embryogenesis require coordination of the cell cycle oscillator, the dynamics of the cytoskeleton and the cytoplasm. As yet, it remains unclear how spatially restricted biochemical signals are integrated with physical properties of the embryo to generate collective cell cycle dynamics. Biochemical oscillations are initiated by local Cdk1 inactivation close to the nuclei and spread through the activity of mitotic phosphatase PP1 to generate cortical myosin II gradients. These gradients generate cortical and cytoplasmic flows that control proper nuclear positioning. Despite being in the very low Reynolds number regime, we find that Stokes flow does not adequately describe these flows. We will describe the physical properties of the flows, its role in nuclear migration and synchronization of the cell cycle in *Drosophila* embryos.

12:39 PM B66.00006: Quantifying the forces associated with body elongation in a chicken embryo

FENGZHU XIONG (Presenter), CHON U CHAN, WENZHE MA, Harvard University, BERTRAND BÉNAZÉRAF, Centre de Biologie Intégrative, Université Toulouse, L MAHADEVAN, OLIVIER POURQUIE, Harvard University — The role of mechanical forces in the context of morphogenesis and growth regulation in an embryo is now well accepted. Yet, it is still a challenge to perform mechanical measurements and manipulations on a whole embryo to obtain quantitative insights. Here we use chick embryos in the gastrulation stage to study how the tissues that form the body axis coordinate their rates of elongation. We found that the coordination and axis straightness are achieved via a positive feedback loop involving mechanics, as revealed by surgical implantation of soft gels and mechanical manipulation with magnetic pins. We also show that cell movement is required for the generation of, and can be a response to, the tissue forces. Finally, we deploy custom tools to apply force-clamps on the embryo over long times to affect both the growth and form of the embryo.

*The authors acknowledge the National Institutes of Health (NIH) for funding support*

12:51 PM B66.00007: Patterns make patterns: how hierarchical self-organization couples cell geometry to biochemical dynamics - Experiment

TZER HAN TAN (Presenter), Physics, Massachusetts Institute of Technology, MANON WIGBERS, FRIDTJOF BRAUNS, Physics, Ludwig Maximilian University of Munich, ZAK SWARTZ, Whitehead Institute, Massachusetts Institute of Technology, ERWIN FREY, Physics, Ludwig Maximilian University of Munich, NIKTA FAKHRI, Physics, Massachusetts Institute of Technology — Many cellular and developmental processes rely crucially on self-organization of protein patterns in space and time. When these protein patterns are coupled to force generation pathways, they can precisely pattern mechanical stress during processes such as cell division or tissue folding. Importantly, these mechanical processes generate shape deformations and cytoplasmic flows, which can modulate intracellular reaction-diffusion dynamics. This suggests a close coupling between cell mechanics and biochemical dynamics. But how do these protein patterns respond to a mechanically changing environment? Here, we use the Rho GTPase driven surface contractions waves in starfish oocytes as a model system to study these effects. By constraining oocytes in microfabricated shape chambers, we found that the behavior of the Rho waves can be qualitatively modulated. Further experiments show that the upstream regulator Cdk1 forms a cytosolic gradient which is modulated by cell geometry, forming a template for downstream pattern formation. We demonstrate that the surface contraction wave is a result of a cascade of coupled protein patterns, which we call ‘hierarchical self-organization’.

1:03PM B66.00008: Patterns make patterns: how hierarchical self-organization couples cell geometry to biochemical dynamics - Theory

MANON WIGBERS (Presenter), Ludwig-Maximilians University Munich (LMU), TZER HAN TAN, Massachusetts Inst of Tech-MIT, FRIDTJOF BRAUNS, Ludwig-Maximilians University Munich (LMU), NIKTA FAKHRI, Massachusetts Inst of Tech-MIT, ERWIN FREY, Ludwig-Maximilians University Munich (LMU) — Many cellular and developmental processes rely crucially on self-organization of protein patterns in space and time. When these protein patterns are coupled to force generation pathways, they can precisely pattern mechanical stress during processes such as cell division or tissue folding. Importantly, these mechanical processes generate shape deformations and cytoplasmic flows which, in turn, can modulate intracellular reaction-diffusion dynamics. This suggests a close coupling between cell mechanics and biochemical dynamics. But how do these protein patterns respond to a mechanically changing environment? Here, we use the Rho GTPase driven surface contractions waves in starfish oocytes as a model system. We combine experimental results with a reaction-diffusion model and show how a cascade of coupled protein patterns creates a feedback loop between the Rho membrane dynamics and the cell shape. We posit that such hierarchical self-organization is a general mechanism for cells to sense changes in its global geometry.
1:15PM B66.00009: Tuning biochemical patterns by dynamic mechanical deformations  MELIS TEKANT (Presenter), PETER FOSTER, NIKTA FAKHRI, Massachusetts Institute of Technology — Throughout embryonic development biochemical patterns are crucial for initiating and guiding vital cellular processes. As the geometry of the biological system evolves, patterns also adapt to reflect the new geometry, suggesting that patterning and geometrical deformations are closely coupled. Yet the mechanisms underlying this coordination are not fully understood. Here, we use cortial Rho activity in the oocytes of the starfish *Patricia miniata* as a model system to explore such coupling in evolving mechanochemical systems. In addition to being highly deformable, the oocyte exhibits versatile and tunable dynamical patterns on the membrane. Through the use of micropipette aspiration, we impose geometrical constraints on the oocyte that can be actively tuned. The evolution of the pattern in response to the changing geometry is probed in real time, revealing the underlying properties of the dynamics. This method provides a novel approach to studying the interplay between biochemical patterning and mechanically evolving biological systems.

1:27PM B66.00010: Active mechanics of starfish oocytes  PETER FOSTER (Presenter), NIKTA FAKHRI, Massachusetts Institute of Technology — During meiosis, starfish oocytes exhibit a dramatic surface contraction wave characterized by a band of large-scale deformation traveling from the vegetal pole to the animal pole. This inherently mechanical process is driven by active stresses generated by actomyosin contraction. What are the mechanical properties of these oocytes? How can modulating cytoskeletal organization affect the emergent mechanics and the contraction wave dynamics? Here, we present experimental results beginning to address these questions. Using micropipette aspiration, we find that the mechanical properties are well described by a modified Maxwell model, allowing us to quantitatively measure the viscosity, surface tension, and elastic modulus. These mechanical measurements are complemented by work combining quantitative light microscopy and pharmacological inhibition to assess cytoskeletal contributions to the emergent contraction wave dynamics. For example, using the actin inhibitor cytochalasin D, we find a dose dependent decrease in the magnitude of the contraction. This work represents a step towards understanding cytoskeletal contributions to the emergent dynamics and mechanics in starfish oocytes and in actin cortices more generally.

1:39PM B66.00011: Steady-state contractile actin flow in *Xenopus* egg extract droplets  JIANGUO ZHAO (Presenter), KENGO NISHI, Faculty of Physics, University of Gottingen, CHRISTOPH F. SCHMIDT, Department of Physics, Duke University — The actin cytoskeleton of eukaryotic cells is a highly dynamic viscoelastic “active material”. A typical cell maintains a cortex lining that supports the cell membrane, a polymer network consisting of actin, myosin motors and a plethora of regulatory proteins. Actin turns over between polymeric and monomeric forms on a time scale of minutes. Myosin motors generate active contractile stresses that can induce large-scale actin flow, which is essential for the transport of cytoplasmic components, locomotion as well as shape changes of cells. How exactly so many interacting biochemical processes result in static or dynamic steady states is unclear. Using water-in-oil droplet containing cytoplasmic extract of *Xenopus laevis* eggs as a model system for an active cytoskeleton, we could produce radially convergent continuous flow of polymerized actin that persist over time scales much longer than the turn-over time of a single actin filament. We mapped the spatiotemporal distribution of this contractile persistent actin flow. Interestingly, we found that macromolecular cargo present in the extract gets transported into the center of the droplet and compacted into a jammed state. We demonstrated this by tracking embedded IR fluorescent single-walled carbon nanotubes as mechanical probes.

1:51PM B66.00012: Mechanical competition leads to dynamic instabilities and heterogeneity in stem-cell derived cardiomyocytes*  DANIEL HÄRTTER (Presenter), TIL DRIEHORST, Third Institute of Physics-Biophysics, University of Göttingen, WOLFRAM ZIMMERMANN, Institute for Pharmacology, University of Göttingen Medical School, CHRISTOPH F. SCHMIDT, Department of Physics, Duke University — Cooperative and synchronized contraction of sarcomeres is important for the optimal function of cardiomyocytes. Theories of collective molecular motor dynamics, however, predict the possibility of emergent phenomena such as dynamic instabilities and spontaneous oscillatory motion due to non-monotonic force-velocity relations. We have tracked the contractions of individual sarcomeres in stem-cell derived cardiomyocytes by endogenous fluorescent labeling of α-actinin 2 using CRISPR/Cas9 technology. Cardiomyocytes were attached to micropatterned elastic substrates with various Young’s moduli between 7 and 60 kPa. On soft substrates, sarcomeres in one cell contracted coherently, whereas contractions became increasingly incoherent and heterogeneous with increasing substrate stiffness. These findings suggest that competition between sarcomeres, enforced by rigid mechanical boundary conditions, perturbs dynamic coherence. Using a simple dynamic model, we show that elastic coupling of z-lines to the substrate in conjunction with a non-monotonic force-velocity relation can account for many of the observed features.

*ERC
2:03PM B66.00013: Cilia coordinated temporal-spatial flow in the mammalian brain* YONG WANG (Presenter), Fluid Physics, Pattern Formation and Biocomplexity, Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany, SHOBA KAPOOR, Genes and Behavior, Max Planck Institute for Biophysical Chemistry, Göttingen, Germany, CHRISTIAN WESTENDORF, Fluid Physics, Pattern Formation and Biocomplexity, Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — The walls of the ventricular system of mammalian brain are lined with ependymal cells, each of which sprouts a bundle of cilia that constantly beat and thereby maintain directional cerebrospinal fluid (CSF) flow. A transport network driven by coordinated motile cilia inside the ventral third ventricle (v3V) was reported recently. This network contains several CSF flow streams, generates flow patterns such as separatrix and whirl, and may coordinate the delivery of CSF components to different target sites within the ventricle. Particle tracking showed that in mouse brain this flow network locally differs between the two sides of the v3V and changes with age, which implies an age-dependent complex delivery system for CSF constituents. We also studied numerically the contribution of the temporal-spatial flow pattern to the overall CSF flow within the 3D ventricular cavity, and uncover likely physiological consequences of the flow pattern.

*We thank the Max Planck Society for financial support.

Monday, March 4, 2019 11:15 AM - 2:15 PM

Session B67 APS/SPS: Undergraduate Research II B67.00001: Visualizing Contact Area Growth in Frictional Interfaces* THOMAS PILVELAIT (Presenter), SHMUEL RUBINSTEIN, School of Engineering and Applied Sciences, Harvard University, SAMUEL DILLAVOU, Physics, Harvard University — Seemingly static interfaces between two solids are in fact dynamic. These multicontact interfaces (MCIs) exert enormous stresses on tiny contact areas, causing time-dependent deformation, also known as aging. Though these phenomena are ubiquitous in engineering and the sciences (e.g. from micromachines to plate tectonics), their underlying mechanisms are not yet well understood. Quantitative, 2D measurements of the real contact area between a polymer solid and a glass plate are obtained over a variety of normal loads and time steps. By varying geometric and elastic properties of our samples, we induce variations in the 2D structure of contact growth, which give insight into the mechanisms that produce aging in frictional interfaces.

*T.P. acknowledges support from the Harvard College Research Program.

B67.00002: Ultrafast Laser Ablation of Graphene under Water Immersion* ETHAN RICHMAN (Presenter), MAC SELESNICK, YU-TIEN CHOU, YANPEI DENG, LOGAN KAEBLING, ZIWEI LIANG, GREY MCALAINE, CAMERON MILLER, CHRISTOPHER LAFRATTA, PAUL CADDEN-ZIMANSKY, Bard College — We report on a technique to pattern 2-D materials by ultrafast laser ablation. This resist-free method is performed in single step using a Ti:sapphire laser coupled to a microscope with a programmable x-y stage. While close examination of samples ablated in ambient air revealed persistent defects, a novel modification to the technique by carrying out the ablation under water immersion dramatically reduced the observed defects. In addition to using this technique to create submicron graphene wires, its application to other 2-D materials, such as hexagonal boron nitride, is detailed.

*We thank the Sherman Fairchild Foundation for funding, as well as the Bard Summer Research Institute.

B67.00003: Theoretical Study of Amorphous Graphene* VICTOR BARONE (Presenter), BLAIR TUTTLE, Penn State Erie — Amorphous graphene is a two-dimensional sheet of carbon atoms with three fold coordination. The atoms in amorphous graphene mostly form hexagons but there are regions of interconnected 5, 6, 7 and 8 sided objects with carbon atoms at the vertices. Here we use density functional calculations to explore the mechanical and electronic properties of amorphous graphene.

*Research supported by Tuttle’s NSF RUI-DMR 1506403. This research was conducted using Advanced Cyber Infrastructure computational resources provided by The Institute for Cyber Science at The Pennsylvania State University.
**11:51 AM B67.00004: Mechanism to Generate Larger Strain in Two-Dimensional Materials**

MELISSA BOWMAN (Presenter), ANGELA COE, GUOHONG LI, EVA ANDREI, Rutgers University, New Brunswick — Two-dimensional (2D) materials, especially graphene, are very sensitive to strain due to every atom residing at the surface. Theory predicts that when graphene experiences large strain, its electronic properties change dramatically. In particular for strain in excess of 20% a strain-dependent gap is expected to develop in its band structure, providing a mechanism to switch its transport properties on and off. Thus far however strain levels achieved with standard techniques could not exceed a few percent. We present a piezoelectrically controlled technique that can introduce, in a controlled way, a continuously variable amount of uniaxial strain in 2D materials reaching up to ~25% where graphene ruptures.

*Work supported by NSF-DGE 1842213 (A.M.C.), DOE-FG02-99ER45742 (E.Y.A.), NSF-MRI 1337871 (G. L.), and NSF-DMR 1708158 (G.L.).

**12:03 PM B67.00005: Effect of Lattice Mismatch Strain in Oxygen Deficient Strontium Titanate Films**

FRANCIS WALZ (Presenter), JOSEPH CARTELLI, AZRIEL WEINREB, ANTON WIGGINS, JEFFREY SIMPSON, RAJESWARI M KOLAGANI, Towson University, OLEKSIY SVITELSKI, Physics, Gordon College — SrTiO3 (STO) is a quantum paraelectric material which exhibits electronic phenomena that are interesting for technological applications. Applications of STO include its use as a dielectric layer in semiconductor devices, and as a photocatalytic material. Varying the oxygen content in STO affects the crystal structure and electronic properties which are important for such applications. In oxygen deficient STO (SrTiO3-y), the valence of the titanium ion and the average ionic sizes are different from those of the stoichiometric form (SrTiO3), leading to structural and electronic changes. Our study focuses on the structure and electronic properties of oxygen deficient epitaxial thin films of STO grown by Pulsed Laser Deposition on substrates with varying degrees of lattice mismatch. Previous work in our laboratory has shown that tensile strain promotes oxygen deficiency in epitaxial thin films of another perovskite oxide CaMnO3-y. Such coupling may be employed to engineer novel phases in thin films. We explore whether a similar coupling between strain and oxygen stoichiometry is present in STO. We will present the results of x-ray diffraction, electrical conductivity, Raman spectroscopy and atomic force microscopy studies.

**12:15 PM B67.00006: Annealing and Characterization of Niobium Oxide Films Deposited With Atomic Layer Deposition**

ANDREW H. ROWLEY, ZACHARY ROBINSON (Presenter), SUNY Brockport, ALEXANDER C. KOZEN, ASEE Postdoctoral Fellow residing at U.S. Naval Research Laboratory, MARK TWIGG, SHARKA PROKES, U.S. Naval Research Laboratory — Niobium oxides have seen a rise in interest due to their potential usefulness in optical, electronic, and memristive devices. Specifically, Nb2O5 and NbO2 have bandgaps of ~3.5 eV and ~1.2 eV, respectively. Nb2O5 is a high-k dielectric (k~41) and has a high refractive index (n~2.2). Both materials have the potential to be used in nonvolatile or volatile memristor devices. Amorphous thin-films of Nb2O5 and NbO2 were grown with atomic layer deposition on 4" Si(110) wafers with native oxide. The wafers were diced into 1 cm squares, and annealed in both inert and reducing environments in an atmospheric pressure tube furnace. The anneals were performed for up to 120 minutes, with temperatures ranging from 550 °C up to 1000 °C. It was found with X-ray diffraction and Raman spectroscopy that the amorphous Nb2O5 crystallizes at 550 °C, and nucleates crystalline NbO2 islands at 750 °C. Anneals performed at 1000 °C were found to be fully recrystallized as NbO2. As-deposited amorphous NbO2 was found to crystallize at similar temperatures. For both NbO2 and Nb2O5, trends were observed in the sample morphology, indicating that annealing temperature and duration are important in the reduction and recrystallization of as-grown Nb2O5 and NbO2 on SiO2.

**12:27 PM B67.00007: Perovskite Films on Plasmonic Metamaterials**

ASSATA ACEY (Presenter), Physics, Bryn Mawr College, GIORGIO ADAMO, HARISH KRISHNAMOORTHY, CESARE SOCI, Physics and Applied Physics, Nanyang Technological University, MICHAEL LIM, Physics and Astronomy, Rowan University — Perovskites are of rising importance for current applications in the field of sustainable energy. Of particular interest are the optical properties of patterned perovskite films. The properties of these gratings have been studied with simulations in COMSOL, providing predictions of how the reflection and absorption at different wavelengths may be tuned by varying the configuration of perovskite-coated gratings. Using inputs values for n and k determined through ellipsometry of the perovskite film, this work has led to promising grating designs that are now candidates for testing. One fabricated grating did not perform according to prediction, implying degradation in the material over time that was later confirmed.

*The authors acknowledge support from NSF-IRES 1559410.
12:39PM B67.00008: Optical properties of AlAu alloyed and intermetallic thin films* ABDUL QADEER REHAN (Presenter), MARIAMA REBELLO SOUSA DIAS, University of Richmond — Noble metal alloys have been widely investigated as an alternative to pure metals for improving the optical response of optoelectronic devices operating in the visible range of the electromagnetic spectrum. However, their use is hardly extended to the ultra-violet (UV) range. As an alternative, aluminum-based alloys could expand the functionality of photonic devices into the UV range of the spectrum. In this work, we fabricated and measured the optical response of a binary mixture of gold (Au) and aluminum (Al) thin films. The thin films were deposited on a glass substrate via the co-sputtering method. The dielectric functions were measured using spectroscopic ellipsometry. Also, we investigated how the optical response of the thin films changed under a wide range of temperatures, from 25°C to 200°C. We demonstrate that, in some cases, a bimetallic material can outperform their pure metal counterparts after the temperature treatment, e.g., Al0.15Au0.85 shows an increased quality factor of its localized surface plasmon (QLSP) than pure Au and Al. Moreover, we observe that Al-rich thin films are stable, no significant changes were noticed in its dielectric function, as temperature increased.

*University of Richmond Arts & Sciences Summer Fellowship.

12:51PM B67.00009: Exploring the effects of bismuth clustering on the energy band gap of GaBi\textsubscript{x}As\textsubscript{1-x} semiconductors* JOHN CARLTON (Presenter), ARTHUR LIN, GARNETT BRYANT, University of Maryland, College Park, JQI, NIST — Substituting Bi anions in place of As allows for effective tuning of the energy band gap of GaBi\textsubscript{x}As\textsubscript{1-x}. Such band gap control has applications in spintronics (quantum computing) and optoelectronics (photovoltaics). The energy band gap of dilute GaBi\textsubscript{x}As\textsubscript{1-x} alloys is dependent on the alloy configuration, in addition to the alloy concentration. In order to explore the effects of Bi configuration in dilute GaBi\textsubscript{x}As\textsubscript{1-x} alloys, an atomistic, nearest-neighbor, sp\textsuperscript{3}d\textsuperscript{*} tight-binding Hamiltonian is used to determine the energy levels for statistically constructed alloy supercells with random, clustered, and gaussian weighted distributions. By correlating these energies to both qualitative and quantitative measures of Bi clustering, the effects of Bi clustering are explored. From our theoretical calculations, we show that increases in Bi clustering correlate with greater decrease in band gap energies. Additionally, in more densely clustered configurations, we see higher total Bi probability for hole states and faster Bi band broadening congruent with the band anti-crossing model for GaBi\textsubscript{x}As\textsubscript{1-x}.

*This project is funded by the National Science Foundation under DMR – 1505628.

1:03PM B67.00010: Effects of Temperature on the Vibrational Mode Dynamics of Cubane* ANTHONY FROEHLICH (Presenter), GUOPING ZHANG, Indiana State University — Ab initio calculations and the Boltzmann distribution are utilized to determine the effects of temperature on the vibrational modes of cubane. Attention is paid to the propagation of energy throughout the normal modes as temperature changes, providing information about chemical and physical characteristics of cubane and their relationship to temperature. The order in which the energy levels of normal modes increase, the effect of this energy on the movement of atoms in a molecule, and the effects of this movement on chemical characteristics are the desired results of this project.

*US Department of Energy, contract no. DE-FG02-06ER46304 Indiana State University Department of Chemistry and Physics
Monte-Carlo Simulations of Magnetic Ising Models for Sodium Cobaltate*

JOSEPH LANIER (Presenter), Xavier University, PATRICK T GEMPERLINE, Physics, Auburn University, DAVID MORRIS, Xavier University — Sodium cobaltate is a material whose physical properties depend strongly on the concentration of sodium. It is unique because it acts as a thermoelectric material, and a superconductor at different concentrations of sodium. The sodium ions move within layers sandwiched between CoO2 layers. The sodium ions can occupy two different types of site; one low energy and one high energy. These sites neighbor each other, and by representing the two sites as pseudospin vectors pointing to the occupied site, we can study the ordering of sodium ions by simulating how the pseudospins interact with each other via the Ising Hamiltonian. This is done with the use of a Monte-Carlo Metropolis simulation with the results being presented here. The code is used to study the lowest energy structure of sodium cobaltate at different sodium concentrations.

*Hauck Foundation

Specific heat of Pr1-xNdxOs4Sb12*

YEH-CHIA CHANG (Presenter), SHOJI D HISHIDA, PEI-CHUN HO, California State University, Fresno, M BRIAN MAPLE, UC San Diego, TATSUYA YANAGISAWA, Hokkaido University — Filled skutterudites are the compounds that show the formula RM4X12. R is the rare earth metal, M is the transition metal, and X is the pnictogen. They will show rich varieties of strongly correlated electron behaviors, which attract our interest. The sample we focus on is a doping system, Pr1-xNdxOs4Sb12. PrOs4Sb12 show unconventional superconductivity, while NdOs4Sb12 exhibit ferromagnetism at low temperature. Therefore, there is a competition between two properties. In order to understand the compound better, we do the heat capacity measurement from 11K to 300K. From the curve of the specific heat of Pr1-xNdxOs4Sb12, parameters can be extracted out by the curve fitting with a combination of the Debye, Einstein, and Sommerfeld models. These parameters include Debye temperature, Einstein temperature, and electronic specific heat coefficient and can show the properties of the materials, such as the stiffness of the crystal structure, the rattling effect of the rare earth metal, and electron correlation. From the data analysis, we try to find out the trend of parameters depending on Nd concentration.

*Research at CSU-Fresno is supported by NSF DMR-1506677; at UCSD by US DOE DE-FG02-04ER46105 and NSF DMR-1810310; at Hokkaido U. by JP15H05885 and JP18H04297.

Investigating the Far-IR Optical Properties of Hg1-xCdxSe Semiconductor Alloys*

JOHN W LYONS (Presenter), FRANK C PEIRIS, Kenyon College, GREGORY N BRILL, U.S. Army Research Laboratory — Far-IR reflectivity was used to analyze phonon modes and obtain dielectric functions of a series of Hg1-xCdxSe thin films deposited on both ZnTe/Si(112) and GaSb(112) substrates. The data were supplemented by ellipsometric scans in the mid-IR to visible range to assist in modeling the dielectric functions. The combination and simultaneous modeling of these data allowed the determination of not only the phonon and free-carrier activity but also the complex dielectric function over an extremely large range of energies.

*The work at Kenyon is funded by DMR-1609245

Floquet Hofstadter Butterfly on the Kagome and Triangular Lattices*

ARIEL BARR (Presenter), LIANG DU, QI CHEN, AARON BARR, GREGORY FIEITE, University of Texas at Austin — Recently, the interactions of materials with light have attracted considerable interest from the materials science community. "Hofstadter's butterfly" refers to a fractal energy spectrum which occurs when a perpendicular magnetic field of extreme magnitude distributes the electronic energy levels of a lattice in a pattern resembling a butterfly. Lattices with a Hofstadter spectrum exhibit quantum Hall conductance, and under the influence of periodic driving, produce pairs of counter-propagating chiral edge modes which are robust against static disorder. We use Floquet theory to theoretically study the influence of a periodic driving potential provided by monochromatic circularly and linearly polarized light on the Hofstadter butterfly energy spectrum and Chern numbers of Kagome and triangular lattices. We find that as the lattices are exposed to driving, dramatic changes in the energy spectrum occur: reflection symmetry is broken, band width is altered, band inversion is observed, and polarization directional dependence can be identified. Further, we identify polarization-directional dependence of the Chern numbers. This work is currently under review at Phys Rev B, and can be found on Arxiv: arXiv:1808.02057

*We gratefully acknowledge funding from the Army Research Office and NSF.
2:03PM B67.00015: Cytoskeletal Dynamics of Neurons Measured by Combined Fluorescence and Atomic Force Microscopy*  PETER MOORE (Presenter), CRISTIAN STAII, Tufts University — Mechanical properties of neurons represent a key factor that determines the functionality of neuronal cells and the formation of neural networks. The main source of mechanical stability for the cell is a biopolymer network of microtubules and actin filaments that form the main components of the cellular cytoskeleton. This biopolymer network is responsible for the growth of neuronal cells as they extend neurites to connect with other neurons, forming the nervous system. Here we present experimental results that combine atomic force microscopy (AFM) and fluorescence microscopy to produce systematic, high-resolution elasticity and fluorescence maps of cortical neurons. This approach allows us to apply external forces to neurons, and to monitor the dynamics of the cell cytoskeleton. We measure how the elastic modulus of neurons changes upon changing the ambient temperature, and identify the cytoskeletal components responsible for these changes. These results demonstrate the importance of taking into account the effect of ambient temperature when measuring the mechanical properties of cells.

Session B69 FED: The Role of Physics Departments in Educating Teachers BCEC 052A - Monica Plisch, American Physical Society APS - Tag(s): Education, Invited, Undergraduate

11:15AM B69.00001: The national landscape for STEM teacher education [invited]  MICHAEL MARDER (Presenter), University of Texas at Austin — For 35 years, STEM education for secondary students in the US has been in a state of crisis. Less than 40% of US high school students take physics, when in most of Europe and Asia 4 years of physics are customary. Computer science is in such shortage that states do not even try to require it, and we scarcely know how many students take it.

The story of the last 35 years is not as bad as it seems. There has been steady progress in some areas, and in some states and at some times strong improvement that went unrecognized. The key to the future is more and better teachers. Through programs such as PhysTEC from the American Physical Society and UTeach, physicists are helping lead the way.

11:51AM B69.00002: Get the Facts Out: Changing the conversation around physics teacher recruitment* [invited]  WENDY ADAMS (Presenter), Physics, Colorado Sch of Mines — The Get the Facts Out campaign is a joint effort between four societies and the Colorado School of Mines to change the conversation about high school and middle school physics, chemistry, and math teaching careers. We have developed a toolkit, based on pilot interventions that show positive results in shifting perceptions among students and faculty, and which have been shown to outperform traditional recruitment efforts, which is designed to be customizable and adaptable to the local situation. The materials and strategies include: (1) both student-facing and faculty-facing resources and a how-to guide for running interactive events, including but not limited to slide decks, clicker questions, and handouts with national survey data on retention, job satisfaction, and student loan forgiveness; (2) sample informational handouts on teacher salaries, comparisons of teacher and faculty salaries, and retirement benefits, with instructions on how to customize these with local data; and (3) brochures and posters that incorporate tested messaging strategies. In this presentation both the tools and the research and development behind them will be shared.

*This work is supported by the National Science Foundation IUSE and Noyce programs DUE-1821710/1821462.

12:27PM B69.00003: Improving undergraduate physics instruction and physics teacher preparation through the use of Learning Assistants* [invited]  VALERIE OTERO (Presenter), University of Colorado Boulder — Undergraduate Learning Assistants (LAs) help faculty make changes to their courses by encouraging active engagement. Through their work with students along with a special pedagogy course, LAs establish empathy for their peers as they learn physics, and they help them navigate large amounts of course material and motive students to persist. Through this process, students, their professors, and the LAs become more attuned to research-based strategies for teaching physics and to the complexities of building equitable learning environments that lead to student success. This sets the stage for better prepared physics teachers and for physics majors to find their way to physics teacher certification programs. In addition, the presence of LAs in courses leads to better learning outcomes, decreased failure rates, and improved outcomes for students from groups traditionally underrepresented in physics. The LA program will be described and program outcomes will be discussed. Conjectures about the mechanisms that are effecting change will also be discussed.

*Partially funded by NSF (#0302134, #0537870, #1557351), the University of Colorado Boulder, PhysTEC, Amgen, HHMI, Ball Aerospace, and Halliburton.
1:03PM B69.00004: A thriving physics teacher preparation program at Rowan University* [Invited]  KARENMagee-Sauer (Presenter), TREVOR I. Smith, PATRICK CHESTNUT, PHILIP LA PORTA, DAVID R. Klassen, Rowan University — The Department of Physics & Astronomy at Rowan University received a 3-year (2015 – 2018) Comprehensive Grant from the PhysTEC program. As part of this grant, Rowan attempted to build a sustainable framework for recruiting, retaining, training, inducting and mentoring future high school physics teachers. Rowan closely followed PhysTEC's “Key Components” for successful high school physics teacher education programs. A strong emphasis at the Rowan PhysTEC site was creating student research opportunities in Physics Education Research, early teaching experiences in a high school setting, an LA program to help recruit interest to teaching, and creating a vibrant high school physics teacher network in the South Jersey region. Another notable aspect was Rowan's success in creating a community within the department dedicated to supporting PhysTEC activities and leveraging our PhysTEC experience into helping gain other external grant opportunities. In this talk, we will present ideas and actions that were particularly successful in sustaining our PhysTEC activities. Rowan University is a Carnegie-classified Doctoral University (Moderate Research Activity) with approximately 19,000 students. Its main campus is located in Glassboro, N.J., 20 miles southeast of Philadelphia.

1:39PM B69.00005: Next Gen PET: An effective, NGSS-aligned curriculum for future elementary teachers* [Invited] EDWARD PRICE (Presenter), California State University, San Marcos — The physical science preparation of prospective elementary school teachers has the potential for long-lasting and far-reaching impact. To this end, the Next Generation Physical Science and Everyday Thinking (Next Gen PET) curriculum has been designed to provide students with learning experiences aligned with the Next Generation Science Standards. Versions of the research-based, guided-inquiry materials are available for either small or large enrollments, and covering either physics or physical science content. These options provide instructors with flexibility regarding content and implementation format, as documented by case studies of faculty members' course designs. An extensive online instructor's guide* includes student and instructor materials, homework activities, videos of experiments and demonstrations, classroom video clips of student interactions, test banks, and more. An associated online faculty learning community** provides an opportunity for faculty to collaboratively improve their instruction, study student thinking and conduct classroom-based research using the Next Gen PET curriculum. The materials are in use by over 50 faculty around the U.S., and a study of over 1,500 students found significant improvements on multiple-choice and constructed-response tasks following the course. This talk will describe the curriculum, instructor resources, student learning outcomes, and online faculty community.

Session B80 APS/SPS: Meet Your Future: Careers in the Private Sector Westin Grand Ballroom B -

Tag(s): Careers, Industry, Undergraduate

11:45AM B80.00001: Meet Your Future: Careers in the Private Sector — FIAP and APS Careers will host a special lunchtime session in which representatives from industry will briefly describe their career path and answer questions about physics careers in the private sector. Topics will include work opportunities for physicists in industry, strategies for successfully pursuing industrial jobs, and advice on how to thrive in this exciting and challenging work environment.

The panelists this year are:
Scott Davis, Analog Devices Senior Manager, Electro-Optical System Development
Rachael Floyd Janis Research, Senior Cryogenic Physicist and Applications Engineer
Amy Herhold, ExxonMobil Director, Physics and Mathematical Sciences
Audra Macie, BAE Systems Senior Principal Systems Engineer
Matthew Thompson, BAE Systems, Technology Development Manager

Note that this session will be held in the Westin Hotel, not the Convention Center. Join us for a slice of pizza and gain many useful insights into this career path.
2:30PM C01.00001: Temperature Dependence of Charge Transport in an Undoped Weyl Semimetal – Y₂Ir₂O₇*
PATRICK LABARRE (Presenter), University of California, Santa Cruz, LIANYANG DONG, Florida State University, JENNIFER TRINH, University of California, Santa Cruz, THEO SIEGRIST, Florida State University, ARTHUR P RAMIREZ, University of California, Santa Cruz
— An undoped Weyl Semimetal (WSM) is predicted to exhibit resistivity varying with temperature as $\rho \propto T^{-4}$ in the presence of a random Coulomb potential screened by thermally generated charge carriers. Here we show that, in hydrothermally grown polycrystalline samples of the WSM Y₂Ir₂O₇, $\rho = \rho_0 T^{-4}$ over four orders of magnitude in $\rho$. The prefactor, $\rho_0$, agrees with theoretical estimates within the random potential model using reasonable materials parameters. The model works well beyond its range of applicability, extending into the high-resistivity region where the Ioffe-Regel parameter, $k_T l \ll 2\pi$.

The importance of strong electron correlations suggests this is behavior characteristic of a "bad-WSM".

2:42PM C01.00002: Higher-Order Symmetry Enriched Topological Phases*
CIARÁN HICKEY (Presenter), VATSAL DWIVEDI, TIM ESCHMANN, SIMON TREBST, University of Cologne — Higher-order topological insulators (TIs) exhibit boundary physics typically associated with lower dimensional TIs, e.g. 2-d second-order TIs exhibit localized 0-d zero energy corner modes. This physics is topologically protected as long as certain lattice symmetries are preserved, akin to topological crystalline insulators. So far, these phases have largely been explored in the context of non-interacting fermion systems. However, we know that symmetries may also "enrich" the physics of interacting topological phases, such as quantum spin liquids or fractional quantum Hall states. Is it possible to realize "higher-order" boundary physics in strongly interacting topological phases? In this talk, we discuss exactly such higher-order symmetry enriched topological phases, including an example of an exactly solvable spin model with a quantum spin liquid ground state that indeed exhibits topologically protected corner modes, a hallmark of second-order TIs.

2:54PM C01.00003: Topological Phases of the Interacting SSH and Kitaev Models on the Bethe Lattice
PATRICK J WONG (Presenter), ANDREW K MITCHELL, School of Physics, University College Dublin — Topological phases of matter have been intensely studied in recent years, but there still remain a number of open questions regarding the interplay of topology and strong interactions in condensed matter systems, including the role of topological invariants. Two prototypical models in one dimension exhibiting non-trivial topological phases are the SSH model and the Kitaev chain. Here we study generalizations of these models on the Bethe lattice, showing that topological phases with bulk zero-modes can be realized in higher dimensions. We then consider interacting versions of these Bethe SSH and Kitaev models with local Hubbard interactions, $U$. These topological Hubbard models are solved exactly in infinite dimensions at $T=0$ using dynamical mean field theory with the numerical renormalization group as an impurity solver.

For the Bethe SSH Hubbard model with interactions $U<U_c$ below a critical strength, bulk gapped sites at $U=0$ develop a power-law pseudogap density of states, while sites with topological zero-mode poles at $U=0$ are augmented by power-law diverging quasiparticle Kondo peaks. A bulk Mott insulating phase is realized for $U>U_c$. A method of characterizing the topological phases of the systems in the presence of interactions based on their Green's functions is discussed.
3:06PM C01.00004: Interacting multi-channel topological boundary modes in a quantum Hall valley system
MALLIKA RANDERIA (Presenter), KARTIEK AGARWAL, Princeton University, BENJAMIN EZEKIEL FELDMAN, Stanford University, HAO DING, HUIWEN JI, ROBERT CAVA, SHIVAJI SONDHI, Princeton University, SIDDHARTH A PARAMESWARAN, University of Oxford, ALI YAZDANI, Princeton University — Quantum Hall ferromagnets (QHFMs) are two-dimensional electronic phases with spontaneously broken spin or pseudospin symmetry whose wavefunctions also have topological properties. Domain walls between distinct broken symmetry QHFM phases are predicted to host gapless one-dimensional (1D) modes that emerge due to a topological change of the underlying electronic wavefunctions at such interfaces. Although a variety of QHFMs have been identified in different materials, probing interacting electronic modes at these domain walls has not yet been accomplished. Here we use a scanning tunneling microscope (STM) to directly visualize the spontaneous formation of boundary modes, within a sign-changing topological gap, at domain walls between different valley-polarized quantum Hall phases on the surface of bismuth. By changing the valley occupation and the corresponding number of modes at the domain wall, we can realize different regimes where the valley-polarized channels are either metallic or develop a spectroscopic gap. This behavior is a consequence of Coulomb interactions constrained by the symmetry-breaking valley flavor, which determines whether electrons in the topological modes can backscatter, making these channels a unique class of interacting Luttinger liquids.

3:18PM C01.00005: Interesting behavior of magnetoresistance in single crystals of CeBi*
BRINDA KUTHANAZHI (Presenter), NA HYUN JO, LI XUANG, YUN WU, SERGEY BUDKO, ADAM KAMINSKI, PAUL CANFIELD, Physics, Iowa State University/Ames Laboratory — Cerium monopnictides, CeX (X= Sb, Bi) have gained renewed interest as potential candidates to host non-trivial topological band structure along with magnetism. High quality single crystals of CeBi were grown out of Bi self-flux. Systematic measurements of temperature and magnetic field dependent resistivity and magnetization were conducted on CeBi. A rich H-T phase diagram was mapped out. Interestingly, extremely large magnetoresistance was observed at low temperature, and large negative magnetoresistance was detected at the intermediate temperature regime. To obtain a better understanding of the system, the electronic structure is also being studied.

3:30PM C01.00006: Orbital Edelstein effect from spontaneous symmetry breaking*
GEREMIA MASSARELLI (Presenter), BRYCE WU, ARUN PARAMEKANTI, University of Toronto — Coupling between charge and spin, and magnetoelectric effects more generally, have been an area of great interest for several years, with the sought-after ability to control magnetic degrees of freedom via electric currents serving as an impetus. The orbital Edelstein effect is a magnetoelectric effect consisting of a bulk orbital magnetization induced by an electric current. It is the orbital analogue of the spin Edelstein effect, in which the carriers’ spin gives rise to the magnetization. The orbital Edelstein effect has recently been investigated in the context of Weyl materials. Motivated by these developments, we examine a toy model in which a crystal exhibits such an orbital Edelstein effect upon symmetry breaking via density-wave order which reduces it to a gyrotrropic crystal class.

3:42PM C01.00007: Observation of Double Weyl Phonons in Parity-Breaking FeSi*  
HU MIAO, Brookhaven National Laboratory, TIANTIAN ZHANG, LE WANG, Institute of Physics, DEREK MEYERS, Brookhaven National Laboratory, AYMAN SAID, Argonne National Laboratory, YILIN WANG, Brookhaven National Laboratory, YOUNGUO SHI, HONGMING WENG, ZHONG FANG, Institute of Physics, MARK DEAN (Presenter), Brookhaven National Laboratory — Condensed matter systems have now become a fertile ground to discover emerging topological quasiparticles with symmetry protected modes. While many studies have focused on fermionic excitations, the same conceptual framework can also be applied to bosons yielding new types of topological states. Motivated by Zhang et al.’s recent theoretical prediction of double Weyl phonons in transition metal monosilicides [Phys. Rev. Lett. 120, 016401 (2018)], we directly measure the phonon dispersion in parity-breaking FeSi using inelastic x-ray scattering. By comparing the experimental data with theoretical calculations, we make the first observation of double Weyl points in FeSi, which will be an ideal material to explore emerging bosonic excitations and its topologically nontrivial properties.

3:54PM C01.00008: Berryogenesis: self-induced Berry flux and spontaneous non-equilibrium magnetism*  
MARK RUDNER (Presenter), Niels Bohr Institute, JUSTIN SONG, Nanyang Technological University — Spontaneous symmetry breaking is central to the description of interacting phases of matter. In this talk I will discuss a new mechanism through which a driven interacting system subject to a time-reversal symmetric driving field can spontaneously magnetize [1]. Strong internal ac fields of a metal driven close to its plasmon resonance may enable Berryogenesis: the spontaneous generation of a self-induced Bloch band Berry flux. The self-induced Berry flux supports and is sustained by a circulating plasmonic motion, which may arise even for a linearly polarized driving field. Berryogenesis relies on feedback due to interband coherences induced by internal fields, and may readily occur in a wide variety of multiband systems. We anticipate that graphene devices, in particular, provide a natural platform to achieve Berryogenesis and plasmon-mediated spontaneous non-equilibrium magnetization in present-day devices.

4:06PM C01.00009: Higher angular momentum band inversions in two dimensions  
JORN W F VENDERBOS (Presenter), YICHEN HU, CHARLES KANE, Physics and Astronomy, University of Pennsylvania — This talk discusses a special class of topological phase transitions in two dimensions described by the inversion of bands with relative angular momentum higher than 1. A band inversion of this kind, which is protected by rotation symmetry, separates the trivial insulator from a Chern insulating phase with higher Chern number, and thus generalizes the quantum Hall transition described by a Dirac fermion. Higher angular momentum band inversions are of special interest, as the non-vanishing density of states at the transition can give rise to interesting many-body effects. We introduce a series of minimal lattice models which realize higher angular momentum band inversions. Interaction effects are considered, focusing on the possibility of electron-hole condensation, which breaks rotational symmetry. We further describe how the notion of higher angular momentum band inversions can be generalized to time-reversal invariant systems. Such band inversions can be viewed as transitions to a topological insulator protected by rotation and inversion symmetry, and provide a promising venue for realizing correlated topological phases such as fractional topological insulators.

4:18PM C01.00010: Real-space recipes for interacting topological crystalline states  
CHEN FANG (Presenter), ZHIDA SONG, Chinese Academy of Sciences, YANG QI, Fudan University — We present a unified scheme for constructing all topological crystalline states, bosonic and fermionic, free and interacting, from real-space building blocks and connectors. Building blocks are finite-size pieces of lower dimensional topological states protected by onsite symmetries alone, and connectors are “glue” that complete the open edges shared by two or multiple pieces of building blocks. The resulted assemblies are selected against two physical criteria we call the “no-open-edge condition” and the “bubble equivalence”, which, respectively, ensure that each selected assembly is gapped in the bulk and cannot be deformed to a product state. The scheme is then applied to obtaining the full classification of bosonic topological crystalline states protected by several onsite symmetry groups and each of the 17 wallpaper groups in two dimensions and 230 space groups in three dimensions. We claim that our real-space recipes give the complete set of topological crystalline states for bosons and fermions, and prove the boson case analytically using a spectral sequence expansion of group cohomology.
4:30PM C01.00011: Non-Topological Majorana Zero Modes in Inhomogeneous Spin Ladders* ROBERT KONIK (Presenter), Brookhaven National Laboratory, NEIL ROBINSON, University of Amsterdam, ALEX ALTLAND, Universitat zu Koln, REINHOLD EGGER, Heinrich-Heine-Universitat, NIKLAS GERGS, Utrecht University, WEI LI, Beihang University, ALEXEI TSVELIK, ANDREAS WEICHSELBAUM, Brookhaven National Laboratory — We show that the coupling of homogeneous Heisenberg spin-1/2 ladders in different phases leads to the formation of interfacial zero energy Majorana bound states. Unlike Majorana bound states at the interfaces of topological quantum wires, these states are void of topological protection and generally susceptible to local perturbations of the host spin system. However, a key message of our work is that in practice they show a high degree of resilience over wide parameter ranges which may make them interesting candidates for applications.

4:42PM C01.00012: Symmetry-protected exceptional rings in two-dimensional correlated systems* TSUNEYA YOSHIDA (Presenter), Department of Physics, University of Tsukuba, ROBERT PETERS, NORIO KAWAKAMI, Department of Physics, Kyoto University, YASUHIRO HATSUGAI, Department of Physics, University of Tsukuba — Emergence of exceptional points in two-dimensional systems is one of the characteristic phenomena in non-Hermitian systems. In this talk, we elucidate the impacts of symmetry on the non-Hermitian degeneracies. In particular, we analyze correlated systems with chiral symmetry in equilibrium where the imaginary-part of the self-energy induces the non-Hermitian phenomenon. Intriguingly, our analysis discover novel topological degeneracies which we call symmetry-protected exceptional rings (SPERs). Furthermore, we demonstrate that SPERs emerge in a correlated honeycomb lattice by employing the dynamical mean-field theory combined with the numerical renormalization group.

The numerical calculations were performed on supercomputer at the ISSP in the University of Tokyo, and the SR16000 at YITP in Kyoto University.

4:54PM C01.00013: Large magneto-elastoresistance in WTe2* NA HYUN JO (Presenter), Department of Physics and Astronomy, Iowa State University/Ames Laboratory, LIN-LIN WANG, Ames Laboratory, PETER P. ORTH, GIL DRACHUCK, SERGEY L. BUD'KO, PAUL CANFIELD, Department of physics and astronomy, Iowa State University/Ames Laboratory — Elastoresistance is the relative change of a material's resistance under strain. Its value depends on two contributions: one coming from changes in the sample's geometry and another from changes of the electronic properties such as carrier densities or scattering rates. In common metals like copper, the geometric contribution dominates a temperature-independent elastoresistance with a value of about 2. In other materials, including Bi, changes in the electronic properties dominate. We find that WTe2 is a member of the second group exhibiting an elastoresistance as large as -20. Moreover, we discover that the magnetic field has a dramatic effect on the elastoresistance in WTe2, resulting in values of elastoresistance in applied magnetic field between -80 to 120. We present a detailed analysis of this phenomenon combining results from DFT calculations and quantum oscillation measurements. We conclude that such large magneto-elastoresistance can be realized in other semimetals with crystal structures similar to WTe2.

*This work is supported by the US DOE, Basic Energy Sciences under Contract No. DE-AC02-07CH11358; Gordon and Betty Moore Foundation EPiQS Initiative (Grant No. GBMF4411). Peter P. Orth acknowledges support from Iowa State University Startup Funds.

5:06PM C01.00014: Topological Order and Subsystem Symmetry JULIAN MAY-MANN (Presenter), TAYLOR HUGHES, University of Illinois at Urbana-Champaign — When a system is invariant under a subsystem symmetry, it is as if it has a "gauge" symmetry on particular subregions. Motivated by this observation, we show that subsystem symmetries can lead to topological features reminiscent of those found in topological gauge theories. This is done by considering a subsystem symmetry generalization of a Chern-Simons field theory. Because of the subsystem symmetry, this model has a robust ground state degeneracy on torus and localized zero energy corner modes.
The concept of topology in condensed matter physics has been widely recognized since the theoretical discovery of topological insulators by Kane and Mele. Recently, the electron correlation effects on topological properties have attracted much attention because of nontrivial features that do not emerge in weakly correlated electron systems, such as topological Kondo insulators, magnetic orders in topological insulators, etc.

In the previous study, it has been elucidated that in the presence of spin U(1) symmetry, even ferromagnetic (FM) systems can acquire topological properties; system with spin U(1) symmetry can have a spin-selective gap which results in nontrivial topological properties. In general, however, spin U(1) symmetry is considered to be broken in heavy-fermion systems because of their strong spin-orbit coupling (SOC). This fact motivates us to ask whether the above topological phases can be realized in the presence of SOC.

In this study, we demonstrate that even in the absence of spin U(1) symmetry, ferromagnetic phases with mirror symmetry can have the topological properties. In particular, we analyze an effective model describing a thin film of SmB$_6$, and find the topological state in a half-metallic FM phase characterized by a mirror Chern number.

**Monday, March 4, 2019 2:30 PM - 5:30 PM**

**Session C02 DMP DCOMP GMAG: Dielectric & Ferroic Oxides -- Magnetolectric Effects**

2:30PM C02.00001: Multiferroics: hidden functionalities beyond magnetolectric coupling [Invited]  MANFRED FIEBIG (Presenter), Department of Materials, ETH Zurich — Requirements to “good multiferroics” are tough. They are supposed to have a spontaneous magnetization and polarization, preferably parallel to each other, with a strong magnetolectric coupling between them. Inevitably, this leads to a multiferroic state that is described by a very complex set of order parameters – complex enough to provide the symmetry degrees of freedom to fulfil so many requirements at once [1]. With the focus on electric-field-controlled magnetic order, it goes unnoticed that these degrees of freedom will permit many functionalities other than a refined magnetolectric coupling. In my talk, I will describe the quest for such functionalities in our group. I will discuss up to four cases. (i) For the multiferroic hexagonal manganites I will show that amplitude and phase of the order parameter may exhibit different coherence length. Taking this into account, we resolve the long-standing controversial question of how exactly the topological ferroelectric state in this system arises [2]. (ii) The emergence of a magnetic bulk phase transition out of the spin structure in the domain walls is shown for (Tb,Dy)FeO$_3$. (iii) Inversion of a ferroelectric and a ferromagnetic multi-domain state in homogeneous external fields is demonstrated: In each domain, the direction of the order parameter is reversed but the domain pattern as such is left untouched [3].

3:06PM C02.00002: Theory of orbital magnetic quadrupole moment and magnetolectric susceptibility* ATSUO SHITADE (Presenter), RIKEN Center for Emergent Matter Science, HIKARU WATANABE, YOUICHI YANASE, Department of Physics, Kyoto University — We derive a quantum-mechanical formula of the orbital magnetic quadrupole moment (MQM) in periodic systems by using the gauge-covariant gradient expansion. This formula is valid for insulators and metals at zero and nonzero temperature. We also prove a direct relation between the MQM and magnetolectric (ME) susceptibility for insulators at zero temperature. It indicates that the MQM is a microscopic origin of the ME effect. Using the formula, we quantitatively estimate these quantities for room-temperature antiferromagnetic semiconductors BaMn$_2$As$_2$ and CeMn$_2$Ge$_{2-x}$Si$_x$. We find that the orbital contribution to the ME susceptibility is comparable with or even dominant over the spin contribution.

*This work was supported by Grants-in-Aid for Scientific Research on Innovative Areas “JPhysics” (Grant No. JP15H05884) and “Topological Materials Science” (Grant No. JP16H00991) from the Japan Society for the Promotion of Science (JSPS), and by JSPS KAKENHI (Grants No. JP15K05164 and No. JP15H05745).
3:18PM C02.00003: Inelastic Neutron Scattering measurements on phonon-magnon coupling in BiFeO3
GUANGYONG XU (Presenter), ZHIJUN XU, National Institute of Standards and Technology, JOHN A. SCHNEELOCH, University of Virginia, JINSHENG WEN, Nanjing University, MASAKI MATSUDA, BARRY L. WINN, DANIEL PAJEROWSKI, Oak Ridge National Lab, YANG ZHAO, National Institute of Standards and Technology, CHRIS STOCK, Univ of Edinburgh, PETER M GEHRING, National Institute of Standards and Technology, T. USHIYAMA, Y. YANAGISAWA, Y. TOMIOKA, TOSHIMITSU ITO, AIST, Japan, ROBERT J BIRGENEAU, Univ. of California, Berkeley — We use inelastic neutron scattering to study phonons in multiferroic BiFeO3. When the low energy optic phonon is probed, an intensity enhancement is observed when the system enters the antiferromagnetic phase at TN=640K. It is interpreted as a possible dynamic coupling between phonons and magnons through the DM interaction. Polarized neutron measurements are performed to confirm the lattice nature of this enhancement, in other words, to show that this is more a “magneto-phonon” mode rather than a “electro-magnon” mode. We will also discuss neutron scattering measurements on higher energy phonons that could also be affected by the proposed dynamic coupling.

3:30PM C02.00004: RIXS excitations of polar magnet Fe2Mo3O8
HSIAO-YU HUANG (Presenter), AMOL SINGH, National Synchrotron Radiation Research Center, ABHISHEK NAG, KEJIN ZHOU, ANDREW WALTERS, MIRIAN GARCIA-FERNANDEZ, Diamond Light Source, JUN OKAMOTO, ASHISH CHAINANI, National Synchrotron Radiation Research Center, YU-MIIN SHEU, Department of Electrophysics, National Chiao Tung University, TAKASHI KURUMAJI, YOSHINORI TOKURA, Department of Applied Physics, University of Tokyo, CHIEN-TE CHEN, DI-JING HUANG, National Synchrotron Radiation Research Center — Cross control of magnetization (electric polarization) by an external electric (magnetic) field, i.e. magnetoelectric (ME) effect, is a key in designing novel multiferroic devices. The polar magnet Fe2Mo3O8 has been demonstrated to be a promising multiferroic material recently. The ME coupling is not only strong but also compositionally tunable. Upon Zn doping higher than 12.5%, the antiferromagnetic ground state becomes ferrimagnetic state accompanying a change in ME coefficient. To study the electronic structure of (Fe1-xZnx)2Mo3O8, we carried out comprehensive measurements including Hard X-ray photoemission, soft x-ray absorption and resonant inelastic X-ray scattering. Our results disentangle the electronic properties of octahedral and tetrahedral Fe2+ and provide spectroscopic evidence that the doped Zn favors to replace tetrahedral Fe in the doped compound. We observed peculiar temperature and polarization dependences of low-energy RIXS excitations across the phase transition of Fe2Mo3O8.

3:42PM C02.00005: Local magneto-electric response of Cr2O3 investigated with spin polarized positive muons*
MARTIN DEHN (Presenter), Department of Physics & Astronomy and Stewart Blusson Quantum Matter Institute, University of British Columbia, DONALD J ARSENEAU, SARAH R DUNSIGER, BASSAM HITTI, TRIUMF, STEFAN HOLENSTEIN, Physik-Institut, Universität Zürich, MICHAEL FECHNER, Max Planck Institute for the Structure and Dynamics of Matter, HUBERTUS LUETKENS, Paul Scherrer Institut, W ANDREW MACFARLANE, RYAN M. L. MCFADDEN, Department of Chemistry, University of British Columbia, QUINTIN N MEIER, Department of Materials, ETH Zürich, GERALD D MORRIS, TRIUMF, ZAHER SALMAN, Paul Scherrer Institut, NICOLA SPALDIN, Department of Materials, ETH Zürich, ROBERT F KIEFL, Department of Physics & Astronomy and Stewart Blusson Quantum Matter Institute, University of British Columbia — The bulk properties of the prototypical linear magneto-electric antiferromagnet Cr2O3 have been extensively studied. Here, we report on a muon spin rotation (μSR) study using spin polarized muons to probe the local magneto-electric response in order to investigate magnetoelectricity on a microscopic level. We find that the muon, a light interstitial probe, occupies several distinct stopping sites in Cr2O3, and displays a rich dynamic behavior that we interpret in the context of local muon hopping and thermally activated site transitions. Furthermore, when Cr2O3 is prepared in a single magnetic domain, a shift in the local magnetic field is observed in response to an applied electric field, with the sign of the shift depending both on the field direction and domain state. The origin of this apparent magneto-electric effect is discussed.

*NSERC Canada and Stewart Blusson Quantum Matter Institute
3:54PM C02.00006: Magnetoelectric Effect in Type II Multiferroic HoFeWO$_6$  MOEIN ADNANI TAKANTAPEH (Presenter), HUNG-CHENG WU, NARAYAN POUDEL, MELISSA GOOCH, LIANGZI DENG, ZHENG WU, PAUL C. W. CHU, Texas Center for Superconductivity and Department of Physics, University of Houston — In type II multiferroics, the ferroelectricity originates from the magnetic ordering as it breaks the inversion symmetry. In this work, we investigated multiferroicity in HoFeWO$_6$ which belongs to the RFeWO$_6$ (R=Rare-earth) system recently suggested to be type II multiferroic [1]. We found that this compound orders antiferromagnetically below $T_N$ ~17 K. Observation of an anomaly in dielectric constant and dielectric loss, as well as a polarization switchable by an electric field at the same temperature, reveal the ferroelectric nature of this transition.

We further found that below the temperature $T_C2$ ~5 K there appears a polarization ($P_2$) in opposite direction of the ($P_1$) at $T_C1$ ~17 K. While external magnetic field suppresses the polarization in the first transition ($P_1$), at a critical field $H_C1$ ~1T we observe a flipping of the direction of $P_2$. In addition, magnetic field dependent dielectric constant measurements show a magneto-dielectric effect of ~ 1.5% at 2 K for a critical field $H_C1$ ~1T. The metamagnetic behavior at low temperature with similar critical field indicates their direct relationship and the field induced nature of this observation.

4:06PM C02.00007: Electric-field control of magnetization, Jahn-Teller distortion and orbital ordering in ferroelectric ferromagnets* LAN CHEN, CHANGSONG XU, Physics Department, University of Arkansas, HAO TIAN, Department of Materials Science and Engineering, Nanjing University, HONGJUN XIAO, Physics Department, Fudan University, JORGE INIGUZ, Materials Research and Technology Department, Luxembourg Institute of Science and Technology, YURONG YANG (Presenter), LAURENT BELLAIChE, Physics Department, University of Arkansas — Controlling the direction of the magnetization by an electric field in multiferroics that are both ferroelectric and strong ferromagnetic will open the doors to the design of next generation of spintronics and memory devices. Unfortunately, this has never been achieved so far mostly because these materials are very scarce and/or may not have a large enough magnetoelectric coupling. Here, using first-principles simulations, we report the discovery that PbTiO$_3$/LaTiO$_3$ (PTO/LTO) superlattice does possess such highly-desired control, as evidenced by the electric-field-induced rotation of 90° and even full possible reversal of its magnetization in some cases. Moreover, such “wunderbar” systems also exhibit Jahn-Teller distortions, as well as orbital orderings, that are switchable by electric field, therefore making PTO-LTO of importance for the tuning of electronic properties too. Other possible materials possessing such couplings are also discussed, which further renders the presently reported electric controls to be a new general strategy to tune various properties of functional materials.

4:18PM C02.00008: Multiferroic Behavior in Fe doped BaTiO$_3$ single crystals* PETER FINKEL (Presenter), MARGO STARUCH, United States Naval Research Laboratory, HATEM ELBIDWEIHY, ECE Department, US Naval Academy, MARKYS CAIN, Electrosciences, Ltd, PAUL THOMPSON, ESRF — Single crystals of BaTiO$_3$ (BTO) that have been doped at the titanium site with Fe$^{3+}$ or Mn$^{3+}$ have previously been shown to demonstrate large and recoverable electrostrains of up to 0.8 % that is thought to be due to the alignment of defects (i.e. O$^{2-}$ vacancies) with the crystallographic symmetry in the ferroelectric state when the samples are aged.[1,2] There is also the possibility that the incorporation of a magnetic ion could give rise to a magnetic signature and even potentially multiferroic coupling in these doped samples, the possibility of which has not been previously investigated. This would be of great interest as a new path to single phase multiferroic materials. In this presentation, results from magnetic and ferroelectric measurements will be presented for a 0.5% Fe doped BTO crystal. Anomalies in the magnetization at the ferroelectric-ferroelectric phase transitions, magnetocapacitance effects, and changes in the polarization with applied magnetic field confirm the existence of magnetoelectric coupling. The potential origins of this phenomenon will be discussed.

4:30PM C02.00009: Magnetodielectric effect in ErFeO$_3$ single crystals  DONG GUN OH (Presenter), HWAN YOUNG CHOI, YOUNG JAI CHOI, NARA LEE, Yonsei Univ — We investigated magnetodielectric effect of orthoferrite single crystals of ErFeO$_3$, synthesized by the flux method using PbO flux. The canted antiferromagnetic order of Fe$^{3+}$ moments arises below $T_N \approx 640$ K and a spin reorientation transition occurs at $T_{SR} \approx 93$ K, which accompanies the rotation of weak net magnetic moments from the c- to a-axis. As the temperature is further decreased, a long-range magnetic order of $\text{Er}^{3+}$ spins emerges at $T_{ER} \approx 4$ K. From our investigation of anisotropic dielectric constant measurements, the magnetodielectric effect, described as the variation in the dielectric constant by applying external magnetic fields, is found in a broad range of temperature. Especially, the temperature dependence of dielectric constant exhibits a sharp anomaly at $T_{ER}$, as similarly observed in magnetic susceptibility along the c axis. In addition, a nonlinear variation in the isothermal dielectric constant, with a similar hysteretic behavior of the magnetic-field derivative of magnetization, is observed. The simultaneous non-linear variations of isothermal magnetization and dielectric constant below $T_{ER}$ suggest the important role of magnetic rare earth ions in magnetoelectric characteristics of the orthoferrite compound.

4:42PM C02.00010: Magnetoelectric properties in antiferromagnets composed of square cupolas $A$(TiO)Cu$_4$(PO$_4$)$_4$ ($A = \text{Ba, Sr, Pb}$)  YASUYUKI KATO (Presenter), YUKITOSHI MOTOME, University of Tokyo — We study the magnetoelectric properties in a newly synthesized series of quasi-two-dimensional magnets $A$(TiO)Cu$_4$(PO$_4$)$_4$ ($A = \text{Ba, Sr, Pb}$), by the cluster mean-field theory for a minimal quantum spin model [1,2]. The important building block of these compounds is Cu$_4$O$_{12}$ forming antiferromagnetic square cupolas where the local inversion symmetry is absent, and the Dzyaloshinskii-Moriya interaction is activated. By this antisymmetric interaction, the so-called quadrupole type spin configuration is stabilized at zero magnetic field. For nonzero magnetic fields, the magnetization curves are experimentally obtained up to above the saturation field for all $A$, and several anomalies are observed depending on the magnetic field directions. Our analysis well reproduces the full magnetization curves by tuning model parameters. Elaborating the phase diagram of the model, we show that the anomalies are explained by magnetoelectric phase transitions. Our theory also accounts for the dielectric anomaly observed in experiments. Furthermore, we show that the magnetoelectric behavior is well explained by the cluster multipole decomposition of complex spin configurations stabilized under the magnetic field.

4:54PM C02.00011: Realizing Magnetoelectric Coupling with Hydroxide as a Knob$^*$  JINYANG NI (Presenter), Department of physics, Fudan University — Materials with a coexistence of magnetic and ferroelectric order (i.e., multiferroics) provide an efficient route for the control of magnetism by electric fields. Unfortunately, a long-sought room temperature multiferroic with strongly coupled ferroelectric and ferromagnetic (or ferrimagnetic) orderings is still lacking. Here, we propose that hydrogen intercalation in antiferromagnetic transition metal oxides is a promising way to realize multiferroics with strong magnetoelectric coupling. Taking brownmillerite SrCoO$_{2.5}$ as an example, we show that hydrogen intercalated SrCoO$_{2.5}$ displays strong ferrimagnetism and large electric polarization in which the hydroxide acts as a new knob to simultaneously control the magnetization and polarization at room temperature. We expect that ion intercalation will become a general way to design magnetoelectric and spintronic functional materials.

5:06PM C02.00012: Magnetoelectric coupling effect in a new multiferroic RbFe(SO$_4$)$_2$  JUNJIE YANG (Presenter), Central Michigan University — In the past decade, intense efforts have been directed at the discovery of new multiferroic materials. To search new multiferroic materials, a lot of researches have been focusing on frustrated magnets which usually have complicated magnetic structure. For example, multiferroicity has been discovered in a triangular lattice antiferromagnet RbFe(MoO$_4$)$_2$. Recently we successfully grew high quality single crystals of RbFe(SO$_4$)$_2$ which is isostructural to the multiferroic RbFe(MoO$_4$)$_2$. In this work, we will discuss the ferroelectric polarization, dielectric constant and strong magnetoelectric coupling effect in RbFe(SO$_4$)$_2$ single crystals.
5:18PM C02.00013: Loss of spin polarization of tunnelling currents due to electrostatic screening at magnetoresistive ferromagnet/ferroelectric tunnel junctions*  IBRAHIM MISIRIOGLU (Presenter), CANHAN SEN, WAEL ALDULAIMI, OMID MORADI, Sabanci University — Magnetoelectric coupling inherent to the bulk of multiferroic films or control of spin orientation in magnetic layers via piezoelectric strain in composite layers have been two forthcoming approaches to enable electric control of magnetic order. Spin-dependent screening occuring at dielectric/ferromagnetinterfaces is another magnetoelectric effect important for spin selective tunnel junctions. Here, we analyze the spin-dependent screening of ferroelectric polarization in a film interfacing ferromagnetic electrodes using the continuity equations. We show that local spin population (LSP) in spin subbands near the interfaces can dramatically deviate from bulk, which is in qualitative agreement with recent first principles results. We compute the tunneling currents for majority and minority spins using the Wentzel-Kramers-Brillouin approximation and demonstrate that spin polarization tends to disappear for increasing values of ferroelectric polarization in direct connection with the increase in subband LSP for minority spins. We argue that the reduction in TMR due to spin mixing at the interfaces will be much more prominent in comparison to defect scattering and magnon-driven losses in spin polarization.

Session C03 DCMP: Novel Topological Systems BCEC 107B - Haiming Deng, City College of New York

2:30PM C03.00001: Observation of topological edge modes via smart patterning*  DAVID J. APIGO (Presenter), KAI QIAN, CAMELIA PRODAN, New Jersey Institute of Technology, EMIL PRODAN, Yeshiva University — In this talk we present a novel quasi-periodic system supporting topological edge modes made of magnetically coupled mechanical spinners. The system is patterned such that it possesses a naturally multi-gapped phonon spectrum where energy cannot propagate. This behavior occurs solely due to the system’s patterning, no fine tuning of the system is required. Typically, fine tuning in periodic systems is required to break topological symmetry classes; however, due to its unique structure, the reported pattern displays topological behavior. We present experimental results that demonstrate the mapping of chiral bands within the large gaps of the system’s phonon spectrum by scanning over phason shifts in the pattern. By varying the phason, bulk behavior remains unchanged; however, the edge states shift connecting two bulks bands they reside in. This study demonstrates the robust nature of the edge states in the reported quasi-periodic system and suggests that they are novel platforms for studying these unique properties.

2:42PM C03.00002: Electric tuning of topological properties in a symmetric broken gap quantum well  TIAGO DE CAMPOS, University at Buffalo, The State University of New York, MARCELO A. TOLOZA SANDOVAL (Presenter), Universidade Federal da Bahia, LEOVILDO DIAGO-CISNEROS, Departamento de Física Aplicada, Universidad de La Habana, GUILHERME M SIPahi, Instituto de Física de São Carlos, Universidade de São Carlos — A mainstream within topological insulators, GaSb/InAs quantum wells (QWs) present a broken gap alignment for the energy bands which supports the quantum spin Hall insulator phase [1,2] and forms an important building block in the search of exotic states of matter [3]. Such QWs have electrons and holes are confined in different layers, leading to a wide range of possibilities to tune the topological properties. In this work, we study the inverted band structure of a symmetric GaSb/InAs QWs under the influence of an electric field applied along the growth direction, using the 8-band k.p model and the envelope function approximation. Without external fields, the collapse of the energy gap occurs in ~10 nm for the InAs layer (where the conduction and valence states become degenerate) and the application of an electric field opens the gap with an inverted band structure. The behavior of the hybridization gap and of the corresponding edge states are investigated considering a gradual increasing of the electric field modulus, which shows that they can be externally tuned in this system.

2:54PM C03.00003: In-situ Fermi level tuning of semiconductor thin films on graphene during scanning tunneling microscopy studies*  
YULIA MAXIMENKO (Presenter), ZHENYU WANG, CHARLES STEINER, DAVIDE IAIA, VIDYA MADHAVAN, University of Illinois at Urbana-Champaign — Doping can often drive the system into interesting quantum phases such as superconductivity or the pseudo-gap phase. Typically, doping is controlled during fabrication by adjusting the dopant impurity ratios or tuning the chemical composition of the main elements. For a detailed atomically-resolved study of a material with a complex phase diagram, it is beneficial to implement in-situ Fermi level (EF) tuning that can be done by gating. Gating is a somewhat robust technique in transport measurements, but combining it with epitaxial film growth and scanning tunneling microscopy (STM) presents many technical challenges. Here, we report the design of a robust back-gating device for a versatile thin film growth and subsequent EF tuning inside STM. Graphene serves as the platform for epitaxial growth, while a range of materials can be used as an insulating gate depending on the particular experiment. We demonstrate successful EF tuning in both Bi$_2$Te$_3$ and SnTe films in STM. We study the strength of the effect in terms of Schottky barriers between materials, film thickness, and quality of the gate and report a magnetic field study of back-gated thin films of topological insulators.

3:06PM C03.00004: Thermodynamic probe of the bulk gap in the quantum spin Hall insulator 1T'-WTe$_2$*  
SERGIO DE LA BARRERA (Presenter), QINGRUI CAO, Department of Physics, Carnegie Mellon University, JIAQIANG YAN, Materials Science and Technology Division, Oak Ridge National Laboratory, BENJAMIN MATTHEW HUNT, Department of Physics, Carnegie Mellon University — Single-layer 1T'-phase WTe$_2$ has recently drawn great interest as a candidate material for hosting an intrinsic quantum spin Hall insulator state at low temperature, a highly attractive property for numerous studies and applications. Such a state requires topologically-protected helical edge states coincident with a bulk band gap. Initial calculations of the 1T'-WTe$_2$ electronic structure predicted semimetallic bands, however, several studies have shown simultaneous experimental evidence of edge states and a bulk gap in photoemission, tunneling spectroscopy, and electron transport. The nature of this gap, however, is not fully resolved, with disagreements between predicted gaps from first-principles calculations and spectroscopic measurements in various conditions. Here, we probe the thermodynamic properties of fully-encapsulated single-layer 1T'-WTe$_2$ using low-temperature capacitance to illuminate the discussion of this gap and its single-particle or interaction-driven origin.

3:18PM C03.00005: Quantifying charge-to-spin conversion efficiency in magnetically-doped topological insulator heterostructures*  
QUANJUN PAN (Presenter), XIAOYU CHE, QIMING SHAO, Electrical and Computer Engineering Department, University of California, Los Angeles, YABIN FAN, Microsystems Technology Laboratories, Massachusetts Institute of Technology, LEI PAN, HAO WU, PENG ZHANG, MOHAMMAD MONTAZERI, KANG L. WANG, Electrical and Computer Engineering Department, University of California, Los Angeles — We deployed a magneto–optical mangetometer and an electrical loop shift method to directly quantify the charge-to-spin conversion efficiency in a magnetically-doped topological insulator heterostructure. While these two approaches are essentially different in their experimental principles, quantitative agreements are found in values obtained by the two approaches. This consistency strongly suggests both methods can accurately estimate the charge-to-spin conversion efficiency without some ambiguity reported previously with other approaches. The charge-to-spin conversion efficiency, which is parameterized by the spin Hall angle tangent, is estimated to be 0.46 and 0.38 at 12K by the magneto–optical mangetometer and the electrical loop shift method, respectively. This value is at least one order larger than those of conventional heavy metals. Our results also reveal that magneto–optical mangetometer and loop shift methods are both reliable and easily accessible for investigation of magnetization dynamics in TI-based magnetic structures.

3:30PM C03.00006: Investigating the ferromagnetism-induced surface gap formation and effects of optical excitations in Cr-doped topological insulators (TIs)*

Adrian Llanos (Presenter), Department of Materials Science, California Institute of Technology. Chien-Chang Chen, Marcus Teague, Department of Physics, California Institute of Technology. Peng Zhang, Lei Pan, Koichi Murata, Kang Wang, Department of Electrical Engineering, University of California, Los Angeles. Nai-Chang Yeh, Department of Physics, California Institute of Technology — Despite the exciting observation of the quantum anomalous Hall effect (QAHE) in Cr-doped (BixSb1-x)2Te3 compounds, the microscopic origin of ferromagnetism (FM) and the temperature (T) evolution of the anomalous Hall (AH) resistance in these magnetic TIs remain poorly understood. We perform scanning tunneling spectroscopic and electrical transport studies on MBE-grown magnetic TIs, including uniformly 10% Cr-doped (BixSb1-x)2Te3 and bilayer systems consisting of a layer of pure (BixSb1-x)2Te3 on top of a 10% Cr-doped (BixSb1-x)2Te3 layer. In the STS studies on the bilayer system, a surface gap Δ opens up at T_{C2D} ~ 180 K, much higher than the bulk Curie temperature T_{C3D} ~ 35 K determined from the onset of AHE. The spatial distribution of Δ is largely homogeneous, and Δ increases with decreasing T, reaching Δ = (59±7) meV at 147K. Additionally, longitudinal (R_{xx}) and AH (R_{xy}) resistance are measured both with and without light. An increase in R_{xy} and decrease in R_{xx} is observed in the bilayer system under circularly polarized (CP) light (wavelengths λ =1600 ~ 1700 nm). In contrast, both R_{xx} and R_{xy} are suppressed under CP light for uniformly Cr-doped (BixSb1-x)2Te3. The physical implications of these findings will be discussed.

3:42PM C03.00007: Interfaces and superlattices of the topological insulator Bi2Se3*

Niraj Aryal (Presenter), Efstratios Manousakis, Physics, Florida State University and National High Magnetic Field Laboratory — Interface states of topological materials are important for both emergent fundamental phenomena and for their potential application in future electronics and computing devices. Here, we propose different ways of manipulating the position of the energy of the surface Dirac states in the topological insulator (TI) Bi2Se3 relative to the bulk Fermi level, their linearity, their location, etc., by making contact with different materials. Our predictions are made by using density functional theory and model Hamiltonians. For example, in the case of an interface of a TI with a band insulator (BI) we find that the location of the interfacial topological state moves out of the topological insulator boundary to the BI side. When a TI forms an interface with a metal we find that the topological surface states can show oscillatory behavior which propagates inside the metal. We also present results for superlattices formed of a topological insulator with a band insulator.

*This work was supported in part by the U.S. National High Magnetic Field Laboratory, which is funded by NSF DMR-1157490 and the State of Florida.

3:54PM C03.00008: Microwave Impedance Microscopy of WTe2

Joshua Kahn (Presenter), University of Washington, Yanmeng Shi, University of California, Riverside, Zaiyao Fei, University of Washington, Brian A Francisco, Ben Niu, University of California, Riverside, Xiaodong Xu, University of Washington, Yongtao Cui, University of California, Riverside, David Henry Cobden, University of Washington — WTe2 is a van der Waals layered material that behaves as a 2D topological insulator when exfoliated down to a monolayer, supporting edge modes that should be topologically protected. Microwave impedance microscopy (MIM) is a technique that allows real-space mapping of conductivity with a resolution of < 50 nm, and is thus a powerful tool for studying these edge modes that reveals many features that are not accessible to transport measurements alone. Using MIM we observe that the edge is gapless and the edge conduction path conforms to microscopic corners and cracks in the edge and features internal to the monolayer flake. This is consistent with their topological nature and has important consequences for interpreting transport measurements and for making devices employing the 1D helical modes. We also study the behavior of multilayer WTe2, twisted bilayer WTe2, and monolayer WTe2 combined with other materials, such as different capping layers and 2D ferromagnets.

4:06PM C03.00009: Topological Classification Table Implemented with Classical Passive Meta-Materials*

Yafis Barlas (Presenter), Physics, Yeshiva University — Topological condensed matter systems from class A and class AII of the classification table have received classical electromagnetic and mechanical analogs. They topological phases exhibit protected wave-guiding which has been demonstrated experimentally. In this talk, we introduce a map which generates classical analogs for all entries of the classification table, using only passive elements. Physical mechanical models can be realized for all strong topological phases in dimension 2, as well as for three classes in dimension 3. As an example, we will show how the Kitaev topological super-conducting chain and it's braiding properties can be realized in classical systems.

*Keck Foundation
4:18PM C03.00010: Non-Local Spin Transport in Topological Insulator Nanowires  
POK LAM TSE (Presenter), GRACE LU, University of Southern California — The momentum and spin of charge carriers in Topological Insulators (TI) are constrained to be perpendicular due to spin-orbit coupling. Sb$_2$Te$_3$ is a TI material with a bulk band gap of 0.28 eV and surface states consisting of a single Dirac cone in the band gap. Single crystalline Sb$_2$Te$_3$ nanowires were synthesised. E-beam lithography were used to pattern two outer Au leads and two magnetic tunnel junctiion (MTJ) inner leads on individual Sb$_2$Te$_3$ nanowires. The MTJ leads consist of a free Py (Ni$_{80}$Fe$_{20}$) layer, whose magnetization determines the magnitude and direction of spin current injected into nanowire.

The two-point resistance between Au contacts under magnetic field sweep showed positive magneto-resistance, originating from weak anti-localization of carriers in nanowire induced by spin-orbit interaction, serves as evidence of a strong impact of spin orbit interaction in nanowires.

The symmetry of non-local spin valve (NLSV) signal is dramatically different from that of a NLSV with a channel that lacks spin-momentum locking (SML) (e.g. graphene). Two parallel states of the injector and detector magnetic moments give rise to different NLSV voltage values, which is never observed in conventional NLSVs. This unusual symmetry is a signature of SML in Sb$_2$Te$_3$ nanowire surface state.

4:30PM C03.00011: Numerical signatures of topology in disordered insulators*  
DOMINIC REISS (Presenter), ALBERT BROWN, FENNER HARPER, XU LIU, RAHUL ROY, Physics and Astronomy, University of California, Los Angeles — We investigate a number of numerical signatures which distinguish the topological and trivial phases of disordered insulators. In particular, we consider three dimensional systems with time-reversal symmetry (class AII) and numerically construct a set of maximally commuting spin-like operators using local unitary circuits. The properties of the resulting spin operators may be used to identify the topology of the underlying phase. Using similar methods, we also construct analogues of Wannier functions for disordered systems with symmetry. Finally, we discuss extensions of this approach to other spatial dimensions and symmetry classes.

4:42PM C03.00012: Scattering from Monolayer and Bilayer Step Edges on Topological Sb(111)*  
ADITYA MAHADEVAN (Presenter), Physics, Harvard University, HAIMEI ZHANG, Physics, Wellesley College, JIANFENG GE, YANG HE, Physics, Harvard University, ANJAN SOUMYANARAYANAN, ASTAR, SHIANG FANG, JENNIFER HOFFMAN, Physics, Harvard University — The topological semimetal antimony (Sb) has a layered structure that cleaves easily along the 111 plane, typically exposing large, atomically flat terraces separated by bilayer steps. Reflection and transmission of 2D surface states from these step edges can be used to quantify the topological protection against backscattering. Here we use scanning tunneling microscopy (STM) to image the cleaved surface of Sb(111). In addition to the expected bilayer steps, we occasionally find monolayer steps, as well as a combination of mesa, stair, and valley terraces. We use spectroscopic STM to probe the quantized energy levels of surface states on each of these terraces, and compare to the energy quantization that would be expected from the visible terrace width. Our analysis indicates that surface states are more easily transmitted under adjacent terraces, i.e. there is less backscattering from upward step edges.

*Experiments were supported by National Science Foundation DMR-1410480.
Quantized anomalous Hall conductance in a bulk dilute Mn-doped topological insulator Bi$_2$Te$_3$ at high temperatures

4:54PM C03.00013: HAIMING DENG (Presenter), ZHIYI CHEN, SHIHUA ZHAO, City College of New York, SIMON TURKEL, ABHAY PASUPATHY, Physics, Columbia University, LUKASZ PLUCINSKI, Physics, Forschungszentrum Juelich, MARCIN KONCZYKOWSKI, LSI, Ecole Polytechnique, AGNIESZKA WOLOS, Physics, University of Warsaw, KYUNGWHA PARK, Physics, Virginia Tech, LIA KRUSIN-ELBAUM, City College of New York — Thus far Quantized anomalous Hall (QAH) has only been realized in the mK range in ultra-thin (5-10nm) MBE films of heavily Cr- or V-doped (Bi,Sb)$_2$Te$_3$, where the Curie $T_c$ could be as high as 60 K but the onset of Anomalous Hall effect (AHE) was at a much lower $T$. Here we report achieving Hall conductance quantization in the Kelvin range in dilute (2%) Mn-doped thick (50-300 nm) single crystals of Bi$_2$Te$_3$ by taking a different approach to tune the Fermi level $E_F$ into the Dirac gap. Our technique employs high energy-electron beams (2.5MeV) to create charged defect states in the bulk and thermal annealing protocols to control both $E_F$ and the surface bandstructure of the initially n-type Mn-doped Bi$_2$Te$_3$. In contrast to previous work, the magnetization $M$ was found to be mean-field-like and carrier independent, with $M$ and AHE onsetting at the same $T_c$ ~ 13 K. We observe conductance quantization $G_{xy} = 1.0098 \ h/e^2$ not in the bulk gap but on the bulk conduction band where, remarkably, conduction electrons do not contribute to AHE. We will discuss the correlation of surface and bulk AHE with magnetism in this dilute system. The cross-correlation of transport data with STM and ARPES will be discussed.

In gap states in topological Kondo insulators: Optical properties evidence

5:06PM C03.00014: ROBERTO FRANCO PEÑALOZA (Presenter), EDWIN RAMOS, JERESON SILVA VALENCIA, National University of Colombia, MARCOS SERGIO FIGUEIRA DA SILVA, Instituto de Fisica, Universidade Federal Fluminense — We investigate optical properties: ARPES, PES and optical conductivity of topological Kondo insulators; in particular we study the manifestation of In gap states in the ARPES and PES results, taking into account the presence of antiferro-magnetic short range correlations. We consider an additional narrow band to the otherwise completely localized f-electrons, by adding a term to the periodic Anderson model which allows a small hopping of the localized electrons between neighboring sites of the lattice. This new model is adequate to study a novel class of intermetallic 4f and 5f orbitals materials: the Kondo topological insulators. For simplicity, we consider a version of the periodic Anderson model on a two dimensional square lattice. Previously we shows that the anti ferro-magnetic correlations plays an important role on the gap opening of the topological Kondo insulators (1); in this work we discuss the manifestation of the in gap states in the ARPES and PES results, our results for the different symmetry points are similar to the reported for SmB$_6$ (2).

Engineering topological superlattices: Phase diagrams and electronic properties

5:18PM C03.00015: DEEPTI JAIN (Presenter), PAVEL P SHIBAYEV, ELIO KOENIG, MARYAM SALEHI, JISOO MOON, Rutgers University, New Brunswick — So far, the majority of topological materials being investigated have been bulk crystals or thin films. A much less-explored area is combining different topological materials with trivial insulators and creating a new topological phases with distinct electronic properties, in the form of topological superlattices. We have studied a topological superlattice composed of topological insulator Bi$_2$Se$_3$, and normal insulator In$_2$Se$_3$ of different thickness. In this talk, we will discuss the low-temperature magnetotransport measurements and field theoretical calculations which show how the electronic properties of topological superlattices evolve with unit-layer thicknesses. We will further discuss if it is plausible to implement other more complex topological phases such as artificial 3D Dirac and Weyl semimetals from TI superlattices

*Gordon and Betty Moore foundation

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C04 DMP: Dirac/Weyl Semimetals -- Nodal-line Semimetals and Beyond BCEC 107C - Lu Li, University of Michigan - Tag(s): Focus
2:30PM C04.00001: Electronic structure of topological nodal semimetals [Invited] TAY-RONG CHANG (Presenter), Physics, National Cheng Kung University, GUANG BIAN, Physics, U. of Missouri, SUYANG XU, Physics, MIT, GUOQING CHANG, Physics, Princeton U., ARUN BANSIL, Physics, Northeastern U., ROBERT CAVA, Chemistry, Princeton U., HSIN LIN, Physics, Academia Sinica, ZAHID HASAN, Physics, Princeton U. — Topological phases in condensed matter physics have attracted intense worldwide interest in the past decade because these phases lie outside the framework of Landau's spontaneous symmetry breaking paradigm. The early period of the field explored topological insulators (TIs). Three-dimensional (3D) TIs are distinct from the conventional band insulators in that they feature a bulk energy gap driven by spin-orbit coupling effects, and gapless surface states protected by time-reversal symmetry. In the last few years, the focus has shifted from insulators to topological semimetals (TSMs). Three types of TSMs have been identified, namely, Dirac, Weyl, and nodal-line semimetals. Dirac and Weyl semimetals are 3D analogs of graphene in which the bulk band structure disperses linearly from the nodal point in all three momentum directions, while the nodal-line semimetals display 1D nodal loops in the 3D Brillouin zone. In addition to the graphene-type (type-I) TSMs, the novel type-II TSMs where the band dispersion strongly violates Lorentz symmetry have also been studied extensively. In this talk, we will review a range of materials predictions including type-II Dirac semimetals [1], tunable Weyl semimetals [2], and nodal-line semimetals [3-5] by using first-principles calculations, and discuss various exotic phenomena observed experimentally in these compounds.

3:06PM C04.00002: Topological nodal line semimetals without drumhead surface states* QIU-BO CHENG (Presenter), Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, CHING-KAI CHIU, Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, HONGMING WENG, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences — Topological nodal lines are protected by reflection symmetry or space-time inversion symmetry. The symmetries can quantize Berry phase in a proper basis and the π Berry phase stems from the presence of the protected topological lines. However, it has been shown that the only π Berry phase cannot lead to the presence of the stable drumhead surface states, which connect the bulk nodal lines. The other essential condition for the drumhead surface states is that no atoms should be located at the symmetry centers in the crystal structure. However, in condensed matter systems most of the topological nodal line semimetals fail this requirement and possess the drumhead surface states. In this talk, we show several concrete topological nodal line materials not possessing any drumhead surface states. The examples demonstrate that the bulk-boundary correspondence has very strict conditions for crystalline symmetries.

*the Strategic Priority Research Program of the Chinese Academy of Sciences, Grant No. XDB28000000 National key R&D Program of China, Grant No. 2016YFA0300600 NSFC, Grant No. 11421092

3:18PM C04.00003: Material realization of Z2 monopole nodal lines in ABC-stacked graphdiyne JUNYEONG AHN, Department of Physics and astronomy, Seoul National University, DONGWOOK KIM (Presenter), YOUNGKUK KIM, Department of Physics, Sungkyunkwan University, BOHM-JUNG YANG, Department of Physics and astronomy, Seoul National University — A topological nodal line semimetal refers to a topological state of matter characterized by protected one-diemsional gapless excitations in momentum space. Z2 Berry phase nodal line semimetal is one of the most widely studied topological nodal line semimetals with many material realizations. Here, another class of nodal line semimetal exists, referred to as Z2 monopole nodal line semimetals. This class of nodal line semimetal is remained widely unexplored without a suggested material realization yet. Using first-principles calculations, we show that a three-dimensional carbon allotrope, ABC-stacked graphdiyne (ABC-GDY), realizes the Z2 monopole nodal line semimetal [1]. We characterize a Z2 Stiefel-Whitney number and a linking number that dictate the Z2 monopole nodal line semimetal phase in ABC-GDY. We also show that ABC graphdiyne hosts two-dimensional Stiefel-Whitney insulating phase in two-dimensional subsystems of the Brillouin zone, which can be considered as a fragile topological insulator phase. We present nested wilson loop spectrum and hinge state to show the higher order band topology of ABC-GDY as well. Our findings suggest that ABC graphdiyne should serve as a new venue for the study of topological semimetals.
3:30PM C04.00004: Nodal surface semimetals: Theory and materials realization
WEIKANG WU (Presenter), YING LIU, Singapore University of Technology and Design, SI LI, Beijing Institute of Technology, CHENGYONG ZHONG, Chongqing University of Posts and Telecommunications, ZHI-MING YU, Singapore University of Technology and Design, XIAN-LEI SHENG, Beihang University, YUXIN ZHAO, Nanjing University, SI LI, Beijing Institute of Technology, CHENGYONG ZHONG, Chongqing University of Posts and Telecommunications, ZHI-MING YU, Singapore University of Technology and Design — We theoretically study the three-dimensional topological semimetals with nodal surfaces protected by crystalline symmetries. Different from the well-known nodal-point and nodal-line semimetals, in these materials, the conduction and valence bands cross on closed nodal surfaces in the Brillouin zone. We propose different classes of nodal surfaces, both in the absence and in the presence of spin-orbit coupling (SOC). In the absence of SOC, a class of nodal surfaces can be protected by spacetime inversion symmetry and sublattice symmetry, and characterized by a $Z_2$ index, while another class of nodal surfaces are guaranteed by a combination of nonsymmorphic two-fold screw-rotational symmetry and time-reversal symmetry. We show that the inclusion of SOC will destroy the former class of nodal surfaces but may preserve the latter provided that the inversion symmetry is broken. We further generalize the result to magnetically ordered systems and show that protected nodal surfaces can also exist in magnetic materials without and with SOC, given that certain magnetic group symmetry requirements are satisfied. Several concrete nodal-surface material examples are predicted via the first-principles calculations. The possibility of multi-nodal-surface materials are discussed.

3:42PM C04.00005: Possible pressure-induced topological quantum phase transition in the nodal line semimetal ZrSiS
DERRICK VANGENNEP (Presenter), Department of Physics, University of Florida, TIFFANY PAUL, Department of Applied Physics, Stanford University, CHASE W. YERGER, Department of Physics, University of Florida, SAMUEL T WEIR, Physics Division, Lawrence Livermore National Laboratory, YOGESH KUMAR VOHRA, Department of Physics, University of Florida at Birmingham, JAMES J. HAMLIN, Department of Physics, University of Florida — ZrSiS has recently gained attention due to its unusual electronic properties: nearly perfect electron-hole compensation, large, anisotropic magneto-resistance, multiple Dirac nodes near the Fermi level, and an extremely large range of linear dispersion of up to $\sim 2$ eV. We have carried out a series of high pressure electrical resistivity measurements on single crystals of ZrSiS. Shubnikov-de Haas measurements show two distinct oscillation frequencies. For the smaller orbit, we observe that the phase of the oscillations changes by $\sim 0.5$ between $\sim 0.16-0.5$ GPa. This change in phase is accompanied by an abrupt decrease of the cross-sectional area of this Fermi surface. We attribute this change in phase to a possible topological quantum phase transition. The phase of the larger orbit exhibits a Berry phase of $\pi$ and remains roughly constant up to $\sim 2.3$ GPa. Resistivity measurements to higher pressures show no evidence for pressure-induced superconductivity to at least 20 GPa.

3:54PM C04.00006: Observation of Dirac nodal lines in rutile oxide IrO$_2$
JOICENNE NELSON (Presenter), LUCA MORESCHINI, Cornell University, JASON KAWASAKI, University of Wisconsin, Madison, ELI ROTENBERG, Advanced Light Source, Lawrence Berkeley National Laboratory, DARRELL G. SCHLOM, KYLE M SHEN, Cornell University — The complex oxide IrO$_2$ is predicted to be a dirac nodal line semimetal protected by nonsymmorphic symmetry. Some of its intriguing physical properties include a large spin hall effect, significant magnetoresistance, and a hall effect where the sign of the carrier may be controlled by an external magnetic field. Previously there has been no direct evidence of the topological features of the band structure. This is a non trivial prediction because the relevant orbitals Ir 5d and O 2p are known to often host strong electron correlations and spin orbit coupling. Using a combination of reactive oxide molecular beam epitaxy and Angle-Resolved Photoemission Spectroscopy we show that IrO$_2$ is a Dirac nodal line semimetal in agreement with the predictions of Sun et. al. This is the first experimental observation of nodal lines protected by nonsymmorphic symmetry. Significantly the crossing points are protected even in the case of large spin orbit coupling characteristic of iridates. Furthermore they cross the fermi level making IrO$_2$ an ideal system to study the low energy properties of Dirac nodal line materials.
4:06PM C04.00007: Multiple topologically non-trivial bands in non-centrosymmetric YSn$_2$  
YANGLIN ZHU (Presenter), Tulane University, TIANTIAN ZHANG, Institute of Physics CAS, JIN HU, Department of Physics, University of Arkansas, JAMIN KIDD, Tulane University, DAVID E GRAF, National High Magnetic Field Laboratory, XIN GUI, WEIWEI XIE, Department of Chemistry, Louisiana State University, MENGZE ZHU, XIANGLIN KE, Department of Physics and Astronomy, Michigan State University, HUIBO CAO, Quantum Condensed Matter Division, Oak Ridge National Laboratory, ZHIQIANG MAO, Tulane University — We show that, in non-centrosymmetric compound YSn$_2$, the slightly distorted square lattice of Sn generates multiple topologically non-trivial bands, one of which likely hosts nodal line and tunable Weyl semimetal state induced by the Rashba spin-orbit coupling (SOC) and proper external magnetic field. The quasiparticles described as relativistic fermions from these bands are manifested by nearly zero mass and non-trivial Berry phases probed in de Haas–van Alphen (dHvA) oscillations. The dHvA study also reveals YSn$_2$ has a complicated Fermi surface (FS), consisting of several 3D and one 2D pockets. Our first principle calculations show the point-like 3D pocket at Y point on the Brillouin zone boundary hosts the possible Weyl state. Our findings establish YSn$_2$ as a new interesting platform for observing novel topological phases and studying their underlying physics.

4:18PM C04.00008: Unraveling the Topological Nature of ZrSiTe using Scanning Tunneling Microscopy*  
BRANDON STUART (Presenter), JISUN KIM, SEOKHWAN CHOI, University of British Columbia, LESLIE SCHOOP, Chemistry, Princeton, DOUGLAS BONN, SARAH BURKE, University of British Columbia — 3D topological Dirac semimetals have been a topic of immense study since their experimental realization in 2014. The family of materials ZrSiX (X = S, Se, Te) are topological nodal-line Dirac semimetals, which exhibit a nodal-line band crossing encircling the Γ-point, and two Dirac cones at the X-point protected by a non-symmorphic symmetry. From this family, ZrSiS was the first material to be experimentally studied, and was shown to have two Dirac cones at ± 0.5 V [1]. It was predicted that due to the size difference, substituting S with Te would result in a uniaxial strain along the c-axis, shifting the upper Dirac cone towards the Fermi level [2]. Using low temperature scanning tunneling microscopy and spectroscopy we uncover the surface structure of ZrSiTe, which cleaves easily between ZrTe layers. We observe several unique defects, some of which span multiple lattice sites. Furthermore, by employing quasiparticle interference (QPI), we can resolve the scattering properties of the electrons, and unravel the complex topological nature of the band structure.

*Work funded by the following agencies: CFI, CFREF, NSERC, and MPI.

4:30PM C04.00009: Topological Phases of Zintl Compounds Ba$_3$X$_2$Y$_4$ (X=Zn, Cd; Y=As, Sb)*  
TAN ZHANG (Presenter), Chinese Academy of Sciences, SI-MIN NIE, Department of Materials Science and Engineering, Stanford University, HONGMING WENG, ZHONG FANG, Chinese Academy of Sciences — Based on first-principles calculations and effective k.p model analysis, we have studied three Zintl compounds, including Ba$_3$Zn$_2$As$_4$, Ba$_3$Cd$_2$As$_4$ and Ba$_3$Cd$_2$Sb$_4$, to reveal their electronic band topology under different conditions, such as including and not including spin-orbit coupling (SOC) and different external strains. We find that these family materials are close to the boundaries of several topological phases. When SOC is ignored, there are topological nodal lines around Fermi energy due to band inversion between valence and conduction bands at one or two time-reversal invariant momenta, which can be tuned by proper strain. When SOC is further included, these nodal lines are gaped and these materials become weak or strong topological insulators (TIs). They are suitable for studying topological phase transition.

*We acknowledge the supports from the Ministry of Science and Technology of China (Grants No. 2016YFA0300600 and 2018YFA0305700) the National Natural Science Foundation (Grant No. 11674369) and the Chinese Academy of Sciences (Grant No. XDB07000000).
4:42PM C04.00010: Topological hourglass Dirac semimetal in $\text{Ag}_2\text{BiO}_3$  

BAHADUR SINGH (Presenter), Shenzhen University, Shenzhen, China, BARUN GHOSH, Indian Institute of Technology Kanpur, India, CHENLIANG SU, Shenzhen University, Shenzhen, China, HSIN LIN, Academia Sinica, Taipei, Taiwan, AMIT AGARWAL, Indian Institute of Technology Kanpur, India, ARUN BANSIL, Northeastern University, Boston (MA), USA — Materials with tunable charge and lattice degrees of freedom provide excellent platforms for investigating multiple phases that can be controlled via external stimuli. We show how the charge-ordered ferroelectric oxide $\text{Ag}_2\text{BiO}_3$, which has been realized experimentally, presents a unique exemplar of a metal-insulator transition under an external electric field. Our first-principles calculations combined with a symmetry analysis, reveal the presence of a nearly ideal hourglass-Dirac-semimetal state in the nonpolar structure of $\text{Ag}_2\text{BiO}_3$. The low-energy band structure consists of two hourglass-like nodal lines located on two mutually orthogonal glide-mirror planes in the absence of spin-orbit coupling (SOC) effects. These lines cross at a common point and form an interlinked chain-like structure, which extends beyond the first Brillouin zone. Inclusion of the SOC opens a small gap in the nodal lines and results in two symmetry-enforced hourglass-like Dirac points on the $C_2\gamma$ screw rotation axis. Our results indicate that $\text{Ag}_2\text{BiO}_3$ will provide an ideal platform for exploring ferroelectric-semiconductor to Dirac-semimetal transition by the application of an external electric field.

4:54PM C04.00011: Pseudo Dirac-Nodal-Sphere Semimetal  

JIANFENG WANG (Presenter), Beijing Computational Science Research Center, FENG LIU, University of Utah, BING HUANG, Beijing Computational Science Research Center — Topological semimetals (TSMs) in which conduction and valence bands cross at zero-dimensional (0D) Dirac nodal points (DNPs) or 1D Dirac nodal lines (DNLs), in 3D momentum space, have recently drawn much attention due to their exotic electronic properties. Here we generalize the TSM state further to a higher-symmetry and higher-dimensional Dirac nodal sphere (DNS) or pseudo DNS (PDNS) state, with the band crossings forming a 2D closed or approximate sphere at the Fermi level. Such TSM state can exhibit unique electronic properties, such as peculiar collective plasmons, making DNS/PDNS a new type of fermion beyond DNP/DNL paradigm. Despite the difficulties to achieve the ideal DNS state in realistic crystals, we successfully demonstrate two possible types of PDNS states underlied by different crystalline symmetries, which are characterized with a spherical backbone consisting of multiple crossing DNLs and approximate band degeneracy in between the DNLs. Importantly, we identify all the possible band crossings with pairs of 1D irreducible representations to form the PDNS states in 32 point groups. Furthermore, we discover that strained $\text{MH}_3$ ($M = \text{Y, Ho, Tb, Nd}$) and $\text{Si}_3\text{N}_2$ are materials candidates to realize these two types of PDNS states, respectively.

5:06PM C04.00012: Exceptional lines in topological semimetals and superconductors*  

ALEXANDER ZYUZIN (Presenter), Aalto University, KRISTOF MOORS, University of Luxembourg, RAKESH P. TIWARI, McGill University, THOMAS L SCHMIDT, University of Luxembourg — We consider the impact of the disorder on the spectrum of three-dimensional Weyl and nodal-line semimetals. We show that the combination of disorder and a tilted spectrum leads to a non-Hermitian self-energy contribution that can split a Weyl node and nodal line into a single nodal ring and pair of exceptional lines, respectively. In nodal-line semimetals, these exceptional lines form the boundary of an open and orientable bulk Fermi ribbon in reciprocal space on which the energy gap vanishes. We find that the surface of such a disorder-induced bulk Fermi ribbon in general lies orthogonal to the direction of the tilt, which can be exploited to realize a bulk Fermi ribbon with nontrivial topology by means of a tilt vector that twists along a nodal loop.

We also consider the dispersion of the quasiparticles excitations in nodal superconductors in presence of weak disorder. Similarly to the semimetals, the complex self-energy correction to the Green function of quasiparticles due to disorder gives rise to the non-Hermitian BdG Hamiltonian describing the quasiparticle spectrum with exceptional points and lines.

Two-dimensional nonsymmorphic Dirac semimetal in chemically modified group-VA Monolayer with Black Phosphorene structure

KYUNG-HWAN JIN (Presenter), HUAQING HUANG, University of Utah, ZHENGFEI WANG, University of Science and Technology of China, FENG LIU, University of Utah — The symmetry-protected 2D Dirac semimetals have attracted intense interest due to their intriguing properties. Here, we investigate the 2D nonsymmorphic Dirac semimetal state by chemically modified group-VA 2D puckered structure. Based on first-principles calculations, we demonstrated 2D Dirac fermionic states not only exist, but in fact occur with two different types: one is a Dirac nodal line (DNL) structure in one-side modified phosphorene structure with negligible SOC; the other is a hourglass fermion protected by nonsymmorphic symmetry for the heavy elements with strong SOC. In the absence of SOC, the DNL exhibits anisotropic behavior and unique electronic properties, such as constant density of states. The Dirac node is protected from gap opening by nonsymmorphic symmetry. With the inclusion of SOC, the DNL states are split to form the hourglass dispersion due to broken inversion symmetry and Rashba SOC interaction. Moreover, around certain high symmetry points in the Brillouin zone, the spin orientation is enforced to be along a specific direction. The essential physics of 2D nonsymmorphic Dirac states is further analyzed by effective tight-binding models and group theory.

Session C05 DMP: Topological Superconductivity: Twisted Layers, Heterojunctions, Interfaces

BCEC 108 - Arun Bansil - Tag(s): Focus

2:30PM C05.00001: Topological Chiral Superconductor with Spontaneous Vortices and Supercurrent in Twisted Bilayer Graphene

FENGCHENG WU (Presenter), Condensed Matter Theory Center, University of Maryland, IVAR MARTIN, Argonne National Laboratory — We present a study of d-wave superconductivity in twisted bilayer graphene within mean-field theory, and demonstrate new phenomena that arise due to the moire superlattice. In the d-wave pairing, the relative motion (RM) of two electrons in a Cooper pair can have either $d_x$ or $d_y$ symmetry, which carry opposite angular momenta. Due to the enlarged moire superlattice, the center-of-mass motion (COMM) can also carry a finite angular momentum without breaking the moire periodicity. By matching the total angular momentum, which has contributions from both the RM and the COMM, $d_x$ and $d_y$ RMs are intrinsically coupled in a way such that the COMM associated with one of the RMs has a spontaneous vortex-antivortex lattice configuration. Another new phenomenon is that the chiral d-wave state carries spontaneous bulk supercurrent. We also discuss the superconductivity gap structure. The chiral d-wave superconductors are gapped and also topological as characterized by quantized Chern number. Nematic d-wave superconductors, which could be stabilized when the six-fold rotational symmetry of the twisted bilayer graphene is broken, for example by uniaxial strain, are gapless with point nodes.

2:42PM C05.00002: Theory of Superconductivity in Magic-Angle Twisted Bilayer Graphene

NOAH BRAY-ALI (Presenter), Physics, CSU Dominguez Hills — Superconductivity in graphene bilayers occurs at certain “magic angles” of relative orientation between the layers. At these angles, the Moire-Bloch bandstructure becomes nearly flat at the Fermi energy. To describe superconductivity in these flat-band graphene bilayers, we extend the theory of superconductivity previously developed for single-layer graphene doped away from the Dirac point to the saddle point in the bandstructure on the edge of the Brillouin zone. The dominant channel for condensation is still spin-singlet Cooper pairing with $d_x+i d_y$ pair wavefunction, as we show using a perturbative renormalization group argument. Going beyond perturbation theory, we compute the entanglement spectrum using the Bardeen-Cooper-Schrieffer wavefunction and compare the result to the spectrum expected from the conformal field theory of a pair of free massless chiral Majorana fermions confined to the edge.

*The author acknowledges support from the California State University, Dominguez Hills Faculty Research Initiative and computational facilities provided by the campus computing center.
Flat bands and superconductivity in twisted bilayer graphene: insights from full scale Bogoliubov-de Gennes solutions.*

TOMAS LOTHMANN (Presenter), JOHANN SCHMIDT, FARIBORZ PARHIZGAR, ANNICA M BLACK-SCHAFFER, Uppsala University — The recently experimentally observed, possibly unconventional, superconducting state in twisted bilayer graphene (TBLG) opens up a highly tunable playground for correlated systems and exotic orders, where optimal conditions for exotic superconductivity are believed to result from a twist induced flattening of the electronic bands. Here we test the distinctive role of the flat bands in the formation and enhancement of superconductivity in TBLG and we detail the resulting implications for unconventional chiral $d+id$ superconductivity. We show these results from the self-consistent solutions of the complete Bogoliubov-de Gennes (BdG) equations of the full tight-binding Hamiltonian of TBLG, which in the case of magic twist angle TBLG with its long wavelength moiré interference pattern poses a formidable computational challenge that we rigorously address with a novel numerical approach.

A unified numerical approach to topological semiconductor-superconductor heterostructures

GEORG W. WINKLER (Presenter), ANDREY ANTIPOV, BERNARD VAN HECK, Station Q, Microsoft, ALEXEY A SOLUYANOV, University of Zurich, LEONID GLAZMAN, Yale University, MICHAEL WIMMER, Delft University of Technology, ROMAN LUTCHYN, Station Q, Microsoft — We develop a unified numerical approach for modeling semiconductor-superconductor heterostructures and apply it to topological Majorana nanowires. Our approach takes into account on equal footing important key ingredients: proximity-induced superconductivity, orbital and Zeeman effect of an applied magnetic field, spin-orbit coupling as well as the electrostatic environment. As a model system, we consider indium arsenide (InAs) nanowires with epitaxial aluminum (Al) shell and demonstrate qualitative agreement of the obtained results with the existing experimental data. Finally, we characterize the topological superconducting phase emerging in a finite magnetic field and calculate the corresponding topological phase diagram.

Spin-resolved Andreev transport in quantum Hall edges of a proximitized van der Waals heterostructure*

&OUML;NDER G&OUML;L (Presenter), YUVAL RONEN, BRENNAN DIZDAR, SI YOUNG LEE, YOUNG JAE SHIN, Harvard University, DANIAL HAEI NAJAFBADI, University of Massachusetts Lowell, ZEYU HAO, JONATHAN ZAUBERMAN, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, PHILIP KIM, Harvard University — Topological superconductivity is a phase of matter that hosts non-Abelian quasiparticles, the building blocks for error-protected quantum computation. A well-known example is the Majorana quasiparticle. While several materials have been demonstrated to support topological superconductivity, most of them do not allow for the implementation of a universal set of protected logic gates. Van der Waals materials present a unique playground for topological superconductivity because they readily provide the ingredients to realize the quasiparticles suitable for universal topological quantum computation. Here, we show experiments on van der Waals heterostructures towards engineering non-Abelian quasiparticles from the quantum Hall state with induced superconductivity. Local electrostatic control of the graphene device enables spin-resolved Andreev transport. Advanced heterostructures including atomically flat (graphite) gates that fully encapsulate graphene significantly bring down the magnetic fields required for symmetry-broken and fractional quantum Hall states.

Electronic structure of semiconductor/superconductor interfaces from angle-resolved photoemission experiments

SERGEJ SCHUWALOW, Center For Quantum Devices and Microsoft Quantum Materials Lab - Copenhagen, Niels Bohr Institute, University of Copenhagen, NIELS SCHRÖTER (Presenter), Paul Scherrer Institute, CANDICE THOMAS, Department of Physics and Astronomy, Station Q Purdue, and Birck Nanotechnology Center, Purdue University, ALLA CHIKINA, MARCO CAPUTO, JONAS KRIEGER, Paul Scherrer Institute, GEOFFREY GARDNER, Department of Physics and Astronomy, Station Q Purdue, and Birck Nanotechnology Center, Purdue University, VLADIMIR STROCOV, GABRIEL AEPPLI, Paul Scherrer Institute, MATTHIAS TROYER, Microsoft Quantum, MICHAEL MANFRA, Department of Physics and Astronomy, Station Q Purdue, and Birck Nanotechnology Center, Purdue University, PETER KROGSTRUP, Center For Quantum Devices and Microsoft Quantum Materials Lab - Copenhagen, Niels Bohr Institute, University of Copenhagen — Hybrid epitaxial semiconductor/superconductor heterostructures have recently shown promise as a platform to realize Majorana zero modes. To pave the way towards the engineering of such heterostructures for quantum information applications, it is imperative to obtain information about their electronic properties at the semiconductor/superconductor interface. Here, we report on recent soft X-ray angle-resolved photoemission experiments to obtain key electronic material parameters for III-V semiconductor/aluminium interfaces, such as effective mass, charge density, and band offset.
3:42PM C05.00007: Topological Superconductivity on Moire Superlattices* [Invited] CENKE XU (Presenter), LEON BALENTS, CHAO-MING JIAN, University of California, Santa Barbara — Surprising correlated phenomena such as superconductor and insulator at fractional electron fillings have been observed in systems with Moire superlattice. We study the nature of these correlated phenomena, and explore the possibility of topological superconductivity in these systems using different approaches. The Dirac valley degree of freedom allows these system to form either spin triplet or spin singlet topological superconductor, depending on the sign of an effective “Hund’s coupling”. Experimental predictions such as magnetic flux quantization can be made based on the particular type of pairing. We will also investigate the nature of the observed insulators, and map the effective spin-valley physics of the insulator at both 1/2 and 1/4 filling to the boundary of a higher dimensional symmetry protected topological (SPT) state. The spin-valley physics of the insulators is governed by a Lieb-Shultz-Mattis theorem which can be interpreted as the boundary ’t Hooft anomaly of the higher dimensional SPT state.

*NSF Grant DMR1506119, DMR1151208, and the David and Lucile Packard Foundation

4:18PM C05.00008: Transparent Contacts between Quantum Anomalous Hall Insulators and Superconductors* MORTEZA KAYYALHA (Presenter), DI XIAO, RUOXI ZHANG, JAEHO SHIN, JUE JIANG, FEI WANG, YIFAN ZHAO, LING ZHANG, CHAO-XING LIU, QI LI, MOSES H. W. CHAN, NITIN SAMARTH, CUI-ZU CHANG, Pennsylvania State University — A quantum anomalous Hall (QAH) insulator coupled to an s-wave superconductor is predicted to harbor a chiral topological superconducting phase, the elementary excitations of which (i.e. chiral Majorana fermions) upon non-Abelian braiding operations can form topological quantum qubits. Here, we fabricated the QAH/Nb hybrid heterostructures and first studied their two-terminal conductance. We found that the two-terminal conductance constantly shows a half-quantized value in the entire range of the magnetic field where the magnetization is well-aligned. Next, we studied the contact transparency between the QAH and Nb films. When the QAH layer is tuned to the metallic regime by gating, we observed Andreev reflections, i.e., a large enhancement of the resistance when a DC bias voltage across the magnetic TI/Nb junction is increased above the Nb superconducting gap. This observation indicates a transparent interface between the QAH and Nb layers. Our study provides a more comprehensive understanding of the relation between the superconducting proximity effect and the observation of the half quantized two-terminal conductance in the QAH/Nb hybrid structure.

4:30PM C05.00009: Coherent single-electron transport in hybrid superconductor-semiconductor Coulomb islands* ALEXANDER WHITICAR (Presenter), ANTONIO FORNIERI, EOIN C O’FARRELL, ASBJORN C. C. DRACHMANN, Center for Quantum Devices and Station Q Copenhagen, University of Copenhagen, TIAN WANG, CANDICE THOMAS, SERGEI GRONIN, GEOFFREY GARDNER, MICHAEL MANFRA, Department of Physics and Astronomy and Station Q Purdue, Purdue University, CHARLES M MARCUS, FABRIZIO NICHELE, Center for Quantum Devices and Station Q Copenhagen, University of Copenhagen — The spatial separation of Majorana modes is expected to allow coherent transport of single electrons through a Coulomb blockaded one-dimensional topological superconductor [1]. Here we investigate phase coherent transport in a hybrid Al-InAs Coulomb island embedded in an Aharonov-Bohm interferometer. When a magnetic field is applied, the energy of a discrete sub-gap state is lowered below the charging energy and conductance oscillations are observed with a magnetic flux period of h/e (h is the Planck constant and e is the elementary charge), which indicates coherent transport of single electrons. The oscillation amplitude is maximized when the Coulomb peaks are 1 electron (1e) periodic, while the interference signal is suppressed when transport is 2e periodic or the island is in the normal state. The observation of phase-coherent transport enables us to investigate the coupling of Majorana modes from two separated topological wires with the goal of creating a topological qubit.

*This research was supported by Microsoft, and the Danish National Research Foundation
4:42PM C05.00010: Nonreciprocal charge transport at topological insulator/superconductor interface  KENJI YASUDA (Presenter), HIRONORI YASUDA, Department of applied physics, The University of Tokyo, TIAN LIANG, RYUTARO YOSHIMI, Center for Emergent Matter Science, RIKEN, ATSUSHI TSUKAZAKI, Institute for Materials Research, Tohoku University, KEI TAKAHASHI, Center for Emergent Matter Science, RIKEN, NAOTO NAGAOSA, MASASHI KAWASAKI, Department of applied physics, The University of Tokyo, YOSHINORI TOKURA, Center for Emergent Matter Science, RIKEN — Topological superconductor (TSC) is attracting growing interest for its potential application to topological quantum computation. The superconducting proximity effect on the topological insulator (TI) surface state is one promising way to yield the topological superconductivity. The superconductivity realized at the interface between TI Bi2Te3 and non-superconductor FeTe is one of such candidates because the mutual interaction between superconductivity and topological order is expected. Here, to detect the effect of spin-momentum locking in the Cooper pair, we investigate nonreciprocal transport; i.e. current-direction dependent resistance, which is sensitive to the broken inversion symmetry of the electronic state. The largely enhanced nonreciprocal phenomenon is detected in the Bi2Te3/FeTe heterostructure associated with the superconducting transition. The emergent nonreciprocal signal at low magnetic fields is attributed to the current-induced modulation of supercurrent density under in-plane magnetic fields perpendicular to current, exemplifying the close connection between the superconductivity and the topological electronic state at the interface.

4:54PM C05.00011: Transport in Superconductor-Topological Insulator-Superconductor 2D Arrays*  VINCENT HUMBERT (Presenter), GREG MACDOUGALL, NADYA MASON, University of Illinois at Urbana-Champaign — Once coupled to s-wave superconducting material, three-dimensional topological insulators (TIs) – providing spin momentum locking of the electrons and spin polarized current at the surface – are expected to show novel properties and unconventional superconductivity. To probe the interplay between TI surface properties and superconductivity, we fabricated 2D superconducting island arrays on exfoliated flakes of the 3D TI Bi2Se3. Such two-dimensional junction arrays have been shown to undergo Kosterlitz-Thouless transitions toward a superconducting state. Transport and Fraunhofer spectroscopy measurements carried out on our devices show unusual, asymmetric behavior. In particular, the measurements provide evidence of charged vortices on the topological surface.

5:06PM C05.00012: Uniaxial Strain Effect on Superconductivity in LaAlO3/SrTiO3 Nanostructures*  XINYI WU (Presenter), MEGAN BRIGGEMAN, JOSEPH ALBRO, JIANAN LI, Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, Materials Science and Engineering, Univ of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Physics and Astronomy, University of Pittsburgh — We investigate the effects of uniaxial strain on superconductivity in nanowires created at the LaAlO3/SrTiO3 interface using conductive atomic force microscope (c-AFM) lithography [1]. C-AFM-written areas are associated with Z-oriented ferroelastic domains, surrounded by in-plane insulating regions [2]. Application of external uniaxial stress is expected to displace the ferroelastic domain boundaries, either inward or outward, depending on the sign. Our initial experiments indicate that tensile and compressive strains profoundly affect the superconducting state at milli-Kelvin temperatures. Uniaxial stretching of the nanowire in the parallel direction is found to completely suppress the superconducting state, while reversal of the applied strain restores superconductivity. We discuss implications for understanding possible role of ferroelastic domain walls in electron-pairing mechanisms.

Monday, March 4, 2019 2:30 PM - 4:54 PM

Session C06 DCMP: Electronic States in S and Te Chalcogenides  BCEC 109A - Rico Schoenemann, National High Magnetic Field Laboratory
2:30PM C06.00001: Physical Properties of Low Dimensional Ternary Transition-Metal Sulfides* SHERMANE BENJAMIN (Presenter), ALISA DRENNER, MITCH BAKER, MICHAEL SMITH, JOHN J NEUMEIER, Montana State University, Bozeman — Transition-metal sulfides exhibit behaviors such as metal-insulator transitions, superconductivity, and magnetism. They provide an interesting class of compounds for comparison to transition-metal oxides. In this work, polycrystalline SrTa2S5 and BaTa2S5 samples were synthesized. Large (15 x 15 x 0.25 mm3) single crystals of BiNbS3 were grown by chemical vapor deposition. SrTa2S5 and BaTa2S5 superconduct at Tc=2.14 K and 3.2 K, respectively. BiNbS3 shows no signs of superconductivity above ~0.4 K. The magnetic properties, specific heat, electrical resistivity, structural analysis, and compositional analysis will be discussed. The influence of hydrostatic pressure on the electrical resistivity will be presented.

*Work at Montana State University was conducted with financial support from the US Department of Energy (DOE) DE-SC0016156.

2:42PM C06.00002: Bulk and topological effects on the optical conductivity of BaNiS2* RICARDO LOBO (Presenter), ESPCI Paris, CNRS, Sorbonne University — The BaCo1-xNi2S2 system forms a solid solution with an almost Mott like insulating phase when x=0 to a weakly correlated conductor in the Ni end member. This weakly correlated material has a series of interesting topological properties such as a hidden spin polarization due to a Rashba coupling and three dimensional Dirac-like cones close to the Fermi level. Here, I will discuss the temperature dependence of the optical conductivity (σ) of this material. The room temperature real part of σ shows a Drude like peak followed by a linear-in-frequency region. Upon cooling the material there is a spectral weight transfer from about 0.1 eV to 0.3 eV. Interestingly the linear region remains unchanged as a function of temperature. Combining the optical measurements with first principle calculations shows that this spectral weight transfer is a competition between regular carriers and Dirac-like bands.

2:54PM C06.00003: Photoemission study on a special type of multiferroics: GaV4S8 & GeV4S8 AMOL SINGH (Presenter), National Synchrotron Radiation Research Center, JUNG-HAN LI, Department of Physics, National Tsing-Hua University Taiwan, YEN-FA LIAO, HSIAO-YU HUANG, YEN-YI CHU, JING CHANG, KU-DING TSUEI, National Synchrotron Radiation Research Center, LUNYONG ZHANG, Laboratory for Pohang Emergent Materials and Max Plank POSTECH Center for Complex Phase Materials, Pohang University of Science and Technology, Pohang 790-784, Korea, SANG-WOOK CHEONG, Department of Physics and Astronomy, 136 Frelinghuysen Road, Piscataway, New Jersey 08854, USA, Rutgers Center for Emergent Materials, MICHEL A VAN VEEENDAAL, Department of Physics, Northern Illinois University, DeKalb, IL 60115, USA, DI-JING HUANG, National Synchrotron Radiation Research Center — The lacunar spinels (AV4S8) with A=Ga and Ge, consisting of tetrahedral (AS4)n- and weakly linked cubane (V4S4)n+ are unique in known skyrmions because of a sizable ferroelectric polarization of ~ 1 μC/cm2 and polar crystal structure. Their electronic properties depend on the special degrees of freedom of the basic electronic units of V4S8. These materials are classified as a special class of Mott insulators in which strong electron correlations arise from weak intercluster hybridization. From the viewpoint of ionic formula, average valency of V is 3.25+ in GaV4S8 and 3+ in GeV4S8, yet exact valency of V in these compounds is not known. We conducted hard X-ray photoemission to study the electronic structure of GaV4S8 & GeV4S8 single crystals and to investigate the valency of V in these compounds. The V 2p photoemission spectra are best explained with (V4S4)5+ and (V4S4)6+ for GeV4S8 and GaV4S8 respectively. Further S 2p XPS spectra shows results consistent with the scenario of dynamical Jahn-Teller distortion in the paraelectric phase.

3:06PM C06.00004: Orbital-Order Driven Ferroelectricity and Dipolar Relaxation Dynamics in Multiferroic GaMo4S8 KORBINIAN GEIRHOS (Presenter), STEPHAN KROHNS, Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, HIROYUKI NAKAMURA, TAKESHI WAKI, YOSHIKAZU TABATA, Department of Materials Science and Engineering, Kyoto University, ISTVÁN KÉZSMÁRKI, PETER LUNKENHEIMER, Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg — GaMo4S8, a compound of the lacunar spinel family, was recently shown to exhibit non-canonical, orbitally-driven ferroelectricity [1]. Our dielectric spectroscopy measurements on this multiferroic material reveal complex relaxation dynamics, above as well as below its Jahn-Teller transition at TJT= 47 K [2]. Above the Jahn-Teller transition, two types of coupled dipolar-orbital dynamics were found: On the one hand, relaxations within cluster-wise regions with strong-range polar order, as known from relaxor ferroelectrics. On the other hand, critical fluctuations of only weakly interacting dipoles, resembling the typical dynamics of order-disorder type ferroelectrics. Below TJT, the system is driven into long range ferroelectric order by the onset of orbital order and dipolar dynamics within the ferroelectric domains is observed: The found marked differences to the skyrmion host GaV4S8 seem to be related to the different structural distortions in these systems.

3:18PM C06.00005: Noise spectroscopy study of metal-insulator transition in CuIr$_2$S$_4$ DASHARATH ADHIKARI

(Presenter), AHMED ALI, ALI M ALSAQQA, COLIN P KILCOYNE, Physics, University at Buffalo, NOBUHIRO MATSUMOTO, National Metrology Institute and Chemical Measurement Laboratory, SAMBANDAMURTHY GANAPATHY, Physics, University at Buffalo — Single crystals of the CuIr$_2$S$_4$ exhibit a metal-insulator transition (MIT) at a critical temperature ($T_c$) ~ 231 K, accompanied by simultaneous charge ordering and spin dimerization, making it an interesting system to study the interplay of interaction among many degrees of freedom. By employing low-frequency electrical noise spectroscopy, we observe that the power spectral density (PSD) of the resistance fluctuations peaks around $T_c$ likely due to the formation of domains of opposite phase. The ultra-low frequency window of our measurements serves as a tool to measure the increased scattering of charge carriers near $T_c$ due to nucleation, pinning and/or propagation of domains. The probability density function (PDF) of the fluctuations in the transition region shows a significant deviation from the expected Gaussian behavior further supporting the intermixing of phases near $T_c$. In addition, an abrupt phase transition with a threshold behavior can also be triggered electrically from the insulating phase. The analysis of the PSD, PDF and 1/f behavior suggests a significant role of the domains in the electrically driven case too.

3:30PM C06.00006: Anomalous conductivity near percolative metal-insulator transition in monolayer MoS$_2$

BYOUNG HEE MOON (Presenter), JUNG JUN BAE, GANG HEE HAN, HYUN KIM, HOMIN CHOI, YOUNG HEE LEE, Center for Integrated Nanostructure Physics, Institute for Basic Science (IBS) — Conductivity of the insulating phase increases generally upon increasing a drain-source voltage due to the field-enhanced hopping or heating effect. Here, we report the opposite behavior, and anomalous metallic to insulating phase transition driven by a voltage at low voltage regime in monolayer molybdenum disulfide. We ascribe these features to the inhomogeneous state of the system in which the transport is governed by a percolation. At the higher voltage regime, the insulating phase is transformed further to the metallic phase, exhibiting unique multi-phases in this system. In this talk, we discuss these anomalous behaviors and their implications in a metal-insulator transition in two-dimension.

3:42PM C06.00007: Optical Thermal Measurements of Thermal Diffusivity in 1T-TaS$_2$

ERIK KOUNTZ (Presenter), JIECHENG ZHANG, AHARON KAPITULNIK, Physics, Stanford University — Thermal response of electronic materials can detect phase transitions and transport processes. Moreover, micron-scale measurements avoid sample imperfections such as dislocations, grain boundaries, and other defects, and allow for proper averaging on macroscopic samples. We use a photo-thermal microscope for high resolution thermal diffusivity and optical reflectivity measurements. A laser beam is focused at the surface of the targeted sample; the laser power is modulated to create a periodic, point-like heat source. A nearby laser measures the local reflectivity. In this talk we focus on 1T-TaS$_2$, a quasi-2D Mott insulator with various competing charge density wave (CDW) orders and a proposed quantum spin liquid phase at low temperature [1]. We study the nature of the phase transitions through anomalies in differential reflectivity (dR/dT) and the transport behavior though measurements of thermal diffusivity ($D_Q$). In particular, anomalies in dR/dT at the 180K- and 345K-CDW transitions are discussed in terms of the nature of the phase transitions and $D_Q$ is discussed in terms of its implications on transport mechanisms.

3:54PM C06.00008: Real space imaging of tuneable magnetic order in Fe$_{1+x}$Te with $x>0.12$

CHRISTOPHER TRAINER (Presenter), CHI MING YIM, PETER WAHL, University of St Andrews — Magnetism is thought to play an important role in the development of the superconductivity in the Iron chalcogenide superconductors. In the parent material, FeTe, the magnetic phase diagram is very complex with unusual magnetic states developing as a function of excess Iron doping [1]. We have conducted a spin-polarized scanning tunnelling microscopy study on samples of FeTe with different levels of excess Iron concentrations by in-situ prepared magnetic tips [2]. Using a ferromagnetic tip in a cryogenic STM in a vector magnetic field [3,4], we have been able to map out the magnetic order at the surface on an atomic scale in all three spatial directions. By collecting Fe atoms from the surface with the STM tip the excess Fe concentration of the surface can be tuned locally. For samples of Fe$_{1+x}$Te with $x>0.12$ our results reveal a magnetic transition from a single-q to a multi-q order as a function of local excess iron concentration [4]. I will discuss these results and compare them with the neutron scattering measurements.

4:06PM C06.00009: Visualizing uniaxial-strain-manipulation of antiferromagnetic domains in Fe$_{1+y}$Te using spin-polarized scanning tunneling microscope*  JOEL FRIEDMAN (Presenter), MARIAM KAVAI, IOANNIS GIANNAKIS, JUSTIN LESEN, Binghamton University, PAWEL ZAJDEL, Institute of Physics, University of Silesia, PEGOR AYNAJIAN, Binghamton University — The quest to understand correlated electronic systems has pushed the frontiers of experimental measurements towards development of new experimental techniques and methodologies. Here we use a novel home-built uniaxial-strain device integrated into our variable temperature scanning tunneling microscope (STM) that enables one to controllably manipulate in-plane uniaxial strain in the samples and probe their electronic response at the atomic scale. Using STM with spin-polarization techniques, we visualize antiferromagnetic (AFM) domains and their atomic structure in Fe$_{1+y}$Te, the parent compound of iron-based superconductors, and demonstrate how these domains respond to applied uniaxial-strain. We observe the bi-directional AFM domains in the unstrained sample, with an average domain size of ~ 50-150 nm, to transition into a single unidirectional domain under applied uniaxial-strain. Our findings open a new direction to utilize a valuable tuning parameter in STM as well as other spectroscopic techniques both for tuning the electronic properties as well as inducing symmetry breaking in quantum material systems.

*We acknowledge support from the U.S. National Science Foundation (NSF) CAREER under award No. DMR-1654482.

4:18PM C06.00010: Dimensional crossover in a van der Waals ferromagnet detected by spin correlation driven distortions  ALON RON (Presenter), Department of Physics, California Institute of Technology, ELI ZOGHLIN, Materials Department, University of California, Santa Barbara, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, STEPHEN WILSON, Materials Department, University of California, Santa Barbara, DAVID HSIEH, Department of Physics, California Institute of Technology — Magneto-elasticity – the structural deformation of a crystal in response to a change in its magnetic energy – is commonly detected across magnetic long-range ordering (LRO) transitions and yields insight into magnetic ground state energetics. In principle, distortions are also induced by magnetic short-range ordering (SRO), which provide complementary information about short-range correlations and energetics that are essential for understanding how LRO is established. However these distortions are difficult to resolve because the associated atomic displacements are exceedingly small and do not break symmetry. Here we demonstrate high-multipole nonlinear optical polarimetry as a sensitive and mode selective probe of SRO induced distortions using CrSiTe$_3$ as a testbed. This compound is composed of van der Waals bonded sheets of ferromagnetically interacting Heisenberg spins that, in isolation, would be impeded from LRO by the Mermin-Wagner theorem. Our results show that CrSiTe$_3$ evades this law via a two-step crossover from two- to three-dimensional magnetic SRO above its Curie temperature ($T_c=31$K), manifested through two previously undetected totally symmetric distortions at $T_{2D} \sim 110$K and $T_{3D} \sim 60$K, respectively. Such data open new avenues for mechanical control of magnetism.

4:30PM C06.00011: Thermal Expansion in Ba$_3$Zr$_2$S$_7$*  NATHAN KOOCHER (Presenter), Materials Science and Engineering, Northwestern University, RYAN KLEIN, ALISON ALTMAN, DANNA FREEDMAN, Chemistry, Northwestern University, JAMES M RONDINELLI, Materials Science and Engineering, Northwestern University — Ferroelectric perovskite oxides have recently been used in solar applications because their polarity allows for the separation of photocarriers when under illumination to generate a photocurrent. Oxides, however, often have band gaps that are beyond the solar-optimal regime (>3.3 eV); for this reason, perovskite-structured chalcogenides have been proposed as suitable candidate materials owing to their lower band gaps (= 2 eV). An understanding of the thermal expansion behavior of photovoltaic materials is important so as to prevent large stresses and strains during fabrication and operation of the photovoltaic device. Here, we evaluate the structural, lattice dynamical, and thermodynamic properties of Ruddlesden-Popper chalcogenide Ba$_3$Zr$_2$S$_7$ using the self-consistent quasi-harmonic approximation within density functional theory. These properties are compared to the thermal expansion of other Ruddlesden-Popper compounds, which allows us to suggest guidelines for engineering thermal expansion in the Ruddlesden-Popper structure type with diverse chemistries.

*This work was supported by the National Science Foundation's MRSEC program (DMR-1720139.) at the Materials Research Center of Northwestern University.
THOMAS KOEHLER (Presenter), SEBASTIAN PAAECKEL, SALVATORE MANMANA, University of Gottingen — We describe the formation of charge-density patterns induced by spin-selective photoexcitations of interacting fermionic systems with an underlying magnetic microstructure. Using tensor-network methods for one-dimensional model systems, we find stable charge-density patterns for a wide range of parameters. We discuss a generic mechanism explaining this effect for systems that possess a periodic modulation of local observables in any dimension. Realizations in pump-probe experiments on materials and by experiments with ultracold gases on optical lattices are proposed.

Session C07 DCMP: Heavy Fermion and Correlated Electron Metals BCEC 109B - James Hamlin, University of Florida

2:30PM C07.00001: Spin-orbit interaction and quasiparticle bands in locally non-centrosymmetric heavy-fermion systems* GERTRUD ZWICKNAGL (Presenter), Inst. f. Mathemat. Physik, TU Braunschweig, Braunschweig, Germany, SEUNGYUN KHIM, MANUEL BRANDO, CHRISTOPH GEIBEL, MPI for Chemical Physics of Solids, Dresden, Germany — Non-centrosymmetric heavy-fermion systems (HFS) have gained much interest in the past decade. In these materials, the lack of inversion symmetry in combination with strong spin-orbit interaction and magnetic interactions can lead to novel phenomena. In this talk, we present calculations of the heavy quasiparticle bands in Ce- and Yb-based HFS from the tetragonal 122-family. This class of materials comprises compounds with the inversion-symmetric ThCr2Si2 structure as well as systems with the locally non-centrosymmetric CaBe2Ge2 structure. The calculations are performed by means of the Renormalized Band method which proceeds from a Dirac-relativistic description of the electronic structure and accounts for Crystalline Electric Field effects and the mass renormalization due to strong local correlations. We discuss results for YbIr2Si2 which crystallizes in both structures depending on preparation condition. Further on, we present results on the new HFS CeRh2As2.

*This work was supported by the ANR-DFG project Fermi-NESt.

2:42PM C07.00002: The high-field/high-pressure relationship of magnetic order and nematicity in the heavy fermion superconductor CeRhIn5* TONI HELM (Presenter), High Magnetic Field Laboratory, Helmholtz Zentrum Dresden Rossendorf, AUDREY GROCKOWIAK, Tallahassee, National High Magnetic Field Laboratory, FEDOR BALAKIREV, JOHN SINGLETON, Los Alamos, National High Magnetic Field Laboratory, KENT SHIRER, MARKUS KOENIG, Max Planck Institute for Chemical Physics of Solids, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory, STANLEY W TOZER, Tallahassee, National High Magnetic Field Laboratory, PHILIP MOLL, Institute of Materials, Ecole Polytechnique Federale de Lausanne — Recently, a nematic signature, i.e. a sudden resistivity anisotropy above a critical field \( B^* \ = 28 \) T, has been observed in CeRhIn5[1]. This heavy fermion antiferromagnet (\( T_N = 3.85 \) K) superconducts under pressure above \( p_c \ = 23 \) kbar, associated with an antiferromagnetic quantum critical point (QCP). The reported nematic behavior survives at ambient pressure only until magnetic order is suppressed at a critical field of \( B_c = 51 \) T, associated with a second QCP[2,3]. An open question is if and how the two QCPs, \( B \)-induced nematicity and \( p \)-induced superconductivity (SC) are related. Here we report high-field (up to 65 T) / high-pressure (up to 40 kbar) studies of magnetotransport in CeRhIn5. The combination of plastic diamond-anvil-cells, pulsed magnets, and focused-ion-beam microstructures enabled us to investigate this region in the \((p,T,B)\) phase diagram. We show that nematicity and SC reside in distinct regions. Our experiments reveal a surprising enhancement of magnetic order in high fields with pressure.

Quantum confinement of electronic states in a bulk heavy fermion crystal

NICOLAS GAUTHIER
(Presenter), JONATHAN SOBOTA, MAKOTO HASHIMOTO, ZHIXUN SHEN, Stanford University — Electronic states become quantized when confined in a potential well. This well-known phenomenon is observed for example in quantum dots or thin films [1]. In these cases, the confinement is created artificially by the microscopic dimensions of the system. Surprisingly, we recently observed the presence of confined electronic states in a bulk crystal of CeCoIn$_5$, a prototypical heavy fermion superconductor [2]. Our recent ARPES results revealed multiple electronic bands that were not observed previously [3-5] and are not predicted by theory [6]. Interestingly, the energy position of these bands follows the simple relation expected for a quantum well. In comparison to thin films, the origin of the confinement potential creating these quantized states in CeCoIn$_5$ is still unclear and requires more investigations.

Structural and Physical Properties of CeAu$_2$Bi: a New Frustrated Antiferromagnet Candidate

MARIO MODA PIVA (Presenter), Universidade Estadual de Campinas, FILIP RONNING, JOE D THOMPSON, Los Alamos National Laboratory, PASCOAL PAGLIUSO, Universidade Estadual de Campinas, PRISCILA ROSA, Los Alamos National Laboratory — Ce-based compounds often display emergent phenomena due to the interplay between competing magnetic interactions, crystalline electrical field (CEF) effects, and the Kondo effect. Here we report the structural and physical properties of the new heavy-fermion compound CeAu$_2$Bi. CeAu$_2$Bi crystallizes in a hexagonal structure (P6$_3$/mmc) with lattice parameters of $a = 4.8867(5)$ Å and $c = 9.3748(13)$ Å. This structure presents Ce planes containing a triangular lattice, which has the potential of displaying geometrical frustration. Antiferromagnetic ordering, however, takes place at $T_N = 3.1$ K, and is enhanced as a function of pressure, reaching 4.2 K at 18 kbar. We discuss our experimental results in the light of band structure calculations.

Theory of multipolar order and unconventional superconductivity in heavy fermion systems; importance of nonlocal vertex corrections

RINA TAZAI (Presenter), HIROSHI KONTANI, Nagoya University — In heavy-fermion systems, higher-rank multipole operators are active thanks to the strong spin-orbit interaction (SOI). Therefore, multipole fluctuations cause rich quantum critical phenomena, such as unconventional superconductivity and hidden-order phase. However, the microscopic pictures of these phenomena have not been fully understood. To solve these issues, we study higher-rank multipole fluctuations by considering the vertex corrections (VCs), which represent higher-order many body effects, on the basis of multi-orbital Periodic Anderson Model [1]. We find that the significant effects are given by Aslamazov-Larkin process, which originate from strong interference between multipole fluctuations. Due to the AL-VC, various types of multipole fluctuations develop simultaneously near the magnetic QCP. Especially, some electric multipole (quadrupole or hexadecapole) fluctuations are drastically enlarged, which remain small in mean field theories. Thus, various interesting phase due to the electric multipole fluctuations are expected to be realized in heavy fermion systems. In this talk, we discuss both the s-wave superconductivity in CeCu$_2$Si$_2$ [1] and the hidden-order phase in CeB$_6$, which are reported by recent improved experiments. [1] R. tazai and H. kontani, arXiv:1807.11427.
Recent experiments on heavy fermion materials have revealed a range of compounds that are both metallic and have local magnetic moments that reside on geometrically frustrated lattices. An interesting example of frustration, realized in a number of materials, is provided by systems with a valence bond solid ground state, which exhibit a magnetic transition in the same universality class as Bose-Einstein condensation (BEC) in an applied magnetic field. Moreover, recent experiments on YbAl$_3$C$_3$ suggest that this compound may realize a magnon BEC transition in the presence of an itinerant conduction band. Motivated by these observations, we consider a one-dimensional two-leg spin ladder with a valence bond solid ground state doped with itinerant fermions. Using the Density Matrix Renormalization Group we study the system as a function of Kondo coupling, magnetic field and the density of itinerant fermions. In addition, we use analytical techniques to map out the phase diagram and study the critical properties, and compare limiting cases with the numerically exact DMRG results. We also discuss the application of our results to 2D and 3D systems.

*P. Volkov is supported by a Rutgers CMT Postdoctoral Fellowship.

Reducing dimensionality is a powerful approach to increasing the influence of quantum fluctuations. Not only do quantum fluctuations become stronger in two- and one-dimensions, recent theoretical work using tools from quantum information science (tensor networks, etc.) allow exceedingly accurate studies of correlated electron systems in 1d. With this motivation we investigate quasi-1D 4f and 5f-based metallic compounds possessing non-trivial magnetic order. Using transport and thermodynamics we investigate the electronic and magnetic correlations in these systems and compare with theoretical understanding.

*Work at Los Alamos was performed under the auspices of the US DOE, Division of Materials Sciences and Engineering.

When the temperature drops below a characteristic temperature $T^*$, heavy electrons gradually emerge with further enhanced effective electron mass. The coexistence of ferromagnetism and HF state can be well interpreted by the dual properties (itinerant and localized) of 3d electrons. This work expands the limit of ferromagnetic HF materials from f- to d-electron systems and illustrates the positive correlation between ferromagnetism and HF state in the 3d-electron material, which is quite different from the f-electron systems.

4:18PM C07.00010: Charge dynamics and untapped redox potential in a Mn$^{1+}$- based electrode.*
DIVYANSHI SAR (Presenter), S. ALEXANDER BREITWEISER, New York University, RUMIN QIAO, ALI FIROUZI, Natron Energy, LIN MIAO, ROURAV BASAK, New York University, SHAHROKH MOTALLEBI, CHRISTIAN VALENCIA, MAI FUJIMOTO, COLIN WESSELLS, HANNAH ISRAEL, YI-DE CHUANG, WANLI YANG, LEWIS A WRAY, Natron Energy — Manganese hexacyanomanganate (MnHCMn) with an unusual Mn$^{1+}$ charged valence state has recently been identified as a promising sodium ion anode material, in spite of what appears to be an unfavorable closed-shell electron configuration. I will present an analysis of MnHCMn charge dynamics with bulk- and surface-sensitive soft X-ray absorption spectroscopy (sXAS) and resonant inelastic X-ray scattering (RIXS) at the Mn L3 edge. A charge transfer collective mode is observed, and found to represent the likely energy of the next charging redox plateau, which is yet unachieved in redox experiments. This reveals a unique capability that RIXS can provide for strongly correlated battery electrode materials, and suggests a significant untapped potential for MnHCMn anodes.

*D. Sar acknowledges fellowship support from Natron Energy.

4:30PM C07.00011: Scanning Tunneling Microscopy and Spectroscopy on the Metallic Delafossite PdCoO$_2$*
DIBYASHREE CHAKRABORTI (Presenter), School of Physics and Astronomy, University of St Andrews, SEUNGHYUN KHIM, ANDREW MACKENZIE, Physics of Quantum Materials, Max Planck Institute of Chemical Physics of Solids, PETER WAHL, School of Physics and Astronomy, University of St Andrews — The metallic delafossite PdCoO$_2$ has risen to the limelight in the past few years [1]. Due to unusually long mean free paths, the electron fluid exhibits hydrodynamic effects [2]. The anisotropic crystal structure leads to a quasi-2D character of the electronic states making the material suitable for surface sensitive techniques. Because of the polar nature of the surface, exciting physics is observed such giant Rashba spin-splitting [3] and itinerant ferromagnetism [4]. In our study, we have investigated the different surface terminations of PdCoO$_2$ with low temperature Scanning Tunneling Microscopy. We will discuss their assignment and spectroscopic signatures.

4:42PM C07.00012: Collective Modes in SrTi$_{1-x}$Nb$_x$O$_3$ Measured with meV-Resolution EELS*
SAMANTHA RUBECK (Presenter), MELINDA RAK, MATTEO MITRANO, ALI HUSAIN, JIN CHEN, University of Illinois at Urbana-Champaign, ALEXANDER EDELMAN, PETER B LITTLEWOOD, University of Chicago, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — The emergence of superconductivity in low carrier solids does not follow the behavior of conventional BCS superconductivity. Niobium doped strontium titanate, SrTi$_{1-x}$Nb$_x$O$_3$, which becomes a superconductor at densities as low as 5.5×10$^{17}$ cm$^{-3}$ [1], is theorized to come about due to the hybridization of the longitudinal optic phonons with the plasmons. In this talk, I will present measurements of the collective charge excitations of SrTi$_{1-x}$Nb$_x$O$_3$ using momentum-resolved inelastic electron scattering (M-EELS). We observed a variety of acoustic and optic phonons in the range 0-200 meV that have been implicated in the superconducting pairing in this material. In addition, we observed an electronic mode at 25 meV that we identify as a valence plasmon from the Nb free carriers. I will discuss evidence for hybridization of these modes for different Nb concentration, $x$.

4:54PM C07.00013: Infrared nano-imaging of Luttinger liquid plasmons in single walled carbon nanotubes
SHENG WANG (Presenter), FENG WANG, University of California, Berkeley — Quantum-confined electrons in one dimension (1D) constitute a Luttinger liquid, which features charge spin separation and other intriguing properties distinctly different from the Fermi liquid. Single walled carbon nanotubes (SWNTs) provide the ideal platform to explore such Luttinger liquid physics due to strong lateral quantum confinement and the presence of nanotubes of different species. But a systematic study of how the Luttinger liquid behaviors in carbon nanotubes depend on intrinsic and extrinsic factors such as chirality and doping has been lacking. We performed comprehensive infrared nano-imaging of Luttinger liquid plasmons in carbon nanotubes with different parameters and provide novel insights into Luttinger liquid physics in carbon nanotubes. This in-depth understanding of Luttinger liquid physics in SWNTs is not only of fundamental interests, but also pave the way for various nanophotonic applications based on carbon nanotubes.
5:06PM C07.00014: Investigation of Broken Time Reversal Symmetry in the Pr-rich side of Pr$_{1-x}$Nd$_x$Os$_4$Sb$_{12}$

PEI-CHUN HO (Presenter), Physics, California State University, Fresno, DOUGLAS E MACLAUGHLIN, Physics, University of California, Riverside, M BRIAN MAPLE, Physics, University of California, San Diego, LEI SHU, Physics, Fudan University, ADRIAN HILLIER, ISIS Neutron and Muon Sources, Science & Technology Facilities Council, OSCAR BERNAL, Physics, California State University, Los Angeles, TATSUYA YANAGISAWA, Physics, Hokkaido University, P. K. BISWAS, ISIS Neutron and Muon Sources, Science & Technology Facilities Council, JIAN ZHANG, CHENG TAN, Physics, Fudan University, SHOJI D HISHIDA, TAYLOR MCCULLOUGH-HUNTER, Physics, California State University, Fresno — One of the intriguing features that indicate unconventional superconductivity (SC) in the filled skutterudite compound PrOs$_4$Sb$_{12}$ is the broken time reversal symmetry (TRS). The preliminary analysis of our most-recent results of µSR experiments in Pr$_{1-x}$Nd$_x$Os$_4$Sb$_{12}$ of x=0.05, 0.1, 0.15 and 0.2, at 0 magnetic field, a combined exponential and Gaussian relaxation behavior was found. As T decreases, the exponential rate λ increases, while the Gaussian rate Δ has a slight decrease below $T_c$. The increase of Δ below $T_c$, previously observed in PrOs$_4$Sb$_{12}$, is not seen for x≥0.05, indicating that TRS is no longer broken. λ here is expected to be mainly dynamic in nature and has a strong temperature dependence below $T_c$. λ grows with increasing x, which may be due to a quantum critical point or transition below 0.05K. The origin of the anomalous shape of λ(T) in TF-µSR below $T_c$ for of x=0.15 and 0.2 is currently unknown.

5:18PM C07.00015: Tilted Weyl-Kondo Semimetal in Heavy Fermion Systems

SARAH GREFE (Presenter), HSIN-HUA LAI, Rice University, SILKE PASCHEN, Vienna University of Technology, QIMIAO SI, Rice University — Recently we have introduced a time-reversal-symmetry (TRS) invariant periodic Anderson model on a noncentrosymmetric and nonsymmorphic lattice and demonstrated a Weyl-Kondo semimetal (WKSM) [1]. This strongly correlated, Kondo driven, topological semimetal phase has been evidenced in the recently discovered heavy fermion semimetal Ce$_3$Bi$_4$Pd$_3$ [2]. In condensed matter systems without Lorentz invariance, a term that tilts the Weyl nodes is naturally present. In this study, we generalize the periodic Anderson model to realize a Tilted Weyl-Kondo Semimetal (TWKSM). We show how the tilted Weyl nodes allow for measurable properties that probe the topological nature of the TWKSM.

BCEC 150 - Pengcheng Dai, Rice University

2:30PM C08.00001: Field-induced transitions from superconductors to Bose metal in La$_{1.875}$Ba$_{0.125}$CuO$_4$* JOHNN TRANQUADA (Presenter), YANGMU LI, GENDA GU, QIANG LI, ALEXEI TSVELIK, Brookhaven National Laboratory, JASMINKA TERZIC, PAUL G. BAITY, DRAGANA POPOVIC, National High Magnetic Field Lab — What happens to the pairing correlations in a cuprate superconductor when superconducting order is suppressed with a magnetic field? We have studied this problem in LBCO x=1/8, where 2D superconductivity appears below 40 K, but 3D order only occurs below 5 K, presumably due to pair-density-wave order intertwined with the spin- and charge-stripe orders. At $T = 0.35$ K, a c-axis magnetic field initially induces finite dissipation near 10 T, followed by re-entrant 2D superconductivity between 18 and 22 T [1]. The resistance per CuO$_2$ plane rises to $h/(4e^2)$ near 31 T, but then saturates at $2h/(4e^2)$ at higher fields. The saturation of the resistance indicates metallic behavior, but the fact that the Hall coefficient is ~ 0 indicates a lack of quasiparticles. We conclude that conduction is by incoherent hopping of pairs between charge stripes, indicating that stripes are good for pairing, but not phase coherence.

2:42PM C08.00002: The Valence Transition Model of Pseudogap, Charge-Order and Superconductivity in Electron- and Hole-Doped Copper Oxides. SUMITENDRA MAZUMDAR (Presenter), University of Arizona — I propose an integrated theoretical approach to spatial broken symmetries and superconductivity in electron- and hole-doped cuprates, as well as many other strongly correlated systems [1]. I propose that there occurs a discrete jump in ionicity Cu(2+)-to-Cu(1+) at optimal doping in the conventionally prepared electron-doped compounds and at the pseudogap phase transition in the hole-doped materials; the unusually high ionization energy of the closed shell Cu(1+)-ion, taken together with the doping-driven reduction in the 3D Madelung energy drives the transition. The undoped states behave as effective 1/2-filled Cu-band with the closed shell electronically inactive O(2-) ions; the doped states behave as correlated two-dimensional geometrically frustrated 1/4-filled oxygen hole-bands, now with electronically inactive closed-shell Cu(1+) ions. The charge-ordered state in the frustrated O-band is a period 4 paired Wigner crystal of spin singlets with broken C4 symmetry. Correlated-electron superconductivity results from the destabilization of the paired Wigner crystal. The theory gives the simplest yet most comprehensive understanding of experiments in the normal states, and is easily extended to many other unconventional superconductors.

2:54PM C08.00003: The Effect of Uniaxial Pressure on the High-Temperature Superconductor YBa2Cu3O7−x MARK E BARBER (Presenter), Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, TOSHINAO LOEW, HUN-HO KIM, Max Planck Institute for Solid State Research, Stuttgart, Germany, MARCIN KONCZYKOWSKI, Laboratoire des Solides Irradies, Ecole Polytechnique, France, BERNHARD KEIMER, Max Planck Institute for Solid State Research, Stuttgart, Germany, ANDREW MACKENZIE, CLIFFORD HICKS, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — The phase diagram of the high-temperature cuprate superconductors encompasses a variety of intertwined phases. Typically the phase diagram is traversed using chemical doping or magnetic field, but uniaxial pressure offers an alternative clean tuning parameter. Recently, large a-axis uniaxial pressures in YBa2Cu3O6.67 have been shown to stabilise a three-dimensional long-range-ordered charge density wave, analogous to that achieved with large c-axis magnetic fields, but at zero field [1]. Using GaAs-based Hall probe susceptometers, we have investigated the strain dependence of ∼1/8-doped YBCO with high spatial precision, up to pressures of at least 1.5 GPa, crossing the transition into long-range CDW order.

3:06PM C08.00004: Investigations of the pseudogap phase in overdoped Bi2+xSr2−xCaCu2O8+δ with μSR* SHAYAN GHEIDI (Presenter), KOLAWOLE ABAYOMI AKINTOLA, Simon Fraser University, ANDRE COTE, Kwantlen Polytechnic University, ALEX FANG, Simon Fraser University, SARAH R DUNSGER, TRIUMF, JEFF SONIER, Simon Fraser University — A recent μSR study of Bi2+2Sr2−CaCu2O8+δ (Bi2212) single crystals revealed the presence of weak quasi-static magnetism in the pseudogap (PG) phase [A. Pal et al., Phys. Rev. B 97, 060502(R) (2018)]. However, it is unclear whether the magnetism is associated with the PG, as muon diffusion above T ~ 160 K prevented determination of an onset temperature. In an attempt to circumvent this limitation, we have carried out sensitive muon Knight-shift and new zero-field muon spin relaxation (ZF-μSR) measurements of overdoped Bi2212. The temperature dependence of the muon Knight shift in the normal state exhibits a saturation below a temperature that scales with Tc, whereas the ZF-μSR relaxation rate appears to track the hole-doping dependence of the PG temperature T*. In addition, our measurements of highly overdoped Bi2212 provide evidence for phase separation. The results suggest the presence of two distinct phases above Tc.

Magnetic Excitations in Highly Underdoped Superconducting HgBa₂CuO₄₊δ*

ZACHARY ANDERSON (Presenter), YANG TANG, University of Minnesota, VIKAHM NAGARAJAN, University of California, Berkeley, MUN CHAN, Los Alamos National Laboratory, CHELSEY J DOROW, University of California, San Diego, GUICHUAN YU, University of Minnesota, DOUGLAS L ABERNATHY, ANDREW D CHRISTIANSON, Oak Ridge National Laboratory, LUCILE MANGIN-THRO, PAUL STEFFENS, Institut Laue-Langevin, YVAN SIDIS, PHILIPPE BOURGES, Laboratoire Léon Brillouin, CEA-CNRS, MARTIN GREVEN, University of Minnesota — Antiferromagnetic (AF) spin correlations are prominent across the phase diagram of the cuprate superconductors, and it has been proposed that they mediate Cooper pairing and are responsible for various pseudogap phenomena. HgBa₂CuO₄₊δ (Hg1201) is a simple-tetragonal compound with a single CuO₂ plane per unit cell and the highest optimal Tc among single-layer cuprates, and thus a model system for the study of the AF response of the quintessential CuO₂ planes. Our previous work has shown that the AF excitations in moderately to optimally-doped Hg1201 are distinctly different from what had been observed in other cuprates; namely, the low-energy response is commensurate and gapped, resulting in a 'Y'-shaped, rather than 'X'-shaped dispersion. Here we present our recent inelastic neutron scattering measurements of the AF excitations in heavily underdoped Hg1201.

*The work at the University of Minnesota was funded by the Department of Energy through the University of Minnesota Center for Quantum Materials under DE-SC-0016371.

Tracing the origin of charge density waves in cuprates*

FRYDERYK LYZWA (Presenter), Department of Physics and Fribourg Center of Nanomaterials, University of Fribourg, Chemin du Musée 3, 1700 Fribourg, Switzerland, MILAN ORLITA, LNCMI, CNRS-UGA-UPS-INSA, 25, Avenue des Martyrs, 38042 Grenoble, France, BING XU, CHRISTIAN BERNHARD, Department of Physics and Fribourg Center of Nanomaterials, University of Fribourg, Chemin du Musée 3, 1700 Fribourg, Switzerland — Since the discovery of the so-called pseudogap phenomenon in the 1990’s, the origin of the state properties of the underdoped cuprate high TC superconductors have been intensively studied [1]. An important step towards the identification of the HTSC pairing mechanism was the discovery, that a charge density wave (CDW) exists in large parts of the underdoped phase diagram [2-5]. It was shown, that in zero magnetic field (B=0) the short-ranged, static CDW is induced by defects, while a long-range CDW can be induced for high B-fields along the c-axis (perpendicular to the CuO₂ layers).

Here we aim to search for the origin of this CDW, its role in the pseudogap phenomenology and its relationship with superconductivity (competing or interwined order). We performed reflection experiments from THz-NIR region (50cm⁻¹-6000cm⁻¹) while applying high magnetic fields up to B=30Tesla.

*This study was funded by the LNCMI-CNRS, member of the European Magnetic Field Laboratory (EMFL) and by the Schweizerischen Nationalfonds (SNF) through project 200020-172611.
An outstanding challenge in high-Tc cuprates is to understand how charge density wave order is related to the pseudogap and superconducting phases [1]. To address this issue it is important to extract the energy scale $\Delta_{CDW}$ associated with the charge modulations, and to compare it with the pseudogap (PG) $\Delta_{PG}$ and the superconducting gap $\Delta_{SC}$. However, while $T_{CDW}$ is well-characterized from earlier works [2] little has been known about $\Delta_{CDW}$ until now. We will report the extraction of $\Delta_{CDW}$ for several cuprates using electronic Raman spectroscopy [3]. We observe that $\Delta_{CDW}$ increases in a manner similar to the doping dependence of $\Delta_{PG}$ and $\Delta_{SC}$. This reveals that the three phases have a common microscopic origin. In addition, we find that $\Delta_{CDW} \approx \Delta_{SC}$ over a substantial doping range, which suggests that CDW and superconducting phases are intimately related, for example intertwined or connected by an emergent symmetry [1, 4-6].

The nature of the pseudogap phase of cuprate superconductors remains a mystery. In that phase, the Fermi surface is transformed even though translational symmetry is not broken [1]. A possible explanation is a spin-liquid-like state with topological order [2].

The thermal Hall conductivity $\kappa_{xy}$ has recently emerged as a powerful probe of insulators with unusual forms of magnetism, such as quantum spin liquids [3] and quantum spin ice [4].

We report extensive measurements of the thermal Hall conductivity $\kappa_{xy}$ in several families of cuprates across a wide range of dopings. We observe a large and negative thermal Hall response at temperatures below the pseudogap temperature $T^*$, which appears immediately below the pseudogap critical doping $p^*$. The negative $\kappa_{xy}$ contrasts with the positive electrical Hall conductivity $\sigma_{xy}$ and, moreover, the magnitude of $\kappa_{xy}$ increases as doping is reduced towards $p = 0$, whereas $\sigma_{xy}$ vanishes as the material becomes an insulator.

The negative $\kappa_{xy}$ is therefore due to neutral heat carriers and it points to spin chirality [5], or perhaps topological excitations.

Pressure induced suppression of the Pseudogap in the cuprate superconductor Nd-LSCO probed by thermoelectric measurements

ADRIEN GOURGOUT (Presenter), AMIRREZA ATAEI, MARIE-EVE BOULANGER, SVEN BADOUX, Universite de Sherbrooke, DAVID E GRAF, National High Magnetic Field Laboratory, Florida State University, JIANSHI ZHOU, Mechanical Engineering, University of Texas, NICOLAS DOIRON-LEYRAUD, LOUIS TAILLEFER, Universite de Sherbrooke — In cuprate superconductors, one of the most mysterious phase is the Pseudogap (PG). It seems linked to the superconducting dome, but the nature of their connection remains unknown. It onsets at a doping p* and is characterized by a drop in carrier density n from n=1+p above p* to n=p below. In resistivity and Hall effect, an upturn is seen at low temperature in both quantities[1]. In Nd_{0.4}La_{1.6-x}Sr_{x}CuO_{4} (Nd-LSCO), at ambient pressure, p*=0.23. A recent study from our group showed that by applying hydrostatic pressure, one can suppress the PG in Nd-LSCO and move p* to a lower doping[2]. At p=0.22, the upturns in resistivity and Hall effect are fully suppressed with 2GPa. The underlying mechanism for this effect is rooted in the Fermi Surface (FS), which imposes that the PG cannot open on an electron-like FS. Here we present a confirmation of these results, by means of Seebeck and Nernst effect measurements under pressure up to 2GPa and in magnetic fields up to 31.2T. In both quantities, the increase due to the PG is strongly suppressed by pressure at p=0.22, but shows only a weak effect at p=0.24, which further supports our interpretation that pressure tunes the pseudogap critical point p* to lower dopings in Nd-LSCO.

Interwined orders in the ground state of the Emery model in the underdoped regime*

ETTORE VITALI (Presenter), California State University, Fresno, SHIWEI ZHANG, ADAM C CHICIAK, Physics, College of William and Mary — We perform extensive Auxiliary-Field Quantum Monte Carlo (AFQMC) calculations for the three-band Hubbard (Emery) model in the underdoped regime, in order to study the ground-state properties of Copper-Oxygen planes in the cuprates. Interfacing generalized Hartree-Fock calculations with cutting-edge AFQMC techniques, we are able to resolve small energy scales, which is crucial for determining the complex candidate orders in such a system. We will present results as a function of hole-doping and charge-transfer energy.

*Supported by NSF and Simons Foundation

Coexistence of Superconductivity and Antiferromagnetism in the Hubbard model for cuprates*

ALEXANDRE FOLEY (Presenter), SIMON VERRET, ANDRE-MARIE TREMBLAY, DAVID SENECHAL, Universite de Sherbrooke — Antiferromagnetism and d-wave superconductivity are the most important competing ground-state phases of cuprate superconductors. Using cellular dynamical mean-field theory (CDMFT) for the Hubbard model, we revisit the question of the coexistence and competition of these phases in the one-band Hubbard model with realistic band parameters and interaction strengths. Using an exact diagonalization solver, we improve on previous works with a more complete bath parametrization which is carefully chosen to grant the maximal possible freedom to the hybridization function for a given number of bath orbitals. Compared with previous incomplete parametrizations, this general bath parametrization shows that the range of microscopic coexistence of superconductivity and antiferromagnetism is reduced for NCCO and confined to electron-doping with parameters relevant for hole-doped YBCO and LSCO.

Superconducting phase fluctuations and gap-filling phenomenology in the underdoped cuprates*

MIGUEL ANTONIO SULANGI (Presenter), JAN ZAANEN, Leiden University — We revisit the role of superconducting phase fluctuations in the cuprates as probed by various spectroscopic methods. We assume that the fluctuations of the phase of the d-wave superconducting order parameter are governed solely by a two-dimensional classical XY model and that no amplitude fluctuations are present. We find that much of the “filling-of-the-gap” phenomenology seen in the cuprates is captured by this simple model. At temperatures below the Kosterlitz-Thouless transition, the system behaves as a spatially uniform d-wave superconductor whose gap is proportional to the modulus of the spatial average of the order parameter. Above the KT transition, the vortex-dominated phase exhibits behavior that becomes more normal-like with increasing temperature. Fermi arcs in the spectral function are present near the KT transition. We also examine the effect of spatial inhomogeneity in the classical XY model and consider how the coexistence of superconducting and pseudogap-like regions seen in the cuprates can be reproduced using this model.

*This work was supported by the Netherlands Organisation for Scientific Research (NWO/OCW).
In order to further investigate the relationship between magnetism and superconductivity we have performed measurements of ultrasonic velocity and attenuation in LSCO. Around p=1/8, several anomalies are observed in the sound velocity and attenuation, associated with superconductivity and magnetic freezing. The competition between the two orders parameters is tuned with a magnetic field which enhances magnetic correlations at the expense of superconductivity.

2:30PM C09.00001: Numerical study of the momentum and doping dependence of “hot spots” and single-particle spectra in electron-doped cuprates*  
BRIAN MORITZ (Presenter), SLAC National Accelerator Laboratory, YAO WANG, Harvard University, EDWIN HUANG, Stanford University, THOMAS DEVEREAUX, SLAC National Accelerator Laboratory — We present a systematic study of the single-particle spectral function in electron-doped cuprates determined from state-of-the-art numerical calculations using cluster perturbation theory. By comparing the appearance of the “hot spots” as a function of momentum and electron filling, we conclude that the Hubbard model with an intermediate interaction U can well capture recent experimental observations from photoemission in Nd$_{2-x}$Ce$_x$CuO$_4$. This work suggests that microscopic mechanisms similar to the hole-doped cuprates may drive the short-ranged anti-ferromagnetism, and ultimately superconductivity, even on the electron doped side, and set the stage for further theoretical explorations.

*This work was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under Contract No. DE-AC02-76SF00515. The computational work was performed using the resources of the National Energy Research Scientific Computing Center (NERSC).

2:42PM C09.00002: Phenomenological Theory for Pseudogap and Superconducting Phases of High-Temperature Superconductors  
JIANHAO ZHANG (Presenter), SEN LI, Institute for Advanced Study, TSINGHUA UNIVERSITY, YAO MA, Department of Applied Physics, Xi’an Institute of Technology, ZHENG-YU WENG, Institute for Advanced Study, Tsinghua University — We present a phenomenological Green’s function to characterize the superconducting and pseudogap phases of the cuprates based on a microscopic theory of doped Mott insulators. In this framework, the “Fermi arc” and “superconducting kink” phenomena in ARPES experiments can be systematically obtained as a function of doping. We demonstrate that the phase-string-induced fractionalization plays a crucial role in leading to this exotic Green’s function paradigm.

2:54PM C09.00003: Intrinsic Pair Density Waves in CDMFT Improve Agreement with Cuprates*  
SIMON VERRET (Presenter), ALEXANDRE FOLEY, Institut quantique, RQMP, Université de Sherbrooke, JYOTIRMROY ROY, Université de Sherbrooke. Present address, University of Toronto, MAXIME CHARLEBOIS, Institut quantique, RQMP, Université de Sherbrooke. Present address, University of Tokyo, Applied Physics, DAVID SENSECHAL, ANDRE-MARIE TREMBLAY, Institut quantique, RQMP, Université de Sherbrooke — Cluster dynamical mean-field theory (CDMFT) is one of the most successful methods to treat strongly correlated electrons systems. It is well known, however, that CDMFT leads to an artificial breaking of translational invariance. Here, we investigate how this manifests itself. We report artificial density waves taking the shape of the cluster (cluster density waves) in all our CDMFT solutions. In particular, we report pair density waves in the superconducting solution. We discuss how these artificial density waves help the agreement of CDMFT with the low-energy spectra of cuprate high temperature superconductors. Namely, we find subgap structures similar to those found in tunnelling experiments and a related separation between nodal and anti-nodal gaps in the spectral weight, as observed in photoemission experiments. This agreement with cuprates suggests that spatial inhomogeneity is an important ingredient to explain the low-energy spectrum of cuprates, even in the strongly correlated case.

3:06PM C09.00004: FLEX+DMFT approach for superconductivity in multi-band systems: A study on bilayer Hubbard model  
DAISUKE OGURA (Presenter), KAZUHIKO KUROKI, Osaka University — Broadly speaking, to enhance the superconducting transition temperature $T_c$, a strong paring interaction and a light electron effective mass are favorable. However, the strong pairing interaction not only enhance superconductivity, but also results in the strong quasi-particle renormalization in general. As a way to circumvent this dilemma, we can consider the multi-band Hubbard model as discussed in the previous studies [1, 2]. In multi-band systems, spin fluctuations with finite energy arising from interband scattering channels can develop and act as an effective pairing interaction. Finite energy fluctuations do not cause an abovementioned strong competition between the quasi-particle renormalization and superconductivity. To treat both local and non-local correlations, we have applied the FLEX (fluctuation exchange) + DMFT (dynamical mean-field theory) method [4, 5] to the bilayer Hubbard model. In the presentation, we will discuss the correlation effects and the superconductivity arising from the interband pair scattering.

with our previously reported results [2] where Ω is a constant below $\pi$. The inclusion of the variation of penetration lengths, and critical current and normalized superfluid densities as functions of temperature and of doping $\delta$.

We compare our current results for the condensation energy, the upper and lower critical fields, the coherence and superconducting gap as functions of temperature and of doping $\delta$.

4:06PM C09.00009: Influence of the variation of the number of Cooper pairs on the properties of underdoped YBa$_2$Cu$_3$O$_{6+x}$ cuprates

PATRICIA SALAS CASALES (Presenter), MIGUEL SOLIS, Instituto de Física, Universidad Nacional Autónoma de Mexico — We extend the Layered Boson-Fermion Model of superconductivity [1] to include the increase of the number $f(T)$ of Cooper pairs as temperature decreases from $T_\alpha$ to $T = 0$, for underdoped cuprate superconductors YBa$_2$Cu$_3$O$_{6+x}$.

We compare our current results for the condensation energy, the upper and lower critical fields, the coherence and superfluid densities as functions of temperature and of doping $x$, with our previously reported results [2] where $f(T) = f$ is a constant below $T_\alpha$. The inclusion of the variation of $f$ substantially improves our results when compared with the experimental results.

*We thank partial support form grants CONACyT 221030, DGAPA-PAPIIT IN107616 and DGAPA-PAPIIT IN110319.
4:18PM C09.00010: Vortex structure and Hall conductivity in d-wave superconductors  
VLADIMIR KALNITSKY (Presenter), NETANEL LINDNER, Physics, Technion - Israel Institute of Technology, EREZ BERG, Physics, University of Chicago, SEBASTIAN D HUBER, Physics, ETH Zurich — The Hall conductivity $\sigma_{xy}$ serves as an important experimental probe for determining the sign of charge carriers in materials. In type II superconductors models of vortex dynamics predicted $\sigma_{xy}$ to have the same sign as in the normal state; that is, the same as the charge carriers. However, Hall measurements showed that $\sigma_{xy}$ changes sign as a function of temperature in YBCO and other cuprates, in contradiction to these predictions. Recently it was shown that a sign reversal of $\sigma_{xy}$ occurs in a generic model for an s-wave superconductor, due to a topological transition in the vortex core. We show that a similar effect occurs in a model for a d-wave superconductor, and find a rich phase diagram of $\sigma_{xy}$ as a function of interaction strength and doping $p$: in addition to a sign reversed phase, we find a phase in which $\sigma_{xy} \sim p$. While such a relation implies a small Fermi surface, the model does not exhibit a bulk Fermi surface reconstruction.

4:30PM C09.00011: Electronic States Induced by Doping a Mott Insulator in the Presence of Antiferromagnetic Order  
MASANORI KOHNO (Presenter), National Institute for Materials Science — Recent theoretical studies on the Mott transition suggest that magnetically excited states emerge in the Mott gap in the single-particle spectrum with the dispersion relation shifted by the Fermi momenta following the doping of a Mott insulator [1--4]. This characteristic is difficult to explain in terms of mean-field quasiparticles in antiferromagnetic order. Here, by taking into account spin fluctuation in the random-phase approximation, electronic states exhibiting momentum-shifted spin-wave dispersion relation are shown to emerge in the Mott gap following the doping of a Mott insulator even though antiferromagnetic order persists [5]. The results imply that the emergence of electronic states exhibiting momentum-shifted magnetic dispersion relation is a general and fundamental characteristic of the Mott transition regardless of whether antiferromagnetic order exists or not.

4:42PM C09.00012: High Tc superconductivity in strong electron-phonon interacting systems with frustrated charge order  
ZIXIANG LI (Presenter), MARVIN L COHEN, DUNGHAI LEE, University of California, Berkeley — In this talk, I will discuss how geometric frustration inhibits charge order and allows superconductivity to benefits from strong electron-phonon coupling. We perform sign-problem-free Quantum Monte Carlo simulation to study Holstein model with strong electron-phonon coupling on triangular and square lattices. Our simulation indicates that geometric frustration of charge density wave enables strong superconductivity to exist under much wider conditions in temperature and electron-phonon coupling strength. In particular, under geometric frustration a novel coexistence phase where superconducting coherence develops within a charge ordered state exists in a strong electron-phonon coupling regime.

4:54PM C09.00013: Continuing search for the origin of HTSC: DFT studies of selected copper oxide proxy structures reviewed and paths forward suggested  
PAUL GRANT (Presenter), IBM RSM Emeritus & Principal, W2AGZ Technologies — In this presentation, we review our past attempts to uncover the pairing mechanism underlying high temperature superconductivity in copper oxide compounds and suggest possible paths forward.\footnote{Paul Grant, http://meetings.aps.org/link/BAPS.2016.MAR.R25.8} \footnote{P.M. Grant, Journal of Physics: Conference Series 129 (2008) 012042, doi:10.1088/1742-6596/129/1/012042} \footnote{C. Starr, Phys. Rev. 60, 241 (1941)} \footnote{Paul Grant, https://meetings.aps.org/Meeting/FWS17/Session/B2.10} One such path would be to derive and generalize pairing coupling functions to apply to DFT + U computed eigenstates in order to estimate Cooper pair coupling strengths arising from a combination of both lattice and spin excitations. Interestingly, such interactions were found in transition metal alums some 78 years ago as manifested in linking their respective Debye and Curie temperatures.\footnote{C. Starr, Phys. Rev. 60, 241 (1941)} We suggest repeating such experiments today on the copper oxide compounds as a function of hole/electron concentration, along with a possible computational strategy to pursue in the interpretation of the results\footnote{Paul Grant, https://meetings.aps.org/Meeting/FWS17/Session/B2.10} to finally resolve the fundamental origin of high temperature superconductivity.
Singlet $s^{\pm}$-wave pairing in quasi-one-dimensional ACr$_3$As$_3$ (A=K, Rb, Cs) superconductors

LI-DA ZHANG (Presenter), Beijing Institute of Technology, XIAOMING ZHANG, Institute for Advanced Study, Tsinghua University, JUAN-JUAN HAO, Beijing Institute of Technology, WEN HUANG, Institute for Advanced Study, Tsinghua University, FAN YANG, Beijing Institute of Technology — The recent discovery of quasi-1D Cr-based superconductivity has generated much excitement. We study in this work the superconducting instabilities of a representative compound, the newly synthesized KCr$_3$As$_3$ superconductor. Based on inputs from DFT calculations, we first construct an effective multi-orbital TB Hamiltonian to model its low-energy band structure. We then employ standard RPA calculations to investigate the superconducting instabilities of the resultant multi-orbital Hubbard model. We find the leading pairing symmetry realized in this material is singlet $s^{\pm}$-wave pairing. This singlet pairing is driven by spin-density wave fluctuations enhanced by FS. We design a phase-sensitive measurement to identify the $s$-wave pairing. The $s^{\pm}$-wave pairing in KCr$_3$As$_3$ shall also exhibit a subgap spin resonance mode near the nesting vector, which can be tested by inelastic neutron scattering measurements. We also propose further application of KCr$_3$As$_3$ by utilizing it to induce TRI TSC via proximity effect. Our study shall be of general relevance to all superconductors in the family of ACr$_3$As$_3$ (A=K, Rb, Cs). Reference: arXiv: 1809.07117

Superconductivity in systems exhibiting the Altshuler-Aronov anomaly*

RICHARD HLUBINA (Presenter), Comenius University in Bratislava, BRANISLAV RABATIN, Department of Physics, Florida State University — Dirty superconductors close to the metal-insulator transition frequently exhibit a pseudogap in the normal state due to the Altshuler-Aronov (AA) effect. In this talk we show that, making use of generalized Eliashberg equations, the AA effect and superconductivity can be described on equal footing. We derive explicit expressions for the Coulomb pseudopotential in 3D, taking into account also the anomalous diffusion. We present a full numerical solution for two normal-state and two anomalous self-energies. In the normal state, we amend the known results for the purely electronic AA effect; with electron-phonon coupling turned on, we find additional anomalies in the density of states close to the phonon energy. We study how the critical temperature and density of states of strongly disordered 3D superconductors change with normal-state resistivity. We find that the type of transition from the superconducting to the insulating state depends on the strength of electron-phonon coupling: at weak coupling there exists an intermediate normal state, whereas at strong coupling the transition is direct.

Session C10 DMP: Fe-based Superconductors III

Phase diagram of a hetero-structured iron-based superconductor Sr$_2$VO$_3$FeAs [Invited]

JUN SUNG KIM (Presenter), Physics, Pohang University of Science and Technology — The interplay of spin and orbital degrees of freedom induces various magnetic or nematic phases, coexisting with the superconductivity, and leads to rich phase diagrams in iron-based superconductors (FeSCs). Among various iron-based superconductors, Sr$_2$VO$_3$FeAs holds a unique position as a naturally-assembled heterostructure of a FeSC and a Mott-insulating vanadium oxide, in which the unusual $C_4$ symmetric phases are recently identified and found to be highly distinct from those found in other FeSCs. In this talk, I will present our experimental explorations on these unusual phase transitions in the FeAs layers of Sr$_2$VO$_3$FeAs, and discuss the possible role of the magnetic proximity coupling and the resulting frustration of the otherwise dominant Fe stripe and V Neel fluctuations for stabilizing hidden orders in FeSCs.

Self-induced magnetic flux structure in magnetic superconductor*

VITALII VLASKO-VLASOV (Presenter), ALEXEI E KOSHELEV, JINKE BAO, DUCK YOUNG CHUNG, MERCOURI KANATZIDIS, ULRICH WELP, WAI-KWONG KWOK, Argonne National Laboratory — We image the temperature evolution of the distribution of the magnetic induction in single crystals of the magnetic superconductor EuRbFe$_4$As$_4$. In contrast to the traditional Meissner flux expulsion, the samples cooled in constant magnetic fields show unusual vortex patterns revealing a strong enhancement of the internal magnetic flux density upon approaching the magnetic transition temperature. The observed patterns demonstrate a cooperative response of the magnetic subsystem, which acts as an internal pump of the magnetic flux, and the superconducting system, which controls the delivery of vortices into the bulk of the sample. We suggest possible current distributions responsible for the observed flux patterns.

*The work was supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division.
3:18PM C10.00003: STM/STS study of superconducting properties modified by Ca deposition on Ca$_{10}$(Pt$_4$As$_8$)$_5$*(Fe$_2$As$_2$)$_5$* JISUN KIM (Presenter), SEOKHWAN CHOI, BRANDON STUART, AMY QU, Stewart Blusson Quantum Matter Institute, University of British Columbia, SILU HUANG, RONGYING JIN, Department of Physics and Astronomy, Louisiana State University, DOUGLAS BONN, SARAH A. BURKE, Stewart Blusson Quantum Matter Institute, University of British Columbia — Ca$_{10}$(Pt$_4$As$_8$)$_5$ contains both superconducting building blocks (Fe$_2$As$_2$ layers) and conducting spacers (Pt$_4$As$_8$ layers), unlike insulating spacers in other Fe-based superconductors. Prior work showed the important role played by the charge environment and surface structures in its superconducting properties: evidence for superconductivity is absent in bare Pt$_4$As$_8$ surface but recovers when Ca atoms are atop [1]. Different surface reconstructions also lead different superconducting features. We use scanning tunneling microscopy and spectroscopy (STM/S) to directly confirm the role of charge balance and surface structures on superconductivity in this compound. Cleaving provides large areas of bare Pt$_4$As$_8$ layer, which originally does not show superconducting features. Depositing additional Ca atoms on the bare Pt$_4$As$_8$ surface, while the sample is on the STM scanning stage, results in changes in spectral features. We will discuss the relationship between surface structures and superconducting features based on the Ca structures formed by controlling the deposition temperature.

3:30PM C10.00004: Prediction of (Li$_{0.8}$Co$_{0.2}$OH)CoSb as A New Superlatticed Superconductor* PING CUI (Presenter), M. USMAN MUZAFFAR, WENJUN DING, JIANG ZENG, WEI QIN, ZHENYU ZHANG, ICQD, University of Science and Technology of China — We study theoretically the superlattice material of (Li$_{0.8}$Co$_{0.2}$OH)CoSb as a new candidate superconductor, in which the superconducting layer CoSb has the same crystal structure as FeSe, but with stronger spin-orbit coupling (SOC). Through density functional theory calculations, we find that substitution of Li by Co in the spacing layer not only minimizes the lattice mismatch between the spacing and superconducting layers in the ab plane, but also helps to stabilize the overall structure of the system. Moreover, we have investigated the detailed nature of charge transfer and found that Co in the spacing layer can significantly enhance the interlayer charge transfer, which is essential for achieving superconductivity. The predicted system is not only likely to add a new member into the superconducting family, but may also offer new opportunities for realizing topological superconductivity because of the stronger SOC.

*Supported by NNSF of China and MOST.

3:42PM C10.00005: Temperature- and pressure-dependent electronic structure evolution of quasi-one-dimensional iron chalcogenide ladder compounds, BaFe$_2$S$_3$, and BaFe$_2$Se$_3$: optical studies and DFT calculations JUNGSEEK HWANG (Presenter), SEULKI ROH, SOOHYEON SHIN, JAEKYUNG JANG, Sungkyunkwan University, ZHENXIAN LIU, George Washington University, G LAWRENCE CARR, Brookhaven National Laboratory, JOO YULL RHEE, TUSON PARK, Sungkyunkwan University — Since the discovery of a pressure-induced iron-based superconductor, BaFe$_2$S$_3$ (BFS), intensive studies have been performed on BFS and a similar compound BaFe$_2$Se$_3$ (BFSe). Both compounds are antiferromagnetic insulators, with increasing pressure they show metallic phases and eventually become superconductors under very high pressure. We measured reflectance spectra of those two compounds by controlling two experimental tuning parameters: temperature and pressure. From our temperature-dependent measured reflectance spectra of both samples using polarized lights, we obtained anisotropic optical conductivity along two crystal axes. We observed bandgaps in both samples along the ladder direction at low temperature. We also observed pressure-induced insulator-metal transitions (IMT) in both samples from our pressure-dependent measured mid-infrared reflectance spectra of both samples at 300 K using diamond anvil cells. The density functional theory calculations were also performed to understand the measured experimental spectra. In this presentation, we will present our results and discuss on them.
Melting of vortex lattice in magnetic iron-pnictide superconductor RbEuFe₄As₄*  
ALEXEI E KOSHELEV (Presenter), KRISTIN WILLA, ROLAND WILLA, MATTHEW SMYLIE, JINKE BAO, DUCK YOUNG CHUNG, MERCOURI KANATZIDIS, ULRICH WELP, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory — The iron-based superconductors are characterized by sizable thermal fluctuations due to high transition temperatures and small coherence lengths. We report calorimetric and transport observations for the vortex-lattice melting in the magnetic iron-pnictide superconductor RbEuFe₄As₄ with Tc ≈ 37K and dHc²/dT ≈ 4T/K. The melting transition is seen as a sharp drop of the resistivity and a step of the specific heat at the magnetic-field-dependent temperature. The typical step height is ∼ 4-5% of the zero-field jump, similar to YBa₂Cu₃O₇ and in agreement with theoretical estimates. The specific-heat peak due to the latent heat expected for very clean materials, however, was not observed. The melting line lies in the temperature/magnetic-field plane noticeably below the upper-critical-field line, and the vortex-liquid state occupies a significant portion of the phase diagram. The location of the melting transition is in quantitative agreement with theoretical predictions without fitting parameters.

Influence of magnetic ordering on the vortex matter in RbEuFe₄As₄ single crystals*  
MATTHEW SMYLIE, ULRICH WELP, WAI-KWONG KWOK, JINKE BAO, DUCK YOUNG CHUNG, MERCOURI KANATZIDIS, YILMAZ SIMSEK, KRISTIN WILLA, ALEXEI E KOSHELEV, Materials Science Division, Argonne National Laboratory, LEONARDO CIVALE (Presenter), MPA-Condensed Matter and Magnet Science, Los Alamos National Laboratory — Eu-containing Fe-based superconductors are ideal systems to study the interplay of superconductivity and magnetic order. The superconductor RbEuFe₄As₄ has Tc~37K and undergoes a magnetic ordering of the Eu at Tm~15K. We studied vortex pinning and dynamics in RbEuFe₄As₄ single crystals as a function of temperature (T), magnetic field and orientation (Θ) by angular dependent magnetization. The critical current density (Jc) of the pristine crystals is low, indicative of small disorder, and weakly anisotropic. Introduction of aligned columnar defects (CDs) by heavy ion irradiation increases Jc, but produces almost no changes in Tc and Tm. In the crystals with CDs, Jc(Θ) exhibits a lockin phase, the fingerprint of correlated pinning. Both pristine and irradiated crystals show clear evidence of the influence of the magnetic order on the vortex matter. In pristine crystals, the rate of decrease in Jc with T slows down in the proximity of Tm. Irradiation enhances this effect, with Jc(T) becoming nonmonotonic and developing a local maximum near Tm. In both cases, flux creep rates exhibit local minima around the magnetic transition, indicating an increase in the vortex pinning energy.

Comparison of S- and Te-substitution effects in FeSe thin films*  
FUYUKI NABESHIMA (Presenter), TOMOYA ISHIKAWA, NAOKI SHIKAMA, ATSUTAKA MAEDA, University of Tokyo — We have successfully grown single crystalline films of FeSe₁₋ₓSₓ with x ≤ 0.43 via pulsed laser deposition. As x increases, the structural transition temperature decreases and the superconducting transition temperature, Tc, shows a gradual decrease even when the structural transition disappears. We observed a new kink structure in the resistivity-temperature curves for films with large x, which is likely due to a magnetic transition. The obtained phase diagram of FeSe₁₋ₓSₓ is in contrast to that of FeSe₁₋yTeₓ films, which shows a sudden increase of Tc at the composition where the structural transition disappears[1]. These results demonstrate that the relationship between the nematicity and the superconductivity is not universal in FeSe, suggesting that the nematicity does not play a primary role in the superconductivity in this system[2].

Verwey-like Transition in $\beta$-Fe$_{4+\delta}$Se$_5$ Nanowires of Fe-vacancy Ordering

TUNG-SHENG LO (Presenter), KUNG-YU YEH, CHUNG-CHIEH CHANG, PHILLIP WU, Institute of Physics, Academia Sinica, KUEI-SHU CHANG-LIAO, Department of Engineering and System Science, National Tsing Hua University, MING-JYE WANG, Institute of Astronomy and Astrophysics, Academia Sinica, MAW-KUEN WU, Institute of Physics, Academia Sinica — The magnetotransport and the source-drain frequency dependence of $\beta$-Fe$_{4+\delta}$Se$_5$ nanowires are investigated. The nanowires feature Fe-vacancy ordering and mixed valence of Fe. The resistance shows a first-order metal-insulator transition of transition temperature at ~30K in the absence of magnetic fields. Colossal positive magnetoresistance is observed at temperatures around 30K. The metal-insulator transition presents uniaxial anisotropy with the c-axis in field-orientation dependence. The frequency dependence in resistance below the metal-insulator transition temperature is similar to features in magnetite nanowires at temperatures lower than the Verwey temperature. Our results reveal that the Fe-vacancy-ordered $\beta$-Fe$_{4+\delta}$Se$_5$ nanowires undergo a magnetic first-order phase transition strongly involving spin-orbital coupling with $d_{z^2}$ orbitals.

Observation of low-energy phonon anomalies in Ca$_{0.73}$La$_{0.27}$FeAs$_2$

ZHENZHONG SHI (Presenter), SACHITH DISSANAYAKE, Department of Physics, Duke University, DIPANSHU BANSAL, Department of Mechanical Engineering & Materials Science, Duke University, WENLI BI, AHMET ALATAS, Advanced Photon Source, Argonne National Laboratory, STEPHEN J KUHN, BRODIE POPOVIC, Department of Physics, Duke University, EVE EMMANOUILIDOU, NI NI, Department of Physics and Astronomy, University of California, Los Angeles, OLIIVER DELAIRE, Department of Mechanical Engineering & Materials Science, Duke University, AYMAN SAID, Advanced Photon Source, Argonne National Laboratory, SARA HARAVIFARD, Department of Physics, Duke University — Couplings between lattice and charge or spin degrees of freedom underpin a wide range of phenomena in strongly correlated electronic systems. Fe-based superconductors provide an important platform in probing the phonon effect on high temperature superconductivity, where spin-phonon interaction is expected to dominate. Ca$_{0.73}$La$_{0.27}$FeAs$_2$, considered as a parent compound of the 112 family, has an antiferromagnetic ground state, which gives way to a superconducting state at high pressure. We have performed a systematic inelastic X-ray scattering study on single crystals of Ca$_{0.73}$La$_{0.27}$FeAs$_2$, at both ambient and high pressure, and compared the results with density functional theory (DFT) calculations. A low-energy phonon anomaly was observed, and its nature will be discussed.

STM and Nernst measurements on tetragonal and orthogonal phase of Fe(Se$_{1-x}$S$_x$)

MASAHIRO HAZE (Presenter), WEN-KAI HUANG, DAIKI SANO, SHIGERU KASAHARA, MASAHIRO NARITSUKA, TOMOKA SUEMATSU, TOMOYA TANIGUCHI, YUICHI KASAHARA, Department of Physics, Kyoto University, TAKASADA SHIBAUCHI, Department of Advanced Materials Science, University of Tokyo, YUJI MATSUDA, Department of Physics, Kyoto University — The crossover from the Bardeen-Cooper-Schrieffer (BCS) state for weakly paired fermions to the Bose Einstein condensation (BEC) state of tightly-bound pairs has attracted much attention as a new paradigm of superconductivity. In the BCS-BEC crossover regime, exotic phenomena, such as pseudogap formation owing to preformed pairs above superconducting transition temperature $T_c$, have been predicted.

It has been reported that multiband iron-based superconductor FeSe with the small Fermi energies is located at the BCS-BEC crossover regime. Moreover, very recent heat capacity and ARPES measurements have suggested a possibility that the tetragonal phase of Fe(Se$_{1-x}$S$_x$) ($x > 0.17$) is located at the state closer to the BEC limit. Pairing fluctuation and pseudogap formation above $T_c$, however, have not been reported so far.

In this study, we perform STM and Nernst measurements on FeSe$_{0.87}$S$_{0.13}$ and FeSe$_{0.75}$S$_{0.25}$, which are in the orthogonal and tetragonal phases, respectively. In our Nernst measurements, well exceeding Gaussian fluctuations are observed above $T_c$ in FeSe$_{0.75}$S$_{0.25}$, while pseudogap formation is not observed by the STM measurements. We will discuss the present results in terms of the BCS-BEC crossover in multiband superconducting systems.

Session C11 DMP DCOMP FIAP: Defects in Semiconductors -- Energy Materials

Lyons, United States Naval Research Laboratory - Tag(s): Focus
2:30PM C11.00001: Bright triplet excitons in cesium lead halide perovskites [Invited] ALEXANDER EFROS (Presenter), United States Naval Research Laboratory — The observation of a ground optically forbidden “dark” exciton state in semiconductor nanocrystals was first reported in the seminal paper of Nirmal et al. in 1995. ¹ Later research in nanowires, nanorods, and nanoplatelets has shown that the ground exciton state in all these semiconductor structures is a dark exciton, leading us to believe that the ground exciton must be dark. Because dark excitons release photons slowly, hindering emission, semiconductor nanostructures that disobey this rule have been sought. Three years ago however cesium lead halide perovskite (CsPbX₃, with X = Cl, Br or I ) nanocrystals were grown, which demonstrated very bright photoluminescence (PL) with quantum yield 50-90% at room temperature. This bright emission was traced to a very short radiative decay time. The nanocrystals emit light about 20 and 1,000 times faster than any other semiconductor nanocrystal at room and cryogenic temperatures, respectively. The increase of the decay time with temperature is inconsistent with a dark ground state exciton suggesting that in these nanocrystals the ground exciton state is bright. We use an effective-mass model and group theory to demonstrate the possibility of such a ground bright state existing, which can occur when the strong spin–orbit coupling in the conduction band of perovskites is combined with the Rashba effect.² We then apply our model to CsPbX₃ nanocrystals, and measure size- and composition-dependent fluorescence at the single-nanocrystal level. The bright triplet character of the lowest exciton explains the anomalous photon-emission rates of these materials. The existence of this bright triplet exciton is further confirmed by analysis of the fine structure in low-temperature fluorescence spectra.

3:06PM C11.00002: Formation of DY Defect Centers in Bi-Doped Hybrid Halide Perovskites SUHUAI WEI (Presenter), JINLING LI, JINGXIU YANG, Beijing Computational Science Research Center — The DX center is a major killer defect that limits the n-type doping in some four-fold coordinated semiconductors. It is a deep negatively charged defect complex converted from a nominal shallow donor defect, which can serve as a trap center of electrons, thus is detrimental to the performance of optoelectronic devices. Similar to the DX center, we find that a donor-yielded complex center (DY center) also exists in six-fold coordination semiconducting materials. For example, Bi is commonly used as n-type dopant in perovskite APbX₃. However, our first-principles calculations show that the DY centers are formed in Bi doped MAPbBr₃ when the Fermi level is high in the gap, but, interestingly, it does not form in MAPbI₃. The reason that the DY center is formed in MAPbBr₃ instead of MAPbI₃ is attributed to the high conduction band minimum (CBM) of MAPbBr₃. Our results are able to explain recent puzzling experiment observations and the thorough discussions of the formation and the properties of the DY center in perovskites provide enlightening insights to the defect study in six-fold coordinated semiconductors.

3:18PM C11.00003: Significantly Different Solubility of Li, Na and K Dopants in Cu(In,Ga)Se₂ and Cu₂ZnSn(S,Se)₄ Solar Cells XIAN ZHANG, MENGLIN HUANG, SHIYOU CHEN (Presenter), East China Normal University — The doping of alkaline elements such as Na, K, Rb and Cs in Cu(In,Ga)Se₂ (CIGS) and Cu₂ZnSn(S,Se)₄ (CZTSSe) thin film solar cells had been intensively studied for decades and was shown to be critical for achieving high photovoltaic efficiency. However, the doping of the light alkaline element Li has been much less studied. Using the first-principles calculations, we show here that the formation energy of Li dopants is very low in CIGS and CZTSSe, while the formation energies of Na and K dopants are much higher, so the doping concentration (solubility) of Li can be very high in the CIGS and CZTS lattices at room temperature, much higher than those of Na and other heavier alkaline elements. Na and K may be doped into the CIGS and CZTSSe lattices with a high solubility at high temperature, but the dopants will diffuse out of the grains and prefer staying on the grain boundaries at room temperature because of the low solubility in the lattice. The concentration increase of the hole carriers after the alkaline doping will be discussed based on the calculated solubility.
3:30PM C11.00004: Modeling of disorder in II-IV-V2 semiconductors for tuning of novel properties  JACOB CORDELL (Presenter), Materials Science, Colorado School of Mines/National Renewable Energy Laboratory, JIE PAN, Materials Science, National Renewable Energy Laboratory, GARRITT TUCKER, Mechanical Engineering, Colorado School of Mines, STEPHAN LANY, Materials Science, National Renewable Energy Laboratory — The customization of multinary semiconductors has attracted great interest in the science community for a diverse set of novel applications. The properties of these materials can be fine-tuned by controlling composition and atomic ordering. However, an understanding of the structure-synthesis-property relationship is essential for a rational design. In this contribution, we use two II-IV-V2 materials: ZnSnN2 and ZnGeN2 as examples to illustrate the ordering effects. Model Hamiltonian based Monte Carlo simulations were used to create structures with different degrees of disorder. The energies and electronic structures were estimated from first principles calculations. We find that energies of ZnSnN2 can be well approximated by a Motif Hamiltonian which incorporates only short-range ordering. We demonstrate that, only with the consideration of disorder and oxygen contamination, the net doping level in ZnSnN2 can be lowered to agree with experiments (10^{17} cm^{-3}). However, for ZnGeN2, long-range ordering effects step in, and thus, we use the Cluster Expansion Hamiltonian to create disordered structures. The thermodynamics and optoelectronic properties of disordered ZnGeN2 will be discussed.

3:42PM C11.00005: Sulfur Vacancies as the Origin of n-type Doping in Unintentionally Doped Pyrite FeS2 Single Crystals*  BRYAN VOIGT (Presenter), WILLIAM MOORE, MICHAEL MANNO, JEFF WALTER, CHRIS LEIGHTON, University of Minnesota, ERAY S. AYDIL, New York University — Pyrite FeS2 has long been considered an ideal semiconductor for low-cost solar cells as it is composed of earth-abundant, non-toxic, inexpensive elements, has a suitable band gap (0.95 eV), and absorbs sunlight strongly. Disappointing power conversion efficiencies, however, have plagued pyrite solar cells. An important unanswered question is the origin of the n-type behavior seen in unintentionally-doped pyrite single crystals and thin films. Here, we present the first substantial electronic transport evidence that sulfur vacancies are this n-type dopant by varying sulfur vapor pressure (P_S) during single crystal growth. Crystals grown under high P_S exhibit semiconducting behavior, with transport activation energies of 225 meV and 300 K electron densities (n_{300K}) of 10^{16} cm^{-3}. Decreasing P_S increases n_{300K} to >10^{17} cm^{-3} and decreases the activation energy ten-fold, evidencing an evolution towards an insulator-metal transition. These trends are independent of metal impurity concentrations and, moreover, n_{300K} is too large to be explained by these impurities.

*Work supported by Xcel Energy through the Renewable Development Fund, and by the NSF through the UMN MRSEC.

3:54PM C11.00006: The nature of band gap of Co3O4 – a revisit from first-principles*  TYLER SMART (Presenter), Physics, University of California, Santa Cruz, TUAN ANH PHAM, Quantum Simulations Group, Lawrence Livermore National Laboratory, YUAN PING, Chemistry and Biochemistry, University of California, Santa Cruz, TADASHI OGITSU, Quantum Simulations Group, Lawrence Livermore National Laboratory — Cobalt Oxide (Co3O4) has emerged as a highly promising material for a wide variety of energy technologies, including hydrogen generation through solar-water-splitting and Li ion batteries. Yet, a detailed understanding of the electronic properties of this material is largely lacking. For example, contradicting experimental results have been reported for the optical gap, leading to two commonly reported values of 0.8 eV and 1.6 eV. Here we have employed hybrid functional calculations compliant with the generalized Koopmans' theorem, to demonstrate that the intrinsic band gap of Co3O4 is ~1.6 eV. Meanwhile, the ~0.8 eV transition found experimentally is due to the presence of polaron or defect states. In particular, our calculations predict the spontaneous formation of electron and hole polarons, that in turn exhibit significant contribution to the absorption spectra of the material and are responsible for the optical excitation at 0.8 eV. Finally, we resolve the nature of the stable spin states of electron and hole polarons, and we discuss how the interaction between polarons with n-type dopants (carbon) could improve the electrical conductivity of this intrinsic p-type material.

*NSF under grant No. DMR-1760260. Part of this work was preformed at LLNL under the DOE EERE.
Grain-size dependent carrier compensation in Cu$_2$O*  

GARIMA AGGARWAL (Presenter), SANDEEP KUMAR MAURYA, BALASUBRAMANIAM KAVAIPATTI RAMANATHAN, Energy Science and Engineering Department, Indian Institute of Technology Bombay, India — Cuprous oxide (Cu$_2$O) is an absorber material for low cost solar cells and various fundamental phenomena have been explained using this material. Phase pure Cu$_2$O samples with different grain sizes, in the range of 400 µm to 3 mm, were obtained by thermal oxidation of a Cu sheet. The temperature dependent carrier concentration of all samples follows the compensated semiconductor model. In this model, two independent monovalent acceptors (N$_{A1}$, N$_{A2}$) are assumed with one compensating donor level (N$_D$) and the carrier concentration is obtained from charge neutrality condition. It is observed that the difference in energy levels between two acceptors is ~80 meV, pertaining to a normal and a split Cu-vacancy in Cu$_2$O as acceptor defects. Interestingly, the concentration of donor defects increases with increasing grain boundary cross section (Λ$_{GB}$), from 5.8×10$^{13}$ cm$^{-3}$ for a sample with Λ$_{GB}$=0.22×10$^{-3}$ µm$^{-1}$ to 3.0×10$^{14}$ cm$^{-3}$ for a sample with Λ$_{GB}$=0.45×10$^{-3}$ µm$^{-1}$. It indicates that the grain boundaries act as source of compensating donor defects in Cu$_2$O. This study suggests that the increment in grain size of Cu$_2$O can improve the performance of electronic devices based on it.

*KRB acknowledges IRCC, IIT Bombay for providing funding (Grant No. 12IRCCSG014).

Structural and electronic properties of amorphous In$_2$O$_3$:Li,Na from first principles  

IVAN ZHURAVLEV (Presenter), JULIA MEDVEDEVA, Physics, Missouri University of Science and Technology — Amorphous oxide semiconductors (AOS) have found wide application in consumer electronic devices due to their unique properties, namely, high carrier mobility and transparency in the visible. Among the AOS materials, indium-based oxides show best overall performance. Additional cations, such as Zn, Ga, or Sn, allow one to tune the structural, electronic, and optical properties of ternary and quaternary AOS over wide ranges [1-2].

Here we present a thorough systematic analysis of the structural, electronic, and optical properties of amorphous In$_2$O$_3-x$ doped with Li and Na. From the theory of glass formation, it is known that alkali metal oxides such as Li$_2$O and Na$_2$O serve as structural modifiers, increasing the materials density. We employ ab-initio molecular dynamics liquid-quench simulations and accurate density-functional calculations to understand how addition of Li or Na affects the local In-O structure as well as medium-range In-In structure that determines the morphology of the amorphous network. The resulting electronic and optical properties of Li and Na doped amorphous indium oxide are investigated as a function of density, quench rates, cation composition, and oxygen stoichiometry.

Probing the Electronic States in GaAsNBi Alloys*  

ANDRA CHEN (Presenter), JORDAN M OCCENA, Materials Science and Engineering, University of Michigan, CAGLIYAN KURDAK, Physics, University of Michigan, RACHEL GOLDMAN, Materials Science and Engineering, University of Michigan — Although solar energy is the most abundant renewable energy source, an approach to combine energy harvesting and energy storage is urgently needed. Recently, solar to hydrogen (STH) conversion using photoelectrochemical cells (PEC) has emerged as a promising approach to harvest and store solar energy. Indeed, record STH efficiency is predicted for a tandem PEC which includes a 1.05 eV bandgap junction.  

Recently, we synthesized a novel alloy, gallium arsenide nitride bismide, which is nearly lattice-matched to gallium arsenide, with bandgaps tunable from 0.87 to 1.34 eV. To determine the energy bandoffsets and electronic states of GaAsNBi alloys, we are examining GaAs/GaAsNBi/GaAs single quantum well structures with dilute concentrations of N and Bi. Using a combination of photoluminescence spectroscopy, in conjunction with capacitance-voltage measurements and 1D-Schrödinger-Poisson simulations, we determine the band offsets and deep levels in GaAs/GaAs$_{1-x,y}$N$_x$Bi$_y$/GaAs heterostructures.

*We gratefully acknowledge support of the NSF, DMR 1810280.
4:42PM C11.00010: A theoretical study of the out-of-plane electrical transport of n-type thermoelectric SnS*  JUAN CUI (Presenter), Mechanical Engineering, The University of Hong Kong, JIAQING HE, Department of Physics, Southern University of Science and Technology, YUE CHEN, Mechanical Engineering, The University of Hong Kong — As a promising thermoelectric material containing non-toxic and abundant elements, SnS has attracted significant research focus in recent years. To further improve the thermoelectric energy conversion efficiency of SnS, it is critical to have a thorough understanding of its electronic structure. In this work, we have calculated the band structure of SnS from first principles using the HSE06 hybrid functional to unveil the detailed valence band features. We have then compared the band features of SnS with those of the analogue SnSe, which was recently shown to have a very high thermoelectric figure of merit. By further investigating the doping effects of n-type impurities on the electronic structure and electrical transport properties of SnS, we identify resonant states near the bottom of the conduction band and find a considerable increase of electron delocalization along the out-of-plane direction of the layer crystal structure. Boltzmann transport calculations show that these effects on the electronic structure may result in enhanced electrical transport properties.

*This work is supported by the Research Grants Council of Hong Kong under project numbers 27202516, 17200017 and F-HKU703/16T. We are grateful for the research computing facilities offered by ITS, HKU.

4:54PM C11.00011: scanning tunneling microscopy of defects in SnS2  MANOJ SINGH (Presenter), BISHNU SHARMA, BONING YU, Physics, Clark University, LYUBOV TITOVA, Physics, WPI, RONALD GRIMM, Chemistry, WPI, MICHAEL C BOYER, Physics, Clark University — We present our room- temperature scanning tunneling microscopy measurements of SnS2, a quasi-two dimensional layered semiconductor. SnS2 is a material of interest due to its high carrier mobility and its potential use in applications including in photonics, electronics, and solar energy conversion. Understanding the surface properties of SnS2 are particularly important for its incorporation and optimization in applications. Here we present our surface characterization of SnS2 and detail several surface features including surface/subsurface defects which locally distort the crystal lattice.

Monday, March 4, 2019 2:30 PM - 5:30 PM

2:30PM C12.00001: Indirect bandgap measured in β'-phase In2Se3 crystals by angle-resolved photoemission spectroscopy*  MICHAEL FUHRER (Presenter), JAMES COLLINS, CHUTIAN WANG, ARC Centre of Excellence in Future Low-Energy Electronics Technologies, ANTON TADICH, Australian Synchrotron, YUEFENG YIN, ARC Centre of Excellence in Future Low-Energy Electronics Technologies, SHUJIE TANG, SUNG-KWAN MO, Advanced Light Source, Lawrence Berkeley National Laboratory, CHANG LIU, CHANGXI ZHENG, NIKHIL MEDHEKAR, MARK T EDMONDS, ARC Centre of Excellence in Future Low-Energy Electronics Technologies — In2Se3 is a widely studied van der Waals (vdW) layered material and its many structural phases have attracted attention for their promise as semiconducting platforms for photovoltaics, use as an isostructural buffer layers in topological insulator superlattices, and recently as room temperature ferroelectrics1,2. The details of its electronic structure however have not been fully elucidated by experiments. We report on a combined angle-resolved photoemission spectroscopy and density functional theory study which reveals an indirect bandgap with highly anisotropic conduction and valence bands in bulk crystals of commercially obtained β'-phase In2Se3. The n-doped crystals exhibit large effective mass hole bands with maxima slightly offset from Γ, as well as small effective mass electron valleys which sit at M/M' points, with minima at M/M' lower in energy by about 0.3eV, resulting in an indirect bandgap of 1.41eV, and a direct bandgap at Γ in excess of 1.7eV.

2:42PM C12.00002: Theory of “Emergence of excitonic superfluid at topological-insulator surfaces”*  
RUI WANG (Presenter), Shanghai Jiao Tong University, YASEN HOU, RUI XIAO, LUKE MCCLINTOCK, HENRY CLARK TRAVAGLINI, JOHN PAULUS FRANCIA, University of California, Davis, HARRY FETSCH, Harvey Mudd College, ONUR ERTEN, Arizona State University, SERGEY SAVRASOV, University of California, Davis, BAIGENG WANG, Nanjing University, ANTONIO ROSSI, INNA VISHIK, University of California, Davis, ELI ROTENBERG, Lawrence Berkeley National Laboratory, DONG YU, University of California, Davis — We study the BCS condensation of excitons on topological-insulator surfaces. With presence of a screened Coulomb interaction between excited electrons and holes, the BCS excitons can be formed with predicted transition temperature up to 40K. The thermal fluctuation is found to disturb the long-range order by creating vortex excitations. It lowers the mean-field estimation of the transition temperature and drives the transition into the Kosterlitz-Thouless type. The BCS condensation of excitons forms ground state with quantum coherence that leads to the experimentally observed long-range transport of photocurrent. We also discuss possible generation of the topological p+ip excitonic insulators at topological-insulator surfaces.

2:54PM C12.00003: Optical Selection Rules and Optical Nonlinearities of Excitonic States in Monolayer MoS2*  
DANIEL SOH (Presenter), Sandia National Laboratories California, ERIC CHATTERJEE, Ginzton Laboratory, Stanford University, CHRISTOPHER ROGERS, Sandia National Laboratories California, DODD J GRAY, HIDEO MABUCHI, Ginzton Laboratory, Stanford University — The monolayer MoS2 exhibits a strong optical response from the stable excitonic states even at room temperature, due to the large binding energy of the reduced dimension. We present that the topological chirality in MoS2 binding the valleys and the spins determines not only the linear but also the nonlinear optical responses. Using the massive Dirac Hamiltonian to provide efficient handling of the nonlinear processes, we perform a perturbative calculation in the low-temperature and weakly excited limit. We then derive the linear and the nonlinear optical susceptibilities. We calculated those for particularly the second- and the third-harmonic generations, two-photon absorption, and optical Kerr effect, based on the prescribed optical selection rules. We compare the optical responses of the monolayer MoS2 with our previous results on graphene, adopting the Keldysh-type wave functions and the S-matrix treatment. We also present the figure of merit for efficient optical Kerr device applications.

3:06PM C12.00004: Photoluminescence studies of monolayer WSe2 in proximity with BiFeO3 thin films.  
ANIL RAJAPITAMAHUNI (Presenter), NEREA ONTOSO, CIC nanoGUNE, SAEDEH FAROKHPOOR, University of Groningen, JOSE IGNACIO PASCUAL, CIC nanoGUNE, BEATRIZ NOHEDA, University of Groningen, REYES CALVO, CIC nanoGUNE — We have studied the photoluminescence (PL) properties of 1-layer WSe2 in proximity with multiferroic BiFeO3 (BFO) thin films. Using pulsed laser deposition, we have grown epitaxial single crystalline BFO films of 20 -80 nm thick on SrRuO3 buffered (001) SrTiO3 substrates. X-Ray and AFM characterizations show the films have high crystallinity and smooth surface. Piezo-response force microscopy studies show that the as-grown PZT films have uniform polarization pointing away from the substrate. We then transferred WSe2 flakes onto 300 nm SiO2 and BFO using elastic film assisted micro-mechanical exfoliation. Optical microscopy combined with Raman spectroscopy is used to identify and determine the layer number of WSe2 flakes. Spatially-resolved PL spectroscopy measurements are performed using a scanning confocal microscope to investigate the valley excitonic properties of WSe2 in proximity with BFO. When compared to SiO2, we observed a quenching in PL signal for WSe2 on BFO at 300 K. We have also studied the effect of temperature and magnetic fields on the valley polarization of monolayer WSe2 in proximity with multiferroic BFO thin films.
3:18PM C12.00005: Tunable Optical Absorption by Excitons in Xenes via an External Electric Field*  MATTHEW BRUNETTI (Presenter), CUNY Graduate Center, OLEG BERMAN, ROMAN KEZERASHVILI, Physics, CUNY - City Tech — We study the binding energies and optical properties of direct and indirect excitons in monolayers and double-layer heterostructures of Xenes: silicene, germanene, and stanene. The exciton eigenenergies, optical transition energy, oscillator strength, and absorption coefficient are calculated [1]. An external electric field tunes the eigenenergies and optical properties of excitons by changing the effective mass of charge carriers. The Schrödinger equation with field-dependent exciton reduced mass is solved by using the Rytova-Keldysh (RK) potential for direct excitons, while both the RK and Coulomb potentials are used for indirect excitons. For indirect excitons, we show that the choice of interaction potential can cause significant changes in the eigenenergies. Finally, our results show that the choice of material parameters has a significant effect on the binding energies and optical properties of direct and indirect excitons. These calculations contribute to the rapidly growing body of research regarding the excitonic and optical properties of this new class of two-dimensional semiconductors.

3:30PM C12.00006: Emergence of excitonic superfluid at topological-insulator surfaces* YASEN HOU (Presenter), University of California, Davis, RUI WANG, Shanghai Jiao Tong University, RUI XIAO, LUKE MCCLINTOCK, HENRY CLARK TRAVAGLINI, JOHN PAULUS FRANCIA, University of California, Davis, HARRY FETSCH, Harvey Mudd College, ONUR ERTEM, Arizona State University, SERGEY SAVRASOV, University of California, Davis, BAIGENG WANG, Nanjing University, ANTONIO ROSSI, INNA VISHIK, University of California, Davis, ELI ROTENBERG, Lawrence Berkeley National Laboratory, DONG YU, University of California, Davis — Excitons are spin integer particles that were predicted to condense into a coherent quantum state at sufficiently low temperature more than 50 years ago. Nonetheless, transport of exciton condensates is not yet understood and it is unclear whether an exciton condensate is a superfluid or an insulating electronic crystal. Topological insulators (TIs) with massless particles and unique spin textures have been theoretically predicted as a promising platform for achieving exciton condensation. Here we report experimental evidence of excitonic superfluid phase at the surface of three-dimensional (3D) TIs. We unambiguously confirmed that electrons and holes are paired into charge neutral bound states by the electric field independent photocurrent distributions. And we observed a millimetre-long transport distance of these excitons up to 40 K, which strongly suggests dissipationless propagation. The robust macroscopic quantum states achieved with simple device architecture and broadband photoexcitation at relatively high temperature are expected to find novel applications in quantum computations and spintronics.

3:42PM C12.00007: Interlayer exciton diffusion in MoSe2/WSe2 heterostructures* JUNHO CHOI (Presenter), WEI-TING HSU, Department of Physics, University of Texas at Austin, TX 78712, United States, LI-SHUAN LU, HUI-YU CHENG, Department of Electrophysics, National Chiao Tung University, Hsinchu 30010, Taiwan, LIUYANG SUN, KHA TRAN, ANDRÉ ZEPEDA, MARSHALL CAMPBELL, MATTHEW STAAB, KAYLEIGH R JONES, Department of Physics, University of Texas at Austin, TX 78712, United States, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute of Material Science, 1-1 Namiki, Tsukuba, Ibaraki 205-0044, Japan, CHIH-KANG SHIH, XIAOQIN (ELAINE) LI, Department of Physics, University of Texas at Austin, TX 78712, United States, WEN-HAO CHANG, Department of Electrophysics, National Chiao Tung University, Hsinchu 30010, Taiwan — Excitons with large binding energy are formed in atomically thin semiconductors because of the insufficient dielectric screening outside of the 2D layers. In a vertical heterostructure consisting of MoSe2 and WSe2 monolayers, the type-II band alignment leads to the rapid transfer of electron to the MoSe2 layer and hole to the WSe2 layer, forming interlayer excitons with drastically different properties than excitons confined within one monolayer. We investigate the interlayer exciton diffusion in MoSe2/WSe2 heterostructures. We compare a mechanically stacked heterostructure with hexagonal boron nitride (hBN) encapsulation and one grown by chemical vapor deposition (CVD). Spatially and time-resolved photoluminescence measurements are performed at low-temperature. Interlayer exciton diffusion length and coefficient are extracted in both heterostructures and found to be rather different.

Valley Selective Optical Routing in Hyperbolic Metamaterials

SRIRAM GUDDALA (Presenter), MANDEEP KHATONIAR, NICHOLAS YAMA, VINOD M MENON, Department of Physics, City College of New York, New York-10031, USA. — At the monolayer limit, the 2D transition metal dichalcogenides materials such as WS$_2$, WSe$_2$, and MoS$_2$ etc., are endowed with direct bandgap and high binding energy excitons at individually addressable two degenerate valleys in momentum space at K and K’ points in the first Brillouin zone. In recent years, there has been growing interest in achieving control over the selective valley excitation/emission by means of optical, electrical, and magnetic fields and explore this valley degree of freedom as an efficient way of data transfer, computing and storage technology, called valleytronics. We describe and experimentally demonstrate the optical control on selective valley excitation and emission routing through spatially confined subwavelength electromagnetic modes in an anisotropic metamaterial with hyperbolic dispersion. The directionality of selective valley exciton emission depends on the handedness of that valley’s circular polarization emission. The demonstrated capability of our hyperbolic metamaterial -TMD hybrid system is free from precise nanoscale structural dimensions and most importantly broadband response and shows great potential to develop prototype devices such as valley filters or valley-based qubits for quantum computing/communications.

Non-adiabatic effects in exciton-mediated Raman scattering from first principles

SVEN REICHARDT (Presenter), Department of Materials, University of Oxford, LUDGER WIRTZ, Physics and Materials Science Research Unit, University of Luxembourg, ANDREA MARINI, Division of Ultrafast Processes in Materials (FLASHit), Istituto di Struttura della Materia of the National Research Council Italy — We present a fully quantum mechanical, _ab initio_ approach for the calculation of optical properties of solids, in particular resonant Raman scattering. Starting from the fundamental observable, we derive a fully general description of light scattering by matter beyond the commonly used semi-classical approximations for the electron-nuclei interaction. Our approach captures both direct and phonon-mediated light absorption as well as inelastic light scattering.

We provide a concrete computational recipe for the calculation of resonant Raman intensities beyond the approximation of static (adiabatic) phonons and including excitonic effects. Applying our approach to several materials, we discuss the effects of non-adiabaticity on the Raman intensity. The latter are not captured by frozen-phonon-based approaches [1,2] and so far could only be described by neglecting excitonic effects [3,4], which, however, are predominant in low-dimensional semi-conductors.

Probing the nonlinear response of strongly coupled plasmon-WSe$_2$ system

CHENTAO LI (Presenter), HAYK HARUTYUNYAN, XIN LU, AJIT SRIVASTAVA, Emory University — Two-dimentional transition metal dichalcogenides (TMDs) have recently emerged as a class of material that shows a great potential for strong light-matter interaction at the nanoscale. Signatures of strong coupling, such as Rabi-splitting in the linear optical spectra, have been observed by placing TMDs in optical nanocavities. Typically, plasmonic nanocavities and nanostructures are used to reach the appropriate parameters for the observation of strong coupling regime. However, most studies utilize dark field (DF) scattering experiments rather than photoluminescence (PL) for the demonstration of strong coupling phenomena, whereas the observation of PL splitting in this system has rarely been reported. Thus, more convincing evidences of strong coupling are still needed.

We have successfully assembled gold nanoparticles and TMD materials (WSe$_2$) to investigate the strong light-matter interaction in TMDs. Interestingly, our simulation based on a two-oscillator toy model predicts that second harmonic generation will show a pronounced spectral splitting in this regime. Thus, we suggest that probing of these systems in the nonlinear regime may give clearer evidence of strong coupling that could not be observed in the linear measurements.

**4:30PM C12.00011: Probing the phonon scattering in the strong light-matter coupling regime**

XIAOZE LIU (Presenter), JUN YI, SUI YANG, University of California, Berkeley, ERH-CHEN LIN, National Tsing-Hua University, YUE-JIAO ZHANG, JIAN-FENG LI, Xiamen University, YUAN WANG, University of California, Berkeley, YI-HSIEN LEE, National Tsing-Hua University, ZHONG-QUN TIAN, Xiamen University, XIANG ZHANG, University of California, Berkeley — The strong light-matter coupling is the core of cavity quantum electrodynamics (CQED), which leads to discoveries of fascinating phenomena in solid state system such as Bose-Einstein condensation and photon blockade. Indirect evidence indicates non-fluorescence processes such as phonon scattering are critical to these phenomena. However, the understanding of such processes remains elusive due to their non-radiative nature smeared by the overwhelming fluorescence in cavities. Here we directly probe phonon scattering based on Raman spectroscopy in the strong coupling regime in a plasmonic cavity embedded with a monolayer MoS2. The studied non-fluorescence process is significantly modified by the hybrid properties of the newly formed half-light half-matter quasiparticles, i.e., polaritons. For the first time, we observe nonlinearly enhanced valley-dependent phonon modes, involved with stimulated lattice vibrations and inter-valley scatterings. This work provides a new perspective to investigate fundamental quantum processes in the strong coupling regime.

**4:42PM C12.00012: Ultra-long wavelength Dirac plasmons in graphene capacitors**

DAVID MELE (Presenter), HOLGER GRAEF, MICHAEL ROSTICHER, Laboratoire Pierre Aigrain, CNRS - Ecole Normale Supérieure, LUCA BANSZERUS, CHRISTOPH STAMPFER, JARA-FIT and 2nd Institute of Physics, RWTH Aachen University, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, ERWANN BOCQUILLON, GWENDAL FÊVE, JEAN-MARC BERROIR, Laboratoire Pierre Aigrain, CNRS - Ecole Normale Supérieure, EDWIN HANG TONG TEO, School of Electrical and Electronic Engineering, Nanyang Technological University, BERNARD PLAÇAIS, Laboratoire Pierre Aigrain, CNRS - Ecole Normale Supérieure — Graphene is a recognized 2D platform for plasmonics in the THz and mid-IR domains. These high-energy plasmons couple to the dielectric surface modes, giving rise to hybrid plasmon-polariton excitations. The ultra-long wavelength GHz range addresses the low energy end of the spectrum, where Dirac plasmons are damped by ohmic losses but essentially decoupled from environment. Using hBN encapsulated graphene [1], we demonstrate a plasma resonance capacitor [2] showing a quarter-wave plasmon mode, at 40 GHz, with a quality factor Q=2. The resolution of the resonant technique yields precise determinations of the electronic compressibility, kinetic inductance, and mean free-path, in good agreement with theory. The 100µm-long wavelength allows engineering of doping-modulated devices where plasmons are controlled by Klein tunneling. Downscaling for room temperature operation opens up perspectives in microwave detection for wireless communication and sensing [3].

*Funding from the European Union ‘Horizon 2020’ research and innovation programme under grant agreement No.785219 ‘Graphene Core’ and from the ANR-14-CE08-018-05 ‘GoBN’.

**4:54PM C12.00013: Strong coupling in metal-WS2 hybrid system**

JINWEI SHI (Presenter), DAHE LIU, Physics, Beijing Normal University, CHIH-KANG SHIH, Physics, University of Texas at Austin, YI-HSIEN LEE, SHANGJR GWO, National Tsing-Hua University — Metallic particle array as an effective plasmonic cavity has attracted great interest. Coupling between such plasmonic cavity and gain materials have been reported. In this work, we studied two kinds of polaritons in such system. First, we studied the strong coupling between groove localized surface plasmon resonance (LSPR) and lattice surface plasmon polariton in a metallic groove array. We found that the optical response of such system is different from the ordinary weak coupling surface lattice resonance. A giant Rabi splitting of ~440 meV was observed, both angle and pitch tuning. The underlying mechanism is analyzed. Next, we studied the coupling between the metallic grating and the exciton in WS2 monolayer. LSPR was used. The parallel electric field within the groove can provide an effective coupling to the excitons of monolayer WS2. To overcome the problem of angle tuning reported in previous work, we developed a depth chirped grating to realize the resonance tuning. A moderate Rabi splitting of 56 meV was observed. These works demonstrate the potential application in strong coupling devices based on plasmonic cavity.

5:06PM C12.00014: Optical absorption spectra of monolayer transition metal dichalcogenides at high doping levels

MINDA DENG (Presenter), CHUN-LAN WU, Stanford University, ZILIANG YE, Stanford University & University of British Columbia, YI CUI, Stanford University, TONY F HEINZ, Stanford University & SLAC — The absorption spectra of semiconducting transition metal dichalcogenides (TMDCs) at monolayer thickness are dominated by excitonic transitions due to the strong Coulomb interactions associated with the materials’ reduced screening and dimensionality. It has been shown that the excitons in these materials can be tuned electrically by using a Si back gate to achieve carrier density up to several times $10^{12}$ cm$^{-2}$. Here we extend these studies to higher carrier densities through the use of electric double layer gating technique with the ionic solid conductor LaF$_3$ as the electrolyte. In this fashion, we are able to electrostatically gate monolayer WSe$_2$ to a density of a few $10^{13}$ cm$^{-2}$. While earlier investigations showed shifts in exciton (and charged exciton) energies and binding energies, the excitonic absorption features remained relatively strong and distinct. At carrier densities in the $10^{13}$ cm$^{-2}$ range, however, we find that the excitonic absorption features are no longer observable. The progression of the measured absorption spectra with increasing doping density is compatible with the behavior expected for a Mott transition from the excitonic regime to an electron–hole plasma regime, as was previously reported for the case of strong photodoping of TMDC monolayers.

5:18PM C12.00015: Nonperturbative nonlinear effects in the dispersion relations for TE and TM plasmons on two-dimensional materials

VERA ANDREEVA (Presenter), MITCHELL LUSKIN, School of Mathematics, University of Minnesota, DIONISIOS MARGETIS, Department of Mathematics, University of Maryland — We analytically obtain the dispersion relations for transverse-electric (TE) and transverse-magnetic (TM) surface plasmon-polaritons in a nonlinear two-dimensional (2D) conducting material with inversion symmetry lying between two Kerr-type dielectric media. To this end, we use Maxwell’s equations within the quasielectrostatic, weakly dissipative regime. We show that the wavelength and propagation distance of surface plasmons decrease due to the nonlinearity of the surrounding dielectric. In contrast, the effect of the nonlinearity of the 2D material depends on the signs of the real and imaginary parts of the third-order conductivity. Notably, the dispersion relations obtained by naively replacing the permittivity of the dielectric medium by its nonlinear counterpart in the respective dispersion relations of the linear regime are not accurate. We apply our analysis to the case of doped graphene and make predictions for the TM-polarized surface plasmon wavelength and propagation distance.

Session C13 DMP GMAG: 2D Materials (General) -- Magnetic and Thermal Properties

2:30PM C13.00001: Magnetic order in the cleavable van der Waals crystal Fe$_2$GeTe$_2$ *ANDREW MAY (Presenter), Oak Ridge National Laboratory, DMITRY OVCHINNIKOV, University of Washington, QIANG ZHENG, RAPHAEL HERMANN, STUART CALDER, Oak Ridge National Laboratory, BEVIN HUANG, ZAIYAO FEI, University of Washington, YAOHUA LIU, Oak Ridge National Laboratory, XIAODONG XU, University of Washington, MICHAEL A MCGUIRE, Oak Ridge National Laboratory — Van der Waals bonded materials with intrinsic magnetism play a key component in several aspects of present-day materials physics. In this study, we report the structure and properties of Fe$_{5-x}$GeTe$_2$. The average crystal structure obtained from single crystal x-ray diffraction contains disorder associated with occupation of Fe/Ge split sites. Atomic-resolution STEM has been utilized to inspect the local crystal structure and has revealed local ordering. The magnetism has been characterized using magnetization measurements on single crystals, as well as powder neutron diffraction and Mössbauer spectroscopy on a polycrystalline sample. The crystals have been successfully exfoliated, and Hall effect measurements on nanoflakes confirm magnetic order near room temperature. These results demonstrate that Fe$_{5-x}$GeTe$_2$ will be a promising material for incorporation into van der Waals heterostructures and devices.

2:42PM C13.00002: Single Crystal Neutron Diffuse Scattering on Nonstoichiometric Quasi-2D Ferromagnetic Fe₃₋ₓGeTe₂*  
YAOHUA LIU (Presenter), STUART CALDER, Neutron Scattering Division, Oak Ridge National Laboratory, ANDREW MAY, Materials Science and Technology Division, Oak Ridge National Laboratory, YAWEI HUI, Computer Science and Mathematics Division, Oak Ridge National Laboratory — Two-dimensional (2D) van der Waals magnetic materials hold great potential for spintronics. Particularly, the recent discovery of gate-tunable room-temperature ferromagnetism in atomically thin Fe₃₋ₓGeTe₂ makes it a promising candidate toward voltage-controlled low-dispersion devices. However, the magnetic properties of Fe₃₋ₓGeTe₂ show a considerable dependence on the stoichiometry. To better understand the role of the Fe-deficiency, we have performed single crystal neutron diffuse scattering at the CORELLI spectrometer at the Spallation Neutron Source to investigate the local structure. The nonstoichiometric sample shows highly structured diffuse scattering patterns in the HK plane with a weak q dependence along the L direction. As revealed from the cross-correlation analysis with the statistical chopper, the observed diffuse scattering is mainly of a static origin. The L dependence can be partially attributed to the stacking faults. To produce the HK plane diffuse scattering features, we have performed Monte Carlo simulations to model the short-range order of the Fe vacancies and considered the lattice relaxation around the Fe vacancies.

*This research used resources at Spallation Neutron Source, a DOE Office of Science User Facility operated by the Oak Ridge National Laboratory.

2:54PM C13.00003: Skyrmions in the Moire of van der Waals 2D Magnets*  
QING TONG (Presenter), Physics and Electronics, Hunan University, FEI LIU, Physics, The University of Hong Kong, JIANG XIAO, Physics, Fudan University, WANG YAO, Physics, The University of Hong Kong — We explore the skyrmion formation and control possibilities in 2D magnets from the ubiquitous moiré pattern in vdW heterostructures. Using the example of a ferromagnetic monolayer on an antiferromagnetic substrate, we demonstrate a new origin of skyrmions in the 2D magnets, from the lateral modulation of interlayer magnetic coupling by the locally different atomic registries in moiré. The moiré skyrmions are doubly degenerate with opposite topological charge, and trapped at an ordered array of sites with the moiré periodicity that can be dramatically tuned by strain and interlayer translation. At relatively strong interlayer coupling, the ground states are skyrmion lattices, where magnetic field can switch the skyrmion vorticity and location in the moiré. At weak interlayer coupling limit, we find metastable skyrmion excitations on the ferromagnetic ground state that can be deterministically moved between the ordered moiré trapping sites by current pulses.

*The work is supported by the Croucher Foundation, the Research Grants Council and University Grants Committee (17303518P, AoE/P-04/08) of Hong Kong SAR.

3:06PM C13.00004: Design and discovery of van der Waals magnets toward room temperature devices* [Invited]  
FAZEL FALLAH TAFTI (Presenter), MYKOLA ABRAMCHUK, KENNETH BURCH, GAVIN B OSTERHOUDT, SAMANTHA JASZEWSKI, YIPING WANG, Boston College — Chromium trihalides were recognized as magnetic Van der Waals materials since 1920s. They were studied vigorously during 1950s to 70s when fundamental theories of magnetic ordering, exchange interactions, and magnetic anisotropy were developing. Recent advances in device fabrication and magneto-optical measurements lead to the discovery of 2D magnetic ordering in CrI₃ monolayers with great potential for atomically thin devices. CrCl₃, CrBr₃, and CrI₃ are stable in air and easy to exfoliate, therefore ideal for applications. Here, we present the chemical pathway to tune all the physical properties of these materials by mixing different halide species. We use CrCl₃₋ₓBrₓ as a benchmark to show the design principles of mixed halides where isovalent substitution of Br for Cl occurs during a chemical vapor transport process. Remarkably, all physical properties including the van der Waals gap, the magnetic ordering temperature, the ferromagnetic exchange coupling, the optical gap, and the magnetic anisotropy are tuned linearly as a function of x. Our results demonstrate unprecedented control over the magneto-optical properties of CrCl₃₋ₓBrₓ required for a range of applications from spintronics to biomedical industries.

*The authors acknowledge funding by the National Science Foundation under awards DMR-1708929 and DMR-1709987.
Transition metal dichalcogenides (TMDs) are atomically thin semiconductors of the type MX$_2$ with M being a transition metal (such as Mo, W etc.) and X being a chalcogen atom (such as S, Se and Te). TMDs have recently attracted considerable attention because of their novel electronic and optical properties. Little attention is given to the synthesis and characterization of chromium dichalcogenides. Here, we introduce a new method for obtaining Cr$_2$S$_3$ via vapor-solid growth mechanism. Polycrystalline Cr-sulfide sample was synthesized by heating a mixture of Cr and S in a sealed and evacuated silica tube (<10$^{-5}$ mbar) at 500°C for 24 hours and then 800°C for another four days. At 800 °C, with the help of Ar as carrier gas, we deposited Cr$_2$S$_3$ on sapphire samples. AFM images showed only quasi-two-dimensional triangular islands on otherwise flat samples. The phase and structural analysis of as synthesized powder were examined by a powder X-ray diffractometer. Some of the XRD peaks match well with the calculated XRD data for Cr$_2$S$_3$ confirming the quasi-2D nature of the islands observed in the AFM images.

This work was supported by the following grant: NDEPSCoR #UND0021231.

Integrating two-dimensional(2D) magnet with topological insulator is an exciting topic. Other than the possible proximity induced magnetic ordering inside topological insulator, the 2D magnet/ topological insulator heterostructure can also lead to more efficient spin orbit torque switching, or the formation of magnetic skyrmions. The recent discovery of room temperature ferromagnetic ordering in 2D material MnSe$_2$ and VSe$_2$ further brings more potential in such heterostructure systems. In this talk, we report the synthesis and characterization of 2D magnet MnSe$_2$ and VSe$_2$ on topological insulator Bi$_2$Se$_3$. Monolayer and few layers of MnSe$_2$ and VSe$_2$ are grown on Bi$_2$Se$_3$ with molecular beam epitaxy. The material quality and magnetic property are characterized with RHEED, XRD, XPS, and SQUID. Furthermore, the 2D magnet/ topological insulator heterostructures are characterized with STM to study their atomic structure and local electronic properties. Finally, recent progress of measuring the local magnetic properties of these films with spin-polarized STM will also be discussed.

This project is mainly supported by the US Department of Energy (Grant No. DE-SC0018172).

Synthesis, Raman scattering and transport studies of quasi-two-dimensional magnetic Cr$_2$S$_3$ nanoplates

The recent discovery of intrinsic ferromagnetism in atomically thin crystals has sparked a growing effort in synthesizing two-dimensional magnetic materials for new spintronic applications. In this work, we synthesized quasi-two-dimensional Cr$_2$S$_3$ nanoplates via a facile sulfurization approach, in which Cr metal was annealed in sulfur atmosphere. Depending on the thickness of Cr layers, the Cr$_2$S$_3$ nanoplates were grown either epitaxially or non-epitaxially (i.e. randomly oriented) on the sapphire substrates. Raman scattering studies suggest that both types of nanoplates have a rhombohedral R3 structural phase, which in its bulk form shows weak ferromagnetism below a metal-insulator transition (MIT) temperature (~120K). Density-functional calculations clearly identified most of the Raman-active peaks and their vibrational patterns. The epitaxially grown nanoplates exhibit an enhanced MIT up to ~260 K, while the non-epitaxial sample shows an insulating behavior that can be described by the variable-range-hopping model.

Work supported in part by NSF DMR-1506460, CAREER Grant No. DMR- 1760668, and NSF DMR 1709781
4:18PM C13.00008: Electron Spin Resonance of Magnetic Two-Dimensional Covalent Organic Frameworks* ABIGAIL FIRM (Presenter), VALERIE A. KUEHL, JOSEPH MURPHY, JOHN O. HOBERG, WILLIAM RICE, University of Wyoming — Two-dimensional (2D) materials have generated significant interest because of their unique electrical, optical, and magnetic single-layer behaviors. However, the inability to add electrical or magnetic dopants to a substantial set of 2D materials hinders their ability to be incorporated into device architectures. Here, we synthesize 2D covalent organic frameworks (COFs) that have a lattice of nanopores, which we are able to synthetically fill with magnetic ions (Mn$^{2+}$) that are hexagonally arranged. We use a host of characterization techniques, such as x-ray diffraction, TEM, NMR, and FTIR, to demonstrate that our COFs are ordered, nanoporous, and 2D. Magnetic ion filling is empirically shown through electron spin resonance measurements. Unlike the unfilled COFs, which have a single peak at $g=2.0$, the Mn-filled COFs show a hyperfine-split, sextet of peaks with a spin relaxation time of ~0.5 ns and a 19 G exchange splitting. The ability to chemically change the nanopore spacing and the inter-ion distance, combined with our confirmation of the hexagonal Mn$^{2+}$ ion arrangement, suggests the possibility of using these 2D COFs for potential quantum spin liquids or in magneto-optical devices.

*We acknowledge support from the UW School of Energy Resources and the A&S Dean’s Office.

4:30PM C13.00009: Anisotropic structural dynamics of monolayer crystals revealed by femtosecond surface x-ray scattering* I-CHENG TUNG, Argonne National Laboratory, ARAVIND KRISHNAMOORTHY, University of Southern California, SRIDHAR SADASIVAM, HUA ZHOU, QI ZHANG, Argonne National Laboratory, KYLE SEYLER, GENEVIEVE CLARK, University of Washington, Seattle, EHREN MANNEBACH, CLARA M NYBY, FRIEDERIKE ERNST, Stanford University, DILING ZHU, JAMES M GLOSSNIA, MICHAEL E KÖZINA, SANGHOON SONG, SILKE NELSON, SLAC National Accelerator Laboratory, HIROYUKI KUMAZOE, FUYUKI SHIMOJO, Kumamoto University, RAJIV KALIA, PRIYA VASHISHTA, University of Southern California, PIERRE DARANCET, Argonne National Laboratory, TONY F HEINZ, Stanford University, AIICHIRO NAKANO, University of Southern California, XIAODONG XU, University of Washington, Seattle, AARON M LINDENBERG, Stanford University, HAIDAN WEN (Presenter), Argonne National Laboratory — The direct structural characterization of nonequilibrium processes within a monolayer crystal remains a challenge due to significantly reduced scattering volume. In this work, we demonstrate femtosecond surface x-ray diffraction in combination with crystallographic model-refinement calculations to measure the ultrafast structural dynamics of monolayer WSe$_2$ crystals on a substrate. We found the absorbed photon energy is preferably coupled to the in-plane lattice vibrations within 2 picoseconds while the out-of-plane lattice vibration amplitude remains unchanged during the first 10 picoseconds. The model-assisted fitting suggests an asymmetric intralayer spacing change upon excitation. The demonstrated methods unlock the benefit of x-ray scattering to quantitatively measure ultrafast structural dynamics in atomically thin materials and across interfaces.

4:42PM C13.00010: Vibrational Properties of van der Waals Materials SABINE NEAL (Presenter), Department of Chemistry, University of Tennessee, HEUNG SIK KIM, Department of Physics and Astronomy, Rutgers University, AMANDA HAGLUND, Department of Materials Science and Engineering, University of Tennessee, KEVIN SMITH, Department of Chemistry, University of Tennessee, MICHAEL CROCKER MARTIN, HANS BECHTEL, Lawrence Berkeley National Laboratory, G LAWRENCE CARR, Brookhaven National Laboratory, DAVID VANDERBILT, KRISTJAN HAULE, Department of Physics and Astronomy, Rutgers University, DAVID GEORGE MANDRUS, Department of Materials Science and Engineering, University of Tennessee, JANICE LYNN MUSFELDT, Department of Physics and Astronomy, Department of Chemistry, University of Tennessee — Single sheet van der Waals materials have become increasingly important over the last decade because of their broad range of applications in areas such as catalysis, energy storage, and microelectronics. These single/few layer constructs have been thoroughly analyzed by Raman spectroscopy but all infrared spectroscopy to date has been unsuccessful due to the inability to overcome the diffraction limit. The investigation of characteristic ungerade infrared modes is, however, crucially important in understanding material functionality. Synchrotron infrared nanospectroscopy, a fusion of near-field optical microscopy with high brightness infrared synchrotron radiation, has overcome this fight for photons and enabled a better understanding of size-induced effects, including quantum confinement and symmetry breaking which lead to distinctive chemical, electronic, optical, and thermal properties that are quite different from the single crystal. This approach will be illustrated with the complex magnetic semiconductor, MnPS$_3$.

4:54PM C13.00011: Phonons and thermal transport in hafnium disulphide (HfS$_2$)*  JIE PENG (Presenter), PETER CHUNG, Mechanical Engineering, University of Maryland, College Park, SINA NAJMAEI, MADAN DUBEY, Sensors and Electron Devices Directorate, United States Army Research Laboratory — Recent studies have shown that hafnium disulphide (HfS$_2$) exhibits many desirable properties such as high room-temperature mobility, finite bandgap, and high on-off current ratio that are favored by electronic devices. Despite the large number of existing studies of HfS$_2$, thermal transport properties have not been fully explored and the related question of how temperature affects the thermal properties remain unanswered. In this work, we report anharmonic phonons in HfS$_2$ via first-principle calculations. Key calculated properties include the fully anisotropic Gruneissen parameters, specific heats, coefficients of thermal expansion, and anisotropic thermal conductivity. The study of thermal expansion found interesting behaviors that suggest the structure of HfS$_2$ gives rise to negative Gruneissen parameters where the frequency or energy of a mode can decrease with applied pressure. The associated phonon lifetimes and specific heats also are used to examine mode contributions to the anisotropic thermal conductivity. Our results also confirm that the overall out-of-plane thermal conductivity of HfS$_2$ is small, on the order of 1 W/mK, suggesting the promise of HfS$_2$ application to thermoelectric devices.

5:06PM C13.00012: Anisotropic thermal conductivity of printed films made of 2D-materials based inks  MIZANUR RAHMAN (Presenter), Department of Physics and Astronomy, York University, Toronto, ON, Canada, KHALED PARVEZ, CHAOCHAO DUN, CINZIA CASIRAGHI, School of Chemistry, University of Manchester, United Kingdom, SIMONE PISANA, Department of Electrical Engineering and Computer Science, York University, Toronto, ON, Canada — Graphene and other 2-dimensional (2D) materials are the subject of intense research due to their distinct properties, particularly for electronic and optoelectronic applications. Solution-processed 2D materials can accelerate the progress even further due to their compatibility with flexible substrates, large scale and low-cost device fabrication. In addition, printed films of such inks, could have potential use in thermal and thermoelectric applications. However, very little is known about the thermal properties of 2D-materials based inks due to the challenge and complexity associated with measuring their thermal properties, which are highly anisotropic. To develop applications based on the thermal properties of 2D-materials based inks, it is of fundamental importance to understand the relation between structure and property, and to determine how electron and heat transport relate in 2D materials.

Here, we present the electrical conductivity and in-plane and out-of-plane thermal conductivity of graphene and other 2D-materials thin films, produced by ink-jet printing of water-based 2D-materials inks. Thermal anisotropies of 40:1 are observed together with ultra-low cross-plane thermal conductivity well below 1 W/mK.

5:18PM C13.00013: Temperature Dependent Phonons of Transition- Metal Dichalcogenides Calculated from Spectral Energy Density: Thermal Lattice Conductivity as an Application*  ARASH MOBARAKI, Bilkent University, CEM SEVIK, Eskisehir Technical University, DENIZ ÇAKIR, Department of Physics and Astrophysics, University of North Dakota, OGUZ GULSEREN (Presenter), Bilkent University — Predicting the mechanical and thermal properties of quasi two dimensional transition metal dichalcogenides (TMDs) is an essential task necessary for their implementation in device applications. Although, rigorous density functional theory (DFT) based calculations are able to predict mechanical and electronic properties, mostly they are limited to zero temperature. Classical molecular dynamics (MD) facilitates the investigation of temperature dependent properties, but its performance is highly depend on potential used for defining interactions between atoms. In this study, we calculated temperature dependent phonon properties of single layer TMDs, namely MoS$_2$, MoSe$_2$, WS$_2$, and WSe$_2$, by utilizing Stillinger-Weber (SW) type potentials with optimized sets of parameters with respect to the first principle results. The phonon lifetimes and contribution of each phonon mode in thermal conductivities in monolayer MoS$_2$, MoSe$_2$, WS$_2$, and WSe$_2$ are systematically investigated by means of spectral energy density (SED) method. The obtained results from this approach are in good agreement with previously available results from Green-Kubo (GK) method.

Session C14 DMP: 2D Materials (Metals, Superconductors, and Correlated Materials) -- Superconductivity  BCEC 153C - Eric Spanont, University of California, Santa Barbara - Tag(s): Focus
Probing the Superfluid Density and the Superconducting Gaps under Pressure in 2H-NbSe2

ZURAB GUGUCHIA (Presenter), Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, FABIAN VON ROHR, Department of Chemistry, University of Zürich, ORAIN JEAN CHISTOPHE, RUSTEM KHASANOV, ALEX AMATO, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, ABHAY PASUPATHY, Department of Physics, Columbia University, ZAHID HASAN, Laboratory for Topological Quantum Matter & Advanced Spectroscopy, Princeton University, HUBERTUS LUETKENS, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, YASUTOMO J UEMURA, Department of Physics, Columbia University — We report on high-pressure (pmax = 2.1 GPa) muon spin rotation experiments probing the temperature-dependent magnetic penetration depth λ(T) in the layered superconductor 2H-NbSe2. Upon increasing the pressure, we observe a substantial increase of the superfluid density nS/m* ∼ 1/λ2, which we find to scale linearly with Tc. This linear scaling is considered a hallmark feature of unconventional superconductivity, especially in high-temperature cuprate superconductors. Our current results, along with our earlier findings on 1T'-MoTe2 [1], demonstrate that this linear relation is also an intrinsic property of the superconductivity in transition metal dichalcogenides, whereas the ratio Tc/TF is approximately a factor of 20 lower than the ratio observed in hole-doped cuprates. We, furthermore, find that the values of the superconducting gaps are insensitive to the suppression of the quasi-two-dimensional CDW state, indicating that the CDW ordering and the superconductivity in 2H-NbSe2 are independent of each other.

Exponential decrease of the collective vortex state energy with layer number in 2H-NbSe2

AVISHAI BENYAMINI (Presenter), EVAN TELFORD, DA WANG, DANTE KENNES, KENJI WATANABE, Columbia University, TAKASHI TANIGUCHI, ANDREW MILLIS, National Institute of Materials Science, JAMES HONE, CORY R DEAN, ABHAY PASUPATHY, Columbia University — In the last years, a new generation of superconductors truly in the two-dimensional limit has been discovered in van der Waals materials. Recently, it has been shown that these type-II SCs can be extremely sensitive to external perturbation which pushes the system into a non-equilibrium steady state exhibiting metallic-like behavior [1]. Here we study the equilibrium and non-equilibrium phase diagrams of few-layered 2H-NbSe2 with minimal external perturbations. At finite magnetic field we observe a current-induced crossover to a non-activated metallic-like regime with a critical current that reduces with layer number. We discuss our results both phenomenologically and in the vortex picture which we compare with time-dependent Ginzburg-Landau simulations. In the vortex-picture we attribute the crossover to a transition from a pinned to unpinned vortex liquid. Finally, we demonstrate that by spreading non-uniform currents, we stabilize different vortex steady states in different spatial locations, potentially leading to novel interfaces.

Strongly enhanced Andreev reflection in ultra-transparent NbSe2/ bilayer graphene junctions

JING LI (Presenter), National High Magnetic Field Laboratory, Los Alamos National Lab, HAILONG FU, Department of Physics, The Pennsylvania State University, HAN-BING LENG, Department of Physics, Huazhong University of Science and Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, CHAOXING LIU, Department of Physics, The Pennsylvania State University, XIN LIU, Department of Physics, Huazhong University of Science and Technology, JUN ZHU, Department of Physics, The Pennsylvania State University — Van der Waals (vdW) layered materials with diverse properties provide an alternative route to construct future generations of miniaturized electronic devices. The prospect of constructing superconducting circuits from all vdW materials is attractive from many different viewpoints. Making transparent superconductor to normal conductor (S-N) junctions is a critical step in this endeavor. Here we present measurement and simulations of Andreev reflection (AR) in ultra-transparent NbSe2/ bilayer graphene (BLG) S-N junctions constructed via vdW stacking. The resistance across the junction is as low as 13 Ω, indicating a highly transparent NbSe2/ BLG interface. In these devices, the proximity effect penetrates to the BLG side for at least 500 nm. We observe strongly enhanced AR in the differential conductance measurement across the junction. The zero-bias conductance peak reaches up to 1.7 times the normal value. We present a comprehensive study of the AR by systematically varying the carrier density and temperature in different devices. A model is constructed to capture the rich features of the experimental data. Important factors include the spatial decay of the superconducting gap, the effect of the carrier density profile near the interface and the interface transparency.
3:06PM C14.00004: Dynamically-created Josephson Junctions in thin layers of NbSe2

STEVEN TRAN (Presenter), University of Maryland, College Park — Niobium Diselenide (NbSe2) is a member of the transition metal dichalcogenides (TMDs) family which displays superconducting properties and is host to charge density waves (CDWs) down to its monolayer limit. These properties alongside its hexagonal structure make it an interesting material to study physics within its two dimensional limit. Here, we report on fabrication and low-temperature transport measurements of atomically-thin layers of NbSe2 in four-terminal configurations. We observe the formation of phase slip lines across our NbSe2 sheets which appear as non-zero resistances in the superconducting state. The formation of the phase slip lines dynamically creates Josephson junctions (JJs). We interact with these dynamically-created JJs through the application of RF and magnetic fields. Interestingly, we observe a deviation from the conventional behavior of JJs in the presence of RF and a skewed Fraunhofer pattern in the presence of a magnetic field. We model our observations in the presence of RF by assuming a coupling of a JJ to a CDW. We found that the dynamics of the CDW influence the behavior of the JJ to produce results that qualitatively agree with our experiment.

3:18PM C14.00005: Thinning-Induced Metastable Superconductivity in a Correlated 2D Material: 1T-IrTe2

MASARO YOSHIDA (Presenter), RIKEN Center for Emergent Matter Science, KAZUTAKA KUDO, MINORU NOHARA, Research Institute for Interdisciplinary Science, Okayama University, YOSHIHIRO IWASA, Department of Applied Physics, The University of Tokyo — Recently, reduced thickness was found to dramatically impact not only the static electronic structure (e.g. graphene, MoS2), but also the dynamic ordering kinetics (e.g. 1T-TaS2) [1]. The ordering kinetics of first-order phase transitions becomes significantly slowed with decreasing thickness, and metastable supercooled states can be realized by thinning alone. We therefore focus on layered iridium ditelluride (IrTe2), a charge-ordering system that is transformed into a superconductor by suppressing its first-order transition. Here, we discovered a persistent superconducting zero-resistance state in mechanically-exfoliated IrTe2 thin flakes [2]. The maximum superconducting critical temperature was identical to that of the bulk crystal which is chemically optimized, and the emergent superconductivity was revealed to have a metastable nature. The discovered robust metastable superconductivity suggests that 2D material is a new platform to induce, control, and functionalize metastable electronic states that are inaccessible in bulk crystals. [1. M. Yoshida et al. Sci. Adv. 1, e1500606 (2015); 2. M. Yoshida et al., Nano Lett. 18, 3113 (2018)]

3:30PM C14.00006: Dynamic phase diagram at zero magnetic field in 2D superconducting MoS2

YU SAITO (Presenter), University of California, Santa Barbara — Recent discoveries of two-dimensional (2D) crystalline superconductors [1] have led to clarifications of various intrinsic nature in magnetic fields. For example, 2D crystalline superconductors with weak pinning are very fragile against out-of-plane magnetic fields, and thus show a quantum metallic state due to quantum fluctuations [2] (though this phenomenon is still under debate [3]). However, there has been no report for how the BKT state at zero magnetic field evolves into the normal state through the dynamic states with increasing current in such systems. In this talk, we report on transport properties at zero magnetic field in ion-gated MoS2 as a function of current and temperature. We show a clear BKT transition and anomalous kinks observed in resistance-temperature and current-voltage curves, and discuss the dynamic phase diagram based on these data, which contains a variety of current-induced nonequilibrium states originating from not only thermal but also quantum dissociation of vortices and antivortices.

3:42PM C14.00007: Superconductivity in WTe2

JOSHUA FOLK (Presenter), University of British Columbia — tbd

4:18PM C14.00008: Quantum and classical vortex ratchets in a trigonal 2D superconductor

YUKI ITAHASHI (Presenter), YU SAITO, TOSHIYA IDEUE, Department of Applied Physics, University of Tokyo, TSUTOMU NOJIMA, Tohoku University, YOSHIHIRO IWASA, University of Tokyo — One of the unique features of recently emerging 2D superconductors is the quantum metallic state, which is a temperature-independent finite resistive state that appears once finite magnetic field is switched on [1, 2]. This quantum metallic state exhibits a sharp contrast with the conventional superconductor-insulator transition in conventional 2D systems, where the metallic state appears only at a single critical point. To investigate the vortex dynamics which governs the resistance in the quantum metallic state, we have investigated the nonreciprocal transport in gated MoS2, an archetypal noncentrosymmetric 2D superconductor with trigonal symmetry. We found that the second harmonic resistance $R_{xx}^{2\omega}$ appears when the vortex motion is controlled by the classical vortex flow, while $R_{xx}^{2\omega}$ is substantially suppressed when the vortex motion is in quantum creep region. The present result indicates that the trigonal 2D superconductor is a new model system for investigation of quantum and classical ratchets.

4:30PM C14.00009: Superconductivity in TaSe₂ epitaxial thin films  

YUKI TANAKA (Presenter), HIDEKI MATSUOKA, MASAKI NAKANO, YOSHIHIRO IWASA, University of Tokyo — Transition metal dichalcogenides (TMDs) draw much attention because of their intriguing properties emerging at two-dimensional (2D) limit. Nowadays, some groups have succeeded in exfoliation of metallic TMDs such as NbSe₂ and TaS₂ down to a monolayer limit, unveiling new aspects of 2D physical properties. One remarkable example is unconventional superconductivity achieved by combination of large spin-orbit coupling and broken inversion symmetry, where spin-momentum-locked Cooper pairs play an important role in their superconducting states. Another unique feature is the relationship between superconductivity and charge-density wave (CDW), which has been discussed both in NbSe₂ and TaS₂. In this work, we focus on TaSe₂, which has also been known to have similar electronic structure and exhibit both superconductivity and CDW in its bulk form. There is one paper reporting electronic structure of monolayer TaSe₂ [1], but electrical transport properties of TaSe₂ ultrathin films have not been investigated so far. In this presentation, we report on fabrication of high-quality TaSe₂ thin films by molecular beam epitaxy, and show their transport properties with reduced dimensions.

4:42PM C14.00010: Sign reversing Hall effect in atomically thin high temperature superconductors  

SHU YANG FRANK ZHAO (Presenter), NICOLA POCCIA, MARGARET G. PANETTA, CYNDIA YU, JEDEDIAH W. JOHNSON, HYOBIN YOO, Harvard University, RUIDIAN ZHONG, GENDA GU, Brookhaven National Laboratories, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, SVETLANA POSTOLOVA, Institute for Physics of Microstructures, VALERII VINOKUR, Argonne National Laboratory, PHILIP KIM, Harvard University — We fabricate van der Waals heterostructure devices using few unit cell thick Bi₂Sr₂CaCu₂O₈₊δ for magnetotransport measurements. The superconducting transition temperature and carrier density in atomically thin samples can be maintained close to that of the bulk samples. As in the bulk sample, the sign of the Hall conductivity is found to be opposite to the normal state near the transition temperature but with a drastic enlargement of the region of Hall sign reversal in the temperature-magnetic field phase diagram as the thickness of samples decreases. Quantitative analysis of the Hall sign reversal based on the excess charge density in the vortex core and superconducting fluctuations suggests a renormalized superconducting gap in atomically thin samples at the two-dimensional limit. Preprint available at arXiv:1809.06944.

4:54PM C14.00011: Spatially Resolved Electronic Structure of Bi₂Sr₂₋ₓLaₓCuO₆₊δ in the Two-dimensional Limit  

HENGSHENG LUO (Presenter), LIGUO MA, PENG CAI, Physics Department, Fudan University, DONGJOON SONG, National Institute of Advanced Industrial Science and Technology, RUIDIAN ZHONG, Brookhaven National Laboratory, JIAN SHEN, Physics Department, Fudan University, GENDA GU, Brookhaven National Laboratory, HIROSHI EISAKI, National Institute of Advanced Industrial Science and Technology, XIANHUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Physics Department, Fudan University — Dimensionality plays a fundamental role in high-temperature superconductivity; all high-temperature superconductors adopt a layered crystal structure, and much of high-temperature superconductor theory is based on purely two-dimensional (2D) models. Here we exfoliate Bi₂Sr₂₋ₓLaₓCuO₆₊δ (referred to as La-Bi₂2201) single crystals down to monolayers (half unit cell) at liquid nitrogen temperature under ultra-high vacuum. A monolayer La-Bi₂2201 contains only a single layer of CuO₂ plane, and therefore represents a cuprate superconductor in the ultimate 2D limit. We study the electronic structure of monolayer La-Bi₂2201 at atomic scale using scanning tunnelling microscopy and spectroscopy.

5:06PM C14.00012: Visualizing the electronic structure of monolayer Bi₂Sr₂CaCu₂O₈₊δ  

LIGUO MA (Presenter), YIJUN YU, PENG CAI, Physics Department, Fudan University, RUIDIAN ZHONG, Brookhaven National Laboratory, CUN YE, JIAN SHEN, Physics Department, Fudan University, GENDA GU, Brookhaven National Laboratory, XIANHUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Physics Department, Fudan University — Although high-temperature superconductors are a complex and diverse family of materials, they all adopt a layered crystal structure, in which two-dimensional lattices stack together to form the three-dimensional bulk. This curious fact begs the question: does high-temperature superconductivity (HTS) exist in an isolated monolayer, and if so, is the two-dimensional HTS—and various other correlated phenomena related to HTS—different from its three-dimensional counterpart? The answer to these questions may provide important insights on the role of dimensionality in HTS. Here, we fabricate atomically thin cuprate Bi₂Sr₂CaCu₂O₈₊δ that retains HTS down to monolayer (i.e. half unit cell) limit. The electronic structure of monolayer Bi₂Sr₂CaCu₂O₈₊δ is probed with scanning tunneling microscopy and spectroscopy. Survey of the electronic phases – superconductivity, pseudogap, charge order and Mott insulating state – reveals that they are indistinguishable from those in the bulk. Out results, therefore, indicates that essential physics of HTS is contained in a monolayer Bi₂Sr₂CaCu₂O₈₊δ.
Tunable high-temperature superconductivity in monolayer Bi\textsubscript{2}Sr\textsubscript{2}CaCu\textsubscript{2}O\textsubscript{8+δ}  

YIJUN YU (Presenter), LIGUO MA, PENG CAI, Fudan University, RUIDAN ZHONG, Brookhaven National Lab, CUN YE, JIAN SHEN, Fudan University, GENDA GU, Brookhaven National Lab, XIANGHUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Fudan University — Dimensionality plays a central role in high-temperature superconductivity (HTS). Layered cuprate superconductors hold the record of $T_c$ at ambient pressure. Cuprates in the two-dimensional (2D) limit would provide valuable insights on the nature of HTS and offer unprecedented tunability in their material properties. Half-unit-cell-thick single crystal of Bi\textsubscript{2}Sr\textsubscript{2}CaCu\textsubscript{2}O\textsubscript{8+δ} (referred to as monolayer Bi-2212) is such an ideal 2D system. Here we fabricate transport devices from monolayer Bi-2212 samples obtained by exfoliation and study the evolution of superconductivity as the dimensionality and doping level is varied. We find that superconductivity remains intact in monolayer Bi-2212. Finite size scaling analysis at superconductor-to-insulator transition (SIT) reveals distinct critical behaviors at different disorder levels. Our study leads to a unified picture of SITs previously reported in cuprate systems.

Monday, March 4, 2019 2:30 PM - 5:18 PM

Session C15 DMP: 2D Materials (Semiconductors) -- Multilayers & Heterostructures II BCEC

2:30PM C15.00001: Electronic and thermoelectric transport in two-dimensional layered-structure material  

SHI-JUN LIANG (Presenter), JUNWEN ZENG, Nanjing University, XIN HE, LIJUN ZHANG, Jinlin University, DAVID SINGH, University of Missouri, FENG MIAO, Nanjing University — Electronic and thermoelectric transport properties have been the extensively studied topics in the two dimensional materials. Hicks and Dresselhaus predicted that the reduction in dimensionality of materials can enhance the thermopower power factor. However the observation of confinement-induced enhancement of thermoelectric power factor predicated by Hicks and Dresselhaus has been challenging. In this work, we firstly studied the electronic transport mechanism of InSe nanoflakes in the presence of the magnetic field and gate voltage. We observed the gate-tunable weak antilocalization phenomenon and a very long coherent length of up to 320 nm at 1.7 K. The scattering mechanisms were analysed in details. Furthermore, we investigated the thermoelectric properties in the InSe thin film and revealed that the Seebeck coefficient and power factor can be enhanced by the enhanced DOS arising from the size confinement effect when the thickness of InSe thin film is thinned down. Most importantly, we experimentally identified the condition for drastically enhancing the thermoelectric power factor in the 2D layered-structure materials.

2:42PM C15.00002: Moiré Valleytronics: Realizing Dense Arrays of Topological Helical Channels*  

CHEN HU (Presenter), VINCENT MICHAUD-RIOUX, Center for the Physics of Materials and Department of Physics, McGill University, WANG YAO, Department of Physics and Center of Theoretical and Computational Physics, University of Hong Kong, HONG GUO, Center for the Physics of Materials and Department of Physics, McGill University — In hexagonal 2D crystals, the valley degree of freedom is characterized by non-trivial Berry curvatures. Valley-dependent topological helical channels are novel conducting states without back scattering, which can benefit to low power consumption in practical applications. We propose a general, robust and experimentally-feasible platform, the moiré valleytronics, to realize high-density arrays of 1D topological helical channels in real materials at room temperature. We demonstrate the idea using a long-period 1D moiré pattern of graphene on hBN by first-principles calculation. Through calculating the Berry curvature and topological charge of the electronic structure associated with various local graphene/hBN stackings in the moiré pattern, it is revealed that the helical channel arrays originate intrinsically from the periodic modulation of the local topological orders by the moiré pattern.

*This work is financially supported by the Natural Science and Engineering Research Council (NSERC) of Canada (H. G.) and the Research Grants Council of Hong Kong (HKU17302617). We thank Compute Canada and the High Performance Computing Center of McGill University for substantial computational support.
2:54PM C15.00003: Guiding experimental investigation of a pentagonal layered material through theoretical modeling/simulation  LIANGBO LIANG (Presenter), KAI XIAO, ALEXANDER PURETZKY, GIANG NGUYEN, AN-PING LI, DAVID GEOHEGAN, BOBBY G SUMPTER, Oak Ridge National Laboratory — PdSe₂ is a new 2D layered material with an in-plane pentagonal network and stronger-than-vdW interlayer coupling. It offers great trade-off between carrier mobility, band gap, and air stability for 2D electronics [JACS, 139, 14090 (2017)]. Here I will highlight how first-principles modeling/simulation guided experiments to explore its electronic and vibrational properties. Because of strong interlayer coupling, its band gap varies significantly from 1.3 eV (monolayer) to 0.06 eV (bulk), based on both calculations and measurements. Our Raman scattering simulation revealed that, unlike graphene and MoS₂, the PdSe₂ layers are no longer quasi-rigid in low-frequency interlayer vibrations. Therefore, the thickness dependence of the interlayer Raman modes’ frequencies in PdSe₂ deviates significantly from the linear chain model (LCM), which was verified by Raman measurements. A revised LCM was developed to account for the layer non-rigidity [2D Materials, 5, 035016 (2018)]. Finally, according to our nudged elastic band calculations, the pentagonal structure and strong interlayer coupling lead to low diffusion barriers for defects, and hence both intralayer and interlayer hopping of defects can occur relatively easily, as observed by scanning tunneling microscope [PRL, 121, 086101 (2018)].

3:06PM C15.00004: Optical properties of monolayer MoSe₂/layered antiferromagnet heterostructures  MASARU ONGA (Presenter), YUSUKE SUGITA, TOSHIYA IDEUE, YUJI NAKAGAWA, RYUJI SUZUKI, YUKITOSHI MOTOME, YOSHIHIRO IWASA, University of Tokyo — Van der Waals heterostructure has attracted much interest because of its high extensibility by using various layered materials. Furthermore, the recent discovery of 2D magnets has provided us a new platform to investigate magnetic van der Waals heterointerfaces, leading to novel studies on spin-/valley-tronics [1]. Here we report a new type of magnetic van der Waals heterointerface using monolayer transition metal dichalcogenides (especially MoSe₂) and layered antiferromagnets. We fabricated the samples by using all-dry-transfer method in inert atmosphere and performed photoluminescence measurements at low temperature. The characteristic spectra are observed below the transition temperature of the magnets, which suggests that the magnetic ordering can affect the exciton property of MoSe₂ directly.

3:18PM C15.00005: Mobility and quantum mobility of a 2DEG in modern GaAs/AlGaAs heterostructures  MICHAEL SAMMON (Presenter), Physics, University of Minnesota, TIANRAN CHEN, Physics, West Chester University, MICHAEL ZUDOV, BORIS SHKLOVSKI, Physics, University of Minnesota — In modern GaAs/AlGaAs heterostructures with record high mobilities, a two-dimensional electron gas (2DEG) in a quantum well is provided by two remote donor δ-layers placed on both sides of the well. Each δ-layer is located within a narrow GaAs layer, flanked by narrow AlAs layers which capture excess electrons from donors but leave each of them localized in a compact dipole atom with a donor. These excess electrons minimize their Coulomb energy and screen the random potential of charged impurities. We developed a theory of this screening and used it to calculate both the mobility and the quantum mobility of the 2DEG.[1,2] Our results show that the remote donor limited mobilities strongly increase with the filling fraction of excess electrons, and the calculated mobilities drastically exceed the measured values. This suggests that the mobilities are limited either by background charged impurities, or the weakening of screening by additional disorder in the doping layer such as roughness at the GaAs/AlAs interface or spreading of the donors outside of the δ-layer. [1] M. Sammon, M. A. Zudov, B. I. Shklovskii, Phys. Rev. Materials 2, 064604 (2018). [2] M. Sammon, Tianran Chen, B. I. Shklovskii, Phys. Rev. Materials 2, 104001 (2018).

3:30PM C15.00006: Atomic interaction through two-dimensional materials governed by competitive energy fluctuations  *HUASHAN LI (Presenter), Sino-French Institute of Nuclear Engineering and Technology, Sun Yat-Sen University, WEI KONG, JEEHWAN KIM, JEFFREY C GROSSMAN, Massachusetts Institute of Technology — The rapid development of hybrid 2D materials has unveiled its potential to achieve complex functionality. The impact of 2D materials on intermolecular interactions of crystalline materials has not been fully understood. In this study, we computationally investigated a variety of heterojunctions with 2D materials sandwiched by 3D crystal layers.[1] The results suggest that transparency of 2D interlayer is governed by competition between the substrate potential energy fluctuation attenuated, and the binding energy fluctuation generated by 2D interlayer. Although the potential field from covalent-bonded materials is screened by a monolayer of graphene, that from ionic-bonded materials is strong enough to penetrate through a few layers of graphene. Such field penetration is substantially attenuated by 2D hBN, which itself has polarization in its atomic bonds. The insight has been verified by our experiments and further employed to control the transparency via modulating the nature and thickness of 2D interlayer, which eventually leads to the successful remote epitaxial growth of single-crystalline materials across the periodic table.

*We thank the support from the NSFC (11804403) and the GD-NSF (2018B030306036).
Two-dimensional van der Waals (vdW) layered materials have attracted great attention for their applications in flexible electronics and optoelectronics. In this work, we report a comprehensive theoretical study of graphene/graphyne (Gyne/Gyne), graphyne-like BN/graphyne-like BN (BNyne/BNyne) and graphene/graphyne-like BN (Gyne/BNyne) bilayers by density functional theory. These bilayers exhibit distinct stacking dependent characteristics in the ground state electronic structure and have different responses to external strain and electric field. For Gyne/Gyne and Gyne/BNyne bilayers, a biaxial tensile strain increases the band gap while biaxial compressive strain or uniaxial strain, reduces it. For the BNYne/BNyne bilayer the trend is opposite. Under a vertical electric field, the band gap decreases in homo-bilayers Gyne/Gyne and BNYne/BNyne. For the hetero-bilayer Gyne/BNyne, band gap decreases under a positive electric field but remain almost constant in negative electric field. These properties are understood by analyzing the calculated electronic density and potential.

**Microscopic theory of band gap opening and spin-orbit splitting in graphene/TMDC heterobilayers**

Theoretical ab initio calculations have shown a gap opening and an induced spin-orbit splitting in the band structure of graphene from the TMDC layer [1, 2]. These results have been experimentally confirmed by recent magnetotransport experiments showing weak antilocalisation (WAL) [2, 3]. Using perturbation theory, we propose a microscopic model to explain the origin of the gap and of the spin-orbit splitting. We also consider the dependence of the spin-orbit splitting on the misalignment of graphene and TMDC layers.

**Graphene-Oxide-Semiconductor photodetector**

The photodetection properties of a graphene-oxide-semiconductor (GOS) diode have been extensively investigated by measuring current-voltage characteristics under illumination with light-emitting diode (LED). We demonstrate that the newly developed GOS heterostructure, with graphene as a transparent gate electrode to form the inversion layer at the oxide-semiconductor interface, can function as a GOS field-effect transistor (GOSFET) operable at low temperature (T) down to 1.5 K. By studying the gate tunneling current in the GOSFET, we find that the dark current is below ~ 0.1 nA, which is almost two orders of magnitude smaller than that in graphene-Si (GS) Schottky detector diode. Our work paves the way for the implementation of hybrid photodetectors devices fabricated by two-dimensional materials and conventional semiconductors with CMOS integrability.

**Coexistence of Different Charge Transfer Mechanisms in the Hot Carrier Dynamics of Hybrid Plasmonic Nanomaterials**

Plasmon induced hot-electron dynamics at the interfaces of metallic nanostructures and semiconductors is of significant importance for photovoltaic and photocatalytic applications. Plasmon-driven charge separation processes were considered to be only dependent on the type of donor-acceptor interactions, i.e., conventional hot electron transfer mechanism for van der Waals interactions and plasmon-induced interfacial charge-transfer transition pathway for chemical bonds. Here we demonstrate the two mechanisms can coexist in a typical metal-semiconductor hybrid plasmonic nanomaterials, both happen on a faster time scale than carrier relaxation process. The origin of the two mechanisms is attributed to the spatial vertical and parallel modes of excited plasmon, where the vertical mode couples to semiconductors much strongly than the parallel one. Our findings provide a new insight into the photoinduced plasmonic carrier dynamics, which is relevant for many potential applications including solar energy conversion, efficient water splitting and photocatalysis.
We discuss the 2D prototype system of hexagonal BN (hBN), a wide bandgap insulator with strong excitonic effects and UV luminescence properties. We investigate the optical properties of few layer hBN, focusing on the Davydov splitting of the lowest bound exciton, which dominates the absorption. We use \textit{ab initio} methods and a model mapping the Bethe-Salpeter equation onto an effective tight-binding Hamiltonian with few parameters. We thus obtain a precise characterization of the symmetries of the excitonic states and their optical selection rules.

We discuss the splitting of excitonic states in systems of \( N \) layers, and construct a simple model for the absorption spectrum as a function of \( N \). We show that for \( N>2 \), one can distinguish between surface and inner excitons. The former are found to be lower in energy and can be optically active.

4:42PM C15.00012: Rapid bimolecular and defect-assisted carrier recombination in hexagonal Boron Nitride

\textsc{Ioannis Chatzakis (Presenter)}, \textsc{Roderick Davidson II}, \textsc{Adam Dunkelberger}, \textsc{Andrea Grafton}, United States Naval Research Laboratory, \textsc{Joshua D Caldwell}, Electrical and Mechanical Engineering, Vanderbilt University, \textsc{Song Liu}, Tim Taylor Dept. of Chemical Engineering, Kansas State University, \textsc{Jaime A. Freitas}, Jr., \textsc{James Clifford Culbertson}, United States Naval Research Laboratory, \textsc{James H. Edgar}, Tim Taylor Dept. of Chemical Engineering, Kansas State University, \textsc{Daniel Ratchford}, \textsc{Chase Ellis}, \textsc{Alex Giles}, \textsc{Joseph G Tischler}, \textsc{Jeffrey Owrutsky}, United States Naval Research Laboratory — Hexagonal boron nitride (hBN) is an indirect wide band gap semiconductor that holds great promise for optoelectronic devices in the ultraviolet regime. Here we report the dynamics of photoexcited charge carriers at room temperature in exfoliated monoisotopic \(^{10}\text{B}\) enriched hBN. Two recombination mechanisms were identified, and their associated time scales measured, using ultrafast two-photon pump, infrared probe transient transmission spectroscopy. Initially, when the free carrier density is high, bimolecular decay dominates recombination with a rate constant of \((1.33 \pm 0.09) \times 10^{-7} \text{ cm}^{-3}/\text{s}\). At later times, the recombination of the free carriers is characterized by an exponential decay with a time constant on the order of a nanosecond, determined by the density of the impurities/defects in the lattice.

4:54PM C15.00013: Understanding the electrical behaviors in van der Waals heterostructure field-effect transistor based on band alignment

\textsc{Seonyeong Kim (Presenter)}, \textsc{Taekwang Kim}, \textsc{Somyeong Shin}, \textsc{Hyewon Du}, \textsc{Minho Song}, \textsc{Hansung Kim}, \textsc{Dain Kang}, Sejong University, \textsc{Chang-Won Lee}, Hanbat university, \textsc{Sunae Seo}, Sejong University — Van der Waals heterostructures based on 2D layered materials have been extensively studied because their unique electronic properties, which can be controlled by optimally selecting the band alignments. Although the rectifying behavior is usually observed in output characteristics of these heterostructures, the underlying transport mechanism have not been fully understood. Here, we investigate transport properties of multilayer \( \text{MoTe}_2/\text{SnS}_2 \) heterostructure field-effect transistor (hetero-FET) fabricated by exfoliating each material and manually stacking them and observe gate-tunable diode-like current rectification. With the qualitative band analysis, we noticed that the interfacial barrier by band bending plays a crucial role to realize the transport properties of hetero-FETs, especially rectification behavior. Our experimental study offers the inspiration for understanding the transport behavior and reference to novel hetero-FETs.
Demonstrating Band Design in Two-Dimensional Covalent Organic Frameworks*

HALLEH BALCH (Presenter), Physics, University of California, Berkeley, AUSTIN EVANS, Chemistry, Northwestern University, RAGHUNATH DASARI, SIMIL THOMAS, KAITLIN SLICKER, HONG LI, Chemistry, Georgia Tech, RUOFAN LI, DAN RALPH, Physics, Cornell University, JEAN-LUC E BREDAS, SETH R. MARDER, Chemistry, Georgia Tech, WILLIAM DICHTEL, Chemistry, Northwestern University, FENG WANG, Physics, University of California, Berkeley — Two dimensional covalent organic frameworks (COFs) are periodic lattices whose rational design can yield novel optoelectronic properties and new heterostructure devices. Analogous to graphene and the inorganic family of 2D materials, 2D COFs are covalently bonded in-plane with out-of-plane bonding through Van der Waals interactions. To date, 2D COF properties are limited by large molecular bandgaps, low intermolecular coupling, and poor control of the material morphology. Here, we report the rational design and characterization of a new, highly conjugated, semiconducting 2D framework. We characterize the structure by X-ray scattering, TEM, and AFM, and demonstrate facile manipulation onto arbitrary experimental platforms. We further employ broadband optical and vibrational spectroscopies to observe electronic behavior emergent in this highly conjugated system.

Session C16 DMP: Transport in Nanostructures -- Quantum dots, nanocrystals, and nanowires

BCEC 155 - Jeremy Levy, University of Pittsburgh - Tag(s): Focus

2:30PM C16.00001: Three-dimensional imaging of material functionality through nanoscale tracking of energy flow* [Invited] MILAN DELOR, HANNAH L WEAVER, QINQIN YU, NAOMI GINSBERG (Presenter), University of California, Berkeley — The ability of energy carriers to move within and between atoms and molecules underlies virtually all biochemical and material function. Understanding and controlling energy flow, however, requires observing it on ultrasmall and ultrafast spatiotemporal scales, where energetic and structural roadblocks dictate the fate of energy carriers. We therefore developed a universal, non-invasive optical scheme that leverages interferometric scattering to track tiny changes in material polarizability created by energy carriers. Our approach enables mapping energy transport trajectories in four dimensions of spacetime with few-nanometer precision and directly correlating them to material morphology. We visualize exciton, charge, and heat transport in polyacene, silicon and perovskite semiconductors and elucidate, in particular, how grain boundaries impact energy flow through their lateral- and depth-dependent resistivities. We reveal new strategies to interpret energy transport in disordered environments that will direct the design of defect-tolerant materials for the semiconductor industry of tomorrow.

Sloan Research Fellowship, a David and Lucile Packard Foundation Fellowship for Science and Engineering, and a Camille and Henry Dreyfus Teacher-Scholar Award.

3:06PM C16.00002: Levy statistics in quasi one-dimensional percolation paths in nano-patterned quantum dot solids TAMAR MENTZEL (Presenter), Physics, Harvard University — Quantum dot (QD) solids hold promise as a tunable platform for applications such as quantum computation and spintronics, and for exploring many-body physics. However, the predicted, novel electronic properties in QD solids have been obscured by disorder caused by structural defects, variability in electronic energy levels of the QDs and charge traps on the QD surfaces. We nano-pattern QD solids with dimensions ~10−100 nm that are free of structural defects found in many larger superlattices. The QDs are strongly coupled (≤1 nm inter-dot spacing), which offsets inhomogeneities in the electronic energy levels in the QD. We find current noise that increases linearly with the average current at high temperatures, and we find random telegraph noise at low temperatures. We show that charge is transmitted along quasi-one-dimensional channels, which open and close at a rate given by Levy statistics. The trapping and release of charge in the QD matrix is the likely cause for these fluctuations. These nano-patterned QD solids enable measurement of the charge transport mechanism intrinsic to the QDs; and, they offer a direct measurement of the influence of charge trapping on the charge transport mechanism.
3:18PM C16.00003: Triplet excitons on the interface of Colloidal Quantum Dots and organic molecules*  TAMAR GOLDZAK (Presenter), ALEXANDRA MCISAAC, TROY VANVOORHIS, Massachusetts Institute of Technology — Colloidal Quantum Dots (QDs) have been long-standing candidates for optoelectronic devices and applications, such as solar photovoltaic, light emitting diodes, detectors, and biological sensing. They are composed of semi-conductor materials, and are synthesized from solution. Their optical and electronic properties change with their size, shape, composition, and surface. In the up-conversion (UC) process two low frequency photons are converted into one high energy photon, this can broaden the absorption spectrum and increase the efficiency of optoelectronic devices. One of the steps in the UC process is the transfer of high energy triplet exciton across the interface of colloidal QD/organic molecule. Using electronic structure calculations combined with experimental observations, we study and try to characterize triplet excitons on various QD structures ligated with organic molecules to get a better understanding of the transfer mechanism. We also use Molecular Dynamics simulations to study the morphology of these interfaces.

3:30PM C16.00004: Layer-Dependence of Charge Transfer Kinetics in Hybrids of 2D MoS2 and PbS/CdS Quantum Dots*  JIA-SHIANG CHEN (Presenter), Department of Materials Science and Chemical Engineering, Stony Brook University, MINGXING LI, MIRCEA COTLET, Center for Functional Nanomaterials, Brookhaven National Laboratory — Two-dimensional (2D) layered transition metal dichalcogenides (TMDs) have attracted tremendous attention owing to their unique optical and physical properties. However, weak photon absorption due to their atomically thin thickness prohibits their spectral sensitivity. Here, 2D-MoS2 with different layers are combined with core/shell PbS/CdS quantum dots (QDs) to produce hybrids with improved photoresponsivity by interfacial charge transfer. The charge transfer kinetics in the hybrids of MoS2 and PbS/CdS QDs has been revealed by time-resolved photoluminescence (PL) microscopy, showing that the charge transfer rate increases with the layer of MoS2 increased due to the increased driving force in between conduction band edge of MoS2 and QDs. We have evaluated the results with the theoretical model of Marcus theory, which is in good agreement with our observation. Understanding the interfacial charge transfer kinetics between QDs and 2D materials is crucial and useful for improving photon-to-current conversion efficiency in next-generation optoelectronics.

*This work was carried out in part at the Center for Functional Nanomaterials, Brookhaven National Laboratory (BNL), which is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-SC0012704.

3:42PM C16.00005: Charge Kondo effects in a quadruple quantum dot in spinless and spinful regimes.  JUHO CHOI (Presenter), GWANGSU YOO, HEUNG-SUN SIM, KAIST — We theoretically study charge Kondo effects in a quadruple quantum dot, whose shape is such that three dots A,B,C are located at the three corners of a triangle respectively and the other dot D is at the center of the triangle. Here, the dots A and B are coupled to reservoirs. We consider a spinless regime under an external magnetic field and a spinful regime in the presence of electron tunneling between the dots A and B, when the system has two-fold degenerate ground-state charge configurations (n_A=1,n_B=1,n_C=1,n_D=0) and (0,0,0,1). In the spinless regime, a single-channel charge Kondo effect occurs. In this case, the two charge configurations act as the pseudospin states of the Kondo effect. In the spinful regime, electrons of the dots A and B in the charge configuration (1,1,1,0) form a spin singlet state, and the system is described by an anisotropic two-channel Kondo Hamiltonian. Because the channel anisotropy is large, the quadruple dot shows a single-channel charge Kondo effect. We compute electron transport through the quadruple dot for the two regimes.
3:54PM C16.00006: Metal-insulator transition in a semiconductor nanocrystal network* BENJAMIN L GREENBERG, Mechanical Engineering, University of Minnesota, ZACHARY ROBINSON (Presenter), YILIKAL Z AYINO, Physics, University of Minnesota, JACOB T HELD, Chemical Engineering and Materials Science, University of Minnesota, TIMOTHY A PETERSON, Physics, University of Minnesota, K. ANDRE MKHOYAN, Chemical Engineering and Materials Science, University of Minnesota, VLAD S PRIBIAG, Physics, University of Minnesota, ERAY S. AYDIL, Chemical Engineering and Materials Science, University of Minnesota, UWE RICHARD KORTSHAGEN, Mechanical Engineering, University of Minnesota — In bulk semiconductors, the metal-insulator transition is described by the well-known Mott criterion. A recent theory proposes a more stringent criterion condition in nanocrystal (NC) networks, dependent on the electron density \( n \) and the inter-NC facet radius \( \rho \): \( n\rho^3 \approx 0.3 \). Here we use plasma-synthesized ZnO NCs coated with Al\(_2\)O\(_3\) via ALD to study the electronic properties of a NC network as a function of \( n \) and \( \rho \). Through a xenon-flashlamp annealing process, we selectively sinter/dope the NC network by flashing the film before/after the ALD infill, allowing independent control of \( \rho \) and \( n \). While we observe large changes in the mobility and \( n \), we do not see finite conductivity \( (\sigma) \) as \( T \to 0 \)K. To cross the transition, prior to the Al\(_2\)O\(_3\) ALD infill we coat the NCs with 8 cycles of ZnO ALD. This changes \( \rho \) from ~1.5 nm to ~2.8 nm and increases the packing density from 33% to 47%. By then tuning \( n \) we achieve a transition from the semiconducting to metallic state, with finite \( \sigma \) as \( T \to 0 \)K. At the transition we see power law conductivity of the unusual form \( \sigma(T) \propto T^{1/5} \), and observe critical scaling behavior when scaling \( \sigma \) by the \( n\rho^3 \) criterion. This is the first conclusive evidence for metallic behavior in a NC network.

4:06PM C16.00007: Manipulation of non-linear heat currents in dissipative quantum dot systems BITAN DE (Presenter), BHASKARAN MURALIDHARAN, Electrical Engineering, Indian Institute of Technology Bombay — The anomalous behavior of phonon transport due to finite electron-phonon interaction is investigated using an Anderson-Holstein based dissipative quantum dot setup in two relevant cases: (a) electron flow stimulated by the voltage bias in the absence of an electronic temperature gradient and (b) electron flow driven by the electronic temperature gradient at zero voltage. We explain the observation of the cumulative effect of voltage and electronic temperature gradient on the non-linear phonon current with the aid of a new transport coefficient called electron induced phonon thermal conductivity. It is demonstrated that under suitable operating conditions in Case (a), the dot can pump in phonons into the hotter phonon reservoir and in Case (b), the dot can extract phonons out of the colder phonon reservoirs. Finally, we elaborate how the non-linear electronic heat current can be stimulated and controlled by engineering the temperatures of the phonon reservoirs.

4:18PM C16.00008: Measurement of the Kondo cloud length via a quantum dot coupled to a 1d interferometer: Theory (1/2) JEONGMIN SHIM (Presenter), Physics, Korea Advanced Institute of Science and Technology, IVAN BORZENETS, Physics, City University of Hong Kong, JASON CHEN, Applied Physics, The University of Tokyo, MICHIHISA YAMAMOTO, SEIGO TARUCHA, CEMS, RIKEN, H.-S. SIM, Physics, Korea Advanced Institute of Science and Technology — The Kondo effect, known as the archetype of many-body correlations, arises from the interaction between a localized magnetic moment and surrounding conducting electrons. Advances of nanotechnology allow us to study the Kondo effect for a single magnetic impurity confined in a semiconductor quantum dot in contact with electron reservoirs. This development also makes it possible to embed a Kondo correlated state into an interferometer. However, the special extent of the Kondo cloud has yet to be measured.

Here, we demonstrate that the Kondo cloud length \( \xi_K \) can be measured in a system of a Kondo correlated quantum coupled to a 1D Fabry-Perot (F-P) interferometer. Using numerical renormalization group and poor man's scaling methods in parallel we characterize the oscillations in Kondo temperature with respect to resonances of the F-P interferometer. We show that the amplitude of the temperature oscillations can be described by the interferometer length as well as the coupling strength. Thus, we demonstrate a system where an experimentally defined length can be used to infer the Kondo length.
4:30PM C16.00009: Measurement of the Kondo cloud length via a quantum dot coupled to a 1d interferometer: Experiment (2/2) IVAN BORZENETS (Presenter), Physics, City University of Hong Kong, JEONGMIN SHIM, Physics, Korea Advanced Institute of Science and Technology, JASON CHEN, Applied Physics, The University of Tokyo, H.-S. SIM, Physics, Korea Advanced Institute of Science and Technology, MICHIHISA YAMAMOTO, SEIGO TARUCHA, CEMS, RIKEN — We have developed an all-solution processed transparent conductor, known as the archetype of many-body correlations, arises from the interaction between a localized magnetic moment and surrounding conducting electrons. Advances of nanotechnology allow us to study the Kondo effect for a single magnetic impurity confined in a semiconductor quantum dot in contact with electron reservoirs. This development also makes it possible to embed a Kondo correlated state into an interferometer. However, the special extent of the Kondo cloud has yet to be measured.

In this work, we perform direct experimental measurement of the Kondo cloud length $\xi_K$ by coupling a Kondo correlated quantum dot to ballistic, multi-channel quantum wires, one of which couples more strongly to the dot and works as a 1D Fabry–Perot (F-P) interferometer defined on a GaAs/AlGaAs heterostructure. We demonstrate that the measured Kondo temperature undergoes resonances with respect to the F-P fluctuations. By looking at the strength of the resonances versus the interferometer lengths, we are able to access the length of the Kondo cloud. We back up our results by comparing the behavior of the interferometer in the Kondo as well as the Coulomb Blockade Regimes.

4:42PM C16.00010: Phonon backscatter, trapping, bottlenecking, and misalignment effects on thermal conductivity of Si Nanostructures FRANCIS VANGESSEL (Presenter), PETER CHUNG, University of Maryland, College Park — Nanostructured systems offer the ability to reduce thermal conductivity which, for instance, may be used to improve the thermoelectric efficiency. The internal surfaces of these nanostructures significantly curtail the ballistic free flight of phonons, and thus resist thermal transport. In this talk, we present a recent investigation of a simple one-parameter geometry that simultaneously modulates backscattering and trapping effects to enable directed study of controlling phonons. The geometry is a simple sequence of chambers offset from one another by a defined distance. We use the geometry to study the effects of phonon backscatter, trapping, bottlenecking, and corner-turning on the thermal conductance in Si nanowires (NWs). By creating a geometry that maximizes backscatter, a roughly 8-fold reduction in thermal conductance below the Casimir limit can be achieved at room temperature which is a factor of four smaller than the nearest reported value in the literature. The geometry is also useful for systematic investigation of other means of controlling phonons and affecting thermal transport. Specifically, we investigate the induced misalignment between the phonon flow and thermal flux due to the shape of the geometry as well as phonon filter-like behavior of the geometry.

5:06PM C16.00012: All-solution processed micro/nano-wires as transparent conducting electrodes CHAOBIN YANG (Presenter), JUAN M. MERLO, LUKE D’IMPERIO, AARON H ROSE, YITZI M CALM, VICTORIA GABRIELE, MARK SCHILLER, KRZYSZTOF KEMPA, MICHAEL J NAUGHTON, Boston College — We have developed an all-solution processed transparent conductive electrode with sheet resistance an order of magnitude smaller than conventional nanowire-based transparent conductors. This is achieved by integrating all-solution-produced microwires1 with nanowires and electroplate welding. As a result, the advantages of these transparent conductors are indium-free, vacuum-free, lithographic-facility-free, metallic-mask-free, with small domain size, high specific conductivity and mechanical flexibility, thus making them an excellent replacement for ITO.

**Session C17 DCOMP: Matter in Extreme Environments: Melting and Melts**

**Monday, March 4, 2019 2:30 PM - 5:06 PM**

**5:18PM C16.00013: Formation of Interfacial Dipole Formations during Contact Electrification**

JAMES CHEN (Presenter), MOHAMAD IBRAHIM CHEIKH, University at Buffalo, The State University of New York, TYLER J HIEBER, ZAYD C LESEMAN, Mechanical and Nuclear Engineering, Kansas State University — This study introduces a plausible origin of the driving force for electron transfer in contact electrification and triboelectrification for dielectric materials. As two material approaches each other, surface lattices of both materials form a weak interaction, the perturbed states of each surface lattice can be approximated a dipole. These surface dipoles induce a potential field in the proximity and provides a driving force for electron transfer. A tribopair of barium titanate and magnesia are investigated as an example. The simulation results show that such tribopair can generate up to 104 V/cm², which is comparable with the experimental measurements in published literature.

*This work is supported by NSF under Award 1662879*

**2:30PM C17.00001: Melting Under Extreme Conditions: Ab Initio Monte Carlo Simulations**

EDISON FLOREZ, CTCP, INMS, Massey University, Auckland, TRYGVE HELGAKER, University of Oslo, WIM KLOPPER, KIT, ANDREW TEALE, University of Nottingham, STELLA STOPKOWICZ, University of Mainz, ELKE PAHL (Presenter), CTCP, INMS, Massey University, Auckland — Melting results for rare gas clusters and solids under extreme pressures and magnetic fields are presented. Phase transitions are simulated by exploring phase space with classical (parallel-tempering) Monte Carlo methods combined with a very accurate computation of the interaction energy of the sampled configurations. We employ many-body expansions where the total interaction energy of the \( N \)-atom system is obtained by decomposing the total energy into two-, three- and higher-body fragments.

For rare gases, this approach works well for melting under ambient conditions\(^1\) and for argon for pressures up to 100 GPa, 1 Million times the atmospheric pressure\(^2\). We work in the isobaric, isothermal ensemble, allowing for atom displacements as well as cell volume adjustments employing periodic boundary conditions. Excellent agreement with experimental data is found up to very high pressures.

Neon clusters in high magnetic fields show elevated melting points and also give fascinating insight in the melting process itself. In a strong homogeneous magnetic field applied in \( z \)-direction the clusters get squeezed in the perpendicular plane as also observed for atoms. Around the melting temperature, we observe an additional squeezing parallel to the magnetic field due to perpendicular paramagnetic bonding responsible for the enhanced melting points. For these studies, dimer potential curves were computed on MP2 and coupled-cluster level depending on the magnetic field, the interatomic distance and the angle of the molecular axis with the magnetic field direction.

*We thank the Marsden fund, Royal Society of New Zealand (MAU1409), the Centre for Advanced Study at Norwegian Academy of Science and Letters and the MacDiarmid Institute for Advanced Materials and Nanotechnology for financial support.*
**3:06PM C17.00002: Fast determination of melting curves at high pressure**

JOHANN BOUCHET (Presenter), VANINA RECOULES, FRANCOIS BOTTIN, MARC TORRENT, CEA, DAM, DIF — Determination of accurate melting curves of materials is an old problem. In the past twenty years, reliable results have been obtained with ab-initio molecular dynamics (AIMD). These simulations are usually based on molecular dynamics of the solid or the liquid (one phase approach), or the direct simulation of the solid-liquid interface (two phases approach) [1]. Unfortunately, AIMD can be very time consuming, and prevent applications on complex systems or heavy elements. Fast alternative methods are necessary, at least to give a starting point for more complex calculations.

The famous phenomenological Lindeman [2] approach based on the comparison of the amplitude of thermal vibrations of atoms with the interatomic distance and proposed more than 100 years ago is still widely used [3]. We have tested its validity for several metals (Au, Al, Fe...) on a large pressure scale. We will also discussed applications on MgO and U in regard to our recent calculations of vibrational frequencies in temperature [4].

**3:18PM C17.00003: Critical point, liquid-vapor coexistence, and melting of Mg$_2$SiO$_4$ from *ab-initio* simulations**

THOMAS R MATTSSON (Presenter), Sandia National Laboratories, GIL SHOHET, Department of Aeronautics & Astronautics, Stanford University, JOSHUA TOWNSEND, LUKE SHULENBURGER, MICHAEL PAUL DESJARLAIS, Sandia National Laboratories — We report density functional theory-based molecular dynamics calculations (DFT-MD) of Mg$_2$SiO$_4$ liquid and vapor across the liquid-vapor coexistence boundary that spanned 0.22-3.22 g/cc in density and 5000-10000 K in temperature. The critical point was estimated through a bootstrap analysis of a collection of DFT-MD isotherms above and below the critical point. Additionally, we describe the structure and composition of the liquid and vapor around the critical point. Finally, we discuss melting behavior at P=1 bar.

*This work was supported by the Z Fundamental Science Program (ZFSP) at Sandia National Laboratories. Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-NA0003525.

**3:30PM C17.00004: Chain melting simulations in dense potassium from a machine-learned atomic potential**

ANDREAS HERMANN (Presenter), HONGXIANG ZONG, VICTOR NADEN ROBINSON, GAVIN WOOLMAN, GRAEME ACKLAND, University of Edinburgh — Compressed potassium forms a host-guest structure above 19 GPa, K-III, where the host and guest structures have incommensurate lattice constants $c_h$ and $c_g$ [1]. The guest structure comprises a linear set of chains with long range order at low temperature and has been observed to de-correlate or “melt” upon heating, while the host structure remains solid [2]. We studied this motion and onset of inter- and intra-chain de-correlation, which lead to the disappearance of guest structure diffraction peaks, by ab initio molecular dynamics (AIMD) using approximants of the incommensurate crystal. The system sizes that can be simulated with AIMD are limited, so a forcefield was trained on the AIMD data set. The trained potential was used to produce potassium’s PT phase diagram up to 60 GPa and 1000 K, correctly predicting the stable solid phases, the chain melt and the full melting line [3].

*Research funding from the ERC (grant HECATE) and computational resources provided through EPSRC (EP/P020194 and EP/P02256/1) are acknowledged.
3:42PM C17.00005: Pre-melting hcp to bcc Transition in Beryllium by First-Principles Phonon Quasiparticle Approach  
DONG-BO ZHANG (Presenter), College of Nuclear Science and Technology, Beijing Normal University, Beijing 100875, China, YONG LU, Beijing Computational Science Research Center, Beijing 100193, China, TAO SUN, Key Laboratory of Computational Geodynamics, University of Chinese Academy of Sciences, Beijing 100088 China, PEIHONG ZHANG, Department of Physics, University at Buffalo, State University of New York, 14260, USA, RENATA WENTZCOVITCH, Department of Applied Physics and Applied Mathematics; Department of Earth and Environmental Sciences and Lamont-Doherty Earth Observatory, Columbia University, 10027, USA — Beryllium (Be) is an important material with wide applications ranging from aerospace components to x-ray ray equipment. Yet a precise understanding of its phase diagram under extreme conditions remains elusive. We have investigated the phase stability of Be using a recently developed hybrid free energy computation method that accounts for anharmonic effects by invoking phonon quasiparticles. We find that the hcp → bcc transition occurs near the melting curve at 0 < P < 11 GPa with a positive Clapeyron slope of $41(4)$ K/GPa, which is more consistent with recent experimental measurements. This work also demonstrates the validity of this theoretical framework based on the phonon quasiparticle to study the structural stability and phase transitions in strongly anharmonic materials.

3:54PM C17.00006: Direct Observation of Shock-Induced Melt Kinetics in a Porous Solid Using Time-Resolved X-Ray Diffraction*  
ANIRBAN MANDAL (Presenter), BRIAN JENSEN, Shock and Detonation Physics (M-9), Los Alamos National Laboratory, Los Alamos, NM 87545, USA, MATTHEW HUDSPETH, SETH ROOT, Dynamic Material Properties, Sandia National Laboratories, Albuquerque, NM 87185, USA, RYAN CRUM, MINTA C AKIN, Physics Division, Lawrence Livermore National Laboratory, Livermore, CA 94550, USA — Time-resolved x-ray diffraction was used to obtain direct (real time) evidence of shock-induced melting and associated kinetics in a porous solid (aluminum (Al) powder). Broadening of the Debye-Scherrer ring corresponding to the (111) peak of Al provided unambiguous evidence of melting. Our data showed that complete bulk melting of the powder could take in excess of 450 ns even when it is shocked to equilibrium pressure-temperature states above the melt boundary. Information on the melt kinetics obtained from our work provide insight into the thermal equilibration time and thermal diffusivity of the material under high-pressure dynamic loading, which are essential to developing well-constrained heat transfer and melting models for Al powder and other porous materials (LA-UR-18-30166).

4:06PM C17.00007: In situ X-ray diffraction of Ce melting under shock loading  
MATTHEW T BEASON (Presenter), BRITTANY BRANCH, BRIAN JENSEN, Los Alamos National Laboratory — With 7 observed crystalline phases below 20 GPa, cerium exhibits a complex phase diagram. In particular, the γ-α phase transition exhibits a large volume collapse (13%-16%) resulting in a low melting pressure for a metal. Sound speed measurements have shown that Hugoniot intersects the melt boundary at 10 GPa with complete melting near 18 GPa; however, the processes and timescales involved are not yet known. This work presents experiments performed at the Dynamic Compression Sector examining the phase evolution of γ-Ce under shock loading. The results indicate that γ-Ce and α-Ce coexist with liquid Ce at pressures near the onset of melt. With increasing pressure, α-Ce is no longer observed; however, γ-Ce persists after impact at pressures beyond 18 GPa. The results indicate significant kinetics, with complete melting observed 200 ns after impact. An experiment performed below the melting pressure shows that the γ-α transition occurs over a similar timescale, with visible peaks for γ-Ce and α-Ce observed over 50 ns after impact. As a result, the γ-α transition appears to exhibit occurs over a relatively long timescale, which is surprising for an isostructural phase transition, and appears to be a significant barrier to melting. (LA-UR-18-30167)
suggest a melting temperature, with diffuse X-ray scattering and visual changes in the sample before and after laser-heating. At POPOV, ROSTISLAV HRUBIAK, High Pressure Collaborative Access Team (HP-CAT), Argonne National Laboratory, NIKOLA DRAGANIC, Shock and Detonation Physics (M-9), Los Alamos National Laboratory, YOGESH KUMAR VOHRA, Department of Physics, University of Alabama at Birmingham, NENAD VELISAVLJEVIC, Shock and Detonation Physics (M-9), Los Alamos National Laboratory — Robust modeling of shock phenomena requires accurate and precise experimental measurements of equations of state and phase diagrams. Zirconium is of particular interest in nuclear applications because of its low neutron cross section. Here, we present the thermal equation of state and melting curve of ultra-high purity Zr in the body-centered cubic (bcc) phase measured using the laser-heated diamond-anvil cell (LHDAC) coupled with in situ synchrotron-based X-ray diffraction (XRD). From quasi-hydrostatic room-temperature compression to pressure ($P$) = ~70 GPa using helium as a pressure transmitting medium, we constrain the bcc-Zr bulk modulus, $K_0 = 120(7)$ GPa and its pressure derivative, $K_0' = 3.0(1)$. Additionally, we have collected LHDAC XRD data over a range of $P = \sim 10 - 40$ GPa and temperature ($T$) = ~1400 – 2200 K to further constrain the bcc-Zr thermal equation of state parameters. Within a separate set of experiments, we have observed melting of bcc-Zr between $P = \sim 10 – 20$ GPa based on plateaus in the $T$ versus laser-power curves coupled with diffuse X-ray scattering and visual changes in the sample before and after laser-heating. At $P = \sim 10$ GPa, initial results suggest a melting temperature, $T_m = 2270(50)$, that implies a melting curve slope of ~14 K/GPa.

2:30PM C17.00009: Melting Line and Structure of Hot dense Fluids probed by X-ray diffraction [Invited] GUNNAR WECK (Presenter), DIF, CEA, FRÉDÉRIC DATCHI, IMPMC, Université Pierre et Marie Curie, GASTON GARBARINO, ESRF, SANDRA NINET, IMPMC, Université Pierre et Marie Curie, JEAN-ANTOINE QUEYROUX, THOMAS PLISSON, PAUL LOUBEYRE, MOHAMED MEZOUAR, DIF, CEA — Warm dense simple molecular fluids constitute a large fraction of planetary interiors. Their current microscopic understanding is essentially based on ab-initio calculations. Novel states are predicted such as: ionic water and ammonia, metallic oxygen and hydrogen, or polymerized carbon dioxide and nitrogen with possible first-order transition. These remain to be tested by experiment. In this contribution, we will present some developments which have enabled to perform structural measurements on dense simple molecular fluids in the 100 GPa range and few thousand Kelvin. An elaborate sample environment has been implemented to homogeneously laser heat the molecular system. A multichannel collimator is used to filter the overwhelming x-ray diffraction background contribution from the diamond anvils. A careful data analysis is applied to extract the liquid structure factor and the radial distribution function. Observing the liquid diffraction is essential to unambiguously determine the occurrence of melting. Measurements on laser heated nitrogen, gold and xenon will be presented to illustrate this experimental approach.

Session C18 DCOMP DCMP DAMOP: Machine Learning Quantum Many-body Models BCEC 156B - Yi Zhang, Cornell University - Tag(s): Focus

2:30PM C18.00001: Quantum Loop Topography for Machine Learning Transport [Invited] YI ZHANG (Presenter), Department of Physics, Cornell University, CARSTEN BAUER, PETER BROECKER, Institute for Theoretical Physics, University of Cologne, PAUL GINSARG, Department of Physics, Cornell University, SIMON TREBST, Institute for Theoretical Physics, University of Cologne, EUN-AH KIM, Department of Physics, Cornell University — Despite the rapidly growing interest in harnessing machine learning in the study of quantum many-body systems, there remains a central challenge in efficiently extracting information from the model simulations of the quantum states and turning the information into formats compatible with the machine learning architecture, such as an artificial neural network. Here we introduce quantum loop topography (QLT): a feature-selection machine learning procedure by evaluating correlators' loop products of the microscopic models at independent Monte Carlo steps. Following the contribution of the current-current correlations, we demonstrate that QLT can probe the distinctive transport properties of diverse states of matter, which are sometimes challenging to access directly. To showcase this approach, we study the emergent superconducting fluctuations as well as the topological phases with quantized Hall transport. We find that the QLT approach detects a change in transport in very good agreement with their established phase diagrams. We also demonstrate that our pre-selection of features relevant to transport allows us to work with a simple neural network, and then offer an interpretation of such a neural network for the analytical decision criteria. The high fidelity and numerical efficiency of our machine learning algorithm also point a way to identify hitherto elusive transport phenomena such as the non-Fermi liquids.
Recent advances in the study of frustrated magnetism with Neural-Network quantum states
KENNY CHOO, TITUS NEUPERT, University of Zurich, GIUSEPPE CARLEO (Presenter), CCQ, Flatiron Institute — Neural-Network quantum states are an actively explored route to solve challenging interacting quantum problems. Early representations of many-body quantum states in terms of artificial neural networks were based on shallow, restricted Boltzmann Machines [1-3]. The benefits of using deeper networks are however emerging in latest research, where the use of suitably adapted deep networks to the quantum domain is proving rewarding. During this talk I will discuss our strategy to represent quantum states using deep convolutional networks. The advantages of this representation will be shown in the particularly challenging case of frustrated magnets in two dimensions. Here, I will show latest applications to the frustrated J1-J2 model on the square lattice. In this case, neural-network quantum states achieve results that are comparable or better than existing state of the art variational methods developed in the past decade.

Symmetries and Many-Body Excitations with Neural-Network Quantum States* KENNY JING CHOO (Presenter), Physik Institut, University of Zurich, GIUSEPPE CARLEO, Center for Computational Quantum Physics, Flatiron Institute, NICOLAS REGNAULT, Laboratoire Pierre Aigrain, Ecole normale superieure, TITUS NEUPERT, Physik Institut, University of Zurich — Artificial neural networks have been recently introduced as a variational ansatz for representing many-body wave functions. While previous efforts have been focused on obtaining ground states, in this work we extend the method to the study of excited states, which is an important task for many condensed matter applications. First, we give a prescription that allows us to target the lowest energy state within a symmetry sector of the Hamiltonian. Second, we give a simple algorithm to compute the low-lying states without symmetries. We demonstrate this approach on the one-dimensional spin 1/2 Heisenberg model and the one-dimensional Bose-Hubbard model and found good agreement where exact results are available. We applied our approach using both the restricted Boltzmann machine (RBM) and the feedforward neural network (FFNN). Interestingly, we obtained more accurate results using a deeper FFNN as compared with a shallower RBM with comparable number of variations parameters.

Learning Quantum Models from Symmetries ELI CHERTKOV (Presenter), BENJAMIN VILLALONGA, BRYAN CLARK, University of Illinois at Urbana-Champaign — Inverse method algorithms that learn models from data, such as machine learning algorithms, have been successful in solving complicated engineering tasks and are increasingly being applied to study quantum systems. Moreover, inverse methods have the potential to automate the discovery of quantum materials with desired properties. With this goal in mind, we present an inverse method algorithm for learning quantum models, i.e., Hamiltonians, from symmetries or integrals of motion. The forward problem of starting from a given Hamiltonian and finding its symmetries, is generically difficult both analytically and numerically. Yet, despite the difficulty of the forward problem, we show that this method can efficiently solve the inverse problem of starting from a desired set of symmetries and finding Hamiltonians obeying those symmetries. In this talk, we describe this inverse method and give examples of its application.

Parent hamiltonians of restricted Boltzmann machine wavefunctions* SAMUEL LEDERER (Presenter), EUN-AH KIM, Cornell University — Wavefunctions based on the restricted Boltzmann machine (RBM) architecture have recently been found to be highly effective in variational calculations on interacting spin models. The promise of RBMs for compactly encoding quantum states motivates study of the structure underlying RBM wavefunctions. Here we tackle the question of what hamiltonians take RBM wavefunctions as eigenstates. Using a recently developed framework for identifying local hamiltonians from wavefunctions, we consider a select set of RBM states, and comment on the features of their parent hamiltonians.

Learning a local Hamiltonian from local measurements

EYAL BAIREY (Presenter), ITAI ARAD, NETANEL LINDNER, Physics, Technion - Israel Institute of Technology — Recovering an unknown Hamiltonian from measurements is an increasingly important task for certification of noisy quantum devices and simulators. Recent works have succeeded in recovering the Hamiltonian of an isolated quantum system with local interactions from long-ranged correlators of a single eigenstate. Here, we show that such Hamiltonians can be recovered from local observables alone, using computational and measurement resources scaling linearly with the system size. In fact, to recover the Hamiltonian acting on each finite spatial domain, only observables within that domain are required. The observables can be measured in a Gibbs state as well as a single eigenstate; furthermore, they can be measured in a state evolved by the Hamiltonian for a long time, allowing to recover a large family of time-dependent Hamiltonians. We derive an estimate for the statistical recovery error due to approximation of expectation values using a finite number of samples, which agrees well with numerical simulations.

Accelerating Density Matrix Renormalization Group Computations with Machine Learning

JACOB MARKS (Presenter), Physics, Stanford University, HONG-CHEN JIANG, THOMAS DEVEREAUX, SIMES, SLAC, and Stanford University — Density Matrix Renormalization Group (DMRG) has achieved great success as a technique for simulating one-dimensional and quasi-two-dimensional quantum systems. One major bottleneck for these computations is the variational procedure for ground state approximation. We investigate the application of machine learning methods to this problem and improve convergence time for various classes of strongly correlated systems.

Observation of topological phenomena in a programmable lattice of 1,800 qubits

JUAN CARRASQUILLA (Presenter), Vector Institute — Here we demonstrate a large-scale quantum simulation of this phenomenon in a network of 1,800 in situ programmable superconducting flux qubits arranged in a fully-frustrated square-octagonal lattice. Essential to the critical behavior, we observe the emergence of a complex order parameter with continuous rotational symmetry, and the onset of quasi-long-range order as the system approaches a critical temperature. We use a simple but previously undemonstrated approach to statistical estimation with an annealing-based quantum processor, performing Monte Carlo sampling in a chain of reverse quantum annealing protocols. Observations are consistent with classical simulations across a range of Hamiltonian parameters. We anticipate that our approach of using a quantum processor as a programmable magnetic lattice will find widespread use in the simulation and development of exotic materials.

Self-learning with neural networks in determinant quantum Monte Carlo studies of the Holstein model.

SHAOZHI LI, Physics, University of Michigan, PHILIP DEE (Presenter), University of Tennessee, EHSAN KHATAMI, Physics, San Jose State University, STEVEN JOHNSTON, University of Tennessee — Machine learning techniques have recently occupied the focus of many investigators in computational many-body physics. In particular, some practitioners of quantum Monte-Carlo have considered the efficacy of various "Self-Learning" techniques which aim to reduce CPU runtime associated with updates and autocorrelation times. We have used artificial neural networks (NN) within determinant quantum Monte-Carlo to improve the scaling of CPU runtime with typical system parameters. This work focuses on a singleband Holstein Hamiltonian, which models Einstein phonons coupled to on-site electrons. We have implemented both fully connected and convolutional NN and used them to study the metallic and insulating phases of this model. To close, we will assess the generality of this approach to other model systems.

4:42PM C18.00010: Unsupervised manifold learning of ground state wave functions*  MICHAEL MATTY (Presenter), YI ZHANG, Cornell University, SENTHIL TADADRI, Massachusetts Institute of Technology, EUN-AH KIM, Cornell University — Quantum many-body wave functions are complex objects that encode much information, but it can be challenging to back out the information. In particular, there is no good way to assess whether a given wave function can be a ground state of some local Hamiltonian. Here we employ an unsupervised machine learning algorithm well-suited for discovering trends in high-dimensional space: manifold learning. We apply our approach to a band insulator and the toric code and demonstrate that our approach can separate ground state wave functions from excited state wave functions without any prior knowledge.

*This work was partially supported by the Cornell Center for Materials Research with funding from the NSF MRSEC program (DMR-1719875). 4:54PM C18.00011: Machinery representation of physics models via structured self-attention network  JUNWEI LIU (Presenter), Hong Kong University of Science and Technology, YANG ZHANG, Max Planck Institute for Chemical Physics of Solids, YUJUN ZHAO, Hong Kong University of Science and Technology — Recently machine learning techniques, especially deep neural networks, are widely used to identify phases and phase transition and speed up the simulations in variety of physical models. However, deep neural networks are often required to model the energy or partition function, which results in heavy computational cost and also limits the application to large system. In this work, we proposed a structured self-attention neural network approach, inspired by mean field theory, to represent the original Hamiltonian via well-structured neural layers. We experiment with the ring exchange Ising model and double exchange model, and show these two models can be well represented by pseudo spin layers and local field layers. Quite different from the sequential neural network, which stores all the information in every single layer, the separation strategy achieves significantly less training time, higher accuracy and straightforward application to large system. We therefore believe the new structural network would also be highly efficient to identify different phases and accelerate the numerical simulations for even complex models.

5:06PM C18.00012: Neural Network Renormalization Group*  SHUO-HUI LI (Presenter), LEI WANG, Institute of Physics — We present a variational renormalization group (RG) approach using a deep generative model based on normalizing flows. The model performs hierarchical change-of-variables transformations from the physical space to a latent space with reduced mutual information. Conversely, the neural net directly maps independent Gaussian noises to physical configurations following the inverse RG flow. The model has an exact and tractable likelihood, which allows unbiased training and direct access to the renormalized energy function of the latent variables. To train the model, we employ probability density distillation for the bare energy function of the physical problem, in which the training loss provides a variational upper bound of the physical free energy. We demonstrate practical usage of the approach by identifying mutually independent collective variables of the Ising model and performing accelerated hybrid Monte Carlo sampling in the latent space.

5:18PM C18.00013: Learning density functional theory mappings with extensive deep neural networks and deep convolutional inverse graphics networks*  KEVIN RYCZKO (Presenter), Department of Physics, University of Ottawa, DAVID STRUBBE, Department of Physics, University of California, Merced, ISAAC TAMBLYN, National Research Council of Canada — In this work, we show that deep neural networks (DNNs) can be used in conjunction with Kohn-Sham density functional theory (KS-DFT) for two-dimensional electron gases in simple harmonic oscillator and random potentials. Using calculations from the Octopus real-space DFT code we show that extensive DNNs (EDNNs) can learn the mappings between the electron density and exchange, correlation, external, kinetic and total energies simultaneously. Our results hold for local, semi-local, and hybrid exchange-correlation functionals. We then show that the external potential can also be used as input for an EDNN when predicting the aforementioned energy functionals, bypassing the KS scheme. Additionally, we show that EDNNs can be used to map the electron density calculated with a local exchange-correlation functional to energies calculated with a semi-local exchange correlation functional. Lastly, we show that deep convolutional inverse graphics networks can be used to map external potentials to their respective self-consistent electron densities. This work shows that EDNNs are generalizable and transferable given the variability of the potentials and the ability to scale to an arbitrary system size with an O(N) computational cost.

*The authors would like to thank NSERC.
2:30PM C19.00001: Quantum Monte Carlo Study of Strongly Interacting Fermi Gases in Two Dimensions: BCS-BEC Crossover, Spin-orbit Coupling, and Dynamical Response Functions* [Invited] HAO SHI (Presenter), Simons Foundation, PETER ROSENBERG, SIMONE CHIESA, ETTORE VITALI, College of William and Mary, SHIWEI ZHANG, Simons Foundation — We describe recent advances in auxiliary-field quantum Monte Carlo techniques, which enable calculations on large lattices to reliably compute ground-state and excited-state properties in the thermodynamic limit. Exact calculations are performed on the two-dimensional strongly interacting, unpolarized, uniform Fermi gas with a zero-range attractive interaction. An equation of state is obtained, with a parametrization provided, which can serve as a benchmark and allow accurate comparisons with experiments. The pressure, contact parameter, and condensate fraction are determined systematically vs. the interaction strength. Rashba spin-orbit coupling is then included to examine its interplay with superfluidity and the resulting pairing and spin structures and correlations. The imaginary-time propagation of Slater determinants is used to compute the pairing gap in the two-dimensional Fermi gas. The spectral functions, and the density and spin structure factors are then obtained using analytic continuation to provide unique tools to visualize the BEC-BCS crossover. We will also discuss briefly calculations in optical lattice systems and comment on the prospect for precision calculations in spin-imbalanced systems.

3:06PM C19.00002: "Quasielectrons in Lattice Moore–Read Models" SOURAV MANNA (Presenter), Quantum Many-Body Systems, Max Planck Institute for the Physics of Complex Systems, D-01187, Dresden, Germany, JULIA WILDEBOER, Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky, 40506-0055, USA, ANNE E. B. NIELSEN, Quantum Many-Body Systems, Max Planck Institute for the Physics of Complex Systems, D-01187, Dresden, Germany — Anyons are fractionally charged quasiparticles which are neither fermions nor bosons. Anyons exhibit fractional statistics and important for topological quantum computation. Anyonic Moore–Read states provides a well explored description for the insertion of quasiholes in the continuum. However, quasielectron insertion creates a singularity in the continuum state which further complicates the problem. In this work we show that the singularity problem can be avoided by placing quasielectrons in fractional quantum Hall lattice systems. We construct Moore–Read Pfaffian states for filling fraction 5/2 and incorporate quasiholes and quasielectrons. We investigate density profile, charge, size and braiding properties of the anyons by means of a Metropolis Monte Carlo simulation. Further we derive a few body parent Hamiltonian for the states. Additionally we investigate density profile, charge and shape of the anyons in the Kapit–Mueller model by employing an exact diagonalization technique. We compare our results for the analytical states with the anyons in the Kapit–Mueller model.

3:18PM C19.00003: Dispersion Relation of the GMP Mode in the Nematic Phase of Fractional Quantum Hall States* UMANG MEHTA (Presenter), DAM THANH SON, Physics, University of Chicago — We compute the dispersion relation for the GMP mode of the fractional quantum Hall effect in the nematic phase for Jain sequences at large N using Golkar, Nguyen, Roberts and Son’s ‘higher-spin theory’ for magnetorotons. The dispersion relation is computed to all orders in the momentum expansion and is valid wherever the momentum expansion holds. It captures the magnetoroton minimum at finite momentum in the regime where the momentum expansion still holds.

3:30PM C19.00004: Interacting Chern insulators: Diagrammatics well beyond the lowest order*  
IGOR TUPITSYN (Presenter), NIKOLAI PROKOF’EV, University of Massachusetts Amherst — We study phase diagram of the interacting spin-1/2 Haldane model with chiral phase $\varphi=\pi/2$ at half-filling. Both on-site and long-range Coulomb repulsive interactions (Haldane-Hubbard-Coulomb model) are considered. The problem with on-site interaction $U$ alone was addressed in the past by a variety of approximate and finite size methods that produced results in disagreement with each other both quantitatively and qualitatively. Conventional Quantum Monte Carlo methods, capable of dealing with "reasonable" system sizes, are ineffective here due to the fermionic sign problem. We employ the Diagrammatic Monte Carlo (DiagMC) technique to (i) accurately locate topologically nontrivial phases in the $(\triangle, U)$-plane ($\triangle$ is the inversion symmetry breaking on-site energy) and (ii) demonstrate the strong effect of typically discarded in theoretical considerations long-range part of the Coulomb interaction. The DiagMC technique is not subject to the conventional fermionic sign problem and allows one to deal with arbitrary shape of interaction potential in an approximations free manner. Final results with controlled accuracy are obtained by computing vertex corrections from higher-order diagrams until convergence is reached.

*We thank the Simons Collaboration on the Many Electron Problem for support.

3:42PM C19.00005: Critical torus spectrum of the Gross-Neveu-Yukawa field theory*  
MICHAEL SCHULER, Institute for Theoretical Physics, University of Innsbruck, STEPHAN HESSELMANN (Presenter), Institute for Theoretical Solid State Physics, RWTH Aachen University, SETH WHITSITT, Joint Quantum Institute, NIST and the University of Maryland, THOMAS C LANG, Institute for Theoretical Physics, University of Innsbruck, STEFAN WESSEL, Institute for Theoretical Solid State Physics, RWTH Aachen University, ANDREAS LÄUCHLI, Institute for Theoretical Physics, University of Innsbruck — We compute the low-energy critical torus spectrum of the Gross-Neveu-Yukawa universality class, which features $N=4$ component Dirac spinors that spontaneously break a $Z_2$ chiral symmetry, in $D=(2+1)$ dimensions. A possible lattice realization of such Dirac fermions is provided by the interacting $t$-$V$ model of spinless fermions on the honeycomb lattice. We use a combination of Exact Diagonalization and Quantum Monte Carlo simulations to compute the energy spectrum on finite-size clusters with periodic boundaries, and perform an extrapolation to the thermodynamic limit. We show that the interaction between the spinor field and the scalar order-parameter field strongly influences the torus spectrum at the critical point, and propose the critical spectrum as a universal fingerprint of the critical Gross-Neveu-Yukawa field theory. Moreover, we estimate the renormalization of the Fermi velocity in the Dirac phase from the interaction induced corrections to the energy spectrum, and extrapolate the observed linear renormalization up to the critical point. Finally, we contrast the Fermi velocity renormalization in the spinless $t$-$V$ model with the situation in the spinful Hubbard model.

3:54PM C19.00006: Unconventional pairing symmetry of interacting Dirac fermions on a π-flux lattice  
HUAIMING GUO (Presenter), Department of Physics, Beihang University — The pairing symmetry of interacting Dirac fermions on the π-flux lattice is studied with the determinant quantum Monte Carlo and numerical linked-cluster expansion methods. The $s^*$- (i.e., extended s-) and d-wave pairing symmetries, which are distinct in the conventional square lattice, are degenerate under the Landau gauge. We demonstrate that the dominant pairing channel at strong interactions is an unconventional $ds^*$-wave phase consisting of alternating stripes of $s^*$- and d-wave phases. A complementary mean-field analysis shows that while the $s^*$- and d-wave symmetries individually have nodes in the energy spectrum, the $ds^*$ channel is fully gapped. The results represent a new realization of pairing in Dirac systems, connected to the problem of chiral d-wave pairing on the honeycomb lattice, which might be more readily accessed by cold-atom experiments.
4:06PM C19.00007: Universal trends in interacting two-dimensional Dirac materials* SAIKAT BANERJEE (Presenter), Condensed Matter Physics, University of Augsburg, Germany, DAVID ABERGEL, Condensed Matter Physcis, Nordic Institute for Theoretical Physics, HANS AGREN, Theoretical Chemistry and Biotechnology, KTH Royal Institute of Technology, Sweden, GABRIEL AEPLLI, Condensed Matter Physcis, Paul Scherrer Institute, ALEXANDER BALATSKY, Condensed Matter Physcis, Nordic Institute for Theoretical Physics — We investigate the extent to which the category of Dirac materials provides general statements about the behavior of both fermionic and bosonic Dirac quasiparticles in the interacting regime. For both quasiparticle types, we find common features in the renormalization of the conical Dirac spectrum by interactions. This feature motivates us to declare that Dirac materials form a separate and well-defined category with universal properties. To support this view, we compute the self-energy for both types of quasiparticles with different interactions and collate previous results from the literature whenever necessary. The computations are performed both at zero and finite temperature. Guided by the systematic presentation of our results in Table I, we conclude that long-range interactions generically lead to an increase of the slope of the single particle Dirac cone, whereas short-range interactions lead to a decrease. The quasiparticle statistics does not impact the self-energy correction for long-range repulsion but does affect the behavior of short-range coupled systems, giving rise to different thermal power-law contributions.

4:18PM C19.00008: Universal Fermi-surface anisotropy renormalization for interacting Dirac fermions with long-range interactions* SHAFFIQUE ADAM (Presenter), Yale-NUS College, JIA NING LEAW, HO KIN Y TANG, MAXIM TRUSHIN, National University of Singapore, FAKER ASSAAD, Universität Würzburg, SANKAR DAS SARMA, University of Maryland — Recent evidence suggest an intriguing universal relationship between the Fermi surface anisotropy of the non-interacting parent two-dimensional electron gas and the strongly correlated composite Fermi liquid formed in a strong magnetic field close to half-filling. Inspired by these observations, we explore more generally the question of anisotropy renormalization in interacting 2D Fermi systems. Using a recently developed [1] non-perturbative and numerically-exact projective quantum Monte Carlo simulation as well as other numerical and analytic techniques, only for Dirac fermions with long-range Coulomb interactions do we find a universal square-root decrease of the Fermi-surface anisotropy [2]. Our proposed universality can be tested in several anisotropic Dirac materials including graphene, topological insulators and organic conductors.

4:30PM C19.00009: Energy scales and quasi-particle behavior of fermions in the normal state of flat-band systems* PRAMOD KUMAR (Presenter), Department of Applied Physics, Aalto University, VANHALA TUOMAS, Department of Physics and Arnold Sommerfeld Center for Theoretical Physics, Ludwig Maximilians-University, Munich, Germany, SEBASTIANO PEOTTA, PAIVI TORMA, Department of Applied Physics, Aalto University — We explore the energy scales and quasi-particle behavior in the paramagnetic normal state of the repulsive Hubbard model on the Lieb lattice. The special geometry of the Lieb lattice, a face-centered 2D square lattice, has a flat dispersion, which leads to various novel electronic phases with the inclusion of many-body interactions [1, 2]. Singularity in the density of states can lead to the breakdown of quasi-particle behavior at finite temperature. The interplay of the singularity and the interaction determine the energy scale to observe such non-Fermi liquid behavior. We address this using dynamical mean field theory (DMFT), a very well-established methodology for correlated many-body systems. We have used continuous-time quantum Monte Carlo (CTQMC), an exact impurity solver, within DMFT. We also comment on particle-hole mapping between attractive and repulsive Hubbard model with a unitary transformation and the corresponding electronic properties.

*Academy of Finland and European Research Council
It is demonstrated by explicit construction that the intricate links among short-range-entangled (SRE) states across different dimensions have a vivid embodiment in the realm of symmetry protected topological (SPT) phases with crystalline symmetry. We systematically study three-dimensional bosonic topological phases protected by any space group symmetry $G$. We prove that these phases are classified by $H_{\varphi}^5(G;\mathbb{Z}) \times H_{\varphi}^1(G;\mathbb{Z})$, where $\varphi$ indicates $g \in G$ acting on $\mathbb{Z}$ as multiplying $\varphi(g)=\pm 1$ depending on whether orientation is preserved by $g$ or not. The factor $H_{\varphi}^5(G;\mathbb{Z})=H_{\text{Borel}}^4(G;U(1))$, known as the group cohomology proposal for classifying bosonic SPT phases, corresponds to only the phases presented by some SRE 2-skeleton without presence of $E_8$ state or its multiples (i.e., two-dimensional chiral bosonic phases characterized by quantized thermal Hall effect). The extra factor $H_{\varphi}^1(G;\mathbb{Z})$ describes inequivalent $E_8$ state configurations and can be easily read off directly from the international (Hermann-Mauguin) symbol for $G$. Moreover, our result supports the Generalized Cohomology Hypothesis in the case of crystalline symmetries.

Transferable screened range-separated hybrids for layered materials  
ASHWIN RAMASUBRAMANIAM (Presenter), Mechanical & Industrial Engineering, University of Massachusetts Amherst, DAHVYD WING, LEEOR KRONIK, Department of Materials and Interfaces, Weizmann Institute of Science — The optoelectronic properties of layered semiconductors can vary significantly between bulk (3D) phases and their single- or few-layer, 2D counterparts. In particular, the vastly different asymptotic behavior of dielectric screening in 2D and 3D structures poses a challenge for designing screened range-separated hybrid (SRSH) functionals that are accurate for both bulk and low-dimensional systems. We present a simple yet effective approach for simultaneously tuning the fraction of short-range exact exchange and the range-separation parameter that delivers tuned SRSH functionals for 2D sheets and 3D bulk phases of layered semiconductors. The ground-state SRSH eigenvalues are found to be in excellent agreement with bandstructures from accurate, manybody GW calculations. Excited state properties are predicted using time-dependent DFT calculations, based on the SRSH functional, and are also found to be in good agreement with absorption spectra obtained from GW and Bethe-Salpeter (BSE) calculations. The ability to develop SRSH functionals that are only material- but not structure-specific opens up avenues for systematic and accurate studies of layered materials and their nanostructures at a fraction of the cost of many-body calculations.

First-principles study of bioinspired perylene diimide molecular nanowires*  
ALIYA MUKAZHANOVA (Presenter), Division of Materials Science and Engineering, Boston University, NATHAN FREY, Department of Physics, Boston University, KASIDET TRERAYAPIWAT, Department of Chemistry, Boston University, AMIR MAZAHERIPOUR, ANDREW BARTLETT, HUNG NGUYEN, ALON A. GORODETSKY, Department of Chemical Engineering and Materials Science, University of California, Irvine, SAHAR SHARIFZADEH, Department of Electrical and Computer Engineering, Boston University — Perylene-3,4,9,10-tetracarboxylic diimide (PTCDI) has excellent electrochemical and photophysical properties that makes it a promising material for optoelectronic devices. Molecular nanowires consisted from PTCDI derivatives can be placed in DNA like base by standard automated oligonucleotide synthesis. Here, we study the electronic and optical properties of a series of recently synthesized bioinspired perylene diimide molecular nanowires by first-principles density functional theory (DFT) spectroscopy and molecular dynamics (MD). We apply time-dependent DFT with Franck-Condon analysis to study our material. Initial structures are taken from MD and the final vibronic spectra is an average over many structures. By stacking the molecules along a DNA-like backbone and varying the number of stacked molecules from one to four, we determine the role of inter-molecular interactions on the excited-state energetics, as well as vibrational excitations within the molecules. We demonstrate that strong inter-molecular interactions lead to distinct vibrational, electronic, and optical properties for design of new electronic and optoelectronic nanowires.

Phase stability of MnSe, MnTe, and VO2 from total energies in the random phase approximation*  
STEPHAN LANY (Presenter), National Renewable Energy Laboratory — While the limitations (semi-)local density functionals for the electronic structure are widely acknowledged, total energies are usually considered to be rather accurate. However, in transition metal compounds, standard density or even hybrid functionals often predict the wrong ground state structure. Total energy calculations in the random phase approximation (RPA) greatly improve the phase stability prediction, e.g., rock-salt vs wurtzite in MnO, but quantitative predictions are still sensitive on input wavefunction for the RPA energy [1]. Here, we calculate the phase stability for MnSe and MnTe in the rocksalt, nickeline, and wurtzite structures, for the "negative-pressure" phase in MnSeTe alloys [2]. To account for the wavefunction dependence, we perform a variational minimization of the RPA energy with respect to the onsite potentials U and V [1]. In VO2, the failure of standard DFT to produce a band gap can be remedied by simple DFT+U calculation, at the expense of the incorrect prediction that the undistorted antiferromagnetic phase is lower in energy than the experimentally known nonmagnetic monoclinic phase. We further discuss results based on the SCAN functional.

3:54PM C20.00006: Can exact (local) Kohn-Sham potential reproduce band gaps?: Analysis using an analytically solvable two- and three-body models*  YU-ICHIRO MATSUSHITA (Presenter), Tokyo Institute of Technology, TAICHI KOSUGI, The University of Tokyo — We have clarified whether the exact (local) Kohn-Sham(KS) potential reproduces the exact band gap or not [1]. We have investigated the analytically solvable interacting two- and three-body models and calculated the exact electron levels through the one-particle Green's function of the two-body system analytically. Subsequently, we constructed the exact KS potential analytically and compared the obtained KS levels with exact ones. Then, we have found that KS-DFT even with the exact (local) KS potential does not reproduce the exact band gaps.

4:06PM C20.00007: Wannier Koopmans method for band gap calculations of extended systems*  LIN-WANG WANG (Presenter), Lawrence Berkeley National Laboratory, MOUYI WENG, FENG PAN, School of Advanced Materials, Peking University, Shenzhen Graduate School — We have developed a method to correct the density functional theory band gap problem, especially for extended systems. In this method, the Wannier functions are generated and the Hamiltonian is required to satisfy the Koopman theory (the total energy is linearly dependent on the occupation number) when a Wannier function is partially occupied. The resulting Hamiltonian gives a correction term for the Kohn-Sham eigen equation. This method can be considered as an extension of the delta DFT method to bulk systems. We have used this method to study common semiconductors, alkali halides, 2D materials, organic crystals, as well as oxides. We found in general, the accuracy of this Wannier Koopman method (WKM) is on a par with the GW results.

4:18PM C20.00008: WITHDRAWN ABSTRACT

4:30PM C20.00009: High-Harmonic Gereration with quantized fields: Minimal coupling of Pauli Spinors to quantized electromagnetic fields  MARY-LEENA MARTINE TCHENKOE DJOUOM (Presenter), DAVIS DAVE WELAKUH, MICHAEL RUGGENTHALER, HEIKO APPEL, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter — Interaction between classical light and matter lies at the heart of a broad range of applications, such as the generation of spatially and temporally coherent ultraviolet light using the technique of high harmonic generation(HHG)[1]. The semi-classical treatment of HHG is, however, not able to capture the quantum features of light. In the present work, we consider Pauli spinors minimally coupled to quantized electromagnetic fields and investigate HHG with quantized fields. In this talk we will present a numerical implementation of the Pauli-Fierz Hamiltonian and first results for one-dimensional model systems and highlight differences to the usual semi-classical treatment.

Polaritonic chemistry: The influence of mass renormalization

DAVIS DAVE WELAKUH (Presenter), MARY-LEENA MARTINE TCHENKOU DJOUM, MICHAEL RUGGENTHALER, HEIKO APPEL, ANGEL RUBIO, Theory, Max Planck Institute for the Structure and Dynamics of Matter (MPSD) — If molecules are placed inside a cavity or near a plasmonic surface strong light-matter interaction can occur that mixes matter and photon degrees of freedom [1]. This can modify properties of molecules [2] and can even alter chemical reactions due to the changed electromagnetic vacuum. The theoretical descriptions of such novel chemical situations is usually done with simplified few-level models and only recently more advanced ab-initio methods [4] have been developed and applied [5]. However, so far all these considerations have neglected the influence of the changed electromagnetic vacuum on the masses of the particles. That is, while the mass of electrons and nuclei are usually defined with respect to the bare electromagnetic vacuum, in the above cases the electromagnetic vacuum is changed considerably. Here we present first ab-initio studies of how multi-mode fields influence the total mass of the particles and thus change physical observables.

First principles approaches to strong light-matter coupling

JOHANNES FLICK (Presenter), PRINEHA NARANG, Harvard University — In recent years, research at the interface of chemistry, material science, and quantum optics has surged, now opens new possibilities to study strong light-matter interactions at different limits [1,2]. In this new regime, correlated electron, nuclear and photon interactions have to be treated on the same quantized footing [3] and towards this overarching goal, we have introduced a general time-dependent density-functional theory.

In this talk, we review recent developments and show how collective Rabi splitting under strong light-matter coupling emerges for CO2 molecules in optical cavities. Further, we use this novel framework to study how the potential-energy surfaces (PES) of a CO bond stretching in an ensemble of Formaldehyde molecules is modified under collective strong-light matter coupling, demonstrating the novel abilities to alter and open new chemical reaction pathways as well as to create new hybrid states of light and matter in this regime [4].

Time evolution methods for matrix-product states *

SEBASTIAN PAECKEL (Presenter), Georg-August-Universität Göttingen, Institut für Theoretische Physik, ANDREAS SWOBODA, München, Ludwig-Maximilians-Universität, THOMAS KOEHLER, SALVATORE MANMANA, Georg-August-Universität Göttingen, Institut für Theoretische Physik, ULRICH JOSEPH SCHOLLWOECK, München, Ludwig-Maximilians-Universität, CLAUDIUS HUBIG, Garching, Max-Planck-Institut für Quantenoptik — Matrix-product states (MPS) have become the de facto standard for the investigation of one-dimensional quantum many body systems, also out-of-equilibrium. Various approaches have been introduced for computing the time evolution of MPS, e.g., a time-dependent variational principle (TDVP) for MPS as well as matrix product operator (MPOs) representations of the time evolution operator. In this talk I review important developments and compare four commonly used methods applied to five representative examples, including systems with long-ranged interactions or in 2D.

These results give insights to the state-of-the-art treatment of MPS out-of-equilibrium and a guideline for which method to choose for a problem at hand.

Calculating Quantum Corrections to Electronic Transport in Disordered Nanostructures

CHENYI ZHOU (Presenter), HONG GUO, Physics, McGill University — Electronic transport in nanostructures shows strong dependencies on disorder and related quantum effects. The leading-order quantum corrections to the diffusive transport were identified as the weak-localization (WL) and the Altshuler-Aronov (AA) effects. An important issue is to develop a numerical method for computing these quantum corrections starting from the atomistic arrangement. To this end, a diagrammatic scheme based on nonequilibrium Green functions is put forward. We employ a nonlocal expansion technique to generate Cooperon diagrams in order to capture WL. We implement this approach using a tight-binding Anderson model to simulate finite wires containing disorder. In WL regime, our computed conductance agrees well with the exact numerical solution, and the WL corrected resistance shows a nonlinear scaling versus the channel length. The WL induced negative magnetoresistance is also investigated. For AA correction, we extend the numerical GW method by dressing interaction vertices with diffusons, and we apply it to a finite Anderson-Hubbard model. Density of states anomalies are found at energies corresponding to bias voltages, and their size dependence is analyzed. The AA effect in nonlinear transport will also be reported.

*We acknowledge support by NSERC Canada (H.G.).

Session C21 DCOMP DBIO DMP GSOFT: Exploring Free Energy Landscapes in Biology and Materials Science II

Direct and universal bounded entropy evaluation in complex simulations

RAM AVINERY (Presenter), ROY BECK, Tel Aviv University — Complex physical simulations are ubiquitously employed to characterize thermodynamics in diverse systems; free-energy, or related quantities, are often their goal. While enthalpy is calculable using the apriori choice of interactions (i.e., force-field, coupling parameters), entropy remains a challenge to quantify directly. Typically, methods for free-energy estimation are based on thermodynamic relations (e.g., Jarzynski's equality) rather than the independent statistics of the target ensembles.

We have previously demonstrated a universal entropy calculation scheme using loss-less compression algorithms which delivers a tight upper-bound estimate [1]. In this talk, I will describe another novel information-based approach for estimation of entropy. This new approach establishes tight lower and upper entropy bounds for complex simulations. Our novel method, based on counting statistics, is inherently universal and provides a direct estimate for entropy along with margins of error. Given this method's universality and statistical guarantees, we expect it to be highly useful for both simulated and experimentally recorded systems.

Predicting shear transformation events in glasses via energy landscape sampling

BIN XU (Presenter), Beijing Computational Science Research Center, MICHAEL FALK, Johns Hopkins University, JINFU LI, LINGTI KONG, Shanghai Jiaotong University — Shear transformation (ST) events, as the elementary process for plastic deformation of glasses, are of vital importance to understand the mechanical behavior of glasses. Here, by characterizing first-order saddle points in the potential energy landscape, we develop a framework to characterize and to predict the triggering (i.e. locations, triggering strains, and local structural transformations under different shear protocols) of ST events. Verification undertaken with a model Cu-Zr glass reveals that the predictions agree well with athermal quasistatic shear simulations. The proposed framework is believed to provide an important tool for developing a quantitative understanding of the deformation processes that control mechanical behavior of metallic glasses.

2:54PM C21.00003: Utilizing finger prints to construct the disconnectivity graph. DEB DE (Presenter), BASTIAN SCHEFER, SANTANU SAHA, DANIELE TOMERINI, STEFAN A C GOEDECKER, University of Basel — Theoretical studies have identified the dodecahedron of Si20 H20 as the lowest energy structure among many competing configurations several years ago. However this ground state structure has never been observed experimentally. The characteristics of an energy landscape are ultimately the key to understand the existence of a particular configuration. We employ a fingerprint distance (FP)-based exploration of the Potential Energy Surface, to establish relationships between the minima and their connecting transition states (saddle points of the PES). We apply this in a comparative investigation of Si20H20 with two existing structures, namely the C60 and C20H20 fullerenes. The striking differences between the PES of these three systems are used to understand why the global minimum is experimentally observed only for C60 and C20H20. We show that the complex pathways between different metastable configurations and the ground state of the Si20H20 cluster explain the lack of observation of the global minima configuration in experiment.

3:06PM C21.00004: Three birds with one stone: reaction coordinate, thermodynamics and kinetics from all-atom molecular simulations* PRATYUSH TIWARY (Presenter), University of Maryland, College Park — Many molecular systems involve processes with intertwined spatio-temporal resolutions ranging from femtoseconds to days, making it hard to probe them completely using traditional experimental tools. It has been a holy grail to simulate these in all-atom resolution using molecular dynamics methods, but these can go up to only a few hundred microseconds even with the most powerful and custom-built supercomputers. Thankfully, over the decades several sampling algorithms have been proposed that can simulate these complex systems in an accelerated but controllable manner. However, a large class of these methods (arguably all!) need an a priori sense of a low-dimensional reaction coordinate (RC) even before performing the sampling. This has severely limited the usefulness of such sampling methods. In order to deal with this cyclic problem where one needs extensive sampling of the rare events to know the RC, but also needs to know the RC in the first place to perform sampling, it is thus extremely desirable to construct methods that learn the RC as they perform the sampling. Here we will describe two such methods, namely SGOOP [1,2] and RAVE [2] developed by us that use flavors of statistical mechanics and deep learning to solve this problem. We will demonstrate the generality and power of these methods by showing how they give direct predictive insight into biologically important problems such as mechanisms of ligand-protein (including T4L99A lysozyme and tyrosine kinases), and transcription factor-DNA (including Epstein Barr virus binding domain) interactions. Our findings includes an all-atom characterization of metastable and transition states, their stabilities, various rate constants, as well as prediction of deleterious point mutations in the system which could upend the functioning of the protein, DNA or the ligand.

3:42PM C21.00005: Nucleation Kinetics using Generalized Ensemble Simulations* MURALIKRISHNA RAJU, DEEPTI BALLAL, Ames Laboratory, Iowa State University, Ames, XUEYU SONG (Presenter), Department of Chemistry and Ames Laboratory, Iowa State University, Ames, IA50011 — The recently developed generalized replica exchange method (gREM) is employed to sample various coexistence phases efficiently, especially the crystal cluster coexisting with its liquid phase. Namely, the gREM method facilitates comprehensive sampling of phase-transition regions by transforming metastable or unstable energy states in the canonical ensemble to stable ones in the generalized ensemble. Using weighted histogram analysis method (WHAM) analysis, the Gibbs energy as a function of temperature curves can be constructed for the liquid, crystal and various coexisting states. Thus, the nucleation barrier can be extracted without using the classification scheme of liquid and crystal particles. Using the classical nucleation theory, applications to the nucleation kinetics of mW water model and NaCl melt demonstrate that the nucleation rate obtained from our simulation method agrees well with the direct measured nucleation rate from simulations with the same model.

*This work was supported by the U.S. Department of Energy, Office of Basic Energy Science, Division of Materials Sciences and Engineering. The research was performed at the Ames Laboratory. Ames Laboratory is operated for the U.S. Department of Energy by Iowa State University under Contract No. DE-AC02-07CH11358.
3:54PM C21.00006: Understanding inverted solubility through specialized patchy particle models*  
IREM ALTAN (Presenter), Duke University, AMIR KHAN, Trinity College Dublin, SUSAN JAMES, MICHELLE QUINN, Maynooth University, PATRICK CHARBONNEAU, Duke University, JENNIFER MCMANUS, Maynooth University — The high specificity and anisotropy of protein-protein interactions give rise to remarkably rich phase and assembly behaviors. A thorough understanding of these interactions is notably key to forming crystals for protein structure determination. Despite the inherent complexity of these biomolecular systems, coarse-grained patchy models can be used to elucidate the physico-chemical processes that govern protein self-assembly. Here, we consider crystal formation in certain mutants of human γD-crystallin, which remarkably form assemblies that become less soluble as temperature increases. We find that using a minimal patchy model with temperature-deactivated patches recapitulates this inverted solubility trend and provides microscopic insights into the origin of this unusual behavior. This finding provides physical constraints for the observation of retrograde solubility in soft matter more generally.

4:06PM C21.00007: Spikes to Hills: A Continuation of Sticky Hard Sphere Clusters to Long Range Clusters*  
ANTHONY TRUBIANO (Presenter), MIRANDA HOLMES-CERFON, Math, Courant Institute of Mathematical Sciences — Energy landscapes for particles with short range interactions are notoriously difficult to explore computationally. To study the sensitivity of these landscapes to parameters of the interaction potential, we start with the most rugged landscape, the set of sticky hard sphere clusters, and use a continuation procedure to evolve the clusters as the range of the potential increases. This procedure captures most local minima of the smoother landscapes, with those missing being mostly high energy clusters. As the potential smoothens, we characterize the merging of clusters by a graph with tree structure. We find these graphs to be insensitive to the interaction strength at short range, but the graphs corresponding to a Lennard-Jones potential vary more than those for a Morse potential at longer range.

*Anthony Trubiano was supported in part by the Research Training Group in Modeling and Simulation funded by the National Science Foundation via grant RTG/DMS – 1646339.

4:18PM C21.00008: Surveying the Free Energy Landscape of Attractive Colloidal Spheres  
SHANGHUI HUANG (Presenter), Chemistry and Biochemistry, University of Notre Dame, JONATHAN WHITMER, Chemical and Biomolecular Engineering, University of Notre Dame — Controlling the assembly of colloidal particles into specific structures has been a long-term goal in the soft materials community. Much can be learned from the process from the self-assembly by examining the early stage assembly into clusters. For the simple case of hard-spheres with short-range attractions, the small-N rigid structures have been enumerated theoretically and tested experimentally. Less is known, however, about how the free energy landscapes are altered when the interparticle potential is long-ranged. In this work, we demonstrate how adaptive biasing in molecular simulations may be used to pinpoint shifts in the stability of colloidal clusters as the interparticle potential is varied. We also discuss the generality of our techniques and strategies for applications to related molecule systems.

4:30PM C21.00009: Resolving the Interfaces in C₆₀-SubPC Organic Solar Cells Using Molecular Dynamics Simulations*  
JACOB TINNIN (Presenter), Department of Physics, University of Houston, PENGZHI ZHANG, Center for Advanced Computing and Data Science, University of Houston, EITAN GEVA, Department of Chemistry, University of Michigan, BARRY DUNIETZ, Department of Chemistry and Biochemistry, Kent State University, MARGARET CHEUNG, Department of Physics, University of Houston — Organic photovoltaic cells (OPVs) are still associated with relative low efficiencies despite recent advances. As the performance depends on the molecular dynamics (MD) and structure, it is crucial to understand this relationship at a quantitative level. To do this we analyzed the well-studied dyad of boron subphthalocyanine chloride (SubPC) and C₆₀ using MD simulations to understand the effects of device fabrication scheme on the materials interfaces. We developed order parameters to resolve the interface at the molecular level. Using importance sampling, we find an additional interfacial geometry over the two primary configurations addressed in the previous studies. In addition, we show that, due to an energy barrier between basins, the population of structures depends on the initial set-up which is used to differentiate between the fabrication schemes. We expect that the insight we provide will enhance efforts to design effective OPVs.

*This project utilized the computational resources from NERSC, a U.S. DOE Office of Science User Facility operated under Contract No. DE-AC02-05CH11231, as well as the uHPC cluster managed by the University of Houston and acquired through NSF Award 1531814. We are also grateful to the DOE (DE-SC0016501) and the NSF (PHY-1427654) for their support.
4:42PM C21.00010: Bivariate Transition Matrix Monte Carlo Method for Joint Density of States Calculations* YONG HWAN LEE (Presenter), DAVID YEVICK, University of Waterloo — While most thermodynamic variables of a statistical system can be evaluated at all temperatures from the density of states, if a phase transition is present, quantities such as Landau free energy and the probability distribution of the order parameter must instead be determined from the joint density of states which is a function of both the energy and a second variable, typically the order parameter. This talk demonstrates that by combining the transition matrix Monte Carlo method with the bivariate multicanonical sampling the joint density of states can be efficiently and accurately computed. The procedure is then applied to the Ising and Potts models as well as to Ising spin glasses. The Landau free energies, the probability distribution of the order parameter and the Binder cumulants are calculated. Finally, we discuss the implications of our results with regard to the existence of a nonzero temperature phase transition in the two-dimensional Ising spin glass.

4:54PM C21.00011: Policy-guided Monte Carlo: Reinforcement-learning Markov chain dynamics TROELS BOJESEN (Presenter), University of Tokyo — We introduce Policy-guided Monte Carlo (PGMC), a computational framework using reinforcement learning to improve Markov chain Monte Carlo (MCMC) sampling. The methodology is generally applicable, unbiased and opens up a new path to automated discovery of efficient MCMC samplers. After developing a general theory, we demonstrate some of PGMC’s prospects on an Ising model on the kagome lattice, including when the model is in its computationally challenging kagome spin ice regime. Here, we show that PGMC is able to automatically machine learn efficient MCMC updates without a priori knowledge of the physics at hand.

5:06PM C21.00012: Integrating cluster algorithms and transition matrix methods* DAVID YEVICK (Presenter), YONG HWAN LEE, University of Waterloo — The transition matrix procedure accumulates in a single matrix all accepted and rejected transitions generated during biased sampling of statistical systems, increasing the accuracy of calculations of the density of states relative to standard methods that ignore rejected transitions. However, the efficiency of the transition matrix algorithm is limited by the requirement that the system realizations adequately sample the entire physically accessible configuration space. In the Ising model, the slow diffusion of the single spin-flip procedure through this space severely limits the computation speed, especially for large systems.

This talk introduces a more efficient sampling procedure that combines the Wolff and Metropolis algorithms. [1] In particular, the Metropolis acceptance rule is employed at temperatures that slowly increase (or decrease) as the calculation proceeds. Near the critical temperature, however, one or more Wolff cluster flips are periodically performed before reverting to the single spin-flips that are required to populate the transition matrix. Potential methods for extending this strategy to more complicated systems are then proposed.

*NSERC is acknowledged for financial support

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C22 DCOMP DBIO DPOLY DCMP: Building the Bridge to Exascale: Applications and Opportunities for Materials, Chemistry, and Biology III BCEC 157C - Jack Deslippe, Lawrence Berkeley Natl Lab - Tag(s): Focus
OpenAtom: massively-parallel simulations for molecular and electronic dynamics

MINJUNG KIM (Presenter), SUBHASISH MANDAL, Yale Univ, ERIC MIKIDA, KAVITHA CHANDRASEKAR, QI LI, ERIC BOHM, NIKHIL JAIN, LAXMIKANT KALE, University of Illinois at Urbana-Champaign, GLENN MARTYNA, Pimpernel Science, Software and Information Technology, SOHRAB ISMAIL-BEI GI, Yale Univ — OpenAtom (OA) is an open-source, massively parallel software application that performs ab initio molecular dynamics simulations (AIMD) and ground and excited states calculations utilizing a plane-wave basis set. OA shows excellent scaling performance on thousands of compute nodes by employing overdecomposition and asynchrony strategies that the Charm++ parallel framework upon which OA is built provides.

Here, we describe recent advances in OA capabilities: 1) Path-integral Car-Parinello MD simulations implementation and performance results of a hydrogen adsorption in a metal-organic framework (MOF) and 2) release of a GW method implementation for quasiparticle properties and the scaling results up to 32K cores on Mira and Blue Waters. We will also discuss our collaborative efforts and ongoing development in OA concerning the projector augmented wave method, reduced order $O(N^3)$ GW calculations, porting to next generation machines with multiple GPGPUs per node, and extreme scale platform concerns for post-petascale and exascale environments.

*This work is supported by National Science Foundation through grants NSF ACI-1339804 and ACI-1339715.

Automated Discovery of Chemical Mechanisms using Reactive Molecular Dynamics

JAMES KOVAL, AHMED ISMAIL (Presenter), Chemical and Biomedical Engineering, West Virginia University — Reactive molecular dynamics simulations allow for changes in chemical computation through the dynamic calculation of bond orders between atoms. This can allow for the determination of large-scale reaction mechanisms if sufficiently large numbers of reaction events can be captured. Determination of "critical pathways" and elimination of closed "unstable loops" that return to the original reactants therefore requires the study of large systems of potentially tens of thousands of atoms for tens of nanoseconds—creating a large "data science" problem analyzing gigabytes or even terabytes of data. We demonstrate a recently developed algorithm that can construct such reaction mechanisms and pathways as well as provide inputs for quantum mechanical calculations to determine reaction rates. As examples, we apply this approach to the combustion mechanism of non-petroleum-based alternative fuel candidates.

Molecular Dynamics Simulations of an Entire HIV Virion

JUAN PERILLA (Presenter), Chemistry & biochemistry, University of Delaware, TYLER REDDY, Los Alamos National Laboratory — The HIV viral particle contains all the necessary components to infect a human cell. The so-called virion is made of glycoproteins, lipids, the Gag polyprotein, viral RNA and other essential proteins. After budding, several biological process occur inside the virion, including a major re-arrangement of the virion's cargo commonly referred as maturation. Here, we present the steps performed towards the construction of an atomistic model of a mature and immature virion. Our model includes all major components, including glycosylated proteins, twenty-four lipid types and capsid protein. Our effort constitutes one of the major efforts to construct a realistic HIV virion at atomic resolution. In addition, we discuss the techniques developed to prepare the system and the steps required to simulate and analyze our atomistic HIV virion model, which contains over 800 million atoms.

Co-design in molecular dynamics for exascale

SAM REEVE (Presenter), JAMES BELAK, Lawrence Livermore Natl Lab — The continuing push towards exascale computing capabilities and accompanying shift toward heterogeneous hardware has highlighted the need for rethinking of even well-established computational methods. We focus here on molecular dynamics, assessing common algorithmic choices (e.g. ordering of computation and data layout in memory) and discussing new choices for novel machines. This talk will primarily explore how changes in data structure, particularly use of hybrid array-of-structs-of-arrays (AoSoA), i) both enable and require changes to compute kernels and ii) map well to multiple hardware architectures (e.g. both CPU and GPU). This exploration is enabled through the Co-design center for Particle Applications (CoPA) Cabana library for particle-based simulation methods.

*Work performed under the auspices of the U.S. DOE by LLNL under contracts DE-AC52-07NA27344 and supported by the Exascale Computing Project (17-SC-20-5C), a collaborative effort of the U.S. DOE Office of Science and the NNSA.
3:18PM C22.00005: Extending the accuracy, size, and duration of atomistic simulations on exascale hardware*
DANNY PEREZ (Presenter), ARTHUR F. VOTER, ANDERS NIKLASSON, CHRISTIAN NEGRE, MARC CAWKWELL, BLAS PEDRO UBERUAGA, Los Alamos National Laboratory, STEVEN JAMES PLIMPTON, AIDAN THOMPSON, MITCHELL A WOOD, MARY ALICE CUSENTINO, Sandia National Laboratories, BRIAN WIRTH, LI YANG, University of Tennessee, Knoxville — Because of its unparalleled predictive power, molecular dynamics (MD) has established itself as a workhorse of computational materials science. However, the limited strong-scalability of conventional MD combined with the exponential increase in parallelism currently leaves wide swaths of the theoretically-accessible simulation space inaccessible in practice, by only allowing for the simulation of larger systems but not of longer times. Fulfilling the promises of the exascale era will therefore require exposing new levels of parallelism in order to make the whole Accuracy/Size/Time simulation space accessible. The EXAALT project aims at addressing this challenge for systems that evolve through sequences of rare, thermally activated, events. By combining conventional domain decomposition with replication, speculation, and localization approaches, we show that novel computational techniques deployed at the exascale have the potential to dramatically extend the simulation space that will be accessible to MD over the next decade.

*This research was supported by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of two U.S. Department of Energy organizations, the Office of Science and the National Nuclear Security Administration.

3:30PM C22.00006: Large-Scale Simulations of Protein Self-Assembly*
JENS GLASER (Presenter), SHARON GLOTZER, University of Michigan — Despite steady advances in computing methodology and in the accuracy of all-atom force fields, large scale simulations of biological self-assembly processes still defy the current capabilities of computer simulation. However, with simplified models it is sometimes possible to extract the important physics on the relevant time and length scales. Here we present results of our efforts to simulate the nucleation of protein crystals on the Titan supercomputer, employing large-scale simulations of rigid protein models to form the experimentally observed crystal structure. It has been hypothesized that biological crystallization occurs non-classically via an intermediate of a liquid droplet, to overcome the large barriers to nucleation via critical fluctuations. Using a model with an artificially tunable specificity, we test this hypothesis. We outline how more powerful simulations of biological self-assembly can be achieved on upcoming pre-exascale architectures using HOOMD-blue with support for NVLINK node-local communication.

3:42PM C22.00007: First-principles simulations of electronic excitations and real-time dynamics on high-performance super computers*
[Invited] ANDRE SCHLEIFE (Presenter), University of Illinois at Urbana-Champaign — Excited electronic states and their ultrafast dynamics are foundational to how we interact with or probe many materials. Thanks to advanced experimentation, electronic excitations are accessible with high accuracy and time resolution, however, solid theoretical understanding is crucial for a detailed interpretation of experimental results. To this end, first-principles electronic-structure methods, such as many-body perturbation theory and time-dependent density functional theory, are powerful tools that provide highly accurate insight.

In this talk, I will discuss recent examples where we used real-time time-dependent density functional theory and Ehrenfest dynamics to study non-equilibrium electron dynamics coupled to classical ions. We performed simulations for highly energetic projectile ions impacting semiconductors and metals, that, however, suffer from high computational cost owing to small time steps during numerical integration. Massive parallelization and high-performance super computers such as Blue Waters and ALCF are needed, motivating our recent work on evaluating efficient and accurate numerical integrators within the Qb@ll code, e.g. using the PETSc library.

I will also discuss examples for using many-body perturbation theory to predict photon absorption and to establish the connection between structural and optical properties of semiconductors and their nanocrystals. In this context, the accurate computation of exciton binding energies is particularly demanding because it relies on eigenvalues of large dense matrices. I will illustrate how fast iterative eigensolvers help us tackle these problems on Blue Waters and broaden the applicability of many-body perturbation theory towards more diverse material systems.

*This work is supported by NSF (OAC-1740219, DMR-1555153) and used resources of the Argonne Leadership Computing Facility under Contract DE-AC02-06CH11357 and the Blue Waters sustained-petascale computing project (NSF OCI-0725070, ACI-1238993).
4:18PM C22.00008: Massively-parallel time-dependent density functional theory calculations for optical near-field excitations in silicon  
MASASHI NODA (Presenter), Center for Computational Sciences, University of Tsukuba, KENJI IIDA, Department of Theoretical and Computational Molecular Science, Institute for Molecular Science, MAIKU YAMAGUCHI, Graduate School of Engineering, The University of Tokyo, KAZUYA ISHIMURA, Department of Theoretical and Computational Molecular Science, Institute for Molecular Science, TAKASHI YATSUI, Graduate School of Engineering, The University of Tokyo, KATSUYUKI NOBUSADA, Department of Theoretical and Computational Molecular Science, Institute for Molecular Science, KAZUHIRO YABANA, Center for Computational Sciences, University of Tsukuba —

In current frontiers of optical science, electron dynamics in nano-materials has been explored in time domain using ultrashort light pulse. To describe such phenomena, we have been developing a program package SALMON (Scalable Ab-initio Light-Matter simulator for Optics and Nanoscience) that is based on first-principles time-dependent density functional theory. SALMON solves time-dependent Kohn-Sham equation in real time using three-dimensional grid representation. The code is efficiently parallelized with respect to spatial grids, orbitals, and k-points. We have applied the code to wave vector excitations in three silicon bilayers with a Si(111) surface terminated by hydrogen atoms by optical near fields (ONF). To describe electronic excitations accompanying wave vector changes that are promoted by the ONF, we calculated the system composed of 10,240 atoms. The calculation costs 13 hours using 4096 nodes on the K computer at RIKEN Center for Computational Science. We have found that the excitation by ONF is a few orders of magnitude larger than that by the far field. We also find the lowering of the absorption edge by the ONF excitation that is attributed to direct interband transitions with finite wave vector differences.

4:30PM C22.00009: Combined Next-Generation Neutron Vibrational Spectroscopy and High-Accuracy Massively Parallel DFT Calculations Benchmark Electronic Descriptions of Complex Organic Molecular Systems  
ANUP PANDEY (Presenter), ADA SEDOVA, LUKE DAEMEN, YONGQIANG CHENG, ANIBAL J. RAMIREZ-CUESTA, Oak Ridge National Laboratory —

Vibrations in crystals govern their fundamental properties. In organic molecular crystals, low frequency vibrations depend on intermolecular interactions which are difficult to describe accurately with density functional theory (DFT) and must be carefully benchmarked. Inelastic neutron scattering (INS), complemented by accurate theoretical studies, can provide vital information on vibrations and molecular forces. Next-generation INS instruments measure THz and far-IR regions with excellent resolution; the VISION spectrometer is unique in providing high signal allowing for high-quality low-frequency data. Impressive agreement with experimental spectra is obtained using DFT calculations, however, discrepancies still exist. Frequency errors lead to incorrect Helmholtz free-energy estimates used in predictions of the relative stability of crystals, and incorrect intensities indicate poorly described intermolecular forces. By exploiting the parallel nature of finite-displacement methods, we can calculate the spectra of complex pharmaceutical and bio-organic solids using very large basis sets and a number of DFT functionals and dispersion descriptions in a few hours using the Titan supercomputer. Such benchmarks can transform theoretical studies of organic materials.

4:42PM C22.00010: ExaAM: Additive manufacturing process modeling at the fidelity of the microstructure*  
JAMES BELAK (Presenter), Lawrence Livermore Nat Lab, JOHN TURNER, Oak Ridge National Laboratory —

In FY17, the USDOE Exascale Computing Project (ECP) initiated projects to design and develop simulation codes to use exascale computing, including the Exascale Additive Manufacturing Project (ExaAM), a partnership between LLNL, LANL, and ORNL. Exascale Computing will enable AM process modeling at the fidelity of the microstructure. Here we discuss what this means, in particular, tight coupling of Process-Structure-Property calculations. Macroscopic continuum codes are used to simulate the metal melt-refreeze, within which mesoscopic codes (PF and CA) are used to simulate the development of microstructure. This microstructure is then used by crystal plasticity codes to calculate local properties. Here we focus on in situ coupling so that the calculated microstructure is relevant to the complex thermo-mechanical conditions of AM processing. Examples will be given for the SLM process of metal additive manufacturing along with comparison to experimental observations.

*Work performed under the auspices of the U.S. DOE by LLNL, LANL and ORNL under contracts DE-AC52-07NA27344, DE-AC52-06NA25396, DE-AC05-00OR22725, and supported by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of the U.S. DOE Office of Science and the NNSA.
Cross-scale atomistic simulations of crystal plasticity*

VASILY BULATOV (Presenter), Lawrence Livermore Natl Lab — Predictions of crystal plasticity directly from the atomic motion have been regarded as unthinkable given the severe limits on time- and length-scale accessible to direct MD simulations. We will discuss our recent direct MD simulations of compressive straining of single crystals of Ta and Al. One of our simulations, Livermore BigBig (LBB) simulation, is by far the largest MD simulation ever performed: it generated a fully dynamic trajectory of over 2.1 billion atoms over 5 microseconds of simulated MD trajectory. LBB generated nearly 80 exabytes of recordable trajectory data only a tiny fraction of which was saved on disk in a highly compressed/post-processed form available for further analysis. As opposed to multiscale, LBB and other simulations of its magnitude can be regarded as cross-scale being sufficiently large to be statistically representative of collective action of dislocations resulting in macroscopic crystal flow and yet fully resolved to every atomic “jiggle and wiggle”. We will discuss new insights into physics of crystal plasticity brought about by our simulations and discuss challenges and strategies for on-the-fly learning on immense data generated in such simulations.

*Supported by NNSA ASC Program, LLNL Computing Grand Challenge Program and DOE INCITE Program.

Beyond Petascale: HPC and Polymeric Materials Design*

MONOJOY GOSWAMI (Presenter), Oak Ridge National Laboratory — Designing advanced polymeric materials for novel applications is challenging due to the experimental complexity associated with each and every polymer. Achieving success in polymeric materials design consequently relies on trial-and-error experimental techniques that often fail to achieve the predetermined goal. Computational modeling along different experimental techniques, therefore, has become the forefront of research in materials design. Recent developments in HPC, particularly from Petascale to Exascale supercomputing, are quickly shaping the precise design principles of polymeric materials. In this talk, I will highlight the importance of beyond-petascale computing in advanced manufacturing, polyelectrolyte complexation and phase change materials using molecular dynamics simulations that can help achieve future materials design goal.

*This material is based upon work supported by the U.S. DOE, Office of Basic Energy Sciences, Materials Science and Engineering Division. The research used resources of the Oak Ridge Leadership Computing Facility at the Oak Ridge National Laboratory, Contract # DE-AC05-00OR22725. A portion of this research was conducted at the Center for Nanophase Materials Sciences (CNMS), which is a DOE Office of Science User Facility.

Towards Exascale Quantum Transport Calculations

WENCHANG LU (Presenter), EMIL BRIGGS, JERRY BERNHOLC, North Carolina State University — Beyond Moore's law devices will approach nanometer dimensions and operate in the regime where quantum and atomic-scale effects become important. In this regime, classical concepts of device design cease to be predictive and need to be augmented by quantum simulations of key parts of devices and circuits. Based on the non-equilibrium Green's function (NEGF) methodology within the density functional theory, we have developed a NEGF module within the real-space multigrid (RMG) suite of codes (www.rmgdft.org) by which the quantum transport properties can be studied for nanoscale devices containing tens of thousands of atoms. Multilevel parallelization with MPI, threads and/or Cuda programming is implemented to enable adaptation to future exascale supercomputers. The module can be used to simulate and design new quantum devices at the atomic level. For a system with ten thousand atoms, the NEGF module's performance scales linearly from 100 to 1000 nodes on the Summit supercomputer at ORNL. With an efficient implementation of GPU acceleration using the new Cuda-managed memory capability, our benchmark calculations show a 3.5 to 4.5 speed-up over CPU-only calculations.
2:30PM C23.00001: Arctic cloud and sea ice feedbacks from satellite observations and a global climate model*  
[Invited] ARIEL MORRISON (Presenter), Atmospheric and Oceanic Sciences, University of Colorado Boulder — Over the next century, the Arctic Ocean is projected to become seasonally sea ice-free. Assessing feedbacks between clouds and sea ice as the Arctic loses sea ice cover is important because of clouds’ radiative impacts on the Arctic surface. Here, present and future Arctic cloud-sea ice relationships are assessed using spaceborne lidar observations and a fully-coupled global climate model that incorporates a lidar simulator. Using a novel surface mask that restricts the analysis to where sea ice concentration varies, we isolate the influence of sea ice cover on Arctic Ocean clouds during summer and fall. Summer cloud structure and fraction are nearly identical over sea ice and over open water, but more clouds are observed over open water than over sea ice in the fall. With future sea ice loss, modeled summer cloud fraction, vertical structure, and optical depth barely change, while the boundary layer deepens and clouds become more opaque over open water during fall. There is little evidence for a summer cloud-sea ice feedback but strong evidence for a positive cloud-sea ice feedback that emerges during non-summer months as the Arctic warms and sea ice disappears.

3:06PM C23.00002: Spatiotemporal Dynamics of Lake Patterns in a Changing Arctic Tundra Landscape*  
THAO N. NGUYEN (Presenter), Department of Physics and Environmental Science, St. Mary's University, IVAN A SUDAKOV, Department of Physics, University of Dayton — The evolution of Arctic tundra lakes exhibits percolating properties. More specifically, there exists a threshold where initially disjoint lakes gradually transition into a network of complex, interconnected structures on a macroscopic level when the value of some parameter exceeds a critical value. Behaviors of these lakes, primarily characterized by the lake area fraction and fractal dimension of the system, are significant to statistical physics due to their analogous nature to phase transitions. On account of similarities in geographical characteristics of the Arctic tundra landscape and that of slow immiscible fluid invasion processes in porous media, we developed our model based on a standard invasion percolation model under the influence of changing temperature. This model helps to explain the critical percolation threshold in the lake system in order to understand long-term lake dynamics and its contribution to climate change.  

*Funding for this research was provided in part by the University of Dayton College of Arts and Sciences and the Department of Physics.

3:18PM C23.00003: Homotopy Importance Sampler For Noisy Dynamics*  
JUAN RESTREPO (Presenter), ANDREW JENSEN, ROBERT MILLER, Oregon State University — We propose a Bayesian estimation method for moments of a state vector that obeys stochastic nonlinear dynamics and its observations. The method uses a homotopy procedure to improve the convergence of an MCMC importance sampler. Designed to sample non-Gaussian statistics, the method can also be used to sample very low uncertainty Gaussian statistics dynamics. In this talk I will describe the method and show comparisons that suggest that the method is efficient and comparatively accurate on a variety of practical and challenging problems.  

*This research is supported by NSF OCE1434198.

3:30PM C23.00004: Application of the Rayleigh-Debye-Gans (RDG) theory for determining optical properties of biomass burning aerosols.*  
EMMANUEL SARPONG (Presenter), DAMON SMITH, SOLOMON BILILIGN, North Carolina Agricultural and Technical State University — Biomass burning emissions are a major source of fractal aggregates which are clusters of spherules forming aerosols of non-spherical shape. Both the developed and developing world are subject to biomass burning events through agricultural burning, wildfires, and domestic burning applications. Accurate quantification of their optical properties is important both for their measurement and for predicting their radiative effect on climate. RDG assumes that each monomer in the aggregate interacts independently with radiation, by neglecting multiple scattering and shadowing. Absorption is an incoherent process and as a result the absorption of the aggregate is equal to the number of monomers, N, times the absorption of a single monomer. TEM images are used to determine the size parameters of the fractal aggregates. We report use of the RDG theory to fit experimentally measured optical properties to extract the refractive indices of biomass burning aerosols.

3:42PM C23.00005: A theory for global precipitation change  NADIR JEEVANJEE (Presenter), Princeton University, DAVID ROMPS, EPS, UC Berkeley — Global warming simulations robustly show that mean precipitation increases at 1-3% per Kelvin, but we do not know what sets these values. Mean precipitation is constrained by radiative cooling, however, and we demonstrate here that radiative cooling profiles exhibit a certain invariance under warming when plotted in temperature coordinates. This invariance can then be leveraged to derive simple analytical equations for precipitation change with warming. These equations are validated in cloud-resolving simulations of the tropics, and give intuition for why precipitation changes at a rate of 1-3% per Kelvin.

3:54PM C23.00006: Estimation of Hourly and Daily Clearness Indices and Diffuse Fraction, over Port Harcourt and Kano using National Centre for Environmental Prediction and National Centre for Atmospheric Research Satellite Data  OPEYEMI OMOLE (Presenter), Physics Department, College of Education Ikere Ekiti Nigeria, BABATUNDE ADEYEMI, Physics Department, Federal university of Technology Akure — Estimation of clearness index (KT) and diffuse fraction (KD) were calculated using satellite data obtained from National Centre for Environmental Prediction and National Centre for Atmospheric Research data base covering a period of 10 Years (2005 - 2014) for Port Harcourt and Kano stations which are Coaster and Sahel regions respectively. Direct solar data and diffuse solar data collected were added to give the Global solar radiation. The computed clearness index values were used to characterize the sky conditions into clear skies and overcast skies. Port-Harcourt with low clearness index indicated low global solar radiation while Kano with large clearness index indicated high global solar radiation. The implications of these results on the effective utilization of solar energy are discussed. The results also serve as very useful for solar energy collectors in designing and estimation of solar application systems

4:06PM C23.00007: Threshold dependence in the flip-flop model  DOUGLAS KURTZE (Presenter), Saint Joseph's University — The flip-flop salt oscillator model\(^1\) is a simplified dynamical model describing buoyancy-induced oscillations in the ocean. In this model, coupling to the atmosphere can increase the density of water at the surface to the point that it becomes denser than the water beneath, at which point vigorous vertical convection sets in and restores stable stratification. One parameter in this model quantifies the strength of the atmospheric forcing; the dependence of the amplitude and period of the oscillations in vertical mixing on this parameter has been well studied. However, in order for the model to produce oscillations at all, it must allow convective mixing to begin when the stratification is still slightly stable; a “threshold” parameter must be given to specify how close to unstable the stratification must be for convection to begin. The geophysical significance of this parameter is unclear, and typically it is set to some arbitrary small value. We show, however, that the amplitude and period of oscillations in the model depend strongly on this parameter, being proportional to its value and its square root, respectively. Thus numerical results from the flip-flop model need to be interpreted with care.

4:18PM C23.00008: Threshold phenomena in the marine carbon cycle*  DANIEL ROTHMAN (Presenter), Massachusetts Institute of Technology — The history of the marine carbon cycle is punctuated by transient disruptions. These events are typically attributed to anomalous inputs of carbon from external sources or changes in the rates at which carbon is buried in sediments. The magnitude of the events is commonly assumed to scale proportionately to the size of the disturbance. Here I show, via construction and analysis of a 2-dimensional dynamical system, how carbon-cycle disruptions can instead result from nonlinear amplification of relatively small perturbations that exceed a threshold. When the solitary fixed point is stable, small but finite perturbations of the steady state can result in a large-amplitude excitation that precedes the return to the fixed point. The excitation represents runaway ocean acidification. Similar events are observed in the paleoclimate record. In particular, the model’s disruptions exhibit a characteristic size and rate of growth consistent with observations. The threshold for initiating an excitation is also consistent with results inferred from previous disruptions. The modern oceanic uptake of carbon will likely exceed this threshold by the end of the present century.

**4:30PM C23.00009: Implications of Lorenz-Mie scattering by cloud droplets in an absorbing atmosphere for cloud feedbacks* WILLIAM COLLINS (Presenter), DANIEL R. FELDMAN, CHAINCY KUO, Lawrence Berkeley National Laboratory — There is still considerable uncertainty as to the magnitude of cloud feedbacks to anthropogenic climate change. The magnitude is determined by changes in the bulk cloud radiative effects (CREs) on both solar and terrestrial radiation in response to changes in the Earth's average surface temperature. The range of CRE responses of low-altitude liquid clouds is one of the dominant sources of uncertainty. To date, the CREs for these clouds have been computed using variants of classical far-field Mie theory applied to spherical particles (i.e., water droplets) embedded in a non-absorbing medium. At many wavelengths where water vapor is the predominant radiatively active gas, the assumption of a non-absorbing medium is manifestly violated, for example in the near-infrared near the primary and overtone absorption bands of H₂O. For this reason, it is important to redo the calculation of CREs using new, generalized Lorenz-Mie scattering in an absorbing atmosphere (Mishchenko et al, 2017 and 2018). We quantify differences in reflection, transmission, and absorption of sunlight and terrestrial radiation by liquid clouds and the impacts of these differences on low-cloud feedbacks to increasing surface temperatures.

**2:30PM C24.00001: Making Matter from Light: Photon Mott Insulators and Topological Fluids* [Invited] JONATHAN SIMON (Presenter), University of Chicago — Recent developments in quantum optics have enabled strong interactions between individual photons. I will describe work at the University of Chicago harnessing these tools to assemble quantum matter from light: in a collaboration between the Simon and Schuster labs, we have demonstrated dissipative stabilization of a Mott insulator of microwave photons, trapped in an array of transmon qubits; in the Simon lab we have demonstrated that a twisted optical resonator generates artificial magnetic fields for photons trapped within it; we have now employed Rydberg atoms to mediate interactions between these photons and are exploring topological fluids of light. From thermodynamics of driven equilibria to microscopy of entangled systems, photonic materials provide unique opportunities in few-to-many body physics.

**3:06PM C24.00002: Dynamically Tuning One Dimensional Systems Across Quantum Phase Transitions: Classical and Quantal Defects.* ANDREW MILLIS (Presenter), Columbia University, DANTE KENNES, Fachbereich Physik, Freie Universität Berlin — Infinite-system time dependent density matrix renormalization group and Loschmidt-amplitude methods are used to analyse the physics occurring when a one dimensional system is dynamically tuned across a quantum phase transition, either by an ac (`Floquet') drive with time vary amplitude or a simple ramp in Hamiltonian parameters. Tuning the XXZ model between two points in the gapped phase introduces classical defects leading to exponentially decaying correlations as expected; tuning between two points in the gapless phase produces excitations which do not destroy the long-distance power-law behavior, and tuning across the phase transition produces quantum phase slips which appear in pairs and then annihilate. Loschmidt methods are used to interrogate the wave function obtained after (one or multiple) ramps across the critical point of the transverse field quantum Ising model, leading to new understanding of the population of the defects created and of the importance of quantum coherence. Portions of this work were performed in collaboration with A. Ron. A. della Torre, D. Hsieh and C. Karrasch.

3:18PM C24.00003: Nonequilibrium Mass Transport in the 1D Fermi-Hubbard Model* JAN STOLPP (Presenter), Institute for Theoretical Physics, Universität Göttingen, SEBASTIAN SCHERG, THOMAS KOHLERT, Fakultät für Physik, Universität München, JACEK HERBRYCH, Department of Physics and Astronomy, University of Tennessee, PRANJAL BORDIA, Fakultät für Physik, Universität München, ULRICH SCHNEIDER, Cavendish Laboratory, University of Cambridge, FABIAN HEIDRICH-MEISNER, Institute for Theoretical Physics, Universität Göttingen, IMMANUEL FELIX BLOCH, MONIKA AIDELSBURGER, Fakultät für Physik, Universität München — We report on the results of a combined experimental and numerical study of nonequilibrium dynamics of ultracold fermions in a 1d lattice induced by quenching the trapping potential to zero [1]. This leads to an expansion of the cloud in a homogeneous lattice under the influence of interactions. For initial states with a significant admixture of doublons in a sea of singlons, we observe a dynamical demixing of fast expanding singlons from doublons that remain in the center of the system. We interpret this as evidence for fermionic quantum distillation [2]. For initial product states of one fermion per site and random spin orientations, we study the asymptotic expansion velocity. Compared to bosons [3], these velocities depend only very weakly on the interaction strength. We explain this observation by the fact that the Pauli principle significantly limits the amount of interaction energy that can be generated for fermions as compared to bosons.

3:30PM C24.00004: Universal Aspects of Operator Thermalization in Hamiltonian Dynamics* DANIEL PARKER (Presenter), XIANGYU CAO, EHUD ALTMAN, University of California, Berkeley — The long-time behavior of observables in thermalizing quantum systems can often be captured through hydrodynamics, involving just a few local quantities. A key question in quantum dynamics is to derive such behavior from the microscopic behavior and predict quantities such as diffusion coefficients or conductivities. We describe a conjectural form for super-operator Green's functions in thermalizing systems at infinite temperature in any dimension. The conjecture is supported by numerical calculations for a broad range of thermalizing many-body models and exact analytic results for large-q SYK models. The universal asymptotic form of the Green's function suggests an efficient numerical technique for extracting diffusion coefficients of operators in strongly interacting systems. Additionally, the conjecture implies some 'universal' behavior of operators under Hamiltonian dynamics.

3:42PM C24.00005: Observation of Dynamical Quantum Phase Transition in Antiferromagnetic Spinor Bose-Einstein Condensates in a short time region LIYUAN QIU (Presenter), HAOXIANG YANG, TIAN TIAN, HAIYU LIANG, ANJUN CHU, YANBIN YANG, Center for Quantum Information, IIIS, Tsinghua University, YINGMEI LIU, Oklahoma state university, LUMING DUAN, Center for Quantum Information, IIIS, Tsinghua University — In this work, we show direct evidence of the dynamical quantum phase transition (DQPT) in antiferromagnetic spin-1 Na Bose-Einstein condensate system. Initially, the spinor-1 BEC is at its ground state with quadratic Zeeman coefficient $q=11.2$Hz where all atoms are in $|F=1, m_F=0\rangle$ state, i.e. the fraction of spin-0 atoms $\rho_0$ is 1, then at $t=0$, the $q$ suddenly changed to a $q_f$ and the BEC will evolve variable times at this $q_f$. To observe DQPT, first minimum dip depth (Adip) of $\rho_0(t)$ is chosen to be a new order parameter. The experimental result shows that once the final quadratic Zeeman coefficient $q_f$ crossed the transition point, $\rho_0(t)$ will shows large fluctuation and $A_{\text{dip}}$ will arise abruptly. Further, the dip depths $A_{\text{dip}}$ under different quenched parameters $q_f$ shows similar behavior with the long time average $\rho_0(t)$ which indicates the dynamical quantum phase transitions across the critical point.
We demonstrate analytically and numerically that in isolated quantum systems of many interacting particles, the number of many-body states participating in the evolution after a quench increases exponentially in time, provided the eigenstates are delocalized in the energy shell. The rate of the exponential growth is defined by the width $\Gamma$ of the local density of states (LDOS) and is associated with the Kolmogorov-Sinai entropy for systems with a well defined classical limit. In a finite system, the exponential growth eventually saturates due to the finite volume of the energy shell. We estimate the time scale for the saturation and show that it is much larger than the characteristic decay time of the initial state $1/\Gamma$. Numerical data obtained for a two-body random interaction model of bosons and for a dynamical model of interacting spin-1/2 particles show excellent agreement with the analytical predictions.

*NSF Grant No. DMR-1603418.

Dark states are stationary states of a dissipative, Lindblad-type time evolution with zero von Neumann entropy, therefore representing examples of pure, steady quantum states. Non-equilibrium dynamics featuring a dark state recently gained a lot of attraction since their implementation in the context of driven-open quantum systems represents a viable possibility to engineer unique, pure states. In this work, we discuss a driven many-body spin system, which undergoes a transition from a dark steady state to a mixed steady state as a function of the driving strength. This transition connects a zero entropy (dark) state with a finite entropy (mixed) state and thus goes beyond the realm of equilibrium statistical mechanics and becomes of genuine nonequilibrium character. We discuss the relevant long wavelength fluctuations driving this type of transitions and bring it into context with other nonequilibrium phenomena, such as self-organized criticality and bistability.

The transport of spin, instead of charge, is the basis of the field of spintronics. Besides in condensed matter, spin transport has recently been explored in experiments with ultracold atoms which allow spin-selective control. A central phenomenon in the transport of spin current is spin drag, where a chemical potential bias on one spin component induces the transport of the other component via interactions. For attractive contact interactions, the ground state of fermions in one dimension is a singlet superfluid, and spin drag is due to pairing of fermions with opposite spin. This was recently observed in a quantum point contact setup [1]. Motivated by recent transport experiments with ultracold atoms [1, 2], we investigate analytically and numerically the possibility of spin drag of repulsively interacting fermions in a one-dimensional wire, where the ground state is a spin density wave.

References

The concept of quantum many-body scars -- atypical, nonergodic energy eigenstates of an otherwise ergodic many-body system -- was recently introduced to explain the surprising long-lived oscillations observed in an interacting, constrained spin chain following a quantum quench. Here, we provide numerical evidence that a suitable, quasi-local deformation of the system leads to a dramatic increase of the lifetime of the oscillations, even possibly allowing them to last for an indefinitely long time. We show that this seemingly perfect oscillatory dynamics can be understood via an emergent large SU(2)-spin undergoing precession, contained within a special subspace of the many-body Hilbert space, while the rest of the system remains ergodic. The presence of such dynamics severely constrains the structure of certain energy eigenstates in the thermodynamic limit. Furthermore, we introduce a toy model which captures the salient features of quantum many-body scarring.
4:42PM C24.00010: Cooperative Breakdown of the Oscillator Blockade in the Dicke Model  FLORENTIN REITER (Presenter), Department of Physics, Harvard University, THANH LONG NGUYEN, JONATHAN HOME, Institute for Quantum Electronics, ETH Zürich, SUSANNE F YELIN, Department of Physics, Harvard University — Spin-boson models provide an interaction between atoms and harmonic oscillators and lie at the heart of quantum science. The superradiant phase transition in the Dicke model [1] constitutes a prime example of a non-equilibrium phase transition which has recently been realized experimentally [2].

In addition to these steady-state phases, we observe a second dissipative phase transition to a nonstationary phase, which can be understood as a breakdown of the photon blockade which is known from the single-particle context [3]. We demonstrate that our many-body breakdown effect is of cooperative nature and study its dependence on the system size [4]. The model can be realized using standard experimental platforms; in particular we discuss a realization based on trapped ions.

4:54PM C24.00011: Computing Thermalizing Quantum Dynamics without Matrix Product States*  XIANGYU CAO (Presenter), EHUD ALTMAN, University of California, Berkeley — Quantum dynamics of many-body systems is hard to simulate because of the exponentially large Hilbert space. Getting around it and capturing the classical hydrodynamics emerging at large scales presents an actively sought after goal. Based on this idea, we present a new numerical method that represents the variational quantum state by a consistent set of reduced density matrices on overlapping small blocks (increasing block size improves precision, at higher computational cost). Assuming that all other connected correlations vanishes, we obtain a time-dependent variational principle scheme that can be used to approximate generic short-range Hamiltonian evolution/quantum circuits. Like existing methods based on matrix product state/operator, the new approach also respects all local conservation laws, but has the advantage that it can be readily generalized to higher dimensions.

5:06PM C24.00012: Hydrodynamic behavior of non-interacting quantum particles in presence of dephasing  OLES SHTANKO (Presenter), SETH LLOYD, Massachusetts Institute of Technology — In quantum transport problems, thermal environment plays an important role. We demonstrate that additionally to suppressing transport via dephasing, the environment is able to induce new dynamic effects absent in an isolated system. In particular, we show that single particle or gas of free particle in presence of stochastic environment exhibits a formation of vortices and Poiseuille flow, the effects mainly considered as hydrodynamic behavior. We provide a detailed analysis of the phenomenon and derive equations for quasi-viscous flow. The environmentally induced quantum viscosity suggests new possible transport regimes accessible in solid-state devices, isolated atomic systems, and photonic quantum simulators.

5:18PM C24.00013: Scalling theory of quantum ratchet in low temperature limit*  KEITA HAMAMOTO (Presenter), TAKAMORI PARK, HIROAKI ISHIZUKA, University of Tokyo, NAOTO NAGAOSA, RIKEN — Directionality of responses in noncentrosymmetric materials is a central issue in condensed matter physics. The quantum dynamics of particles in an asymmetric washboard potential with dissipation is a typical system. Previous study on the 2nd order mobility have shown the rich physics in this system, the sign reversal of the rectified current and quantum to classical crossover, for instance. However, the relations with the quantum phase transition taking place at certain strength of the dissipation above which the system goes to a localized state, is still a nontrivial issue. Here, we clarified the detailed low temperature behavior of the steady velocity and mobility of a particle under the ratchet potential both analytically and numerically. The exponent in the power law dependence for arbitrary order mobility is determined and summarized in simple scaling forms. The relations to the quantum phase transition is also discussed.

Simulations provide molecular insight into the mechanism of phase separation in these mixtures. The (1-butyl-3-methylimidazolium) cation, [BMMIM] (ternary 1-butyl-2,3-dimethylimidazolium) on the phase diagram. The method we have recently developed. We explore the influence of PEO molecular weight and the C2 methylation of [BMIM] behavior a mixture of poly(ethylene oxide) (PEO) and imidazolium-based ionic liquids using a new molecular simulation solution properties. There are fundamental questions regarding the LCST phase behavior: The critical point is at high importance for use in polymer solid state batteries and temperature sensors, where the ionic liquid allows a tuning of the solvent quality. SAXS and liquid-phase TEM demonstrate that between the B block and the IL were explored in four different ILs. Equilibration occurs after annealing, and the relaxation scattering, small-angle X-ray scattering, and liquid-phase transmission electron microscopy. The effects of solvent quality decrease in size. Exploration of the equilibration kinetics for BEO in ILs is being conducted using temperature-jump light scattering (SANS) to measure the radius of gyration of varying chain lengths of perdeuterated poly(ethylene oxide) in imidazolium-based ILs, which vary in both cation and anion identity. The dependence of coil size on molecular weight yields Flory exponents (χ) for 4 different IL-based solvent systems. For all the solvents studied, the exponents lie within 0.55 and 0.6, indicating moderately good to very good solvent behavior. However, greater expansion of d-PEO coils is observed in ILs comprising cations with longer alkyl chains and less basic anions. Interestingly, variation of the anion has a stronger effect on coil dimensions than the cation. Additional relevant parameters such as temperature and lithium salt addition on the coil dimensions of d-PEO chains in ILs are also explored.

Phase behavior of polymer/ionic liquids mixture: a molecular dynamics study* HYUNTA JUNG (Presenter), ARUN YETHIRAJ, University of Wisconsin - Madison — The phase behavior of polymers in ionic liquids is of practical importance for use in polymer solid state batteries and temperature sensors, where the ionic liquid allows a tuning of the solution properties. There are fundamental questions regarding the LCST phase behavior: The critical point is at high polymer concentrations, and the critical temperature is insensitive to molecular weight. In this work, we study the phase behavior a mixture of poly(ethylene oxide) (PEO) and imidazolium-based ionic liquids using a new molecular simulation method we have recently developed. We explore the influence of PEO molecular weight and the C2 methylation of [BMIM] (1-butyl-3-methylimidazolium) cation, [BMIM] (ternary 1-butyl-2,3-dimethylimidazolium) on the phase diagram. The simulations provide molecular insight into the mechanism of phase separation in these mixtures.

Kinetics of Block Copolymer Micelle Fragmentation in Ionic Liquids* JULIA EARLY (Presenter), TIMOTHY LODGE, University of Minnesota — Recently, more attention has been directed to quantifying the relaxation kinetics of block copolymer micelles. However, there are very few experimental studies quantifying the rates of fragmentation in block copolymer micelles. The micelle radius for poly(1,2-butadiene)-block-polyethylene oxide (BEO) in EO-selective ionic liquids (ILs) depends on the solution preparation method. When BEO is dissolved directly into an IL, the spherical aggregates are large and disperse in size. Upon high temperature annealing, these micelles equilibrate and decrease in size. Exploration of the equilibration kinetics for BEO in ILs is being conducted using temperature-jump light scattering, small-angle X-ray scattering, and liquid-phase transmission electron microscopy. The effects of solvent quality between the B block and the IL were explored in four different ILs. Equilibration occurs after annealing, and the relaxation times exhibit a significant dependence on concentration and solvent quality. SAXS and liquid-phase TEM demonstrate that the core radius decreases by 5 nm after annealing. These experiments demonstrate that relaxation mechanisms other than individual chain exchange dominates in these highly amphiphilic systems.

Effect of Solvent Selectivity on Chain Exchange Kinetics in Block Copolymer Micelles EN WANG (Presenter), DAN ZHAO, TIMOTHY LODGE, FRANK BATES, University of Minnesota — Block copolymer (BCP) micelles in selective solvents are useful for a variety of applications, such as nanolithography, drug delivery, and viscosity modification. The solvent quality is an important factor for both thermodynamics and dynamics of BCP micelles. Previous work revealed the effect of solvent selectivity on thermodynamic properties of BCP micelles formed by poly(styrene-b-ethylene-alt-propylene) (PS-PEP) diblock copolymers in mixed solvents of squalane and 1-phenyldecane. The systematic change of solvent composition tunes the interfacial tension between the core and corona-solvent matrix, embodied in the Flory-Huggins interaction parameter χ. This should also affect the kinetics of chain exchange between micelles. This presentation will describe the consequences of varying the solvent composition on the rate of chain exchange using time-resolved small-angle neutron scattering (TR-SANS). An independent method, static light scattering (SLS), was performed to estimate χ between the core block and the solvent as a function of solvent composition and temperature. Based on TR-SANS and SLS results, the dependence of the chain exchange rate on χ can be quantified.
3:18PM C25.00005: Probing Polymer Solution Conformation along Microparticle Formation Pathways with SANS*  
WILLIAM SHARRATT (Presenter), MARCO ADAMO, JOAO CABRAL, Imperial College London — Polymeric microparticles are ubiquitous in encapsulation and targeted release applications. Their function is predicated on their microstructure, shape and interactions, which determine stability, phase behaviour and release profiles. Polymer solution droplet extraction is an attractive route to control their formation, and understanding the thermodynamic and non-equilibrium pathways involved is crucial for their predictive design. Here, we show microfluidic droplet formation and selective solvent exchange to yield porous polymer microparticles [1] with tunable morphologies [2]. We systematically explore the process with model poly(vinyl alcohol), varying polymer functionality, size, concentration, and droplet size [3]. We map polymer solution conformation with small angle neutron scattering (SANS) and microfluidic-SANS to resolve how chain dimensions evolve with mixed solvent/non-solvents during solidification. Our study elucidates, for the first time, the spatio-temporal evolution of polymer solutions into particles, from molecular to micron scales.

*We thank the EPSRC for funding.

3:30PM C25.00006: Arrested Mobility Effects on the Spinodal Decomposition of Ternary Polymer Solutions*  
JAN ULRIC GARCIA (Presenter), University of California, Santa Barbara, DOUGLAS R. TREE, Brigham Young University, KRIS T DELANEY, GLENN FREDRICKSON, University of California, Santa Barbara — Many polymer membranes are made by immersion precipitation: a polymer solution film is immersed in a nonsolvent bath, inducing phase separation of the film into a polymer-rich phase that becomes the membrane matrix and a polymer-poor phase that becomes the membrane pores. Microstructure formation of these membranes is still not fully understood, given the interdependence of the processes involved: the mass transfer through the film-bath interface, the phase separation of the film, the coarsening of domains, and finally the glass transition that arrests the microstructure. In this work, we use phase-field models of the ternary system to solve the coupled convection-diffusion and momentum equations that describe membrane formation. We model the glass transition using mobility and viscosity contrasts between the polymer-rich and polymer-poor phases. We report how the glassy dynamics changes the microstructures formed by bulk spinodal decomposition. We also study how mass transfer between the bath and film changes with the formation of a glassy interface.

*We acknowledge support from the Center for Scientific Computing from the CNSI, MRL: an NSF MRSEC (DMR-1720256) and NSF CNS-1725797. We also thank Asahi Kasei Corp. for support. JUG acknowledges support from the NSERC PGS-D program.

3:42PM C25.00007: SANS study of the thermodynamics and demixing of highly interacting PaMSAN/dPMMA blends  
YUTAKA AOKI (Presenter), WILLIAM SHARRATT, HAOYU WANG, Chemical Engineering, Imperial College London, SARAH ROGERS, ROBERT DALGLIESH, ISIS-STFC, Rutherford Appleton Laboratory, JULIA HIGGINS, JOAO CABRAL, Chemical Engineering, Imperial College London — Spinodal decomposition of partially miscible polymer blends has the potential to generate well-defined polymeric nanostructured materials. While the Cahn-Hilliard (CH) theory prediction for the initial spinodal lengthscale generally holds, phase sizes attained by thermally-induced demixing are, however, stubbornly much greater that $R_g$. Using Small Angle Neutron Scattering (SANS), we investigate a series of LCST poly(a-methyl styrene-co-acrylonitrile) and deuterated poly(methyl methacrylate) (PaMSAN/dPMMA) blends which exhibit a remarkably steep temperature dependence of $G''$ (and thus $c$), the driving force for demixing [1,2]. We explore the role of PMMA molecular mass ($MW = 40$-$130$ kg/mol), tacticity, composition, and temperature and to map $G''$ and $c$ as a function of these parameters in the one-phase region, employing Random Phase Approximation theory. We then carry out a series of rapid jumps into the unstable and metastable regions, establishing a comprehensive map of lengthscales achieved and theoretically expected, and limits and opportunities for bicontinuous nanostructure design by this approach.

3:54PM C25.00008: Single molecule studies of comb polymer dynamics in semi-dilute solutions*  SHIVANI PATEL (Presenter), CHARLES SCHROEDER, Department of Chemical and Biomolecular Engineering, University of Illinois at Urbana-Champaign — We study the dynamics of single branched polymers in non-dilute solutions using single-molecule fluorescence microscopy (SMFM). In particular, we use a hybrid enzymatic-synthetic approach to synthesize DNA-based branched polymers (comb polymers) that contain a long backbone with multiple side branches grafted at various positions. Following synthesis, we directly study the transient stretching dynamics of single comb polymers in semi-dilute solutions in extensional flow. We compare the transient dynamics of single comb polymers in semi-dilute solutions of linear unlabeled polymers to the dynamics of comb polymers in ultra-dilute solutions. Interestingly, the transient stretching dynamics and relaxation behavior of comb polymers is markedly different in non-dilute polymer solutions, which reveals changes in molecular-scale dynamics due to chain branching and chain-chain intermolecular interactions. We further study the effects of background concentration and polymer topology on comb polymer dynamics in order to elucidate the non-equilibrium behavior of topologically complex polymers. Overall, our work shows that single polymer dynamics can be used to provide a direct link between polymer microstructure and bulk rheological properties.

*We thank NSF CCF 1807526 for funding.

4:06PM C25.00009: Thermodynamics and conformation of PPPO in mixed solvents: towards nanoporous polymeric gas sensors  ROISIN O’CONNELL (Presenter), JOAO CABRAL, JULIA HIGGINS, ALEXANDRA PORTER, Imperial College London — Poly(2,6-diphenyl-p-phenylene oxide) (PPPO) can be processed into high performance nanoporous materials, with applications ranging from gas separations to sensing. An attractive design route involves demixing from solution, generally via spinodal decomposition induced by non-solvent addition, and followed by phase inversion and kinetic arrest. In this work, we investigate the thermodynamics and phase separation of the ternary PPPO/solvent/non-solvent system, combining light and Small Angle Neutron Scattering, and electron microscopy.

We determine the polymer conformation and interaction parameters in binary and ternary solutions across the concentration range relevant for porous polymer formation. Combined with viscosimetry measurements, we establish overlap and concentrated crossovers, $c^*$ and $c^{**}$, and obtain radii of gyration $R_g$ and its dependence on concentration in mixed solvents, as well as the respective $\chi$ parameters. We then determine the demixing pathway for the polymer-rich phase, approaching the glass transition and resulting in its kinetic arrest. Based on these results, we establish a predictive and versatile design strategy for PPPO nanoporous gas adsorbers.

4:18PM C25.00010: Conformations of bottlebrush polymers in dilute solution  SARIT DUTTA (Presenter), MATHEW WADE, DYLAN WALSH, DAMIEN GUIRONNET, SIMON ROGERS, CHARLES SING, University of Illinois at Urbana-Champaign — Bottlebrush polymers are a class of highly branched polymers consisting of a central backbone chain with a large number of side chains emanating from it. As the overall structure and stiffness deviates considerably from that of a linear chain, it is important to understand the role of various architectural parameters that determine the conformations of a bottlebrush molecule. We present results that highlight the effects of backbone length, side chain length, and grafting density on the equilibrium static and near-equilibrium dynamic properties of bottlebrushes in dilute solution. Our results are based on a combination of viscometric measurements and computer simulations. The experiments were performed on a series of low polydispersity bottlebrushes comprising of poly(norbornene) backbone and poly(lactic acid) side chains. The simulations were performed on a coarse-grained bead-spring model using a combination of Brownian Dynamics and Monte Carlo. The simulation predictions show quantitative agreement with experimental results, enabling us to probe further structural details not easily amenable to experiments.
4:30PM C25.00011: Diffusion Driven Nonsolvent Induced Phase Separation  DOUGLAS R. TREE (Presenter), Brigham Young University, LUCAS FRANCISCO DOS SANTOS, Universidade Estadual de Maringa, CADEN B WILSON, TIMOTHY R SCOTT, Brigham Young University, JAN ULRIC GARCIA, GLENN FREDRICKSON, University of California, Santa Barbara — Nonsolvent induced phase separation (NIPS) occurs when a polymer solution is brought into contact with a miscible nonsolvent, leading to the precipitation of a polymer-rich phase. Because of its simplicity, NIPS processes are widely used to generate a variety of microstructures in polymer materials such as membranes and micro/nanoparticles. Despite its prevalence, predicting and controlling the microstructure generated by NIPS remains a difficult challenge, owing to the complex interactions between the diffusive transport, hydrodynamics and phase-separation kinetics in the process. In our approach, we use simulations of a "multi-fluid" phase-field model of a ternary polymer solution that incorporates all of these kinetic processes. In the case of NIPS driven by purely diffusive solvent/nonsolvent exchange, we find two regimes capable of generating microstructure via spinodal decomposition: one at times much shorter than the diffusion time of the nonsolvent and one at much longer times. We then use our model to predict (i) which compositions of polymer solution will lead to microstructure formation at both short and long times and (ii) what microstructures emerge as composition is varied.

4:42PM C25.00012: Effects of Side-Chain Deuteration of Poly(N-isopropylacrylamide) on the Thermal Transition Behaviors in Water*  DONGSOOK CHANG (Presenter), KUNLUN HONG, Oak Ridge National Laboratory — Polymers with lower critical solution temperature (LCST) in water are promising building blocks in designing temperature-responsive materials. The thermal transition of polymer and proteins in water is known to depend on deuteration (either of solvent or of polymer/protein), but a full understanding of this phenomenon remains elusive. In this study, we focus on the fact that although partially deuterated poly(N-isopropylacrylamide) (PNIPAm) has been widely used in many studies due to its facile synthesis, its thermal transition behavior has not been independently characterized. We investigate the effect of side-chain deuteration of PNIPAm on its electronic structure, hydrogen bonding, and hydration in water. The thermal transition of PNIPAm with its isopropyl side chain deuterated (d7-PNIPAm) is broader and approximately 2 °C higher than that of h-PNIPAm in dilute solution when measured by microcalorimetry. While the underlying mechanisms are complex, our results currently point to weaker hydrogen bonding of d7-PNIPAm due to a small destabilization of the negative dipole in the amide nitrogen, which results in a weaker cooperativity in hydration.

*This work was performed at the Center for Materials Sciences which is a US Department of Energy (DOE) Office of Science User Facility.

4:54PM C25.00013: Increasing block copolymer dispersity leads to more uniform micelles*  SRITEJA MANTHA (Presenter), SHUANHU QI, Institute of Physics, Johannes Gutenberg University of Mainz, Germany, MATTHIAS BARZ, Institute for Organic Chemistry, Johannes Gutenberg University of Mainz, Germany, FRIEDERIKE SCHMID, Institute of Physics, Johannes Gutenberg University of Mainz, Germany — Synthetic polymers possess some inherent dispersity in their length due to the mechanism of the underlying polymerization reaction. Since nearly every property of the polymers depend strongly on the length of the chain, it is expected that the polymer chain dispersity effects different structural, dynamic and their self-assembly properties in the solution as well as in the melt conditions. In this work we investigate the effect of amphiphilic diblock copolymer chain length dispersity on the size distribution of the spherical micelles formed by them in the solution. Using self-consistent field theory calculations, we show that the monodisperse diblock copolymers form micelles of different sizes in the solution, whereas polydisperse diblock copolymers form micelles which are uniform in size. We attribute this to the fact that the packing of the solvophobic monomers in the micellar core can be optimized if the constituent polymers have different length.

5:06PM C25.00014: Particle Packings in Bidisperse Diblock Copolymer Blends*  
AARON LINDSAY (Presenter), RONALD LEWIS, BONGJOON LEE, MICAH J. HOWARD, TIMOTHY LODGE, FRANK BATES, University of Minnesota - Twin Cities — Recent investigation into the phase behavior of compositionally asymmetric diblock copolymers has resulted in the discovery of a host of previously unanticipated particle packings, including a dodecagonal quasicrystal and several Frank-Kasper (FK) phases. Conformational asymmetry has been shown to favor these fascinating morphologies. However, the number of sufficiently conformationally asymmetric systems available for study is limited. An alternative approach, simply blending two diblocks, has been predicted by self-consistent field theory to allow access to these FK phases, potentially enabling study of these morphologies in a wider range of systems. In this work, we investigated the phase behavior of bidisperse blends of polystyrene-b-poly(1,4-butadiene); the nominally single component diblock copolymer melts show no evidence of FK phase formation. The core block length and relative volume fraction of each polymer was varied, keeping constant the length of the corona block. Small angle X-ray scattering and transmission electron microscopy revealed a rich phase behavior, providing a new means of accessing various particle-packings in diblock copolymer melts.

5:18PM C25.00015: Investigating the Properties and Phase Behavior of Ionic Liquid and Polymer Blends*  
CAITLIN DONOVAN (Presenter), OSCAR MORALES, MALGORZATA CHWATKO, AARON A BURKEY, ALYSHA HELENIC, SEUNGMIN OH, JOAN BRENNECKE, NATHANIEL A LYND, Chemical Engineering, The University of Texas at Austin — Atmospheric carbon dioxide (CO2) traps heat and increases global temperatures. Both ionic liquids (ILs) and polymers have been investigated for use in CO2 capture technologies. However, composite polymer/IL materials could enhance capture and maintain favorable physical properties for industrial usage. Previously, we identified 1-hexyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ([hmim][Tf2N]) as an IL with excellent physical CO2 solubility. We are interested in polyether and ionic liquid composite materials specifically because of the favorable interactions polyethers have with CO2. It is a necessary first step to investigate the phase behavior and properties of these blends.

We present results of the phase behavior of [hmim][Tf2N] blends with hydrophobic polyethers that have appreciable CO2 solubility. The polymers studied include poly(n-butyl glycidyl ether), poly(allyl glycidyl ether), and poly(isopropyl glycidyl ether). Phase behavior was probed using DSC, microscopy and turbidimetry. The effect of the pendant functional groups in the glycidyl ether polymers (isopropyl vs. n-butyl, and the presence of the double bond in the allyl version) was investigated using 2D NMR and FTIR spectroscopies.

Session C26 DQI: Superconducting Circuits: Josephson Amplifiers and Non-reciprocal Devices  
BCEC 160B - Jose Aumentado

2:30PM C26.00001: Broadband design of parametric non-reciprocal devices  
OFER NAAMAN (Presenter), Google Inc - Santa Barbara, JOSE AUMENTADO, NIST, Boulder CO., JOHN M MARTINIS, Google Inc - Santa Barbara — There has been significant recent progress in understanding parametric non-reciprocal devices such as circulators and directional amplifiers based on superconducting Josephson circuits. However, these devices remain of limited practical utility due to their narrow bandwidths - typically in the 10's of MHz. To be useful for multiplexed readout in intermediate scale quantum processors, we must engineer these devices to meet prescribed bandwidth and transmission characteristics. In this talk, we outline a procedure for designing parametric devices with bandwidths up to ~1 GHz. We give design examples for a broadband parametric circulator with better than 20 dB isolation over a 500 MHz band, and a non-reciprocal parametric amplifier with broadband reverse isolation and 20 dB forward gain. We illustrate the devices' predicted performance with simulation of their S-parameters.
Quantum discord in squeezed microwaves

KIRILL FEDOROV (Presenter), STEFAN POGORZALEK, MINXING XU, MICHAEL RENGER, MICHAEL FISCHER, EDWAR XIE, QI-MING CHEN, ACHIM MARX, FRANK DEPPE, RUDOLF GROSS, Walther-Meißner-Institut, Munich, Germany — Quantum discord is known as a general measure for quantum correlations in bipartite systems. It encompasses all nonclassical correlations including entanglement. Quantum discord has many intriguing fundamental properties many of which require experimental verification such as the asymptotic robustness towards environmental noise. We experimentally investigate quantum discord in propagating two-mode squeezed (TMS) microwave states generated with the help of superconducting Josephson parametric amplifiers. We exploit asymmetric noise injection into these TMS states which allows us to demonstrate the robustness of quantum discord as opposed to the sudden death of entanglement. Finally, we discuss the relevance of quantum discord as a resource in quantum communication and sensing, in particular with respect to remote state preparation and quantum radar protocols.

Proposal for a novel directional parametric amplifier requiring no external nonreciprocal components

ANDREW LINGENFELTER (Presenter), VOLODYMYR SIVAK, SHYAM SHANKAR, MICHEL H. DEVORET, Yale Univ — Quantum-limited Josephson parametric amplifiers are an important part of most superconducting qubit readout systems. Parametric amplifiers typically operate in reflection and require external nonreciprocal devices to spatially separate the input and output fields of the amplifier and to protect the qubit from noise propagating from the output field. To achieve this without additional external components, the parametric amplifier should have a matched input port, large forward gain from input to output, ideally zero reverse gain from output to input, a matched output port, and an auxiliary port which provides amplified quantum noise to the output. We propose a novel four-port phase-preserving parametric amplifier that satisfies all of the above requirements. This proposal is a natural extension of the previously realized three-port directional amplifier, but does not require an isolator on its output. We discuss the properties of this proposal, and we present a possible experimental implementation.

Theoretical study of nonreciprocal microwave transmission based on Gebhard-Ruckenstein hopping

SHUMPEI MASUDA (Presenter), Tokyo Medical and Dental University, SHINGO KONO, KEISHI SUZUKI, The University of Tokyo, YUUKI TOKUNAGA, NTT Secure Platform Laboratories, NTT Corporation, YASUNOBU NAKAMURA, The University of Tokyo, KAZUKI KOSHINO, Tokyo Medical and Dental University — Several types of quantum information processing schemes and many of superconducting quantum optics experiments require routing of microwaves in a cryostat. Thus, cryogenic circulator is an important tool, and the loss at the circulators is detrimental especially for quantum information processing. This has been urging many researchers to experimental and theoretical works devoted to lossless on-chip microwave circulators.

In this presentation, we theoretically investigate the nonreciprocal microwave transmission based on the Gebhard-Ruckenstein hopping. We consider a superconducting device that consists of microwave resonators and a coupler. The Gebhard-Ruckenstein hopping between the resonators gives rise to a linear energy dispersion, which manifests chiral propagation of microwaves in the device. This device can work as a microscopic circulator when transmission lines are attached. It is shown that our microwave circulator can be robust against detuning of incident microwaves.

We acknowledge the support from JST ERATO (JPMJER1601) and JSPS KAKENHI (16K05497 and 18K03486).

Exploiting the Kerr-free point of a SNAIL for improvement of dynamic range in parametric amplifiers

VOLODYMYR SIVAK (Presenter), ANDREW LINGENFELTER, NICHOLAS E. FRATTINI, VIDUL JOSHI, WEI DAI, SHYAM SHANKAR, MICHEL H. DEVORET, Yale Univ — Quantum-limited Josephson parametric amplifiers are an important component for most superconducting qubit readout methods. While being well optimized for the noise performance, the scalability of resonant parametric amplifiers is determined predominantly by the ability to boost their dynamic range and bandwidth. The dynamic range of the state-of-the-art "paramps" is limited by the spurious Kerr-induced Stark shifts which detune the paramp from its operating point, leading to the reduction of gain with increased signal power. We show that using a Superconducting Nonlinear Asymmetric Inductive eLement (SNAIL) as an active element, we are able to tune to a Kerr-free sweet spot in the presence of the pump, which exhibits significantly improved 1 dB compression power.

ARO, ONR, AFOSR, and YINQE
Towards a SQUID-based Traveling Wave Parametric Amplifier

LUCA PLANAT (Presenter), KARTHIK SRIKANTH BHARADWAJ, OLIVIER BUISSON, REMY DASSONVILLE, JOVIAN DELAFOREST, FARSHAD FOROUGHI, WIEBKE GUICHARD, SÉBASTIEN LÉGER, VLADIMIR MILCHAKOV, CECILE NAUD, JAVIER PUERTAS, NICOLAS ROCH, Univ. Grenoble Alpes, CNRS, Grenoble INP, Institut Néel, 38000 Grenoble, France — Superconducting Parametric Amplifiers are key to research fields involving microwave signals in the quantum regime, such as superconducting qubits or NEMs because of the large gain they provide and their noise performance. Large interaction time between a weak microwave signal, a strong coherent pump tone and a non-linear medium is required to obtain enough gain. Up to now, this was achieved by coupling the non-linear medium to a resonator. But this is also possible by using distributed non-linear media and working in transmission, thus overriding issues of limited bandwidth due to resonant cavities. When the medium is a Josephson junction, this new class of amplifier is called Josephson Traveling Wave Parametric Amplifier (J-TWPA) [1]. We will present our on-going effort to develop a SQUID-based TWPA. It will allow to tune in situ the characteristic impedance of the TWPA to have a perfect impedance match with the rest of the electronic setup, despite the uncertainty of the electrical properties of the device due to the fabrication process.

Design and Fabrication of Broadband Parametric Amplifiers for Quantum Applications

JOEL GREBEL (Presenter), AUDREY BIENFAIT, ETIENNE DUMUR, HUNG-SHEN CHANG, MING-HAN CHOU, CHRISTOPHER CONNER, Institute for Molecular Engineering, University of Chicago, GREGORY A PEAIRS, Department of Physics, University of California, Santa Barbara, RHYS G POVEY, Institute for Molecular Engineering, University of Chicago, KEVIN SATZINGER, Department of Physics, University of California, Santa Barbara, YOUPENG ZHONG, ANDREW N CLELAND, Institute for Molecular Engineering, University of Chicago — Josephson parametric amplifiers (JPAs) provide a straightforward means for the quantum-limited amplification of signals, with noise approaching 1/2-photon for phase-independent gain [1]. These are an important resource for the single-shot readout of superconducting qubits, allowing high fidelity measurements of single as well as multiplexed qubits. I will describe the circuit designs and fabrication process for JPAs developed at the University of Chicago, fabricated in a new nanofabrication facility. The process includes low-loss dielectric deposition, superconducting crossovers, and a Dolan-bridge based Josephson junction definition. We will present data on lumped-element JPA devices with state-of-the-art gain, saturation power, and bandwidth [2], and describe different circuit designs for achieving large bandwidths [3].

Development of all aluminum Josephson Travelling Wave Parametric Amplifiers (TWPA)

SHAHID NAWAZ (Presenter), University of California, Berkeley, KEVIN O’BRIEN, Research Laboratory of Electronics – MIT, IRFAN SIDDIQI, University of California, Berkeley — Josephson parametric amplifiers (JPA) have demonstrated high measurement fidelity in qubit readout applications, and near quantum-noise-limited operation in many fundamental physics experiments. While conventional single junction JPAs have limited bandwidth and low saturation power, traveling wave devices can operate with GHz of instantaneous signal bandwidth and the power handling capacity needed for multiplexed readout. We report on progress toward developing an all-aluminum traveling wave parametric amplifier (TWPA) utilizing aluminum oxide capacitor technology. Such devices would require significantly less dielectric material than current silicon dioxide capacitors, potentially reducing the insertion loss observed in state-of-the-art niobium amplifiers.

*This work was supported by the Army Research Office and the Department of Energy.

4:18PM C26.00010: A Fast Tunable, Large Bandwidth Superconducting Microwave Switch* HUNG-SHEN CHANG

(Presenter), University of Chicago, KEVIN SATZINGER, UC Santa Barbara; University of Chicago, YOUPENG ZHONG, AUDREY

BIENFAIT, MING-HAN CHOU, CHRISTOPHER CONNER, ETIENNE DUMUR, JOEL GREBEL, University of Chicago, GREGORY A

PAIRS, UC Santa Barbara; University of Chicago, RHYS G POVEY, ANDREW N CLELAND, University of Chicago — Fast controlled

switches are a key feature in classical communication architectures, and likely will play an analogous role in quantum

communication applications. Conventional semiconductor-based microwave switches have been used with

superconducting quantum circuits, enabling for example the in-situ measurement of multiple devices via a common

readout chain. However, these switches dissipate energy when switched, making them unsuitable for applications

requiring rapid, repeated switching. Josephson junction-based switches can be designed for dissipation-free operation

with fast switching, and can be more readily integrated with superconducting quantum circuits, providing a very appealing alternative to semiconductor switches. Here, we present the design and characterization of a lossless single pole double throw (SPDT) superconducting switch based on tunable DC SQUIDs. The switch features fast switching times, large

bandwidth, and a large on/off ratio. Applications for this device include coherent switch of itinerant photons for

applications in quantum information, including quantum computation.

4:30PM C26.00011: Low-loss ferrite waveguide circulator for non-reciprocal circuit QED* YINGYING WANG

(Presenter), THOMAS CONNOLLY, CHEN WANG, Dept. of Physics, Univ. of Mass. Amherst — In a quantum information

processing network, it is highly desirable to have low-loss directional transmission channels with circulators/isolators to

control the information flow while maintaining high fidelity. Moreover, such directional channels can be used to mediate

non-reciprocal interactions between qubits or cavities to stabilize entanglement or novel many-body states. Here, using

single crystalline yttrium iron garnet (YIG) in a waveguide-based package, we realize a microwave circulator with insertion

loss of ~1% and isolation of >20 dB in the quantum regime (at single-photon power and 20 mK temperature). The

circuit can be converted into a multi-mode cavity, which enables detailed study of hybridized magnon-photon spectra

and the internal loss of various modes. The circulator operates at a relatively low magnetic field of 25 mT (significantly

below saturation magnetization of YIG), allowing for direct coupling to transmons qubits and superconducting cavities

under proper magnetic shielding. We will describe our ongoing progress towards a 3D circuit QED platform with non-

reciprocal qubit-qubit interactions.

*This research is supported by the U.S. Army Research Office.

4:42PM C26.00012: Broadband superconducting switches for integrated quantum networks ERIC ROSENTHAL

(Presenter), JILA, University of Colorado, Boulder, CHRISTIAN M.F. SCHNEIDER, Institute for Experimental Physics, University of

Innsbruck, BENJAMIN J. CHAPMAN, Departments of Physics and Applied Physics, Yale, LEILA R. VALE, GENE C. HILTON, National

Institute of Standards and Technology, K. W. LEHNERT, JILA, National Institute of Standards and Technology and the University of

Colorado, Boulder — Switching elements are a generally useful tool in superconducting circuit experiments. They may be

used to reconfigure the connectivity of a network, multiplex qubit readout, and create non-reciprocal devices. In particular,
broadband switches allow for the construction of a broadband, on-chip microwave circulator. For integration with

superconducting qubits, however, these switches must be low-loss and dissipate negligible heat when switching.

Engineering such switches requires reactive circuit elements that tune rapidly between low and high impedance. To

achieve these effects, we develop widely tunable SQUID arrays and present measurements of their performance. We then
describe a new generation of broadband superconducting switches.
4:54PM C26.00013: Josephson Junction-Based Components for Scalable Quantum Computing* BRITTANY RICHMAN (Presenter), Joint Quantum Institute, University of Maryland, College Park, COSMIC RAJ, University of Tokyo, JACOB TAYLOR, NIST — The physical realization of larger quantum computing schemes will require highly scalable signal processing architectures for precise qubit control. Various microwave components are needed for signal routing and isolation, but the size and design of commercially available components are not always feasible for on-chip solutions. With this motivation, we examine how arrays of Josephson junctions in external magnetic fields provide the potential to replace larger devices using the ordering of flux degrees of freedom in the arrays. As a key example, we consider models of circulators, non-reciprocal devices that enable isolation of quantum circuits.

*This research was partially supported by the NSF-funded Physics Frontier Center at the Joint Quantum Institute.

5:06PM C26.00014: Efficient qubit measurements with a nonreciprocal microwave amplifier FLORENT LECOCQ (Presenter), National Institute of Standards and Technology Boulder, LEONARDO M RANZANI, Raytheon BBN Technologies, GABRIEL PETERSON, KATARINA CICAK, JOHN TEUFEL, JOSE AUMENTADO, National Institute of Standards and Technology Boulder — In typical circuit quantum electrodynamics and microwave optomechanics system, the measurement of the observable of interest — the state of a quantum bit or the position of a mechanical oscillator — hinges on the efficient detection of the phase shift that it imparts on a microwave field. Ideal measurement efficiency can only be achieved with a lossless single quadrature measurement apparatus and has been a longstanding challenge. Nonreciprocal parametric amplifiers could enable such high measurement efficiency as they can be directly integrated with the quantum system, avoiding common technical losses due to circulators, cables and connectors used in state-of-the-art amplification chains.

In this talk we will discuss the measurement of a 3D transmon qubit with a Field-Programmable Josephson Amplifier (FPJA, [1]). The FPJA is programmed in situ by a set of microwave drives to perform reciprocal or nonreciprocal frequency conversion or amplification. For each mode of operation, we will monitor the qubit coherence and lifetime, as well as measurement efficiency and backaction.

5:18PM C26.00015: Anomalous Supercurrents in exciton-condensate/normal-barrier/exciton-condensate (EC/N/EC) junctions JUNG-JUNG SU (Presenter), Electrophysics, National Chiao Tung University, YA-FEN HSU, Physics Division, National Center for Theoretical Sciences — The exciton-condensate/normal-barrier/exciton-condensate (EC/N/EC) junction in a bilayer consist of a normal barrier sandwiched between two exciton condensates (ECs), while the two ECs retain a relative phase of $\phi_0$. It is a setup inspired by the superconducting Josephson junction but with a special ingredient – the interlayer tunneling. In EC/N/EC junctions of short-barrier, fractional solitons with topological charge $Q = \phi_0/2\pi$ are predicted to occur. In this paper, however, we focus on the case that the barrier length $d_J$ is larger than the excitonic coherence length $\xi$. We find that the supercurrent occurs because of a distinctive mechanism – an Andreev reflection occurs in one of the EC/N interfaces along with the interlayer tunneling in the barrier. This exotic mechanism gives rise to only a half portion of a fractional soliton that carries a doubled topological charge $2Q = \phi_0/\pi$ (for the same relative phase $\phi_0$). The distinction in topology between the EC/N/EC junctions of short- and long-barrier is reflected in the supercurrents and their current phase relations, which can be observed directly by experiments.

Session C27 DQI: Quantum Thermodynamics and Resource Theories BCEC 160C - Bo Sun, HRL Laboratories - Tag(s): Focus
Quantum to ‘classical’ behaviour in closed-systems thermodynamics: an analysis of the quantum work distribution in driven fermionic chains

KRISSIA ZAWADZKI (Presenter), Department of Physics, Northeastern University, MARCELA HERRERA, ROBERTO MENEZES SERRA, Department of Physics, Federal University of ABC, IRENE D'AMICO, Department of Physics, University of York — The role of many-body interactions in work and entropy production at nanoscales has become a trend topic mainly boosted by increasing interest of probing the laws of thermodynamics for few particle systems. When we turn to the case of strongly correlated systems, one might be interested in probing phase transitions by means of thermodynamical quantities and their statistics, as, for instance, the moments of the so-called quantum work distribution P(W). We propose to examine this question in the context of out-of-equilibrium Hubbard chains by inspecting the extracted work \( W \) and the first four central moments \( \langle W - \langle W \rangle \rangle^k \), \((k=1,2,3,4)\) of P(W).

Our analysis inspects the interplay between coupling and dynamical regimes, i.e., we analyse the thermodynamical quantities from non-interacting to the strongly coupled limits when the driving external field is turned on adiabatically or as a sudden quench. Our results indicate a high sensibility of the third momentum (skewness) to the Mott insulator transition and we discuss how it could be used as an order parameter to probe quantum phase transitions in experimental nanoscopic strongly correlated systems.

Local superfluid distillation of Bose liquids

TYLER VOLKOFF (Presenter), YONGKYUNG KWON, Physics, Konkuk University — By introducing a localized resource theory of quantum coherence, we discuss limits to local distillation of complete superfluidity from imperfect superfluid states. To define the local maximal superfluid resource, we develop a theory of local superfluidity from first principles using local Galilei transformations, and demonstrate the framework in effective and microscopic models of Bose liquids. The combined theoretical framework of local superfluidity and localized resource theory of quantum coherence allows quantum information-based design and analyses of spatially structured superfluid quantum devices.

Work Extraction from a Single Energy Eigenstate

KAZUYA KANEKO (Presenter), EIKI IYODA, TAKAHIRO SAGAWA, Department of Applied Physics, The University of Tokyo — Work extraction from the Gibbs ensemble by a cyclic operation is impossible, as represented by the second law of thermodynamics. On the other hand, recent studies revealed that a thermal equilibrium state can be represented not only by the Gibbs state, but also by a single energy eigenstate. This is referred to as the eigenstate thermalization hypothesis (ETH). We attempt to unify these two perspectives by examining the possibility of extracting work from a single energy eigenstate. Specifically, we performed numerical exact diagonalization of a quench protocol of local Hamiltonians and evaluated the number of work-extractable energy eigenstates. We found that it becomes exactly zero in a finite system size, implying that a positive amount of work cannot be extracted from any energy eigenstate, if one or both of the pre- and the post-quench Hamiltonians are non-integrable. This result suggests that the second law of thermodynamics is true even at the level of individual energy eigenstates if the system is non-integrable (i.e., quantum chaotic), which is analogous to the ETH.

3:06PM C27.00004: DFT protocols for quantum thermodynamics of out-of-equilibrium systems* AMY SKELT, Department of Physics, University of York, KRISIA ZAWADZKI (Presenter), Departamento de Fisica e Ciencia Interdisciplinar, Instituto de Fisica de Sao Carlos, University of Sao Paulo, MARCELA HERRERA, Centro de Ciências Naturais e Humanas, Universidade Federal do ABC, IRENE D'AMICO, Department of Physics, University of York — Quantum thermodynamics strives to understand quantum fluctuations at the nanoscale, with an emphasis on the determination of thermodynamic properties of out-of-equilibrium quantum systems. This already challenging task becomes significantly more complex when many-body interactions give rise to strongly correlated systems. Inspired by the Kohn-Sham approach to Density Functional Theory (DFT), we propose to tackle this problem in a framework where the system is effectively described by non-interacting particles, and extend the protocol introduced in M. Herrera, R.M. Serra, I. D'Amico, Scientific Reports 7, 4655 (2017). Considering all dynamic regimes, from adiabatic to sudden quench, we study the work extraction and entropy production in finite Hubbard chains up to 8 sites, and compare results from various driving potentials. We examine the competition between the evolution time, interaction strength, and thermal regimes, benchmarking approximate results against the exact ones. Our results reveal that the DFT-inspired protocol performs well, with deviation of less than 10%, compared to the exact results up to moderate coupling regimes and, surprisingly for a ground state DFT protocol, up to intermediate temperatures of KT~2-3 J, J the hopping parameter.

*We thank EPSRC for support.

3:18PM C27.00005: Absolute irreversibility and continuous quantum measurement: a fluctuation theorem perspective* SREENATH KIZHAKKUMPURATH MANIKANDAN (Presenter), CYRIL ELOUARD, ANDREW N JORDAN, Department of Physics and Astronomy, University of Rochester — The out-of-equilibrium fluctuations of thermodynamic quantities like entropy production for a small system in contact with a thermal reservoir are constrained beyond the second law using relations known as fluctuation theorems. Here we show that, in the absence of a thermal reservoir, the dynamics of continuously measured quantum systems can also be described by a fluctuation theorem, where the fluctuations originate from inherently probabilistic quantum measurement dynamics. This theorem captures the emergence of an arrow of time in the measurement process, from microscopically reversible quantum state dynamics in continuous quantum measurements. We also demonstrate that the measurement-induced wave-function collapse exhibits absolute irreversibility, such that Jarzynski and Crooks-like equalities are violated. We apply our results to different continuous measurement schemes on a qubit: dispersive measurement, homodyne and heterodyne detection of qubit's fluorescence.

3:30PM C27.00006: Thermodynamics of fast quantum gates* CYRIL ELOUARD (Presenter), Department of Physics and Astronomy, University of Rochester, MASSIMILIANO ESPOSITO, University of Luxembourg, ALEXIA AUFFÈVES, Institut Néel - CNRS, ANDREW N JORDAN, Department of Physics and Astronomy, University of Rochester — Quantum computation gates rely on the possibility to perform qubit rotations in the Bloch sphere faster than decoherence. Strikingly, a thermodynamic description analyzing the coherent energy exchanges between the qubit and the driven field is still missing. Previous studies have focused on long timescales [1-2], much larger than one Rabi period, blurring out any coherent phenomenon, and are therefore inadequate to study e.g. the work cost of fast gates. Here we propose a thermodynamic description that is valid at short time-scales, where the dynamics is captured by the Optical Bloch Equations, featuring coherent excitation exchanges between qubit and the field. We identify the first and second law and their quantum components. The derivation of an integral and a detailed Crooks quantum fluctuation theorems ensures the thermodynamic consistency of our theory. Predictions from earlier Floquet-based (long time-scale) approaches are recovered in relevant regimes. Our results contribute to bridge the gap between quantum thermodynamics on the one hand, and quantum optics and quantum computation on the other hand.

3:42PM C27.00007: Quantum of information and its fluctuations in a conductor heat current* [Invited] YASUHIRO UTSUMI (Presenter), Physics Engineering, Mie University — Mesoscopic quantum conductors have been tools to investigate thermodynamics in the quantum regime [1]. They also offer a playground to think about entanglement and information transmission. In a quantum conductor, by applying a source-drain bias voltage, entangled electron-hole pairs can be created [2]. Moreover one bit of information content can be conveyed by the arrival or non-arrival of an electron [3]. We revisit this problem by analyzing a novel quantity, the distribution of fluctuating information, particle and heat currents, which is closely related to the Rényi entanglement entropy [4]. Our approach is the full-counting statistics based on the multi-contour Keldysh Green function developed recently [4,5].

To quantify the particle-hole entanglement, one has to remove the contribution from superpositions of different particle number eigenstates, which cannot be created and measured locally [2]. For this purpose, we account for the local electron number constraint and discuss the condition that the maximum accessible entanglement is realized [4].

The quantum physics limits the performance of communication through a conductor [3]. The optimum channel capacity, the maximum rate at which information can be transmitted under a given signal power, i.e. heat current, relates theory of communication and thermodynamics. We demonstrate a universal relation connecting the fluctuation of information, the Rényi entropy of order zero and the optimum capacity [4].

4:18PM C27.00008: Work extraction and Landauer's principle in a quantum spin Hall device INANC ADAGIDELI (Presenter), AHMET MERT BOZKURT, BARIS PEKERTEN, Sabanci University — Landauer’s principle states that erasure of each bit of information in a system requires at least a unit of energy kBT ln2 to be dissipated. In return, the blank bit may possibly be utilized to extract usable work of the amount kBT ln2, in keeping with the second law of thermodynamics. While in principle any collection of spins can be utilized as information storage, work extraction by utilizing this resource in principle requires specialized engines that are capable of using this resource. In this work, we focus on heat and charge transport in a quantum spin Hall device in the presence of a spin bath. We show how a properly initialized nuclear spin subsystem can be used as a memory resource for a Maxwell’s Demon to harvest available heat energy from the reservoirs to induce charge current that can power an external electrical load. We also show how to initialize the nuclear spin subsystem using applied bias currents which necessarily dissipate energy, hence demonstrating Landauer’s principle. This provides an alternative method of “energy storage” in an all-electrical device. We finally propose a realistic setup to experimentally observe a Landauer erasure/work extraction cycle.

4:30PM C27.00009: The dramatic impact of non-energetic coherences on heat flows* CAMILLE LOMBARD LATUNE (Presenter), ILYA SINAYSKIY, FRANCESCO PETRUCCIONE, University of KwaZulu-Natal — We show that the heat flow between a system and a stationary reservoir (under Born-Markov approximation) is dramatically affected by coherences between degenerate levels of the system. To assess the resulting effects of coherences on heat flows we introduce a concept of apparent temperature [1] which crucially takes into account coherences, by contrast with the virtual temperature [2]. It provides an intuitive picture in which non-energetic coherences behave as populations, enabling one to recover seminal results on phaseonium, thermally entangled atoms, and lasing without inversion. Moreover, we predict new effects like the dramatic increase of apparent temperature due to delocalised excitations. One of its manifestations, testable experimentally, is the “apparent thermalization”, where an ensemble of indistinguishable subsystems equilibrates at a much lower (or higher) energy than when interacting separately (or distinguishably) with the bath. Such phenomena stem from the mixture of the dynamics of the populations and coherences, which happens only in presence of degeneracy and is unique to quantum thermodynamics.

Quantum thermalization and optimal control are compatible in a many-body system

FERNEY RODRIGUEZ (Presenter), FERNANDO GÓMEZ-RIUZ, LUIS QUIROGA, Physics, Universidad de Los Andes, NEIL F JOHNSON, Physics, George Washington University — We propose a novel protocol for characterizing and ultimately controlling collective matter-radiation effects that emerge when a many-body quantum system is driven through a critical value of the interaction coupling strength. There are many possible ways to use our scheme to achieve quantum computing and information processing, including controlling superconducting qubits or color defects in diamond by means of quantum light in cavities. We show that apparently disparate phenomena such as thermalization, excited state quantum phase transitions and orthogonality catastrophes can be present in the system when subject to a finite pulsed coupling with the light field. In particular, we demonstrate a connection between the thermalization through entanglement of the global quantum pure system reached at the middle of the pulse, and the controlled production of an orthogonal global state at the end of the pulse. Our results should prove useful in a variety of contexts including the preparation of phases of condensed matter in quantum simulators and the engineering of states in quantum protocols.

Critical point behaviour of a measurement-based quantum heat engine

SUMAN CHAND, ASOKA BISWAS (Presenter), Indian Institute of Technology Ropar — At the critical point (CP), pertaining to quantum phase transition (QPT), the long-range quantum correlation (e.g., entanglement) becomes dominant. We show, in case of an ion-based quantum Otto engine, that such correlation does not necessarily enhance the efficiency of the engine, in the neighborhood of the CP. We choose two trapped ions as the working system, subject to a magnetic field and an internal energy-exchange coupling J1. During the expansion stage of the engine cycle, the adiabatic decrease of the magnetic field from B_H to B_L leads to certain work. The cooling of the system during the exhaust stage is mimicked by a projective measurement of the system into the ground state. During the compression stage, the magnetic field is adiabatically restored to B_H. We find that the critical point B_L=J1/2 poses as a minimum threshold for the system to work as a heat engine. Further, the efficiency of the engine increases with increase of the interaction strength J_1. On the contrary, the coupling to any ancillary system deteriorates the efficiency at the critical point, though such coupling enhances entanglement into the system. Our result suggests that long-range correlation may not be beneficial for an efficient quantum heat engine in the realm of QPT.

Topological work in nonequilibrium quantum thermodynamics

CHARLES STAFFORD (Presenter), Physics, University of Arizona, ABHAY SHASTRY, Chemistry, University of Toronto, YIHENG XU, Physics, U.C. San Diego, MARCO ANTONIO JIMENEZ VALENCIA, Physics, University of Arizona — As a model open quantum system out of equilibrium, we consider a system of electrons coupled to multiple (typically 3) macroscopic electron reservoirs and threaded by an Aharonov-Bohm flux φ. For the noninteracting case, we determine the exact nonequilibrium steady-state density matrix and entropy. We prove that the Nernst theorem (3rd law of thermodynamics) holds without exception for an open quantum system, even for the nonequilibrium case. The general principles are illustrated for the case of a quantum thermocouple. Both the chemical work due to electron exchange between the reservoirs and the topological work due to the Aharonov-Bohm effect must be included in applying the 1st law. The effect of electron-electron interactions on the thermoelectric device performance beyond linear response are investigated.

Observable Thermalization

FABIO ANZA (Presenter), Physics, University of California, Davis — To understand under which conditions thermodynamics emerges from the microscopic dynamics is the ultimate goal of statistical mechanics. Despite the fact that the theory is more than 100 years old, we are still discussing its foundations and its regime of applicability. A point of crucial importance is the definition of the notion of thermal equilibrium, which is given as the state that maximises the von Neumann entropy. Here we argue that it is necessary to propose a new way of describing thermal equilibrium, focused on observables rather than on the full state of the quantum system. We characterise the notion of thermal equilibrium, for a given observable, via the maximisation of its Shannon entropy and highlight the thermal properties that such a principle heralds. Eventually, we bring to light an intimate connection with the Eigenstate Thermalisation Hypothesis.

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C28 DQI: Topological Quantum Information with Majorana Nanowires

Angela Kou, Yale Univ
2:30PM C28.00001: Probing coherent coupling of Majorana modes via single-electron photon assisted tunneling:
Part 1* DEIVIDAS SABONIS (Presenter), DAVID VAN ZANTEN, JUDITH TABEA SUTER, University of Copenhagen, DMITRY PIKULIN, Microsoft Corp, JUKKA VAYRYNEN, Univ of California - Santa Barbara, TORSTEN KARZIG, Microsoft Corp, EOIN C O’FARRELL, DAVYDAS RAZMADZE, University of Copenhagen, KARL D PETERSSON, PETER KROGSTRUP, Microsoft Corp, CHARLES M MARCUS, University of Copenhagen — The coherent coupling between Majorana zero modes localized in distinct topological islands mixes the 1e charge states of islands. This coherent superposition of even and odd parity states is a necessary condition for the operation of topological qubits. We demonstrate the coherent coupling of zero modes in a superconducting double island created in a InAs/Al nanowire. This is achieved by tracking microwave induced charge transitions between the islands. The dispersion of photon assisted tunneling features is 1e periodic and shows the presence of an anti-crossing between even and odd parity charge states.

In this talk we will first characterize the coupling between islands using microwave spectroscopy in the absence of magnetic field and finally discuss the transition into the topological regime.

*Research supported by Microsoft Station Q and Danish National Research Foundation.

2:42PM C28.00002: Probing coherent coupling of Majorana modes via single-electron photon assisted tunneling:
Part 2* DAVID VAN ZANTEN (Presenter), DEIVIDAS SABONIS, JUDITH TABEA SUTER, University of Copenhagen, DMITRY PIKULIN, JUKKA VAYRYNEN, TORSTEN KARZIG, Station Q, Microsoft, EOIN C O’FARRELL, DAVYDAS RAZMADZE, KARL D PETERSSON, University of Copenhagen, PETER KROGSTRUP, Station Q, Microsoft, CHARLES M MARCUS, University of Copenhagen — The coherent coupling between Majorana zero modes localized in distinct topological islands mixes the 1e charge states of islands. This coherent superposition of even and odd parity states is a necessary condition for the operation of topological qubits. We demonstrate the coherent coupling of zero modes in a superconducting double island created in a InAs/Al nanowire. This is achieved by tracking microwave induced charge transitions between the islands. The dispersion of photon assisted tunneling features is 1e periodic and shows the presence of an anti-crossing between even and odd parity charge states.

In this talk we will discuss microwave spectroscopy measurements in the presence of magnetic field and show that the 1e periodicity results from discrete zero-energy states which emerge in magnetic field.

2:54PM C28.00003: Single-shot readout of spin-orbit-split Andreev doublets: motivation and setup* VALLA FATEMI (Presenter), MAX HAYS, KYLE SERNIAK, Department of Applied Physics, Yale University, DANIËL BOUMAN, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, GIJS DE LANGE, Microsoft Station Q Delft, Delft University of Technology, SPENCER DIAMOND, Department of Applied Physics, Yale University, PETER KROGSTRUP, JESPER NYGÅRD, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, ATTILA GERESDI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, MICHEL H. DEVORET, Department of Applied Physics, Yale University — Modern efforts towards constructing exotic superconducting qubits such as Andreev spin qubits and Majorana bound states hinges on spin-orbit coupling. The physics of these unique quantum systems may be explored using the well-developed microwave techniques of circuit QED, which can yield sharp spectral resolution and time-domain information. Here we report on measurements of long InAs-nanowire Josephson junctions embedded in a circuit QED architecture. The Andreev bound state spectrum includes transitions which correspond to the transfer of a single quasiparticle between two spin-orbit-split Andreev doublets. Some of these transitions exhibit large coupling to the on-chip resonator. Thus, fast, time-domain measurement of the many-body state of the junction can be achieved through dispersive readout. In this first part of a joint presentation, we will present the background and motivation, as well as the experimental setup and a theoretical model for our system.

*Work supported by ARO, ONR, NSF, and AFOSR
(Presenter), VALLA FATEMI, KYLE SERNIAK, Applied Physics, Yale University, DANIËL BOUMAN, Qutech and Kavli Institute of Nanoscience, Delft University of Technology, GIJS DE LANGE, Microsoft Station Q Delft, Delft University of Technology, SPENCER DIAMOND, Applied Physics, Yale University, PETER KROGSTRUP, JESPER NYGÅRD, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, ATILIA GERESDI, Qutech and Kavli Institute of Nanoscience, Delft University of Technology, GIJS DE LANGE, Microsoft Station Q Delft, Delft University of Technology, SPENCER DIAMOND, Applied Physics, Yale University — Modern efforts towards constructing exotic superconducting qubits such as Andreev spin qubits and Majorana bound states hinges on spin-orbit coupling. The physics of these unique quantum systems may be explored using the well-developed microwave techniques of circuit QED, which can yield sharp spectral resolution and time-domain information. Here we report on measurements of long InAs-nanowire Josephson junctions embedded in a circuit QED architecture. The Andreev bound state spectrum includes transitions which correspond to the transfer of a single quasiparticle between two spin-orbit-split Andreev doublets. Some of these transitions exhibit large coupling to the on-chip resonator. Thus, fast, time-domain measurement of the many-body state of the junction can be achieved through dispersive readout. In this second part of a joint presentation, we will describe the experimental data and discuss the outlook.

3:18PM C28.00005: Entangling Spins in Double Quantum Dots and Majorana Bound States  MARKO RANCIC
(Presenter), SILAS HOFFMAN, Department of Physics, University of Basel, CONSTANTIN SCHRADE, Massachusetts Institute of Technology, JELENA KLINOVAJA, DANIEL LOSS, Department of Physics, University of Basel — We theoretically investigate the coupling between a singlet-triplet (ST) spin qubit realized in a double quantum dot and a topological qubit composed of Majorana bound states. First, we derive an effective Hamiltonian which facilitates an entangling gate between the two individual qubits, thereby enabling a CNOT gate and, subsequently, a SWAP gate. Using standard readout and single qubit operations of the ST qubit, we show how the former gate can be used to readout the state of Majorana qubit while the latter gate enables universal quantum computation of the topological qubit. We estimate the fidelity of the entangling and SWAP gate operations to be 0.9997 and 0.993, respectively, using parameters that are consistent with realizing both of the qubits within a nanowire. Furthermore, we find that the coupling between the ST qubit and a single Majorana bound state induces an oscillation between the two singlet-triplet levels which has the utility to (1) perform single qubit operations on the singlet-triplet around the x axis without a need for a gradient of Zeeman fields and (2) provide a signature for the presence of zero energy bound states. Lastly, we propose a scheme to extend our setup to a scalable network using the ST-Majorana bound state qubit as the atomic unit.

3:30PM C28.00006: Quasiparticle Poisoning in a Proximitized Semiconductor Nanowire Qubit*  WILLEMIJNTJE UILHOORN (Presenter), ARNO BARGERBOS, JAMES KROLL, JASPER VAN VEEN, QuTech, Delft University of Technology, CHUNG-KAI YANG, Station Q Delft, Microsoft, JESPER NYGÅRD, Center for Quantum Devices and Station Q Copenhagen, Niels Bohr Institute, PETER KROGSTRUP, Station Q Lyngby, Microsoft, LEO KOUWENHOVEN, ANGELA KOU, GIJS DE LANGE, Station Q Delft, Microsoft — Topological qubits are predicted to have very long coherence times due to their inherent protection against local perturbations. However, non-parity preserving processes such as quasiparticle poisoning (QPP) set the bandwidth requirements for controlling topological qubits. Quasiparticle poisoning rates have been recorded in conventional superconducting transmon qubits [1, 2] and in hybrid proximitized semiconductor nanowire junctions [3] at zero magnetic field.

Here we perform QPP measurements on nanowire transmons in a magnetic field by monitoring parity-dependent shifts of the transmon's readout resonator. We investigate the magnetic field dependence of the QPP up to magnetic fields required to reach the topological phase.

Little-Parks effect in a semiconducting nanowire-based superconducting qubit with \textit{in-situ} switching between transport and cQED* 

ANDERS KRINGHØJ (Presenter), THORVALD W LARSEN, OSCAR ERLANDSSON, DEIVIDAS SABONIS, Center for Quantum Devices and Microsoft Quantum Lab–Copenhagen, Niels Bohr Institute, University of Copenhagen, 2100 Copenhagen, Denmark, BERNARD VAN HECK, Center for Quantum Devices and Microsoft Quantum Lab–Copenhagen, Niels Bohr Institute, University of Copenhagen, 2100 Copenhagen, Denmark, and Microsoft Quantum, Microsoft Staq.

We demonstrate \textit{in-situ} switching between coherent cQED measurements and transport measurements based on a full-shell nanowire using a Josephson junction as a gate tuneable switch. These field-compatible devices show flux-dependent lobe spectra in both transport and cQED measurements associated with the Little-Parks effect. Coherent operations are performed both around zero applied field and around 90 mT, corresponding to one flux quantum being threaded through the wire, with a destructive regime in between.

This opens the possibility of detecting the presence of MZMs in one-flux-quantum regime by cQED measurements.

Cavity-based readout and control of Majorana qubits

THOMAS SMITH (Presenter), ARNE GRIMSMO, STEPHEN D BARTLETT, ANDREW C DOHERTY, Univ of Sydney — We discuss readout and control protocols based on coupling Majorana bound states to cavities. In particular, we consider hybrid superconductor-semiconductor nanowires where the Majorana-cavity coupling is mediated by a quantum dot. The resulting qubit-cavity interaction can be operated in the dispersive regime, familiar from circuit QED. Alternatively, a longitudinal interaction can be activated by parametric modulation of the qubit-cavity coupling strength [1]. We explore how these interactions can be used for readout of Majorana qubits, as well as their use for cavity-mediated entangling gates.

Nonlinear quantum optics for the characterization of Majorana qubits*

SAMUEL BOUTIN (Presenter), Institut quantique and Département de Physique, Université de Sherbrooke, ANQI MU, Department of Physics, University of Toronto, PEDRO LOPES, Stewart Blusson Quantum Matter Institute, University of British Columbia, UDSON MENDES, ION GARATE, Institut quantique and Département de Physique, Université de Sherbrooke — Recent developments in the design of Majorana qubits have focused on devices with significant charging energy. In this parameter regime, methods from circuit QED can be used to study topological qubits. In particular, the toolbox of quantum optics opens new possible schemes for the characterization, measurement, and control of Majorana qubits. As a step in this direction, we investigate how the phenomenon of bifurcation in nonlinear cavities, commonly used for measuring qubits, is altered in the presence of Majorana bound states. Our preliminary results indicate that bifurcation could help characterize quasiparticle poisoning events in quantum wires-based Majorana qubits.

On-chip microwave spectroscopy of an InAs nanowire Cooper-pair transistor

DOMINIQUE LAROCHE (Presenter), ALEXANDER PROUTSKI, BAS VAN ‘T HOOFT, QuTech, Delft University of Technology, JESPER NYGÅRD, PETER KROGSTRUP, Center for Quantum Devices and Station Q Copenhagen, University of Copenhagen, LEO P KOUWENHOVEN, ATTIKA GERESDI, QuTech, Delft University of Technology — Controlling both the charging and the Josephson energies of superconducting islands is a crucial requirement for the operation and readout of prospective Majorana-based topological qubits. Here, we present the study of Cooper-pair transistors (CPTs) fabricated from InAs nanowires with superconducting Al shell, a promising platform for the physical realization of topological qubits. By utilizing on-chip microwave spectroscopy, we are able to induce excitations between energy levels of the CPT in a parity conserving manner. We map both the charge- and the photon-like excitations of the system, and show that it is possible to tune the CPT from a Coulomb-blockaded to a transmon-like regime by adjusting the system parameters. The quantum system is exhaustively modeled, allowing us to extract the effective charging and Josephson energies of the CPT. In addition, we study the ground state charge occupation of the CPT and attribute the observed temperature dependence of the even-odd parity structure to the presence of a sub-gap state on the superconducting island.

Rapid single-shot detection of coherent tunneling in an InAs nanowire double quantum dot through dispersive gate sensing

DAMAZ DE JONG (Presenter), JASPER VAN VEEN, LUCA BINCI, AMRITA SINGH, Delft University of Technology, JESPER NYGÅRD, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, PETER KROGSTRUP, Center for Quantum Devices and Microsoft Quantum Lab Copenhagen, Niels Bohr Institute, University of Copenhagen, LEO P KOUWENHOVEN, WOLFGANG PFAFF, JOHN WATSON, Microsoft Station Q Delft, Delft University of Technology — Dispersive gate sensing can enable scalable and high-fidelity readout of solid-state quantum bits. In particular, it has been proposed for fast non-demolition readout of topological qubits that can be measured by single electrons tunneling through zero-energy modes [1, 2]. Such a readout requires resolving the coherent charge tunneling amplitude from a quantum dot in a Majorana zero-mode host system faithfully on short time scales. Here we demonstrate rapid detection of single-electron tunneling between InAs nanowire quantum dots. To this end we have engineered a sensitive dispersive detection circuit by connecting a microwave resonator to a high-lever arm gate. This circuit translates charge tunneling between the dots into a dispersive shift on the resonator [3]. At charge degeneracy the phase shift of a reflected probe signal approaches its maximal possible value of 180 degrees, enabled by the large dot-resonator coupling. This allows us to detect the charge tunneling amplitude with an SNR exceeding two in a microsecond [4]. Our result paves the way for fast high-fidelity measurements of fermion parity in topological qubits.

Dispersive gate-sensing of a quantum dot coupled to a superconducting island

JASPER VAN VEEN (Presenter), DAMAZ DE JONG, LIN HAN, CHRISTIAN PROSKO, QuTech and Kavli Institute of NanoScience, Delft University of Technology, TORSTEN KARZIG, Station-Q, Microsoft Research, PETER KROGSTRUP, JESPER NYGÅRD, Center for Quantum Devices and Station-Q Copenhagen, Niels Bohr Institute, University of Copenhagen, LEO P KOUWENHOVEN, JOHN WATSON, WOLFGANG PFAFF, Microsoft Station-Q at Delft University of Technology — Combining superconductivity with quantum dots in proximitized, semiconducting nanowires has led to many novel phenomena ranging from $\pi$-junctions to Cooper-pair splitters. Currently, these hybrid systems are of interest in the context of Majorana-zero modes (MZMs). In particular, it has been proposed that a topological qubit can be made by coupling a superconducting island hosting MZMs to a dot. However, to date, even trivial superconducting island-dot systems are not yet fully understood.

To increase this understanding, we experimentally study the coupling between a quantum dot and a superconducting island. Dispersive gate-sensing is used to readout because it is directly sensitive to the coupling amplitude between the two systems. We focus on two regimes characterized by their coupling to the leads. For weak, but finite, lead coupling, we identify the relevant charge-transfer processes by comparing a phenomenological model to our data. For a closed system without lead coupling, we can access quasiparticle states allowing us to extract the free energy difference of the island.

Combined, these experiments set the stage for future dot-MZMs experiments. This is necessary for distinguishing dot-trivial superconductor coupling from dot-MZM coupling.
Observation of quantized conductance in quantum point contacts on near surface InAsSb quantum wells* MIHIR PENDHARKAR (Presenter), JOON SUE LEE, MICHAEL A SEAS, ANTHONY MCFADDEN, TAOZHI GUO, CONNOR DEMPSEY, SEAN HARRINGTON, DANIEL J PENNACHIO, TOBIAS BROWN-HEFT, HADASS INBAR, CHRIS PALMSTROM, University of California, Santa Barbara — Topological protection in Majorana Zero Mode (MZM) based quantum computation depends on the induced topological energy gap in the host superconductor-semiconductor hybrid system. Induced topological gap is in turn directly proportional to the spin-orbit coupling in the host system. Certain compositions of InAsSb are expected to have an enhanced spin-orbit coupling as compared to InAs and InSb, thus making InAsSb an ideal platform for robust and scalable topological networks. In this work, top gate control of electron density in near surface InAsSb 2DEGs has been demonstrated. Full depletion can be observed at relatively low top gate voltages, at 2K. Additionally, quantum point contacts on InAsSb 2DEGs show quantized conductance at zero-field at 2K. This work paves the way for coupling superconductivity and enabling the use of near surface InAsSb quantum wells as a host material system for MZM-based topological quantum computation.

Majorana fermions in nanowire-superconductor systems in periodic magnetic fields and their resonant manipulation* VIKTORIA KORNICH (Presenter), University of Wisconsin - Madison, XIAOLI HUANG, TU Delft, MAXIM VAVILOV, MARK G FRIESEN, M. A. ERIKSSON, SUSAN COPPERSMITH, University of Wisconsin - Madison, Y. V. NAZAROV, TU Delft — The nanowire-superconductor structures with a helical magnetic field are known to host Majorana fermions. We show that the structures built in Si can support Majorana fermions even for the field shapes that are very different from helical ones. We discuss various shapes and imperfections of the magnetic field, and present phase diagrams for a wide range of experimental parameters.

Robust micro-magnet geometries for Majorana modes in low g-factor materials SARA TURCOTTE (Presenter), SAMUEL BOUTIN, JULIEN CAMIRAND LEMYRE, ION GARATE, Institut quantique, Université de Sherbrooke, MICHEL PIORO-LADRIERE, Institut quantique, Université de Sherbrooke and Canadian Institute for Advanced Research — Signatures of Majorana bound states (MBS) have been widely reported in semiconductors materials with large spin-orbit coupling and proximity-induced superconductivity [1]. In principle, MBS can also emerge in weakly spin-orbit coupled materials subjected to inhomogeneous magnetic fields [2]. However, in practice small g-factors make it difficult to reach the topological phase. In this work, we explore a versatile approach where spin-orbit coupling arises from a non-uniform magnetic field produced by a micro-magnet array [3]. Using the recently developed RGF-GRAPE algorithm [4], we optimize realistic micro-magnet geometries to find suitable conditions for the emergence of MBS in a one-dimensional wire without intrinsic spin-orbit coupling. In addition, we study robustness of MBS against possible micro-magnet nanofabrication errors. Finally, we identify suitable low g-factor materials commonly used in the microelectronic industry as promising candidates for experimental implementations.

We introduce an ultra-high-impedance superconducting circuit where the role of phase difference across a Josephson junction is replaced by quasi-charge. This Hamiltonian is dual to that of the transmon, in which the kinetic energy term associated with the charging energy is replaced by the inductive energy. Our circuit consists of a small-area Josephson junction shunted by a large linear inductance exceeding one micro-Henry. In such a circuit, the sensitivity of the ground to the first excited state transition is virtually flux insensitive while the flux-tunability of the transitions to higher excited states is largely preserved. Proper circuit design and choice of the fabrication techniques enable the mitigation of the parasitic capacitance previously associated with such large shunting inductances. In this talk, we demonstrate how the device spectra can be adequately described by the dual Hamiltonian and show that the flux dispersion of the qubit transition is reduced down to less than 100 MHz across the entire flux quantum. We also put a limit on the loss tangent of the inductor to be $5 \times 10^{-6}$.

We introduce an ultra-high-impedance superconducting circuit where the role of phase difference across a Josephson junction is replaced by quasi-charge. This Hamiltonian is dual to that of the transmon, in which the kinetic energy term associated with the charging energy is replaced by the inductive energy. Our circuit consists of a small-area Josephson junction shunted by a large linear inductance exceeding one micro-Henry. In such a circuit, the sensitivity of the ground to the first excited state transition is virtually flux insensitive while the flux-tunability of the transitions to higher excited states is largely preserved. Proper circuit design and choice of the fabrication techniques enable the mitigation of the parasitic capacitance previously associated with such large shunting inductances. In this talk, we demonstrate how the device spectra can be adequately described by the dual Hamiltonian and show that the flux dispersion of the qubit transition is reduced down to less than 100 MHz across the entire flux quantum. We also put a limit on the loss tangent of the inductor to be $5 \times 10^{-6}$.

Tunable Josephson phase-slip qubits (JPSQs) present the possibility of constructing effective spin-1/2 Hamiltonians with arbitrary 2-local interactions using superconducting technology. Here, we discuss how this mapping is made, presenting a Pauli-operator breakdown of the current and voltage dipoles of a JPSQ along a qubit annealing path that allows for preparation and readout in addition to the engineered couplings. As an example of the possibilities inherent in these devices, we present a system of JPSQs that adiabatically encodes or decodes a logical qubit in a $[[4,1,2]]$ Bacon-Shor code.

The Josephson phase-slip qubit (JPSQ) [1] is a superconducting circuit that emulates a vector quantum $S=1/2$ system, with an effective dipole moment nearly independent of applied field, even near zero. This makes JPSQs ideal for emulating vector spin interactions, such as non-Stoquastic $+XX$ of interest for quantum annealing. We describe the design and operation of a JPSQ implementation. Using dispersive readout, we demonstrate the predicted periodic tuning with both flux and charge, and measure lifetimes in the microsecond regime. We also characterize the influence of charge jumps on the circuit’s operation. These results confirm the operating principles of the JPSQ and suggest that it could play an important role in a variety of quantum device architectures.

3:18PM C29.00005: Characterization of Josephson phase-slip qubits, Part 2: Annealing* ROBERT HINKEY (Presenter), MOE KHALIL, SERGEY NOVIKOV, DAVID CLARKE, JAMES I. BASHAM, STEVEN DISSELER, ALEXANDER MARAKOV, JEFFREY GROVER, Northrop Grumman - Mission Systems, DAVID K KIM, MIT Lincoln Laboratory, ZACHARY A STEGEN, Northrop Grumman - Mission Systems, ALEXANDER MELVILLE, BETHANY M. NIEDZIELSKI, JONILYN YODER, MIT Lincoln Laboratory, DANIEL A LIDAR, University of Southern California, KENNETH M. ZICK, DAVID FERGUSON, Northrop Grumman - Mission Systems — Josephson phase slip qubits (JPSQs) have been identified as a promising qubit with which to build next-generation quantum annealers. These qubits have charge tunability through the Aharanov-Casher effect. This charge tuning is a signature of their ability to achieve “strong” non-stoquastic XX couplings with “strong” indicating couplings that are large relative to residual single qubit fields. This coupling regime is not known to be possible to achieve with conventional flux qubits. In this talk we present initial characterization measurements of JPSQs that are annealing-compatible and have a large charge dispersion.

3:30PM C29.00006: Classically reversible logic gate coupled to a superconducting qubit: Problem definition (pt. 1) KEVIN DANIEL OSBORN (Presenter), WALTRAUT WUSTMANN, LPS at the University of Maryland, College Park — New research is starting on a digital logic that uses physical and logical reversibility to achieve higher energy efficiency than commercial digital gates which are irreversible. After describing resonant dynamics of topological solitons in classical reversible superconducting gates, we discuss the theoretical coupling to a superconducting qubit. The solitons in this classical logic are fluxons in Long Josephson Junctions (LJJs), and the fluxon polarity (fluxon or antifluxon) represents a bit state. Gate structures consist of input and output LJJs, and a JJ circuit interface in-between is such that an incoming fluxon temporarily exchanges energy with a localized mode, before an output fluxon emerges with operation-defined polarity. This scattering is efficient and fast in 1- and 2-bit gates. While quantum fluctuations are intentionally negligible for classical gate operations, we study fluxon gates coupled with a qubit, as a possible resource for qubit readout. We analyze the gates with a quasiparticle model for the LJJ fields. Depending on the exact interface design, different types of elastic scattering occur. In a quantum regime, with a qubit embedded across the central interface JJ, a quantized version of the quasiparticle model should be a convenient approximation.

3:42PM C29.00007: Classically reversible logic gate coupled to a superconducting qubit: Qubit simulation (pt. 2) WALTRAUT WUSTMANN (Presenter), KEVIN DANIEL OSBORN, LPS at the University of Maryland, College Park — We theoretically study a classically reversible logic gate coupled to a superconducting qubit for potential applications in quantum computing. The classical gate consists of a Josephson junction circuit interface between long Josephson junctions, and the input of the gate is a ballistically traveling fluxon (a topological sine-Gordon soliton). Depending on the gate definition, a fluxon can undergo different types of resonant elastic scattering, e.g., forward scattering as fluxon or antifluxon. Here we report on how the scattering outcome can depend on the state of a qubit that is embedded in the interface, thus potentially allowing the readout of the qubit from the fluxon dynamics. We specifically will show the effect for a fluxonium qubit galvanically coupled through a junction in the gate interface. This presents a large 4pi-phase difference seen by the qubit. Different fluxon scatterings are found in the classical dynamics of the coupled system for the fluxonium qubit states with macroscopically different phases. We will further use a quantized version of a quasiparticle model, originally developed for classical gates, and take into account few fluxonium levels. The newer analysis should allow us to predict state evolution of a qubit strongly coupled to a topological soliton.
3:54PM C29.00008: Quantum information processing using 3D multimode circuit QED* SRIVATSAN CHAKRAM (Presenter), RAVI NAIK, AKASH DIXIT, YAO LU, ALEXANDER ANFEROV, NELSON LEUNG, ANDREW ORIANI, DAVID SCHUSTER, University of Chicago — Multimode superconducting microwave cavities provide a hardware efficient means of engineering a large, high-coherence Hilbert space suitable for quantum information processing. When coupled to a superconducting transmon circuit, they can be used to construct random access quantum processors in which logic gates can be performed between arbitrary pairs of cavity modes via sideband transitions with the transmon [1]. We present our progress toward realizing such a processor using a seamless rectangular 3D multimode cavity - the quantum flute, with a tailored mode dispersion and decay times around a millisecond for tens of cavity modes. To eliminate coherent errors arising from multimode state dependent Stark shifts of the transmon, we introduce an intermediate single-mode 'manipulate' cavity with a tunable coupling to the multimode cavity.

4:06PM C29.00009: Towards Developing a Graphene Josephson junction based qubit device KYLE MCELROY (Presenter), The Johns Hopkins University Applied Physics Laboratory, JESSE E THOMPSON, BRANDON T BLUE, Department of Physics and Nanoscience Technology, University of Central Florida, LAFE SPIETZ, Spietz Applied Sciences, LLC, JACOB EPSTEIN, The Johns Hopkins University Applied Physics Laboratory, MASA ISHIGAMI, Department of Physics and Nanoscience Technology, University of Central Florida, JOAN A HOFFMANN, The Johns Hopkins University — Construction of Josephson weak links is an integral part of superconducting quantum devices. New junction structures have various potential applications as new qubits or sensors. We will discuss the preliminary development of a transmon with a graphene based Josephson junction. The devices are fabricated using epitaxially grown graphene, transferred to a sapphire base with standard lithographic techniques used for junction and antenna layout. The junctions are designed to have 0.3-0.85 nA critical currents and antenna geometry for device resonances between 2-6 GHz and are imbedded in a high Q 3D cavity at 7.7 GHz.

4:18PM C29.00010: Quantum coherent control of graphene-based transmon qubit* JOEL WANG (Presenter), Research Laboratory of Electronics, Massachusetts Institute of Technology, USA, CHARLOTTE BOETTCHER, Dept. of Physics, Harvard University, USA, LANDRY BRETHEAU, Laboratoire des Solides Irradiés, Ecole Polytechnique, France, DANIEL CAMPBELL, Research Laboratory of Electronics, Massachusetts Institute of Technology, USA, BHARATH KANNAN, Research Laboratory of Electronics, Dept. of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, USA, DAVID D OLIVER, Dept. of Physics, Research Laboratory of Electronics, and Lincoln Lab, Massachusetts Institute of Technology, USA, MORTEN KJÆRGAARD, PHILIP KRANTZ, Research Laboratory of Electronics, Massachusetts Institute of Technology, USA, GABRIEL O. SAMACH, Lincoln Lab, Massachusetts Institute of Technology, USA, FEI YAN, Research Laboratory of Electronics, Massachusetts Institute of Technology, USA, JONILYN L YODER, Lincoln Lab, Massachusetts Institute of Technology, USA, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, NIMS, Japan, TERRY PHILIP ORLANDO, Research Laboratory of Electronics, Dept. of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, USA, SIMON GUSTAVSSON, Research Laboratory of Electronics, Massachusetts Institute of Technology, USA, PABLO JARILLO-HERRERO, Dept. of Physics, Massachusetts Institute of Technology, USA, WILLIAM D OLIVER, Dept. of Physics, Research Laboratory of Electronics, and Lincoln Lab, Massachusetts Institute of Technology, USA — Van der Waals (vdW) materials—a family of layered crystals with various functionalities, can be assembled in specific arrangements to create new electronic devices called vdW heterostructures. The extraordinary and versatile electronic properties of these heterostructures, in combination with their epitaxial precision, make vdW-based devices a promising alternative for constructing key elements of novel solid-state quantum computing platforms. We demonstrate quantum coherent control of a superconducting circuit incorporating graphene-based vdW heterostructures. We show that this device can be operated as a voltage-tunable transmon qubit, whose spectrum reflects the electronic properties of massless Dirac fermions traveling ballistically. In addition to the potential for advancing extensible quantum computing technology, our results represent a new approach to studying vdW materials using microwave photons in coherent quantum circuits.(arXiv:1809.05215)

4:30PM C29.00011: Resonator Cavities Compatible with Epitaxial InAs-Al Heterostructures* JOSEPH YUAN (Presenter), MATTHIEU DARTIAILH, WILLIAM ANDREW MAYER, ERIC SONG, KAUSHINI WICKRAMASINGHE, JAVAD SHABANI, Physics, New York University — Epitaxial Al-InAs structures are prime candidates for tunable superconducting qubits, the so-called “gatemon” where the Josephson energy can be tuned in-situ with an applied electric field to an InAs Josephson junction, eliminating the need for flux tuning in superconducting qubits [1]. Here we have characterized microwave cavities needed for coupling to superconducting gatemon qubits. We present resonator quality factors for a fixed design on various levels of the buffer layers used as substrates. We make a comparison to bare InP and Si to establish a comparative baseline.

*We acknowledge support from the US Army Office of Research, ARO: W911NF-18-1-0067

4:42PM C29.00012: Superconducting gatemon qubits based on selective-area-grown semiconductor materials* ALBERT HERTEL (Presenter), LAURITS ORHEIM ANDERSEN, Center for Quantum Devices, Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, NATAIL PEARSOR, Theoretische Physik, ETH Zürich, Zürich, Switzerland, MALCOLM R CONNOLLY, Center for Quantum Devices, Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, VALENTINA ZANNIER, LUCIA SORBA, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, Pisa, Italy, LIU YU, PETER KROGSTUP, Center for Quantum Devices, Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, GEOFFREY C. GARDNER, MICHAEL MANFRA, Purdue University, Station Q Purdue, KARL PETERSSON, CHARLES M MARCUS, Center for Quantum Devices, Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen — Semiconductor-superconductor hybrid gatemon qubits offer a promising path to large scale quantum processors. In contrast to conventional transmon qubits that are controlled using currents, gatemons allow complete control using only gate voltages [1], potentially alleviating challenges to scaling superconducting qubits [2]. Here, we present a novel approach to building gatemons utilizing selective-area-grown InAs structures on an InP substrate [3,4]. This approach allows deterministic placement and straightforward fabrication of the gatemon qubits. We characterize the material and perform first proof-of-principle measurements to demonstrate coherent qubit oscillations. Further work is needed to understand the dominant loss mechanisms and improve coherence times.

4:54PM C29.00013: Control of topological properties in the Kitaev chain by quantum microwave radiation* FABIO MÉNDEZ-CÓRDOBA (Presenter), FERNANDO GÓMEZ-RUIZ, JUAN MENDOZA-ARENAS, FERNEY RODRIGUEZ, Physics, Universidad de Los Andes, CARLOS TEJEDOR, Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, LUIS QUIROGA, Physics, Universidad de Los Andes — We investigate observable signatures coming from the light-matter coupling of a Kitaev chain embedded in a microwave cavity. We study and describe the quantum phases of the system, and the transitions between them, for two different composite fermion-photon model, namely a cavity homogeneously coupled to the whole chain as well as the case of a microwave selectively coupled to an edge site of the chain only. Our results are based on two complementary approaches, an analytic mean-field theory and numerical matrix product state simulations. We find that as a consequence of the interaction between the matter-radiation subsystems, a topological non-trivial phase of the Kitaev chain can be increased and identified by following the behavior of different photon observables such as the mean photon number and the Fano factor. Our analysis reveals a second order phase transition for different types of microwave-fermion couplings. The observed phenomena and the control of the quantum state of the chain assessed with the cavity, make it a potential candidate for further experimental investigations that seek the presence of Majorana fermions in solid-state systems.

Ultra low-loss single-crystalline material platform for high-Q quantum devices

ILYA RODIONOV
(Presenter), ALEKSANDR BABURIN, ILYA A. RYZHIKOV, AIDAR R. GABIDULLIN, DMITRIY O. MOSKALEV, ALINA
DOBRONOSOVA, ALEXEY MATANIN, Functional Micro/Nanosystems, Bauman Moscow State Technocal University — Quantum
technologies is a rapidly grown research area, which have the potential to lead the revolution in supercomputing, sensing,
global communications and security. The leading quantum computing concepts of design like superconductive qubits,
optical quantum computing devices, solid-state and hybrid quantum systems are based on traditional semiconductor
technology platform. However, new materials and nanoscale structures fabrication techniques are needed to explore the
underlying physics and fulfill the subsequent specifications. Losses in thin films, surface, structure and interfaces quality
are coming into the fore.

Here we present a new approach for high vacuum deposition of single-crystalline metallic films with extremely low losses,
which we name the SCULL (Single-crystalline Continuous Ultra-smooth Low-loss Low-cost) process. Fabricated films show
perfect crystallinity (FWHM for \( \omega \)-scan is better than 0.3), best published optical, superconductive, electrical properties and
sub-0.5nm roughness. We demonstrate perfect silver/gold plasmonic films and superconductive aluminum films. With
SCULL films the longest SPP propagation length (200 \( \mu \)m at \( \lambda = 780 \) nm) and the brightest single-photon source (over 35
million photons per second) at room temperature is demonstrated.

Session C30 GSOFT: Liquid Crystals II

BCEC 162B - Nasser Abukhdeir, University of Waterloo - Tag(s): Focus

2:30PM C30.00001: Nanocomposites of Ferroelectric Liquid Crystals and Magnetic Nanoparticles: Potential
Application as a MRI Contrast Agent*

LUZ MARTINEZ-MIRANDA (Presenter), University of Maryland, College Park, PATRICIO
N ROMERO-HASLER, EDUARDO A SOTO-BUSTAMANTE, University of Chile, LYNN K. KURIHARA, NextFED, LAMAR O MAIR,
IRVING N WEINBERG, Weinberg Medical Physics, Inc. — Nanocomposites of ferroelectric liquid crystals in combination with
FeCo magnetic nanoparticles are considered as a MRI contrast agent, by creating a magnetic field as a function of the
body's electric field. The rotational viscosity of the sample needs to be reduced in order to reduce the electric field
strength required for liquid crystal rotation to the values observed in many live biological states. This is achieved by having
the nanoparticles act as lubricants to the ferroelectric liquid crystal. The magnetic field depends on the concentration of
nanoparticles, which cannot be toxic to the biological environment. The concentrations used form aggregates that tend to
exist in stable spherulites, that are also reversible with temperature. We find a relation between the magnetic field and the
number of spherulites per unit area that align as a function of the electric field in the presence of a very small sample such
as our model system. Finally, we present a model of how the electric field rearranges the spherulites and produces the
magnetic field.

2:42PM C30.00002: Can a minimum principle describe shear alignment of liquid crystals?*

XINGZHOU TANG
(Presenter), JONATHAN SELINGER, Kent State University — When a static perturbation is applied to a liquid crystal, the
director configuration changes to minimize the free energy. When a shear flow is applied to a liquid crystal, one might ask:
Does the director configuration change to minimize any effective potential? To address that question, we derive the Leslie-
Ericksen equations for dissipative dynamics, and determine whether they can be expressed as relaxation toward a
minimum. The answer may be yes or no, depending on the number of degrees of freedom. Using theory and simulations,
we consider two specific examples, reverse tilt domains under simple shear flow and dowser configurations [1] under
plane Poiseuille flow, and determine whether each example shows relaxation toward the minimum of an effective
potential.

*This work is supported by NSF Grant No. DMR-1409658.
2:54PM C30.00003: Surface reconstruction of chiral liquid crystalline oligomers under the action of volatile organic compounds  
PETR SHIBAEV (Presenter), Fordham University — Significant changes in surface morphology as well as in chiral fingerprint structure are discovered in solid chiral oligomers and their compositions with low molar mass liquid crystals affected by volatile organic compounds. The changes are manifested by inversion of chiral pattern and surface periodic structure. Surprisingly, the changes are reversible with a relaxation time of several days at room temperature. This reversibility of the effect underscores the importance of chiral structure beneath the surface and not affected by the volatile compounds in restoration of initial morphology. The importance of underlying chirality is also confirmed by the absence of this effect in replicas of chiral surface created by means of common polymers (polystyrene, polyvinylpyridine). The discovered effect is also modelled by means of computer simulations and a simple theoretical model is presented. The discovered effect can find applications in gas detectors and optical devices.

3:06PM C30.00004: High order nonlinear electrophoresis in nematic liquid crystal*  
MOJTABA RAJABI (Presenter), Department of Physics, Kent State University, TARAS TURIV, Advanced Materials and Liquid Crystal Institute, Chemical Physics Interdisciplinary Program, Kent State University, O D LAVRENTOVICH, Department of Physics, Advanced Materials and Liquid Crystal Institute, Chemical Physics Interdisciplinary Program, Kent State University — Electrophoresis is motion of particles relative to a surrounding fluid in a uniform electric field. In anisotropic fluids such as liquid crystals (LC) the particle's velocity growth with the square of the electric field strength [1]. As a result, reversing polarity of the electric field does not change the direction of propulsion, which makes it possible to drive a sustained transport by an alternating-current (AC) field [2]. Here we report a higher-order nonlinear electrophoresis in which the velocity acquires a component proportional to the fourth power of the electric field strength. The effect is observed in a nematic LC with negative anisotropy of dielectric permittivity. The electric field realigns the director around the colloidal particle and thus modifies the geometry of spatial charge separation and the viscous drag; as a result, the velocity dependence on the field acquires higher-order nonlinearities.

*The work was supported by NSF DMREF grant DMS-1729509.

3:18PM C30.00005: Comparison of material parameters among flexible dimer, trimer, tetramer of nematic mesogens*  
ZEINAB PARSOUZ A.SH (Presenter), GRETA BABAKHANOVA, RONY SAHA, MOJTABA RAJABI, TARAS TURIV, Kent State University, CHRIS WELCH, GEORG H MEHL, Department of Chemistry, University of Hull, Hull, UK, JAMES GLEESON, ANTAG ISTVAN JAKLI, O D LAVRENTOVICH, SAMUEL SPRUNT, Kent State University — We compare the temperature dependencies of the birefringence, elastic constants and orientational viscosities for four homologous nematic liquid crystal oligomers: dimer (DTC5C9), its associated trimer and tetramer. These materials all exhibit the twist-bend nematic (NTB) phase. The magnitudes of the splay (K11), twist (K22) and bend (K33) elastic constants, as well as the corresponding orientational viscosities are determined by dynamic light scattering measurements. Interestingly K33 in the dimer and tetramer shows the monotonic decrease with temperature below the nematic-isotropic transition followed by a pretransitional increase close to the nematic to NTB transition. The trimer, in contrast, shows essentially no pretransitional change in K33. This behavior can be attributed to odd-even effect associated with the number of monomer unites in oligomers. The orientational viscosities associated with splay, twist and bend fluctuations in the N phase of dimer, trimer and tetramer are comparable to those of nematics formed by rod-like molecules. All three show strong temperature dependence, increasing sharply near the N – NTB transition.

3:30PM C30.00006: Enhanced Dissipation Behavior of Main-Chain LCE Networks  CRISTINA MARTIN LINARES  (Presenter), ALEJANDRO MARTIN LINARES, Mechanical Engineering, Johns Hopkins University, NICHOLAS TRAUGUTT, UC DENVER, THAO NGUYEN, Mechanical Engineering, Johns Hopkins University, CHRISTOPHER YAKACKI, UC DENVER — Liquid Crystal Elastomers (LCEs) are composed of mesogens bound to an elastomeric network of polymer chains. The orientation of mesogens relative to the polymer network leads to reversible actuation at the nematic-isotropic transition (Tni), soft-elasticity, and enhanced dissipation. Instead of a peak at Tg, the tan-delta curve for LCEs is elevated over Tg-Tni, indicating enhanced dissipation. At large strains, the material exhibits rate-dependent soft-elasticity with hysteresis[1]. We hypothesize that the enhanced dissipation behavior arises from the motion of the mesogens relative to the polymer network and measure the effect of mesogen ordering and network orientation. We developed uniaxial tension tests using 3D-DIC to measure the rate-dependent load-unload response and hysteresis for 3 main chain LCE networks with different microstructures, including polydomain and monodomains. The modulus and hysteresis increased significantly with strain rate for all networks. The modulus for a monodomain stretched parallel to the director was an order of magnitude higher than that of a polydomain. The monodomain stretched perpendicular to the director had the greatest dissipation.

3:42PM C30.00007: Defect nucleation in quenched freely suspended smectic liquid crystal films*  ADAM GREEN  (Presenter), CHEOL PARK, JOSEPH E MACLENNAN, MATTHEW GLASER, NOEL ANTHONY CLARK, University of Colorado, Boulder — Freely suspended films of smectic liquid crystals, which can be as thin as two molecular layers, are a natural choice for studying ordering and phase transitions in 2D. One 2D system of ongoing interest is that of the XY-model, which describes the U(1) symmetry group of rotations, broken by either a complex number or 2D vector. The XY-model gives rise to topological defects, or vortices, with interesting implications for phase transitions in two dimensions eg. Kosterlitz-Thouless transitions. Here, we describe our recent experiments focusing on the nucleation of topological defects in the quasi-2D system of freely-suspended smectic films. By rapidly quenching a film (inducing a rapid phase transition from an ordered to a disordered phase), and studying the evolution of the dynamics with a high-speed video camera, we are able to visualize defect nucleation in smectic C (tilted) films, and we will discuss the role that islands (pancake-like, circular regions with additional smectic layers bounded by an edge dislocation) play in mediating the creation of these defects.

3:54PM C30.00008: Shaping nanoparticle fingerprints at the interface of cholesteric emulsions*  LISA TRAN  (Presenter), Columbia University, HYE-NA KIM, University of Pennsylvania, NINGWEI LI, University of Massachusetts, Amherst, SHU YANG, KATHLEEN STEBE, RANDALL D KAMIEN, University of Pennsylvania, MARTIN HAASE, Rowan University — In this work, we balance the interfacial energy of nanoparticles against the elastic energy of cholesteric liquid crystals to dynamically shape nanoparticle assemblies at a fluid interface. By adjusting the concentration of surfactant that plays the dual role of tuning the nanoparticle hydrophobicity and altering the anchoring of liquid crystals, we pattern nanoparticles at the interface of cholesteric liquid crystal emulsions. Interfacial assembly is tempered by elastic patterns that arise from the geometric frustration of confined cholesterics. Patterns are tunable by varying both surfactant and chiral dopant concentrations. Adjusting the particle hydrophobicity more finely by regulating the surfactant concentration and solution pH further modifies the rigidity of assemblies, giving rise to surprising assembly dynamics dictated by the underlying elasticity of the cholesteric. Because assembly occurs at the interface with the desired structures exposed to the surrounding water solution, particles can be readily cross-linked and manipulated. This study serves as a foundation for better understanding inter-nanoparticle interactions at interfaces by tempering their assembly with elasticity.

4:06PM C30.00009: Twist fluctuations and rotational diffusion of the director near hedgehog defects in nematic droplets
ALEXIS DE LA COTTE (Presenter), OLAF STENULL, Department of Physics and Astronomy, University of Pennsylvania, PETER COLLINGS, Department of Physosc and Astronomy, Swarthmore College, TOM C LUBENSKY, A. G. YODH, Department of Physics and Astronomy, University of Pennsylvania — When strong homeotropic boundary conditions are set at the interface of emulsion droplets containing a nematic liquid crystal (NLC), the spherical confinement combined with the system bulk elasticity is known to produce a point-like defect called a radial hedgehog with topological charge +1. We measure the director fluctuations about this state and compare them to the predictions of a theoretically calculated normal mode analysis. Three distortion modes are evident experimentally using two different optical microscopy techniques. Using polarizing microscopy, we observe the motion of the two extinction axis and identify two angular diffusions: a fast one, following the angle the axes make in respect to each other, and a slow one, tracking the angle they make in respect to the polarizers' orientations. In bright field, we are also able to measure the translational motion of the hedgehog. Analysis of these distortion modes indicates the possibility of an instability toward a twisted hedgehog configuration in droplets of the NLC 5CB.

4:18PM C30.00010: Artificial spin (and Potts) ice of skyrmions in liquid crystals
AYHAN DUZGUN (Presenter), CRISTIANO NISOLI, Los Alamos National Lab — Artificial spin ices [1] are engineered arrays of mutually interacting, frustrated, single domain magnetic nano-islands that can be characterized at the degree of freedom level and designed in different arrangements for different emergent behaviors [2]. Beyond magnets, similar ideas have been exported to trapped colloids [3] and vortices in pinned superconductors [4]. In this work, we present a proposal to realize them in a new platform: Liquid crystals. Liquid Crystals possess various advantages as a spin ice platform. Skyrmions in liquid crystals [5], can be confined in traps made of light or field gradients where their preferential position in the trap can mimic a binary Ising spin or a Potts variable. By solving partial differential equations for chiral nematic liquid crystals in the presence of constraints, we demonstrate that skyrmions can reproduce the ice-state of square ice and honeycomb ice. We then extend these simulations to Potts systems.

4:30PM C30.00011: Two-Dimensional Hexagonal Boron Nitride Nanosheet as the Planar-Alignment Agent in a Liquid Crystal-Based Electro-Optic Device
RAJRATAN BASU (Presenter), LUKAS ATWOOD, United States Naval Academy — The planar-alignment agent in an electro-optic liquid crystal (LC) device plays an essential role for the LC’s electro-optical characteristics. Rubbed polyimide (PI) layers are conventionally used as the planar-alignment agent in traditional liquid crystal displays (LCDs). Here we experimentally demonstrate that the 2D hexagonal boron nitride (h-BN) nanosheet can serve as the planar-alignment agent in an LC cell. Two h-BN-covered indium tin oxide (ITO) glass slides are placed together to fabricate an LC cell. A nematic LC inside this h-BN-based cell exhibits uniform planar-alignment. This planar-alignment at the molecular scale is achieved due to the coherent overlay of the benzene rings of the LC molecules on the hexagonal BN lattice. This h-BN-based LC cell shows the typical electro-optical effect when an electric field is applied via ITO electrodes. The dielectric measurement across this h-BN-based electro-optic cell shows a standard Fréedericksz transition of the LC, confirming that the 2D h-BN, as the planar-alignment agent, supplies adequate anchoring energy. Finally, we show the h-BN-based LC cell exhibits more optical transparency than a regular PI alignment layer-based LC cell.

4:42PM C30.00012: Peculiar Nonlinear Elasticity of Liquid Crystal Elastomers Revealed by Biaxial Stretching*  
ASAKA TAKEBE, HARUKI TOKUMOTO, KENJI URAYAMA (Presenter), Dept. Macromol. Eng. Sci., Kyoto Institute of Technology —  
Liquid crystal elastomers (LCE) are a combination of liquid crystal and elastomer. The coupling of liquid crystal alignment  
and rubber elasticity results in a unique mechanical property which is often called soft elasticity. The stretching in the  
direction normal to the initial director requires very small mechanical work due to the director rotation along the  
stretching axis. This is clearly observed as a finite plateau region with very low stress in the stress-strain curve. Most of the  
earlier characterizations of finite deformation of LCEs have been conducted using uniaxial stretching. In general, uniaxial  
stretching, however, provides a limited basis for comprehensive understanding of nonlinear elasticity of elastomers,  
because it is only a particular one among all physically accessible deformations. Present work investigates the biaxial  
stress-strain behavior of polydomain nematic elastomers with varying the strains independently in the two directions. We  
have found the peculiarity in nonlinear elasticity of LCEs which has not been characterized by uniaxial stretching  
measurements.

Session C31 DCP: DFT, Embedding, and, Beyond (ES1) BCEC 203 - Timothy Berkelbach, University of Chicago - Tag(s):  
Focus  
2:30PM C31.00001: Projection-based quantum embedding for periodic systems* [Invited]  JASON GOODPASTER  
(Presenter), University of Minnesota — Quantum embedding methods are ideal for describing surface chemistry of large  
periodic systems by using a higher level of theory—such as wave function (WF) theory—for the smaller active site, while  
still accounting for the quantum mechanical interactions with the electrons in the surrounding environment with a more  
computationally tractable level of theory such as density functional theory (DFT). We have developed a projection-based  
quantum embedding approach for the embedding of periodic systems that is numerically exact compared to Kohn-Sham  
DFT. Furthermore, we show that our method can accurately and efficiently reproduce adsorption and reaction energies  
from canonical WF methods and experiments.  
With Huzinaga projection-based embedding, we have shown that the exact KS-DFT calculations and accurate WF-in-DFT  
ergies can be reproduced if both systems are described using the basis set of the full system. However, we find that  
 improved accuracy and efficiency can be obtained for WF-in-DFT if the subsystems are only described in basis functions  
associated with that subsystem. This allows for periodic embedding where the smaller active site is described using non-  
periodic basis functions, and the large environment is treated using periodic basis functions. We have found this approach  
to be highly accurate and significantly cheaper due to the use of a much reduced basis set for the WF region, and it is  
broadly applicable to a large number of chemical systems. With this method, we will be able to accurately describe  
chemistry at interfaces.

Award DE-FG02-17ER16362.  
3:06PM C31.00002: Density Matrix Embedding Theory for Strongly Correlated Solids  HUNG PHAM (Presenter), LAURA  
GAGLIARDI, University of Minnesota — Density matrix embedding theory (DMET) [Phys. Rev. Lett. 2012, 109, 186404] has  
offered a promising wave function-in-wave function embedding method to treat electron correlation for large and  
extended systems. DMET has been gaining some successes for several lattice models and molecular systems. Herein, we  
present an extension of DMET to treat strongly correlated periodic systems, namely pDMET. In our implementation, a unit  
cell is considered as an impurity embedded in the environment made up by other unit cells in the computational supercell.  
The Wannier functions, i.e. the real-space presentation of the wave function, are used to perform the embedding  
calculation. The correlation potential is augmented in the k-space one-electron Hamiltonian to self-consistently minimize  
the difference between the one-electron density matrix at the mean-field level and that at the high-level. We test our  
method using different quantum chemical solvers (e.g. FCI, DMRG-CI, CCSD) on variety of systems, such as one-  
dimensional structure (hydrogen chain), covalent crystal (crystalline silicon), and ionic crystal (magnesium oxide). Finally,  
we discuss the feasibility of extending the method to compute electronic band structures of materials.
Embedded cluster density approximation for exchange-correlation energy: a natural extension of the local density approximation*  
CHEN HUANG (Presenter), Department of Scientific Computing, Florida State University — We developed a local correlation method in the framework of Kohn-Sham density functional theory (KS-DFT). The method is termed embedded cluster density approximation (ECDA) and is a logical extension of the local density approximation. In ECDA, an embedded cluster is defined for each atom based on the finite-temperature density-functional embedding theory. The clusters' XC energy densities are calculated using high-level XC functionals. The system's XC energy is then constructed by patching these locally computed, high-level XC energy densities in the system in an atom-by-atom manner. A key result is the derivation of the relationship between the embedding potential and system's KS potential, based on which we show how to efficiently compute the system's XC potential following the optimized effective potential procedure. The accuracy of ECDA is examined by patching the exact exchange (EXX) and the random phase approximation (RPA) correlation energies in a one-dimensional hydrogen chain, as well as by patching EXX energies in several molecules. We expect ECDA to be a simple, yet effective method to scale up high-level KS-DFT calculations in large-scale strongly correlated systems.

Polaron Modulated Electronic Structures of Doped La$_2$CuO$_4$ by Self-Interaction Corrected Density Functional Theory Approach  
QIUSHI YAO (Presenter), QIANG LIU, Department of Physics, Southern University of Science and Technology — Single-particle ab-initio approaches, e.g., density functional theory (DFT) with standard exchange-correlation functionals, is notorious for its poor treatment of the electronic structures of cuprate superconductors, not to mention their properties upon doping. Here, taking La$_2$CuO$_4$ (LCO) as an exemplar, with both $T$ and $T'$ phase, we show that self-interaction corrected DFT accurately produces the experimentally observed insulator to metal transition, as a function of hole and electron doping concentration, respectively. Based on our calculations, doped carriers form localized polarons under low doping concentration dissolving into extended states upon high doping concentration, thus making the system conducting. The correct description of LCO provides us a practical route to the doping problems of strong correlated materials within Kohn-Sham DFT framework, which is capable to treat a larger supercell than the methods beyond DFT.

Head-to-head comparison of spectral properties of transition-metal oxides using DFT and beyond-DFT methods*  
SUBHASISH MANDAL (Presenter), G.L. PASCUT, KRISTJAN HAULE, KARIN RABE, DAVID VANDERBILT, Physics and Astronomy, Rutgers University, Piscataway, NJ, United States — The development of computational tools for the accurate prediction of the electronic structure of strongly correlated materials has been an active field of research for several decades. As a result, a variety of methods, including density functional theory (DFT), DFT+U, hybrid functionals, meta-GGAs, GW quasiparticle approaches, and DFT-embedded dynamical mean field theory (DMFT), are now available. Among these, the beyond-DFT methods have been instrumental for understanding the electronic structure of strongly correlated systems, but it is unclear how reliable are those methods when applied to typical strongly correlated solids. It is thus of pressing interest to compare the quality of these methods as they apply to different categories of materials. Here we begin by systematically testing these methods on transition-metal oxides (TMOs) such as FeO, CoO, MnO, and NiO, which provide a suitable platform since conventional DFT methods are known to fail to predict their electronic structure accurately. We present a head-to-head comparison of spectral properties as obtained using the listed methods, and compare with experimental photoemission data where available.

*This research is supported by NSF DMREF DMR-1629059 and NSF-DMR-1629346

Bridging molecular dynamics and correlated wave-function methods for accurate finite-temperature properties*  
DARIO ROCCA (Presenter), ANANT DIXIT, MICHAEL BADAWI, SÉBASTIEN LEBÊGUE, Université de Lorraine and CNRS, Nancy (France), TIM GOULD, Griffith University, Nathan (Australia), TOMÁŠ BUČKO, Comenius University and Slovak Academy of Sciences, Bratislava (Slovakia) — We introduce the "$\;`\;selPT`\;" perturbative approach, based on ab initio molecular dynamics (AIMD), for computing accurate finite-temperature properties by efficiently using correlated wave-function methods. We demonstrate the power of the method by computing a prototypical molecular enthalpy of adsorption in zeolite (CH$_4$ on protonated chabazite at 300 K) using the random phase approximation. Results are in excellent agreement with experiment. The improved accuracy provided by selPT represents a crucial step towards the goal of truly quantitative AIMD prediction of experimental observables at finite temperature.

4:06PM C31.00007: Towards a molecular-level understanding of metal-like conductivity in bacterial protein nanowires*  
PETER DAHL (Presenter), Molecular Biophysics and Biochemistry, Yale Univ, ATANU ACHARYA, Chemistry, Yale Univ,  
SIBEL EBRU YALCIN, SOPHIA YI, J. PATRICK O'BRIEN, Molecular Biophysics and Biochemistry, Yale Univ, VICTOR BATISTA,  
Chemistry, Yale Univ, NIHIL MALVANKAR, Molecular Biophysics and Biochemistry, Yale Univ — Protein appendages of Geobacter sulfurreducens exhibit metal-like conductivity and transport electrons at rates rivaling to those of metallic carbon nanotubes. Our recent experiments have revealed an increase in \( \pi \)-stacking upon lowering the pH of nanowires leading to a 100-fold increase in conductivity and carrier density. We employed molecular dynamics simulations to obtain a molecular-level understanding of the enhanced \( \pi \)-stacking obtained under highly acidic pH. Electronic structure calculations were also performed using QM/MM technique to elucidate the frontier orbitals and the energy gap between them. Our MD simulations suggest that under highly acidic pH significant structural rearrangement of the protein structure leads to the enhanced \( \pi \)-stacking. Electronic structure calculation reveals that the enhanced \( \pi \)-stacking results in higher coupling between the carrier states. Hence, conductivity is increases by several fold at highly acidic pH. Our results suggest that significant orbital overlap between adjacent charge carriers is pivotal in the observed conductivity of these nanowires.

4:18PM C31.00008: A finite-field approach to performing GW calculations and solving the Bethe-Salpeter equation  
[Invited] GIULIA GALLI (Presenter), University of Chicago — We describe a finite field approach to compute density response functions, and to compute optical spectra and exciton binding energies of molecules and solids based on the solution of Bethe-Salpeter equation. The approach allows for efficient G0W0 and G0W0\( \Gamma \) calculations as well as for the calculation of optical spectra beyond the random phase approximation.

In addition it utilizes localized orbitals obtained from Bloch states with bisection techniques, thus greatly reducing the complexity of the calculation and enabling the efficient use of hybrid functionals to compute input orbitals, when using a plane-wave representation.

Monday, March 4, 2019 2:30 PM - 5:06 PM

Session C32 DCP: Theory and Experiment for Complex Systems in Gas Phase (A) BCEC 204A -

2:30PM C32.00001: Theory meets experiment in gas-phase spectroscopy: the VMS bridge [Invited] VINCENZO BARONE  
(Presenter), Scuola Normale Superiore — The impressive advances in hardware developments, the availability of powerful graphical interfaces together with the set-up of effective and user-friendly software are leading to a new generation of virtual tools able to deal effectively with the complex systems and phenomena of current interest in the fields of molecular spectroscopy, chemistry (also astrochemistry) and biology. Moving from the presentation of theoretical results as a collection of numbers corresponding to models (often oversimplified) to the \textit{vis-à-vis} comparison between "in silico" and "in vitro" spectral outcomes, possibly combined with 3D renderings and natural interfaces, should at last overcome the diffidence of experimentalists towards theoreticians and bridge the gap between experiment and theory. Among the available virtual instruments, we focus here on the multifrequency spectrometer (VMS) our group has been developing in the last few years (see, V. Barone, WIREs Comput Mol Sci 6, 86-110 (2016)), which allows a \textit{vis-à-vis} comparison of experimental spectra with their simulated counterparts as well as the interpretation of the results in terms of the interplay among different well defined effects. The main building blocks of this tool are, apart from powerful 3D pre- and post-processing tools: (a) first-principle approaches based on composite schemes involving post-Hartree-Fock methods complemented by models based on the density functional theory for the proper description of stationary points and their local environment on the pertinent potential energy surfaces; (b) integrated perturbative/variational treatments for describing nuclear motions beyond the rigid rotor / harmonic oscillator level. In this presentation I will sketch the present status of VMS and the ongoing efforts toward increasing its range of application with special reference to different spectroscopies in the gas-phase. Some case studies will be selected to better illustrate the above concepts.
3:06PM C32.00002: Broadband Rotational Spectroscopy of Odorants and their Complexes: Experiment and Theory in Concert* [invited] MARI EUGENIA SANZ (Presenter), Chemistry, King's College London — Studies of large molecules and their complexes in gas phase using spectroscopic techniques provide experimental data on their structures and interactions that can be directly compared with predictions from theory. One of the most powerful methods for structural determination is rotational spectroscopy, which can identify different coexisting conformations and determine actual atom positions, thus enabling calculation of bond lengths and angles. The development of broadband rotational spectroscopy, allowing fast collection of broad segments of the spectrum at once, has dramatically extended the range and complexity of the molecular systems that can be tackled and opened new opportunities to benchmark theoretical methods.

In this talk we will present our results on the conformations and interactions of several odorants, and their complexes with water and mimics of amino acid residues. Using broadband rotational spectroscopy and quantum chemistry calculations, we have obtained detailed information on their structures and conformational preferences, identifying the global minimum for each system and the prevailing interactions. For the complexes, primary binding sites have been located and the interplay between intra- and intermolecular interactions has been characterised. Comparison between experimental and theoretical results allows evaluation of the theoretical methods used and indicates possible avenues to further improve the theoretical description of complex molecular systems.

3:42PM C32.00003: Exploring conformational landscapes of chiral molecules in their solvation and self-aggregation clusters* [invited] YUNJIE XU (Presenter), University of Alberta — Our research program focuses on applying and developing new spectroscopic tools to bridge the gap of our understanding in terms of structural and dynamical properties of an isolated chiral molecule and of it in liquid phase and in solution. Using broadband rotational spectroscopy aided by high level ab initio calculations, we probe structural diversity and emerging bulk behavior in trimeric and tetrameric aggregates of the transiently chiral 2-fluoroethanol (FE). We show that the FE tetramer is an intriguing system at the interface between gas- and bulk-phase behavior, where the conformational specificity seen in the gas-phase is still experimentally relevant but plays a diminished role relative to the intermolecular topology and cooperative stability. In the second example, we examine conformational landscapes of tetrahydro-2-furoic acid (THFA), a chiral carboxylic acid, and its dimer and its complexes with water molecules in a jet expansion using rotational spectroscopy. We also apply vibrational circular dichroism and Raman optical activity to probe how intermolecular interactions with water and THFA itself influence the aforementioned conformational preference in condense phase directly. The interplay between experiment and theory is essential for all the work described.

*This research was funded by the Natural Sciences and Engineering Research Council of Canada, Canada Foundation for Innovation, Alberta Enterprise and Advanced Education, and by the University of Alberta. We gratefully acknowledge access to the computing facilities by the Shared Hierarchical Academic Research Computing Network, the Western Canada Research Grid (Westgrid), and Compute/Calcul Canada. YX holds a Tier I Canada Research Chair in Chirality and Chirality Recognition.

4:18PM C32.00004: Conformational Preferences of Gas Phase Peptides and Synthetic Foldamers: Challenges to Theory and Experiment* TIMOTHY ZWIER (Presenter), KARL N BLODGETT, CHRISTOPHER P HARRILAL, JOSHUA L FISCHER, JOHN T LAWLER, DEWEI SUN, Purdue University — This talk will describe combined experimental/computational studies of the conformational preferences of isolated, beta-peptide foldamers as neutrals, probing the development of mixed 10/12 helices with size. We will also describe our work on cryo-cooled protonated peptides in the gas phase, including a study of peptides capable of forming salt bridges. In both contexts, the need for accurate and fast exploration of the conformational landscape is crucial to success. The prospects and limits of both theory and experiment will be discussed.

*The authors gratefully acknowledge support for this work from the NSF under grant CHE-1764148.
On optical confinement to length scales arbitrarily smaller than the wavelength. Further discuss some computational progress with regard to coupling efficiency and some prospective technologies based on polarimetry measurements of a tightly focused vortex beam. We module into a near-field scanning optical microscope, we have built a confocal spectroscope for transmittance measurements in the VIS and SWIR, and we report on polarimetry measurements of a tightly focused vortex beam. We have previously reported our novel nanofabrication process, which leverages the conformal nature of atomic layer deposition (ALD), and which produces high aspect ratio nanocoaxes. In this work, we report in more detail some optical transmission measurements, particularly related to signatures of coupling into the fundamental mode. We have relatively few experimental works. To interrogate these structures, we have integrated an optical vortex generation module into a near-field scanning optical microscope, we have built a confocal spectroscopic module for transmittance measurements in the VIS and SWIR, and we report on polarimetry measurements of a tightly focused vortex beam. We further discuss some computational progress with regard to coupling efficiency and some prospective technologies based on optical confinement to length scales arbitrarily smaller than the wavelength.

4:30PM C32.00005: Quantum Dynamics of Intramolecular Double Hydrogen Transfer in Porphycene  
YAIR LITMAN (Presenter), Theory, Fritz Haber Institute of the Max Planck Society, JEREMY OSCAR RICHARDSON, Physical Chemistry, ETH Zurich, TAKASHI KUMAGAI, Physical Chemistry, Fritz Haber Institute of the Max Planck Society, MARIANA ROSSI, Theory, Fritz Haber Institute of the Max Planck Society — The making and breaking of H-bonds on highly anharmonic potential energy surfaces involved in proton and hydrogen transfer reactions require a full-dimensional quantum mechanical treatment of not only electrons, but also of nuclei. Here we demonstrate that dealing with this complexity is necessary for achieving predictive simulations that can solve puzzling properties of these reactions by addressing the intramolecular double hydrogen transfer (DHT) in porphycene[1]. Our theoretical treatment combines dispersion corrected hybrid density-functional theory calculations and path-integral ring-polymer methods. Our simulations predict the position and width of the N-H stretching band of porphycene and DHT rates in excellent agreement with experiments, thus confirming our determination of the tunneling pathways and the anharmonic mode couplings that play a role in this reaction. They also confirm the importance of the usually ignored competition between concerted and stepwise DHT pathways for this system. Our general theoretical approach provides a quantitative framework for a deeper physical understanding of hydrogen transfer dynamics in complex systems. [1] Y. Litman, J. O. Richardson, T. Kumagai, M. Rossi. arXiv:1810.05681 (2018)

4:42PM C32.00006: A Stochastic Non-empirical approach in the problem of the reaction path seeking*  
IURII NAGORNOV (Presenter), RYOSUKE AKASHI, Department of Physics, University of Tokyo — In the atomistic simulation methods, the escaping trajectories, which is rendered rare because of the potential energy barrier, and free-energy landscape along them are usually calculated by applying artificial force and/or empirical collective variables. Our motivation is to develop the method free from such artificial forces and collective variables. We developed a non-empirical scheme to search for the minimum-energy escape paths from the minima of the potential surface to unknown saddle points nearby. This method employs only the local gradient and diagonal part of the Hessian matrix of the potential [R. Akashi, YSN, J. Phys. Soc. Jpn. 87, 063801 (2018)]. In our method we employ a stochastic equation, with which the distribution of the “walkers” representing atomic positions move up the potential surface through the valleys to the saddle points. The key to the successful tracking of the minimum-energy paths is the choice of the initial position. We designed a systematic method to generate initial atomic coordinates and efficiently simulate the paths to the saddle points starting from them. We demonstrate our method with several systems such as argon clusters.

*MEXT as Exploratory Challenge on Post-K computer (Frontiers of Basic Science: Challenging the Limits)

4:54PM C32.00007: N-Body networks for molecular simulation*  
BRANDON ANDERSON (Presenter), RISI KONDOR, TRUONG SON HY, Computer Science, University of Chicago — We introduce a novel deep learning architecture for learning molecular force fields. Our architecture, called CGnet, “bakes in” the underlying rotational invariance of the problem using the Clebsch-Gordan operator. We apply CGnet to the molecular N-Body problem of learning force-fields from ab-initio molecular dynamics simulations. We find state-of-the-art results when applied to the MD-17 dataset. We also train CGnets on QM9 and find competitive results. Finally, we provide a set of tools, called FastCG, along with an interface with PyTorch and Tensorflow, to allow for fast and efficient calculation of CG products, along with their analytical gradients.

*DARPA Young Faculty Award for Multiresolution Machine Learning for Molecular Modeling D16AP00112

Session C33 FIAP: Applied Photonics BCEC 204B - Juan Merlo

2:30PM C33.00001: Optical Confinement in Nanocoaxial Waveguides: Coupling to the Fundamental TEM-Like Mode  
YITZI M CALM (Presenter), LUKE D'IMPERIO, NATE T NESBITT, JUAN M. MERLO, AARON H ROSE, MICHAEL J BURNS, KRZYSZTOF KEMPA, MICHAEL J NAUGHTON, Boston College — The nanocoax has demonstrated confinement of VIS and NIR light, and calculations show that extreme confinement can be achieved by coupling to the fundamental mode. We have previously reported our novel nanofabrication process, which leverages the conformal nature of atomic layer deposition (ALD), and which produces high aspect ratio nanocoaxes. In this work, we report in more detail some optical transmission measurements, particularly related to signatures of coupling into the fundamental mode. While there have been many computational works concerning the excitation of the fundamental mode at optical frequencies, to date there have been relatively few experimental works. To interrogate these structures, we have integrated an optical vortex generation module into a near-field scanning optical microscope, we have built a confocal spectroscopic module for transmittance measurements in the VIS and SWIR, and we report on polarimetry measurements of a tightly focused vortex beam. We further discuss some computational progress with regard to coupling efficiency and some prospective technologies based on optical confinement to length scales arbitrarily smaller than the wavelength.

2:42PM C33.00002: Packaging of surface nanoscale axial photonic microresonators*  MATHIEU COUILLARD
(Presenter), PABLO BIANUCCI, Concordia University — Due to their high Q factor and small volume surface, nanoscale axial photonic (SNAP) resonators have been used to study nonlinear effects, sensing, optomechanics and many other applications. The best way to couple light into SNAP resonators is through the evanescent field of a tapered fiber. However, these tapered fibers are fragile, and SNAPs are very sensitive to their environment. These factors make SNAP resonators difficult to transport and keep intact for long periods of time without some kind of packaging. We present an inexpensive technique for packaging SNAP resonators as a pigtail device using a 3D printed housing and low index optical epoxy. We then report the effects of this packaging technique on the spectra and measure the change in spectra due to impact, heat and environmental impurities.

*We would like to acknowledge support from the National Science and Engineering Research Council (NSERC) of Canada, through the Discovery Grant program (grant 435875-2013).

2:54PM C33.00003: Time Stretch Single-shot Terahertz Analyzer  TIANWEI JIANG (Presenter), CEJO KONUPARAMBAN LONAPPAN, Department of Electrical and Computer Engineering, University of California, Los Angeles, CLÉMENT EVAIN, CHRISTOPHE SZWAJ, ELÉONORE ROUSSEL, MARC LE PARQUIER, SERGE BIELAWSKI, PIAM, Université Lille 1, BAHRAM JALALI, Department of Electrical and Computer Engineering, University of California, Los Angeles — Terahertz technology has important applications in security due to its penetration in common packaging material. Being able to measure bursts of THz signal in real-time has applications in medicine, data communication, compact radar, and particle accelerators. Unfortunately, the established terahertz instrumentation systems have a slow response and are not capable of real-time measurements. Photonic Time Stretch is a data acquisition method which enables continuous recording of fast single shot events over long record lengths. It has been successfully used to capture THz emission due to electron bunching in synchrotrons, and has led to the discovery of new phenomena in optics such as optical rogue waves and soliton molecule dynamics. In this talk we will provide an overview of Time Stretch technology with emphasis on its design for THz operation. We will describe several methods for overcoming the frequency fading phenomena including single sideband, phase diversity and inverse propagation methods as well as balanced detection for common mode rejection to achieve high sensitivity. We will also describe its implementation at optical frequencies.

3:06PM C33.00004: Excitation Dynamics of MoS2 Using Optical Pump-THz Probe Magneto-spectroscopy  ASHLYN BURCH (Presenter), ANDREW GARRISON LINN, BIPLOB BARMAN, Physics, University of Alabama at Birmingham, DENIS KARAISKAJ, Physics, University of South Florida, STEPHEN A MCGILL, National High Magnetic Field Laboratory, DAVID J. HILTON, Physics, University of Alabama at Birmingham — THz spectroscopy is a method that can be used to study transitional metal dichalcogenide material systems on ultrafast time scales by determining the quantum effect of emitted THz radiation and phase on the material under extreme conditions.1 Monolayer molybdenum disulfide (MoS2) has been broadly studied and displays electron-phonon interactions and exciton-exciton scattering that influence the coherence time and often are the driving component for the application of this material.2 These measurements were performed on bulk MoS2, using an optical pump-terahertz probe spectrometer that operated under high magnetic fields (< 25 T) at the National High Magnetic Field Laboratory in Tallahassee, Florida. The response of this material was measured under different constant magnetic fields using an air-biased coherent detection system (ABCD) by tracing optical pump delays while sitting at the peak of the transmitted THz pulse.

3:18PM C33.00005: Bragg Filters for Integrated Photonic Circuity*  QINGYING CHEN (Presenter), SCOTT HOLMSTROM, Department of Physics and Engineering, University of Tulsa, Tulsa 74104, United States, NATHAN TYNDALL, TODD STIEVATER, Optical Science Division, Naval Research Lab, Washington DC 20375, United States — We report the design, fabrication, and measurement of waveguide Bragg filters for use in integrated Raman- and fluorescence-based spectroscopy and sensing systems. A periodic effective index was produced by a series of silicon nitride (SiN) patches located adjacent to and on both sides of a straight SiN waveguide. A chirp was applied to the length and spacing of the patches to broaden the reflection bandwidth. The filters were simulated using an eigenmode expansion solver and manufactured at a photonic integrated circuit (PIC) foundry.

*This material is based on research sponsored by Air Force Research Laboratory under agreement number FA8650-15-2-5220.
Integrated spin wave AND gate using iron garnet film

TAICHI GOTO (Presenter), TAKUYA YOSHIMOTO, Toyohashi University of Technology, CAROLINE ANNE ROSS, Massachusetts Institute of Technology, KOJI SEKIGUCHI, Yokohama National University, ALEXANDER B. GRANOVSKY, Moscow State University, YUICHI NAKAMURA, HIRONAGA UCHIDA, MIHUTERU INOUE, Toyohashi University of Technology — Spin wave (SW) attracts many interest as a candidate of post-CMOS device. Previously we demonstrated XNOR or AND/OR logic gates using interference of forward volume (FV) SW propagating in a 10 μm thick yttrium iron garnet (YIG) film [1]. However the size of these gate is mm order because YIG and electrodes for excitation and detection of SW were fabricated discretely. Therefore, integration of electrodes on YIG and miniaturization of YIG waveguide is essential for demonstration of further functionality.

In this work, we fabricated ψ-shape spin wave waveguide to demonstrate electrodes integrated AND logic gate. A 200 nm thick YIG was fabricated on garnet substrate using liquid phase epitaxy. YIG film was etched into ψ-shape using electron beam lithography and wet etching. The width of YIG film was 14 μm. Then four coplanar waveguides (CPWs) for excitation and detection of FV SW were placed on YIG waveguide. To measure a field dependence of propagation properties of FV SW, CPWs and vector network analyzer were connected via micro-probe to measure the scattering parameters. Successfully, the AND gate using FV SW phase interference was demonstrated, comparable to the case using 10 μm thick YIG. This is the smallest AND gate using spin wave.

Demonstration of Inverse Designed Broadband Cavity-Waveguide Couplers*

JINHIE SKARDA (Presenter), KYOUL YANG, DRIES VERCRUYSSE, NEIL V. SAPRA, LOGAN SU, ALEXANDER Y. PIGGOTT, JELENA VUCKOVIC, Stanford University — The ability to control cavity-waveguide coupling over a wide wavelength span is necessary in a number of applications such as frequency conversion and frequency comb generation. However, achieving a specified target coupling at multiple wavelengths using the conventional approach of evanescent coupling is an outstanding challenge. In our approach, we instead treat the cavity-waveguide coupling region as a 2-input, 2-output port device and optimize the structure to produce the desired coupling spectrum. This inverse design method enables us to specify any coupling spectrum as our optimization objective, and the fabrication-constrained optimization produces coupler structures that are fully fabricable with standard lithography processes. We experimentally demonstrate our ability to control the coupling spectrum between a straight waveguide and racetrack resonator on 220 nm SOI while maintaining a Q factor of about 30,000. Our progress on efficient coupling over an octave span is an important step for integrated nonlinear photonics.

Electrostatically and Optically Gated Field Emission Transistors

WILLIAM JONES (Presenter), Jet Propulsion Laboratory, LUCIA DEROSE, AXEL SCHERER, Applied Physics, California Institute of Technology — Recently, several groups have demonstrated that plasmonically trapped light can optically stimulate ultra-fast field emission of electrons [1] [2] by taking advantage of the sub-wavelength confinement of light at the metal/air interface to generate the intense electric fields needed to tunnel an electron into vacuum. Nanoscale field emission transistors produce the same magnitude fields electrostatically by applying modest voltages over nanoscale distances [3]. We have combined both principles and produced nanoscale field emission transistors integrated into hybrid plasmonic waveguides on a SOI platform. These devices can be optically or electrostatically gated and may serve as building blocks for ultra-fast optoelectronic circuits.

modulated through gate voltage (Vg) applied to a reverse biased III-V Schottky diode [IEEE TED 61(4), pp.1006-1013, 2014].

The 2DEG density in Transistor (HEMT) used in high speed RF circuits and routinely operated at >100GHz frequencies. We present a modified rate beyond 100GBps [Nature 562, pp.101–104, 2018]. We propose a design inspired by III-V High Electronic Mobility heterostructures.

The bandwidth in electro-optic materials is limited by R-C time constants of the electrical contacts, resulting in high bit error rate beyond 100GBps [Nature 562, pp.101–104, 2018]. We propose a design inspired by III-V High Electronic Mobility Transistor (HEMT) used in high speed RF circuits and routinely operated at >100GHz frequencies. We present a modified Drude model to analyze the strength of the plasma dispersion effect of the 2DEG at the III-V interface. The 2DEG density is modulated through gate voltage (Vg) applied to a reverse biased III-V Schottky diode [IEEE TED 61(4), pp.1006-1013, 2014].

Plasma dispersion due to 2DEG is dominant as compared to free charge carriers in the AlGaN barrier. We obtain an analytical expression for the carrier induced electro refraction:

\[ \Delta n = \frac{-e\lambda^2\varepsilon_x (V_g - V_{th})}{8\pi^2c^2n_d(m^*_{2DEG})^2} \]

\( V_{th} \) is threshold voltage corresponding to pinch-off for the 2DEG and other symbols are per standard notation. As compared to multi-quantum well intersubband modulators, the structure we propose is easier to fabricate and analyze. The simple device structure enables several methods of coupling light, making a waveguide manifestation feasible.

\[ \Delta n = \frac{-e\lambda^2\varepsilon_x (V_g - V_{th})}{8\pi^2c^2n_d(m^*_{2DEG})^2} \]

4:54PM C33.00013: Localization of light induced by pulling a fiber* TABASSOM HAMIDFAR (Presenter), PABLO BIANUCCI, Concordia University — Optical microresonators based on whispering gallery modes (WGM) can be potentially used in many areas of science and technology including telecommunications, microfluidics, optomechanics, and others. They are dielectric convex structures that confine light through total internal reflection. Out of the many available types of WGM microresonators, the surface nanoscale axial photonics (SNAP) platform enables fabrication of resonant ultralow loss photonics structures at the surface of an optical fiber. Due to their flexibility, and ultra-low loss, which lead to the creation of high-quality WGMs, they have great potential applications as photonic micro-devices in switching, slowing light, filtering, lasing and sensing with high precision. In this work, we propose a new technique for the creation of SNAPs, by using a regular hydrogen-oxygen torch, which requires less equipment than current techniques. We characterize our resonator by evanescent spectroscopy using a tapered fiber for coupling. The transmission spectra shows that light can be fully localized by pulling a fiber, with the potential to host very low loss resonant modes.

5:06PM C33.00014: Quantum Confined Stark Effect in Phase-Pure Thick-Shell CdSe/CdS Quantum Dots* LEI ZHANG (Presenter), HONGYU YANG, YUFEN YUAN, YIPING CUI, JIAYU ZHANG, Advanced Photonics Center, Southeast University — Colloidal semiconductor quantum dots (QDs) have recently attracted great attention in electric fields sensing via the quantum confined Stark effect (QCSE). Here, the QCSE in ensemble of phase-pure wurtzite CdSe/CdS QDs is studied by applying a uniform external electric field. We observe a clear field-dependent PL and absorption modulations, including the spectral shifts and broadening, as well as the changes in its intensity. The Stark shifts in ensemble emission and absorption are found to be typical quadratic function of the external field. Moreover, the multiexciton states also exhibit obvious optical responses to the electric field, with a decrease of 18% in emission intensities and an increase in the ultrafast lifetime from 25 to 31 ps. The results imply that the field-induced QCSE in the QD ensemble are attributed to the effective suppression of the primary source of local field in such thick-shell QDs, thus proving that an efficient field control over the optical properties (the changes in emission and absorption intensity, spectral shifts, and PL lifetime) in these nanoparticles is feasible and open the potential possibility of field-sensitive QDs to achieve real-time electro-optic sensing.

Session C34 GIMS: Keithley Session BCEC 205A - Tag(s): Invited
2:30PM C34.00001: Making the invisible visible: Spins probed with soft x-rays* [Invited] ELKE ARENHOLZ (Presenter), Lawrence Berkeley National Laboratory — The advancement of spintronics relies on our improved understanding spin based phenomena and our ability to engineer materials with specific magnetic and transport properties. In this talk, we will highlight the contributions optimized soft x-ray based characterization tools can make to this endeavour.

Chiral domain walls are promising candidates for low-energy consumption memory and logic devices. We engineered chiral domain wall arrays in Pt/Co/Cu multilayers and using resonant soft X-ray diffraction find that the chirality of the magnetic spin textures in the surface near region reverses as function of layer thickness due to the interplay of competing driving forces (DMI, magnetic anisotropy, magnetic dipole interaction). [1]

The recent discovery of magnetic long-range order in two-dimensional van der Waals materials opens up new opportunities for spintronics. We employed soft X-ray photoemission electron microscopy (PEEM) to image the domain configuration of Fe₃GeTe₂. We find that the magnetic long-range order in micron scale Fe₃GeTe₂ pattern leads to an unconventional out-of-plane stripe-domain phase that undergoes a transition to an in-plane vortex phase with increasing temperature. [2]

Spin currents are mostly detected indirectly through measurement of spin-torque driven magnetization precession, spin-current induced second harmonic optical effects, inverse spin Hall effect (ISHE), etc. We have succeeded in monitoring a pure ac spin current directly through a Py/Cu/Co multilayer with by X-ray detected ferromagnetic resonance (XFMR). [3]

In this talk, the powerful X-ray instrumentation optimized for these studies of spintronics phenomena will be discussed.

3:06PM C34.00002: Resonant Inelastic X-ray Scattering of Energy Materials: from Fundamental Understandings to Practical Developments* [Invited] WANLI YANG (Presenter), Lawrence Berkeley National Laboratory — The pressing demand of improving the energy device performance calls for new concepts that require characterization techniques beyond conventional probes. With much improved throughput, ultra-high efficiency mapping of Resonant Inelastic X-ray Scattering (mRIXS) has opened up RIXS as such a powerful technique. This has become a timely and critical solution to characterize the novel electronic states of both transition-metals and oxygen involved in electrochemical devices, i.e., batteries, for energy applications.

In this presentation, we first show that the electrochemical performance of batteries is fundamentally defined by many intrinsic physics parameters of the materials, e.g., spin states, ionization energy, crystal field etc., which could be approached through conventional spectroscopy [1]. However, modern concepts based on novel states in batteries are often difficult to be clarified and require tools that are more incisive. We demonstrate that these unconventional states could be clearly addressed through mRIXS experiments [2]. In particular, mRIXS could distinguish the critical lattice oxygen activities in batteries, and precisely quantify its contributions, reversibility, and cyclability upon electrochemical cycling. mRIXS findings clarify many misunderstandings of the mysterious oxygen activities in battery electrodes and indicate independent oxygen behaviors that are intrinsically determined by the material physics, something that has been indiscreetly taken for granted [3]. At the end, we show that mRIXS results have gone beyond fundamental understandings and led to guidelines for future material developments and optimizations.

Laser ARPES on High Temperature Superconductors and Quantum Materials

The mechanism of high temperature superconductivity in the copper-based and iron-based superconductors remains a prominent and challenging issue in condensed matter physics. Angle-resolved photoemission spectroscopy (ARPES), as a powerful technique to directly probe the electronic structure of materials, has played a key role in studying high temperature superconductors, as well as other quantum materials. In this talk, I will first briefly introduce ARPES technique, in particular, the latest development of vacuum-ultra-violet (VUV) laser-based ARPES systems. Then I will highlight some ARPES results on topological materials including Bi$_2$Se$_3$, monolayer silicene, and ZrTr$_5$. Finally, I will report some of our recent results in utilizing the state-of-the-art laser-based ARPES to study high temperature cuprate superconductors and iron-based superconductors.

Joseph F. Keithley Award For Advances in Measurement Science Talk: Science Driven Instrumentation and Applications with Soft X-rays

Sharper and sharper experimental tools are often crucial for understanding of novel physical phenomena and making new discoveries. Today in condensed matter physics we are experiencing need for revolutionary new instrumentation for understanding interplay of many degrees of freedom interacting at different energy, length and time scales. These interactions lead to new phases of matter and emergent phenomena such as high temperature superconductors, topological insulators and two dimensional transition metal dichalcogenides, to name a few. The primary focus of my talk is to present some of the novel soft x-ray instrumentation developed during the last two decades at the Advanced Light Source and their science applications, through various examples for unraveling the emergent phenomena in quantum materials and energy related challenges. My talk will include advanced instrumentation for Angle-Resolved Photoemission Spectroscopy (ARPES), Ambient Pressure XPS and Resonant Inelastic X-ray Scattering (RIXS).

2:30PM C35.00001: Circuit Quantum Electrodynamics with superconductor-semiconductor hybrid systems (Invited)
PASQUALE SCARLINO (Presenter), DAVID VAN WOERKOM, ETH Zurich, UDSON MENDES, Univ. of Sherbrooke, CLEMENS MUELLER, JONNE KOSKI, ANDREAS LANDIG, JANN HINNERK UNGERER, CHRISTIAN KRAYLUND ANDERSEN, SIMONE GASPARINETTI, CHRISTIAN REICHL, WERNER WEIGSCHERER, KLAUS ENSSSLIN, THOMAS IHN, ETH Zurich, ALEXANDRE BLAIS, Univ. of Sherbrooke, ANDREAS WALLRAFF, ETH Zurich — Semiconductor qubits rely on the control of charge and spin degrees of freedom of electrons or holes confined in quantum dots (QDs). Typically, semiconductor qubit-qubit coupling is short range, effectively limiting qubit distance to the spatial extent of the wavefunction of the confined particle (a few hundred nanometers). This is a significant constraint towards scaling of QD-based architectures to realize dense 1D or 2D arrays of QDs. Inspired by techniques originally developed for circuit QED, we recently demonstrated the strong coupling of individual electrons [1,2] confined in GaAs quantum dots to individual microwave photons, making use of the enhanced electric component of the vacuum fluctuations of a resonator with impedance beyond the typical 50 Ohm of standard coplanar waveguides. In this hybrid technology, we recently realized a proof of concept experiment, where the coupling between a transmon and a double QD (DQD) is mediated by virtual microwave photon excitations in a high impedance SQUID array resonator, which acts as a quantum bus enabling long-range coupling between dissimilar qubits [3]. Similarly, we achieved coherent coupling between two DQD charge qubits separated by approximately 50 um [4]. In the dispersive regime, we spectroscopically observed qubit-qubit coupling as an avoided-crossing in the energy spectrum of the DQD charge qubits. The methods and techniques developed in this work are transferable to QD devices based on other material systems and can be beneficial for spin based hybrid systems [5].

3:06PM C35.00002: Towards cavity-mediated coupling of spin-qubits (Invited)
FELIX BORJANS (Presenter), XANTHE CROOT, XIAO MI, JASON R PETTA, Department of Physics, Princeton University — While single-qubit gates with fidelities approaching superconducting qubits have been demonstrated [1] and two-qubit gates based on nearest-neighbour exchange are being realized with improved performance on length scales of a few hundred nanometers [2-4], cavity-mediated coupling of spin-qubits over ~1 cm distances remains an outstanding challenge. With the recent demonstration of strong-coupling of a single electron-spin to the electric field of a cavity photon [5, 6], this long-range entanglement between two spin-qubits is within reach. Here we present recent progress in our effort to complete this milestone.

3:18PM C35.00003: Multi-qubit entangling gates for spins in silicon (Invited)
MICHAEL GULLANS (Presenter), JASON R PETTA, Physics, Princeton University — Implementing large-scale algorithms on a quantum computer will require efficient gate compilation strategies to reduce overhead. We recently demonstrated an efficient CNOT gate for spins in Si [1]. The gate operates in a regime where the magnetic field gradient exceeds exchange. By turning on exchange, it is possible to implement a CNOT gate in a single step using resonant microwave excitation. We will discuss possible extensions of the resonant gate in more complex device architectures [2] and present a detailed analysis of multi-qubit gate fidelities.

*Research sponsored by ARO grant No. W911NF-15-1-0149 and the Gordon and Betty Moore Foundation's EPIQS Initiative through Grant GBMF4535.
We present results on superconducting resonators made of thin titanium nitride, studied in an in-plane magnetic field. By implementing a lattice of penetration holes with sizes comparable to the superconducting penetration length, we observe the resonators remain resilient to small out-of-plane magnetic fields. The resonators are then combined with novel 2D materials to serve as a sensitive quantum-coherent probe of condensed-matter properties.

3:42PM C35.00005: Design of Multi-chip Module with High Impedance Microwave Resonators for cQED Experiments with Si/SiGe Quantum Dots

We describe in a general perturbation theory approach the origin of the couplings of a spin qubit to a superconducting cavity as a low-energy limit. Special attention is paid to the so-called curvature couplings related to qubit’s quantum capacitance, which is derived as a low-energy limit of a perturbation expansion to second order. We discuss the applicability of these couplings to current experiments with multi-dot spin-qubits, including single-, double, and triple-dot quantum dot qubits, as well as with superconducting qubits.

3:54PM C35.00006: Integrating singlet-triplet qubits with superconducting resonators

*This work was supported by the Army Research Office Grants No. W911NF-15-1-0203 and No. W911NF-17-1-024.
In this work we explore this sweet-spot regime, which provides both resilience to charge noise and strong dipolar coupling to the resonator. We analyze the trade-offs between strong coupling, relaxation, dephasing, and leakage to the (0,2) singlet state, and we maximize the resulting gate fidelities. We identify a wide window in parameter space over which the qubit-resonator system can achieve two-qubit gate fidelities above 95%.

**4:30PM C35.00009: Two-qubit gates between quantum dot spins coupled by a resonator**† ADA WARREN (Presenter), EDWIN BARNES, SOPHIA ECONOMOU, Virginia Tech — Recent experimental work with silicon qubits has shown that it is possible, using an inhomogeneous magnetic field, to strongly couple the modes of a superconducting resonator to the spin of a single electron trapped within a double quantum dot. This suggests the possibility of realizing long-range spin-spin interactions mediated by cavity photons. We present here our theoretical calculation of the effective interaction between distant quantum dot spins coupled via a resonator and our proposed cavity-mediated two-qubit gate.

*This work is supported by the Army Research Office (W911NF-17-0287).

**4:42PM C35.00010: Highly coherent spin states in carbon nanotubes coupled to cavity photons**† TINO CUBAYNES (Presenter), MATTHIEU DELBECQ, MATTHIEU DARTIAILH, RÉOUVEN ASSOULY, MATTHIEU M DESJARDINS, LAURIANE CONTAMIN, Laboratoire Pierre Aigrain UMR 8551, Ecole normale Supérieure - PSL Research university, CNRS, Université Pierre et Marie Curie - Sorbonne Universités, Université Paris Dider, LAURE BRUHAT, Microtechnology and nanoscience, Chalmers University of Technology, ZAKI LEGHTAS, FRANCOIS MALLET, AUDREY COTTET, TAKIS KONTOS, Laboratoire Pierre Aigrain UMR 8551, Ecole normale Supérieure - PSL Research university, CNRS, Université Pierre et Marie Curie - Sorbonne Universités, Université Paris Dider — Circuit quantum electrodynamics allows one to probe, manipulate and couple superconducting quantum bits using cavity photons at an exquisite level. Mesoscopic-QED inherits the c-QED toolbox and applies it to quantum dot circuits. In this talk, I will present a spin-qubit encoded in a carbon nanotube based double quantum dot with non-collinear ferromagnetic contacts. Using the c-QED spin-photon interface, we drove a single electronic spin and performed microwave spectroscopy of it. From this measurement we identified a decay rate which can be tuned to be as low as 250kHz. The cooperativity of the spin-photon interface is also measured as a function of the detuning, allowing to identify an optimal working point. These coherence properties, which are attributed to the use of pristine carbon nanotubes stapled inside the cavity, should enable coherent spin-spin interaction via cavity photons and compare favorably to the ones recently demonstrated in Si-based circuit QED experiments.

**4:54PM C35.00011: Magnon-photon coupling between a superconducting resonator and a thin film permalloy stripe**† YI LI (Presenter), Department of Physics, Oakland University, TOMAS POLAKOVIC, YONGLEI WANG, JING XU, SERGI LENDINEZ, ZHIZHI ZHANG, JUNJIA DING, TRUPTI KHAIRE, HILAL SAGLAM, Materials Science Division, Argonne National Laboratory, RALU DIVAN, Center for Nanoscale Materials, Argonne National Laboratory, JOHN E. PEARSON, WAI-KWONG KWOK, ZHILI XIAO, VALENTYN NOVOSAD, AXEL F HOFFMANN, Materials Science Division, Argonne National Laboratory, WEI ZHANG, Department of Physics, Oakland University — Coherent processing of magnetic excitations has received increasing attentions for spin-wave-based functionality such as magnonics, cavity spintronics and quantum information processing. They usually involve strong coupling of different excitations, such as magnons and photons, which leads to their hybridized modes.

In this work, we achieve strong magnon-photon coupling of a device ferromagnet of Ni$_{80}$Fe$_{20}$ (Py) to a high-quality NbN coplanar superconducting resonator. Microwave characterizations at 1.6 K show a high quality factor Q~10000. A Py 30 nm stripe was then fabricated on top of the resonator with a 10-nm MgO spacer. We observe a strong anti-cross between the superconducting resonator mode and the Kittel mode of the Py stripe. A maximum coupling strength of $g_{eff}$/f=100 MHz is obtained at about 5 GHz when the biasing field is orthogonal to the microwave field from the resonator. The anti-crossing is completely suppressed when the biasing field is parallel to the resonator microwave field. Our results provide new pathways for implementing on-chip magnonic devices with efficient and coherent information transducers.

*This work was supported by DOE-BES, Materials Science and Engineering Division, and CNM under Contract No. DE-AC02-06CH11357, and NSF-DMR-1808892
ANDREAS LANDIG, JONNE KOSKI, PASQUALE SCARLINO (Presenter), DAVID VAN WOERKOM, CHRISTIAN REICHL, WERNER WEGSCHEIDER, ANDREAS WALLRAFF, KLAUS ENSSLIN, THOMAS IHN, Department of Physics, ETH Zurich, Switzerland — A coherent link connecting different qubits over long distances is necessary to benefit from the advantages in gating or coherence times of different qubit implementations in a future quantum processor. We realize such a link between a spin qubit and a transmon qubit in a circuit quantum electrodynamics architecture [1] similar to a recent work that involved a charge qubit and a transmon qubit [2]. The spin qubit is a resonant exchange qubit [3] formed by three electrons in a gate defined triple quantum dot in a GaAs/AlGaAs heterostructure. The qubit states are split energetically by exchange interaction. Consequently, the spin qubit can be operated at zero magnetic field and exhibits a decoherence rate of $\gamma^2/2\pi \approx 10\text{MHz}$, limited by hyperfine interaction in the host material. The transmon qubit has $\gamma^2/2\pi \approx 0.7\text{MHz}$ limited by Purcell decay. Both qubits are capacitively coupled to a high impedance SQUID array resonator with coupling strengths of $g_{SQ}/2\pi \approx 50\text{MHz}$ and $g_{T}/2\pi \approx 180\text{MHz}$ for the spin and transmon qubit, respectively. We demonstrate resonant and dispersive interaction between the two qubits mediated by real and virtual microwave photons.

Session C36 DBIO: Statistical Physics of Large Populations of Cells: from Microbes to Tissues I

2:30PM C36.00001: A unifying theory of branching morphogenesis [Invited] BENJAMIN SIMONS (Presenter), Physics, University of Cambridge — Branching morphogenesis has been a subject of abiding interest. Although much is known about the underlying signaling pathways, it remains unclear how the macroscopic features of branched organs, including their size, network topology and spatial patterning, are encoded. Here we show that, in the mouse mammary gland, kidney and pancreas, these features can be explained quantitatively within a single unifying framework of branching and annihilating random walks. Based on large-scale organ reconstructions, genetic lineage tracing and proliferation kinetics, we show that morphogenesis follows from the collective proliferative activity of sublineage-restricted equipotent self-renewing progenitors localized at ductal tips that drive a process of ductal elongation and stochastic tip bifurcation. By correlating ductal termination with proximity to maturing ducts, this dynamics results in the specification of a complex network of defined density and statistical organization. These results show that branched epithelial structures in mammalian tissues develop as a self-organized process, reliant upon a strikingly simple, but generic, set of local rules, without recourse to a rigid and deterministic sequence of genetically programmed events.

3:06PM C36.00002: Diversity, dynamics and defense in microbial communities* [Invited] DEVAKI BHAYA (Presenter), Carnegie Institution for Science — Cyanobacteria are an ancient group of microbes that can carry out photosynthesis and nitrogen fixation. They are important members of microbial communities in terrestrial and aquatic environments. They thrive in moderate and harsh environments where they can adapt to desiccation stress and extremes of heat or cold. For several years we have focused on extremophile communities that form stratified biofilms or microbial mats in the hot springs of Yellowstone National Park. In these communities, 16S rRNA diversity has been correlated with environmental gradients of temperature and light. The genomes of two Synechococcus isolates that dominate at different temperatures in the mats, has provided key insights into genomic and metabolic diversity within these populations. Metagenomic data in combination with deep amplicon sequencing from these communities, revealed an unexpectedly high degree of genomic micro-diversity. We have also attempted to explore the co-evolution of host and cyanophage populations in the microbial mats, by creating viromes and exploiting CRISPR spacer information. Finally, we are also interested in probing the importance of phototaxis and motility in these structured communities. I will describe our findings in the context of how these moderately complex communities are ideally suited to probing how physical forces and chemical gradients in combination with genetic diversity shape microbial community structure and organization. The future of modeling complex interactions and the ability to test hypotheses in synthetic communities will be explored.

3:42PM C36.00003: Coevolutionary dynamics in the immune system [Invited] ARMITA NOURMOHAMMAD (Presenter), Max Planck Institute for Dynamics and Self-organization — The vertebrate adaptive immune system provides a flexible and diverse set of molecules to neutralize pathogens. Yet, viruses such as HIV can cause chronic infections by engaging in a coevolutionary arms race with the adaptive immune system: The B-cell receptors in the adaptive immune system diversify to neutralize the virus and HIV evolves to evade the immune response. While it is clear that HIV exerts strong selection on the adaptive immune system, the modes of immune response are still unknown. Here I introduce a non-equilibrium framework to characterize the rapid coevolution of immune cells and pathogens. By tracing the immune repertoire of HIV patients over time and reconstructing the history of the accumulated mutations within patients, I show evidence for strong co-adaptation of the immune repertoire and HIV. I argue that rapid affinity maturation of the immune system upon viral expansion and a quasi-stationary response during chronic infection characterize the B-cell response to HIV.

4:18PM C36.00004: Cooperative growth and cell-cell aggregation in marine bacteria* [Invited] OTTO X CORDERO (Presenter), Civil and Environmental Engineering, Massachusetts Institute of Technology — Bacterial cooperation, whereby cells secrete compounds that can facilitate the growth of neighboring cells, has been extensively studied through the lens of evolutionary biology. However, the environmental implications of cooperation and the ecological scenarios under which it takes place remain much less understood. In this talk I will discuss the conditions under which cooperative growth emerges in microbial populations that degrade complex organic materials in the ocean. I will show that organisms that are poor secretors of hydrolytic enzymes use chemotactic behavior to form cell-cell aggregates that enable individuals to increase local concentrations and efficiently uptake the solubilized organic matter. By contrast, when organisms secrete highly active enzymes dynamics turn competitive, cells avoid aggregation and the efficiency of carbon uptake drops. I will discuss the theoretical limits of aggregation and how bacterial isolates from the ocean can overcome these limits in the laboratory by developing multicellular behaviors. I will back up these results with theory, data from individual based models and experiments with natural isolates. Finally, I will discuss the potential role of social cheaters in the natural environment, based on a study with hundreds of micro-scale particle colonization experiments in natural seawater.

4:54PM C36.00005: How adaptive immunity constrains the composition and fate of large bacterial populations* [Invited] SIDHARTHA GOYAL (Presenter), MADELEINE BONSMA-FISHER, University of Toronto — Features of the CRISPR-Cas system, in which bacteria integrate small segments of phage genome (spacers) into their DNA to neutralize future attacks, suggest that its effect is not limited to individual bacteria but may control the fate and structure of whole populations. Emphasizing the population-level impact of the CRISPR-Cas system, recent experiments show that some bacteria regulate CRISPR-associated genes via the quorum sensing (QS) pathway. Here we present a model that shows that from the highly stochastic dynamics of individual spacers under QS control emerges a rank-abundance distribution of spacers that is time invariant, a surprising prediction that we test with dynamic spacer-tracking data from literature. This distribution depends on the state of the competing phage–bacterium population, which due to QS-based regulation may coexist in multiple stable states that vary significantly in their phage-to-bacterium ratio, a widely used ecological measure to characterize microbial systems.

Session C37 GMAG DCMP DMP: Spin Liquids: Alpha-RuCl3 BCEC 206A - Arnab Banerjee, Oak Ridge National Laboratory - Tag(s): Focus

2:30PM C37.00001: Kitaev spin liquids in spin-orbit coupled correlated materials* [Invited] HAE-YOUNG KEE (Presenter), University of Toronto — Recently, a new family of correlated honeycomb materials with strong spin-orbit coupling have been promising candidates to realize the Kitaev spin liquid. In particular, a half-integer quantized thermal Hall conductivity was reported in alpha-RuCl3 under the magnetic field. Using a generic nearest neighbour spin model with bond-dependent interactions, I will present numerical evidence of an extended regime of quantum spin liquids. I will also discuss how to achieve a chiral spin liquid near ferromagnetic Kitaev interaction in the presence of the magnetic field leading to the quantized thermal Hall conductivity.

*NSERC of Canada
3:06PM C37.00002: Field induced quantum spin liquid with spinon Fermi surfaces in the Kitaev model*  
HONG-CHEN JIANG, Stanford Institute for Materials and Energy Sciences, SLAC and Stanford University, CHANGYAN WANG (Presenter), Department of Physics, The Ohio State University, BIAO HUANG, Department of Physics and Astronomy, University of Pittsburgh, YUAN-MING LU, Department of Physics, The Ohio State University — Recent experimental evidence for a field-induced quantum spin liquid (QSL) in α-RuCl₃ calls for an understanding for the ground state of honeycomb Kitaev model under a magnetic field. In this work we address the nature of an enigmatic gapless paramagnetic phase in the antiferromagnetic Kitaev model, under an intermediate magnetic field perpendicular to the plane. Combining theoretical and numerical efforts, we identify this gapless phase as a U(1) QSL with spinon Fermi surfaces. We also reveal the nature of continuous quantum phase transitions involving this U(1) QSL, and obtain a phase diagram of the Kitaev model as a function of bond anisotropy and perpendicular magnetic field.

*This work is supported by NSF under award number DMR-1653769 (CYW,YML), by U.S.ARO (W911NF11-1-0230), AFOSR (FA9550-16-1-0006), MURI-ARO (W911NF17-1-0323) (BH), by the Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract DE-AC02-76SF00515 (HCJ), and in part by NSF grant PHY-1607611 (YML).

3:18PM C37.00003: Magnetic field induced intermediate gapless spin-liquid phase with a spinon Fermi surface*  
NIRAVKUMAR D. PATEL (Presenter), NANDINI TRIVEDI, The Ohio State University — Quantum spin liquids have generated considerable excitement in the condensed matter physics community. We employ the density matrix renormalization group to study the Kitaev model with a magnetic field in the H∥[111] direction. We show the presence of an intermediate phase, between the gapped Kitaev spin liquid and partially field polarized phase, that is a candidate spin liquid. We show that the spin-spin correlations in real-space obey power-law decay that is indicative of gapless spin excitations. Additionally, we present calculations of specific heat, entropy, and spin susceptibility at the finite temperature to provide further evidence of a gapless phase. Using the peaks of spin structure factor, we propose an existence of a spinon Fermi surface in the intermediate phase.

3:30PM C37.00004: Pristine graphene contacts to exfoliated α-RuCl₃ crystals  
JESSE BALGLEY (Presenter), BOYI ZHOU, Washington University, St. Louis, PAULA J KELLEY, DAVID GEORGE MANDRUS, Oak Ridge National Laboratory, ERIK HENRIKSEN, Washington University, St. Louis — The layered Mott insulator α-RuCl₃ has garnered significant attention as a candidate to host a Kitaev quantum spin liquid, harboring fractionalized excitations and Majorana fermion-like spin excitations. Though significant progress has been made toward understanding how these phenomena manifest in α-RuCl₃, experimental procedures to date have largely consisted of probes for pristine bulk samples. However α-RuCl₃ may be readily exfoliated down to monolayer thicknesses. We show that we can achieve good electrical contact to α-RuCl₃ using monolayer graphene, enabling direct measurement of the resistivity. In this talk, we present device configurations for interrogating exfoliated α-RuCl₃ crystals in the few-layer limit by the fabrication of graphene/α-RuCl₃ heterostructures. We further discuss measurements of the Mott gap via optical spectroscopy.

3:42PM C37.00005: Effect of pressure, stress and electronic modification on alpha-RuCl₃*  
SANANDA BISWAS (Presenter), STEPHEN WINTER, ROSER VALENTI, Physics, Goethe University Frankfurt — The honeycomb Mott insulator, α-RuCl₃, is being intensively studied as a candidate for realizing Kitaev physics. One of the areas of current research is to find routes to enhance Kitaev interactions in order to stabilize a possible spin liquid, by increasing exchange frustration by the application of external perturbations such as magnetic field, doping or pressure. We have explored these possibilities by applying stress and electronic modifications. In this talk, I will discuss effects of these perturbations on structural, electronic, vibrational and magnetic properties.

*SFB/TR 49
attention for a candidate of the Kitaev model, α-RuCl$_3$, showing spin liquid behaviour under magnetic field. Owing to the frustrated bond-dependent exchange interactions on a honeycomb spin lattice. The observation has recently attracted

4:30PM C37.00009: New Features in the Field-dependent Thermal Conductivity of α-RuCl$_3$ at Low Temperatures*

PETER CZAJKA (Presenter), TONG GAO, JINGJING LIN, Department of Physics, Princeton University, PAULA J KELLEY, ARNAB BANERJEE, CHRISTIAN BALZ, JIAQIANG YAN, DAVID GEORGE MANDRUS, STEPHEN NAGLER, Oak Ridge National Laboratory, NAI-PHUAN ONG, Department of Physics, Princeton University — α-RuCl$_3$ is currently the most promising and well-studied candidate for realizing the unique physics of the Kitaev model. Because the energy scale of the exchange interactions is understood to be quite high (J ~ 100K), measurements at low temperatures have been somewhat scarce and it’s behavior below 2K remains largely unexplored. This is especially true for thermal transport experiments, which have proven to be an incredibly powerful probe of excitations and phase transitions in insulating magnets. We present measurements of the thermal conductivity as a function of temperature and in-plane magnetic field that were performed between 0.4 and 1.7K. We identify several new features in $\kappa_{xx}(B)$ that occur between 7 and 11T, a regime located between the long range ordered and fully polarized states and where spin liquid behavior is thought to occur. Possible explanations for these new features as well as their relation to the recent observation of a half-integer quantized thermal hall conductance will be discussed.

*We acknowledge support from the Department of Energy (DE-SC0017863) and the Gordon and Betty Moore Foundation’s EPiQS Initiative (Grant No. GBMF4539).
4:42PM C37.00010: High Temperature Fermi Statistics from Majorana Fermions in an Insulating Magnet*  
YIPING WANG (Presenter), GAVIN B OSTERHOUDT, Boston College, YAO TIAN, Apple inc., PAULA J KELLEY, ARNAB BANERJEE, Oak Ridge National Lab, THOMAS A GOLDSTEIN, JUN YAN, umass Amherst, JOHANNES KNOLLE, Blackett Laboratory, Imperial College London, JOJI NASU, Tokyo Institute of Technology, YUKITOSHI MOTOME, University of Tokyo, STEPHEN NAGLER, DAVID GEORGE MANDRUS, Oak Ridge National Lab, KENNETH BURCH, Boston College — Majorana fermions, particles that are their own anti-particles, can emerge in insulating magnets as excitations with fractions of the constituent's quantum numbers. Interest in Majoranas is driven by their potential for quantum computation, and as evidence of novel topological states. Observations have been limited to liquid helium temperatures as edge modes in topological superconductors and quantum spin liquids (QSL) without combined evidence of particle-hole symmetry, Fermi statistics, and presence in the bulk. Here we report all three in α-RuCl3, at temperatures exceeding liquid nitrogen via new energy gain as well as loss Raman spectra and a unique framework to identify the statistical properties of the Kitaev QSL. α-RuCl3 is close to the Kitaev QSL, where bond-dependent Ising interactions produce excitations that are non-local in terms of spin flips. Consistent with particle-hole symmetric excitations obeying Paul-exclusion, the sum of the energy loss and gain responses are nearly temperature and energy independent. Our new method can be used to identify the unique properties of QSLs, and demonstrates the promise of α-RuCl3 for efforts in topological phases and quantum computation.

4:54PM C37.00011: Origin of the saw-tooth torque in spin-orbital-coupled magnets: Application to α-RuCl3*  
ROSER VALENTI (Presenter), KIRA M. RIEDL, STEPHEN WINTER, Goethe University Frankfurt — Honeycomb Kitaev candidate materials based on 4d5 and 5d5 metals have been recently shown to commonly display a distinct saw-tooth angular dependence of the magnetic torque over a wide range of magnetic fields. By a combination of density functional theory calculations, exact diagonalization and semiclassical considerations, we show here that bilinear anisotropic interactions and/or g-anisotropy are each sufficient to explain the observed torque response, which may be distinguished on the basis of high-field measurements. We argue that these finding unify the understanding of magnetic torque experiments in a variety of Kitaev candidate materials.

2:30PM C38.00001: Thermal evolution of quasi-one-dimensional spin correlations within the anisotropic triangular lattice of α-NaMnO2  
REBECCA DALLY (Presenter), University of California, Santa Barbara, ROBIN CHISNELL, LELAND HARRIGER, NIST Center for Neutron Research, National Institute of Standards and Technology, YAOHUA LIU, Neutron Scattering Division, Oak Ridge National Laboratory, JEFFREY W LYNN, NIST Center for Neutron Research, National Institute of Standards and Technology, STEPHEN WILSON, University of California, Santa Barbara — The temperature dependence of the magnetic order on the spatially anisotropic triangular lattice of α-NaMnO2 will be presented. Single crystals were studied via time-of-flight and triple-axis neutron diffraction measurements, which revealed the transition into a commensurate, collinear antiferromagnetic ground state with \( k = (0.5, 0.5, 0) \) occurs below \( T_N = 22 \) K. Above this temperature, the transition is preceded by the formation of a coexisting, short-range ordered, incommensurate state below \( T_{IC} = 45 \) K whose two dimensional propagation vector evolves toward \( k = (0.5, 0.5) \) as the temperature approaches \( T_N \). At high temperatures \( (T > T_{IC}) \), quasielastic scattering reveals one-dimensional spin correlations along the nearest neighbor Mn-Mn "chain direction" of the MnO6 planes. Our data are consistent with the predictions of a mean field model of Ising-like spins on an anisotropic triangular lattice, as well as the predominantly one-dimensional Heisenberg spin Hamiltonian reported for this material.
2:42PM C38.00002: Thermal control of spin excitations in the coupled Ising-chain material RbCoCl$_3$*  
CHRISTIAN RUEGG (Presenter), MATTIA MENA, Neutrons and Muons Research Division, Paul Scherrer Institute, NORA HAENNI, Department of Chemistry and Biochemistry, University of Bern, SIMON WARD, Neutrons and Muons Research Division, Paul Scherrer Institute, EVA HIR TENLECHNER, Institut Laue Langevin, ROBERT BEWLEY, ISIS Facility, Rutherford Appleton Laboratory, CLAUDIUS HUBIG, ULRICH JOSEPH SCHOLLWOECK, Arnold Sommerfeld Center, Ludwig Maximilians University, BRUCE NORMAND, Neutrons and Muons Research Division, Paul Scherrer Institute, KARL KRAEMER, Department of Chemistry and Biochemistry, University of Bern, DESMOND F MCMORROW, London Centre for Nanotechnology, University College London — We have used neutron spectroscopy to investigate the spin dynamics of the quantum ($S = 1/2$) antiferromagnetic Ising chains in RbCoCl$_3$. The structure and magnetic interactions in this material conspire to produce two magnetic phase transitions at low temperatures, presenting an ideal opportunity for thermal control of the chain environment. The high-resolution spectra we measure of two-domain-wall excitations therefore characterize precisely both the continuum response of isolated chains and the `Zeeman-ladder' bound states of chains in three different effective staggered fields in one and the same material. We apply an extended Matsubara formalism to obtain a quantitative description of the entire dataset, Monte Carlo simulations to model the magnetic order, and finite-temperature DMRG calculations to interpret the spectral features of all three phases, providing a complete understanding of the multi-faceted Ising physics of RbCoCl$_3$.

2:54PM C38.00003: Spin dynamics in quasi-one-dimensional antiferromagnets*  
SYLVAIN CAPPONI (Presenter), Toulouse university, MAXIME DUPONT, UC Berkeley, EDMOND ORIGNAC, Ecole Normale Supérieure de Lyon, NICOLAS LAFLORENCIE, CNRS & Toulouse university — Theoretically challenging, the understanding of the dynamical response in quantum antiferromagnets is of great interest, in particular for both inelastic neutron scattering (INS) and nuclear magnetic resonance (NMR) experiments. In such a context, we theoretically address this question for quasi-one-dimensional quantum magnets, e.g., weakly coupled spin chains for which many compounds are available in nature. In this class of systems, the dimensional crossover between a three-dimensional ordered regime at low temperature towards one-dimensional physics at higher temperature is a nontrivial issue, notably difficult concerning dynamical properties. We present a comprehensive theoretical study based on both analytical calculations and numerical simulations which allows us to describe the full temperature crossover for the NMR relaxation rate $1/T_1$ or the dynamical structure factor probed by INS, from one-dimensional Tomonaga-Luttinger liquid physics to the three-dimensional ordered regime, as a function of interchain couplings [1].

3:06PM C38.00004: Spin-1/2 antiferromagnetic chiral chains: the sine-Gordon model and beyond.* [Invited] PAUL GODDARD (Presenter), Department of Physics, University of Warwick, JUNJIE LIU, Department of Physics, University of Oxford, SHUNICHIRO KITAKA, Institute for Solid State Physics, University of Tokyo, ROGER JOHNSON, Department of Physics, University of Oxford, TOM LANCASTER, Centre for Materials Physics, Durham University, JOHN SINGLETON, National High Magnetic Field Laboratory, Los Alamos National Laboratory, TOSHIRO SAKAKIBARA, YOSHIMITSU KOHAMA, Institute for Solid State Physics, University of Tokyo, ROGER JOHNSON, Department of Physics, University of Oxford, ZACHARY MANSON, JAMIE MANSON, Department of Chemistry and Biochemistry, Eastern Washington University — The dramatic effect of an alternating local spin environment on the properties of the spin-1/2 antiferromagnetic chain was first discovered through high-field neutron scattering and heat capacity experiments on copper-benzoate, which revealed the development of an energy gap on application of magnetic field. This was perplexing until it was found that the behaviour of this system, and a handful of others, could be described by the sine-Gordon model of quantum-field theory. Under the influence of the applied field, the gap emerges thanks to the presence of internal staggered fields and DM interactions that are a direct result of the staggered Cu(II) octahedra.

Here, we report on the molecule-based chiral spin chain \([\text{Cu(pym)}(\text{H}_2\text{O})_4]\text{SiF}_6\cdot\text{H}_2\text{O}\) (pym = pyrimidine), which at first glance could be a sine-Gordon chain, but with an added twist: a 41 screw. Electron-spin resonance, magnetometry and heat capacity measurements reveal the presence of staggered g tensors, a rich low-temperature excitation spectrum, a staggered susceptibility and a spin gap that opens on the application of a magnetic field. These phenomena are reminiscent of those previously observed in non-chiral sine-Gordon materials. In the present case, however, the size of the gap and its measured linear field dependence do not fit with the sine-Gordon model as it stands. We propose that the differences arise due to additional terms in the Hamiltonian resulting from the chiral structure.

*This project has received funding from the European Research Council (grant no. 681260). We also thank the NHMFL, EPSRC, STFC, Royal Society, NSF (grant no. DMR-1703003, DMR-1157490), DoE and the State of Florida.

3:42PM C38.00005: Formation of a Longitudinal Mode in One Dimensional Yb$_2$Pt$_2$Pb* WILLIAM GANNON, Stewart Blusson Quantum Matter Institute, University of British Columbia, IGOR ZALIZNYAK, Brookhaven National Laboratory, LIUSUO WU, Southern University of Science and Technology, ALEXEI TSVELIK, Brookhaven National Laboratory, FRANZ DEMMEL, ISIS Neutron Source, Rutherford Appleton Laboratory, GEORG EHLERS, ANDREI PODLESNYAK, Oak Ridge National Laboratory, MEIGAN ARONSON (Presenter), Stewart Blusson Quantum Matter Institute, University of British Columbia — The low energy magnetic excitations measured with neutron scattering (NS) in Yb$_2$Pt$_2$Pb are spinons on one dimensional chains, in good agreement with the expectations of the XXZ Hamiltonian for nearly isotropic $S=\pm 1/2$ magnetic moments despite the large, rare earth Yb$^{3+}$ moments that make up the system [1]. In applied magnetic field, we observe spinon confinement into bound states coinciding with a longitudinally polarized interchain mode [2]. New NS measurements probe the dispersion of this mode as a function of field in the vicinity of the confinement transition. We find weak modifications to the quantum continuum for fields approaching the critical field of 0.7 T, with the mode growing in intensity as field is increased through the transition. Interestingly, the antiferromagnetic order is strongly pinned with periodicity that does not evolve smoothly as a function of field as seen previously in a different orientation [2]. Rather, there is an abrupt transition to a weak, completely incommensurate order at 1.3 T with the mode correspondingly returning spectral weight to the continuum, reflecting strong low dimensional fluctuations even at fields near saturation.

*Funding provided by NSF-DMR-1807451

3:54PM C38.00006: Thermal fluctuation in low dimensional systems - an experimental, computational and analytical study* NOAM KESTIN (Presenter), THIERRY GIAMARCHI, University of Geneva — We apply a near optimal density matrix renormalization group scheme (T-DMRG) to weakly coupled spin-half ladders. By doing so, one can reach sufficiently good resolution in the calculation of spin-spin correlations at finite temperature. We compare the results with analytic predictions such as the one of the Tomonaga Luttinger liquid, and experiments on compounds such as (\text{C}_{3}\text{H}_{12})_2 \text{Cu Br}_2 \text{Cl}_2.

*This work is supported by the Swiss National Science Foundation under Division II.
4:06PM C38.00007: Coercivity Dependence on Chain Length in a Low-Dimensional Magnetic System  THOMAS GREDIG (Presenter), KEVIN CANO, California State University, Long Beach — Single chain magnets deposited in the form of thin films can have tunable average chain lengths. A small molecule, iron phthalocyanine, is sublimed on a non-interacting substrate in the form of a thin film with a thickness of about 100 nm. The molecule's central ions form magnetic chains that are oriented parallel to the substrate surface. Furthermore, the average chain length is varied using the substrate deposition temperature in order to achieve a set of different magnetic responses as measured in magnetic hysteresis loops. The coercivity increases strongly with samples that have longer chain lengths. For comparison, a model with reduced dimensions based on single domain spherical magnetic particles in the superparamagnetic regime is developed and applied to this data set. The lower-dimensionality markedly extends the range of grain sizes over which the coercivity increases.

4:18PM C38.00008: Normal Modes of a Spin Cycloid or Helix* RANDY FISHMAN (Presenter), Oak Ridge National Laboratory, TOOMAS ROOM, National Institute of Chemical Physics and Biophysics, Estonia, ROGÉRIO DE SOUSA, Department of Physics and Astronomy, University of Victoria, Canada — Although spin cycloids and helices are quite common, remarkably little is known about the normal modes of a spin cycloid or helix with finite length on a discrete lattice. Based on simple one-dimensional lattice models, we numerically evaluate the normal modes of a spin cycloid or helix produced by either Dzyaloshinskii-Moriya (DM) or competing exchange (CE) interactions. The normal modes depend on the type of interaction and on whether the nearest-neighbor exchange is antiferromagnetic (AF) or ferromagnetic (FM). In the AF/DM and FM/CE cases, there is only a single Goldstone mode; in the AF/CE and FM/CE cases, there are three. For FM exchange, the spin oscillations produced by non-Goldstone modes contain a mixture of tangential and transverse components. For the DM cases, we compare our numerical results with analytic results in the continuum limit.

4:30PM C38.00009: The dynamic structure factor in impurity-doped spin chains in a magnetic field  IMKE SCHNEIDER (Presenter), KEVIN JÄGERING, University of Kaiserslautern, ANNABELLE BOHRDT, Physics, TU Munich, SOFIA BRENNER, DANIEL WESSEL, SEBASTIAN EGGERT, University of Kaiserslautern — We consider the dynamic structure factor in impurity doped spin-1/2 chains for general anisotropy, magnetic field and momentum. The impurities lead to effectively isolated finite chain segments with a discrete spectrum and characteristic correlations, which have a distinct effect on the dynamic structure factor. We present very accurate results for the low energy spectral weight obtained by numerical Density Matrix Renormalization Group techniques and identify the character of dominant excitations. We find that due to the impurities spectral weight is shifted away from the two-particle continuum into regions where no signal would be expected for undoped chains. Further, we compare with bosonization and find surprisingly good agreement with the numerical results. This has direct relevance for recent experiments on spin chains and ultracold gases and shows that, contrary to expectations, bosonization works especially well for short chains and in the vicinity of divergences.

4:42PM C38.00010: First-principles investigation of the complex lattice, charge, orbital, and spin structures in the spinel CuIr2S4* XILIANG JIN, Jilin University, China, WEIGUO YIN (Presenter), Brookhaven National Laboratory — The CuIr2S4 thiospinel undergoes a metal-insulator transition at 230K on cooling accompanied by very large variations in the Ir-Ir bond lengths and the loss of localized magnetic moments. This phenomenon has been interpreted in terms of a unique octamer model and orbitally driven one-dimensional Peierls transition. Here we report systematic first-principles studies of the crystal structures, electronic band structures, and phonon spectra of CuIr2S4, as well as the effects of electron-phonon, electron-electron, and spin-orbit interactions. Wannier function analysis is used to derive the effective low-energy Hamiltonian. Our results suggest a new way to understand this material.

*U.S. DOE-BES, Division of Materials Science and Engineering, under Contract No. DE-SC0012704.

4:54PM C38.00011: New spin-filtering mechanism through atomic chains without magnetic field: first-principles study  TOMONORI TANAKA (Presenter), YOSHIHIRO GOHDA, Tokyo Institute of Technology - Suzukakedai Campus — We investigated a new one-dimensional (1D) Rashba system, Bi-adsorbed in atomic chains, using first-principles calculations. One of the most stable structures in the system shows unconventional spin textures, which is the reversal of the spin polarization direction in Rashba bands. This result suggests a new spin-filtering mechanism through atomic chains. Similar mechanisms to ours, 1D spin filter, have been proposed already. However, our mechanism has a great advantage; previous spin-filtering mechanisms require the external magnetic field, whereas ours does not need the magnetic field. This feature is suitable for spintronic applications.
5:06PM C38.00012: Very slow spin dynamics in a ferromagnetic chain with three-body interactions  KEVIN BEACH
(Presenter), KHAGENDRA ADHIKARI, University of Mississippi — Projector Monte Carlo methods can be adapted to quantum spin models in which the Hamiltonian is a sum of local three-body operators. I discuss the case of spin-half chains whose interactions are pairwise ferromagnetic but contingent on the spin state at a third adjacent site. The resulting family of Hamiltonians, which includes the Fredkin spin chain and its t-deformed cousins, is frustration-free but highly nontrivial. The phase diagram includes states with large entanglement and unusually slow dynamics. Since the Monte Carlo can be carried out independently within each spin sector, I am able to present numerical data for the ground state and various low-lying excitations.

2:30PM C39.00001: Asymmetric g Tensor in Low-Symmetry Two-Dimensional Hole Systems* [Invited]  ROLAND WINKLER (Presenter), Northern Illinois University, C. GRADL, C. SCHUELLER, T. KORN, University of Regensburg — Zeeman coupling characterized by the g factor is a key ingredient to developing novel spin-based technologies such as quantum information protocols. In low-symmetry systems, the g factor becomes a second-rank tensor (a 3×3 matrix) that couples the spin to the magnetic field B. It has long been believed that this tensor g only affects the energy splitting in a magnetic field. We demonstrate [1] that it also encodes the direction of the axis about which the spins precess in the external field B. In general, this axis is not aligned with B. Using time-resolved Kerr rotation measurements performed on a sequence of low-symmetry two-dimensional hole systems in GaAs/AlAs quantum wells, we show that this feature of the tensor g manifest itself in unusual precessional motion as well as distinct dependencies of hole spin dynamics on the direction of the magnetic field B. A detailed theoretical analysis of these experiments allows us, for the first time, to determine the individual components of the full tensor g for [113]-, [111]- and [110]-grown samples. We also derive transparent analytical expressions for the components of the tensor g, complemented with accurate numerical calculations yielding very good agreement between experiment and theory.

Second-rank tensors characterizing materials properties such as electrical conductivity and dielectric constant are usually symmetric. In contrast, our study demonstrates that the tensor g is generally neither symmetric nor antisymmetric. Opposite off-diagonal components can differ in size by up to an order of magnitude. Consequently, the coupling of spins to the magnetic field varies drastically upon interchanging the direction of magnetic field and spin. This work extends the general concept of optical orientation to the regime of nontrivial Zeeman coupling.

*This work was supported by the NSF under Grant No. DMR-1310199.

3:06PM C39.00002: Enhancement of the Spin-Orbit Coupling in Silicon by Bismuth Doping  FABIEN RORTAIS (Presenter), SOOBEOM LEE, RYO OHSHIMA, SERGEY DUSHENKO, YUICHIRO ANDO, MASASHI SHIRAISHI, Kyoto University — Si possesses a low spin-orbit coupling, it allows a long spin lifetime but limits new device-designing possibilities in spintronics, particularly with the spin-charge conversion effects to create an all-Si spin devices. The purpose of this study is to create a sizable spin-orbit interaction in Si by implantation of a heavy element, bismuth (Bi).

To compare the spin-orbit coupling strength in the Si channel with and without Bi doping (SOI:P:B and SOI:P, respectively), we measured quantum corrections to the conductance in function of temperature. The elastic diffusion length (L_d), the spin-orbit coupling length (L_{so}) and the phase coherence length (L_{\phi}) can be extracted from the magnetoconductance data by using the Hikami-Larkin-Nagaoka model. L_d has the same order of magnitude (10 nm-25 nm) for both samples, however L_{so} decreased after the Bi doping (with the strongest decrease from 177 nm to 35 nm at 2 K). In the case of SOI:P:Bi, the Bi doping induced a spin-orbit coupling length of the same order of magnitude with the phase coherence length (L_{so} = 54 nm and L_{\phi} = 35 nm at 2K).

The increased spin-orbit coupling strength led to observe the crossover between the WL and the WAL. These results demonstrate a control over the strength of the spin-orbit coupling in Si channel using Bi doping.
3:18PM C39.00003: Strain engineering of Rashba-Dresselhaus spin-orbit coupling and intrinsic spin-Hall effect in Si
PAUL C LOU, ANAND KATAILLHA, RAVINDRA G BHARDWAJ, SANDEEP KUMAR (Presenter), University of California, Riverside —
The weak intrinsic spin-orbit coupling and centrosymmetric crystal structure are critical bottlenecks in the development of Si spintronics because it leads to insignificant spin-Hall effect (spin current generation) and inverse spin-Hall effect (spin current detection) even though it results into long spin diffusion length at room temperature. In this experimental study, we use strain gradient to break the structural inversion symmetry, which causes flexoelectric effect and charge separation. This leads to the Rashba-Dresselhaus spin-orbit coupling in the bulk of Si along with Si interface. The cubic Rashba-Dresselhaus spin-orbit coupling lifts the spin degeneracy of band structure introducing intrinsic spin-Hall effect, which is uncovered using spin-Hall magnetoresistance measurement in Ni$_{80}$Fe$_{20}$/MgO/p-Si freestanding thin film. The strain gradient effects are uncovered using piezoresistive behavior due to thermal expansion induced compressive stresses. The intrinsic spin-Hall effect is observed in both n-doped and p-doped Si thin films. This experimental study brings the Si spintronics closer to reality. This work demonstrates that strain gradient can be used for spin current generation, detection and control in Si.

3:30PM C39.00004: ABSTRACT WITHDRAWN

3:42PM C39.00005: Unidirectional magnetoresistance in a bulk Rashba ferromagnet
RYUTARO YOSHIMI (Presenter), CEMS, RIKEN, KENJI YASUDA, MIT, ATSUSHI TSUKAZAKI, IMR, Tohoku Univ., MINORU KAWAMURA, KEI TAKAHASHI, CEMS, RIKEN, MASASHI KAWASAKI, University of Tokyo, YOSHINORI TOKURA, CEMS, RIKEN — The Rashba effect is the spin band splitting due to broken inversion symmetry through spin-orbit coupling, typically observed at surfaces and interfaces. Recently, some noncentrosymmetric crystals have been found to have the bulk Rashba bands that are larger than surface/interface ones. Nonreciprocal transport of quantum particles such as electron, spin and phonon is known to occur by further breaking time reversal symmetry in such a material without inversion symmetry. In particular, the interplay with magnetism in spin-polarized bands may enhance the nonreciprocal charge transport. In this study, we investigated the unidirectional magnetoresistance in thin films of Ge$_{1-x}$Mn$_x$Te, which is a bulk ferromagnetic Rashba semiconductor. The magnitude of nonreciprocal transport shows a strong dependence on carrier density, which suggests that the scattering process on Fermi surface is essential for the nonreciprocal transport in the system.

3:54PM C39.00006: The temperature and doping dependence of inverse spin Hall effect in n-GaAs
ZHEN JIANG (Presenter), School of Physics and Astronomy, University of Minnesota, SAHIL PATEL, Departments of Electrical and Computer Engineering and Materials, University of California, Santa Barbara, PAUL CROWELL, School of Physics and Astronomy, University of Minnesota, CHRIS PALMSTROM, Departments of Electrical and Computer Engineering and Materials, University of California, Santa Barbara — We have carried out measurements of the inverse spin Hall effect (ISHE) in a series of n-GaAs epilayers doped near the metal-insulator transition. Spin currents are generated using epitaxial Fe/GaAs (001) Schottky tunnel barriers. The ISHE is detected in a simple Hall cross geometry, and precession in a static magnetic field (the Hanle effect) is used to separate the effect from background contributions. We find that the ISHE voltage at low temperatures is much larger than expected based on previous measurements of the direct spin Hall effect. The enhancement is accompanied by significant distortion of the Hanle curves, suggesting that hyperfine interactions play a significant role. Comparison with non-local spin valve measurements over the entire doping range (3 x 10$^7$ cm$^{-3}$ to 7 x 10$^7$ cm$^{-3}$) and at temperatures up to 110 K indicates that local inhomogeneities in the hyperfine field, which disappear as the temperature increases, may be responsible for the enhancement.

In this study, we employed ultrafast Time Resolved Differential Reflectivity (TRDR) and ultrafast time resolved Magneto-optic Kerr Effect (MOKE) on InAs$_x$P$_{1-x}$ ternary alloy. In recent years, InAs$_x$P$_{1-x}$ ternary alloys have attracted extensive attention due to the immense prospect for various optoelectronic applications including optical telecommunication, broadband photodetectors, mid-IR lasers, and also quantum communication devices.\textsuperscript{1,2} As the switching rates in devices are pushed to higher frequencies in optoelectronic and spintronic devices, it is required to perform comprehensive studies of the carrier and spin relaxation dynamics in semiconductors on a femto-second timescale. Here we report carrier and spin dynamics of n-type InAs$_x$P$_{1-x}$ films in a broad optical region (700 nm and 1000 nm). Also, we observed the generation of coherent oscillations which could be related to photo-induced coherent acoustic phonons. The InAs$_x$P$_{1-x}$ films are ~1.2 micron thick grown on semi-insulating InP (001) wafers and the carrier concentrations are estimated to be 1x10$^{17}$ cm$^{-3}$.

Ubiquitous Spin-Orbit Coupling in a Screw Dislocation with High Spin Coherency

LIN HU (Presenter), HUAQING HUANG, University of Utah, ZHENGFEI WANG, University of Science and Technology of China, WEI JIANG, XIAOJUAN NI, YINONG ZHOU, University of Utah, V ZIELASEK, University of Bremen, MAX G LAGALLY, University of Wisconsin, BING HUANG, FENG LIU, University of Utah — We theoretically demonstrate that screw dislocation (SD), a 1D topological defect widely present in semiconductors, exhibits ubiquitously a new form of spin-orbit coupling (SOC) effect. Differing from the widely known conventional 2D Rashba-Dresselhaus (RD) SOC effect that typically exists at surfaces or interfaces, the deep-level nature of SD-SOC states in semiconductors readily makes it an ideal SOC. Remarkably, the spin texture of 1D SD-SOC, pertaining to the inherent symmetry of SD, exhibits a significantly higher degree of spin coherency than the 2D RD-SOC. Moreover, the 1D SD-SOC can be tuned by ionicity in compound semiconductors to ideally suppress spin relaxation, as demonstrated by comparative first-principles calculations of SDs in Si/Ge, GaAs, and SiC. Our findings therefore open a new door to manipulating spin transport in semiconductors by taking advantage of an otherwise detrimental topological defect.

Ubiquitous Spin-orbit Coupling in a Screw Dislocation of Semiconductors

BING HUANG (Presenter), LIN HU, Beijing Computational Science Research Center, FENG LIU, University of Utah — We demonstrate that screw dislocation (SD), a 1D topological defect widely present in semiconductors, exhibits ubiquitously a new form of spin-orbit coupling (SOC) effect. Differing from the widely known conventional 2D Rashba-Dresselhaus (RD) SOC effect that typically exists at surfaces/interfaces, the deep-level nature of SD-SOC states in semiconductors readily makes it an ideal SOC. Remarkably, the spin texture of 1D SD-SOC, pertaining to the inherent symmetry of SD, exhibits a significantly higher degree of spin coherency than the 2D RD-SOC. Moreover, the 1D SD-SOC can be tuned by ionicity in compound semiconductors to ideally suppress spin relaxation, as demonstrated by comparative first-principles calculations of SDs in Si/Ge, GaAs, and SiC.

Extreme asymmetry of 90-degree domain walls in multilayered films of (Ga,Mn)(As,P)

VITALII VLASKO-VLASOV, WAI-KWONG KWOK, Materials Sciences Division, Argonne National Laboratory, SINING DONG, XINYU LIU (Presenter), MALGORZATA DOBROWOLSKA, J K FURDYNA, Department of Physics, University of Notre Dame — We image the magnetic domain structure during remagnetization of MBE grown multilayered films of a diluted magnetic semiconductor (Ga,Mn)(As,P) with digital modulations of the phosphorus concentration. The samples show two in-plane easy magnetization axes corresponding to the <100> cubic and [110] uniaxial anisotropies, typical for the GaMnAs system. Their remagnetization occurs in two steps through the nucleation and growth of 90-degree domains. Unexpectedly, the domain boundaries align precisely with the easy axes in contrast to our micromagnetic calculations using the measured magnetic parameters of the samples. We discuss how such totally asymmetric Neel domain walls can appear due to Dzyaloshinskii-Moriya interactions enhanced by the multiple sharp interfaces in the multilayered films.

*Magnetic characterization of the films at Argonne was supported by the U.S. Department of Energy, Office of Science, Materials Sciences and Engineering Division. Synthesis of the films at Notre Dame University was supported by the NSF Grant DMR14-00432.
Large perpendicular magnetic anisotropy and anisotropic electronic structure of the new ferromagnetic semiconductor (Ba,K)(Zn,Mn)2As2 single crystal studied by angle-dependent x-ray magnetic circular dichroism

SHOYA SAKAMOTO (Presenter), SLAC National Accelerator Laboratory, GUOQIANG ZHAO, Chinese Academy of Sciences, YOSUKE NONAKA, KEISUKE IKEDA, ZHENDONG CHI, YUXUAN WAN, MASAHIRO SUZUKI, The University of Tokyo, TSUNEHARU KOIDE, KEK, SADAMICHI MAEKAWA, JAEA, CHANGQING JIN, Chinese Academy of Sciences, ATSUSHI FUJIMORI, The University of Tokyo — (Ba,K)(Zn,Mn)2As2 is a new ferromagnetic semiconductor isostructural to 122-type Fe-based superconductors. The Curie temperature (Tc) reaches 230 K for polycrystalline samples exceeding the highest Tc = 200 K of (Ga,Mn)As. In relation to the anisotropic crystal structure, this material has large perpendicular magnetic anisotropy.

In the present study, we have investigated the origin of the perpendicular magnetic anisotropy by angle-dependent x-ray magnetic circular dichroism (AD-XMCD) measurements. The XMCD spectra were similar to those of (Ga,Mn)As and showed multiplet features. This indicates the localized nature of the Mn 3d electrons being consistent with the carrier-induced-ferromagnetism scenario. The angle-dependent measurements yielded the anisotropy field of 0.8 T. The XMCD spectra taken under the transverse geometry (TXMCD), where the spin aligns perpendicular to the x ray, showed finite dichroic signals. This originates from the aspherical distribution of 3d electrons, and indeed the TXMCD spectra were reproduced by the configuration interaction cluster-model calculation incorporating D4h crystal-field splitting. We suggest that degenerate p-dxz,yz hybridized orbitals at the Fermi level are responsible for the magnetic anisotropy of this compound.

Session C40 GMAG DMP: Magnetic Structure in Bulk Oxides

2:30PM C40.00001: Spin density wave order and its influence on the unconventional metallic states in carrier-doped Srnx+1IrnxO3n+1 systems*

STEPHEN WILSON (Presenter), University of California, Santa Barbara — The discovery of spin-orbit assisted or J_eff=1/2 Mott insulating states in select 4d and 5d transition metal oxides has fueled a number of predictions of novel electronic phases that emerge once the parent Mott phase is quenched. Depending on the structure type, examples of these phases span from unconventional superconductivity to new manifestations of correlated topological electronic states. The seminal examples of J_eff=1/2 Mott states found in the homologous Ruddlesden-Popper series Srnx+1IrnxO3n+1 are a versatile platform for understanding the mechanism for the collapse of the Mott state as the J_eff=1/2 band is driven away from half filling and for resolving the presence of nearby electronic instabilities. In this talk, I will present some of our recent work exploring the competing states accessed via chemically doping these compounds. Upon electron-doping into Sr2IrO4 and hole-doping into Sr3Ir2O7, spin density wave states emerge and provide clues to the nature of the unconventional metals that form in each. A “diagonal” spin density wave state analogous to those formed in the underdoped high-Tc cuprates appears in electron-doped Sr2IrO4 and suggests a link between the competing ground states of La2-xSrxCuxO4 and Sr2-xLa2xIrO4. In hole-doped Sr3Ir2O7, the slow collapse of the Mott state reveals an intermediate strange metal regime where spin density wave order survives beyond the collapse of the Mott charge gap. I will discuss these two examples and the implications of each in understanding the phase diagrams of more strongly correlated Mott states.

3:06PM C40.00002: Evolution of Magneto-Orbital order Upon B-Site Electron Doping in Na1-xCa4Mn7O12 Quadruple Perovskite Manganites*

ROGER JOHNSON (Presenter), University of Oxford, FRANCESCO MEZZADRI, Istituto dei Materiali per Elettronica e Magnetismo, PASCAL MANUEL, DMITRY KHAYAVIN, ISIS Facility, STFC, EDMONDO GILJOLI, Istituto dei Materiali per Elettronica e Magnetismo, PAOLO G. RADAELLI, University of Oxford — We present the discovery and refinement by neutron powder diffraction of a new magnetic phase in the Na1-xCa4Mn7O12 quadruple perovskite phase diagram, which is the incommensurate analogue of the well known pseudo-CE phase of the simple perovskite manganites. We demonstrate that incommensurate magnetic order arises in quadruple perovskites due to the exchange interactions between A and B sites. Furthermore, by constructing a simple mean field Heisenberg exchange model that generically describes both simple and quadruple perovskite systems, we show that this new magnetic phase unifies a picture of the interplay between charge, magnetic, and orbital ordering across a wide range of compounds.

3:18PM C40.00003: Magnetic Properties of the Q1D Solid Solution Ca_{1-x}Na_{x}Cr_{2}O_{4} Studied with Neutrons and Muons

ELISABETTA NOCERINO (Presenter), OLA KENJI FORSLUND, Applied Physics, KTH Royal Institute of Technology, YASMIN SASSA, Physics and Astronomy, Uppsala University, DANIEL ANDREICA, Physics, Babes-Bolyai University, HIROSHI NOZAKI, Toyota Central research and Development Lab, GEDIMINAS SIMUTIS, JEAN-CHRISTOPHE ORAIN, Paul Sherrer Institut, HIROYA SAKURAI, National Institute for Materials Science, RUSTEM KHASANOV, Paul Sherrer Institut, JUN SUGIYAMA, IZUMI UMEGAKI, Toyota Central research and Development Lab, MARTIN MÅNSSON, Applied Physics, KTH Royal Institute of Technology — In this work we present the results of the measurements carried out by neutron powder diffraction and muon spin rotation/relaxation (μ+SR) in ambient and high pressure on the $x = 1$ (NaCr$_2$O$_4$) and $x = 0$ (CaCr$_2$O$_4$) members of the solid solution Ca$_{1-x}$Na$_x$Cr$_2$O$_4$ and on the intermediate compound $x = 0.5$ (Ca$_{0.5}$Na$_{0.5}$Cr$_2$O$_4$). The $x = 1$ results show a unique spin structure where the Cr moments in each zig-zag chain are aligned ferromagnetically along the c-axis, whereas antiferromagnetically along the a-axis between the adjacent zig-zag chains. The $x = 0$ results show the formation of a complex magnetic order below $T_N$, that is consistent with an incommensurate AF (IC-AF) order. The investigation on the intermediate compound Ca$_{1-x}$Na$_x$Cr$_2$O$_4$ shows a fast-relaxing component, possibly indicating a spin-glass state. Moreover, the magnetic order was shown to be almost completely unsensitive to pressures (up to $p \approx 25$ kbar), hereby revealing that the effect from the tuning of the spin density of the chains is clearly dominant.

*This research is fully funded by the Swedish Foundation for Strategic Research (SSF) within the Swedish national graduate school in neutron scattering (SwedNess).

3:30PM C40.00004: Experimental observation on Jeff=1/2 state in CuAl2O4

HWANBEOM CHO (Presenter), CHOONG HYUN KIM, Department of Physics and Astronomy, Seoul National University, ARA GO, Center for Theoretical Physics of Complex Systems, Institute for Basic Science (IBS), HOSUB JIN, Department of Physics, Ulsan National Institute of Science and Technology (UNIST), JE-GUEN PARK, Department of Physics and Astronomy, Seoul National University — The spin-orbit entangled pseudo-spin state, Jeff=1/2 has driven intriguing phenomena such as high-Tc superconductivity, quantum spin liquid, and topological semimetal. This studies have been conducted on 4d or 5d compounds but 3d systems haven’t been focused on. The Jeff=1/2 states in 3d systems including cuprates haven’t been considered to emerge in condensed matter physics. One reason is the spin-orbit coupling constant of 3d is smaller than that of Ru (4d) or Ir (5d) ions and the other is that many 3d systems have distorted-crystal structures which lead quenched orbital angular momentum. However, we suggest CuAl2O4 is a candidate material to induce Jeff=1/2 states. Cubic symmetry of the crystal structure verified by single crystal XRD supports Jeff=1/2 nature. Moreover, X-ray absorption spectroscopy also shows this nature following the electric dipole selection rule.

3:42PM C40.00005: Magnetism in spin-orbit coupled oxides

[Invited] ARUN PARAMEKANTI (Presenter), University of Toronto — Transition metal oxides with 4d and 5d ions provide a glimpse into unusual facets of spin-orbit coupled magnetism. In this talk, I will discuss how a theoretical study of resonant inelastic X-ray scattering enables us to extract single-site effective Hamiltonian parameters relevant to “bottom-up” modelling of such materials, including iridates, rhenates, and osmates. Such single-site Hamiltonians are useful to extract spin-exchange interactions, study its sensitivity to lattice distortions, and to understand bulk magnetism. We illustrate this via the exploration of frustrated Jeff=1/2 Mott insulators on the face-centered cubic lattice. These results are applicable to a wide class of materials called double-perovskites. Finally, we show how thin films of spin-orbit coupled metallic magnets may host tunable skyrmion crystals induced by strain and magnetic field, and potentially exhibit a phenomenon we term “topological quantum oscillations”.

*AP is funded by NSERC of Canada through a Discovery Grant, and was partly supported by the Canadian Institute for Advanced Research under the Quantum Materials programme.
4:18PM C40.00006: Magnetic properties of single crystalline Nd$_2$O$_3$^*  BINOD RAI (Presenter), Materials Science and Technology Division, Oak Ridge National Lab, GABRIELE SALA, Neutron Scattering Division, Oak Ridge National Lab, ANDREW D CHRISTIANSON, ANDREW MAY, Materials Science and Technology Division, Oak Ridge National Lab — Triangular-lattice magnets have recently attracted interest due to their exotic phases like frustrated magnetism, quantum spin liquids, and topological spin textures that originate from competing interactions. The nearest-neighbor and next-nearest-neighbor magnetic interactions are crucial to realizing these exotic phases. Nd$_2$O$_3$ is a triangular-lattice compound that crystallizes in the trigonal centrosymmetric space group $Pm1$. Very recently, long-range magnetic order below $T_N = 0.55$ K was revealed by studies on polycrystalline samples of Nd$_2$O$_3$ using neutron diffraction and thermodynamic measurements. The reported frustration ratio of $= 43$ suggests Nd$_2$O$_3$ is a frustrated system driven by competing interactions. We have synthesized single crystals of Nd$_2$O$_3$ to further characterize the intrinsic magnetic properties. This talk will emphasize the anisotropic magnetic properties of Nd$_2$O$_3$ single crystals and the temperature--magnetic field phase diagram.

^*This research was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

4:30PM C40.00007: Muon spin rotation study of the rare-earth quantum dimer system Yb$_2$Si$_2$O$_7$  REDHA ROUANE (Presenter), ARASH AKBARI-SHARBAF, XAVIER BAZIER-MATTE, JEFFREY QUILLIAM, Département de Physique, Université de Sherbrooke, Sherbrooke, QC, Canada, GAVIN L HESTER, KATE A ROSS, Department of Physics, Colorado State University, Fort Collins, Colorado, USA — In quantum dimer systems, a zero-field singlet state can give way to Bose-Einstein condensation (BEC) of triplons under applied magnetic field [1]. We will present work on the material Yb$_2$Si$_2$O$_7$, an effective spin-1/2 antiferromagnet where Yb ions form an anisotropic honeycomb lattice with two different bonds length. It is expected that Yb spins form dimers on the shortest Yb-Yb bonds, and the resulting singlet-triplet gap has been observed with specific heat and inelastic neutron scattering. Between critical fields $H_{C1} = 0.4$ T and $H_{C2} = 1.4$ T, an antiferromagnetic phase reminiscent of a BEC of triplons is observed. We will present a low-temperature µSR investigation of this Yb-based quantum dimer system. Below the critical field $H_{C1}$, our measurements confirm the lack of magnetic order, yet also exhibit anomalous spin relaxation, which might be explained through hyperfine enhancement or a perturbation of the local environment by the implantation of a muon. At longitudinal magnetic fields near and above $H_{C1}$, a dramatic increase in muon spin relaxation, associated with antiferromagnetic order, is observed.

4:42PM C40.00008: Effects of Oxygen Deficiencies in CaMn$_2$O$_4$-δ  MELISSA GOOCH (Presenter), HUNG-CHENG WU, LIANGZI DENG, Physics, Texas Center for Superconductivity at the University of Houston, HUNG-DUEN YANG, Physics, National Sun Yat-sen University, PAUL C. W. CHU, Physics, Texas Center for Superconductivity at the University of Houston — Manganese oxides over the last few years have experienced a considerable increase in research interests due to their rich and complex phase diagrams, that are a result of the flexibility of the manganese ions oxidations states. The compounds in the Ca-Mn-O system provide an excellent platform, where theoretically predicted multiferroic behavior could exist. Many manganese oxides have already been thoroughly investigated; however, a potential candidate CaMn$_2$O$_4$ is still not well understood to date.

Polycrystalline CaMn$_2$O$_4$ samples were synthesized and annealed in oxygen and argon flows respectively to further explore the effect of oxygen deficiencies on the physical properties. From temperature dependent dc magnetization and heat capacity measurements, the previously reported antiferromagnetic ordering near 220 K was observed for both samples. However, a spontaneous polarization ($P_S$) was observed near 253 K for only the oxygen annealed sample without applied magnetic field, while no $P_S$ was observed for the argon annealed sample. In addition, the dielectric and loss measurements revealed anomalies above 260 K with the time and magnetic field dependent phenomena in both samples. Detailed measurements for both samples are ongoing to gain greater insight into this complex system.
Determined lattice distortion of Ba$_2$NaOsO$_6$  
RONG CONG (Presenter), RAVINDRA NANGUNERI, VESNA F MITROVIC, BRENDA RUBENSTEIN, Brown University — Exotic quantum phases have been proposed in magnetic Mott insulators with strong spin-orbit coupling. Our recent nuclear magnetic resonance (NMR) studies of the Mott insulator Ba$_2$NaOsO$_6$ established that local lattice distortions precede the onset of canted ferromagnetic order$^{1,2}$. It was suggested that lattice distortions are a manifestation of the orbital order that drives the magnetism in this class of materials$^3$. To decipher the microscopic nature of the putative orbital order, we investigate different lattice distortion models and calculate their associated NMR observables. Results of various distortion models will be discussed in this talk.

A strongly correlated polar metal LiOsO$_3^*$  
JIANSHI ZHOU (Presenter), JOHN GOODENOUGH, Mechanical Engineering, University of Texas at Austin, KAZUNARI YAMAURA, Superconducting Properties unit, National Institute for Materials Science, XIANG LI, Y. SHIRAKO, Mechanical Engineering, University of Texas at Austin — LiOsO$_3$ is metallic and undergoes a second-order transition to a polar phase at $T_c$=140 K. This unusual property provides a unique opportunity to study the interplay between itinerant electrons and electric dipoles. We report a suite of measurements of the properties of LiOsO$_3$ versus temperature, including resistivity and magnetoresistance on a single crystal sample down to 0.16 K; Seebeck coefficient, Hall coefficient, high-precision magnetization, and the specific heat were made on polycrystalline samples. The results indicate that electrons become strongly correlated in responding to ferroelectric ordering of dipoles.

We have monitored how the thermal conductivity is changed by dipole fluctuations at the transition and how it is influenced by ferroelectric domain boundaries at low temperatures to obtain information on interaction between the electrons and the dipoles. The observation of a transition from glassy to phonon-like thermal conductivity on cooling through $T_c$ provides a solid proof that the ferroelectric transition is an order-disorder, not a displacive transition.

Ground state properties of Sr$_2$RuO$_4$: dynamical mean-field description based on spin-orbit entangled basis$^*$  
HYEONG JUN LEE (Presenter), Center for Theoretical Physics of Complex Systems, Institute for Basic Science, CHOONG HYUN KIM, Center for Correlated Electron Systems, Institute for Basic Science, ARA GO, Center for Theoretical Physics of Complex Systems, Institute for Basic Science — We investigate the ground state wavefunction and dynamical properties of Sr$_2$RuO$_4$ at zero temperature, using the density functional theory plus dynamical mean-field theory with the exact diagonalization solver. We especially focus on the interplay between the spin-orbit and Hund's coupling by considering the full rotationally invariant Kanamori interaction Hamiltonian.

Near the Fermi level, the quasi-particles and low-lying excitations are well described by spin-orbit coupled basis. They exhibit a distinguished self-energy behavior that reflects the signature of the magnetic response and the orbital dependent-correlations of the Hund's metal. We will discuss how these responses are related to the two-fold degeneracy of ground state.

$^*$This work was supported by Institute for Basic Science (IBS) in Korea (IBS-R024-D1 (HJL, AG) and Grant No. IBS-R009-D1 (CHK))

Monday, March 4, 2019 2:30 PM - 5:30 PM

BCEC 209 - Yu-Sheng Ou, University of Delaware - Tag(s): Focus
2:30PM C41.00001: Competing spin transfer and dissipation at Co/Cu(001) interfaces on femtosecond timescales

[Invited] ANDREA ESCHENLOHR (Presenter), Faculty of Physics, University Duisburg-Essen, Germany — Spin dynamics driven by optical excitation with femtosecond (fs) laser pulses offers fascinating possibilities in the ultrafast manipulation of spin-dependent microscopic processes in magnetically ordered materials and heterostructures. In particular, fs spin currents are very promising for future ultrafast spintronics applications. However, the role of the interface in fs spin dynamics is to date largely unexplored. By means of a combined experimental-theoretical approach, we identify the fundamental microscopic processes during optically induced, fs charge and spin transfer at a model epitaxial ferromagnet/paramagnet interface for technologically relevant ferromagnetic heterostructures. A comparison of fs time-resolved, interface-sensitive magneto-optical experiments with ab initio time-dependent density functional theory on the Co/Cu(001) interface demonstrates that the ultrafast spin dynamics originates from spin-dependent charge transfer, including resonantly excited minority spin back-transfer from Cu to Co. Already on timescales below 100 fs, this fs spin transfer competes with dissipation of spin angular momentum mediated by spin-orbit coupling [1].

3:06PM C41.00002: Domain dynamics of a ferromagnetic CoFe/Ni multilayer in response to ultrafast optical pumping

DMITRIY ZUSIN (Presenter), University of Colorado, Boulder / JILA, EZIO IACOCCA, University of Colorado, Boulder, LOIC LE GUYADER, European X-Ray Free-Electron Laser Facility GmbH, ADAM BLONSKY, University of Colorado, Boulder / JILA, ALEX REID, WILLIAM F SCHLOTTER, SLAC National Accelerator Laboratory, Menlo Park, CA, United States, TIANMIN LIU, DANIEL J HIGLEY, Stanford University / LCLS, Menlo Park, CA, United States, PHOEBE TENGandin, CHRISTIAN GENTRY, University of Colorado, Boulder / JILA, SHEENA PATEL, ANATOLY SHABALIN, NELSON HUA, STJEPAN HRKAC, University of California San Diego, HANS T. NEMBACH, JUSTIN SHAW, Quantum Electromagnetics Division, NIST, Boulder, CO, United States, MARK A HOEFER, University of Colorado, Boulder, HENRY C KAPTEYN, MARGARET MARY MURNANE, University of Colorado, Boulder / JILA, ERIC FULLERTON, University of California San Diego, HERMANN DURR, Uppsala University, Sweden, THOMAS SILVA, Quantum Electromagnetics Division, NIST, Boulder, CO, United States — We studied a response of nanoscale magnetic domains in a 50 nm thick [Co90Fe10/Ni] multilayer to a femtosecond laser pulse by use of time-resolved soft X-ray resonant magnetic scattering (RMS) at the Linear Coherent Light Source. By collecting X-ray diffraction at high scattering angles, we observe the 1st, 3rd and 5th order RMS intensity peaks and thus capture the dynamics of fine magnetic features. We observe a rapid shift in the position of all diffraction orders towards smaller scattering angles and a simultaneous reduction of their magnitude. Surprisingly, higher orders start to decline relative to the 1st order only after a few picoseconds. With our data, we develop a method to extract real-space domain dynamics. We find that the dynamics across the domains are non-uniform, with smaller domains demagnetizing stronger than their larger neighbors. The domain walls remain relatively unchanged and start to broaden only after a few picoseconds. Using our models we attribute this behavior to a combined effect of non-uniform spin transport and a gradient in the absorption of the laser pump throughout the sample.

3:18PM C41.00003: Simulations of all optical switching using TDDFT

PETER ELLIOTT (Presenter), J. KAY DEWHURST, Max Planck Institute for Microstructure Physics, SANGEETA SHARMA, Max Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, E.K.U. GROSS, Max Planck Institute for Microstructure Physics — Time dependent density functional theory (TDDFT) is an ab-initio method for studying the magnetization dynamics induced by strong laser pulses. We have previously applied TDDFT to study ultrafast demagnetization in simple ferromagnets[1,2] and optical inter sublattice spin transfer (OISTR)[3] where we found we could switch the magnetic ordering from AFM to a transient FM state[4]. In this work, we simulate RE-TM2 compounds in the C15 Laves geometry and ask whether OISTR plays a role in the all optical switching observed in such materials.

3:30PM C41.00004: High harmonic generation in ferromagnetic thin films as a tool to probe spin and charge dynamics* GUOPING ZHANG (Presenter), Indiana State University, MINGSU SI, Lanzhou University, MITSUKO MURAKAMI, YIHUA BAI, Indiana State University, THOMAS F GEORGE, University of Missouri-St. Louis — High-order harmonic generation (HHG) in solids has garnered worldwide attention [1-3]. The materials include metals, semiconductors, insulators, graphene, fullerenes, and topological insulators. However, this has never been explored for magnetic materials. This study represents the first investigation in the field. We show that HHG in Fe(110) and Fe(001) monolayers carries spin information. If a HHG signal is dispersed into the crystal momentum space, the harmonic peak can be assigned to a single transition, a key step to spin-resolved band structure detection. Different from the optical counterpart, the spin HHG only has even orders. Our findings thus predicts a new frontier of magneto-high-order harmonic generation [4].

3:42PM C41.00005: Absence of Correlation between Damping and Crystal Quality in Epitaxial Fe BEHROUZ KHODADADI (Presenter), MIN GAO, JIE-FANG LI, DWIGHT D VIEHLAND, SATORU EMORI, Virginia Tech — Most studies on ferromagnetic relaxation in metallic thin films are performed on polycrystalline structures, which makes it difficult to compare the experimental findings with theoretical calculations. Also it is unclear how microstructure – in addition to electronic properties – would affect damping in such polycrystalline metallic thin films. Our experimental study investigates the interplay between structure and damping in epitaxial thin films of pure Fe, grown on single-crystal MgO and MgAl₂O₄ substrates by magnetron sputtering. Our structural characterization by X-ray diffraction indicates significantly higher crystalline quality for Fe/MgAl₂O₄ as evidenced by pronounced Laue oscillations and an order of magnitude narrower rocking curve, compared to Fe/MgO. However, we find no difference in the value of Gilbert damping parameter α from broadband ferromagnetic resonance measurements up to 50 GHz, i.e., both Fe/MgAl₂O₄ and Fe/MgO consistently exhibit α ≈ 0.003. Our experimental observations are contrary to the expectations that structural disorder should impact ferromagnetic relaxation, and may provide insight into the fundamental mechanism of damping in metallic ferromagnets.

3:54PM C41.00006: Spin wave generator via oscillating vortex-antivortex core pairs at zero external field* LIANG-JUAN CHANG (Presenter), SHANG-FAN LEE, Institute of Physics, Academia Sinica — We demonstrate that the radiation of spin waves can be generated from an oscillating vortex-antivortex core pair. The emission of spin waves was produced by the oscillation of nanoscale magnetic vortex-antivortex core pair in a NiFe disk-film composite structure. The sample consists of a 20-nm-thick, 4 micron long and 1 micron wide NiFe magnonic waveguide, located at the gap of a single-end GS coplanar waveguide circuit, and magnetic disk with thickness 50 nm and diameter 500 nm on top. The vortex cores in the disk was excited by an out of plane radio frequency magnetic field. The dynamic behaviors of the magnetization were studied using a micro-focused Brillouin light scattering spectroscopy (BLS) setup. In addition to the discrete ferromagnetic resonance (FMR) signals above external dc saturation magnetic field, we observed clear signals at zero magnetic field where vortex cores are present. We have found an ultra-flexible mechanism for consistent excitation of propagating spin waves. The frequencies of the spin waves excited are coherently tunable by the driving frequencies from 5 GHz up to 15 GHz. The short wavelength down to 80 nm for 15 GHz was observed.

4:06PM C41.00007: Ramsauer-Townsend Resonance for Spin Waves  PABLO BORYS (Presenter), NASER QURESHI, OLEG KOLONOTSEV, ICAT, Universidad Nacional Autonoma de Mexico — Spin waves are fluctuations about the stable configuration in a ferromagnet. As spin waves are free from Joule heating, they are interesting for technological applications. Controlling spin waves propagating in solids relies on the predefined, constant magnetic parameters. However, recently, it has been shown that it is possible to have a dynamic variation of these parameters. Using a laser, thermal landscapes are created in the magnetic medium that results in a modulation of the saturation magnetization[1].

We excite spin waves on a thin ferromagnetic film using micromagnetic simulations. The film has a region where saturation magnetization is decreased, creating a potential well. We calculate the spin wave reflection coefficient for different widths of the well. We found that there are resonances on the reflection coefficient. These resonances resemble the ones found in the quantum mechanical Ramsauer-Townsend (RT) effect.[2] The RT effect describes an electron wave propagating above a finite potential well and exhibits resonances for certain energies and well widths.

Our results may be of interest for magnonic applications by only varying the width of the well.

4:18PM C41.00008: Exchange Stiffness in pMTJ Free Layers by Magnetometry and Spin-Torque Ferromagnetic Resonance*  JAMILEH BEIK MOHAMMADI (Presenter), JINTING HANG, New York University, BARTEK KARDASZ, GEORG WOLF, MUSTAFA PINARBASI, Spin Transfer Technologies, ANDREW D KENT, New York University — Exchange interactions play a critical role in setting the scale of micromagnetic structure and the spin-wave excitation spectrum in nanometer scale magnetic elements. Specifically, in perpendicularly magnetized free layers of magnetic tunnel junction (pMTJ) nanopillars, exchange, magnetic anisotropy and dipolar interactions determine the spin-wave modes and magnetization reversal pathways. Here we report studies of the exchange stiffness $A$ in composite CoFeB free layers in pMTJ (extended) thin films. Vibrating sample magnetometry (VSM) was used to determine the free layer magnetization versus temperature, which is fit to Bloch's law to determine $A$. We further perform field modulated spin-transfer FMR (ST-FMR) measurements on 30 to 80nm diameter nanopillars to infer the confined spin-wave modes, providing, in principle, an independent means of determining $A$. We discuss the correspondence between these methods and the nature of the spin-transfer excited spin-wave modes in such pMTJ nanopillars.

4:30PM C41.00009: Dynamics of 1D Magnetic Topological Structures*  MARTYNA SEDLMAYR (Presenter), NICHOLAS SEDLMAYR, Department of Physics and Medical Engineering, Rzeszow University of Technology, JAMAL BERAKDAR, Martin-Luther University Halle-Wittenberg, VITALII DUGAEV, Department of Physics and Medical Engineering, Rzeszow University of Technology — In one dimensional ferromagnetic wires domains of collinear ferromagnetic order can be separated by different types of topological, and non-topological, domain walls. Domains of opposite orientation are typically separated by either Bloch or Néel domain walls, whereas domains of the same orientation can be separated by magnetic impurities, or by a one dimensional equivalent of a skyrmion which may be found in quasi-one dimensional wires. We consider the different current induced dynamics and stability of these various magnetic deformations. We will go on to make a thorough investigation of the different magnetoresistance which can be caused by these various forms of domain walls, paying particular attention to the one dimensional skyrmion.

*This work was supported in Rzeszoow University of Technology by the National Science Center in Poland as research Project No. UMO-2017/27/B/ST3/02881.
4:42PM C41.00010: New spin excitations in metals*

VLADIMIR ANTROPOV (Presenter), ALEX WYSOCKI, MANH CUONG NGUYEN, Ames Laboratory, Ames, IA, 50010, USA, ANDREY KUTEPOV, Brookhaven National Laboratory, Upton, NY 11973, USA, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory, Ames, IA, 50010, USA — The spin excitations in metals have been studied using density functional methods. First, we used linear response method with well converged basis set to obtain the spin excitations in para- and ferromagnetic phases of different d metals at all q-vectors and frequencies. Our calculations revealed the existence of new nearly localized in real space spin excitations in metals and we discuss their relation to the existing experiments. We further analyzed the spin correlations in these metals by using the fluctuation dissipation ratio and a corresponding quantum spin ‘noise’. The very large dynamic spin short range order has been identified and will be shown in paramagnetic Pd. These observed unusual features of spin dynamics and the exchange coupling will be discussed using the analysis of microscopical equations of motion for the charge, current and spin densities in the frame of corresponding density functional approach.

*This work was supported by the Office of Basic Energy Science, Division of Materials Science and Engineering. The research was performed at Ames Laboratory, which is operated for the U.S. DOE by Iowa State University under contract # DE-AC02-07CH11358.

4:54PM C41.00011: On and Off-Resonance Spin Wave/Surface Acoustic Wave Coupling Measured Using Brillouin Light Scattering*

KATHERINE E. NYGREN (Presenter), Department of Physics, Colorado State University, JOSEPH D. SCHNEIDER, QIANCHANG WANG, Mechanical and Aerospace Engineering Department, UCLA, DOMINIC LABANOWSKI, SAYEEF SALAHUDDIN, Department of Electrical Engineering and Computer Science, UC Berkeley, GREG CARMAN, Mechanical and Aerospace Engineering Department, UCLA, KRISTEN S. BUCHANAN, Department of Physics, Colorado State University — Surface acoustic waves (SAWs) have a much longer propagation distance than most spin waves, especially in metallic ferromagnets. If spin waves can be effectively coupled to SAWs they can travel farther and SAW/spin wave coupling also offers new opportunities for energy efficient spin wave generation. Here we have used an interdigital transducer (IDT) on a piezoelectric substrate to produce a SAW at 1.8 GHz and we have studied the coupling of the SAW to spin waves in a 20 nm thick Ni thin film using Brillouin light scattering (BLS). A strong signal is observed at the driving frequency \( f \) that varies in intensity as a function of the applied magnetic field. At fields where \( f \) overlaps with the spin wave manifold an additional peak is observed at 2f that is not present at higher fields, which indicates that nonlinear process are active. Measurements were also performed at multiple locations on the nickel pad to characterize how the spin wave decays with distance.

5:06PM C41.00012: Spin wave excitations of magnetic metalorganic materials*

ROBERTO PÉREZ (Presenter), JOHAN HELLSVIK, RICHARD GEILHUGE, Nordic Institute for Theoretical Physics, MARTIN MÅNSSON, KTH Royal Institute of Technology, ALEXANDER BALATSKY, Nordic Institute for Theoretical Physics — The Organic Materials Database (OMDB) is an open database at Nordita that is hosting about 25,000 electronic band structures, density of states and other properties for synthesized 3-dimensional organic crystals. The web interface of the OMDB offers various search tools for the identification of novel functional materials such as band structure pattern matching and density of states similarity search. In this work we extend the OMDB to include magnetic excitation properties. For inelastic neutron scattering we focus on the dynamical structure factor \( S(Q, \omega) \) which contains information on the excitation modes of the material. We introduce a new dataset containing atomic magnetic moments and Heisenberg exchange parameters for which we calculate the spin wave spectra and dynamic structure factor with linear spin wave theory and atomistic spin dynamics. We thus develop the materials informatics tools to identify topological magnon spectra such as Dirac crossings within the class of organic molecular crystals, and reveal mechanisms for the topological protection of the crossings.

Terahertz-frequency magnetization oscillations in an uncompensated ferrimagnet under a spin-transfer torque*  

IVAN LISENKOV, Winchester Technologies, LLC, ROMAN KHYMYN, JOHAN AKERMAN, Physics Dept., University of Gothenburg, NIAN XIANG SUN (Presenter), Northeastern University, BORIS IVANOV, National Taras Shevchenko University of Kiev — Current of spin-polarized electrons can interact with materials exhibiting a long-range magnetic order via a spin-transfer torque (STT). An STT of a sufficient magnitude may compensate damping and the spins come into a self-sustained precession [1]. In ferromagnetic materials the precession frequency is limited to tens of GHz by the value of the external magnetic field. In materials with more than one magnetic sublattice, the strong exchange interaction speeds up the precession frequency up to several THz [2], but due to magnetic compensation, in antiferromagnetic materials the THz frequency output power is small [3]. In our simulations we show that in easy-plane unbiased nearly compensated GdFeCo thin layers: (i) the precession frequency can be in over of THz and controlled by current, (ii) the precession of the Neel vector is conical, where the cone angle is defined by the non-compensation of the sublattices. The conical precession excites an AC spin-current, which can be converted to AC voltage by inverse spin-Hall effect.

Session C42 DQI: Applications of Noisy Intermediate Scale Quantum Computers I

BCEC 210A - Timothy Hsieh, Perimeter Institute for Theoretical Physics - Tag(s): Focus

2:30PM C42.00001: Error-mitigated quantum computation with noisy superconducting qubits* [Invited]  

*This work was supported by the IBM Research Frontiers Institute.

3:06PM C42.00002: A quantum computing algorithm for the investigation of the molecular excited states  
PAULINE OLLITRAULT (Presenter), PANAGIOTIS BARKOUTSOS, STEFAN WOERNER, IVANO TAVERNELLI, IBM Research - Zurich Research Laboratory — Quantum computing is emerging as a new paradigm for the solution of quantum chemistry problems. Recently, the Variational Quantum Eigensolver (VQE) algorithm has been proposed and successfully applied to the simulation of the ground state properties of simple molecular systems in a real quantum device. The calculation of molecular excited state properties constitute an additional challenge for both classical and quantum electronic structure algorithms. In fact, in addition to the calculation of a well-converged ground state wavefunction, one needs to devise schemes for the evaluation of the higher energy states, which - in general - are not accessible through the simple optimization procedure. In this work, a perturbative approach is applied to the ground state wavefunction to derive a pseudo-eigenvalue problem, which size is characterized by a favorable scaling in the number of electrons. The different matrix elements are measured on the quantum hardware using the ground state wavefunction parametrized according to the UCC and the hardware efficient Ansätze described in [Barkoutsos et al., Phys. Rev. A 98, 022322]. The method is applied to the calculation of the excited states of simple molecules, including H₂, LiH and H₂O.
3:18PM C42.00003: Error Mitigation in the Presence of Spatially Correlated Noise  VICKRAM PREMAKUMAR (Presenter), EKMEK ERCAN, JOYDIP GHOSH, MARK G FRIESEN, MARK ALAN ERIKSSON, SUSAN COPPERSMITH, ROBERT JAMES JOYNT, University of Wisconsin - Madison — The most common error models for quantum computers assume the independence of errors on different qubits. However, most noise mechanisms have some correlations in space. We show how to improve quantum information processing for few-qubit systems when spatial correlations are present. This starts with strategies to measure the correlations. Once the correlations have been determined, we can define decoherence measures that are local in Hilbert space. These measures yield criteria to assess the ability of different candidate quantum circuits to carry out a given task with high fidelity. We show that these criteria work in few-qubit systems. Finally, we point out ways in which error mitigation in few-qubit systems can be extended to large-scale quantum information processing.

3:30PM C42.00004: Benchmarking error mitigation techniques on noisy quantum processors  CORENTIN BISOT, EMMANUEL LILETTE, THOMAS AYRAL (Presenter), Atos Quantum Lab — Several error mitigation techniques have been proposed in the recent years to compensate for the errors of noisy, intermediate-scale quantum (NISQ) devices before full-fledged, yet costly error correction methods can be implemented. Here, we present an implementation of a combination of these techniques, and a detailed benchmark based both on realistic noisy simulations and actual computations on current quantum architectures such as, for instance, superconducting transmon processors. We examine the link between the accuracy of the knowledge of the quantum hardware (via tomography), the accuracy on the final observable, and the overhead of mitigation. We also discuss the relevance of these methods for reaching high enough accuracies in applications such as quantum chemistry.

3:42PM C42.00005: Efficient scheduling of noise characterization protocols in quantum computing architectures  RIDDHI SWAROOP GUPTA (Presenter), MICHAEL JORDAN BIERCUK, Quantum Control Laboratory, The University of Sydney — Spectator qubits embedded in quantum computing architectures enable in situ detection of noise processes affecting quantum hardware. Common spatial correlations between processing and spectator qubits present a new resource which may be exploited in efficient scheduling of measurements. We present an algorithmic framework for 2D field mapping in quantum computing architectures using sparse measurements. We adapt classical simultaneous localisation and mapping (SLAM) techniques to enable spatial field characterization using idle qubits, where idle qubits are a static or a dynamically available resource. A Quantum SLAM (QSLAM) framework is implemented via a particle filter that shares information between neighboring qubits while discovering neighborhood sizes relevant to the physical system; an adaptive controller then schedules future measurements based on this algorithm. We use experimental measurements on a linear array of trapped ions subject to an observed but uncontrolled magnetic field gradient. Numeric simulations demonstrate that QSLAM outperforms a brute force approach for estimating the magnetic field gradient by over an order of magnitude across a range of operating parameter regimes. Extensions to incorporating time dynamics are discussed.

3:54PM C42.00006: Superfast encodings for fermionic quantum simulation*  KANAV SETIA (Presenter), Dartmouth College, SERGEY BRAVYI, ANTONIO MEZZACAPPO, IBM, JAMES WHITFIELD, Dartmouth College — Here we revisit the Superfast Encoding introduced by Kitaev and one of the authors. This encoding maps a target fermionic Hamiltonian with two-body interactions on a graph of degree d to a qubit simulator Hamiltonian composed of Pauli operators of weight O(d). A system of m fermi modes gets mapped to n=O(md) qubits. We propose Generalized Superfast Encodings (GSE) which require the same number of qubits as the original one but have more favorable properties. First, we describe a GSE such that the corresponding quantum code corrects any single-qubit error provided that the interaction graph has degree d≥6. In contrast, we prove that the original Superfast Encoding lacks the error correction property for d<6. Secondly, we describe a GSE that reduces the Pauli weight of the simulator Hamiltonian from O(d)to O(logd). The robustness against errors and a simplified structure of the simulator Hamiltonian offered by GSEs can make simulation of fermionic systems within the reach of near-term quantum devices. As an example, we apply the new encoding to the fermionic Hubbard model on a 2D lattice.

4:06PM C42.00007: Experimental Implementation of Quantum Circuit Born Machines in Near-Term Quantum Devices
ALEJANDRO PERDOMO (Presenter), VICENTE LEYTON-ORTEGA, Rigetti Computing, OSCAR PERDOMO, Central Connecticut State University — Finding valuable machine learning that could benefit from noisy intermediate-scale quantum computers is one of the leading research efforts towards the milestone of practical quantum advantage. In this talk, we will focus in the one of most challenging tasks for the machine learning community: the case of generative modeling in unsupervised machine learning. In Ref. [1], a data-driven quantum circuit learning (DDQCL) approach was proposed as a hybrid quantum-classical algorithm capable of training shallow quantum circuits to prepare desirable quantum states. This resulting quantum state is referred as a Quantum Circuit Born Machine (QCBM) [1,2] and it exploits the probabilistic nature of the Born amplitudes from the computational basis states to capture correlations in the classical training data set. This QCBM model can be used to solve unsupervised generative modeling tasks such as image generation and reconstruction. We will discuss results of experimental implementations of QCBMs via DDQCL, as well as ideas for DDQCL variants that could be useful in, for example, quantum state preparation and noise mitigation.

4:18PM C42.00008: Simulations of Real Time Scattering in the 1D Quantum Ising Model*
ERIK GUSTAFSON (Presenter), YANNICK MEURICE, University of Iowa, JUDAH F UNMUTH-YOCKEY, Department of Physics, Syracuse University — We will discuss the results of quantum simulating a real time scattering event in the 1D Quantum Ising spin models using a quantum simulator. We discuss how we can measure the phase shifts of scattering processes. We compare the results from exact diagonalization with those using a quantum simulator. We examine the errors introduced in our simulation by some of the noise that would be present on a real quantum computer. We discuss the efficacy of simulating this model on a quantum computer.

*We thank the Department of Energy for supporting this research under Award Number: DE-SC0019139

4:30PM C42.00009: Quantum Local Search for Graph Community Detection*
RUSLAN SHAYDULIN (Presenter), HAYATO USHIJIMA-MWESIGWA, ILYA SAFRO, Clemson University, SUSAN MNISZEWSKI, Computer, Computational, & Statistical Sciences Division, Los Alamos National Laboratory, YURI ALEXEEV, Computational Science and Leadership Computing Divisions, Argonne National Laboratory — We present Quantum Local Search (QLS) approach and demonstrate its efficacy by applying it to the problem of community detection in real-world networks. QLS is a hybrid algorithm that combines a classical machine with a small quantum device. QLS starts with an initial solution and searches its neighborhood, iteratively trying to find a better candidate solution. One of the main challenges of the quantum computing in NISQ era is the small number of available qubits. QLS addresses this challenge by using the quantum device only for the neighborhood search, which can be restricted to be small enough to fit on near-term quantum device. We implement QLS for modularity maximization graph clustering using QAOA on IBM Q Experience as a quantum local solver. We demonstrate the potential for quantum acceleration by showing that existing state-of-the-art optimization solvers cannot find a good solution to the local problems quickly and provide an estimate of how larger quantum devices can improve the performance of QLS. We apply QLS to the problem of clustering microbiome co-occurence networks and present the preliminary results.

4:42PM C42.00010: Marginals optimization procedure: algorithmically extending the capability of near-term quantum computers
PETER JOHNSON (Presenter), MAX RADIN, AMARA KATABARWA, JHONATHAN ROMERO, YUDONG CAO, Zapata Computing — We are entering an era in which quantum computers can perform contrived tasks that classical computers cannot. However, these devices are far from being able to break RSA encryption or to simulate complex chemical reactions. A big question driving the field is: can we find a practical use for these near-term intermediate scale quantum (NISQ) devices? A promising approach is to explore “variational quantum algorithms”, which treat a quantum circuit much like an artificial neural network to solve optimization problems approximately. These optimization problems include estimating the ground state energy of a small molecule and understanding the structure of social networks.

Variational quantum algorithms have yet to outperform state-of-the-art classical optimization techniques. While improving quantum devices is necessary to achieve this so-called “quantum advantage”, improving quantum algorithms also brings us closer towards this goal. Based on a simple observation about the role of the quantum computer in these algorithms, we have developed a technique which algorithmically extends the depth of a quantum computer. We describe the marginals optimization procedure for improving variational quantum algorithms and demonstrate its performance in simulations and small experiments.
An analog quantum simulator does not employ digital gates with quantum error correction. Yet, one hopes such devices can achieve a "quantum advantage," i.e., enable the simulation of some property that cannot be simulated efficiently on a classical computer. Typically, one considers "universal" properties in condensed matter, as these are the quantities that are robust in the presence of perturbations [1]. What is the relationship between robustness and complexity? Are the robust properties efficiently simulatable on a classical computer, and the complex properties hyper-sensitive to perturbation? To address these questions, we seek to quantify the reliability of an analog quantum simulator while simulating complex systems and thereby identify these universal quantities. We study a "programmable" analog quantum simulator in the 16-dimensional Hilbert space based on optimal control of atomic spins in cesium [2], and study the basic paradigms such as the excited state quantum phase transitions [3] in the Lipkin-Meshkov-Glick (LMG) model [3].

5:06PM C42.00012: Experimental Methods for Improving Heuristic Quantum Algorithms on NISQ Devices*
BRADLEY MITCHELL (Presenter), RAVI NAIK, UNPIL BAEK, DAR DAHLEN, JOHN MARK KREIKEBAUM, University of California, Berkeley, KEVIN P O' BRIEN, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA, VINAY RAMASESH, MACHIEL BLOK, University of California, Berkeley, WIM LAVRIJSEN, COSTIN IANCU, Lawrence Livermore National Laboratory, Berkeley CA, IRFAN SIDIQI, University of California, Berkeley — Heuristic quantum algorithms, such as QAOA (Quantum Approximate Optimization Algorithm) and VQE (Variational Quantum Eigensolver), have the potential for performing useful, classically intractable calculations on NISQ (Noisy Intermediate Scale Quantum) devices, with applications ranging from general optimization to quantum chemistry. Outstanding challenges in implementing these algorithms include error mitigation and minimizing costly calls to quantum hardware. We report experimental developments to identify and address these challenges on a superconducting quantum processor. To this end, we employ techniques including using an expanded Hilbert space of the transmon as a computational space and performing Pauli twirling operations.

*This work was supported by the Department of Energy.

5:18PM C42.00013: State-of-the-art Classical Tools to Benchmark NISQ Devices*
SALVATORE MANDRA (Presenter), Quantum Artificial Intelligence Lab (QuAIL) @ NASA Ames - Stinger Ghaffarian Technologies (SGT), BENJAMIN VILLALONGA, University of Illinois at Urbana-Champaign - Quantum Artificial Intelligence Lab (QuAIL) @ NASA Ames - USRA Research Institute for Advanced Computer Science (RIACS), SERGIO BOIXO, Google Inc., HELMUT KATZGRABER, Texas A&M University, ELEANOR RIEFFEL, Quantum Artificial Intelligence Lab (QuAIL) @ NASA Ames — In the race to show quantum advantage, early quantum devices must be compared to the state-of-the-art classical technology currently available. At the Quantum Artificial Intelligence Lab (QuAIL) at NASA Ames, we are continuously developing new classical algorithms to benchmark/validate quantum hardware and to raise the bar to claim quantum advantage. In my talk, I will present some of our latest state-of-the-art classical tools to optimize classical cost functions (in collaboration with Texas A&M University), including numerical results on hard benchmark problem sets. Moreover, I will present our optimized classical simulator for large quantum circuits (in collaboration with the Google AI team), including numerical simulations of the Google Bristlecone quantum processing unit.

2:30PM C43.00001: Locating the missing superconducting electrons in overdoped cuprates* [Invited] PETER ARMITAGE (Presenter), Johns Hopkins University — Overdoped high-temperature cuprate superconductors have been widely believed to be described by the physics of d-wave BCS-like superconductivity. However, recent measurements indicate that as the doping is increased, the superfluid density decreases smoothly to zero rather than increasing as expected by BCS theory in the absence of disorder. Here, we combine time-domain THz spectroscopy with kHz range mutual inductance measurements on the same overdoped La$_{2-x}$Sr$_x$CuO$_4$ films to determine both the superfluid and the uncondensed carrier density as a function of doping. A significant fraction of the carriers remains uncondensed in a wide Drude-like peak even as $T_\text{c}$, which, when taken with the linear-in-temperature superfluid density, is inconsistent with existing theories for the role of disorder in suppressing the superfluid density in a d-wave superconductor. Our almost eight orders of magnitude in measurement frequency range gives us a unique look at the low frequency spectral weight distribution, which may suggest the presence of quantum phase fluctuations as the critical doping is approached.

3:06PM C43.00002: Density fluctuations in strange metals* [Invited] PETER ABBAMONTE (Presenter), University of Illinois at Urbana-Champaign — Metals exhibit plasmon excitations, which are collective modes one can think of as sound waves in the electron density (as opposed to the atomic density). The so-called "strange metals" are bizarre phases of matter that fail to exhibit well-defined quasiparticles but somehow are still good conductors, leading one to wonder what degree of freedom is actually carrying the charge. A sensible question to ask is, Do strange metals exhibit plasmons? In this talk I will describe momentum-resolved EELS (M-EELS) measurements of several strange metals, notably Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$ which is also a high-temperature superconductor. I will show that plasmon excitations are barely defined in these materials, which instead exhibit an incoherent continuum of charge fluctuations with no particular length or time scale. These fluctuations obey a simple, power law form, suggesting some kind of scale-invariant phase is present, though the data are not consistent with a (textbook) quantum critical point. I will discuss efforts by theorists to explain this phenomenon using holographic approaches based on the AdS-CFT correspondence.

*M-EELS development was partly supported by DOE grant DE-AC02-98CH10886. Crystal growth was supported by DOE grant DESC0012704. P.A. acknowledges support from the EPiQS program of the Gordon and Betty Moore Foundation, Grant GBMF-4542.

3:42PM C43.00003: Universal superconducting precursor in perovskite-based oxides* [Invited] DAMJAN PELC (Presenter), ZACHARY ANDERSON, BIQIONG YU, CHRIS LEIGHTON, MARTIN GREVEN, University of Minnesota — A pivotal challenge posed by unconventional superconductors is to unravel how superconductivity emerges upon cooling from the generally complex normal state. Some of the most prominent unconventional superconductors are oxides: strontium titanate, strontium ruthenate, and the cuprates exhibit greatly different superconducting transition temperatures $T_c$, and although their respective superconducting pairing mechanisms remain unknown, they are thought to differ as well. We use nonlinear magnetic response – a probe that is uniquely sensitive to the superconducting precursor – to uncover remarkable universal behavior in these three distinct classes of oxide superconductors [1]. We find an unusual exponential temperature dependence of the diamagnetic response above the transition temperature $T_c$, with a characteristic temperature scale that strongly varies with $T_c$. We correlate this scale with the sensitivity of $T_c$ to local stress, indicating that the universal behavior is caused by intrinsic, self-organized structural inhomogeneity inherent to the oxides’ perovskite-based structure. Furthermore, the precursor can be strongly influenced by structural disorder, intentionally induced by uniaxial plastic deformation. The results show that structural inhomogeneity is prevalent in perovskite-related superconductors, with far-reaching implications for the interpretation of their electronic properties in general.

4:18PM C43.00004: NMR study of the effect of hydrostatic pressure on charge-density waves and superconductivity in YBa2Cu3Oy [Invited]  MARC-HENRI JULIEN (Presenter), CNRS Grenoble, Laboratoire National des Champs Magnétiques Intenses (LNCMI) — High-Tc superconductivity in the cuprates arises in close proximity to a charge-density wave (CDW) phase. A challenge in the field is to understand how both phenomena compete and whether, behind pure competition, there is a more involved relationship between them. To tackle this question, experiments have used temperature, magnetic field, hole-doping or uniaxial strain as tuning parameters. The effect of hydrostatic pressure, on the other hand, is controversial. Here, using nuclear magnetic resonance (NMR) in YBa2Cu3Oy, we find that the short-range CDW in the normal state as well as the long-range CDW in high fields are weakened only slightly at a pressure of 1.9 GPa. Quantitative analysis of the data supports the hypothesis that virtually all of the increase in Tc upon increasing pressure arises from a gradual decrease of CDW strength up to ~15 GPa. We propose explanations for some of the conflicting conclusions drawn from different experiments and suggest that they may actually shed light on the CDW.

Work done with I. Vinograd, R. Zhou, H. Mayaffre, S. Krämer (LNCMI Grenoble), R. Liang, W.N. Hardy, D.A. Bonn (University of British Columbia)

4:54PM C43.00005: Uniaxial Pressure Control of Competing Orders in a High Temperature Superconductor [Invited]  MATTHIEU LE TACON (Presenter), Karlsruhe Institute of Technology — External control of electronic phases in correlated-electron materials is a long-standing challenge of condensed-matter research. Layered cuprates exhibit antiferromagnetic, charge density-wave (CDW), and high-temperature superconducting ground states which can be tuned by doping and external magnetic fields. However, disorder generated by lattice defects and randomly pinned magnetic vortices greatly complicates the interpretation of these experiments.

Here, we report a high-resolution inelastic x-ray scattering study of the high-temperature superconductor YBa2Cu3O6.67 under uniaxial stress (1), and show that a three-dimensional long range-ordered CDW state can be induced by pressure along the a-axis, in the absence of magnetic fields. The amplitude of the CDW is strongly suppressed below the superconducting transition temperature, indicating strong thermodynamic competition with superconductivity. We also show that the transition is driven by the complete softening of an optical phonon mode.

The results provide new insights into the anomalous normal-state properties of high temperature superconductors and illustrate the potential of uniaxial-pressure control of competing orders in quantum materials.

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C44 : Dynamics in Glassy Systems 8CEC 210C - Andrea Liu, University of Pennsylvania - Tag(s): Invited

2:30PM C44.00001: Connections between classical mean field models with glassy dynamics and quantum SYK models [Invited]  JORGE KURCHAN (Presenter), Ecole Normal Superieure Paris — TBD

3:06PM C44.00002: On the trap model description of glassy dynamics* [Invited]  M. BAITY-JESI, Chemistry, Columbia, NYC, GIULIO BIROLI, Physics, ENS, Paris, CHIARA CAMMAROTA (Presenter), Mathematics, King's College London, UK, ENZO MARINARI, Physics, Sapienza, Rome — The description of activated dynamics of glassy systems in the multidimensional configurational space is a long-standing open problem. In this talk I will discuss about recent studies of the equilibrium and out-of-equilibrium dynamics of a number of models with rough potential energy landscapes. These models provide examples of dynamics where typical relaxation channels go over finite potential energy barriers despite the presence of less-energy-demanding escaping paths in configurational space. This phenomenon is naturally expected to be relevant in the thermally activated regime of realistic models of glass-formers. The numerical and analytic results will show whether, and to what extent, due to this phenomenon the activated dynamics displayed by these models can be effectively described in terms of the fully solvable dynamics of thermally-activated systems like trap models.

*Simons Foundation for the collaboration “Cracking the Glass Problem” (No. 454935 to G. Biroli), ERC grant CIPHERASY (Grant No. 247328), ERC grant NPRGGLASS (No. 279950), ERC grant (No. 694925)
Understanding the geometrical properties of high-dimensional, random energy landscapes is a central problem in the physics of glassy systems, as well as in interdisciplinary applications to computer science, ecology and biology.

In this talk I will discuss a framework to compute the statistical distribution of stationary points of random landscapes, making use of a replicated version of the Kac-Rice formula. I will focus on models which provide a mean-field description of the glass transition, and discuss how to compute the statistics of the energy barriers between local minima of the landscape. I will discuss the dynamical implications on these results, especially for the activated regime of the dynamics.

*Simons Foundation collaboration Cracking the Glass Problem (No. 454935 to G. Biroli)

4:18PM C44.00004: Glassy dynamics: mean-field theory and beyond* [Invited] GRZEGORZ SZAMEL (Presenter), Colorado State Univ — The slowing down of a liquid's dynamics upon approaching the glass transition is accompanied by a number of novel dynamical phenomena: transient localization of particles' positions, strong spatial and temporal fluctuations of the dynamics of individual particles, etc. The description of these dynamics, even at the level of a mean-field theory, is still being developed. I will present a simple theory for the dynamics of mean-field-like models of glass forming liquids. Next, I will turn to the glassy dynamics of one particle moving in a frozen matrix and, in this simpler case, show how one can incorporate dynamic events neglected in the mean-field approach.

*NSF DMR-1608086

4:54PM C44.00005: New computational approaches to dynamics in complex landscapes [Invited] DAVID REICHMAN (Presenter), Columbia University — TBD

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C45 DCMP: Oxide Surfaces and Defects BCEC 211 - Christopher Homes, Brookhaven National Laboratory

2:30PM C45.00001: Surface reaction kinetics of dimethyl methylphosphonate (DMMP) on zirconium hydroxide using attenuated total reflection infrared (ATR-FTIR) spectroscopy* SEOKMIN JEON (Presenter), Chemistry Division at US Naval Research Laboratory, National Research Council Research Associateship Program, ROBERT B BALOW, GRANT C DANIELS, Chemistry Division, US Naval Research Laboratory, JESSE S KO, Chemistry Division at US Naval Research Laboratory, National Research Council Research Associateship Program, PEHR E. PEHRSSON, Chemistry Division, US Naval Research Laboratory — Amorphous zirconium hydroxide (ZH) attracts growing attention due to its high activity for decomposing toxic chemicals, especially chemical warfare agents (CWA). We synthesize zirconium hydroxide films using cathodic electrodeposition and investigate their surface chemistry to a CWA simulant, dimethyl methylphosphonate (DMMP), using attenuated total reflection infrared spectroscopy (ATR).

The ATR data show the accumulation of surface-bound decomposition products, including methoxy and phosphonate derivatives. Time-dependent IR absorption spectra reveal the adsorption, decomposition, and desorption kinetics. Growth of the IR absorption intensities for surface reaction products is evaluated with various adsorption and diffusion kinetic models. Thermodynamic parameters are derived from the adsorption isotherm. The dependence of the kinetic and thermodynamic parameters on reaction temperature will be discussed.

Calcination of amorphous zirconium hydroxide produces crystalline zirconia via a transition to amorphous zirconia. Reduced chemical activity upon calcination correlates with decreased surface area and loss of hydroxyl groups, as confirmed by XPS and ATR data.

Microscopic investigation on surface structures and intrinsic defects of Cu$_2$O(111)*

LY TRINH (Presenter), Department of Physics, BRL, and EHSRC, University of Ulsan, Ulsan 44610, Korea (the Republic of), TAEHUN LEE, Department of Materials Science and Engineering, Yonsei University, Seoul 03722, Republic of Korea, GANBAT DUVJIR, SANGHWA KIM, Department of Physics, BRL, and EHSRC, University of Ulsan, Ulsan 44610, Korea (the Republic of), ALOYSIUS SOON, Department of Materials Science and Engineering, Yonsei University, Seoul 03722, Republic of Korea, SE YOUNG JEONG, Department of Nanoenergy Engineering and College of Nanoscience and Nanotechnology, Pusan National University, Busan 46241, Korea (the Republic of), JUNGDAE KIM, Department of Physics, BRL, and EHSRC, University of Ulsan, Ulsan 44610, Korea (the Republic of) — Copper (I) oxide or cuprous oxide (Cu$_2$O) is known to be a p-type semiconductor with direct band gap of ~ 2.1 eV. Since most binary oxides exhibit n-type behavior originating from the donor nature of oxygen vacancies, Cu$_2$O has been considered as a p-type counterpart for oxide-based electronics. Although some theoretical studies reported about the origin of p-type nature in Cu$_2$O, atomistic experimental study on this issue has not been conducted yet. In this work, we investigate the surface structures and intrinsic defects of Cu$_2$O(111) via home-built low temperature scanning tunneling microscopy (STM). Thin Cu$_2$O(111) layer is prepared on top of Cu(111) film by ambient oxidation, and the surface of Cu$_2$O(111) is cleaned by Ar sputtering and annealing for STM experiments. STM topography reveals the stoichiometric oxygen-terminated surfaces of Cu$_2$O(111). We also directly observed two types of intrinsic defects which show different contrast in topography depending on bias polarity. These defects are identified by comparison with density functional theory (DFT) simulations. The electronic property of defects will be discussed during the presentation.

*This work was supported by the National Research Foundation of Korea [NRF-2015R1D1A1A01057271, NRF-2009-0093818, and NRF-2014R1A4A1071686].

Cu$_2$O island growth during Cu oxidation revealed by correlated in situ ETEM and multiscale simulations*

MENG LI, MATT CURNAN, University of Pittsburgh, XINYU LI, GRAEME HENKELMAN, University of Texas, Austin, WISSAM SAIDI, JUDITH YANG (Presenter), University of Pittsburgh — Fundamental understanding of the surface oxidation process is essential for controlling and predicting oxide growth for catalysts and electronic devices applications. Despite numerous studies on the bulk oxidation process, the initial oxide growth process is still less explored, especially at the atomic scale. In this work, by combining in situ Environmental TEM (ETEM) with multiscale atomistic simulation, the dynamic process of initial Cu$_2$O nano island growth was explored. Our ETEM result shows during Cu(100) oxidation, Cu$_2$O nano islands grow through a layer-by-layer adatom growth mechanism along Cu$_2$O(110) surface. Our simulation results show that comparing with Cu$_2$O(100), Cu$_2$O(110) has lower surface energy, lower Cu diffusion energy and more favorable Cu adsorption energy, leading to easier Cu$_2$O monolayer formation along Cu$_2$O(110) that ultimately caused the observed layer-by-layer oxide growth. These results will enhance the understanding of surface oxidation and will also provide insights into understanding initial oxide growth mechanisms of other metal/alloy systems.

First-principles study of Iridium oxide desorption from iridium low-index surfaces at high temperature

INSUNG SEO (Presenter), Materials Science and Engineering, Tokyo Institute of Technology, SHUNSUKE YOKOTA, YOUSUKE IMAI, ISHIFUKU Metal Industry, YOSHIHIRO GOHDA, Materials Science and Engineering, Tokyo Institute of Technology — Iridium is one of the noble metals. Although iridium has good chemical inertness and mechanical properties especially at high temperature, iridium has a problem to use, due to the desorption problem[1]. It is known that desorption occurs mainly the form of IrO$_3$ molecule below 1775K[2]. To investigate about iridium desorption problem, theoretical understanding of iridium surface oxide is needed. In this study, we investigate surface oxide of low-index iridium surface, such as Ir(100), Ir(110), and Ir(111) to find energetically favorable surface oxide by using first-principles calculations based on density functional theory. Also we use a thermodynamical approach, we can find energetic difference between the low temperature and high temperature.

3:18PM C45.00005: Atomic Structure and Nano-Fracture Mechanics of Semiconductor-Oxide Interfaces
Investigated by Transmission Electron Microscopy and Scanning Force Microscopy

DIPANWITA DUTTA (Presenter), Paul Scherrer Institute, DARIUSZ JARZABEK, Mechanics of Materials, Institute of Fundamental Technological Research, Polish Academy of Sciences, HELMUT SCHIFT, Paul Scherrer Institute, ZYGMUNT RYMUZA, Micromechanics and Photonics, Warsaw University of Technology, THOMAS JUNG, Paul Scherrer Institute — Quantitative Information on interface adhesion and fracture resistance is of importance for electronic and MEMS/NEWS device manufacturing. Here we focus on Scanning Force Microscopy derived methods [1] which reveal the mechanical properties and fracture thresholds of oxide with respect to semiconductor interfaces like SiO$_2$/Si and SiO$_2$/SiC. Load/unload cycles i.e. force vs. distance curves reflect the effect of structural defects on interface strength under the influence of fluids solubilising and modifying surface/interface layers [2]. Nanomechanic properties can be assessed at different time scales. Interface defects are characterized by complementary Microscopic and Spectroscopic Nanoanalysis using STEM and HR-TEM.

3:30PM C45.00006: Amorphous Networks at the Atomic-Scale: Comparing Two-Dimensional Silica and Germania

KRISTEN BURSON (Presenter), Physics, Hamilton College, ADRIAN LEWANDOWSKI, Chemical Physics, Fritz-Haber Institute of the MPG, PHILOMENA SCHLEXER, Materials Science, Università di Milano-Bicocca, CHRISTIN BUECHNER, Lawrence Berkeley National Laboratory, HANNAH BURRALL, Physics, Hamilton College, WOLF-DIETER SCHNEIDER, Chemical Physics, Fritz-Haber Institute of the MPG, GIANFRANCO PACCHIONI, Materials Science, Università di Milano-Bicocca, MARKUS HEYEDE, H J FREUND, Chemical Physics, Fritz-Haber Institute of the MPG — Recently, new insight into the atomic-scale structure of amorphous networks was established through the development of 2D thin-films of known glass formers using scanning tunneling microscopy (STM) in combination with density functional theory (DFT) [1-3]. Here we present a study of two prominent glass-formers, silica and germania, using high-resolution ultra-high vacuum STM to characterize structure. Both SiO$_x$ and GeO$_x$ films were grown on Ru(0001) by physical vapor deposition and subsequent annealing in oxygen, yielding either crystalline or amorphous structures. STM images reveal a hexagonal network with domain boundary structures in atomically flat monolayer films for both glass formers, with germania showing a greater variety of structures. Bilayer films provide for the development of amorphous structure and similar ring structures are seen for both materials. A few exceptions to the structural analogy are seen experimentally and described by DFT, which predicts a stronger interaction with the metal support for germania. This work reveals commonalities and species dependency for glassy structures.

3:42PM C45.00007: A non-invasive SOI gating method of probing pristine chemically-terminated silicon surfaces

LUKE ROBERTSON (Presenter), BRUCE E KANE, Laboratory for Physical Sciences — Silicon has a variety of surface terminations available to it in which surface states are passivated and where 2D electron inversion layers are possible through electrostatic gating. Here, Si(111) surfaces are terminated with hydrogen using a simple wet chemical treatment, and techniques to probe 2D transport on these passivated surfaces have been established. We are presently developing new techniques to probe pristine hydrogen-terminated Si surfaces using a non-invasive SOI flip-chip gating assembly in which all critical device fabrication is performed on the SOI end. Extremely high mobilities, in excess of 300,000 cm$^2$/Vs, have been demonstrated in our previous generation devices, and further refinement of these novel techniques to preserve the pristine nature of these passivated Si surfaces is expected to yield even higher mobilities. Until now, we have focused exclusively on H-Si(111), but are in process of extending our study to include H-Si(100) surfaces. Further, recent progress in halogen-terminated (Cl, Br, I) Si surfaces has provided new avenues for future investigation using our device platform. Architecture details and ohmic contact tests will be presented as well as ongoing low temperature device characterization measurements.

*The Laboratory for Physical Sciences
3:54PM C45.00008: DFT-MD simulations of reaction mechanisms between tricresyl phosphate and Fe₃O₄ (111) surface*  
NAOKI UEMURA (Presenter), SHUJI OGATA, Nagoya Institute of Technology, YOSUKE HARADA, Idemitsu Kosan Co., Ltd. — Tricresyl Phosphate (TCP), used, e.g., as an anti-wear additive reacts to form surface layers on metal and metal oxide under high pressure and high temperature. So far, many experimental and theoretical studies have suggested principal factors that affect the reaction: configurational orientations of P=O group of TCP on the surface, water molecules on the surface, and oxygen atoms of oxidized metal. In a recent DFT study [1], three decomposition mechanisms of TCP on pure iron surfaces was investigated. We here perform DFT-MD simulations of gradually pressurized (~10 GPa) TCP on Fe₃O₄ (111) surfaces to understand the effects of exposed oxygen atoms of the Fe₃O₄ surfaces and of TCP orientations initially relaxed on the Fe₃O₄ surfaces. We thereby find that: (i) the P-O bond that connect to the toluene base of TCP breaks in all cases, (ii) the P-O bond breaking is attributed to the attacking by either oxygen or iron atom of the Fe₃O₄ surfaces, (iii) the adsorption behavior of TCP varies depending on the initial TCP orientations and the amount of exposed oxygen atoms of the Fe₃O₄ surfaces.

4:06PM C45.00009: Exceptional scaling relation exhibited by oxygen reduction reaction intermediates on TiO₂ surfaces  
YOSHIYUKI YAMAMOTO (Presenter), SHUSUKE KASAMATSU, OSAMU SUGINO, The Institute for Solid State Physics, The University of Tokyo — Enhancing the oxygen reduction reaction (ORR) is a major topic of electrocatalysis, and surfaces have long been designed to realize a full alignment of the adsorption energies of the reaction intermediates, O₂*, O*, OH* and OOH*. The alignment is not easy to realize because the adsorption energies often change obeying a linear relationship among them, known as the scaling relation, rather than change independently by modifying the surface. Pristine oxide surfaces tend to show the scaling relation [1], but defective TiO₂, attracted attention as the electrocatalyst beyond Pt, may behave exceptionally because of the measured high reactivity. Our density functional calculations have shown that OH* and OOH* on defective TiO₂ surfaces follow the same scaling relation found for typical pristine oxide surfaces, suggesting defective TiO₂ is not closer to the ideal catalyst. To our surprise, however, there are metastable surfaces whose pristine surfaces exhibit a significantly deviated relation. This exceptional behavior is related to the fact that those surfaces let OOH* dissociate into O* at a two-folded O site and OH* at a Ti. The deviation from the scaling relation suggests a possibility towards realizing an ideal catalyst.

4:18PM C45.00010: Structural and electronic coupling at the surface of SrTiO₃ (001)*  
MOHAMMAD SAGHAYEZHIAN (Presenter), Physics and astronomy, Louisiana State University, S. M. REZAEI, Institute for Research in Fundamental Sciences (IPM), JIANDI ZHANG, E WARD PLUMMER, Physics and astronomy, Louisiana State University — The surface of SrTiO₃ (001) is considered to be weakly polar and in this work, we study the validity of this notion. Using low energy electron diffraction at room temperature, a surface structural distortion was found. Structural analysis shows the presence of strong surface rumpling in the TiO₂ terminated surface with the Ti and O atoms move in and outward. Density functional calculations confirm the measured rumpling, and experimental data show the distortion is localized at the surface. Angle-dependent core-level X-ray photoemission spectroscopy (XPS) shows that the surface rumpling strongly impacts the electronic structure of the surface. Density functional theory demonstrates that the valence state of Ti at the surface is reduced while O is enhanced. In addition, we found the Ti-O bonds are more covalent near the surface. Changes in the XPS satellite structures at the surface are consistent with this picture of the change in bonding, indicating that the (001) surface of SrTiO₃ is not polar and charge rearrangement is a consequence of surface rumpling. We will also present our latest finding on the effect of cubic-tetragonal transition on the surface structure.

*This work was supported by the US Department of Energy (DOE) under Grant No. DOE DE-SC0002136.
Cryogenic force microscopy of Sketched LaAlO₃/SrTiO₃ Nanostructures

JOSEPH ALBRO (Presenter), JESSICA H MONTONE, FENG BI, MENGCHEN HUANG, Physics and Astronomy, University of Pittsburgh, JUNG-WOO LEE, HYUNGWOO LEE, CHANG-BEOM EOM, Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, Physics and Astronomy, University of Pittsburgh —

Local probes can provide insight into the electronic properties of 2D oxide interfaces (in particular, LaAlO₃/SrTiO₃) that are hard to determine using bulk transport methods. Scanning SQUID microscopy has revealed enhanced transport along ferroelastic domain boundaries [1]. Recently, Frenkel et al showed [2] that local pressure applied to the LAO/STO interface can reveal enhanced transport along ferroelastic domain boundaries. We are interested in resolving electron transport in LaAlO₃/SrTiO₃ nanostructures that are “sketched” [3] using conductive-AFM lithography. We describe experiments performed both at room temperature and at low temperatures (<25 K) using a modified vacuum AFM.

Molecular Beam Epitaxy (MBE) Growth of Model Cathode to Study Interfacial Ion Diffusion

BILASH KC (Presenter), JAKE R JOKISAARI, ROBERT KLIE, University of Illinois at Chicago — High performance lithium transition metal oxide battery cathodes, such as LiMn₂O₄, remain a highly active research area. Single-crystals provide well-defined orientations, defect concentrations, homogeneity, and surface terminations that allow isolation of specific chemical and structural aspects of intercalation to be examined. These features make single crystals highly desirable for characterization of pristine and cycled cathodes, compared to polycrystals/particles.

Here we present single-crystal LiMn₂O₄ thin films grown using MBE as model cathodes. Pristine and electrochemically cycled films were characterized using X-ray diffraction (XRD), X-ray photoemission spectroscopy (XPS), transmission electron microscopy (TEM/STEM), and electron energy loss spectroscopy (EELS) to study the effects of surface orientation, Mn dissolution, defects, and solid electrolyte interface (SEI) on the structural changes in the films and interfaces during (de)intercalation.

The authors acknowledge funding from the Joint Center for Energy Storage Research (JCESR), funded by U.S. Department of Energy (DoE). The acquisition of the JEOL JEM-ARM200CF and Gatan Quantum GIF was supported by grants from National Science Foundation (DMR-0959470) and DMR-1626065 respectively.

Homoepitaxial growth of SrTiO₃ by Pulsed Laser Deposition: energetic vs thermal growth

JEFFREY ULBRANDT (Presenter), XIAOZHI ZHANG, University of Vermont, RUI LIU, MATTHEW DAWBER, Stonybrook University, RANDALL HEADRICK, University of Vermont — The role of energetic processes in homoepitaxial growth of SrTiO₃ (STO) by Pulsed Laser Deposition (PLD) was studied via Real-Time X-ray scattering. Two process were developed, an energetic process and a thermal process. Both processes utilized a background gas of 2 mTorr of O₂. The thermal process had an additional 300 mTorr of Helium to act as a buffer gas. Langmuir probe measurements verified the energies of the two process to be between 50-100 electron-volts (eV) and 0.02-0.05 eV respectively. Specular X-ray reflectivity, sensitive to inter-layer transport of material, was the same for both processes. Diffuse scattering, sensitive to the in-plane transport of material, was markedly different. In the thermal process, sharp peaks in the diffuse scattering arise with the growth of each successive layer indicating growth of well correlated islands with a well-defined mean spacing. In the energetic process, diffuse scattering peaks also arise at a similar wavevector, though much weaker and broader. These results suggest an energetic process, such as island breakup, may be responsible for the broadening of the diffuse scattering, in which material from the edges of growing islands is broken off into smaller islands.

Surface Stress in nano-oxides and what it tell us

SIU-WAI CHAN (Presenter), Columbia University — Surface stress of solid surfaces and interfaces is ubiquitous, but has not often been modeled/calculated. In this short talk, experimental results definitely prove that surface stress exists in nanocrystals and can be modified with adsorbents affecting the material's basic properties such as stiffness and thermal expansion. It is particularly influential in surface/interface dominated systems such as thin films and nanoparticles. Whether we choose to deal with it, it will often spring surprises on us during processing for advanced architecture in novel device integration.

NSF DMR Funding 2012-2016
5:18PM C45.00015: Adsorption and destruction of nerve agent sarin and its simulant DMMP on zinc oxide* ROMAN TSYSHEVSKIY (Presenter), SCOTT HOLDREN, University of Maryland College Park, KENAN FEARS, JEFFREY OWRUTSKY, U.S. Naval Research Laboratory, BRYAN EICHHORN, MICHAEL ZACHARIAH, MAJJA M KUKLA, University of Maryland College Park — Discovery and design of new filter materials requires an atomistic level understanding of how these materials interact with toxic agents. High toxicity of chemical warfare agents (CWAs) is the main barrier for experimental study of these compounds which hinders the search for improved filter materials. To fill the gaps in the understanding of CWA interactions with existing and potential filter materials, relatively benign simulant compounds are usually used to replace toxic CWAs. Despite structural similarity of the simulants with real chemical agents the questions have been frequently raised about the reliability of the results obtained for CWA simulants and ability to extrapolate these results to real toxins. Here we report results of our joint DRIFTS, FTIR and DFT study of adsorption and destruction of dimethyl methylphosphonate (DMMP) simulant molecule on ZnO nanoparticles. The synergy between theory and experiment enables further DFT modeling of interactions of the nerve agent sarin with pristine and hydroxylated ZnO surfaces. Results of this work provide new important details on mechanisms and kinetics of destruction of these compounds on ZnO.

*This work was funded by DTRA (HDTRA11510005) R.T. acknowledges support from XSEDE, NERSC, MARCC and UMD supercomputing resources.

Session C46 DMP: 4d/5d Transition Metal Systems -- Chalcogenides and Nonoxides

2:30PM C46.00001: Electrical and Magnetic Properties of PdSb2 and PtBi2 with Multiple Band Degeneracy* RONGYING JIN (Presenter), Louisiana State University — The discovery of topological properties in condensed matter started a new era of physics. Many fermionic particles and phenomena predicted in high energy physics are now experimentally observed in topological materials such as Dirac, Weyl, and Majorana particles. Their nontrivial topology results from crossings of conduction and valence bands. Depending on crystal symmetry, such crossings can result in degeneracy (g) with g = 2, 3, 4, 6, and 8. It is known that g = 2 corresponds to Weyl fermions, and g = 4 corresponds to Dirac fermions. The cases of g = 3, 6, and 8 are of particularly interesting as they can only be found in condensed matter systems, having no high energy analogues as constrained by Poincare symmetry. In this talk, I will present our experimental investigations on a 4d compound PdSb2 with g = 6, and a 5d compound PtBi2 with g = 3. By analyzing both the de Haas-van Alphen and Shubnikov-de Haas oscillations observed in these compounds, we obtain topological properties of the bands. The implications of these findings will be discussed.

*This work was supported by DOE via DE-SC0012432 and DE-SC0016315.

3:06PM C46.00002: Confirmation of Semiconducting Behavior in TaIrGe ETERI SVANIDZE (Presenter), M BOBNAR, I ANTONYSHYN, MARKUS KOENIG, O SICHEVYCH, U BURKHARDT, F WAGNER, YURI GRIN, Max Planck Institute for Chemical Physics of Solids — Despite being exclusively composed of metallic elements, the half-Heusler compound TaIrGe has been predicted to be a semiconductor with a large indirect gap. Several experimental results, however, have shown metallic behavior. This discrepancy between theoretical prediction and experimental observation is assumed to be due to difficulties in material synthesis. Specifically, the presence of several neighboring phases prevents the synthesis of TaIrGe in single-phase form. With that in mind, we implement focused-ion-beam structuring to polycrystalline TaIrGe. This work does not only provide evidence for intrinsic semiconducting behavior of TaIrGe, but also serves as the first example of selective domain structuring in a polycrystalline material. This novel approach gives a rare opportunity to access materials that cannot be synthesized in single-phase form, sparing costly and time-consuming synthesis efforts, which are frequently futile.
SMITA SPEER (Presenter), HONG CHANG, XIN GUI, MADALYNN G. MARSHALL, WEIWEI XIE, RONGYING JIN, Louisiana State University — Transition-metal stannides are known to exhibit strong d-p hybridization, leading to narrow band gap semiconductors. We have successfully grown Ir$_3$Sn$_{7-x}$Mnx single crystals using the flux method. Single crystal x-ray diffraction refinement indicates that Ir$_3$Sn$_{7-x}$Mnx forms a cubic structure (space group Im3m), and the dopant Mn occupies the Sn site. For x = 0.1, the electrical resistivity shows metallic behavior and can be described by $\rho = \rho_o + aT^2 + bT$ between ~22 K and 300 K. An upturn is observed below 22 K, which is due to an antiferromagnetic (AFM) transition as reflected in the magnetization. Unexpectedly, the application of magnetic field results in negative magnetoresistance below the AFM transition. The effect of Mn doping will be discussed.

*This work is supported by the National GEM Consortium and the Department of Physics & Astronomy, LSU-BR

ZHEN WANG (Presenter), GUIXIN CAO, ZHENYU ZHANG, Louisiana State University, MYUNG-GEUN HAN, LIJUN WU, YIMEI ZHU, RONGYING JIN, 2Condensed Matter Physics and Materials Science Departement, Brookhaven National Laboratory, E WARD PLUMMER, Louisiana State University — Transition-metal dichalcogenide IrTe$_2$ has attracted extensive attention because of its intriguing structural transitions, abnormal resistivity, and superconductivity. While it forms a trigonal phase at room temperature, the structure below the phase transition at 280 K is still in debate. With in-situ transmission and scanning transmission electron microscopy (STEM), we study the phase transitions of IrTe$_2$ single crystal from room temperature down to 20 K. The electron diffraction and imaging results show that IrTe$_2$ below 280 K is phase separated, with the coexistence of the well-characterized 5 × 1 × 5 phase, an intergrowth phases with multiple modulated vectors, and the remaining trigonal phase. The 5 × 1 × 5 phase is present down to 20 K, but we never observe the 6 × 1 × 6 or 8 × 1 × 8 phase previously reported. The valence states of IrTe$_2$ for different phases have been investigated by electron energy loss spectroscopy. A clear picture of the temperature-dependent structural evolution of bulk IrTe$_2$, which is essential to understand the unique electric and magnetic behaviors, will be presented.

**Supported by U.S. NSF through grant No. NSF DMR-1504226

RESHEF TENNE (Presenter), Weizmann Institute of Science — Misfit layered compounds (MLC) of the form (MX)$_{1+y}$TX$_2$ (M=Pb, Sn, rare earth, etc.; X=S,Se,Te; T=Sn, Ta, V, etc.) are known since about 50 years and have been studied by various groups. They are made of an alternating lattice made of one layer of a distorted cubic (orthorhombic) sublattice, like PbS (MS), and hexagonal/octahedral lattice of, e.g. SnS$_2$ or NbS$_2$ (TS$_2$) in a periodic arrangement (denoted as MS.TS$_2$ for brevity). Van der Waals forces hold the MX and TX$_2$ layers together, as well as polarization forces which emanate from partial charge transfer from the MX to the TX$_2$ units. Modern techniques allow synthesizing more complex superstructures from the MX and TX$_2$ sublattices. In many cases, the unit length of the two sublattices coincide along the directions b & c and is incommensurate along a. The lattice mismatch between the MX and TX$_2$ sublattices is known to lead to the formation of microscopic cylindrical crystals for many years.

It was hypothesized that combining the lattice mismatch in the MX.TX$_2$ misfit structure and the general instability of nanocrystals from layered compounds, due to edge effects, will lead to nanotubes (and also nanoscrolls) of small diameter (<300 nm) and high aspect ratio (>10). Exploiting variety of solid state chemical techniques nanotubular structures from a large variety of misfit compounds, like SnS.SnS$_2$; PbS.NbS$_2$ and LnS.TaS$_2$ MLC were synthesized. Several CoO$_2$ based MLC tubes were synthesized and characterized as well. Their structure was studied mostly via transmission electron microscopy as well as some DFT calculations. Raman analysis indicate that the interlayer interactions are stronger in the tubular structures, compared with the bulk MLC. Transport properties of single LaS.TaS$_2$ tubes will be reported as well.

4:18PM C46.00006: Generalization of de Gennes factor for the strong spin-orbit coupled systems. HOSHIN GONG (Presenter), Department of Physics, Pohang University of Science and Technology, Pohang, 37673, Korea, KYOO KIM, SUNGDAE JI, MPPC_CPM, Pohang University of Science and Technology, Pohang, 37673, Korea, BONGJAE KIM, Department of Physics, Kunsan National University, Gunsan, 54150, Korea, BYUNG IL MIN, Department of Physics, Pohang University of Science and Technology, Pohang, 37673, Korea — The magnetic exchange interaction parameters of magnetic systems can be obtained from the consideration of energetics within density functional theory (DFT)-based approaches. Spin Hamiltonians, such as the Heisenberg model, are mainly used to fit the various total energies of magnetic configurations obtained from DFT band calculations, which can be directly compared to the experimental findings including spin-wave dispersions. However, for the strong spin-orbit coupled systems, these approaches often fail and predict wrong energy scales compared to the experimental values due to the entanglement of spin and orbital moments. By including the generalized de Gennes factor, which connects the spin and orbital moments to the total moment, we have found that the better description of exchange interaction parameters can be obtained for the strong spin-orbit coupled systems.

4:30PM C46.00007: A Non-Perturbative, Variational Technique of Calculating RIXS Spectral Response Functions KRZYSZTOF BIENIASZ (Presenter), Stewart Blusson Quantum Matter Institute, University of British Columbia — The field of strongly correlated electrons, and in fact condensed matter physics in general, makes heavy use of spectroscopic experiments to pry into the intricate details of the physical properties of solids. In order to explain the spectra measured in such an experiment a theoretical calculation has to be provided, often relying on some effective model of the physical system under consideration. To explain phenomena such as high-\(T_c\) superconductivity in cuprates or exotic magnetic and orbital phases in manganites, a wide range of spectroscopic measurements are performed, each requiring a different setup and apparatus. Among them, RIXS is a prominent technique which allows one to probe different degrees of freedom of a system with precise control over electron transitions. Our aim is to develop a simple yet accurate standard theoretical tool for calculating RIXS response functions, relying on the non-perturbative, variational (momentum average) approximation to calculate the relevant propagators. This approach should bridge between the exact diagonalization of small clusters vs. perturbative expansion techniques, which until now have dominated the theory of RIXS.

4:42PM C46.00008: Thermoelectric studies of Ir\(_{1-x}\)Rh\(_x\)Te\(_2\) (0 ≤ x ≤ 0.3)* YU LIU (Presenter), HECHANG LEI, KEFENG WANG, MILINDA ABEYKOON, JOHN WARREN, EMIL BOZIN, CEDOMIR PETROVIC, Brookhaven National Laboratory — We present the thermal transport properties of Ir\(_{1-x}\)Rh\(_x\)Te\(_2\) (0 ≤ x ≤ 0.3) alloy series where superconductivity emerges as the high-temperature structural transition (\(T_s\)) is suppressed. The isovalent Rh substitution in Ir\(_{1-x}\)Rh\(_x\)Te\(_2\) results in a slight reduction of lattice parameters and in an increase of number of carriers per unit cell. Positive thermopower \(S(T)\) values for all samples indicate the hole-type carriers. The decrease of \(S(T)\) in pure IrTe\(_2\) (x = 0) at \(T_s\) implies that the Fermi surface is related to partial localization of hole-type carriers below the structural transition. Phonon-related thermal conductivity in pure IrTe\(_2\) (x = 0) features a broad maximum around (50 – 60) K, which is significantly suppressed with Rh substitution. This is mostly contributed by the Rh/Ir doping disorder enhanced point defects scattering. Weak-coupled BCS superconductivity in Ir\(_{0.8}\)Rh\(_{0.2}\)Te\(_2\) that emerges at low temperature (\(T_c^\text{zero} = 2.45\) K) is most likely driven by electron-phonon coupling rather than dimer fluctuations mediated pairing.

*This work has benefited from using the X7B beamline at the NSLS at BNL. Thanks Jonathan Hanson for his help with the x-ray diffraction experiment setup. Work at BNL is supported by the US DOE under Contract No. DE-SC0012704.

4:54PM C46.00009: Magnetic Domains in the Strongly Correlated Weyl Semimetal Candidate CeBi* NATHAN DRUCKER (Presenter), YU LIU, CHRISTIAN MATT, HARRIS PIRIE, Department of Physics, Harvard University, NA HYUN JO, BRINDA KUTHANAZHI, SERGEY L. BUD'KO, PAUL C. CANFIELD, Department of Physics and Astronomy, Iowa State University, JENNIFER HOFFMAN, Department of Physics, Harvard University — Weyl Fermions can arise from Dirac semimetals when the degenerate massless states are split by broken time-reversal symmetry into two bands with opposite chirality. Recently, such states have been predicted in the strongly correlated cerium monopnictides, which develop band inversion as spin orbit coupling increases, and are known to host complex magnetic phase diagrams. Thus cerium monopnictides are ideal materials for studying the interplay of magnetism and topology. Here, we use spin-polarized scanning tunneling microscopy to map the magnetic phases of CeSb and CeBi on the atomic scale. We find distinct magnetic domains with differing spin periodicities, separated by abrupt domain walls. Furthermore, we observe quasiparticle scattering from the domain walls and defects in both materials. Control of these magnetic phases in cerium monopnictides provides the possibility of tuning the key energy scales and momentum splitting of Weyl fermions.

5:06PM C46.00010: Probing band topology of Weyl-Kondo semimetal candidates CeSb and CeBi by quasiparticle interference imaging*  
YU LIU (Presenter), CHRISTIAN MATT, HARRIS PIRIE, NATHAN DRUCKER, Department of Physics, Harvard University, NA HYUN JO, BRINDA KUTHANAZHI, SERGEY L. BUD’KO, PAUL CANFIELD, Department of Physics & Astronomy, Iowa State University, JENNIFER HOFFMAN, Department of Physics, Harvard University — Topological materials are characterized by strong spin-orbit coupling and bulk band inversion, leading to protected surface states with momentum-locked spin or chirality. Meanwhile, Kondo systems often host rich magnetic phase diagrams because of their strong electron correlations. Materials with both strong spin-orbit coupling and strong electron correlations are predicted to host even more intriguing topological properties. Here we use scanning tunneling microscopy (STM) and quasiparticle interference (QPI) to image the band structure of the predicted Weyl-Kondo candidates CeSb and CeBi. We probe the dispersion of Ce $p$ and $d$ bands, and identify two accidental crossings, one below and one above the Fermi level. We search for topological surface states, by imaging their scattering from atomic defects and magnetic domain boundaries.

5:18PM C46.00011: Evidence for a purely anionic charge density wave transition in LaAgSb$_2$  
ASHISH CHAINANI (Presenter), JUNG-HAN LI, AMOL SINGH, YEN-FA LIAO, YEN-YI CHU, KU-DING TSUEI, DI-JING HUANG, Condensed Matter Physics, National Synchrotron Radiation Research Center, CHIA-NUNG KUO, CHIN SHAN LUE, Department of Physics, National Cheng Kung University — We study the electronic structure of LaAgSb$_2$, using bulk-sensitive temperature(T)-dependent (20 K – 220 K) Hard X-ray photoemission spectroscopy (HAXPES). LaAgSb$_2$ exhibits two CDW transitions, one below T$_1$ = 207 K along the crystallographic a-axis, followed by a second CDW transition below T$_2$ = 186 K along the c-axis. Recent studies have identified a Dirac-cone band dispersion and nested Fermi surfaces at T = 16 K, but T-dependent measurements were not reported. We use HAXPES to investigate T-dependent changes in the electronic states of La, Ag and Sb in order to identify states responsible for the CDW transition in LaAgSb$_2$. HAXPES core level measurements show that the La 3d and Ag 3d core-levels show negligible changes across the CDW transitions. In contrast, Sb 3d core levels show a clear well-separated satellite formation below T$_1$, and the spectral intensity of the satellite progressively increases on lowering the temperature below T$_2$. The T-dependence of the Sb 3d satellite feature suggests a second order transition, consistent with the known BCS behavior of T-dependent superlattice reflections by x-ray diffraction. The results indicate a purely anionic character CDW transition, with no direct involvement of the La and Ag cationic derived states in the CDW transition.

Session C47 GERA: Electrochemical Interfaces BCEC 213 - Carlos Gutierrez, Sandia Natl Labs

2:30PM C47.00001: Lithium Electroreduction at Metal/Polymer Interfaces for Lithium Metal Batteries via Atomistic Molecular Dynamics Simulation  
JEONGMIN KIM (Presenter), THOMAS MILLER, Caltech — Understanding and stabilizing lithium electrodeposition is a major bottleneck for developing safe and cyclable lithium metal batteries. The process is complicated by the heterogeneous composition and structure of the solid electrolyte interphase (SEI). To establish a molecular understanding of lithium electroreduction, we employ atomistic molecular dynamics simulations to address ion solvation properties and electron-transfer kinetics of electrochemical reactions at a model SEI/metal interface. Our SEI model is a chemically and structurally well-defined homopolymer including poly (ethylene oxide) (PEO) and poly (ethylene carbonate) (PEC). Model electrodes are either pristine or structurally inhomogeneous with pre-existing deposits. Both the electrodes and deposited lithium are modeled using time-dependent induced-charge polarizability. In this talk, we discuss the effects of the SEI and surface-roughness on the kinetics and mechanism of interfacial lithium electroreduction.
Ab Initio Molecular Dynamics Study of the Effect of Lithium Salts on Lithium Superoxide Clustering in Lithium-Air Batteries

EMILY CRABB (Presenter), ARTHUR FRANCE-LANORD, GRAHAM MICHAEL LEVERICK, YANG SHAO-HORN, JEFFREY C GROSSMAN, Massachusetts Institute of Technology — Lithium-air batteries are an active area of research because of their potential to have a much higher energy density than traditional lithium-ion batteries. However, they are not yet commercially viable due to poor efficiency, high charging voltages, and low cycle lifetimes. Experimental studies of Li-air batteries with aprotonic solvents have shown that the O₂ reduction starts when superoxide (O₂⁻) forms in solvent and reacts with Li⁺ to form lithium superoxide (Li⁺-O₂⁻). Solid Li₂O₂ then forms as the final discharge product on the cathode. Recent experimental work has suggested that a better understanding of the factors governing the behavior of the lithium superoxide in solvent could help control the discharge at the cathode. We are therefore modeling systems of lithium salts and LiO₂ molecules in various common solvents such as dimethyl sulfoxide, acetonitrile, and 1,2-dimethoxyethane to examine how the interplay between solvents and salts affects properties such as LiO₂ clustering behavior. Results from these explicit solvent calculations performed using density functional theory calculations and ab-initio molecular dynamics simulations will be presented and discussed.

*This work is supported in part by a grant from Shell, as well as partial support from a DOE fellowship.

Operando soft x-ray spectroscopy characterization of interfacial charge transfer in energy materials and catalysis

JINGHUA GUO (Presenter), YI-SHENG LIU, Lawrence Berkeley National Laboratory — Soft x-ray spectroscopic techniques with operando capabilities offer the unique characterization in energy conversion/storage materials and catalysis in regards to the functionality, complexity, and interactions among constituents within. It has been found that the microstructure and composition of materials as well as the evolution process have a great influence on performances in a variety of fields, e.g., energy conversion and energy storage materials, chemical and catalytic processes. Operando soft x-ray characterization offers an opportunity to uncover the phase conversion, chemical environment change of elements and other very important information of solid/gas and solid/liquid interfaces in real time. We will overview a number of the experimental studies that successfully revealed the catalytic and electrochemical reactions in real time, e.g. solid (Au or hematite films)/liquid (water) electrochemical interface, Mg-ion batteries, and Li-S batteries. The experimental results demonstrate that the operando soft x-ray characterization provides the unique information for understanding the real reaction mechanism.

*This research used the ALS, a DOE Office of Science User Facility under contract no. DE-AC02-05CH11231. This work was supported by the JCESR and HyMARC of the DOE.

Probing Multiscale Ion Transport and Heterogeneities in High Capacity Battery Materials: From Meso to Micronscale

JAGJIT NANDA (Presenter), Oak Ridge National Laboratory — Majority of electrode materials used for advanced lithium based batteries have well defined chemical composition and particle morphology. The chemistry as well as the microstructure can undergo reversible or irreversible changes under continuous electrochemical charge-discharge cycles. These could have measurable impact on the battery capacity and life. The talk will cover the recent work related to applying x-ray transmission imaging combined with near edge absorption spectroscopy (XANES) to study the evolution of chemical oxidation state of the transition metal (TM) cations accompanied by changes in the particle morphology for lithium-manganese rich NMC cathodes (LMR-NMC). 2D XANES images collected for LMR-NMC cathodes at various stages of cycling (4.8-2.5V) can be reconstructed in 3D to measure bulk changes in TM concentration as well as monitor the change in morphology. The later part of the talk will highlight the various multiscale Raman imaging methods for studying electrode-electrolyte interfaces.

*Research done at Oak Ridge National Laboratory is supported by the Assistant Secretary for Energy Efficiency and Renewable Energy, Office of Vehicle Technologies of the U.S. Department of Energy.
KATHERINE HARMON (Presenter), FELIPE JIMENEZ-ANGELES, Northwestern University, SANG SOO LEE, Argonne National Lab, MICHAEL J BEDZYK, MONICA OLVERA DE LA CRUZ, Northwestern University, PAUL FENTER, Argonne National Lab — A driving factor in electrochemical energy storage is the adsorption of ions in an electrical double layer (EDL) at the electrode-electrolyte interface. A complete understanding of the structure-property relationships among charged surfaces, ions, and solvents that give rise to the EDL is needed to optimize capacitive energy storage devices. Here, we present in situ X-ray reflectivity (XR) and resonant anomalous XR (RAXR) results of the atomistic, element-specific structure of the EDL at the interface of a graphene/SiC electrode and aqueous RbCl. RAXR data are analyzed using increasingly complex levels of theory of the EDL structure, starting from the simple Gouy-Chapman model of an exponentially decaying charge distribution, to assess the level of theory needed to describe the data. Classical MD simulations of the system qualitatively agree with the experimental structures. A quantitative analysis of the MD predictions is performed via direct comparison of the experimental data with RAXR signals expected from the predicted structures.

This work was supported by MICCoM, DOE/BES. KH gratefully acknowledges support from the DoD NDSEG program, and the Ryan Fellowship from the Northwestern IIN. XR measurements were performed at the Advanced Photon Source at ANL, a DOE/BES facility.

JUN HARUYAMA (Presenter), Institute for Solid State Physics (ISSP), The University of Tokyo, TAMIO IKESHOJI, MINORU OTANI, National Institute of Advanced Industrial Science and Technology (AIST) — Because charge transfer reactions at electrode/solution interfaces limits the performance of lithium-ion batteries (LIBs), it is considered that Li insertion/desorption reaction at the interface between graphite anode and electrolyte solution. Density functional theory + effective screening medium (ESM) method combined with reference interaction site model (RISM), ESM-RISM [1], is applicable to the charge transfer reaction because the chemical potential of electrons (\(\mu_e\)) corresponds to an electrode potential [2] and the distribution function of the solvation is automatically formulated for the solvation/desolvation structures. The reacting Li is moved from the stable site in graphite to the bulk solution region. The constant-\(\mu_e\) ESM-RISM simulations show that the assuming Li path is accompanied by an electron transfer process. The activation energy at equilibrium potential is approximately 0.6 eV[3], which is consistent with experiments. The dependences of the activation energy and the surface charge density according to the Li content x (LixC6, x=0, 0.5, 1) are further discussed. [1] S. Nishihara and M. Otani, PRB 96, 115429 (2017). [2] J. Haruyama, T. Ikeshoji, and M. Otani, PRM 2, 095801 (2018). [3] J. Haruyama, T. Ikeshoji, and M. Otani, J. Phys. Chem. C 122, 9804 (2018).

PRIYA SRIVASTAVA (Presenter), MONOJIT BAG, Indian Institute of Technology Roorkee — A lot of research has been done on the efficiency improvement of Perovskite Solar Cells by optimization of the film morphology using various techniques including electrochemical impedance spectroscopy (EIS) in a solid-state active device geometry.1 Recently, the optimization of the film morphology at liquid electrolyte interface by EIS is trending as a more simplified and accurate approach.2,3 Here, we have studied the charge transfer at the methylammonium lead tri-iodide (MAPbI3) perovskite-liquid electrolyte interface under the effect of applied bias. By applying the different dc bias from +1V to -1V, it was found that the ion diffusion at low-frequency regime changes significantly with bias. Also, the films show the same trend of change in impedance under positive and negative bias, which reveals the ambipolar nature of the hybrid perovskites. The ions migrate more under light and get accumulated at the interface in the dark as depicted by the Nyquist plot. We have simulated a model to explain the charge kinetics across the interface with different applied bias under dark and light.

References
Here we investigate the electrodeposition dynamics at a solid-solid interface. We find that the stress-field alters the conduction pathways in the electrolyte and gives rise to a non-monotonic ionic transport. Additionally, the strain-energy alters the reaction free-energy landscape and causes further complexations. The electrodeposition at the solid-solid interface turns out to be governed by both the bulk as well as surface characteristics.

The effects can be summarized by desorption of oxygen-containing species from the sample surface and by reactions within the film. Also presented is an estimate of the layer thickness’ time evolution during prolonged SR exposure.

4:18PM C47.00010: Decomposition of phosphorus-containing additives at a charged NMC surface: atomistic modeling insights  
HAKIM IDDIR, JUAN GARCIA (Presenter), ADAM TORNHEIM, Argonne National Laboratory, RITU SAHORE, Oak Ridge National Laboratory, IRA BLOOM, ZHENGCHENG ZHANG, Argonne National Laboratory — Stabilizing the cathode/electrolyte interface at high voltage is necessary to achieve higher capacities while still maintaining capacity retention in Lithium-ion batteries. One strategy is through the use of additives in the electrolyte: components in low concentration (<10%) that have a lower anodic stability than the baseline electrolyte, so that during the initial cycles, the additive will decompose on the charged cathode surface preferentially over the baseline electrolyte. This reaction will then yield a layer which will inhibit further reaction between the electrolyte and the cathode surface. However, the mechanism of improvement remains unclear. In the present work, Density Functional Theory is used to gain insights and understanding on experimental results using a potentiostatic hold technique to evaluate cathode/electrolyte reactivity for two families of additives: phosphites and phosphates. Simulations indicate the susceptibility of the various additives to electrochemical and chemical oxidation, showing chemical oxidation to be much more likely with the phosphite moiety. The identity of the ligands on the phosphorus-containing additive can dramatically affect both the decomposition current and the cathode surface film.

4:30PM C47.00011: Characterization of Electrical Energy Storage Interfaces with Advanced Optical, Electrochemical, and X-ray Probes  
JONATHAN LARSON (Presenter), HANS BECHTEL, ETHAN J CRUMLIN, ROBERT KOSTECKI, Lawrence Berkeley National Laboratory — Novel and improved methods for energy storage are urgently required to enable effective use of renewable energy sources and to facilitate energy demand-response management across time and length scales. While lithium-ion batteries meet many of the criteria required for portable electronics, they are insufficient to meet the requirements for emerging applications (e.g. aerospace) and grid scale storage. New electrical energy storage concepts are needed to meet these current and future demands. Central to the onset of transformational breakthroughs is the need to increase understanding of the fundamental physical and chemical processes that occur in these complex systems. To this end, we plan to impact this space by leveraging synchrotron-enabled scanning broadband nanoscopy and nano-FTIR spectroscopy for local information on permittivity and chemistry, scanning nanobattery probes for local nano-electrochemical testing, and ambient pressure X-ray photoelectron spectroscopy. Here we provide an operational overview, and the advantages of, these cutting-edge characterization techniques for advancing the basic science of electrical energy storage interfaces.

*Funding to support this work was provided by the Energy & Biosciences Institute through the EBI-Shell program.
Lithium-sulfur battery is considered as promising substitute of Li-ion battery for the next generation energy storage system. However, the intermediate process during charging and discharging cycles is not clear. It is believed that Li$_2$S$_2$ is one of the most important intermediate products which may present as insoluble solid phase in the system. In this talk, we considered three phases of crystalline Li$_2$S$_2$ (tetrahedra, triclinic and hexagonal) to investigate their thermodynamic and mechanical stability based on density functional theory. The results show that the hexagonal Li$_2$S$_2$ is relatively stable than the other two phases. The highly anisotropic mechanical characteristics of Li$_2$S$_2$ are shown to be due to the unique arrangement of S-S bonds in these crystalline structures.

Computational Development of an Artificial Solid Electrolyte Interphase for Rechargeable Multivalent Ion Batteries

JOSHUA YOUNG (Presenter), MANUEL SMEU, Physics, Binghamton University — Multivalent ion batteries (MVIB), or those utilizing Mg, Ca, Zn, and Al, are garnering increasing attention as alternatives to Li-ion batteries in non-portable applications such as grid storage, as they are energy dense, cost efficient, and safe. The development of such MVIBs, however, has been hindered by the inability of existing electrolytes to reversibly plate and strip metallic anodes. This is a particular problem in Ca ion batteries, as the solid-electrolyte interphase (SEI, the passivating layer which forms between the electrolyte and anode) does not allow for the migration of Ca$^{2+}$ ions. In this work, we develop an understanding of this SEI using a computational approach combining DFT and ab initio molecular dynamics (AbMD) simulations. First, we show that AIMD can be utilized to predict the decomposition products making up the SEI in a variety of systems containing different anodes and electrolytes. Second, we demonstrate that the use of an amorphous Al$_2$O$_3$ layer between the Ca metal anode and organic electrolyte prevents decomposition while allowing for the transport of Ca ions. We propose that this strategy can aid in the development of rechargeable Ca ion batteries by completely avoiding the formation of an ionically insulating SEI from electrolyte decomposition.

Predicting pseudocapacitve adsorption isotherms through quantum-continuum calculations

NATHAN KEILBART (Presenter), Pennsylvania State University, YASUAKI OKADA, SHINICHI HIGAI, Murata Manufacturing Co., Ltd., ISMAILA DABO, Pennsylvania State University — Pseudocapacitive electrodes function through redox reactions that occur on the surface of the electrode allowing for high charging/discharging rates. Complex interfaces cause much to be unknown about the pseudocapacitive process. Computational modeling has made progress in predicting the response of these systems but further research is needed to optimize performance. A theoretical approach is developed to study pseudocapacitive systems, focusing on ruthenium dioxide (RuO$_2$). Material properties from quantum-continuum simulations are combined with Monte Carlo sampling to predict adsorption isotherms. Computational findings for the RuO$_2$ (110) surface show good agreement with experimental data where the double-layer contribution is shown to be a small fraction of the overall electrochemical response but controls to a overall pseudocapacitive response of the electrode. By focusing on the double-layer contribution, different trends emerge based on the surface orientation. For RuO$_2$ (110), the double-layer capacitance from electronic-structure methods show a small spread while a downward trend is seen for (100) with increasing coverage. By using double-layer capacitance predicted from first principles, good agreement is reached with experiment along the (100) surface orientation.

Decoding the surface instability of perovskite oxides at the atomic level: Sr segregation in La$_{1-x}$Sr$_x$MnO$_{3-\delta}$ in SOFC electrodes

FRANZISKA HESS (Presenter), BILGE YILDIZ, Nuclear Science and Engineering, Massachusetts Institute of Technology — One of the most important and best-studied perovskite materials for energy conversion applications is La$_{1-x}$Sr$_x$MnO$_3$ (LSM). As the oxygen exchange at the surface is typically rate-limiting, tuning of the electrode surface is a key aspect in the development and optimization of materials for energy conversion applications. Sr-doped perovskite materials form passivating Sr-rich layers which inhibit the oxygen exchange at the surface, thus reducing the efficiency of the SOFC. We assess the stability of LSM surface and bulk using a combination of DFT calculations on the GGA+U level and DFT-based thermodynamics. We find the clean LSM(001) surface to be unstable and prone to reconstructions and defect segregation.

Considering a wide variety of near-surface defects, as well as the growth of SrO as clusters, particles or homoepitaxial layers, we come to the conclusion that Sr segregation should be self-limiting because the surface dipole moment is removed by SrO overlayers that do not cover the entire surface. These surface terminations are stable and not prone to further segregation of Sr.

These results allow us to develop a knowledge-based doping strategy that prevents Sr segregation in LSM. Our modeling strategy and principle findings are transferable to other perovskite oxides.
Monday, March 4, 2019 2:30 PM - 4:18 PM

Session C48 DFD GSNP: Fluid-Structure Interactions (FSI) II  BCEC 251 - Frederick Gosselin, Ecole Polytechnique de Montreal - Tag(s): Focus

2:30PM C48.00001: Vortex-induced vibration of a flexibly-mounted cylinder placed in the proximity of a stationary parallel cylinder*  MAHDI RIAZAT, RAMIN GHOREISHI, BRIAN VERMEIRE, MOJTABA KHEIRI (Presenter), Mechanical, Industrial and Aerospace Engineering, Concordia University — Some computational results on the vortex-induced vibrations (VIV) of a flexibly-mounted cylinder placed in the proximity of a stationary parallel cylinder will be presented. Simulations are performed at moderate Reynolds numbers (100<Re<1000), where VIV features of the non-stationary cylinder are examined for various gap sizes between the two cylinders and for different diameters of the stationary cylinder. An in-house fluid-structure interactions solver based on HORUS platform -- an open-source LES/DNS flow solver -- is used for simulations with two- and three-dimensional (2- and 3-D) cylinders. The results for 2-D cylinders of the same diameter at Re=150, the reduced velocity of 5 and for the centre-to-centre distance of 3.5D* (D* being the cylinder diameter) show a broken-symmetry vortex-shedding pattern behind the oscillating cylinder. This is caused by interactions between vortices shedding from the oscillating and stationary cylinders, as well as formation of a gap flow between them. Previous computational studies considered only 2-D cylinders and employed RANS flow solvers coupled with turbulence models.

*MR and MK appreciate support from Concordia University. BV and RG acknowledge support from NSERC, Calcul Quebec, WestGrid, SciNET, Compute Canada, and FRQNT.

2:42PM C48.00002: Modal Analysis of Strongly Coupled Fluid-Structure Interaction Problems*  ALEXANDRE COUTURE (Presenter), FREDERICK GOSSELIN, STÉPHANE ÉTIENNE, Department of Mechanical Engineering, Polytechnique Montreal — With recent trends in many energy markets, the use of hydroelectric turbines is shifting from base power delivery to grid regulators. The emergence of intermittent renewable energy sources is increasing the need for the use of turbines in off-peak conditions and frequent starts and stops. These cause transient phenomena that can be damageable to the fatigue life of the main turbine components. To tackle this issue, knowledge of the turbines vibration modes frequency and damping coefficient is essential. In this context, we developed a new modal analysis method for strongly coupled fluid-structure interaction (FSI) problems. The proposed technique couples linear elastic equations and linearized Navier-Stokes equations in a finite element formulation. This allows for the evaluation of the frequency and damping coefficient of the coupled modes of complex structures subject to important flows without the need for computationally heavy fully coupled non-linear time-integration FSI simulations. For now, a proof of concept has been elaborated using the 2D flag flutter problem and it was validated using 3D hydrofoil experiments.

*This work is supported by the Natural Sciences and Engineering Research Council of Canada (NSERC), FRQNT and the Trottier Energy Institute.

2:54PM C48.00003: Modal analysis of a spinning disk in a dense fluid as a model for high head hydraulic turbines*  MAX LOUYOT (Presenter), Laboratory for Multiscale Mechanics, Department of Mechanical Engineering, Polytechnique Montreal, BERND NENNEMANN, CHRISTINE MONETTE, Andritz Hydro Canada Inc., 6100 Trans Canada Hwy., Pointe-Claire, H9R 1B9, Québec, Canada, FREDERICK GOSSELIN, Laboratory for Multiscale Mechanics, Department of Mechanical Engineering, Polytechnique Montreal — In high head Francis turbines and pump-turbines in particular, RSI is an unavoidable source of excitation that needs to be predicted accurately. Precise knowledge of turbine dynamic characteristics, notably the variation of the rotor natural frequencies with rotation speed and added mass of the surrounding water, is essential to assess potential resonance and resulting amplification of vibrations. In these machines, the rotating disk-like structures of the runner crown and band as well as the head cover and bottom ring give rise to the emergence of diametrical modes and a mode split phenomenon for which no efficient solution method exists to date. Fully coupled FSI methods are too computationally expensive; hence, a simplified method based on the modal force approach would be a powerful tool for the design and expected life prediction of these turbines. This work presents the development of an analytical model for a rotating disk in a dense fluid, which accurately predicts the natural frequency split as well as the natural frequency drift that are observed in experiments. Additionally, the analytical model gives an explanation on the physical origin of the mode split phenomenon.

*We would like to thank the MITACS program and Andritz Hydro for funding this work.
3:06PM C48.00004: Force and wake observations for a circular cylinder undergoing forced 2-DOF motion in a free stream  JASON M DAHL (Presenter), ERDEM AKTOSUN, Ocean Engineering, University of Rhode Island — A series of forced motion experiments were performed for a circular cylinder undergoing combined in-line and cross-flow motion in a free stream. Variation of the in-line amplitude, cross-flow amplitude, reduced velocity, and phase between in-line and cross-flow motions were made for a Reynolds number of 7620, with a total of 9555 experiments. Forces were measured for all experiments and PIV visualization of the wake was made for select experiments. Specific phases between in-line and cross-flow motion are shown to have multiple possible wakes depending on the length of the experiment, with specific motion combinations being particularly sensitive to the conditions of the experiment. Although all forced motions were symmetric, asymmetry was observed in the wake for specific combinations of motion parameters, leading to asymmetric forcing and large mean lift. The measured forces and resulting wake are particularly sensitive to the phasing between in-line and cross-flow motion, indicating that if using forces derived through forced motion experiments for the prediction of 2-DOF vortex-induced vibrations, one should have sufficient resolution in the phase parameter in order to properly capture the variation in forces.

3:18PM C48.00005: Insights on the pressure distributions of controlled ice-induced vibration experiments ERSEGUN DENIZ GEDIKLI (Presenter), TORODD NORD, Norwegian University of Science and Technology — Increased need for energy pushed offshore wind, oil, and gas companies into deeper waters in the Arctic and Subarctic regions, bringing extra challenges with it. It is observed that dynamic interaction between the offshore structure and floating ice sheet might result in ice-induced vibrations, which can contribute to fatigue damage. To better understand this complex phenomenon, forced ice-induced vibration experiments are carried out in the ice tank at the Hamburg Ship Model Basin (HSVA), Hamburg, Germany. In the tests, different rigid structures are forced through the still ice by systematically changing the ice speed. Pressure distributions in the ice-structure interface and resulting structural motions are analyzed using two multivariate analysis methods: 1) proper orthogonal decomposition and 2) smooth orthogonal decomposition. Results indicate that both methods capture the dominant pressure variations successfully and result responses that are physically interpretable. For example, first pressure mode illustrates the ductile pressure variation on the structure, which varies in the ice drift direction, and some combinations of second and third pressure modes represent the oscillations in the cross-flow direction, which illustrate the complex nature of ice-induced vibrations.

3:30PM C48.00006: Burst-and-coast swimming in zebrafish  BENJAMIN THIRIA (Presenter), RAMIRO GODOY-DIANA, BILL FRANÇOIS, ESPCI ParisTech, FREDERIC LECHENAULT, Ecole Normale Supérieure — Swimming kinematics of small fish such as zebrafish are characterized by intermittent sequences consisting in an active swimming phase directly followed by a passive coast phase. These specific sequences are based on a coupling between sensing and decision: fish use the passive time to sense their environment and prepare their next move. Fish essentially use vision and the lateral line system to see and sense their surrounding environment. The mechanisms that govern this “sensing” to “decision-making” (S2D) process are still to be understood and detailed. This work is an attempt to characterize these sequences using several archetypal model experiments and models gathering hydrodynamics, statistics and behavioral sciences. We will focus on new results obtained from real fish experiments in free swimming and forced gait configurations (using a controlled swimming channel). We will show how the statistics of these S2D sequences evolve with the conditions of the experiment; the important parameters being here the external flow conditions and the size of the habitat, but also the species and the maturity state of the fish (larva, juvenile or adult). We believe that these results will have direct implications on the design and implementation of biomimetic robotic systems.

3:42PM C48.00007: Swimming via size-change: High efficiency propulsion using resonant fluid-structure interactions  GABRIEL WEYMOUTH (Presenter), Faculty of Engineering and Physical Science, University of Southampton — Cephalopods use large-scale structural deformation to propel themselves underwater, changing their internal volume by 20-50%. In this work, the hydroelastic response of a swimmer comprised of a fluid-filled elastic-membrane is studied via analytic, numerical, and experimental methods. The self-propelled soft-body fluid and solid dynamics are shown to benefit greatly from the irreversible jet flow, the reversible internal added-mass variation, and the pulsation in tune with the swimmer’s immersed fundamental frequency. It is shown that even a simplistic size-changing structure can utilize these physical mechanisms to achieve quasi-propulsive power ratios of greater than 100%, i.e. self-propulsion for these swimmers requires less energy than towing at the same speed.
3:54PM C48.00008: Breakdown of continuum models of fluid structure interaction in a nanoporous biological material* STEVEN HARRELLSON (Presenter), Department of Physics, Columbia University, MICHAEL DELAY, XI CHEN, Department of Biological Sciences, Columbia University, AHMET HAMDI CAVUSOGLU, Department of Chemical Engineering, Columbia University, OZGUR SAHIN, Department of Physics, Columbia University — Determining how porous materials interact with permeating fluids is important for understanding their mechanical properties. Existing approaches often treat the permeating fluid as a continuous medium, but for many materials the pore dimension can be on the order of a nanometer, close to the size of a single water molecule. It is not clear how the discreteness of the permeating fluid affects the macroscopic mechanical properties of these materials. Here we show the bacterial spore, a dormant biological nanoporous structure, exhibits mechanical properties that challenge theoretical models based on continuum treatment of water. We found a statistical mechanical treatment of the confined water correctly predicts a range of equilibrium and dynamic properties of the spore, including an extreme slowdown of relaxation kinetics and a highly nonlinear mechanical response. Because the underlying assumptions of this approach are based on the geometry and not specific to the spore chemistry, these findings could also be applicable to other nanoporous materials.

4:06PM C48.00009: Enhancing and controlling parametric instabilities in structures: Application to an electromagnetic pendulum. ARNAUD LAZARUS (Presenter), Department of Mechanical Engineering, Sorbonne Université, SUZIE PROTIÈRE, Institut Jean Le Rond d’Alembert, CNRS — Parametric instabilities are dynamical instabilities arising when the mechanical state of a structure is properly modulated in time. It is sometimes seen as a phenomenon to avoid for sailing ships (parametric rolling) or landing helicopters (ground resonance) but it has also been exploited in vibrating fluids (Faraday waves) or NanoElectroMechanical Systems (parametric amplification). One well-known limitation in fully exploiting classic parametric instabilities based on small periodic modulation of a mechanical state is that inherent friction forces rapidly cancel sub-harmonic parametric resonances. To overcome this drawback, we suggest to formerly modify the state of a mechanical system close to its diverging instability, so that it becomes possible to periodically modulate a system between a naturally oscillating and diverging state. This original way of enhancing and controlling parametric instabilities is illustrated here through the numerical and experimental implementation of an electromagnetic pendulum. Not only we find it is possible to greatly enhance the number of subharmonic instability regions, but it is feasible to control the width of those regions, opening a promising way for frequency filtering in NanoElectroMechanical Systems.

Session C49 DPOLY: Advanced Morphological Characterization of Polymer II: X-ray and Neutron Scattering BCEC 252A - Brian Collins, Washington State University - Tag(s): Focus

2:30PM C49.00001: Role of Chain Length in the Formation of Frank-Kasper Phases in Diblock Copolymers* FRANK BATES (Presenter), RONALD LEWIS III, AKASH ARORA, HALEY BEECH, BONGJOON LEE, AARON LINDSAY, TIMOTHY LODGE, KEVIN DORFMAN, University of Minnesota — Formation of the Frank-Kasper (FK) sigma phase in compositionally asymmetric A-B diblock copolymer melts has been shown using self-consistent mean-field theory (SCFT) to be associated with conformational asymmetry, \( b_A/b_B > 1 \), where \( b \) is the statistical segment length. Small-angle X-ray scattering and rheological measurements performed with narrow dispersity poly(styrene)-b-poly(butadiene) (PS-PB) diblocks show an absence of the FK sigma phase whereas poly(ethylethylene)-b-poly(lactide) (PEE-PLA) diblocks exhibit a wide composition window of this complex phase, where both systems have \( b_A/b_B = 1.3 \). This behavior is associated with block self-concentration expressed through the invariant degree of polymerization \( N(bar) = Nb^6/v^2 \) in which \( v \) is the statistical segment volume. A direct analogy will be drawn between the role of \( N(bar) \) in FK phase formation in diblocks and the value \( N_e(bar) \) that defines the universal crossover from Rouse to reptation dynamics in homopolymer melts, where the block values of \( N(bar) \) for PEE-PLA and PS-PB are less than and greater than \( N_e(bar) \), respectively.

2:42PM C49.00002: PRISM Theory as an Accessible Model for Neutron and X-ray Scattering Experiments of Liquid-Like Polymer Systems  
TYLER MARTIN (Presenter), RONALD JONES, National Institute of Standards and Technology — Polymer Reference Interaction Site Model (PRISM) theory is able to predict the structure and thermodynamics of a wide range of liquid-like polymer systems including polymer melts, blends, solutions, polyelectrolytes, and nanocomposites. Using single-molecule, intra-molecular correlations as input, past studies have used PRISM to model the experimental scattering data of concentrated solutions and melts, including data from small-angle neutron scattering (SANS), small-angle X-ray scattering (SAXS), and wide-angle X-ray scattering experiments (WAXS). Despite its utility in these studies, PRISM theory has remained inaccessible to many scientists seeking to extract thermodynamic and structural information from their scattering data of liquid-like polymer systems. Recently, we have released a computational tool called pyPRISM which aims to reduce the barrier to accessing PRISM theory and allow users to calculate structure factors and total scattering intensities from single-molecule scattering functions. In this talk, we will discuss the features and limitations of using PRISM theory as a scattering model by highlighting our efforts in using pyPRISM to create new models for the scattering of several systems including worm-like micelles, monoclonal antibodies, and bottlebrush polymers.

2:54PM C49.00003: Phase Behavior of Hybrid Inorganic-Organic Diblock Copolymer Electrolytes  
GURMUKH SETHI (Presenter), University of California, Berkeley, IRUNE VILLALUENGA, Lawrence Berkeley National Laboratory, NITASH BALSARA, University of California, Berkeley — Solid polymer electrolytes are advantageous for applications in lithium batteries due to improved chemical stability compared to organic liquid electrolytes. Diblock copolymer electrolytes offer highly tunable nanostructures with both soft, ion-conducting domains and mechanically rigid non-conducting domains. The phase behavior of poly(ethylene oxide)-block-polyhedral oligomeric silsesquioxane acrylate (PEO-POS) mixed with lithium bis(trifluoromethane)sulfonimide (LiTFSI) salt is studied by varying the diblock composition and salt concentration. Using small angle X-ray scattering (SAXS), the morphology and Flory-Huggins interaction parameter is obtained to quantify the thermodynamic interactions. PEO-POS without salt exhibits a classical order-disorder transition. Adding salt dramatically changes the phase behavior and a disorder-order transition is observed upon heating. Upon further salt addition, a transition from lamellae to coexisting lamellae and hexagonally packed cylinders is observed. Our results suggest that the addition of salt plays a more complicated role in this hybrid organic/inorganic electrolytes in comparison to traditional all organic diblock copolymer electrolytes.

3:06PM C49.00004: In Situ Study of ABC Triblock Terpolymer Self-Assembly under Solvent Vapor Annealing  
SANGHO LEE (Presenter), LI-CHEN CHENG, Materials Science and Engineering, Massachusetts Institute of Technology, KEVIN G. YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory, MUHAMMAD MUMTAZ, KARIM AISSOU, Laboratoire de Chimie des Polymères Organiques, CNRS – ENSCPB – Université de Bordeaux, CAROLINE ANNE ROSS, Materials Science and Engineering, Massachusetts Institute of Technology — The morphological transition of core-shell cylinder-forming triblock terpolymers during solvent vapor annealing is monitored in situ using grazing-incidence small-angle X-ray scattering. We investigate the self-assembly behavior of two linear ABC triblock terpolymers, poly(1,1-dimethyl silacyclobutane-block-styrene-block-methyl methacrylate) (PDMSB-b-PS-b-PMMA or DSM) and poly(1,1-dimethyl silacyclobutane-block-styrene-block-lactide) (PDMSB-b-PS-b-PLA or DSL). The morphology, orientation, and period of the microdomains are characterized under a continuous vapor flow of CHCl₃ as a function of deswelling rate and swelling ratio. Films of DSM form in-plane core-shell cylinders, while DSL films predominantly form vertically oriented core-shell cylinders. A reversible order-order phase transformation between spheres and cylinders and a reorientation from in-plane to out-of-plane cylinders occur during the annealing process.

*This work was supported by NSF DMR-1606911. Shared experimental facilities of CMSE, an NSF MRSEC under award DMR-1419807, were used. This research used resources of the Center for Functional Nanomaterials, and the National Synchrotron Light Source II, which are U.S. DOE Office of Science Facilities, at Brookhaven National Laboratory under Contract No. DE-SC0012704.
**3:18PM C49.00005: In-situ Observation of Non-solvent-induced Phase Separation of Cellulose Cuprammonium Solution by Small-Angle X-ray Scattering**. KAZU HIROSAWA (Presenter), TATSUMI IWAMA, MAIKO YAMAGATA, NAOKI SAKAMOTO, AYUMI KUROHARA, YOSHIYUKI SHIOMI, TORU MORITA, Asahi Kasei Corporation — Phase separation caused by permeation of non-solvents into polymer solution is called non-solvent-induced phase separation (NIPS). NIPS are often applied to fabrication processes of polymer materials such as wet-spinning of fibers and porous membranes. For example, NIPS of cellulose cuprammonium solution in water has been utilized to manufacture regenerated cellulose fibers. Hence, understanding the mechanism of NIPS has crucial importance in chemical industries. However, study of NIPS is challenging because it is complicated process which includes time-dependent variation of composition of polymer, solvent, and non-solvent molecules. To understand the structure formation mechanism, we performed in-situ structural analysis on NIPS process of cellulose in cuprammonium solution by means of small-angle X-ray scattering (SAXS). From time-development of SAXS profiles of the cellulose solution, we characterized phase separation structure and the dynamics of structural growth. Eventually, we clarified that network structure having ~ 10 nm characteristic length is formed by desorption of ammonia from cellulose solution into water.

*The SAXS experiment was performed at the Frontier Soft Matter Beamline (FSBL; BL03XU), SPring-8, Hyogo, Japan (proposal No. 2017A7201, 2017B7251).

**3:30PM C49.00006: The Multi-Layered Structure of Novel Cellulose-Coated Oil-in-Water Emulsions Revealed by Contrast Variation Neutron Scattering**. YACHIN COHEN (Presenter), SOFIA NAPSO, DMITRY REIN, Chemical Engineering, Technion - Israel Institute of Technology, ZHENDONG FU, AUREL RADULESCU, Jülich Center for Neutron Science, Heinz Maier-Leibnitz Zentrum — Amphiphilic cellulose chains dissolve molecularly in the ionic-liquid 1-ethyl-3-methylimidazolium acetate. When the solution is mixed vigorously with oil and water a stable oil-in-water emulsion is formed, as water regenerates an amorphous cellulose coating on the oil droplets. Imaging by cryo-transmission electron microscopy indicated a unique multilayered structure of the cellulose coating. Small-angle neutron scattering from these emulsions was measured at three contrasts: full contrast (protiated oil and cellulose in D2O), shell contrast (oil matched to D2O) and core contrast (water matched to cellulose). The fitted model describes a spherical core with two concentric shells. The fitted parameters were the core diameter and thicknesses of the two shells, and the scattering length densities of the inner and outer shells, to account for their cellulose content. Particular attention was focused on whether the inner shell is imbibed by water or oil. It was concluded that the oil core (diameter 67±17 nm) is surrounded by a water-imbibed cellulose hydrogel (~3% cellulose), of thickness 34.5 nm an outer coating of a dense cellulose layer 3.5 nm thick. This novel structure may be utilized as a microreactor for cascade enzymatic reactions.

**3:42PM C49.00007: Probing chemical pathways in polyamide reverse osmosis membranes**. ALEXANDRA PORTER (Presenter), Materials, Imperial College London — Reverse Osmosis (RO) membranes are widely used for sea water desalination applications. As the cost of installing desalination plants at sea is high it has become important to have a fundamental understanding of how the membranes work so that costs can be reduced. Much effort has gone into understanding the bulk properties of the membranes, but little effort on understanding the nanoscale interactions that control ion selectivity. The membranes are made from a polyester backing layer, a polysulfone (PSf) support and a polyamide (PA) membrane which is typically 100-500nm thick in a commercial membrane. Due to the membrane’s complex hierarchical structure, the controllability of ion selectivity remains unclear.

Recent work has suggested that although complex, the structure is actually made out of a single sheet of membrane about 10nm thick that has been ‘crumpled’. There is also evidence that the top and bottom surfaces of the membrane are terminated with different functional groups suggesting that ion permeation pathways across the membrane may be due to chemical variations. Because of the amorphous nature of the polymer it is impossible to visualize any physical or chemical pathways using conventional transmission electron microscopy or scanning TEM (STEM). The only method that can be used to investigate variations in chemistry on the sub nanometre scale is spatially resolved electron energy-loss spectroscopy (EELS).

Here we use monochromated EELS spectrum imaging to map differences in the spatial distribution of C, N and O across flat in-house fabricated 10nm membranes and rough commercially available membranes. Additionally we show clear changes in the fine structure of the C K edge in the different polymer layers (PSf, PA and resin) as well as changes across the membrane itself. The chemical pathways that can be deduced from these findings provide us with a much clearer understanding of the transport mechanisms through the membrane.

*BPICAM*
4:18PM C49.00008: Enzyme Immobilization in Mesoporous Metal-Organic Frameworks by SANS* LILIN HE (Presenter), Oak Ridge National Laboratory, XIAOLIANG WANG, Department of Chemistry, University of South Florida, SHUO QIAN, Oak Ridge National Laboratory, SHENGQIAN MA, Department of Chemistry, University of South Florida — Metal-organic frameworks (MOFs) are an emerging class of solid supports for enzyme immobilization owing to their high accessible pores and tunable pore size and surface for increasing affinity between enzymes and supports. Although the immobilization of enzymes by MOFs has shown improved catalytic efficiency, enzymes’ location in the hierarchical solid matrix, the relationship between enzyme dimension and pore size, and conformations of encapsulated enzymes remain elusive. In this work, we present a small-angle neutron scattering (SANS) characterization of cytochrome C (CyT. C) adsorbed into Tb-TATB under in-situ conditions. The scattering curve of unloaded Tb-TATB showed mass fractal feature arising from the network structure and a shoulder at ~0.03Å presumably corresponding to disordered building blocks or defects in the crystals. The correlation peaks located between 0.07 and 0.4 Å⁻¹ were attributed to ordered arrangement of two nanopores, 39 Å and 47 Å, respectively. Upon loading of the CyT. C, substantial decreasing intensities of Bragg peaks proved the entry of enzyme molecules into the MOF’s cages with entry windows that are smaller than the enzyme.

*The Bio-SANS beamline is supported by DOE BER office. X. W. and S. M. thank National Science Foundation (DMR-1352065).

4:30PM C49.00009: The Influence of Ionic Liquids on the Nanostructure of Polyimide based Aerogels SAMANTHA J. RINEHART (Presenter), University of Tennessee, BAOCRAU N. NGUYEN, Ohio Aerospace Institute, ROCCO P. VIGGIANO, MARY ANN B. MEADOR, NASA Glenn Research Center, MARK DADMUN, University of Tennessee — Aerogels are promising materials for many aerospace applications, including high performance antennae and flexible insulation because of their inherent low density-high surface area properties. Polymeric aerogels, more specifically polyimide aerogels (PIA), provide excellent mechanical properties beyond traditional silica aerogels while maintaining the required thermal stability. NASA has investigated PIA paired with ionic liquids to develop novel mechanically robust electrolyte systems for next generation batteries. PIA surface area, porosity, and pore volume are important properties; however, these measurements are traditionally conducted sans solvent. Because of this, the impact of the ionic liquid on the nanoscale structure of PIA is unclear. To determine the impact of solvent presence, we use small angle neutron scattering to determine solvated PIA skeletal size and composition. Our results indicate that the pores as well as the polyimide skeleton absorb solvent. The amount of solvent uptake in the struts is dependent upon ionic liquid structure as well as polyimide structure. These results broaden the characterization of polymeric aerogels and provide the ability to correlate structural characteristics to their performance.

4:42PM C49.00010: Effect of Electrostatic Interactions Between Nafion and Functionalized Nanoparticles on Ionomer Morphology and Nanoparticle Dispersion ALLISON JANSTO (Presenter), APOORVA BALWANI, Department of Chemical and Biomolecular Engineering, Clemson University, TYLER MARTIN, RONALD JONES, Center for Neutron Research, National Institute of Standards and Technology (NIST), ERIC DAVIS, Department of Chemical and Biomolecular Engineering, Clemson University — Ionomer nanocomposites have emerged as a promising replacement to traditional polymer electrolyte membranes for technologies like vanadium redox flow batteries as they curtail undesired vanadium ion crossover while maintaining high proton conductivity. However, the mechanism by which the introduction of silica nanoparticles (SiNPs) acts to increase ion selectivity remains elusive. Presently, SiNP surface chemistry was systematically altered to determine the relationship between SiNP dispersion, membrane morphology, and vanadium ion transport, via transmission electron microscopy, small-angle neutron scattering (SANS), and ultraviolet-visible spectroscopy, respectively. Results indicate that the SiNP surface chemistry plays a vital role in controlling their dispersion and resultant ionomer morphology, where changes in SANS data were observed as a function of both surface chemistry and SiNPs loading in the ionomer membrane. Further, it was observed that the SiNP dispersion state had a direct impact on the vanadium ion permeation: SiNP aggregation reduced vanadium ion crossover as compared to well-dispersed particles with the same end functionality. Additionally, the overall NP surface charge is a key factor in controlling vanadium ion permeation through these composite membranes.
Due to omniphobic nature of fluoropolymers, block copolymers (BCPs) having fluoropolymer block can be an excellent choice for self-assembly of multi-compartmented nanoparticles. However, the strong incompatibility between fluoroblock and solvent could pose high energy barrier for the exchange of BCPs, kinetically trapping the systems. Herein, we investigated the chain exchange dynamics of the self-assembled fluoroalkyl-BCP micelles as well as their structures using contrast-varied small-angle neutron scattering (SANS) and small-angle X-ray scattering (SAXS). Time-resolved SANS revealed the effects of temperature and fluoroblock length on the exchange dynamics within spherical micelles. Despite of high energy barrier for the fluoroblock pullout from the core domain, the exchange is reasonably fast due to significantly small friction within fluoropolymers. However, as the fluoroblock molar mass approaches 100 kDa, the energy barrier becomes tremendous that the fluoroblocks are actually arrested at the core. Therefore, the chain size of fluoroblock should be wisely chosen to drive self-assembly towards equilibrium in such strongly segregated systems.

The phase behavior of PVBA-b-PS with various volume fractions of PS block ($f_{PS}$) was investigated via small-angle X-ray scattering and transmission electron microscopy. With increasing $f_{PS}$ from 0.1 to 0.8, body-centered-cubic spheres of PS, hexagonally packed (HEX) cylinders of PS, lamellae, and HEX cylinders of PVBA were observed. Interestingly, PVBA-b-PS with $f_{PS} = 0.75$ showed asymmetric lamellar microdomains. We also prepared thin film of PVBA-b-PS on a substrate as a template for spatial arrangement of gold nanoparticles (AuNPs). When the surface of AuNPs was modified with thymine-containing polymer chains, AuNPs were selectively sequestered into PVBA microdomains through the complementary hydrogen bonding between thymine and adenine units.

Session C50 DPOLY GSOFT DMP: Optically and Photonically Active Polymers BCEC 252B - Zhe Qiang, Northwestern University - Tag(s): Focus
Micro- and Nanoporous Polymer Coatings: A Diverse and Promising Platform for Optical and Thermal Regulation

JYOTIRMOY MANDAL (Presenter), YUAN YANG, NANFANG YU, Applied Physics and Applied Mathematics, Columbia University — Polymers vary widely in their intrinsic optical properties – for instance, poly(ethene) (PE) is highly transparent across the visible to far-infrared wavelengths, while poly(vinylidene fluoride-co-hexafluoropropene) (P(VdF-HFP)) is highly emissive in the long-wave infrared (LWIR). When made porous, polymers optically scatter sunlight. As a result, porous P(VdF-HFP) can attain solar reflectance ($R_{\text{solar}}$) > 96% and LWIR emittance ($\varepsilon_{\text{LWIR}}$) ~ 97%, which makes it a near-perfect radiative cooler for buildings. Meanwhile, the high $R_{\text{solar}}$ (~ 80%) and LWIR transmittance (~ 60%) of porous PE makes it useful in thermoregulation devices with tuneable $\varepsilon_{\text{LWIR}}$. Furthermore, by reversibly wetting and drying porous polymers with appropriate fluids, scattering efficiencies of the pores can be greatly altered to cause switching between solar reflective and transparent states (by 74%). Switching between LWIR transparent and absorptive/emissive states (by 60%) can also be achieved. Such optically switchable porous polymer coatings can control heat and light in buildings, and be used for camouflaging. Promisingly, porous polymers are already widely manufactured, making the stated applications viable.

Automated Platform for Investigating Aligned Carbon Nanotube Films

JOSH WALKER (Presenter), University of Wyoming, JEFFREY FAGAN, National Institute of Standards and Technology, HENRY WLAJKOWSKI, University of Wyoming, THOMAS A SEARLES, Howard University, ANGELA HIGHT WALKER, National Institute of Standards and Technology, WILLIAM RICE, University of Wyoming — The one-dimensional nature of single-wall carbon nanotubes (SWCNTs) creates highly directional properties. Utilizing this anisotropy for optoelectronic devices requires researchers to macroscopically align SWCNT ensembles. Recently, surfactant-dispersed SWCNTs were aligned using a manually operated, slow-filtration technique. Building off this method, we present in this work a new platform for reproducibly forming multiple aligned SWCNT films simultaneously. Our parallel filtration setup uses machine vision with pressure feedback control to produce aligned SWCNT films with areas ranging from 2.5 to 9.6 cm$^2$. SWCNT alignment is then determined by polarized optical measurements, such as linear dichroism and Raman spectroscopy. The ability to reproducibly create aligned films enables us to investigate parameters contributing to SWCNT alignment. Specifically, we show that for certain filtration conditions, meniscus pinning produces a spherulite pattern. Additionally, we tune the ionic strength across four orders of magnitude to show the effects of the inter-nanotube electrostatic environment on alignment. These results lead us to a deeper understanding of the physics behind SWCNT directional control.

Cold Plasma Effects on the Optical Properties of Salmon DNA Thin-films

MOSES NNAJI (Presenter), BEN JANG, HEUNGMAN PARK, Texas A&M University - Commerce — Fabrication of organic electronics is attractive due to the prospective lower cost when compared to inorganic devices. In particular, deoxyribonucleic acid (DNA) biopolymers show excellent promise for use in organic electronics due to their great electron-blocking capability and abundance in animal waste products. While DNA thin-films are often created by associating DNA with hexadecyltrimethylammonium chloride (CTMA) surfactant to promote DNA solubility in organic solvents and spin coat higher quality films, some success in reproducing uniform, water-based DNA thin-films on silicon and glass substrates has been achieved by incorporation of methanol as well as implementation of UV-ozone cleaning. Resulting DNA films were then subjected to cold plasma treatment to study the effects on the films via ellipsometry and spectrophotometry, where the refractive index and absorption coefficient have been characterized. Optical changes and potential novel resonance behavior induced by Ar plasma treatment encourage the continued use of Ar plasma under various conditions, as well as the use of other inert noble gases.

3:06PM C50.00004: Optically active self-assembled pi-conjugated peptides* [Invited] CHARLES SCHROEDER (Presenter), University of Illinois at Urbana-Champaign — A major challenge in bioorganic electronics lies in the development of soft, deformable, and (opto)electronically active materials that can assemble into hierarchical structures. We use molecular design and engineering to develop new materials for organic electronics and photonics. In this talk, I discuss recent work that focuses on optically active, pi-conjugated peptides that can be engineered for precise supramolecular assembly. We consider both the kinetics and thermodynamics of assembly using a combination of experiments and modeling. Pi-conjugated peptides are guided to assemble under reaction- or diffusion-dominated conditions, such that the morphology and properties of assembled peptide fiber networks can be controlled by kinetics. A combined spectroscopy-microrheology technique is used to study the sol-gel transition of these materials during assembly, which enables direct measurement of modulus and photophysical properties during gelation. In situ confocal fluorescence microscopy and in situ fluorescence lifetime imaging microscopy (FLIM) are used to characterize peptides during the assembly process. We further demonstrate a facile strategy to macroscopically align supramolecular fibers using a templating method based on sacrificial colloidal microchannels that does not require photolithography. The structural and chemical properties of oligopeptide fibers are characterized using AFM-infrared spectroscopy (AFM-IR), photoinduced force microscopy (PiFM), fluorescence polarization microscopy, and electron microscopy. In addition, the charge transport properties of pi-conjugated peptides are determined under a wide range of applied voltages. Overall, this work illustrates simple yet robust strategies to pattern 1-D supramolecular fibers over large areas, thereby offering new routes for assembling functional organic materials.

*This work was supported by the U.S. DOE, Basic Energy Sciences (BES) under Award # SC-0011847

3:42PM C50.00005: Effect of Polymer Spacer Length in FRET-Based Fluorescent Donor-Acceptor Sensing System CHAN HO PARK (Presenter), BUMJOON KIM, KAIST — In contrast to traditional fluorescent resonance energy transfer (FRET) acceptors, two-dimensional (2D) materials potentially create the long-range energy transfer due to the strong dipole-surface energy transfer. Stimuli-responsive polymers can be an efficient tunable spacer between the FRET donor and 2D acceptor because of their conformational change to the diverse stimuli that allows the dynamic change of distance in a wide range (approximately 1-25 nm). Thus, controlling the length of polymer spacer is the most crucial to maximize the FRET signal in response to the stimuli, because FRET is dominantly distance dependent. In this paper, we present a fluorescent, thermo-responsive block copolymer grafted 2D nanosheets to retain dynamic fluorescence quenching through the change of grafted polymer length. Distance dependent FRET efficiency is studied according to the molecular weight and areal chain density of polymers. The relationship between thermally-responsive FRET and polymer behavior is theoretically calculated and elucidated by measurements of time-resolved fluorescence. Consequently, we first suggest the FRET distance between organic dye and 2D nanosheets and find optimum condition of grafting polymers to maximize the fluorescence response as a function of temperature.

3:54PM C50.00006: Nanostructured Polymer Films Exhibiting Solvent-Responsive Photonic Band Gaps YIFAN XU (Presenter), JACOB A LANASA, ROBERT HICKEY, Materials Science and Engineering and Materials Research Institute, Pennsylvania State University — Tunable and reversible photonic band gap materials generated from nanostructured block polymers have shown applications in displays, sensors and waveguides. Here, we present a way to rationally design the change in the photonic band gap of a lamellar-forming poly(1,2-butadiene)-block-poly(ethylene oxide) (1,2PBD-b-PEO) on the addition of solvents that are able to selectively swell one or both domains. A good solvent for both 1,2PBD and PEO domains, like tetrahydrofuran, leads to the largest increase in the domain spacing, and as a result, the largest change in the photonic band gap. For selective solvents like water and hexane, only one domain swells (PEO or 1,2PBD domain, respectively), leading to smaller changes in the photonic band gap. Cryogenic scanning electron microscopy and small-angle X-ray scattering were used to characterize the structural changes that occur on addition of the different solvents, while optical reflection measurements were used to determine the change in the photonic band gap. The work presented here highlights the necessary parameters for tuning the photonic band gap properties for block polymer materials using the combination of solvent quality (e.g., degree of polymer domain swelling) and changes in the refractive index.
4:06PM C50.00007: Can we design a reconfigurable photonic crystal in the visible light range?*  
ROSE CERSONSKY (Presenter), JULIA DSHEMUCHADSE, JAMES A ANTONAGLIA, GREG VAN ANDERS, SHARON GLOTZER, University of Michigan —  
Crystals with a complete photonic band gap are materials composed of mixed dielectric media which result in the reflection of all electromagnetic waves in a given range of wavelengths, commensurate to the length scale of the crystal, and pose an exciting avenue for novel materials. Diamond is a popular target for photonic crystals, which poses an opportunity for reconfigurable matter: can we create a colloidal crystal that switches reversibly to and from the diamond structure? Drawing inspiration from high-pressure phase transitions of diamond-forming atomic systems, we design a system of particles with polyhedral shapes that transitions from diamond to a tetragonal diamond derivative upon a small change in pressure and coincides with a noteworthy modulation of the photonic properties of the crystal. We propose that the transition provides a reversible reconfiguration process for a potential new colloidal material, and we draw parallels between this transition and the materials from which we take inspiration.  

*This work was done with support by the National Science Foundation, Division of Materials Research Award # DMR 1120923, the University of Michigan Rackham Merit Fellowship program, a Simons Investigator Award from the Simons Foundation, and NSF GRF Grant No. DGE 1256260.

4:18PM C50.00008: Photonic band gaps in self-assembled colloidal crystals  
DUANDUAN WAN (Presenter), SHARON GLOTZER, University of Michigan —  
Using computer simulations, we explore the effect of thermal disorder on the photonic band gap in a self-assembled photonic crystal. We find that photonic band gaps can exist over a large range of intermediate packing fractions and that the widest gap does not necessarily appear at the densest packing fraction. Further, we show that with judicious choices of particle shape, packing fraction, and particle internal structure, self-assembly can be a promising method to make photonic crystals with large band gaps despite the presence of disorder.

4:30PM C50.00009: The Importance of Being Inhomogeneous: Simulation Approaches for Liquid Crystal Optical Metasurfaces in the Visible*  
JAMES DOLAN (Presenter), Institute for Molecular Engineering, Argonne National Laboratory, HAOGANG CAI, Center for Nanoscale Materials, Argonne National Laboratory, LILY DELALANDE, XIAO LI, Institute for Molecular Engineering, University of Chicago, JUAN DE PABLO, Institute for Molecular Engineering, Argonne National Laboratory, DANIEL LOPEZ, Center for Nanoscale Materials, Argonne National Laboratory, PAUL F NEALEY, Institute for Molecular Engineering, Argonne National Laboratory —  
Optical metasurfaces—planar nanostructured devices which can arbitrarily tailor the wavefront of light—may be reconfigured by changing their dielectric environment. The application of external fields to liquid crystals is a particularly promising means by which to tune the optical properties of otherwise static metasurfaces. However, despite recent advances, there is still much progress to be made towards this goal. An outstanding issue is the behavior of liquid crystals adjacent to the nanoparticle “meta-atoms”. The optics of the device depend sensitively on this behavior, especially as the wavelength of operation approaches the visible and, therefore, the length scale of distortions in the liquid crystal director field. Here, we will demonstrate—through combined simulations and experiments—that it is not only the anisotropy of the liquid crystal which is important, but also its spatial inhomogeneity, if one wishes to accurately describe, and therefore predict, the optical properties of liquid crystal metasurfaces.  

*This work was supported by the Midwest Integrated Center for Computational Materials—and was performed, in part, at the Center for Nanoscale Materials—U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences (5J-30161-0010A and DE-AC02-06CH11357).

4:42PM C50.00010: Liquid crystal based photonic topological insulators  
HAMED ABBASZADEH (Presenter), Lorentz Institute, Leiden University, MICHEL FRUCHART, VINCENZO VITELLI, The James Franck Institute and Department of Physics, University of Chicago, WIM VAN SAARLOOS, Lorentz Institute, Leiden University —  
Topological photonics harness the physics of topological insulators to control the behavior of light. An example of such control is to find modes of a photonic system that are robust against material imperfections. In this talk, we propose to use a soft-matter platform based on liquid crystals to implement some classes of photonic topological insulators. In such systems, the spatial orientation of the molecules introduces an extra geometric degree of freedom which in conjunction with suitably designed structural properties leads to the creation of topologically protected states of light. The use of soft building blocks potentially allows for reconfigurable systems that exploit the interplay between light and the soft responsive medium.
Electrically tunable structural colors of cholesterics with oblique helicoidal director

OLENA IADLOVSKA (Presenter), Advanced Materials and Liquid Crystal Institute / Department of Physics, Kent State University, Kent, OH 44242, USA, GRAHAM R MAXWELL, Advanced Materials and Liquid Crystal Institute, Kent State University, Kent, OH 44242, USA, MATEUSZ MRUKIEWICZ, Advanced Materials and Liquid Crystal Institute, Kent State University, Kent, OH 44242, USA; Institute of Applied Physics, Military University of Technology, 00-908 Warsaw, P, GRETA BABAKHANOVA, Chemical Physics Interdisciplinary Program, Advanced Materials and Liquid Crystal Institute, Kent State University, Kent, OH 44242, USA, SERGIJ V SHIYANOVSKI, Advanced Materials and Liquid Crystal Institute, Kent State University, Kent, OH 44242, USA, O D LAVRENTOVICH, Advanced Materials and Liquid Crystal Institute / Department of Physics, Kent State University, Kent, OH 44242, USA — A cholesteric liquid crystal was recently shown (Xiang, J. et al., Phys. Rev. Lett. 112, 217801 (2014); Xiang, J. et al., Adv. Mater. 27, 3014 (2015)) to exhibit a peculiar oblique helicoidal state (ChOH) when acted upon by an electric field. The period of ChOH structure depends strongly on the applied field, which enables electrically tunable structural colors in an extraordinary broad spectral range from ultraviolet to infrared. We present experimental and theoretical studies of light reflection from ChOH as a function of the electric field, surface anchoring, and incident angle. Unlike the case of conventional cholesterics, ChOH shows tunable reflection at periodicities that correspond to both pitch (for oblique incidence) and half-the-pitch. Reflection spectra are used for the first in-situ measurements of bend elastic constant of the chiral material.

Switchable on-demand Pancharatnam-Berry phase modulation in polymer-stabilized cholesteric liquid crystals

BENJAMIN KOWALSKI (Presenter), TIMOTHY J WHITE, Chemical and Biological Engineering, University of Colorado at Boulder, MATTHEW S MILLS, Air Force Research Laboratory — Cholesteric liquid crystals (CLCs) self-assemble into chiral Bragg reflectors. It has recently been shown that by spatially patterning the reflector's helical phase, a geometric (Pancharatnam-Berry) phase modulation can be imparted on the reflected beam. Here we combine this approach with electrically driven reflection band tuning of polymer-stabilized liquid crystals. As a demonstration of this capacity, we show dynamically switchable, polychromatic generation of nondiffracting beam modes. We present a novel projection lithography system for reconfigurable helical phase landscape patterning, and analyze the fundamental limits on resolvable feature size in this landscape.

Session C51 DPOLY: Recent Developments in Nonequilibrium Dynamics and Rheology of Entangled Polymer Liquids

BCEC 253A - Shiqing Wang, Univ of Akron - Tag(s): Invited

Molecular Rheology of Entangled Polymeric Fluids: New Discoveries and Remaining Challenges

BAMIN KHOMAMI (Presenter), University of Tennessee — Quantitative understanding of the influence of environmental variables on the dynamic evolution of microstructure in polymeric fluids plays a central role in soft matter physics as well as the processing of a wide variety of soft materials. Atomistic simulation via non-equilibrium molecular dynamics (NEMD) offer a viable alternative to experiment wherein the dynamics of individual macromolecules can be tracked independently, thus allowing for relevant calculations of their single-chain configurational properties as well as bulk-average properties, which in turn allows detailed examination of the fundamental tenants of reputation/ tube based theories for flow of entangled polymeric fluids.

In this presentation, I will review the progress made in fundamental understanding of non-equilibrium dynamics of polymeric melts as well as the remaining challenges in development of a unified approach for predicting dynamics of this class of fluids in processing flows commonly used to produce structural and functional soft materials. Specifically, I will discuss: (1) Non-Equilibrium Molecular Dynamics Simulations (NEMD) results that depict existence of new phenomena that challenges the fundamental tenants of theories and models used to describe fast flow of entangled polymeric fluids, (2) the intricate connection between single chain dynamics and the macroscopic response of this class of fluids including the intriguing phenomena of shear banding and configurational microphase separation in elongational flow.

*Financial support was provided by the National Science Foundation under Grant No. CBET-1602890. Computational resources for this project were provided by allocation of advanced computational resources by the National Institute for Computational Sciences (NICS) and the Oak Ridge National Laboratory Joint Institute for Computational Sciences and the Extreme Science and Engineering Discovery Environment (XSEDE), ACI-1548562/TG-CTS150054..
3:06PM C51.00002: Rheological behavior of entangled polymer melts and solutions in fast extensional flow* [Invited]
QIAN HUANG (Presenter), Department of Chemical and Biochemical Engineering, Technical University of Denmark — Extensional rheology of polymer liquids is highly sensitive to molecular architecture. Accurate and reliable stress-strain measurements of extensional flow play a crucial role in understanding the nonlinear rheological properties of polymers. However, extensional flow is difficult to measure reliably.

In the first part of this presentation, we compare the stress-strain measurements of entangled polymer melts and solutions between two types of state-of-the-art extensional rheometers, namely the Sentmanat extensional rheometer (SER) and the filament stretching rheometer (FSR). While necking instabilities, which prevent steady flow, are observed in SER at some specific range of normalized stretch rate (Weissenberg number), kinematically steady extensional flow can be achieved in FSR with the help of an online control scheme [1]. At higher Weissenberg numbers, elastic fracture happens in both SER and FSR [1]. The significance of the observed necking, steady extensional flow, and elastic fracture will be discussed in the presentation.

In the second part, we show the results of extensional rheology measured in FSR for entangled polymer liquids with different molecular architectures, including linear, star, comb, and ring polymers. Some results are also compared with the ones measured in SER. Interpretation of the rheological results will be presented and compared with the results from ex-situ small angle neutron scattering (SANS). Furthermore, stress relaxation measurements following steady extensional flow for a linear polymer melt will be presented, together with the corresponding results of ex-situ SANS. We show that the chain stretch idea in the tube model can be critically tested through analyzing the SANS data at different time in stress relaxation process.

*Financial support from the Aage og Johanne Louis-Hansen Foundation is gratefully acknowledged.

3:42PM C51.00003: Forced-Based Microscopic Theories of the Equilibrium Dynamics and Nonlinear Rheology of Entangled Rod and Chain Polymer Liquids [Invited] KENNETH SCHWEIZER (Presenter), University of Illinois at Urbana-Champaign — Using ideas from microscopic glass physics, force-based statistical mechanical theories for the transverse tube confinement field of liquids of zero-excluded-volume rods (needles) and chains have been constructed based solely on dynamic uncrossability which is exactly enforced at the two body level. Coils are coarse grained to chains of self-consistently-determined primitive-path steps. Tube localization emerges above a universal critical degree of interpenetration, and the melt tube diameter scales with packing length. Importantly, the confinement field is anharmonic, softening for large transverse displacements, corresponding to a finite maximum entanglement force. The predicted form of the confinement field is in excellent agreement with f-actin solution experiments and chain melt simulations. The tube field softens with orientation, hardens for affinely stretched chains, and is potentially destroyed beyond a critical stress (microscopic yielding). Nonequilibrium theories and simple constitutive equations under continuous startup shear have been constructed. For chain melts, new physical aspects include a dynamic tension blob scaling construction of a grip force that is the microscopic origin of stretching, a force imbalance criterion for termination of affine deformation and onset of retraction, the influence of entanglement length heterogeneity, an emergent form of convective constraint release, and rate-accelerated retraction of strongly stretched chains. For fast deformations we predict novel fractional power law scalings with rate for the stress overshoot and undershoot, steady state total and orientational stress and contour length stretch, a universal master curve in the elastic-viscous crossover regime, and strong connections between the overshoot and steady state. No adjustable parameter numerical predictions are quantitatively compared with multiple experiments and simulations. This work was done in collaboration with Shi-Jie Xie and Daniel Sussman.
A central problem in polymer rheology is to understand how the intra- and interchain configurations are transformed by the macroscopic deformation. The rheo-small-angle-neutron-scattering (rheo-SANS) technique has long held the promise of offering a molecular perspective on this issue. However, despite decades of development, the full potential of this experimental technique is yet to be realized. By combining and extending several key concepts in the literature and drawing upon the so-called spherical harmonic expansion technique, here we describe a new framework (Phys. Rev. X 7, 031003 (2017); Phys. Rev. Lett. 121, 117801 (2018)) for connecting the SANS experiments and the molecular rheology of polymeric liquids. We show how several two-point spatial correlation functions, such as the anisotropic single-chain structure factor and pair distribution function, can serve as a bridge between rheo-SANS experiments on the one hand and theoretical studies on the other, providing a convenient platform for molecular rheology of polymers. To demonstrate the power of this idea, we will discuss in this talk our recent SANS experiments on deformed homopolymer melts as well as polymer blends.

Shear banding in semidilute polymeric solutions: Experiments and modeling* [Invited] NATALIE GERMANN (Presenter), Technical University of Munich — Shear banding is the formation of localized velocity bands with different shear rates, and is observed in semidilute polymer solutions and other soft materials. DNA solutions are convenient model systems owing to their characterization in standard rheometric geometries without edge fracture. Furthermore, their wall slip can be minimized by using glycerol as a solvent. In this talk, we focus on the investigation of shear banding of 13 mg/ml of 115 kbp double-stranded DNA (dsDNA) and 11 mg/ml of 50 kb single-stranded DNA (ssDNA) in glycerol/aqueous buffer solutions and compare the results with our recent works on polyacrylamide and polyethylene oxide. The frequency sweep of dsDNA corresponds to that of a soft gel with a small dependence at intermediate frequencies. On the other hand, the behavior of ssDNA is comparable to that of a dense micellar solution having a unique local minimum related to micellar breakage. Due to the much smaller persistence length, ssDNA is more flexible and easily creates small structural units most likely in association with glycerol. The strain sweep of dsDNA is strain thinning and the shear bands are mainly strain-dependent. Early strain stiffening with weak bands is observed for ssDNA followed by a terminal flow regime of the collapsed structure. To summarize our recent activities on shear banding, we will briefly discuss here our mesoscopic modeling and simulation efforts in mixed flows (e.g., 4:1 contraction, die extrusion).

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C52 DPOLY DBIO: Polyelectrolyte Complexation II: Phase Behavior and Solutions Dynamics BCEC 253B - Samanvaya Srivastava, University of California, Los Angeles - Tag(s): Focus

2:30PM C52.00001: Polyelectrolyte solution confined between oppositely charged dielectric surfaces* DEBARSHEE BAGCHI (Presenter), TRUNG NGUYEN, MONICA OLVERA DE LA CRUZ, Materials Science, Northwestern University — We study a polyelectrolyte solution confined between two oppositely charged dielectric surfaces by a coarse-grained molecular dynamics simulations. Randomly charged beads as in sodium polystyrene sulfonate with varying degrees of sulfonation are modeled using implicit solvent with explicit ions. The charged electrodes that confine the polyelectrolyte solution are considered to be made of a low dielectric constant material such as graphene. We employ an efficient algorithm for computing the induced charges and investigate various properties of our system, such as the capacitance and its relation to the polymer conformation and charge density. We observe counter-intuitive phenomena such as charge amplification where a layer of ions adsorb close to a surface of same charge to allow more polymer adsorption.

*NSF DMR Award No. 1611076
Incorporating Molecular Structure into a Transfer Matrix Theory of Complex Coacervation

TYLER LYTLLE, CHARLES SING (Presenter), University of Illinois at Urbana-Champaign — Polymeric complex coacervation is a phase-separation process involving two oppositely-charged polyelectrolytes in an aqueous salt solution, where a polymer-dense phase is formed due to electrostatic interactions between the polyelectrolyte species. The resulting coacervate materials have seen widespread use in industry as viscosity modifiers and encapsulants, and are used in polymer research as an interaction motif for charge-driven self assembly. Despite this utility, a fundamental physical description of this process has remained elusive; a recent resurgence of interest in coacervation has led to a number of candidate theories. Here we present a transfer matrix theory that maps coacervate structure to a one-dimensional adsorption model, leading to a theory that can predict both coacervate phase behavior and local charge correlation features. We show that straightforward modifications to the theory can be used to account for a number of molecular features, including divalent ions, linear charge density, polymer stiffness, and polymer architecture. Comparison to simulation and experiment shows that we can capture qualitative trends that inform the molecular design of polymer complex coacervates.

Structure-Property Relationships for Oligonucleotide Polyelectrolyte Complex Micelles

JEFFREY VIEREGG (Presenter), MICHAEL LUECKHEIDE, ALEX MARRAS, MATTHEW TIRRELL, Institute for Molecular Engineering, University of Chicago — When a charged-neutral hydrophilic block copolymer is mixed with an oppositely-charged polyelectrolyte, micro-phase separation occurs, producing core-shell nanoparticles referred to as polyelectrolyte complex micelles by analogy to hydrophobically-driven micellization. PCMs have been proposed as a solution to the urgent problem of therapeutic delivery of (anionic) oligonucleotides into cells, as the dense polyelectrolyte core and neutral corona can shield the oligonucleotides from degradation and improve biodistribution. Several promising results have been reported, but until recently no structure-function relations existed to guide design of PCMs, and little data existed on the effect of chemical modifications to either polyelectrolyte. By combining small-angle X-ray scattering, multi-angle light scattering, and cryo-electron microscopy, we have characterized the morphology and internal structure of PCMs formed by oligonucleotides of varying size, structure, and chemical composition with poly(lysine)-poly(ethylene glycol) block copolymers. I will present results that illustrate the connections between molecular features and PCM morphology, as well as rules for producing oligonucleotide PCMs of desired size and shape with exceptionally low polydispersity.

Probing the size of coacervate core micelles

DEBRA AUDUS (Presenter), Materials Science and Engineering Division, National Institute of Standards and Technology, BRADY GARRINGER, Chemical Engineering, Boise State University, HAYLEY BOIGENZAHN, Chemical Engineering, University of Wisconsin-Madison — Coacervate core micelles, composed of diblock copolymers with oppositely charged blocks forming the core and neutral, hydrophilic blocks forming the corona, are of use for applications including drug delivery as the core can encapsulate hydrophilic, charged cargo. For such applications, it is essential to understand how the polymer architecture can be used to tune the size of these micelles. Using a model that captures the essential physics coupled with computational methods, we probe how the core size, corona size, and aggregation number.

Salt-concentration-dependent structure of Complex Coacervate Core Micelles

TAEYOUNG HEO (Presenter), SOOHYUNG CHOI, Department of chemical engineering, Hongik University — Complex coacervation is a liquid-liquid phase separation when two oppositely charged polyelectrolytes are mixed in an aqueous solution. Because of the nature of electrostatic interaction, the coacervates are highly responsive to solution condition such as ionic strength. In this study, complex coacervate core micelles (C3Ms) are formed by simple mixing of AB and A'B diblock copolyelectrolyte solutions in an aqueous solution where A and A' are oppositely charged blocks, and B is PEO block. Since the cores are coacervates, the C3Ms are also highly responsive to salt concentration. We investigate the salt-concentration-dependent structure of C3Ms with various molecular weight of charged block using dynamic light scattering (DLS) and small-angle X-ray/Neutron scattering (SAX/NS). As salt concentration increases, the aggregation number and core radii of C3M decrease. This reflects that the interfacial area per chain increases due to reduced interfacial tension between cores and solvent at higher salt concentration. In addition, salt resistance of C3Ms becomes stronger as the molecular weight is larger.
3:30PM C52.00006: Structural Evolution and Formation Kinetics of Polyelectrolyte Complex Micelles  HAO WU (Presenter), JEFFREY TING, MATTHEW TIRRELL, University of Chicago — Polyelectrolyte complex (PEC) micelles form when oppositely charged block polyelectrolytes are mixed together in aqueous media. The polyelectrolyte blocks, driven by electrostatic interaction, associate and phase separate, leading to a dense, polymer-rich PEC core stabilized by a neutral block corona. These nanoscale PEC micelles have various biomedical applications including RNA therapeutic delivery, tissue engineering, and diagnostics. The formation kinetics of PEC micelles, however, remains unknown. We employ time-resolved SAXS to investigate the formation kinetics of PEC micelles and the effects of various parameters on the growth rate. We focus on a model polyelectrolyte system that we have expertise in synthesis and has been extensively studied: poly(ethylene oxide)-block-poly(vinyl benzyl trimethyl ammonium chloride) (PEO-b-PVBTMA) complexed with either poly(ethylene oxide)-block-poly(styrene sulfonate sodium) (PEO-b-PSSNa) or poly(acrylic acid sodium) PAAc. Achieving a nanoscale description of the growth kinetics via TR-SAXS experiments will contribute towards enhancing our understanding of the complexation-driven assembly processes, and allow better design of polyelectrolyte complex based materials for biomedical applications.

3:42PM C52.00007: Dynamics of liquid coacervates formed by oppositely charged polyelectrolytes  CHRISTIAN APONTE-RIVERA (Presenter), MICHAEL RUBINSTEIN, Duke University — Mixtures of oppositely charged polyelectrolytes can undergo a phase separation to form a polymer rich phase, called a coacervate, and a polymer depleted phase. The polymer rich phase can be a soft, viscous liquid, or a solid complex. Both types have drawn much attention in the literature due to their technological applications as well as their role in biological systems. Models have been developed to predict thermodynamic properties of the coacervates. However, much less attention has been given to modeling coacervate dynamics. We develop a scaling theory to predict the dynamics of entangled and unentangled asymmetric liquid coacervates formed from oppositely charged polyelectrolytes. The theory predicts the scaling of properties such as the relaxation modulus and shear viscosity of the coacervate, and the diffusivity of the polyelectrolyte chains. The scaling theory highlights the different dynamic regimes of the system, and how the dynamic properties can be tuned by experimentally controllable parameters such as the degree of polymerization or the number density of charges along the polyelectrolyte backbone, providing a means with which to rationally design dynamic properties for technological applications.

3:54PM C52.00008: Polymer chemistry and effect on the linear viscoelasticity on polyelectrolyte complexes  YALIN LIU (Presenter), CRISTIAM F. SANTA CHALARCA, University of Massachusetts Amherst, REBECCA A. OLSON, RICHARD N. CARMEAN, Department of Chemistry, University of Florida, TODD EMRICK, University of Massachusetts Amherst, BRENT SUMERLIN, Department of Chemistry, University of Florida, SARAH PERRY, University of Massachusetts Amherst — Polyelectrolyte complexes are formed through the electrostatic interaction of oppositely charged polymers. Depending the identity of salt, polyelectrolyte complexes can result in both solid precipitates and/or a liquid-liquid phase separation known as complex coacervation. The material properties can also change based on variations in the polymer chemistry, and the complex interplay between electrostatic interactions and water structure, controlled by salt. We tested three different polymer systems over a range of polymer chain lengths and salt conditions to understand how variations in polymer chemistry affect the thermodynamic phase behavior and the resulting material dynamics. The linear viscoelasticity of each polymer system was investigated under different salt conditions to enable a time-salt superposition and facilitate a broader characterization of the stress relaxation behavior. We compare differences in the slope of the horizontal shift factors as a function of salt concentration, which can be related to the activation energy barrier for the rearrangement of ionic interactions between polymers. The goal of this systematic study is to establish a general understanding of how molecular-level parameters can be used to tune the phase behavior and viscoelastic properties.

4:06PM C52.00009: Ionic-group-dependent phase behavior of polyelectrolyte coacervates  SOJEONG KIM (Presenter), School of Chemical and Biological Engineering, Seoul National University, SOOHYUNG CHOI, Department of Chemical Engineering, Hongik University, WON BO LEE, School of Chemical and Biological Engineering, Seoul National University — Complex coacervates are polymer-rich phases of liquid-liquid phase separation when two oppositely charged polyelectrolytes are mixed in aqueous solutions. Previously, Voorn-Overbeek model (VO model), simple and intuitive combination of the entropy of mixing and electrostatic interaction, was proposed to capture the behavior of complex coacervates. Since the VO model doesn't account for the chain connectivity of polyelectrolytes and chemistry-specific details, advanced models have been suggested up to now. However, experimental data of model system is rare to compare with the theoretical description. In this study, 4 polyelectrolytes are prepared (e.g., strong/weak and polyanion/cation) and thus 4 pairs of polyelectrolyte complex coacervates are investigated to map out the phase diagrams as a function of the pair of the ionic group. It is found that the phase diagram shows distinctive features including (1) the salt resistance and the area of two-phase region are significantly dependent on the pairs of polyelectrolytes, and (2) the tie lines in the binodal curve show negative slope. We believe chemical-specific parameters play an important role to control phase behavior, and this observation shed a new light on the fascinating and biologically important topic of complex coacervation.
RONALD LARSON (Presenter), ALI SALEHI, Chemical Engineering, University of Michigan — We develop a modeling framework for phase behavior and transport of oppositely charged polyelectrolytes (PE) in coacervates and Layer-by-Layer (LbL) assemblies that accounts for diffusion of both oppositely charged chains and their complexation. The core of the phase behavior model is the development of a free energy model that includes free energies for ion pairing, counterion condensation, charge regulation, electrostatic free energy, as well as elastic energy of the network and Flory Huggins entropy and enthalpy. We quantify a very strong influence of ion pairing and counterion condensation on phase behavior, and on the distribution of salt and polyelectrolyte species between the coacervate and supernatant phases, and find consistency of predictions with experimental data. From this free energy model, and an extended Stefan-Maxwell flux law based on the Doi-Onuki Rayleighian approach, the transport of PE chains, salts, and waters through polyelectrolyte LbL films are modeled, including the effects of chemical and electrostatic potentials, as well as mechanic stresses. The result is a unified approach that connects phase behavior to transport in polyelectrolyte assemblies, and may eventually allow rates of Layer-by-Layer assembly to be inferred from measurements of phase behavior and rheology.

*The support of the National Science Foundation under grant DMR 1707640 is gratefully acknowledged.

4:54PM C52.00011: Teaching a New Dog Old Tricks: Phase Inversion in Polyelectrolytes  
DAVID DELGADO (Presenter), KAZI SADMAN, QIFENG WANG, KENNETH R SHULL, Northwestern University — While the design and synthesis of water filters required no activation; whereas for a low PAAm ionization level, the formed network was weak but consistent. Oscillatory shear deformation experiments revealed a strong dependence of the storage and loss moduli on the PAAm ionization degree of the system components, a strong network was formed but only after sonication, i.e. as a result of an activation; whereas for a low PAAm ionization level, the formed network was weak but required no activation.

5:06PM C52.00012: Stretchable Ionic Double Layer at the Interface Between Crosslinked Networks of Ionic Liquids  
HYEONG JUN KIM (Presenter), University of Massachusetts Amherst, BAOHONG CHEN, ZHIGANG SUO, Harvard University, RYAN HAYWARD, University of Massachusetts Amherst — Polymerized ionic liquids (PILs) are an emerging class of ion conducting materials wherein one of the ionic moieties in the ionic liquids is covalently attached to a polymer backbone. Crosslinked networks of ionic liquids (NILs) allows solid-state electrolyte that can selective conduct single ions. Herein, two oppositely charged NILs were prepared based on 1-ethyl-3-methyl imidazolium (3-sulfopropyl) acrylate ([ES]) and (1–(2–acyloxyethy)–3–buthyl–imidazolium bis(trifluoromethane) sulfonimides ([AT]). At the interface of [ES]/[AT], we show that an ‘ionic double layer’ (IDL) is formed. The mobile ions are diffused away from the interfacial region, resulting in a build-up of excess fixed charges with a capacitance of ~ 1 mF/cm². This IDL leads to asymmetric current flow when the polarity of the bias voltage is altered, analogous to the electrical rectification of a semiconductor diode. Moreover, the elastic properties of NILs allow a physical deformation which provides an electrical response that can be used for strain sensing or energy harvesting without the need for an external bias voltage. Our finding serves as a fundamentally new platform for a liquid-free, elastic and stretchable ionic diode that can harvest ambient mechanical energy such as human motion.

5:18PM C52.00013: Complexation and network formation in a suspension of oppositely charged cellulose nanocrystals and poly(allylamine)  
ARKADII ARINSTEIN (Presenter), PATRICK MARTIN, GLEB VASYLYEV, MOR BOAZ, GUANG CHU, EYAL ZUSSMAN, Nano-Engineering group, Department of Mechanical Engineering, Technion - Israel Institute of Technology — The structure formation, determined by tunable electrostatic interactions, in systems consisting of negatively charged cellulose nanocrystals (CNC) and a positively charged flexible weak polyelectrolyte, poly(allylamine) (PAAm), is discussed. Water dispersions, contained 3 wt.% CNC and 0.0364 wt.% PAAm of high molecular weight (65 kDa) that corresponds to the ionizable group stoichiometric ratio of system components, were examined. Variation in the dispersion pH allowed controlling the PAAm and CNC ionization level and hence the electrostatic interactions of the system constituents. For samples with high charge density, steady state viscosity measurements demonstrated cluster formation which consist of several CNC rods connected (due to ionic coupling) by PAAm tie macromolecules. Under certain conditions, these clusters (micro-gels) start to grow, merge and finally form a global network providing system elasticity. Oscillatory shear deformation experiments revealed a strong dependence of the storage and loss moduli on the PAAm ionization level. For high ionization degree of the system components, a strong network was formed but only after sonication, i.e. as a result of an activation; whereas for a low PAAm ionization level, the formed network was weak but required no activation.
Mechanophore activation in a crosslinked polymer matrix via instrumented indentation
CHELEA DAVIS (Presenter), MITCHELL L RENCHECK, Purdue University, JEREMIAH WOODCOCK, National Institute of Standards and Technology, MUZHO WANG, Northwestern University, RYAN BEAMS, STEPHAN STRANICK, AARON FORSTER, JEFREY GILMAN, National Institute of Standards and Technology — Scratches in transparent polymer coating and barrier layers can cause a host of problems, impacting optical (haze, light transmission, etc.) and mechanical properties (permeability, structural integrity, etc.) The primary focus of this project is to investigate the mechanical activation of a mechanophore (MP)-containing transparent polymer coating. Taking advantage of the amine functionality present in a polyetheramine/bisphenol A epoxy network, we have covalently attached a commercially available Rhodamine dye into a transparent, thermoset polymer. Utilizing the scratch profiles available on a typical nanoindenter, the load was varied so that a transition between ductile (plastic) to brittle deformation was observed within a single scratch. Subsequent fluorescence imaging of the MP-epoxy surfaces revealed the extent of fluorescence activation induced by the mechanical deformation. It has been shown that the Rhodamine-based mechanophore can be used to identify brittle fracture and local stress concentrations prior to macroscopic failure. Fluorescence lifetime and hyperspectral imaging of damage zones provide additional insight into the local deformation around each scratch.

Tryptophan based co-polymer as Fluorescence Turn-Off sensor for explosive detection
VISHAL KUMAR (Presenter), SOUMITRA SATAPATHI, Indian Institute of Technology Roorkee — The highly sensitive and reliable detection of explosives is of paramount importance for civilian and military security.1,2 Here, we report the synthesis and sensing applications of a highly emissive and electron-rich tryptophan based copolymer Poly[(N,N-dimethylacrylamide)-co-(Boc-Trp-EMA)] (RP)(Φf=35%) which exhibited high sensitivity and selectivity towards DNT, TNT and TNP with LOD 3.39, 2.55 and 0.7μM, respectively. In solution, PL signal from RP co-polymer gets quenched upon addition of aliquots of DNT, TNT and TNP caused by photo-induced electron-transfer i.e. quantified by plotting Stern–Volmer plot (KSV=7.6×10³,1.1×10⁴ and 3.3×10⁴ M⁻¹ for DNT, TNT and TNP). The quenching mechanism was further established by time-resolved PL and steady state absorption spectroscopy which was found to be predominantly dynamic in nature as lifetime of RP (2.1 ns) is reduced to 0.9, 0.8 and 1.3 ns for DNT, TNT and TNP. To explore the possibility of using the fluorescent co-polymer as sensor array, a prototype thin film polymer sensor was fabricated using drop-casted thin film of RP which was able to detect saturated nitroaromatic vapor in real time with high selectivity. The initial PL intensity of the 20 nm thin film of RP was quenched to 19% for DNT, 13% for TNT and 4% for TNP in just 2 min.

Tough and Photoluminescent Diblock Copolymer Elastomers via Lanthanide Coordination
FENG JIANG (Presenter), XIN ZHANG, DOUG HENDERSON, WONSEOK HWANG, ROBERT M BRIBER, HOWARD WANG, University of Maryland, College Park — Thermoplastic elastomers (TPEs) of poly(methyl methacrylate)-block-poly(n-butyl acrylate-co-vinyl imidazole) (PMMA-b-P(BA-co-VI)) diblock copolymers have been synthesized as a model system to demonstrate supramolecular photoluminescence (PL) TPEs via lanthanide coordination. Europium ion (Eu³⁺) with a red PL and terbium ion (Tb³⁺) with a green PL have been selected as the lanthanide ions to coordinate the imidazole groups of the soft block. Upon microphase separation, hard PMMA blocks form spherical domains in the continuous matrices of the soft P(BA-co-VI) phase. At a volume fraction of 0.29, PMMA hard sphere domains act as a physical network in the matrix. Upon incorporating lanthanide ions, the soft P(BA-co-VI) matrix is cross-linked through metal coordination to form a second physical network. Synergistic interaction and reinforcement of local segmental coordination network and global glassy particle percolation network greatly enhance both the tensile strength and toughness of TPEs without compromising the stretchability. Moreover, the PL spectrum of TPEs can be continuously tuned by varying the composition and molar ratio of Eu³⁺/Tb³⁺.
3:06PM C54.00004: Temperature and pH Dual-Responsive Shape-Transforming Block Copolymer Particles with Tunable Optical Property  JUNHYUK LEE (Presenter), BUMJOON KIM, chemical and biomolecular engineering, KAIST — We report a simple and robust strategy to prepare temperature/pH dual-responsive shape-switchable block copolymer (BCP) particles composed of polystyrene-b-poly(4-vinylpyridine) (PS-b-P4VP) and temperature/pH-responsive poly(N-(2-diethylamino)ethyl)acrylamide-r-N-isopropylacrylamide) (poly(DEAEAM-r-NIPAM)) surfactants. The polymer surfactants were carefully designed to produce a dramatic change in relative solubility in response to subtle temperature and pH change near physiological condition (i.e., human body temperature and neutral pH). The shape transition of BCP particles from lens to football shape was observed within very narrow temperature and pH range: no transition for pH 6.0, 40-50 °C for pH 6.5, and 25-35 °C for pH 7.0. Furthermore, the BCP particles showed reversible shape-transforming behavior in response to orthogonal temperature/pH changes. In addition, the incorporation of fluorescent dye-functionalized PS and P4VP into BCP particles allowed colorimetric monitoring of temperature and pH changes, which suggests a promising possibility of these particles in clinical and biomedical application.

3:18PM C54.00005: Effect of calcium ions on the interactions of end-tethered weak polyelectrolytes  RIKKERT NAP (Presenter), IGAL G SZLEIFER, Northwestern University — We use a molecular model, which combines theory with Monte Carlo and Molecular Dynamics simulations, to study the effect of divalent calcium ions on the interactions on the interactions between two planar surfaces end-tethered with poly(acrylic acid)(PAA). Polyelectrolyte-coated colloids and nanoparticles have nanotechnological and biomedical applications such as sensing and imaging. The addition of calcium ions to monovalent electrolyte solutions leads to a dramatic reduction in the size and range of effective interactions between the two polymer layers. This is caused by the formation of favorable calcium bridges that reduce the effective charge of the polymer layers and, at sufficiently high calcium ion concentrations, can cause the polymer layers to collapse. At physiological conditions and calcium ion concentrations above approximately 1mM, the repulsions between the opposing end-grafted surfaces disappear and attractions occur, accompanied by large structural changes of the opposing layers. These attractions are correlated with the occurrence of interlayer divalent calcium bridges and do not occur for PAA layers in contact with reservoir solutions containing only monovalent ions. Finally, the potential for microphase separation within the PAA layer is explored.

3:30PM C54.00006: In situ regeneration of oil absorbent via wettability switch of conjugated polymer surfaces  JIAN XU, Biomedical Engineering, Purdue University, WEI XIU, Brookhaven National Laboratory, YINLUN YUAN, GUOHAO GAO, EUI-HYEOK YANG (Presenter), Mechanical Engineering, Stevens Institute of Technology — Absorbent-based technology shows the possibility of full removal and reclaim of oils from water while bringing little adverse effects to the environment. In spite of their promises, the recycle and regeneration of saturated absorbents have been less-explored. Here, we demonstrate a light-weight high-efficient conjugated polymer foam as oil absorbent capable of in situ regenerating via wettability switch during electrochemical oxidation and reduction. We electopolymerize polypyrrole-dodecylbenzenesulfonate (PPy(DBS)) on the surfaces of commercially available carbon foam. The PPy(DBS) shows oleophilic property when oxidized, absorbing oils (i.e., oils stick to the polymer surface and trapped within the micro-pores of the foam). Under reduction, the surface switches to oleophobic, releasing the oils, while in situ regenerating the polymer surface. Using this approach, in situ absorption and release of various oils is demonstrated. We further demonstrate the wettability switch performance (characterizing the retention force when oxidized and switch time when reduced) of the absorbent during 250 redox cycles. Together, this novel adsorbent shows great promise towards high-efficient continuous oil/water separation applications.

3:42PM C54.00007: Design principle of multi-responsive smart copolymers  CARLOS M MARQUES (Presenter), Institute Charles Sadron, Strasbourg France, DEBASHISH MUKHERJI, Stewart Blusson Quantum Matter Institute, University of British Columbia, Vancouver Canada, KURT KREMER, Max-Planck-Institute for Polymer Research, Mainz Germany — Design of multi-responsive smart, soft materials is at the onset of many developments in polymer physics, chemical physics, biophysics and biochemistry research. A system is known as smart responsive when a slight change in external stimuli can drastically alter its structure, function and stability. Furthermore, when the relevant energy scale is of the order of thermal energy, materials are classified as soft matter and are driven by large conformational/compositional fluctuations. At the same time it is very difficult to address these problems in both experimental and theoretical setups. In this work, combining molecular simulation and experiments, we propose design principles of a wide range of smart copolymer architectures in aqueous and mixed solvent environments. This provides an almost predictable conformational behavior and thus presents a highly tunable smart polymer design principle.

This work has been performed within a fruitful collaboration with several experimental colleagues, especially Mark Watson (Uni Kentucky), Manfred Wagner (MPIP Mainz) and Marc Schmutz (ICS Strasbourg).
3:54PM C54.00008: Controlling Swelling Behavior of Upper Critical Solution Temperature Micelle Containing Layer-by-Layer Films*  VICTORIA ALBRIGHT (Presenter), ALIAKSEI ALIAKSEYEU, VIKTOR SELIN, Materials Science & Engineering, Texas A&M University, JOHN F ANKNER, Spallation Neutron Source, Oak Ridge National Laboratory, SVETLANA A SUKHISHVILI, Materials Science & Engineering, Texas A&M University — We explore the role of binding partner strength on temperature-responsive swelling profiles of hydrogen-bonded layer-by-layer (LbL) films containing upper critical solution temperature micelles (UCSTM) composed of poly(acrylamide-co-acrylonitrile)-block-polyvinylpyrrolidone. LbL films were constructed at acidic pH, at temperatures below the UCST, using poly(methacrylic acid) (PMAA) and the PVPON corona of the UCSTM. By using isothermal microcalorimetry, the interaction between PMAA and PVPON in solution was found to be pH dependent and entropically driven at pH 4. The internal structure of UCSTM LbL films deposited at various pHs was monitored with neutron reflectometry using deuterated PMAA to highlight film stratification, while growth and temperature-responsive swelling profiles of multilayers were studied with spectroscopic ellipsometry. Films assembled at higher pH, featuring more ionized PMAA chains, were less well stratified and displayed larger amplitude temperature-triggered swelling changes than those assembled at lower pH. Using pH to control film stratification and functionality can potentially be used in other hydrogen-bonding polymer assemblies.

*Funding from Texas A&M University Graduate Merit Fellowship, Texas Engineering Experiment Station, and NSF DMR-1610725.

4:06PM C54.00009: Mobility and self-healing in star-polymer vitrimers  SIMONE CIARELLA, WOUTER ELLENBROEK (Presenter), Eindhoven University of Technology — Vitrimers are a rapidly developing class of polymeric materials that combine the strength and resilience of covalently crosslinked elastomers with the malleability of thermoplastics. They owe this remarkable feature to a chemical bond-swap mechanism that allows the polymer network to rearrange its architecture without ever being fully disconnected. We simulate this swap mechanism in molecular dynamics simulations of star polymer networks using a 3-body potential-based method we recently developed [1]. We find that the swapping allows the star polymers to diffuse through the material, even on timescales below the stress relaxation time. This provides a mechanism for self-adhesion and self-healing of fully annealed (non-freshly cut) vitrimer surfaces, highlighting their use as durable structural materials.

4:18PM C54.00010: Molecular Design of Precise Network Polymerized Ionic Liquids for Improved Understanding of Soft Actuators  CHRISTOPHER EVANS (Presenter), CHENGTIAN SHEN, QIUJIE ZHAO, University of Illinois at Urbana-Champaign — Crosslinked network polymerized ionic liquids (n-PILs), with tethered imidazolium cations and mobile bis(trifluoromethane sulfonimide) (TFSI) anions, were investigated as dopant-free (no water or free ionic liquid) soft actuators by sandwiching between flexible electrodes and applying 3V, either AC or DC. These networks are made via a modular synthetic route such that they have tunable polarity and modulus through the choice of either hydrocarbon (HC) or ethylene oxide (EO) monomers and crosslinking density. The $T_g$ is not substantially affected, and the role of conductivity, crosslinking, and modulus can be probed to understand how they systematically affect actuation. Under DC conditions, where conductivity is not a factor, the lower modulus ($E$) allows for greater bending strain with a non-linear $1/E$ relation. Under 0.1 Hz AC potentials, the conductivity is important and couples with modulus to affect beam displacement. The choice of EO monomers and low crosslinking density lead to the best performance due to high conductivity and low modulus. Because the n-PILs are hydrophobic (< 1 wt% water uptake under ambient conditions), they can be operated over a thousand cycles at 3 V with minimal degradation of performance, as leaching of ionic liquids or water splitting are not an issue.

4:30PM C54.00011: Chemically Actuated Liquid Crystal-Based Polymer Printer  YOUNG KI KIM (Presenter), Chemical and Biomolecular Engineering, Cornell University, DANIEL B. WRIGHT, Chemistry, Northwestern University, PRANATI MONDKAR, Chemical and Biological Engineering, University of Wisconsin-Madison, NATHAN C. GIANNESCHI, Chemistry, Northwestern University, NICHOLAS L. ABBOTT, Chemical and Biomolecular Engineering, Cornell University — Liquid crystals (LC) exhibit the mobility of liquids and long-range order of crystals, leading to anisotropic viscoelastic properties. These properties have been used to design responsive soft materials that can amplify a range of chemical/physical stimuli into macroscopic optical outputs. Recently, we have reported a new class of LC materials based on micrometer-sized aqueous droplets dispersed in thermotropic LCs that both optically report targeted stimuli and trigger release of microcargo initially sequestered within the LC. In this presentation, we will show that these LC materials can be programmed to print three-dimensional polymeric networks and assemblies with diverse sizes and morphologies (from nanometer to millimeter) via triggered polymerization. Specifically, we will demonstrate that it is possible to trigger the polymerization of hydrogels or amphiphilic polymers by hosting initiators within microcargo sequestered in LCs. This work illustrates how it is possible to exploit the elasticity of LCs in combination with polymerization processes to achieve multi-scale responses to molecular-level triggering events.
4:42PM C54.00012: THz Vibrations of Metal-Organic Frameworks: Thermal and Mechanical Stability  MATTHEW RYDER (Presenter), Neutron Scattering Division, Oak Ridge National Laboratory — Neutron scattering is a critical technique in understanding how materials behave at the molecular-level. High-resolution inelastic neutron scattering (INS) in conjunction with density functional theory (DFT) was used to study the lattice dynamics of framework materials and revealed a diversity of valuable information relating to the structural flexibility and was able to explain the origins of anomalous elastic phenomena. Intriguing vibrational motions identified the presence of gate-opening and breathing in zeolitic imidazolate frameworks (ZIFs), and ‘trampoline-like’ mechanisms and molecular rotors reminiscent of negative thermal expansion (NTE) in the MIL-140 series and HKUST-1. However, to fully understand how these promising next-generation materials behave in real-life conditions the thermal and pressure response must be carefully studied. The effect of external stimuli (pressure and temperature) can also reveal the nature and underlying mechanisms behind stimuli-induced phase changes and amorphization. Preliminary results obtained using the one-of-a-kind Spallation Neutron Source (SNS) facility at Oak Ridge National Laboratory (ORNL) indicate elevated levels of anisotropic thermal expansion present in a topical series of framework materials known as MOF 74-M.

4:54PM C54.00013: Smart and responsive flexible foams via 3D printing of polymer composites* [Invited] PEIRAN WEI, HOUMING LENG, QIYI CHEN, RIGOBERTO ADVINICULA, EMILY PENTZER (Presenter), Case Western Reserve University — We will report lightweight, highly-compressible, and piezoresistive polymer composite foam structure successfully prepared by 3D printing a thixotropic ink. The structures have exhibits tailorable mechanical strength, high compressibility and remarkable robustness. Inks are composed of nanoclay and carbon black particles in an organic solution polyurethane, and are processed using direct ink writing (DIW) into wearable strain sensor devices. Removal of the clay by chemical etching yields structures with high porosity and good elasticity, which have good compressibility and stable piezoresistive sensing signals at a strain of > 90%. We illustrate these structures can be used in pressure sensing, as well as the sensing of volatile organic solvents. The conductive structures can easily be reprocessed to different shapes and have great potential for lightweight, energy-saving, flexible, highly sensitive, and stable piezoresistive sensors.

Session C55 DPOLY DCOMP DBIO GSNP: Advancing Polymer and Biopolymer Physics though Simulation and Theory I: Biopolymers BCEC 254B - Alexey Onufriev, Virginia Tech - Tag(s): Focus

2:30PM C55.00001: Chromosome organization by loop extrusion and phase separation* [Invited] LEONID MIRNY (Presenter), Massachusetts Institute of Technology — Inferring principles and mechanisms of 3D organization of chromosomes from Hi-C and imaging data is a challenging biophysical problem. Recently we proposed that an active process loop extrusion by SMC complexes is a universal mechanism responsible for formation of domains in interphase, and chromosome compaction and segregation in metaphase. I will review recent experimental studies that provide strong support to loop extrusion as a universal mechanism of chromosome folding.

These experiments have also showed that spatial segregation of euchromatin and heterochromatin is achieved by a different mechanism. To elucidate mechanisms of this spatial segregation, we examined Hi-C and microscopy for cells with inverted nuclei and conventional nuclear architecture. Polymer model base on these data show that attraction between heterochromatic regions drive the phase separation, while interactions with the lamina central for spatial positioning of phases in the nucleus.

Taken together our results demonstrate two major processes shape chromosome organization through the cell cycle: heterochromatin-driven phase segregation and SMC-driven loop extrusion.

3:06PM C55.00002: Modeling interphase chromosomes: Microrheology  ANDREA PAPALE (Presenter), ANGELO ROSA, International School for Advanced Studies — The nucleus of eukaryotic cells is one of the most investigated organelles, but its complete understanding is far from being reached. Recently considerable efforts have been devoted to experimentally analyze its viscoelastic properties, in particular through microrheology techniques.

We employ molecular dynamics computer simulations comparing experimental data with theoretical models. Mimicking experiments, we consider a polymeric model representing the crowding of interphase chromosomes [1] containing hundreds of brownian free particles as in [2]. We consider several sizes for particles from the tiny chromatin fiber to the mesh size of the chromatin solution. Tracking the motion of these fictitious nanoprobes we compute dynamical properties.

Then we investigate a simple variation of this polymeric model including a set of spring which modifies dramatically the viscoelastic properties. Interestingly, we observed the cage-and-escape dynamics peculiar for short times dynamics of nanoprobes seen in experiments.

We generalize also the model to the situation where active regulatory mechanics are present [3].

3:18PM C55.00003: Diffusion of nuclear proteins and its link to 3d chromatin organization*  ASSAF AMITAI (Presenter), Massachusetts Institute of Technology — The interaction of proteins with chromatin regulates many cellular functions. Most DNA-binding proteins interact both non-specifically and transiently with many chromatin sites, as well as specifically and more stably with cognate binding sites. These interactions and chromatin structure are important in governing protein dynamics. These questions can be addressed theoretically using diffusion models. I will show how that the dynamics of proteins is determined by the 3d organization of chromatin in the nucleus. The time to find a chromatin target depends on chromatin organization around it, which determines the local association and dissociation rates.

These ideas can be applied to study the dynamics of nuclear proteins and infer from single particle trajectories the geometry of the structures with which they interact.

*I acknowledge financial support from Massachusetts General Hospital (internal fund 214931).

3:30PM C55.00004: All-Atom Molecular Dynamics simulations of the interaction between viral capsid proteins and single-stranded RNA molecules.*  ZACHARY GVILDYS (Presenter), Chemistry & Biochemistry, University of California, Los Angeles, ROBIJN BRUINSMMA, Physics and Astronomy, University of California, Los Angeles — We carried out All-Atom Molecular Dynamics (MD) simulations of the interaction between the positively charged tails of viral capsid proteins and negatively charged homopolymeric polyU and polyA RNA molecules. Recent experiments showed that the encapsidation of homopolymeric RNA by viral capsids is sensitively dependent on the nature of the RNA nucleotide (C.Beren, L.Dreesens, K.Liu, C.Knobler and W.Gelbart, Biophys.J. 2017, 339). We found that the degree of base-stacking and helical ordering strongly influences the strength of the electrostatic component of the protein-RNA interaction, and hence the ability of the capsid proteins to package single-stranded RNA molecules. We compare the Potential of Mean Force measured by the MD simulations with the predictions of Poisson-Boltzmann theory for electrostatic interactions.

*We would like to thank the NSF-DMR for support under Grant 1610384.

3:42PM C55.00005: Pinning a protein (AQP1) structure by the interacting matrix elements  RAS PANDEY (Presenter), University of Southern Mississippi, PORNTHEP SOMPORNPSUT, Chemistry, Chulalongkorn University — The effect of temperature on a protein (AQP1) structure by a coarse-grained Monte Carlo simulation shows negative and positive responses in its native and denatured phases respectively. The same protein chain is then immersed in an interactive matrix with constitutive elements (i.e. effective solute particles with size comparable to residue) where an aquatic interactions between the residue and solute can be varied. Local and global physical quantities such as contact map, gyration radius, and structure factor are examined as a function of matrix interaction strength at a range of temperatures. The protein structures, from our preliminary studies, are found to be pinned by the solute, the radius of gyration becomes less sensitive to temperature, and structure factor shows a ramified structure with lower effective dimension than that without solute particles. In-depth analysis will be presented as the data will become available.
3:54PM C55.00006: Protein crystallizing assembly via free and grafted linkers*  YUBA DAHAL (Presenter), MONICA OLVERA DE LA CRUZ, Northwestern University — "Proteins have potential to form numerous lattices due to their highly anisotropic shape. However, the forces required to arrange proteins in a periodic fashion are not understood. In this study we introduce a coarse grained MD simulation approach to study the effects of length and geometry of linkers on the 3D crystalline assembly of ferritin protein. We find the optimal linker length dependence on the linker to protein ratio beyond which linkers fail to hold the proteins in a crystalline structure. We also study the effect of the length of the grafted linkers on the formation of the protein arrays. In the linker grafted case, we do not find an optimal length suggesting that the grafting of linkers on the protein surface is a better route to yield rich porosity crystalline structures. Our analysis suggests that the emergence of the optimal linker length is rooted at the expense of rotational freedom of the longer linker. The computationally inexpensive method that we present in this study could be useful as the guidelines to understand the assembly of complex molecules."

*Fairchild foundation

4:06PM C55.00007: Atomistic and Coarse-grained Simulations of Thermoresponsive Biopolymers*  PHILLIP TAYLOR (Presenter), PRHASHANNA AMMU, ARTHI JAYARAMAN, Chemical & Biomolecular Engineering, University of Delaware — This talk focuses on our multi-scale simulation studies on thermoresponsive biopolymers, specifically elastin-like peptides (ELP) and collagen-like peptides (CLP). ELPs are biopolymers that undergo a lower critical solution temperature (LCST)-like phase transition, which means ELPs are soluble below the transition temperature, $T_t$, and insoluble above $T_t$. The $T_t$ of ELPs can be tuned via conjugation to other thermoresponsive biomolecules such as CLPs. In our recent work, we used all-atom (AA) and coarse-grained (CG) simulations to elucidate how the guest residue impacts ELP stiffness, its secondary structure formation, and hydrophobicity and thus, the LCST-like transition of ELP and ELP-CLP conjugates. We used the structural data from AA simulations to modify our previous ELP CG model such that it captures the atomistically-informed stiffness while enabling simulations at experimentally relevant length scales. Our new ELP CG model also accounts for the hydrophobicity of the guest residue and its propensity to form compact, secondary structures. Through these modifications, our CG simulations are able to explain the experimental observations in $T_t$ of ELP and ELP-CLP conjugates with W and F as the guest residues.

*We thank NSF Grant 1703402 for financially supporting this work.

4:18PM C55.00008: Brownian Dynamics Simulation of Single Biomolecules: Contact Formation and Hydrodynamic Radius*  STEFFEN MÜHLE (Presenter), Third Physical Institute, Georg-August-University Goettingen, MAN ZHOU, Department of Biochemistry, University of Oxford, ARINDAM GHOSH, JÖRG ENDERLEIN, Third Physical Institute, Georg-August-University Goettingen — The conformational flexibility and dynamics of unfolded peptide chains is of major interest in the context of protein folding. The rate with which amino acids at different positions along the peptide chain meet sets an upper speed limit for protein folding. By using single-molecule photo-induced energy transfer (PET) spectroscopy, we have systematically measured end-to-end and end-to-internal site contact formation rates for several intrinsically disordered protein fragments (10 to 40 amino acids), and have also determined their hydrodynamic radius using dual-focus fluorescence correlation spectroscopy (2FCS). For interpreting the measured values, we have developed a Brownian dynamics model (a discretized elastic rod in a thermal bath including hydrodynamic interactions) which quantitatively reproduces all measured data surprisingly well while requiring only two fit parameters. The model provides a complete picture of the peptides' dynamics and allows us to translate the experimental rates and radii into molecular properties of the peptides: We find a persistence length of ~0.4 nm and a hydrodynamic radius of ~0.5 nm per amino acid.

Investigation into multivalently binding polymers

EMIKO ZUMBRO (Presenter), ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Biology frequently uses multivalent binding interactions to enhance weak, monovalent binding between molecules such as glycoligands and protein receptors. Synthetic glycopolymers have been shown to successfully bind to targets, such as viruses and toxic proteins. This binding indicates that the use of multivalent polymers can be a promising tool for inhibiting target attachment to and subsequent infection of cells. These polymers would act as decoys, suppressing virulence without killing their target and thus minimizing the development of resistance. Many studies have focused on creating multivalent binders with high affinity and high specificity to a single target. In contrast, we investigate how to design polymers that have broad-spectrum binding affinity, so that a single multivalent polymer could be used to inhibit multiple targets. We use a reactive-binding, Brownian dynamics simulation to examine how patterning of heterogeneous binding sites along a polymer chain control binding affinity of a polymer to multiple types of targets. Our results provide direction for designing polymeric inhibitors able to bind multiple targets simultaneously.

The authors were supported by the Department of Defense through the National Defense Science & Engineering Graduate Fellowship Program.

Disorder mediated oligomerization of chromosome translocation proteins of DISC1 gene.

DAVIT POTOYAN (Presenter), Iowa State University — Disrupted-in-Schizophrenia 1 (DISC1) gene is one of the highest risk factors for neural development including schizophrenia and other chronic mental illnesses. Depending on cellular context DISC1 gene expresses proteins of different length which have markedly different binding and oligomerization propensities. Due to highly disorder content the molecular level understanding of DISC1 protein assembly and oligomerization has been missing. We have carried out high throughput molecular dynamics simulations of all DISC1 expressed proteins at the coarse grained level to investigate conformational ensembles and oligomerization pathways of DISC proteins at the level of monomers dimers and various tetrameric combinations. Our findings reveal that disorder content present in DISC1 acts as a graded switch mediating non-additive binding and oligomerization preferences.

Characterizing the counterionic cloud of DNA-functionalized nanoparticles with molecular dynamics simulations

ALI EHLEN (Presenter), KURINJI KRISHNAMOORTHY, SUMIT KEWALRAMANI, MICHAEL J BEDZYK, MONICA OLVERA DE LA CRUZ, Northwestern University — DNA-functionalization of proteins allows for cell penetration and self-assembly of protein systems that have the potential for applications in therapeutics and other fields. However, the impacts of the resulting electrostatic interactions associated with the DNA shell and counterionic cloud are still being explored. Here, we use molecular dynamics simulations to examine the stability of a protein's DNA shell in the presence of DNase, as it relates to the composition of this counterionic cloud. We use molecular dynamics simulations and a simple thermodynamic model in tandem with SANS measurements to understand the composition of this cloud under varying salt conditions and protein shapes. This work builds on previous efforts to calculate this composition of this cloud using DFT calculations; detailed molecular dynamics simulations have been used to incorporate multiple species of ion as well as excluded volume effects and correlations.

Exploring the Structure and Dynamics of Carbohydrate Nanoparticles using Molecular Dynamics Simulations

ANDREW NAGEL (Presenter), MOHAMMAD HASSAN KHATAMI, HENDRICK W DE HAAN, University of Ontario Institute of Technology — PhytoSpherix is a carbohydrate-based nanoparticle composed of glucose units joined in a dendritic manner. These particles are of interest as they are a biodegradable and biocompatible nanomaterial. In this work, we present results from all-atom molecular dynamics simulations (GROMACS) of a PhytoSpherix-like particle. The particle is dynamically grown until it contains ~1100 glucose units. Analysis of structural features is conducted as the particle equilibrates to a relaxed state. The complex internal structure is characterized by hydrophobic interactions between chains and water-containing areas in contact with hydrophilic regions of the carbohydrate. Results concerning the dynamics inside of the particle are also examined. This characterization can assist the development of new applications for PhytoSpherix particles.

**5:18PM C55.00013: Investigating the Structure of Phytoglycogen using Coarse-Grained Simulations**

NICOLE DROSSIS (Presenter), HENDRICK W DE HAAN, Science, University of Ontario Institute of Technology — Phytoglycogen is a dendritic nanoparticle composed of repeatedly branching chains of glucose. Despite glucose being a common form of energy storage in plants, many questions still remain about the structure of this naturally occurring particle. In this work, pytoglycogen was modelled with a coarse-grained approach, simplifying each glucose unit to a single particle. A hydrophobic attraction between chains was observed in atomistic simulations and this was modelled in the coarse-grained simulations with a simple attraction between glucose particles. The strength of this attraction was used as a free parameter to investigate how changing it changes the structure of the particle. The simulated particles with radii similar to those seen in experiment were observed to have a hairy colloid shape, with a dense core and hairs extending out from the core.

**Monday, March 4, 2019 2:30 PM - 5:18 PM**

**Session C56 GSNP: Networks of Oscillators** BCEC 255 - Daniel Lathrop, University of Maryland, College Park

**2:30PM C56.00001: Synchronous Clustering in Multilayered Networks**

LOUIS PECORA (Presenter), United States Naval Research Laboratory, KAREN BLAHA, Mechanical Engineering, University of New Mexico, KE HUANG, Electrical Engineering, University of New Mexico, FABIO DELLA ROSSA, Mechanical Engineering, University of New Mexico, MANI HOSSEIN-ZADEH, Electrical Engineering, University of New Mexico, ABU BAKAR SIDDIQUE, FRANCESCO SORRENTINO, Mechanical Engineering, University of New Mexico — The topic of cluster synchronization of oscillators in networks has an active history and has recently experienced renewed interest in the nonlinear dynamics community because of the use of such graph theory tools as symmetries and equitable partitions to predict what cluster structures are possible, calculate their dynamic stability, and characterize their bifurcations as they desynchronize. Another recent network structure that has caught the interest of the dynamics community is multilayered networks. We show how to extend the graph theory tools to multilayered networks. Certain multilayered networks have a structure that allows their dynamics to be simplified and fit into the existing structure of analysis of synchronous clusters. We also present a recent experiment on a simple 4-oscillator multilayer system. We show what can be discerned from experimental data including bifurcation plots and desynchronization patterns. This is the first experiment on cluster synchronization that we know of that uses totally analog oscillators with no computer-aided control of the oscillators. We also will discuss how some of the concepts can be generalized.

**2:42PM C56.00002: Spontaneous data clustering using collective synchronization in a network of phase oscillators**

TAKAYA MIYANO (Presenter), SHINYA TAKARAMOTO, Ritsumeikan University — We developed a method for spontaneous data clustering based on Kuramoto’s model for collective synchronization. A network of phase oscillators, to the natural frequencies of which multivariate data are input, achieves partial synchrony owing to short range interaction between neighboring phase oscillators. The common frequencies of the partial synchronous groups represent major feature patterns of the multivariate data. As a case study, we apply our method to actually observed time series of wind velocity and show major feature patterns of the wind data.

Interdependent and competitive dynamics in multilayer networks: synchronization and epidemics

MICHAEL DANZIGER (Presenter), Northeastern University, IVAN BONAMASSA, Department of Physics, Bar-Ilan University, STEFANO BOCCALETTI, CNR - Institute for Complex Systems, SHLOMO HAVLIN, Department of Physics, Bar-Ilan University — Since 2010, research on interdependent networks of networks, has demonstrated relevant new percolation phenomena including cascading failures and abrupt discontinuous transitions [1, 2]. However, this approach is limited to cases where connectivity can be taken as a proxy for functionality. Here, we present new research on interacting network dynamics exhibiting a wide range of new phenomena which are observed in the real-world but absent in previous models. By extending the concept of connectivity and dependency links to dynamical processes, we are able to shed light on real-world complex systems from social networks to the brain. We demonstrate our approach by implementing interdependent and competitive synchronization based on the Kuramoto model [3, 4] and SIS epidemics. This new framework provides a key missing link in the modeling of real-world multilayer networks. The talk is based on our recent manuscript [5].

Synchronization of chaotic oscillators using partial state space linear control*

KEYUR MISTRY (Presenter), Indian Institute of Technology Bombay, SUDESHNA DASH, National Institute of Technology, Tiruchirappalli, SIDDHARTH TALLUR, Indian Institute of Technology Bombay — The idea of synchronization of chaotic oscillators traces its origin to pioneering work by T. L. Carroll and L. M. Pecora in the late 1980s. Numerous implementations reported over the last three decades either require all state variables of a master oscillator to generate a locking signal to entrain the slave oscillators, or use a subset of the state variables, albeit with nonlinear transfer function. We present a novel methodology in which locking signal is generated as i) a linear combination of ii) a partial subset of state variables of the oscillators. The unused state variables can be exploited for applications in cryptography. A generalized algorithm for controller design is presented, and the efficacy of this algorithm is proved by analyzing the piece-wise oscillator as multi-mode linear system. Root-locus method is used to compute feedback gain. Simplicity of the control system makes it possible to reliably realize all-analog, all-digital, or mixed-signal implementations for electronic oscillators, with low power and cost overheads. The methodology is validated through numerical simulations and experiments using op-amp based electronic circuits.

Almost Perfect In-Phase and Anti-Phase Chaotic and Periodic Phase Synchronization in Large Arrays of Diode Lasers*

YEHUDA BRAIMAN (Presenter), NIKETH NAIR, Computational Sciences and Engineering Division, Oak Ridge National Laboratory, Oak Ridge TN 37831, ERIK BOCHOVE, Directed Energy Directorate, Air Force Research Laboratory, Kirtland AFB, New Mexico, 87117 — We studied phase synchronization in large arrays of weakly coupled single mode semiconductor laser diodes [1,2]. We show that if the coupling topology is chosen appropriately, the laser array exhibits robust and almost perfect phase synchrony (including chaotic and non-chaotic phase synchrony). Furthermore, one can define coupling topologies that lead to chaotic anti-phase synchronization. When diodes are coupled via a decayed non-local coupling scheme, the leading spatial mode can be stable. This leads to an almost-perfect phase synchronous state where the phases are synchronized, even though the system is not being exactly on the synchronization manifold. This almost-perfect phase synchronous state is robust to noise and frequency and phase disorder and can be realized under periodic (fixed-intensity limit cycle) continuous-wave and chaotic behavior.

Global Frequency Locking of Networks of Coherently Coupled Lasers  

JIAJIE DING (Presenter), MOHAMMAD-ALI MIRI, Queens College — Nonlinear dynamics of networks of coupled oscillators is a subject of great interest in various disciplines ranging from electrical circuits and chemical reactions to biological cells and social systems. A universal property of such networks is a self-organized oscillation at a common frequency, which is often referred to as synchronization. Here, we investigate the frequency locking of a network of coupled lasers. In this regard, we introduce a first-order nonlinear coupled-mode model for optical oscillators representing semiconductor lasers. We show that two coupled oscillators with different individual frequencies can be synchronized in frequency when the mutual coupling rate exceeds a critical level. The threshold coupling is calculated and explored in the parameter space of the system. Next, we investigate synchronization in one- and two-dimensional arrays of lasers with uniform nearest neighbor coupling and explore the synchronization threshold as a function of the size of the network. Finally, we discuss that a more complex network topology is required in order to enforce global synchronization in a large network of coupled lasers.

Optimal fluctuation pathways to desynchronization in coupled oscillator networks*  

JASON HINDES (Presenter), United States Naval Research Laboratory — There is great interest in understanding how topology, dynamics, and uncertainty conspire to produce rare and extreme events in networks. This is particularly the case for coupled oscillator networks since they appear at the core of many biological and physical systems where noise and uncertainty play a significant role. A primary example is desynchronization in power grids from input-power fluctuations. In this talk, we develop theory for the most-likely, or optimal, pathway of noise-induced desynchronization in phase-oscillator networks (with and without inertia) and in Stuart-Landau oscillator networks. We quantitatively characterize the scalings and patterns for the optimal path and the probability of desynchronization as a function of network topology and local dynamics, and compare the behavior for the various models. Lastly, we discuss the effects of non-Gaussian, “pulse” noise, and controls on the input power, on desynchronization. Such effects are especially relevant for power grids with renewable energy sources.

Control of a Multistable 3-ring Network of Chemical Oscillators*  

CHRISTOPHER SIMONETTI (Presenter), MICHAEL NORTON, MARIA ELENI MOUSTAKA, SETH FRADEN, Brandeis University — The Belousov-Zhabotinsky reaction is a limit cycle oscillator with dynamical attributes comparable to neurons. By fabricating microfluidic wells filled with the BZ chemistry, we create reaction-diffusion networks with rich dynamical patterns that can yield fundamental insights into dynamics of neural networks. A simple network of three inhibitor-coupled wells connected in a ring possesses two stable, dynamical steady states: clockwise and counterclockwise traveling waves. By photo-chemically perturbing the wells’ intrinsic frequencies we can force the system to switch states. In this work, we explore the steady states as a function of applied light gradient using the Kuramoto phase model and Vanaag-Epstein model for photosensitive BZ. Optimal control theory is then applied to determine the most efficient way to drive the system from one attractor to another.

Features of a rich attractor space in a system of repulsively coupled Kuramoto oscillators*  

SHADISADAT ESMAEILI (Presenter), Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech, DARKA LABAVIC, Universite de Lille, France, HILDEGARD MEYER-ORTMANNS, Jacobs University Bremen, Germany, MICHEL PLEIMLING, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — Rhythmic behaviors with a wide range of periods emerge from populations of coupled oscillators in many phenomena in nature. The Kuramoto model is one of the simplest models of coupled oscillators vastly used to explain many such phenomena. Choosing a repulsive coupling and a proper topology in this model leads to frustration and, as a result, versatile features of multistability. Also, by choosing non-homogeneous natural frequencies, in a large enough system orbits emerge with very long periods that are orders of magnitude longer than the natural frequencies. To understand the characteristics of the phase space we study the effects of tuning parameters like the coupling constant and the width of the frequency distribution.

4:18PM C56.00010: Overcoming oscillation quenching in coupled nonlinear oscillators*  NANNAN ZHAO (Presenter), ZHONGKUI SUN, Northwestern Polytechnical University — Rhythmic oscillation activity plays an important role in various natural and artificial systems. However, the appearance of oscillation quenching phenomena can lead to a loss or degradation of intrinsic function for many practical systems. In this work, we introduce a simple method based on the external positive feedback that can efficiently revoke these quenching states in different coupling schemes. Taking the limit cycle Stuart-Landau systems as example, we have illustrated numerically and analytically that tuning the feedback strength can shrink drastically the oscillation quenching regions in the parameter space. Our study will provide a new and general framework to retrieve the rhythmicity or the strengthen the robustness for dynamic activity of coupled nonlinear systems.

4:30PM C56.00011: Effects of variation of coupling offset \( \alpha \) in electronic oscillator experiments*  MACMILLAN WHEELER (Presenter), TAYLOR GURREITHUN, SHELBY STEGMAIER, DAVID MERTENS, Eckerd College — In biological systems that exhibit synchronization, oscillators within a single population vary in many aspects. To provide controlled experimental insight into how these variations affect synchronization, we have built an ensemble of highly configurable electronic oscillators. These oscillators have programmable speed, coupling strength, waveform shape, and coupling phase offset, known as \( \alpha \) in the Sakaguchi-Kuramoto model. Moreover, each oscillator can have a distinct coupling offset. We have examined how \( \alpha \) affects the degree of synchronization, and how variations in \( \alpha \) within a population alter the stability of the synchronous state. We will also compare our findings with those presented in the literature.

4:42PM C56.00012: Relaxation oscillators, limit cycle oscillators, and somewhere in between: experimental exploration of waveform variation in synchronizing oscillators*  TAYLOR GURREITHUN (Presenter), MACMILLAN WHEELER, SHELBY STEGMAIER, DAVID MERTENS, Eckerd College — In biological systems that exhibit synchronization, oscillators within a single population vary not only in their natural rates, but in many other characteristics. To study such variations experimentally, we have built an ensemble of highly configurable electronic oscillators. These oscillators have programmable speed, coupling strength, coupling phase offset, and waveform. Each oscillator's waveform can be tuned from approximately sinusoidal to relaxational, effectively altering the interaction from a nearly sinusoidal one to a more complex form. To our knowledge, interactions between oscillators with different waveforms have not been examined. In this talk, we will present our findings on how variations in waveform in a single population affect the system's ability to synchronize.

4:54PM C56.00013: Dynamics of the Kuramoto-Sakaguchi Oscillator Network with Asymmetric Order Parameter  JAN ENGELBRECHT (Presenter), Boston College, BOLUN CHEN, Brandeis University, RENATO MIROLLO, Boston College — Kuramoto oscillator networks are an important idealized class of oscillator models. We consider a generalized network in which the order parameter is the sum of the complex oscillator phases, but with non-identical coefficients. We analyze this model using a dimensional reduction from dynamics on an N-dimensional state space to a flow on the unit disk, where the natural hyperbolic metric facilitates the analysis. We give a fairly complete classification of the asymptotic dynamics with careful consideration of the subtleties of the flow near the disk's boundary, which includes both fully synchronized states and \((N-1,1)\) states where all but one of the oscillators are synchronized. The geometric connection also allows us to identify conditions for the flows to be gradient, or Hamiltonian or even simultaneously gradient and Hamiltonian. Examples of new behavior in the asymmetric model include, \((N-1,1)\) attractors with a basin of non-zero measure and homoclinic and heteroclinic non-periodic orbits to/from sync and \((N-1,1)\) states in the Hamiltonian case.

5:06PM C56.00014: Double-Period Breathers in a Driven-Damped Lattice  GOLAN BEL (Presenter), Environmental Physics, Ben-Gurion University of the Negev, BOIAN S ALEXANDROV, ALAN REGINALD BISHOP, KIM Ø RASMUSSEN, Theoretical Division, Los Alamos National Laboratory — Spatially localized and temporally oscillating solutions, known as discrete breathers, have been experimentally and theoretically discovered in many physical systems. We considered a lattice of coupled damped and driven Helmholtz-Duffing oscillators in which we found a spatial coexistence of oscillating solutions with different frequencies. Specifically, we demonstrated that stable period-doubled solutions coexist with solutions oscillating at the frequency of the driving force. Such solution represents period-doubled breathers resulting from a stability overlap between subharmonic and harmonic solutions and exist up to a certain strength of the lattice coupling. Our findings suggest that this phenomenon can occur in any driven lattice where the nonlinearity admits bistability (or multi-stability) of subharmonic and harmonic solutions.
2:30PM C57.00001: Characterization of fracture in topology-optimized bio-inspired networks*  CHANTAL NGUYEN (Presenter), Department of Physics, University of California, Santa Barbara, DARIN PEETZ, Department of Civil and Environmental Engineering, University of Illinois at Urbana-Champaign, AVIK MONDAL, Department of Physics, University of Michigan, AHMED ELBANNA, Department of Civil and Environmental Engineering, University of Illinois at Urbana-Champaign, JEAN CARLSON, Department of Physics, University of California, Santa Barbara — Trabecular bone is a flexible, lightweight bone tissue that exhibits an anisotropic microarchitecture resembling a web of interconnected struts (trabeculae). We simulate trabecular bone architectures with multi-objective topology optimization, effectively reverse-engineering trabecular structure by optimizing biologically-motivated objectives. Starting from an identical volume, we generate different topologies by varying the objective weights for compliance, surface area, and stability. We model these topologies as disordered, spatially-embedded networks where edges represent trabeculae and nodes represent branch points where trabeculae meet. We simulate mechanical loading on finite-element models where each edge is replaced by a beam, enabling direct comparison of mechanics and topology at multiple scales ranging from that of individual edges/beams to the network at large. We compare the mechanical response of the various topology-optimized networks and identify mechanisms of crack propagation. We characterize and predict crack pathways with community detection methods inspired by similar applications in the study of granular materials.

2:42PM C57.00002: Directed aging and memory: Teaching an old foam new tricks  NIDHI PASHINE (Presenter), DANIEL HEXNER, University of Chicago, ANDREA LIU, University of Pennsylvania, SIDNEY ROBERT NAGEL, University of Chicago — As a material ages, its physical properties change. Under an applied stress, it plastically deforms in order to relieve the internal stress in incremental steps. At each instant, it lowers the stress in the most effective way. Thus, over long times, the final state of the material depends on the external stresses it was exposed to during the aging process. A material thus has a memory of the stresses to which it was exposed during the aging process. We exploit this property and direct the aging process with specific protocols in such a way that our material reaches a distinct, final state with a prescribed and desired functionality. In order to demonstrate this behavior, we use sheets of foam that we cut with a laser cutter and place under stress in such a way that the material develops unusual elastic properties. To accelerate the aging process, we apply heat to the sample. We have been able to modify the Poisson's ratio of our system considerably; we can make a sample that was initially nearly incompressible and make it auxetic (negative Poisson's ratio). We can likewise take an auxetic sample and make it incompressible. We have also been able to train local behavior so that a sample responds with a prescribed local deformation in response to a global perturbation.

2:54PM C57.00003: Design and Control of Finite Conformational Changes in Mechanical Networks*  JASON KIM (Presenter), DANIELLE BASSETT, University of Pennsylvania — Conformational changes in physical networks play a crucial role in many systems, enabling error correction in DNA replication, cooperativity in hemoglobin, and mechanical capacities in metamaterials. Important work has begun to delineate the relationship between network structure and instantaneous conformational change. However, these efforts have failed to address finite conformations, which are critical for the successful function of most physical networks. Here we establish a simple framework for the design and control of mechanical spring networks in 2 and 3 dimensions. Specifically, for a set of nodes with arbitrarily specified initial and final positions, we characterize all bipartite networks with zero energy at these positions, demonstrate transitions between these positions, and design multi-stable networks for information storage. Finally, we use hysteresis and bi-stability to design networks demonstrating cooperativity.

3:06PM C57.00004: Pattern Selection in Brine Shrimp Swarms  ANDREA WELSH (Presenter), FLAVIO FENTON, Georgia Institute of Technology — Swarming is a ubiquitous self-organization phenomenon which occurs in many biological systems such as flocks of bird and insect, schools of fish, and collections of bacteria. This sort of behavior emerges spontaneously, arising without any sort of centralized control or leadership. Many crustaceans such as brine shrimp produce swarms, in which individuals cluster together rather than spreading out uniformly in their environment. The size and distribution of these swarms are governed by local interactions between individuals. We will discuss the three-dimensional patterns that can be observed in brine shrimp swarms, specifically of the Great Salt Lake strain of *Artemia franciscana*, at high concentration. These patterns can be easily observed with simple tabletop experiments; however, the causes of these patterns are unknown. We experimentally test the effects of certain environmental conditions on the development of these swarms. We then develop a model an agent based model of shrimp which yields the same sort of spatial patterns as those that are observed. The model reproduces the basic length and times scales of the patterns, the type patterns selected, and the stability of those patterns.

3:18PM C57.00005: The effects of inhibitory neuron fraction on the dynamics of an avalanching neural network*  JACOB CARROLL (Presenter), ADA WARREN, UWE CLAUS TAUBER, Virginia Tech — The statistical analysis of the collective neural activity known as avalanches provides insight into the proper behavior of brains across many species. In this talk we present a neural network model based on the work of Lombardi, Herrmann, de Arcangelis et al. that captures the relevant dynamics of neural avalanches, and we show how the active neuron fraction can be used as a control mechanism to introduce exponential cut-offs in the distributions of avalanche strength and duration, transition the power spectral density of the network out of an epileptic regime, and drive the evolution of the network structure over time.

3:30PM C57.00006: A general geometric framework for knitted fabric elasticity  MICHAEL DIMITRIYEV (Presenter), KRISHMA SINGAL, ELISABETTA MATSUMOTO, Georgia Institute of Technology — Knitting is a process in which yarn, an essentially filament-like material, is shaped in space to form a fabric, an essentially sheet-like material, via stitching together a lattice of slip-knots. Due to fabric-level dependence on the stitch pattern, a single yarn can be used to create a large variety of fabric geometries and material responses. Moreover, the elasticity of knits remains poorly understood, as evidenced by the lackluster performance of spring-lattice models. We seek a continuum elastic model that predicts the three-dimensional shape of knitted fabric. This model should have the flexibility to be adapted to describe a wide range of stitch patterns and elasticity models. To this end, we have developed a geometric framework for relating the yarn path to the emergent surface geometry of the fabric. The generality of our approach allows for a systematic coarse-graining of yarn degrees of freedom, without *a priori* specification of a model of yarn elasticity. Thus, we are able to arrive at a stitch pattern-dependent, continuum elastic model of knits by assuming a simple phenomenological model of yarn, whilst allowing for the possibility of including more realistic yarn mechanics and experimental comparison.

3:42PM C57.00007: Model-dependent and model-independent control of biological network models*  JORGE GT ZANUDO (Presenter), Cancer Program, Broad Institute, GANG YANG, REKA Z ALBERT, Department of Physics, Pennsylvania State University — Network models of cell signaling and regulation are ubiquitous because of their ability to integrate the current knowledge of a biological process and test new findings and hypotheses. An often asked question is how to control a network model and drive it towards its dynamical attractors (which are often identifiable with phenotypes or stable patterns of activity of the modeled system), and which nodes and interventions are required to do so. In this talk, we introduce two recently developed network control methods - feedback vertex set control and stable motif control - that use the graph structure of a network model to identify nodes that drive the system towards an attractor of interest (i.e., nodes sufficient for attractor control). Feedback vertex set control makes predictions that apply to all network models with a given graph structure and stable motif control makes predictions for a specific model instance, and this allows us to compare the results of model-independent and model-dependent network control. We illustrate these methods with various examples and discuss the aspects of each method that makes its predictions dependent or independent of the model.

3:54PM C57.00008: TBD —
4:06PM C57.00009: Thouless and Relaxation Time Scales in Many-Body Quantum Systems*  MAURO SCHIULAZ (Presenter), Yeshiva University, E. JONATHAN TORRES-HERRERA, Benemerita Universidad Autonoma de Puebla, LEA SANTOS, Yeshiva University — We study the time scales involved in the relaxation process of isolated quantum many-body systems. Using experimental observables and a realistic many-body quantum model, we unveil three different time scales: a very short time that characterizes the early fast decay of the initial state, and two much longer times that increase exponentially with system size. These are the Thouless time, $t_{Th}$, and the relaxation time, $t_R$. The Thouless time refers to the point beyond which the dynamics acquire universal features, and relaxation happens when the evolution reaches a stationary state. We show that in chaotic systems, $t_{Th} < t_R$, while for systems approaching a many-body localized phase, $t_{Th}$ tends to $t_R$. We also compare these results with those for random matrices, and study how self-averaging properties depend on time scales.

4:18PM C57.00010: Cyber-physical risks of hacked Internet-connected vehicles*  SKANDA VIVEK (Presenter), DAVID B YANNI, PETER YUNKER, JESSE L SILVERBERG, Georgia Institute of Technology — The interface of Internet-connectivity and automotive technology promises to dramatically improve transportation. However, with these known benefits come unknown risks, especially since Internet-connected vehicles have become targets for computer hacking. Vehicles, unlike sensitive data, can collide or physically interact when their systems become compromised, and there is a broad class of scenarios generically leading to Internet-connected vehicles being suddenly and simultaneously disabled. Here, we investigate how large-scale hacking affects traffic flow using agent-based simulations, and discover the critical relevance of percolation for predicting outcomes on a multi-lane road. Inspired by this discovery, we develop and validate an analytic percolation-based model to rapidly assess the effect of hacking. We then apply our analytic model to investigate the outcomes on the street network of Manhattan (NY, USA), revealing a latent risk. A small number of disabled vehicles can gridlock the city and substantially reduce access to emergency services. By discovering percolation as the phenomenological driver of city-wide disruption, we simultaneously uncover a strategy for risk-mitigation.

2:30PM C58.00001: Droplets that decay, droplets that fährt: Restriction enzymes induce degradation, bubbling and propulsion in a DNA liquid phase*  OMAR SALEH (Presenter), University of California, Santa Barbara, TIM LIEDL, Department of Physics, Ludwig-Maximilians-Universitat, Munich — Multi-armed DNA particles (`nanostars') can be engineered to have weak inter-particle attractions, causing them to phase separate into liquid droplets. We are motivated to study this system both on the general grounds that bio-macromolecular liquids are interesting, and with the specific idea of using it to create a chromatin-inspired active matter system. To that end, we studied the interactions of proteins with DNA nanostar droplets, particularly measuring droplet degradation by DNA-cleaving restriction enzymes. Despite the droplet's small DNA volume fraction, enzyme degradation occurred primarily on surface of droplets, likely because enzyme transport was arrested by binding of the protein to the DNA. The degradation rate was surprisingly insensitive to variations in the number of restriction sites, but did vary with the strength of bonds between DNA particles. With certain tricks it was possible to force the enzyme inside the droplet, which caused the enzyme to carve out vacuoles that rose to the droplet surface and popped, driving droplet motion. I will discuss potential mechanisms behind this enzyme-induced motility.

*We thank the Alexander von Humboldt Foundation for support.
we are developing theoretical models to study the competition between flow force which induces clusters and electrostatic temperature to investigate whether adhesion also played a role in cluster formation. Comparing with experimental data, overcome electrostatic repulsion. Since particles deform and adhere when heated above Tg, we varied the ambient transition temperature (Tg) that could be robustly tuned from 0 °C to 80 °C. We find that fluid flow induced by evaporation evolution to be observed by light microscopy as a function of evaporation rates, salt concentrations and particle drying latex with initial volume fraction of 50% in a microfluidic channel, in a manner that allows the dynamic structure of the clusters is important to optimizing coating formulation. This talk reports a study of cluster formation induced by formation in colloidal suspensions is often observed during drying, and understanding the origins and physical properties of the clusters is important to optimizing coating formulation. This method is simple yet robust and easy to implement, and is straightforwardly scalable, involving a synergetic action of electric-field assembly, capillary and electrostatic interactions. Various aspects of our method, including the role of particle size and the voltages needed, are studied in detail.

Polymeric nanoparticles (NPs) are promising candidates for a wide range of applications such as colloidal self-assembly and targeted therapeutics. Flash Nanoprecipitation (FNP) is a scalable technique for fabricating monodisperse polymeric NPs through rapid micromixing of a polymer solution with a miscible poor solvent. In this simulation work, we are studying the fabrication of Janus NPs with one solvophilic and one solvophobic hemisphere, and their behavior at liquid-liquid interfaces. We performed coarse-grained molecular dynamics simulations of the FNP process using two types of solvophobic homopolymers and one type of amphiphilic blockcopolymers (BCPs). We investigated the influence of various process parameters on the resulting NPs morphology, namely, the composition and concentration of the BCPs. We determined the parameter space where amphiphilic Janus or core-shell NPs can be formed, and studied the conformation of BCPs at the NPs surface. Finally, we placed the fabricated NPs at the interface between two immiscible liquids. We observed a significant reduction of the interfacial tension when either core-shell or Janus NPs were placed at the interface compared to systems without NPs, demonstrating the potential of polymeric NPs as colloidal stabilizing agents.

Cluster formation in colloidal suspensions is often observed during drying, and understanding the origins and physical properties of the clusters is important to optimizing coating formulation. This method is simple yet robust and easy to implement, and is straightforwardly scalable, involving a synergetic action of electric-field assembly, capillary and electrostatic interactions. Various aspects of our method, including the role of particle size and the voltages needed, are studied in detail.

Simulating Hepatitis B Virus antiviral agents* FARZANEH MOHAJERANI (Presenter), BOTOND TYUKODI, MICHAEL F HAGAN, Brandeis University — The infectivity of a virus depends on the complete assembly of a protein shell (capsid) around the viral nucleic acid. Molecules which block or alter assembly pathways have the potential to be used as antiviral agents. Recent in vitro experiments have identified a class of small molecules (assembly effectors) that accelerate assembly of Hepatitis B virus (HBV) capsids. In vivo experiments have shown that this acceleration of assembly in vitro correlates to antiviral activity in cells. However, the mechanism by which these molecules alter assembly pathways is unclear. In this talk I will describe a computational model which allows extremely efficient simulation of assembly dynamics of large protein shells. I will then show how application of this model to HBV assembly can elucidate the mechanism of action of assembly effectors. In particular, I will describe how the assembly effectors result in malformed capsid shapes, as seen in experiments.

Disorder Foreshadows Order in Colloidal Cubes* ABHISHEK SHARMA (Presenter), FERNANDO A ESCOBEDO, Robert Frederick Smith School of Chemical and Biomolecular Engineering, Cornell University — Prior molecular simulations have revealed that dense suspensions of hard nano-cubes are remarkable in that they form a mesophase near the ordering transition which is highly unusual when compared to typical crystals, plastic crystals, or liquid crystals. Monte Carlo simulations are used to study the disorder-to-order phase transition for a bulk system of colloidal hard cubes. It is observed that the ordered phase does not form via nucleation from the disordered phase, despite the prevalence in the latter of small locally ordered domains occurring transiently and sparsely. Instead, as the isotropic phase is brought to a marginally metastable concentration, such ordered domains increase in size and number, eventually reaching a critical point where they percolate the entire system and consolidate to form the mesophase. This process, quite different from nucleation observed for other particle shapes, arises presumably from a small interfacial tension. Simulations reveal that cubes infallibly form single-grain ‘crystals’ in the mesophase. This is traced to the abundant delocalized and transient vacancies and the high particle mobility in the mesophase which lead to formation of an active ‘recrystallization zone’ next to any grain boundary.

Structure and dynamics of kinked line-slip defects in confined colloidal crystals NABILA TANJEEM (Presenter), VINOTHAN N MANOHARAN, Harvard University — Line-slip defects are found in crystals confined to the surface of a finite sized cylinder. These defects are identified by a line of particle pairs, each of which has one fewer contact than in bulk. They are known to appear in ground state of a cylindrical crystal when the cylinder cannot accommodate a perfect crystal. We study the structure and dynamics of these defects using an experimental system where submicron-sized colloidal spheres self-assemble into hexagonal lattices on a silica fiber with a diameter of a few micrometers. We find that most line-slip defects have kinks in them. A kink can be recognized from a discontinuity in the line-slip structure. The simplest kink in a line slip has four fewer bonds compared to a straight line-slip without any kink. We observe that the number of kinks in a line-slip defect does not change significantly over long time, but instead shows small fluctuations. We show that the average kink density is related to the average roughness of a 2D crystal grain. We find that by tuning the strength of interaction, we can tune the size of the crystal and the total length of the line-slip defects, allowing us to control the number of kinks in a line-slip defect and hence its shape.

Defect mediated coarsening of colloidal crystals on a cylinder* WILLIAM WILKIN (Presenter), NABILA TANJEEM, VINOTHAN N MANOHARAN, CHRISTOPHER RYCROFT, Harvard University — We perform Brownian dynamics simulations to investigate how geometrically stabilized defects in colloidal crystals on a cylindrical surface facilitate the approach to equilibrium. At intermediate times, a patchwork emerges of grains that generically exhibit vacancy-roughened helical line-slip defects, resulting in an ensemble of crystallites distinct from what is observed in the growth of crystals on planar surfaces. Interfaces between adjacent crystal grains typically exhibit a characteristic notch at the point of intersection with the line slip defect; this acts as a source for excitations of the line slip defect, coupling interfacial relaxation on opposite ends of each crystallite.

4:18PM C58.00010: Directing Colloidal Assembly via Selective Depletion  MENA YOUSSEF (Presenter), STEFANO SACANNA, Chemistry, New York University — The ability to synthesize and assemble matter on the colloidal scale has recently been at the forefront of research in materials science and nanotechnology. In particular, the ability to direct the assembly of colloids in a directional manner presents a challenge, as many methods of assembly are inherently nonselective. In this work, colloids are synthesized via an emulsion-based method and depletants are made to selectively adsorb onto colloidal surfaces to direct assembly, thus allowing for depletion to only occur under certain conditions. We are able to achieve selective assembly by introducing polymers, changing the pH, and tuning the nature of the depletant. We demonstrate selective assembly by selectively forming single or mixed crystals from a bidispersed suspension of particles by modifying the environment that the colloids are suspended in. We further demonstrate degree of selectivity of the depletion interaction in our colloidal systems by directing the patch-to-patch assembly of Janus colloids into complex structures. Selective depletion offers a new tool to direct assembly in colloidal systems and has the potential to be used to direct the hierarchical assembly of building blocks such as patchy particles and Janus colloids towards desired complex structures.

4:30PM C58.00011: Stability and Free Energy of Nanocrystal Chains and Superlattices*  XUN ZHA (Presenter), ALEX TRAVESSET, Iowa State University — I present simulations of hydrocarbon-capped monodisperse nanocrystal superlattices. I compute the free energy for both bcc and fcc, including several ligand lengths, as well as the entropy and Gibbs free energy. We find that bcc superlattices with oriented or random nanocrystal cores have slightly different free energy and lattice constant. Consistent with experimental findings, we observe that nanocrystals capped with relatively long ligands form bundles. We also compared our calculated lattice constants to experimental values and predictions for the OTM (Orbifold Topological Model).

*NSF, DMR-CMMT 1606336 “CDS&E: Design Principles for Ordering Nanoparticles into Super-crystals”

4:42PM C58.00012: Multiscale Modeling of Precursor Molecule Alignment for Improving Pitch-Based Carbon Fiber Production*  YANMING WANG (Presenter), CUIYING JIAN, TAISHAN ZHU, NICOLA FERRALIS, JEFFREY C GROSSMAN, Massachusetts Institute of Technology — Carbon fiber (CF) is a versatile material widely applied in many fields, and one main method to produce CF is from pitch, a viscoelastic material composed of aromatic hydrocarbons. Though it is well known that the early stage alignment of precursor molecules has significant effects on the pitch-based fibers, a deeper understanding of its underlying microscopic mechanisms is lacking. Here we perform fully atomistic (FA) and coarse-grained (CG) simulations to study the alignment of pitch molecules. While the FA simulations generates accurate atomistic descriptions, the CG simulations provide a means to efficiently explore larger time and length scales. The ellipsoid algorithm is adopted to extract geometric features of these molecules from the FA trajectories, enabling a quantitative analysis of the intermolecular alignment as well as the construction of anisotropic CG particles. Our multiscale simulations identify the dependences of alignment on the molecule size, temperature and loading conditions. Further, the model suggests specific additives and operation conditions that can improve the molecule alignment. These calculations provide guidelines for optimizing the synthesis pathways for low cost and high-quality CF.

*The project is supported by DOE program DE-FOA-0001629.

4:54PM C58.00013: Controlled Self-Assembly of Peptide Nanotubes via Sequence Modification and Kinetic Control*  YU TIAN (Presenter), FRANK POLZER, University of Delaware, HUIXI ZHANG, JEFFERY G SAVEN, Department of Chemistry, University of Pennsylvania, KRISTI KIICK, DARRIN POCHAN, University of Delaware — Synthetic peptides with the high sequence- and shape-specificity can serve as the assembly building blocks for the construction of controllable and complex nanoarchitectures. Computational design was employed to design peptides that can form antiparallel, alpha-helical tetrameric coiled-coil bundles in solution that then further assemble into higher order structures with targeted organization. The bundles self-assemble into homogenous nanotubes at pH 4.5. As analyzed by cryo-TEM, SAXS and STEM, a mono-layer tilted-bundle model is proposed to explain the nanotube structure. The charged state and distribution of the peptide bundles associated with the acidic solution condition are believed to be the reason triggering the formation of nanotubes. Rational sequence modifications were applied to control the dimensions of the nanotubes or to disrupt the tube nanostructure or to add metal-binding functionality. Moreover, kinetic control was applied in the assembly process to produce a branched nanotube morphology. Further crosslinking treatment can be applied to the branched nanotube system for the development of stable hyper-branched materials with potential applications.

RAVI KUMAR PUJALA (Presenter), School of Physics, University of Hyderabad — We propose an alternative method to tune the electrostatic interactions to obtain a transition from a repulsive to an attractive system of nanoplatelets by increasing the alcohol concentration, i.e. increasing the Bjerrum length. A phase diagram of Laponite® in alcohol solutions has been proposed, which clearly demarcates regions of stable sol, unstable sol, transparent gel, turbid gel, glass, and flocculation. A new class of soft materials, called nanoclay-organogels, was deeply explored using confocal and scanning electron microscopy that depicted spongy architecture and presence of nano and micron size pores inside the gel matrix indicating the hierarchical self-assembly of the nanoplatelets in the binary solvent. Universal power-law scaling of storage modulus and yield stress with alcohol concentration was observed. We have extensively examined the dispersion stability, aggregation and gelation behaviour of Laponite nanoplatelets in different alcohol -water binary solvents, thereby proposing a universal description of nanoclay dispersion in alcoholic solutions, which is poorly probed and marginally understood in the literature.

JIYEONG GU (Presenter), VICTOR DE LA CRUZ, Physics and Astronomy, California State University Long Beach — A monolayer of close-packed nanospheres can be used as a template or a mask to produce interesting magnetic nanostructures. Multi-step spin coating process was used to create the densely packed monolayer of nanospheres. Various parameters, such as, spin speed, spin acceleration, spin duration, nanosphere concentration, volume of the solution deposited on the substrate, the duration of each step, and the interval in between the steps, were adjusted to maximize uniform area of monolayer. After a systematic study, we found that the excess solution between the nanospheres should be removed quickly during the spin-coating process so the spheres move closer each other and form the close-packed monolayer. The spin coated nanospheres were examined using an optical microscope and a scanning electron microscope. Magnetic materials, such as Permalloy or cobalt, were sputter coated on top of monolayer nanospheres. Magnetic switching behavior of these curved magnetic thin films were investigated using an alternating gradient magnetometer, a vibrating sample magnetometer, and through the magneto-optical Kerr effect measurement. Nanocap layer showed a wider magnetic switching and distinctive magnetic anisotropy compared to the flat thin film samples.

**Session C59 GSOFT GSNP: Rheology and Flow of Soft Matter I** BCEC 257B - Li-Chiun Cheng, Massachusetts Institute of Technology - Tag(s): Focus

**2:30PM C59.00001: Rheology of glassy and jammed emulsions**

CONG CAO (Presenter), ERIC WEEKS, Emory University — We study the rheology of monodisperse emulsions with various mean droplet sizes. Above a critical volume fraction, these systems will exhibit solid-like behaviors and possess a yield stress. Previous simulation work suggests that for small thermal particles, rheology will see a glass transition; for large athermal systems, rheology will see a jamming transition. However, at the crossover of thermal and athermal regimes, the glass and jamming transitions may be well separated and observed at different volume fractions for a fixed mean droplet size. We conduct an experiment by shearing different sizes of emulsion droplets (500 nm-5 μm diameter) with a rheometer. In this way, we measure rheological properties near the critical volume fraction. By varying the shear rate and particle size, our experiments cover a wide range of Péclet number (the ratio of shear and thermal motions), including the crossover regime.

*NSF(DMR-1609763)*
2:42PM C59.00002: Viscous fingering instabilities in carbon black gels* THIBAUT DIVOUX (Presenter), Civil and Environmental Engineering, CNRS / Massachusetts Institute of Technology, BADIS MARSIT, Mechanical Engineering, Massachusetts Institute of Technology, YACOUBA KALOGA, Civil and Environmental Engineering, CNRS / Massachusetts Institute of Technology, IRMGARD BISCHOFBERGER, Mechanical Engineering, Massachusetts Institute of Technology — Pattern formation in fluids occurs in numerous physical processes in which mechanical mixing, chemical reactions, evaporation and/or surface effects play a key role. When the pattern develops in a non-Newtonian fluid, the non-linear rheology interferes with the patterning process, which often generates a richer dynamics than that commonly observed for a Newtonian fluid. Here we focus on the viscous fingering instability in a time-dependent yield stress fluid. We study experimentally the flow of a carbon black gel sandwiched in a parallel plate geometry, for which the upper plate is being lifted up at constant velocity. We show the existence of a critical initial gap spacing and a critical lift velocity, above which the flow becomes unstable, leading to the growth of viscous finger originating from the Saffman-Taylor instability at the fluid-air interface. The resulting pattern in the gel consists in a tree-like branched structure, whose wavelength surprisingly follows the scaling established for Newtonian fluids. The signature of the fluid non-linear rheology lays in the spatial extent of the pattern, which is governed by the yield strain of the gel. Finally, we show that varying the shear history of the gel, one can produce patterns with a wealth of new morphologies.

2:54PM C59.00003: Microrheology of pH-Responsive Nanoparticle Monolayers at Fluid Interfaces SHIYI QIN (Presenter), XIN YONG, Binghamton University — The effect of shear on the structure and dynamics of polyelectrolyte-grafted nanoparticles (PGNP) straddling at a water–oil interface was investigated through mesoscale simulations. Using electrostatic dissipative particle dynamics, long-range electrostatic forces are solved in a triclinic simulation box, which allows us to apply continuous shear deformation to the monolayer. The monolayers with different particle coverages were examined under shear and degree of ionization of PGNPs were set to be high. While undisturbed, the particles arrange themselves on a hexagonal lattice due to the long-range electrostatic interactions. As the monolayer with low particle concentration is subjected to the shear flow, the free voids allow particles to move in the shear direction. However, strong inter-particle forces at high particle concentration result in the collective motion of domains to repair the adjacent defect. The in-plane structure of monolayer is analyzed by structure factor and Voronoi diagram. The dynamics of local domains are observed through snapshots and averaged velocity contours. The rheology measurements of the monolayer were also performed under small-amplitude oscillatory shear and the results were correlated with the detailed structure evolution.

3:06PM C59.00004: Microscopic Rearrangements in the Flow of Polydisperse Dense Emulsions* YONGLUN JIANG (Presenter), CARLOS S ORELLANA, ERIC WEEKS, Emory University — We study the flow of dense polydisperse quasi-two-dimensional emulsions. In particular, we are interested in highly polydisperse samples with the largest droplets as much as ten times the size of the smallest. The droplets are confined between two parallel glass plates and driven to flow by a syringe pump. We use video microscopy to examine how rearrangements differ for large and small droplets. In particular, we find the large droplets follow the mean flow, while the small droplets move more erratically. We try to quantify these results by looking at the nearest neighbor changes and nonaffine motions. We explore different means of defining affine motion, including definitions based on nearest neighbors and definitions based on regions of space. The former varies quite a bit depending on the size of droplets, whereas the latter is simpler but lacks a sensitivity to droplet size.

*NSF (CBET-1804186)
Rheological and Microstructural studies of semi-dense and dense suspensions in a Periodic Poiseuille Flow using Core-Modified Dissipative Particle Dynamics* ERIKA BARCELOS (Presenter), SHAGHAYEGH KHANI, Macromolecular Science and Engineering, Case Western Reserve University, ARMAN BOROMAND, Department of Mechanical Engineering and Materials Science, Yale University, MÔNICA NACCACHE, Department of Mechanical Engineering, Pontifícia Universidade Católica do Rio de Janeiro, JOAO MAIA, Macromolecular Science and Engineering, Case Western Reserve University — Shear-thickening is a nonlinear rheological behaviour often observed in semi-dense and dense suspensions at increasing shear rates and is commonly associated with microstructural changes in the material. Therefore, understanding the rheology-microstructure correlation has a fundamental importance in the development of many industrial and technological processes. Core-Modified Dissipative Particle Dynamics was employed as a computational method to capture the physics involved in the flow of semi-dense and dense suspensions subjected to a periodic Poiseuille flow at two confinement ratios. The interplay between hydrodynamic and frictional interactions in promoting shear-thickening was investigated as well as the microstructure evolution of those systems at increasing shear rates. Velocity profiles were found to increase with the Péclet number and the shear-thickening response was stronger and took place sooner for dense suspensions at narrower gap sizes. The microstructure followed the rheological trend, clusters of particles being bigger in size for denser and more confined systems.

Active Microrheology in Emulsion Glass NESRIN SENBIL (Presenter), University of Fribourg, MARKUS GRUBER, University of Konstanz, CHI ZHANG, University of Fribourg, MATTHIAS FUCHS, University of Konstanz, FRANK SCHEFFOLD, University of Fribourg — Microscopic observations of probe particles under passive or force driven motion provides unique insights into the dynamics of colloidal dispersions. Here, we study experimentally the motion of polystyrene probe particles seeded in a micron scale oil-in-water emulsion system. We apply a well-defined constant force on the probe particles via a gradient intensity laser line trap and determine the displacements and probability distributions at various forces in the fluid and glass. Over the range studied, our emulsion droplets acts like hard spheres displaying a jamming and glass transition at 64% and 59% packing fractions, respectively. Both PS particles and emulsion droplets are sterically stabilized and identical in size. The crossover from localized to delocalized behavior happens at a threshold force which highly depends on the composition and corresponding cage strength (in the glass) and cage relaxation (in the fluid). Our experiments reveal intermittent dynamics and bimodal van Hove distribution functions around a depinning transition at a threshold force. For smaller forces, linear response connects the mean displacement and the quiescent mean squared displacement. We compare our observations to Mode coupling theory and find qualitative and semi-quantitative agreement.

Tuning friction and rheology at material-nanoparticle-liquid interfaces with an external electric field.* BIPLAV ACHARYA (Presenter), CAITLIN M SEED, DONALD W BRENNER, ALEX I SMIRNOV, JACQUELINE KRIM, North Carolina State University — Nanoparticles, both with and without polymeric surface coatings, dispersed in solutions are in common use as rheological and friction modifiers. The surface functionalization of the nanoparticles therefore provides a unique opportunity for active electro-tunable control of their flow in liquid. We report the use of electrophoretic forces to tune friction and rheology at material-nanoparticle-liquid interfaces with static or low frequency (0.6 – 50 mHz) electric fields. Negatively charged TiO2 or positively charged Al2O3 nanoparticles suspended in water were repositioned relative to a planar platinum surface of a quartz crystal microbalance, which was then used to monitor friction levels. Active electro-tunable control of friction was achieved, and investigated as a function of electric field frequency. Kinetic effects corresponding to nanoparticle repositioning at the solid interface were discovered to occur at glass-like time scales. The studies also reveal that nanoparticles manipulated by electric fields can act as “cantilever-free” atomic force probes capable of “tapping mode” exploration of interfacial properties and nanoscale interactions in geometries inaccessible to optical and micromechanical probes.

*National Science Foundation Award Number DMR1535082
3:54PM C59.00008: Understanding the effect of confinement on the viscosity of bacterial suspensions*  
ZHENG-YANG LIU (Presenter), KECHUN ZHANG, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota — Bacterial suspensions, a premier example of active fluids, show intriguing rheology different from their counterpart colloidal suspensions. When the confinement length scale is comparable or smaller than the intrinsic length scale of bacterial suspensions, we expect to see a qualitative change of their flow behaviors. Here, by using a microfluidic channel viscometer, we investigate the viscosity of *E. coli* suspensions under different degrees of confinement. For low concentration suspensions, we observe strong shear thickening at low flow rates. More importantly, a strong confinement effect is found when the confinement length is comparable to the running length of single bacterium. The viscosity of bacterial suspensions decreases by a factor of 2.5, when the confinement decreases from 50 down to 25 microns. In contrast, for high concentration suspensions, we observe strong shear thinning at low shear rates. The confinement leads to an increase rather than decrease of viscosity when the confinement length is comparable to the size of collective swarming of bacterial suspensions. Our study reveals the dynamics of bacterial suspensions under confinement and provides new insights into the transport of active fluids in confined geometries.

4:06PM C59.00009: Upstream vortex and elastic wave in the viscoelastic flow around a confined cylinder  
PAUL SALIPANTE (Presenter), National Institute of Standards and Technology, BOYANG QIN, Department of Mechanical Engineering & Applied Mechanics, University Of Pennsylvania, STEVEN HUDSON, Department of Mechanical Engineering & Applied Mechanics, University Of Pennsylvania — The flow of a viscoelastic fluid past a cylinder is a classic benchmark problem that is not completely understood. Using novel holographic particle velocimetry to measure 3D flow fields, we report two main discoveries of the elastic instability upstream of a single cylinder in confined microchannel flow. After the onset of corner vortices upstream of the cylinder, we find that the vortex becomes unsteady and switches between two distinct flow states, leading to symmetry breaking perpendicular to the cylinder axis that is highly three-dimensional in nature. Second, we show that the disturbance of the elastic instability propagates far upstream via an elastic wave and is weakly correlated with that in the cylinder wake. The wave speed and the extent of the instability increase with Weissenberg number, indicating an absolute instability in viscoelastic fluids.

4:18PM C59.00010: Glassy Dynamics in a Simulated Cell Monolayer with Division and Death*  
MICHAEL CZAJKOWSKI (Presenter), Department of Physics, Georgia Tech, DANIEL SUSSMAN, Soft and Living Matter Program, Dept of Physics, Syracuse University, M. CRISTINA MARCHETTI, Dept of Physics, UC Santa Barbara, M. LISA MANNING, Soft and Living Matter Program, Dept of Physics, Syracuse University — Recent experiments have indicated that quasi two-dimensional epithelial tissues undergo a transition to a rigid state which shares many characteristics with traditional particulate glass. At the same time, numerical work has suggested that the presence of cell division and death in dense particle-based models for tissues will always destroy signatures of glassy dynamics such as caging. Can then glassy behavior be recovered in real tissues where cells commonly divide and die? We address this question with a vertex-type model of motile tissue modified to include a balanced rate of cell division and death. The division and death rate competes with the motility-driven rate of cell rearrangement to control the tissue dynamics. We show that glassy dynamics is recovered for slow division and death rates. Further quantifying the displacements coming from a single division or death event, we are able to accurately predict the crossover between motility-dominated and division/death-dominated rheology.

4:30PM C59.00011: Reversibility and diffusion in a meso-scale model for amorphous under cyclic shear.  
KAREEM ABDELSHAFY (Presenter), Northeastern University, BOTOND TYUKODI, brandeis University, DAMIEN VANDEMBROUQC, ESPCI Paris, CRAIG MALONEY, Northeastern University — We present results on a meso-scale model of amorphous plasticity subject to cyclic shear. We show that, after a transient, depending on the amplitude of cycling, the steady state behavior falls into one of three cases, in order of increasing strain amplitude: i) pure elastic behavior with cessation of all plastic activity, ii) reversible periodic plasticity with the period being an integer number of strain cycles (not necessarily a single cycle), and iii) irreversible plasticity with long-time diffusion. This behavior is consistent with what is seen in experiments on 2D amorphous particle rafts and confocal microscopy of emulsions and in athermal quasi-static particle-based simulations. We further show that, in the large amplitude regime, the steady state single-cycle plastic strain field is localized along line-like structures similar to the ones seen during avalanches during steady plastic shear, but there is little persistence in the localization from one cycle to the next.
4:42PM C59.00012: Front Microrheology of the non-Newtonian behaviour of blood  AURORA HERNANDEZ-MACHADO (Presenter), Fisica de la Materia Condensada, Universitat de Barcelona — We introduce a new framework to study the non-Newtonian behaviour of fluids at the microscale based on the analysis of front advancement. We apply this methodology to study the non-linear rheology of blood in microchannels. We carry out experiments in which the non-linear viscosity of blood samples is quantified at different haematocrits and ages. Under these conditions, blood exhibits a power-law dependence on the shear rate. In order to analyse our experimental data, we put forward a scaling theory which allows us to define an adhesion scaling number. By applying this scaling theory to samples of different ages, we are able to quantify how the characteristic adhesion energy varies as time progresses [1]. We also analyze numerically the rheology of dilute red blood cell suspensions in pressure driven flows at low Reynolds number in terms of the elasticity of the cells. We identify the relevant aspects of cell elasticity that contribute to the rheological response of blood [2]. We have related the viscosity of healthy, anemic and alpha-thalasemic blood samples with the bending rigidity of the erythrocyte membrane [3].

4:54PM C59.00013: Coarse-graining amorphous plasticity: shear-banding and rejuvenation  BOTOND TYUKODI, Brandeis University, ARMAND BARBOT, REINALDO GARCIA GARCIA, MATTHIAS LERBINGER, SYLVAIN PATINET, DAMIEN VANDEMBROUQ (Presenter), PMMH, CNRS/ESPCI Paris — The plastic behavior of glasses and disordered solids displays a rich and complex phenomenology, from scale free avalanches to localization of the strain field in shear bands. The recent years have seen an increasing effort of modeling of these phenomena at different length and time scales. In complement of numerous numerical simulations at atomistic scale of model or more realistic glasses, a new class of lattice models has emerged at mesoscopic scale that rely on the coupling between a local threshold dynamics and elastic interactions. The latter "Eshelby" interaction is associated to the internal stress induced by local rearrangements taking place in the surrounding elastic matrix and is characterized by a quadrupolar symmetry. While these lattice models reproduce most of the phenomenology observed in amorphous plasticity, a quantitative link remains to be done with atomistic simulations. Here we use a technique recently developed to characterize local yield stress in atomistic simulations to propose and study the quantitative connection between simulations operating at atomistic and mesoscopic scales.

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C60 FED: Life, the Universe, and Everything: Teaching Biology to Physicists and Physics to Biologists BCEC 258A - Laurie McNeil, University of North Carolina at Chapel Hill - Tag(s): Education , Invited, Undergraduate

2:30PM C60.00001: Physics, biology and chemistry: teaching at the interface between the natural sciences [Invited] RHONDA DZAKPASU (Presenter), Georgetown University — The biological physics major at Georgetown University was created to attract premed students who might otherwise major in biology. Many of these students will have taken physics and calculus – frequently at the AP level – in high school and are often not aware that physics can be a viable path to medical school. This talk will discuss our philosophy in developing the major and the requirements to complete the major; I will focus on the two-semester sequence in biological physics and the independent research project. I will also present some of the benefits as well as the challenges that we have experienced as we work to refine the major as well as what types of paths our majors take after they graduate.

3:06PM C60.00002: ISC: An Integrated, Quantitative Introduction to the Natural Sciences at Princeton University [Invited] JOSHUA SHAEVITZ (Presenter), Princeton University — The Integrated Science Curriculum (ISC) at Princeton is an integrated, mathematically and computationally sophisticated introduction to physics and chemistry, drawing on examples from biological systems. This year long, four course sequence is a multi-disciplinary course taught across multiple departments and intended for students considering a career in science. Briefly, ISC teaches introductory Physics, Chemistry, Molecular Biology and Computer Science in an integrated setting through a combination of lectures, precepts, and laboratory exercises. The 2018-19 academic year represents our fifteenth year teaching the course and I will present a progress report on how the program has evolved over time.
**3:42PM C60.00003: Quantitative biology and the "hacker lab" : An interdisciplinary graduate program at UCSD**

[Invited] PHILBERT TSAI (Presenter), Physics, University of California, San Diego — The Quantitative Biology Program (Qbio) is a new integrative graduate specialization program that consists of a combination of theory classes, experimental labs, seminars, and critical reading courses. The program draws select graduate student from five different departments across three division at UCSD: physics, biology, chemistry, bioengineering, and biomedical sciences. In this talk, we will survey the program structure, but focus on two unique aspects of the program: the interactive critical reading program and the Qbio Hacker lab.

In brief, the Qbio Hacker lab serves as both classroom and shared resource. First, students enroll in a single-quarter “boot-camp” lab course. Though a combination of lectures and hands-on experimental modules, student work together in interdisciplinary pairs to achieve a basic proficiency in experimental skills ranging from 3D fabrication for instrumentation to computer-electronics-hardware interfacing to optical design for modern microscopy to fundamentals of microfluidics. The students then enroll in a second-quarter “project/rotation” quarter in which the students utilize their newly-developed experimental skills and resources to design and tackle a pilot research project under the guidance of individual Qbio faculty. Additionally, students work together in small groups through an interactive critical reading program, spending multiple weeks on an individual research paper to critically analyze its data, results, and theoretical claims. Through these multiple interdisciplinary interactions, students cement a foundation in reaching across fields to investigate biological phenomena with the full array of quantitative and technological tools available to them.

*We gratefully acknowledge funding from:

**4:18PM C60.00004: From Probability, Dynamics, and Modeling to Biology, Physics, and Instrumentation: Constructing an Upper-Division Course That Majors and Nonmajors Actually Take**

[Invited] PHILIP C NELSON (Presenter), Physics/Astronomy, University of Pennsylvania — Despite great progress in pedagogy, the actual content of upper-division Physics courses would in many cases be familiar to a time traveler from another century. I'll outline a strategy that I and others have used to create several new courses. Briefly, it involves: (1) Identifying an ongoing scientific revolution as a destination, then asking what classic frameworks are needed to go beyond mere description; (2) Identifying general-purpose skills that are needed for this and other current research; and (3) If necessary, asking what existing course could be remodeled to offer this new one within existing departmental constraints. For example, in a biological physics context the answers could involve (1) The current revolutions in optics; (2) Basic skills involving modeling, including probabilistic models; and (3) Revising the syllabus of "Modern Physics" or another such course. More broadly, I'll mention other case studies where this approach has worked, some rough metrics of success, and some new textbooks embodying these ideas.

*National Science Foundation PHY--1601894.
4:54PM C60.00005: Introductory Physics for Life Sciences: Design Principles, Resources, and Community*

CATHERINE CROUCH (Presenter), Swarthmore College — A national network of physics faculty have developed frameworks and extensive resources for teaching introductory physics to life science students in a way that highlights the value of physics in understanding biology, biochemistry, and medicine. These courses seek to give students practice in applying physics to analyze biologically significant phenomena. As more departments become interested in offering such courses, there is a need for curricular materials and support for faculty teaching such courses for the first time and adapting them to their local context.

The Living Physics Portal will provide a state-of-the-art online platform for sharing and developing such curricula. It will allow instructors to find materials through a searchable interface with extensive implementation metadata. More importantly, it will allow those who are new to such courses to learn from experienced instructors about the special features and challenges of such courses; and it will allow those who develop materials, whether novices or experienced, to share their materials for feedback at an early stage, or submit them for consideration for a “vetted collection” for materials that have been extensively used and refined.

This talk will present the motivation for and research supporting the introductory physics for life sciences approach, followed by an introduction to the capabilities of the Portal.

*The Living Physics Portal is funded by NSF (DUE #1624185); curriculum development and some research at Swarthmore funded by the Howard Hughes Medical Institute (Science Education Grant to Swarthmore College); other research funded by NSF (DUE #1122941, #1710875) and Swarthmore College.

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C61 GSOFT DBIO GSNP: Active Matter I

2:30PM C61.00001: Bend instability and topological defects in 3D active nematics*

GUILLAUME DUCLOS (Presenter), Martin A. Fisher School of Physics, Brandeis University, DANIEL BELLER, Department of Physics, University of California, Merced, POOJA CHANDRAKAR, Department of Physics, University of California, Santa Barbara, MINU VARGHESE, Martin A. Fisher School of Physics, Brandeis University, DEBARGHYA BANERJEE, Max Planck Institute for Dynamics and Self-Organization, Göttingen, MATTHEW PETERSON, ARVIND BASKARAN, Martin A. Fisher School of Physics, Brandeis University, FEDERICO TOSCHI, Department of Applied Physics, Eindhoven University of Technology, VINCENZO VITELLI, James Franck Institute and Department of Physics, University of Chicago, SEBASTIAN STREICHAN, Department of Physics, University of California, Santa Barbara, ROBERT ALAN PELCOVITS, THOMAS POWERS, Department of Physics and School of Engineering, Brown University, APARNA BASKARAN, MICHAEL F HAGAN, Martin A. Fisher School of Physics, Brandeis University, ZVONIMIR DOGIC, Department of Physics, University of California, Santa Barbara — Active nematics describes a phase of matter where active particles that consume energy to produce mechanical work assemble at high density in a state with orientational order but no positional order. In this talk, I will show how the active nematic framework allows us to better understand aspects of the collective behaviors that emerge in bioinspired materials. In particular, I will present our recent efforts to describe the emergence of flows and topological defects in 3D active nematics composed of a passive colloidal liquid crystal doped with active microtubules and molecular motors. I will first describe the generic bend instability that emerges in a flow-aligned 3D active gel and show how the interplay between activity, nematic elasticity and confinement controls the wavelength of this activity driven instability. I will then present current work on the emergence of flows and topological defect in 3D.

*We acknowledge support from the Brandeis NSF MRSEC, Bioinspired Soft Materials, DMR-1420382 and the Human Frontier Science Program.
3:06PM C61.00002: Defect unbinding and a motile Kosterlitz-Thouless transition in active nematics*  
SURAJ SHANKAR (Presenter), Physics Department and Syracuse Soft and Living Matter Program, Syracuse University, SRIRAM RAMASWAMY, Centre for Condensed Matter Theory, Department of Physics, Indian Institute of Science, M. CRISTINA MARCHETTI, Department of Physics, University of California, Santa Barbara, MARK BOWICK, Kavli Institute for Theoretical Physics — Active nematic liquid crystals formed by a collection of self-driven particles on a two-dimensional substrate exhibit complex spatio-temporal dynamics and spontaneous defect proliferation. An important consequence of the non-equilibrium drive is the spontaneous motility of strength +1/2 disclinations that drives flow in the system. Starting from the hydrodynamic equations of active nematics, we derive effective equations for the topological defects as interacting overdamped particles with pair forces and active torques. Using these equations we then show that activity lowers the defect-unbinding transition temperature driving a nonequilibrium variant of the Kosterlitz-Thouless transition into a state of defect chaos. Crucially, we find rotational noise stabilizes nematic order at low activity leading to a re-entrant transition. For large activity, orientational torques on the defects combined with many-body screening allows the spontaneous appearance of a polar defect ordered liquid, rationalizing previous work into a comprehensive phase diagram for two-dimensional active nematics.

3:18PM C61.00003: Activity driven defect ordering in an active nematic on an anisotropic substrate*  
DANIEL PEARCE (Presenter), Dept. Of Physics, University of Geneva — We investigate the effect of an anisotropic substrate on the turbulent dynamics of a simulated two dimensional active nematic. This results in an effective anisotropic friction and viscosity, with the orientation of the anisotropy being defined by the substrate. In this system we observe the emergence of global nematic order of topological defects that is controlled by the degree of anisotropy in the viscosity and the magnitude of the active stress. No such alignment is seen in passive liquid crystals with anisotropic viscosity confirming that ordering is driven by the active stress. We then closely examine the active flow generated by a single defect to show that the kinetic energy of the flow is orientation dependent, resulting in a torque on the defect to align them with the anisotropy in the substrate.

*I acknowledge the support of SNSF/NCCR Chemical Biology.

3:30PM C61.00004: Self-organized dynamics of confined active nematics*  
ACHINI OPATHALAGE (Presenter), MICHAEL NORTON, MICHAEL P. N. JUNIPER, S.ALI AGHVAMI, BLAKE LANGESLAY, SETH FRADEN, Department of Physics, Brandeis University, ZVONIMIR DOGIC, Department of Physics, University of California at Santa Barbara — We study the role of boundary conditions on a simplified experimental model of biological active matter composed of extensile filamentous bundles of microtubules driven by clusters of kinesin motors, to elucidate the structure and dynamics of active nematic liquid crystals. These bundles form a quasi-2D active nematic liquid crystals when sedimented onto a surfactant-stabilized oil-water interface. We further confine this system onto circular boundary conditions, imposing a total topological charge of +1. For diameters of 400 micrometer and larger, multiple +/- ½ defects continuously nucleate and annihilate at the boundary as well as in the confinement core and generate flows of either handedness. As the diameter is reduced, defects periodically nucleate at the boundary with slow dynamics and migrate toward the confinement core rendering a fast pairwise procession, referred to as doubly-periodic dynamics. Existing continuum theories fail to predict this phenomenon and we hypothesize what additional physics needs to be included to reconcile experiment and theory.

*Experimental analysis was supported by DOE-BES through DE-SC0010432TDD. Developing microfluidic technology was supported by Brandeis MRSEC through NSF-MRSEC-1420382. Computational work was supported by NSF-DMR-1810077.
ANDREY SOKOLOV (Presenter), Argonne National Laboratory, RUI ZHANG, ALI MOZAFFARI, JUAN DE PABLO, University of Chicago, ALEXEY SNEZHKO, Argonne National Laboratory — Living liquid crystal (LLC), a synthetic material combining a lyotropic liquid crystal and swimming bacteria, demonstrates a number of out-of-equilibrium phenomena ranging from active turbulence to creation and annihilation of motile topological defects. In this talk, we report a spontaneous formation of undulation bands in circularly aligned LLC. The interplay between elasticity of liquid crystal and bacteria-induced hydrodynamic forces results in the emergence of a remarkable branched pattern of radially elongated bands of a highly curved director field. The average number of such branches is increasing with the distance from the center of the pattern and leads to the emergence of a radial fractal tree or a snowflake structure. Our experimental observations show that the shape of this structure, as well as a number of bands, is controlled by the activity of bacteria and elasticity of liquid crystal and suggest a new concept for a manipulation of active nematics at a microscale.

*This work was supported by the US DOE, Office of Basic Energy Sciences, Division of Materials Science And Engineering, under contract No. DE AC02-06CH11357

RUI ZHANG (Presenter), STEVEN REDFORD, University of Chicago, PAUL RUIJGROK, Stanford University, NITIN KUMAR, ALI MOZAFFARI, AARON DINNER, VINCENZO VITELLI, University of Chicago, ZEV BRYANT, Stanford University, MARGARET GARDEL, JUAN DE PABLO, University of Chicago — Active matter gives rise to intriguing spontaneous flows and motion whose collective behavior is difficult to steer and tailor, thereby placing limits on potential applications. Here, we present a new method to control the dynamics of an active liquid crystal. Theory shows that through the interplay of local active stresses it is possible to create anchoring effects that help confine activity-induced topological defects. This prediction is confirmed by hydrodynamic simulations of active nematics. Simulations further demonstrate that at moderate-to-high activity, local active stresses can be used to create defect pairs at will and direct the motion of +1/2 defects on demand; at low activity, such stresses can induce a spontaneous flow without strong elastic distortions of the nematic. Our calculations are compared to experiments of a flexible active liquid crystal.

ALI MOZAFFARI (Presenter), RUI ZHANG, Institute for Molecular Engineering, University of Chicago, ANDREY SOKOLOV, ALEXEY SNEZHKO, Materials Science Division, Argonne National Lab, JUAN DE PABLO, Institute for Molecular Engineering, University of Chicago — Active nematics represent a class of active systems, operating out of thermodynamic equilibrium that consists of self-driven units with long-range orientational ordering. Our numerical simulation was inspired by the experimental observation of the development of deformation patterns of branched, radially elongated elastic bands of the director field in living liquid crystals (suspension of self-propelled swimming bacteria in bio-compatible lyotropic liquid crystal).

As a model system, we chose a suspension of elongated rods which exerts extensile active stresses and we employed the theory of active nematodynamics to study the spatiotemporal dynamics of this system. The interplay of activity induced spontaneous flow which drives the system away from the minimum of the free energy, and the orientational ordering of the liquid crystal give rise to rich dynamical behavior over length scales much larger than the size of each individual active entity. Continuum simulations of the active nematic explain how activity fueled instabilities result in appreciable spatial inhomogeneities of the nematic ordering, giving rise to the formation of alternating bands of opposite curvature. Our study examines regimes beyond experimental limits providing important insights into the origin of the observed pattern.
4:18PM C61.00008: “Catapulting” of topological defects through elasticity bands in active nematics  NITIN KUMAR, James Franck Institute, University of Chicago, RUI ZHANG (Presenter), Institute for Molecular Engineering, University of Chicago, STEVEN REDFORD, James Franck Institute, University of Chicago, JUAN DE PABLO, Institute for Molecular Engineering, University of Chicago, MARGARET GARDEL, James Franck Institute, University of Chicago — Local injection of energy in active liquid crystals (LC) results in spontaneous defect generation and emerging complex flows. Elucidating the role of competition between activity and nematic elasticity is crucial to understanding this phenomenon. Here, we present our experimental results on nematic LCs composed of short actin filaments, driven by myosin motors where the elasticity is tuned by varying the filament length, \( l \). We find that for \( l = 2 \) µm where the elasticity is high compared to an LC with \( l = 1 \) µm, elongated regions of uniform bend distortions form, which we define as elasticity bands. The bands are evocative of domain walls observed in hydrodynamic simulations of active nematics. The emergence of a shoulder in the elastic energy distribution provides an explanation – a nematic LC with high elasticity tends to minimize the total elastic deformation by localizing it to narrow regions in space. Moreover, we find that as the activity decays, the LC dissipates excess elastic energy by eliminating these bands resulting in “catapulting” of +1/2 defects at a very high speed which scales inversely with the width of the band. Our results are fully supported by hydrodynamic simulations of active nematics and advance our understanding of complex flows in active liquid crystals.

4:30PM C61.00009: Emergent lengthscales in confined 3D Active Incipient Nematics*  MINU VARGHESE (Presenter), Physics Department, Brandeis University, YI FAN, Department of Engineering, Brown University, ARVIND BASKARAN, Physics Department, Brandeis University, KUN-TA WU, Physics Department, Worcester Polytechnic Institute, ZVONIMIR DOGIC, Physics Department, University of California, Santa Barbara, SETH FRADEN, MICHAEL F HAGAN, Physics Department, Brandeis University, KENNY BREUER, Department of Engineering, Brown University, APARNA BASKARAN, Physics Department, Brandeis University — An incipient nematic is a system whose density is smaller than the critical density for isotropic-nematic transition. The stationary isotropic state, which is the stable equilibrium of a passive incipient nematic, can be destabilized by the effects of extensile activity combined with flow alignment. We study the properties of flows that arise from this instability in confined 3D systems. Calculations from hydrodynamic theory, and experimental measurements on a microtubule-based system show long-range velocity correlations, in the absence of such correlations in nematic order. Further, we show that there exists a confinement-independent lengthscale intrinsic to flows in an active incipient nematic that determines its bulk behavior.

4:42PM C61.00010: Avalanches and Clogging in Active Matter Systems  CYNTHIA REICHHARDT (Presenter), CHARLES REICHHARDT, Los Alamos National Laboratory — Jamming and clogging have been extensively studied in passive soft matter systems such as granular matter or colloids moving through disordered environments such as obstacle arrays. Here we consider a system of disks moving through a random obstacle array and examine the transition to a clogged state as function of obstacle density as we go from the passive particle limit to an active matter limit. In the passive case, for a fixed disk density there is a well defined obstacle density above which the system reaches a clogged state. As the activity is increased, the disks can become mobile again when the activity breaks up the clogs; however, for large activity, which corresponds to long run times in a run-or-tumble system, the disks undergo intermittent clogging and we find that above a certain activity level, the unclogging events exhibit a power law distribution. We argue that the activity induced clustering brings the system into a critical state associated with local regions that have reached the jamming density known as point \( J \). For infinite run times or the ballistic active matter limit, the system can reach a completely clogged state with no avalanches for disk densities that are much lower than those at which clogging is observed for passive particles.
Controlling collective patterns has attracted interest due to their potential in exploiting their hidden ordered phase of active bacterial suspension. Here, by imposing a geometric boundary condition, we study controlled collective motion of *Escherichia coli* bacteria inside designed microwells. In a doublet circles, two vortices emerge but their spinning directions show two distinct phases of either parallel pattern (ferromagnetic vortices, FMV) or anti-parallel one (anti-ferromagnetic vortices, AFMV). The transition from FMV to AFMV occurs when the ratio of vortex size to vortex distance is $\sqrt{2}$. Analytical solution with mean-field approximation accounts for this geometric rule [1]. By using this relation, we can control quadruplet pairing of bacterial vortices. Moreover, in a triplet circles, coexistence of FMV and AFMV pairings is emerged despite frustration, and the transition point from FMV pattern to coexisted phase is shifted because frustration stabilizes FMV pattern. Our result proposes simple design of boundary as promising mean in order to understand collective ordering of bacterial vortices.

Microswimmers such as bacteria exhibit collective behavior that can be controlled when placed in a nematic liquid crystal (NLC) with long-range orientational order [1]. We explore the collective motion of motile *Bacillus subtilis* dispersed in an aqueous solution of DSCG, a lyotropic chromonic NLC. The director field, imposed through photoalignment, contains defects of topological charge +1 which serve as attractors for bacteria. We vary the azimuthal angle of the director from 0 to 90 degrees to have predominant director distortions of either splay, bend, or a mixture of the two. The bacteria exhibit collective circular motion around +1 defects, with the radius of maximum concentration and velocity increasing as bend distortion dominates over splay. The experiment presents an example of how microswimmers interact with attractor type singular defects with different degrees of splay or bend deformation. The ability to control the collective motion of microswimmers can be used as a source of energy to power microscopic mechanical systems.

Magnetotactic bacteria are inherently magnetic motile micro-organisms. Hence, their swimming orientations are readily controlled by external magnetic fields making them a valuable model active matter system. When oriented perpendicular to a surface, they experience attractive hydrodynamic interactions that result in spontaneous self-organization (clustering). By tuning the cell density and magnetic field strength, this ordering may be systematically removed and restored, permitting construction of a phase boundary defining the onset of ordering and experimental exploration of cluster kinetics. The self-organization process is quantified using an order-parameter independent approach based on lossless compression algorithms (Lempel-Ziv), as well as a more conventional method employing the radial distribution function. These analyses reveal that the clusters scale logarithmically in time, representing a non-equilibrium analog of the “self-focusing” regime of charged colloids, and implying that the interplay between hydrodynamic attraction and magnetic repulsion control the kinetics. Furthermore connections between experimentally determined pair-wise interactions and the many-body dynamics, as well as the role viscous dissipation plays in stabilizing the structures will be discussed.
In recent years, enormous data sets have begun to appear in real-space visualizations (scanning probes) and reciprocal-space visualizations (scattering probes) of electronic quantum matter. Increasing volume and variety of such data present new challenges and opportunities that are ripe for a new approach: machine learning. However, the scientific questions in the field of electronic quantum matter require fundamentally new approaches to data science for two reasons: (1) quantum mechanical imaging of electronic behavior is probabilistic, (2) inference from data should be subject to fundamental laws governing microscopic interactions. In this talk, I will review the aspects of machine learning that are appealing for dealing with quantum complexity and present how we implemented a machine learning approach to the analysis of scanning tunneling spectroscopy data and X-ray scattering data.

4:18PM C62.00004: Autonomous Quantum Materials Research: Phase Mapping [Invited]  A. GILAD KUSNE (Presenter), Materials Measurement & Science Division, National Institute of Standards & Technology, TIEREN GAO, Materials Science & Engineering Dept, University of Maryland, BRIAN DECOST, JASON HATTRICK-SIMPERS, Materials Measurement & Science Division, National Institute of Standards & Technology, APURVA MEHTA, SLAC, ICHIRO TAKEUCHI, Materials Science & Engineering Dept, University of Maryland — The last few decades have seen significant advancements in materials research tools, allowing researchers to rapidly synthesize and characterize large numbers of samples - a major step toward high-throughput materials discovery. Machine learning has been tasked to aid in converting the collected materials property data into actionable knowledge, and more recently it has been used to assist in experiment design. In this talk we present the next step in machine learning for materials research - autonomous materials research systems. We first demonstrate autonomous measurement systems for phase mapping, followed by a discussion of ongoing work in building fully autonomous systems. For the autonomous measurement systems, machine learning controls X-ray diffraction measurement equipment both in the lab and at the beamline to identify phase maps from composition spreads with a minimum number of measurements. The algorithm also capitalizes on prior knowledge in the form of physics theory and external databases, both theory-based and experiment-based, to more rapidly hone in on the optimal results.

4:54PM C62.00005: Machine learning modeling of superconducting critical temperature* [Invited] VALENTIN STANEV (Presenter), University of Maryland, College Park — Machine learning has emerged as a powerful new research tool that can be used to answer many scientific questions in unconventional ways. In this talk I will discuss how it can help us address one of the most challenging problems in the study of quantum matter – finding connection between superconductivity – in particular critical temperature $T_c$ – and chemical/structural properties of materials. I will present several recently developed machine learning methods for modeling $T_c$ of the 12,000+ known superconductors available via the SuperCon database. These models use coarse-grained predictors based only on the chemical composition of the materials. They demonstrate good performance and strong predictive power, with learned predictors offering insights into the mechanisms behind superconductivity in different families. The models can be combined into a single pipeline and employed to search for potential new superconductors. Searching the entire Inorganic Crystallographic Structure Database led to the identification of 35 compounds as candidate high-$T_c$ materials. I will also discuss how machine learning can be used to guide and accelerate the experimental process.

Session C63 DBIO: Quantum Phenomena, Instrumentation, and Techniques in Biology

BCEC 259A - Jason Hafner, Rice University

2:30PM C63.00001: Ab-initio Electronic Structure Calculations of Entire Metalloproteins* CARLOS ROMERO-MUÑIZ (Presenter), MARÍA ORTEGA, Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, JOSÉ G. VILHEN, Basel University, ISMAEL DÍEZ-PÉREZ, Material Science and Physical Chemistry, Universidad de Barcelona, JUAN CARLOS CUEVAS, RUBEN PEREZ, LINDA ANGELA ZOTTI, Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid — In this work we present a theoretical approach to deal with entire metalloproteins at quantum level. In particular we focus on single-Cu azurins and cytochrome c, which contains a heme group with its typical Fe-center. In this approach we consider the complete structure of these proteins as a whole rather than limiting our analysis to relevant fragments of coordination complexes. This is accomplished by combining fully ab-initio calculations based on density functional theory with atomic-scale molecular dynamics simulations. Beyond the main features arising from the metallic ions, our study reveals that the role played by the peripheral parts of the proteins could be of remarkable importance. More precisely, we find that oxygen atoms belonging to carboxyl groups of acidic amino acids, distributed all over the protein contribute to electronic states near the HOMO in the case of azurins. The contribution of the outer regions to the electronic structure of metalloproteins had so far been overlooked. Our results stress the need to investigate them thoroughly; this is especially important in prospect of understanding complex processes like the electronic transport through metal-metalloprotein junctions.

Quantum Mechanics of Proteins in Water: The role of Plasmon-like Solute-Solvent Interactions

MARTIN STOEHR (Presenter), ALEXANDRE TKATCHENKO, University of Luxembourg — van der Waals dispersion interactions form a major component of both intra-protein and protein-water interactions. As such, they play an essential role for the spontaneous folding of proteins in water. van der Waals forces arise from long-range electron correlation and are thus inherently quantum-mechanical and many-body in nature. Nevertheless, they are typically only treated in a phenomenological manner via pairwise potentials. Here, we employ an explicit quantum-mechanical framework based on the many-body dispersion formalism, which allows us to highlight the importance of the many-body character of dispersion interactions for protein energetics and protein-water interactions. As such, our study provides insights into the fundamental quantum-mechanics of proteins in water. Contrary to commonly used pairwise approaches, many-body quantum effects significantly affect relative stabilities during protein folding in the gas-phase. Embedding in an aqueous environment leads to a quenching of such effects and stabilizes native conformations. Remarkably, this arises from a high degree of delocalization and collectivity of protein-water dispersion interactions. Our findings are exemplified on several prototypical proteins, emphasizing their broad validity in the biomolecular context.

Discrimination of bosonic loss: Applications to biological samples and photo-degradable materials

GAETANA SPEDALIERI (Presenter), STEFANO PIRANDOLA, SAMUEL LEON BRAUNSTEIN, University of York — We consider quantum discrimination of bosonic loss based on both symmetric and asymmetric hypothesis testing. In both approaches, an entangled resource is able to outperform any classical strategy based on coherent-state transmitters in the regime of low photon numbers. In the symmetric case, we then consider the low energy detection of bacterial growth in culture media. Assuming an exponential growth law for the bacterial concentration and the Beer-Lambert law for the optical transmissivity of the sample, we find that the use of entanglement allows one to achieve a much faster detection of growth with respect to the use of coherent states. This performance is also studied by assuming an exponential photo-degradable model, where the concentration is reduced by increasing the number of photons irradiated over the sample. This investigation is then extended to the readout of classical information from suitably-designed photo-degradable optical memories (quantum reading).

Surface-Enhanced Raman Scattering as a Tool for Biomembrane Structure

JASON HAFNER (Presenter), Physics & Astronomy, Rice University — Gold nanostructures focus light to the molecular length scale at their surface. The large optical intensity leads to surface-enhanced Raman scattering (SERS) from nearby molecules. SERS spectra contain information on molecular position and orientation relative to the surface but are difficult to interpret quantitatively. Here we describe a ratiometric analysis method that combines SERS and unenhanced Raman spectra with theoretical calculations of the optical field and molecular polarizability. The analysis was also applied to fluid phase phospholipid bilayers that contain tryptophan on the surface of gold nanorods. The lipid double bond was found to be oriented normal to the bilayer and 13 Å from the nitrogen atom. Tryptophan was found to sit near the glycerol headgroup region with its indole ring 43° from the bilayer normal. The potentiometric membrane probe di-4-ANEPPS has also been detected and its orientation characterized in the lipid bilayer. This new method can determine specific interfacial structure under ambient conditions, with microscopic quantities of material, and without molecular labels.

Previous studies have indicated selective biological cell damage due to local rapid thermalization [1] effects induced by laser irradiation. We have studied the effects of intense pulsed laser radiation on the prokaryote S. cerevisiae and eukaryote E. coli. These species are comparable to either cells found in the human body or pathogenic cells, respectively. We obtained the optical absorption spectra for the cells, and found frequency bands in the far-infrared (FIR/THz) range where notable spectral differences emerge. We report results of strong laser illumination at these selected bands.

The dynamics of concentrated suspensions of the crystallin eye-lens protein alpha crystallin was measured using x-ray photon correlation spectroscopy. For pure alpha crystallin suspensions the diffusive dynamics near the peak in the hard sphere structure are well described by a polydisperse hard sphere model. The intermediate scattering factor can be described by a stretched exponential function, and the concentration dependence of the relaxation time agrees with predictions from Langevin dynamics simulations.

We report a novel method, dual color axial nanometric localization by Metal Induced Energy Transfer (dcMIET), and combine it with Förster Resonant Energy Transfer (FRET) for resolving structural details in cells on the molecular level. We demonstrate the capability of this method on cytoskeletal elements and adhesions in human mesenchymal stem cells (hMSCs). Our approach is based on Fluorescence-Lifetime-Imaging Microscopy (FLIM), and allows for precise determination of the 3D architecture of intracellular structures, here in particular, stress fibers anchoring at focal adhesions, thus yielding crucial information to understand cell-matrix mechanics. In addition to resolving nanometric structural details along the z-axis, we use FRET to gain precise information on the distance between actin and vinculin at focal adhesions. Here, we will present data where we use our method to follow the maturation of focal adhesions and acto-myosin fibers in hMSCs over time and show that actin fibers are nearly parallel to the substrate yielding an inclination angle of only 0.2°.

3:54PM C63.00008: Separation of Protein and Water Dynamical Transitions Using Terahertz Spectroscopy*

AKANSHA SHARMA (Presenter), DEEPU GEORGE, ANDREA MARKEZ, University at Buffalo, The State University of New York — Terahertz Time Domain spectroscopy (THz TDS) has been used to characterize the protein dynamical transition [1, 2]. The dynamical transition has been considered a manifestation of the slaving of protein motions to thermally activated motions of the solvent, however recently is has been reported that sharp temperature increases in protein dynamics occur independent of the solvent [3]. Potentially terahertz spectroscopy can resolve both the protein and water dynamical transitions using the ~ 5 THz intermolecular water vibrational line and the broad ~ 1.0 THz absorption arising from the protein intramolecular motions. Here we use a combination of THz TDS and FTIR to examine this possibility and resolve the protein and water contributions using a combination of spectral decomposition and concentration dependent measurements. Concentration dependent measurements using hen egg white lysozyme (HEWL) confirm that the transition measured at 1 THz is dominated by the protein dynamics.

*Work supported by NSF grants DBI 1556359 and MCB 1616529.

4:06PM C63.00009: Non-destructive prediction of transcriptomic profiles by Raman microscopy

KOSEKI KOBAYASHI-KIRSCHVINK (Presenter), YUICHI WAKAMOTO, Department of Basic Science, Graduate School of Arts and Sciences, University of Tokyo — Raman microscopy can report on whole single-cell molecular compositions in both comprehensive and non-destructive manners. However, molecular compositions of cells are diverse and compounds such as proteins have severe spectral overlaps, making them nearly intractable to interpret. Instead of pursuing the spectral decomposition, we show that transcriptomic profiles of Schizosaccharomyces pombe and Escherichia coli can be computationally linked and be predicted from their single-cell Raman spectra. Our method employs the low-dimensional structure of transcriptomes, and learns a non-linear linkage between the transcriptomes and Raman spectra. Permutation tests show that the probability of accidentally finding the same prediction precision level is extremely low (p-value<0.0001), suggesting that the prediction is real. These results demonstrate that whole-cell Raman spectra could unravel cellular omics information in non-destructive manners, opening the possibility of conducting living-cell genomic analyses.

4:18PM C63.00010: Probing Mechanical Properties of Biomolecules using Nanopores

PRASAD BANDARKAR (Presenter), ROBERT HENLEY, HUAN YANG, MENI WANUNU, PAUL WHITFORD, Physics, Northeastern University — Nanopore translocation is a promising label-free single molecule technique to distinguish between bio-molecules. The confined nature of the nanopore restricts the allowed conformations of the molecules or necessitates a conformational change. These effects are reflected in the observed current traces and thus help us in measuring the flexibility of these biomolecules. Recently, we applied molecular dynamics simulations using a structure-based model to observe a correlation between the maximum RMSF of the protein and the width of the experimental current blockade distribution. This suggests that protein translocation can be utilized as a high-throughput method to distinguish between functional conformers in proteins. Applying this technique to translocation of tRNA offers an interesting challenge since the tRNA is expected to undergo a conformational change due to the constricted size of the nanopore. Using the same energy landscape techniques, we have calculated the mean first passage time (MFPT) for crossing the rate-limiting free-energy barrier for multiple tRNA species. We find agreement between the MFPT values and the experimental translocation times. Further, these calculations suggest that the experiments specifically observe transient partial unfolding of tRNA.
4:30PM C63.00011: Interferometric scattering for label-free electrokinetic trapping of single nanoparticles*
ABHIJIT A LAVANIA (Presenter), ALLISON H. SQUIRES, PETER D. DAHLBERG, W E MOERNER, Stanford University — Anti-Brownian ELectrokinetic (ABEL) trapping is a technique to trap single particles in solution, enabling extended characterization of their properties. It utilizes photon-by-photon fluorescence to estimate a particle's position, and fast electrophoretic and electroosmotic feedback forces to counteract Brownian motion and confine a particle to the center of a nanofluidic chamber. This enables the observation of photophysical properties, diffusion constants, and electrokinetic mobility. However, trapping is limited to particles that are either tagged with a fluorescent label, or have bright native fluorescence. Here we present the Interferometric Scattering Anti-Brownian ELectrokinetic trap (ISABEL trap), which uses interferometric scattering to enable fast detection and trapping of non-fluorescent particles. The weak scattered light from a nanoparticle is enhanced by interference with a strong reflection from a nearby interface. This enables direct and extended-duration study of single particles that do not fluoresce, or which exhibit intermittent fluorescence or photobleaching.

4:42PM C63.00012: Study of interaction of Bovine Serum Albumin with Gold Nanoparticles
KAVINDYA SENANAYAKE (Presenter), ASHIS MUKHOPADHYAY, Wayne State University — The protein-nanoparticle conjugates have potential applications in the fields of colloidal science and biophysics. We study the pH-dependent thickness of bovine serum albumin (BSA) layer on gold nanoparticles (AuNPs). pH-dependent conformations of BSA were determined between pH values 4 and 8. Comparison of pH-dependent hydrodynamic radii results of BSA-AuNp conjugates with Langmuir binding isotherm will be presented.

4:54PM C63.00013: Spatiotemporal dynamics of Pma1 in Saccharomyces cerevisiae using a reversibly interacting tag-probe system*
SUSAN PRATT (Presenter), Physics, Yale University, MICHAEL HINRICHSEN, Molecular Biophysics and Biochemistry, Yale University, LYNNE REGAN, School of Biological Sciences, University of Edinburgh, YONGDENG ZHANG, JOERG BEWERSDORF, Cell Biology, Yale University, BENJAMIN P BRATTON, JOSHUA SHAEVITZ, Physics, Princeton University, SIMON G MOCHRIE, Physics, Yale University — When fluorescent proteins (FPs) are directly fused to a protein of interest, they can interfere with wild-type protein functionality. For example, when plasma membrane (PM) protein Pma1, in *Saccharomyces cerevisiae*, is directly fused to an FP, it is mislocalized to the cells' vacuoles. To circumvent such problems, we are developing a versatile live-cell imaging strategy in which a fluorescently-labeled tetratricopeptide repeat affinity protein (TRAP) probe can reversibly bind to a conjugate 5 amino-acid peptide tag, which is bound to the target protein's C-terminus. We demonstrate the utility of this reversibly binding tag-probe system, showing that it properly localizes Pma1 to the PM. To further characterize the behavior of Pma1, we present the results of fluorescence recovery after photobleaching (FRAP), and single-particle tracking photoactivated localization microscopy (sptPALM) measurements under total internal reflection fluorescence (TIRF) illumination. Remarkably, we find significant differences in the diffusional dynamics of Pma1 imaged using our novel labeling methodology, and Pma1 directly fused to FP.

*We acknowledge support of the NIGMS via AWDA10958.

5:06PM C63.00014: Real-time Electrophysiological Monitoring of Anti-histamine Drug Effects on Live Cells via Reusable Carbon Nanotube Sensor
JIN-YOUNG JEONG (Presenter), VIET ANH PHAM BA, DONG-GUK CHO, HANEUL YOO, Department of Physics and Astronomy, Seoul National University, Korea, VAN-THAO TA, Department of Chemistry, Hanoi National University of Education, Vietnam, SEUNGHUN HONG, Department of Physics and Astronomy, Seoul National University, Korea — Here, we developed a real-time electrophysiological method for monitoring the effects of drugs on live cells via a reusable carbon nanotube field-effect transistor (CNT-FET) sensor. The real-time electrophysiological responses of an individual HeLa cell could be measured repeatedly with the system. The sensor measured the electrical signal induced by the activity of histamine type 1 receptors on a HeLa cell regulated by histamine. Furthermore, the effects of drugs such as cetirizine and chlorphenamine on the HeLa cell were assessed. Remarkably, we exploited only a single sensor to record the activity of numerous HeLa cells to reduce the errors caused by device-to-device variations. Our method provides reliable and statistically-meaningful data to study the activity of live cells. We could expect our method using the reusable CNT-FET sensors to contribute to the pharmaceutical and biological research.

Monday, March 4, 2019 2:30 PM - 5:18 PM

Session C64 DBIO: Biopolymers II (DNA, RNA, Biocompatible, Gels) BCEC 259B - Caroline Werlang,
Massachusetts Institute of Technology - Tag(s): Focus
2:30PM C64.00001: The Mechanism of DNA Junction Melting
ABRAHAM KIPNIS (Presenter), ISHITA MUKERJI, FRANCIS STARR, Physics Department, Wesleyan University, Middletown, CT — Four-way Holliday junctions play vital roles in genetic recombination, DNA damage repair, and other mechanisms of chromosomal rearrangement. Here we examine the melting of Holliday junctions through a combination of FRET experiments and MD simulations. We show that melting of this junction initiates at specific locations. At physiological salt concentrations, the junction “folds” into a stacked conformation consisting of two crossing pseudo-duplexes, and our results indicate that melting proceeds as a quasi-independent process along these pseudo-duplexes, rather than as a uniform process throughout the junction. We interrogate the melting locally by measuring FRET from fluorescent nucleotide analogs strategically placed at several locations in the junction. To help interpret the FRET data, we use the coarse-grained 3SPN.2 model to simulate the junction melting. By analyzing an ensemble of simulations, we describe approaches to characterize junction conformation and the dynamics of melting. Our results demonstrate the ability of the 3SPN.2 model to predict structural and dynamic aspects of Holliday junctions and offer a two-step mechanism for junction melting.

2:42PM C64.00002: Dynamic conversion of RNA in crowded environments: implication of significance of micro-viscosity against molecular confinement
JOON HO ROH (Presenter), University of Maryland, College Park, MADHUSUDAN TYAGI, Center for Neutron Research, National Institute of Standards and Technology, SARAH A WOODSON, Biophysics, Johns Hopkins University, JOSEPH CURTIS, Center for Neutron Research, National Institute of Standards and Technology, ROBERT M BRIBER, University of Maryland, College Park — The conformational behavior of RNA in densely packed intracellular conditions is a long-standing area of interest and is critical for understanding biologically important dynamics in a living cell. The effect of viscosity at the solvent-accessible surface area on the concerted conformational motions of tRNA in crowded conditions must be considered. We have examined the effect of PEG-induced crowding on the internal dynamics of unfolded and folded tRNA using ps ~ ns Quasi-Elastic Neutron Scattering spectroscopy (QENS) to probe the role of the local micro-viscosity as a function of the molecular confinement effects from crowding. At temperatures lower than water crystallization (Tc) and higher than dynamic glass transition temperature (Td) of tRNA, the conformational flexibility becomes larger with more confinement, and it is suppressed more strongly at higher temperatures. The dynamic conversion across Tc indicates the significance of the micro-viscosity versus molecular confinement, both of which can orthogonally vary with crowding conditions. Comparison of dynamics from QENS with the aid of molecular dynamics simulations provides insight into the physical origin of this dynamic conversion and its coupling with the local structure of water at the macromolecular surface.

2:54PM C64.00003: Diffusion and Conformational Dynamics of Linear and Circular DNA in Crosslinked Cytoskeleton Composites*
KATHRYN REGAN (Presenter), DEVYNN WULSTEIN, SHEA RICKETTS, RYAN J. MCGORTY, RAE ROBERTSON-ANDERSON, University of San Diego — In order to carry out key cellular processes, DNA molecules must diffuse through the crowded cytoskeletal network, comprised of thin semiflexible actin filaments and thick rigid microtubules. Each of these cytoskeletal filaments can also be crosslinked to varying degrees, altering the network structure and dynamics and hence the impact on DNA diffusion and conformational dynamics. Here, we use single-molecule conformational tracking to investigate the effect of cytoskeleton crosslinking on the transport properties and time-varying conformations of diffusing DNA molecules. Specifically, we track the center-of-mass, size, and shape of single linear and circular DNA molecules diffusing in crosslinked composites of actin and microtubules. We quantify transport coefficients, anomalous diffusion scaling exponents, lengths and timescales of intramolecular fluctuations, and shape and size dynamics of DNA. We determine the role of DNA topology (circular vs linear) as well as cytoskeleton crosslinking motif on DNA dynamics and conformations. Our results shed light on how macromolecular topology and network structure impact macromolecular mobility in crowded cell-like environments.

*This work was funded by NIH NNIGMS Grant No. R15GM123420, AFOSR Grant No.FA9550-17-1-0249, and NSF-CBET-1603925
3:06PM C64.00004: Binding of oligos to DNA secondary structures*  OLIVIA ZOU (Presenter), SHIRA ROSENBERG, WILLIAM B ROGERS, Brandeis University — RNAs are molecules that rely on their 3D structure to regulate cell processes, such as delivering molecules or making proteins. Therefore, disrupting the structure of RNA could help us better understand or even modulate these functions. In principle, one way to do this is to bind DNA oligonucleotides to the RNA to change its conformation so that it no longer works. In practice, this is a difficult task as the complex secondary and tertiary structures of RNA often prevent DNA from binding stably. We aim to understand the kinetic and thermodynamic reasons why oligonucleotides fail to bind to secondary structures. In this talk, I will describe a series of experiments investigating the binding of short DNA oligonucleotides to nucleic acids with prescribed secondary structures. We design a set of hairpins, bulge loops, and internal loops with various loop and toehold lengths, which should result in different opening rates when the oligo binds. A fluorescent probe binds to all these structures, allowing us to make measurements of the amount of unfolded molecules. Preliminary results show that opening rates of different secondary structures vary by orders of magnitude, with hairpins being fastest, and internal loops being slowest.

3:18PM C64.00005: Molecular Dynamics Simulation of Supercoiled DNA with Mismatched Base Pair-Probing the Role of Structural Defect on Plectoneme Pinning  PARTH RAKESH DESAI (Presenter), SIDDHARTHA DAS, Department of Mechanical Engineering, University of Maryland, College Park, KEIR C NEUMAN, NHLBI, National Institute of Health — Mismatch repair (MMR) proteins correct mismatches in DNA. The exact mechanism by which MMR proteins recognize mismatch is still not well understood, but it is believed that the process involves introducing a sharp bend in the DNA and flipping out the mismatched base. Recent, single-molecule magnetic tweezers-based DNA supercoiling studies, conducted at salt concentrations of 0.5 M NaCl and higher, have shown that the mismatched base pair will always localizes at the end of the plectoneme loop and this may facilitate mismatch detection. Theoretical studies have found that the localization of mismatched base pair in the plectoneme end loop, at 0.2 M NaCl, becomes probabilistic. However, these studies were limited to positively supercoiled DNA. Here, we carry out molecular dynamics simulation to study supercoiling of DNA in presence of mismatched base pairs. We study both positively and negatively supercoiled DNA at salt concentration of 0.2 M NaCl using the oxDNA model. We simulate a DNA molecule with 0, 2, 4 and 6 consecutive G:T type mismatches. We find that the plectoneme localization at the mismatched base pair becomes probabilistic. We will present the details of the relationship between the number of mismatched base pairs and the probability of plectoneme localization.

3:30PM C64.00006: Mechanical Properties of DNA Replication  STUART SEVIER (Presenter), MIT — Successful DNA replication requires significant mathematical and physical constraints to be met. The helical structure of DNA results in interwound replicated strands of DNA causing over twisting in the unreplicated portion of DNA presenting a significant topological barrier to cellular division. Though the basic conceptual elements of this process have long been known the necessary physics has just recently been developed. In this work, we outline the basic mathematical and physical properties of an idealized DNA replication process. The resulting framework makes predictions on the relative concatenation of replicated DNA and supercoiled unreplicated DNA generated during replication. These elements are central in understanding the mechanical nature of the replication machinery as well as in transcription replication conflicts.

3:42PM C64.00007: Quantifying free energy pathways of competitive DNA-ligand interactions  ALI ALMAQWASHI (Presenter), King Abdulaziz University — DNA intercalators are considered for potential DNA targeted therapeutics. The kinetics of simple DNA intercalators are well-modeled and characterized in single molecules studies. However, DNA-ligand that have multi-binding modes including intercalation are often studied in equilibrium approach, which does not address the governing free energy pathways. It is crucial to map the transition pathways, in particular, for competitive DNA-ligand interactions that alter DNA extension, which provides insights for rational drug design. While intercalation elongates DNA, other binding modes can be distinguished by distinct rates of increase or decrease of DNA extension. For practical experimental conditions, a frame work is proposed here to analyze the kinetics of DNA-ligand multi-binding modes probed by time-dependent and force-dependent DNA extension. This enables characterizing and quantifying the free energy pathways in order to identify and further optimize the molecular binding mechanism.
In my talk, I present the Looping and Clustering model [1], a simple statistical physics approach to describe how proteins assemble into a protein-DNA cluster with multiple loops. Our analytic model predicts binding profiles of ParB proteins in good agreement with data from high precision ChiP-sequencing – a biochemical technique to analyze the interaction between DNA and proteins at the level of the genome. The Looping and Clustering framework provides a quantitative tool that could be exploited to interpret further experimental results of ParB-like protein complexes and gain some new insights into the organization of DNA.

**4:06PM C64.00009: Coarse-grained molecular simulation studies of effect of solvent quality on melting thermodynamics of oligonucleic acids (ONA) and ONA-polymer conjugates**

PRHASHANNA AMMU (Presenter), ARTHI JAYARAMAN, Chemical & Biomolecular Engineering, University of Delaware — Hybridization or melting thermodynamics of oligomers of nucleic acids (e.g., DNA, RNA, PNA) duplexes is dependent on oligonucleic acid (ONA) backbone chemistry, length, base sequence and composition, and solvent chemistry. Understanding how solvent quality affects ONA stability, in free state and when conjugated to polymers is important for use of ONA in nucleotide-based bio- and nano-technologies. In this talk, I will present our recent molecular simulation work using a coarse-grained model capable of capturing the specific and directional H-bonds between complementary bases in ONA, in implicit solvents. We found that, as the solvent quality worsens for the polymers conjugated to neutral and flexible ONAs (such as PNA), the ONA melting temperature increases for all the ONA sequences, G-C content and polymer length studied. For negatively charged and semi-flexible ONAs (DNA-like), the conjugation of longer solvophobic polymer (as compared to ONA length) decreases the ONA melting temperatures while conjugation of relatively shorter solvophobic polymer, similar to ONA length, does not affect melting temperatures for all the ONA sequences and G-C content studied.

**4:18PM C64.00010: Terahertz Spectroscopic Study on Protein Myoglobin: Polymer-Like Behavior of Vibrational Density of States**

LEONA MOTOJI (Presenter), TATSUYA MORI, Division of Materials Science, University of Tsukuba, YASUHIRO FUJI, AKITOSHI KOREEDA, Department of Physical Sciences, Ritsumeikan University, YUE JIANG, KENTARO SHIRAKI, YOHEI YAMAMOTO, SEIJI KOJIMA, Division of Materials Science, University of Tsukuba — We performed terahertz time-domain spectroscopy on protein myoglobin to investigate the boson peak dynamics which universally appears in glassy materials and fraction which is expected to universally appear in polymer glasses. The obtained spectral shape of log ε“ vs log frequency [ε“: the imaginary part of complex dielectric constants] indicates that the fracton region appears above the boson peak frequency. The fractal and fracton dimensions were evaluated from the obtained spectra.

**4:30PM C64.00011: Dynamics of supercoiled knotted DNA: largescale rearrangements and persistent multistrand interlocking**

LUCIA CORONEL (Presenter), International School for Advanced Studies, ANTONIO SUMA, Temple University, CRISTIAN MICHELETTI, International School for Advanced Studies — Catalytic processes in bacterial plasmid introduce knots and supercoiling. The effect of the latter has been separately and extensively studied, however much less is known about their concurrent action. Thus, to study the kinetic and metric changes introduced by complex knots and supercoiling in 2kbp-long DNA rings, we use molecular dynamics simulation and oxDNA, a mesoscopic DNA model, finding several unexpected results. First, two distinct states dominate the conformational ensemble, they differ in branchedness and knot size; secondly, fluctuations between these states are as fast as the metric relaxation of unknotted rings. Nevertheless, certain boundaries of knotted and plectonemically wound regions can persist over much longer timescales. These regions involve multiple strands that are interlocked by the cooperative action of topological and supercoiling constraints. Their long liver character may be relevant for the simplifying action of topoisomerases.
4:42PM C64.00012: Fast combinatorial nanofluidic device for the dynamic study of biomolecular interactions* SAROJ DANGI (Presenter), PARMINDER KAUR, HAI PAN, HONG WANG, ROBERT RIEHN, North Carolina State University — We present a nanofluidic device for fast combinatorial exposure of stretched and localized DNA molecules to reagents, such as DNA binding proteins, salts, and restriction enzymes. Nanofluidic devices with channel sizes close to the persistence length of DNA have long been used to stretch, visualize, and study biomolecular interactions that modify the configuration of DNA. However, there is a temporal limitation on how long you can study the interaction dynamics before the probing light photocleaves DNA and fluorescence dyes. In addition, study of the interactions among DNA and multiple reagents in different sequences needs the rapid exchange of buffers. Such studies in the nanochannels with traditional passive exchange of buffers via diffusion process is not feasible. Our device allows the simultaneous or the sequential exposure of multiple reagents with active flow of buffers. The buffers could be exchanged under 20 sec while DNA molecule still confined in the field of view. To illustrate the concept of the device, we will show the conformational change of DNA in the varying ionic concentration, restriction enzymes and DNA binding proteins.

4:54PM C64.00013: Multiscale Modeling of DNA Translocation through Multiple Nanopores TOWFIQ AHMED (Presenter), Los Alamos National Laboratory, ANIKET BHATTACHARYA, Physics Department, University of Central Florida — We report preliminary results for a multiscale modeling scheme to decipher signals recorded for a translocating DNA through a series of nanopores. We propose to relate the time series of the cross-correlation current from different pores calculated from ab initio studies [1] to the velocity correlation obtained by carrying out Brownian dynamics simulation on a coarse-grained (CG) model of a DNA as well as the nano-pores [2]. By suitable choices of different pore-polymer interactions we propose to relate the results obtained from a simple CG model to more refined but computationaly expensive models.

5:06PM C64.00014: DNA-based molecular force sensors in reconstituted actin networks* CHRISTINA JAYACHANDRAN (Presenter), Third Institute of Physics - Biophysics, University of Göttingen, 37077 Göttingen, Germany, MAX WARDETZKY, Institute of Numerical and Applied Mathematics, University of Göttingen, 37077 Göttingen, Germany, FLORIAN REHFELDT, Third Institute of Physics - Biophysics, University of Göttingen, 37077 Göttingen, Germany, CHRISTOPH F. SCHMIDT, Third Institute of Physics - Biophysics, University of Göttingen, 37077 Göttingen, Germany, Department of Physics,Duke University, Durham, NC 27708, USA — Actin, a major cytoskeletal biopolymer of eukaryotic cells self-assembles into networks of crosslinked filaments and bundles and is largely responsible for cellular shape and mechanical stability. Actin assemblies are also responsible for active cellular processes ranging from migration, division and intracellular transport to morphogenesis. Crucial for such processes is the spatial and temporal regulation of the structure and dynamics of the networks and the generation of force, mostly by myosin motors. To measure forces in cytoskeletal networks, we have developed a FRET based molecular force sensor consisting of a DNA hairpin loop, which can be cross-linked into actin networks. We characterized the force sensor via fluorescence lifetime imaging.

Session C65 DBIO: Biomaterials: Structure, Function, Design I BCEC 260 - Suzanne Kane, Haverford College -
Tag(s): Focus
Hierarchical biological materials – structure, design and synthesis

MARKUS BUEHLER (Presenter), Massachusetts Institute of Technology — What if we could design materials that integrate powerful concepts of living organisms - self-organization, the ability to self-heal, tunability, and an amazing flexibility to create astounding material properties from abundant and inexpensive raw materials? This talk will present a review of bottom-up analysis and design of materials for various purposes - as structural materials such as bone in our body or for lightweight composites, for applications as coatings, and as multifunctional sensors to measure small changes in humidity, temperature or stress. These new materials are designed from the bottom up and through a close coupling of experiment and powerful computation as we assemble structures, atom by atom. We review case studies of joint experimental-computational work of biomimetic materials design, manufacturing and testing for the development of strong, tough and smart mutable materials for applications as protective coatings, cables and structural materials. The use of a new paradigm to design materials from the bottom up plays a critical role in advanced manufacturing, providing flexibility, tailorability and efficiency.

The hidden structure of mouse and human enamel

PUPA GILBERT (Presenter), University of Wisconsin - Madison — Enamel is the hardest and most resilient tissue in the human body. The morphology of human and mouse enamel is well established: it consists of space-filling, aligned, parallel, ~100 nm wide, microns-long nanocrystals, bundled into 5-micron-wide rods. The orientation and arrangement of enamel crystals, however, are poorly understood yet they confer outstanding materials properties. We show with polarization-dependent imaging contrast (PIC) mapping that in mouse enamel, within a rod, crystals are co-oriented with one another but not with the long axis of the rod in human enamel they are not co-oriented with either: the c-axes of adjacent crystals are most frequently mis-oriented by 1°-30°, and their orientation gradually changes up to 30°-90° within a rod. Molecular dynamics simulations demonstrate that the mis-orientations of adjacent crystals observed in human enamel induce crack deflection. This toughening mechanism, therefore, contributes to make our enamel last a lifetime.

Does the crystal structure of shark teeth make them stronger?

CAYLA STIFLER (Presenter), AMBER LIM, BENJAMIN HARPT, CHANG-YU SUN, PUPA GILBERT, University of Wisconsin - Madison — C. megalodon, a huge ancient shark, was capable of producing bite forces as large as 110,000-180,000 N. In comparison, great white sharks, a much smaller modern analogue, can only exert a force of 7,400 N when biting. In both cases, the mechanical stress that the teeth undergo suggests that there might be mesoscale structural features in the fluorapatite crystals in enameloid, which contribute to the superior mechanical properties. Previously, we used PIC (Polarization-dependent Imaging Contrast) mapping to reveal an intricate woven structure in the fluorapatite crystals in parrotfish enameloid, and hypothesized that this structure contributes to enameloid's impressive stiffness. PIC maps from megalodon and great white shark reveal the mesoscale c-axis orientations of enameloid crystals, which contribute to understanding the structure that allows shark teeth to withstand the large bite forces.
3:30PM C65.00004: Bound-state mobility within the nuclear pore complex  LAURA MAGUIRE (Presenter), Physics and BioFrontiers, University of Colorado Boulder, MICHAEL W STEFFERSON, M. BETTERTON, Physics, University of Colorado Boulder, LOREN HOUGH, Physics and BioFrontiers, University of Colorado Boulder — Biopolymeric filters are essential to life. Nuclear transport in particular is an unusual form of filtering in which the flux of select large particles is greatly enhanced over that of smaller nonspecific molecules. The nuclear pore complex, a channel lined with intrinsically disordered FG nucleoporins, facilitates all transport between the nucleus and cytoplasm. It prevents most macromolecules from crossing the nuclear envelope while allowing the passage of transport factors and their cargo. While the basic biochemical interactions leading to transport are well-understood, the detailed mechanism remains a topic of significant debate. We have developed a model of nuclear transport which predicts that nuclear pore selectivity is largely determined by the mobility of FG nucleoporin–transport factor complexes within the pore. We test this prediction by measuring bound-state diffusion of transport factors in tunable nuclear pore mimics which consist of hydrogels filled with FG nucleoporins. Bound-state diffusion is determined for several conditions, including FG nucleoporins of varying length. Bound-state mobility occurs in many biological systems in addition to the nuclear pore complex and could help explain the selectivity of other biopolymeric filters.

3:42PM C65.00005: Emergence of helical growth in fungal cells from a self-organizing cell wall*  FRANCK VERNEREY (Presenter), SHANKAR LALITHA SRIDHAR, REVATHI PRIYANKA MOHAN, Mechanical Engineering, University of Colorado, Boulder, JOSEPH ORTEGA, Mechanical Engineering, University of Colorado Denver — Walled cells such as plants, algae and fungi achieve expansive growth using turgor pressure that helps mediate irreversible wall deformation and regulates their shape and volume. The architecture of the cell wall plays a crucial role in this process where a network of microfibrils and tethers (complex polysaccharides and proteins) dynamically mediate the network topology via continuous detachment and reattachment events. A direct consequence of wall architecture, through microfibril re-orientation, is the helical growth of the fungal cells of Phycomyces Blakesleeanus. Powered by turgor pressure and the biochemistry to regulate molecular processes that induce network organization, these cells can control the growth rate and direction of the helix. The relationship between local molecular mechanisms and global emerging behaviors of these cells is still poorly understood. We present a novel approach based in statistical mechanics to model the organization of microfibrils and tethers in the cell wall. The model is then used to predict (a) the longitudinal elongation and rotation rates along the growth zone and (b) the inversion in rotation direction during growth stages in wild-type sporangiophores, and for radial expansion in piloboloid mutants.

3:54PM C65.00006: Harnessing Design Principles from Glass Sponges for Structurally Robust Lattices  MATHEUS FERNANDES (Presenter), School of Engineering and Applied Sciences, Harvard University, JAMES C WEAVER, Wyss Institute, Harvard University, KATIA BERTOLDI, School of Engineering and Applied Sciences, Harvard University — The glass sponge Euplectella Sp. are predominately deep sea sponges that live in ocean depths of 100-2000m. Beyond their fracture propagation inhibiting material composition, these sponges are perceived to exhibit large structural rigidity and strength against buckling. Since these sponges are primarily made of ‘brittle silica’, buckling strength may be a crucial property in making them resistant to impact and environmentally applied stresses. Structurally, they exhibit a base square-grid architecture and regular ordering of vertical and horizontal struts that form the skeletal system. Furthermore, their base structure is overlaid with double diagonal reinforcement struts, which create a checkerboard-like pattern of open-closed cell structure. Based on its similarity to square lattices found in structural engineering, we explore the following research question: Can we generate design principles for diagonal reinforcements of square beam lattices that are optimally designed to avoid global structural buckling? Here, we present a numerical analysis of the structure deformation under various loading conditions as well as survey different arrangements within similar design space of the sponge. Furthermore, we present experimental evidence that supports our numerical analysis.
4:06 PM C65.00007: TOPOLOGICAL PHONONS IN MICROTUBULES: THE LINK BETWEEN LOCAL STRUCTURE AND DYNAMICS OF MICROTUBULES
SSU-YING CHEN (Presenter), AROOJ ASLAM, CAMELIA PRODAN, physics, New Jersey Institute of Tech, EMIL PRODAN, physics, Yeshiva University — We have developed a model for analyzing thermal energy propagation through a microtubule by tracking its movement over time, and extracting a phonon spectrum of energy states and the speed of energy propagation through a microtubule. The microtubule is a self-assembling protein structure, and it has been reported that changes in the tubulin proteins that make up the bulk structure of the microtubule can alter its dynamic properties, in particular the polymerization and depolymerization rates. The pathways that dictate how local structure affects system wide dynamics has yet to be elucidated by current measurement techniques. This is because previous methods of defining structural properties of the microtubule hinge on static parameters, such as persistence length and Young's modulus, which neglect the dynamic properties of the microtubule and the anisotropic behavior of these local changes. Our methods look at the vibrational energy propagation through microtubules as an energy source for the energy intensive dynamics of the microtubule. In our methodology, the increased spatial resolution accommodates anisotropy along the length of the microtubule and paves the way for developing a dynamic measurement of microtubule mechanics.

4:18 PM C65.00008: Characterization of fracture in topology-optimized bio-inspired networks*
CHANTAL NGUYEN (Presenter), Department of Physics, University of California, Santa Barbara, DARIN PEETZ, Department of Civil and Environmental Engineering, University of Illinois at Urbana-Champaign, AVIK MONDAL, Department of Physics, University of Michigan, AHMED ELBANNA, Department of Civil and Environmental Engineering, University of Illinois at Urbana-Champaign, JEAN CARLSON, Department of Physics, University of California, Santa Barbara — Trabecular bone is a flexible, lightweight bone tissue that exhibits an anisotropic microarchitecture resembling a web of interconnected struts (trabeculae). We simulate trabecular bone architectures with multi-objective topology optimization, effectively reverse-engineering trabecular structure by optimizing biologically-motivated objectives. Starting from an identical volume, we generate different topologies by varying the objective weights for compliance, surface area, and stability. We model these topologies as disordered, spatially-embedded networks where edges represent trabeculae and nodes represent branch points where trabeculae meet. We simulate mechanical loading on finite-element models where each edge is replaced by a beam, enabling direct comparison of mechanics and topology at multiple scales ranging from that of individual edges/beams to the network at large. We compare the mechanical response of the various topology-optimized networks and identify mechanisms of crack propagation. We characterize and predict crack pathways with community detection methods inspired by similar applications in the study of granular materials.

*NSF EAR-1345074 & CMMI-1435920, Institute for Collaborative Biotechnologies (ARO W911NF-09-D-0001), David and Lucile Packard Foundation
Spherulites in coral skeletons are composed of acicular aragonite crystals radiating from common centers and exhibiting a 0°–35° misorientation of crystallographic c-axes across grain boundaries, previously misattributed entirely to a mechanism called non-crystallographic branching [1,2]. Here, we examine skeletons from 9 diverse species with quantitative nanoscale crystal orientation analyses using Polarization-dependent Imaging Contrast (PIC) mapping [3]. We discovered that, in addition to spherulites, 4 of the species also form tiny (0.2–2 µm), randomly oriented, equant crystals, termed sprinkles. Supported by theoretical phase field simulations, we propose that all initially nucleated crystals are randomly oriented sprinkles, and that these later coarsen, with radially oriented crystals growing at the expense of smaller, randomly oriented sprinkles. This mechanism is analogous to solidification or annealing in metals, both of which are high-temperature phenomena, whereas in coral skeletons coarsening occurs at ambient conditions.

Optical characterization of nacre using hyperspectral imaging* [Invited] MIKHAIL A. KATS (Presenter), Electrical and Computer Engineering, University of Wisconsin - Madison — Nacre is an organic-inorganic biomineral that lines the inside of shells of various species of mollusks, and comprises layers of aragonite tablets with thicknesses on the order of hundreds of nanometers, bound by an organic protein. The iridescent appearance of nacre results from thin-film interference effects within this layered structure, even though the layers are quite inhomogeneous due to surface roughness, shell curvature, and the disordered nature of the tablets comprising the aragonite layers.

The average thickness (and variance) of the nacre layers can encode information, for example the ocean temperature at the time of formation. However, obtaining information about the layer thickness typically requires destructive methods involving preparing and imaging cross-sections, and can require many cross-sections to map an entire sample.

Here, we present a method that combines polarized hyperspectral imaging with thin-film modeling, that is capable of nondestructively mapping the thickness of nacre layers across an entire specimen.

2:30PM C66.00001: Mechanical feedback maintains polarization in budding yeast mating projection growth
SAMHITA BANAVAR (Presenter), University of California, Santa Barbara, MICHAEL TROGDON, Salk Institute, BRIAN DRAWERT, University of North Carolina, Asheville, LINDA R PETZOLD, OTGER CAMPAS, University of California, Santa Barbara — Cell polarization is one of the commonly studied cases of spontaneous symmetry breaking in cells and controls many cellular processes, including morphogenesis, in budding yeast. However, the mechanisms that coordinate continued polarization to the growth region during mating projection formation, and the subsequent change in geometry from a spherical cell, remain unknown. We theoretically show that a genetically-encoded mechanical feedback relaying information about cell's geometry is sufficient to maintain key polarity molecules and growth machinery remain localized to the site of growth. We have demonstrated that this same feedback mechanism also results in cell wall stability.

2:42PM C66.00002: Active mechanics in the growth of a bacterial cell wall JORDAN PRICE (Presenter), GIACOMO PO, ALEXANDER JACOB LEVINE, JEFF ELDREDGE, University of California, Los Angeles — It is well known that rod-shaped bacterial cell walls—a thin shell made of a disordered peptidoglycan network—grow rapidly in length. This speed allows cells to divide several times per hour. However, fast growth requires the cell to rapidly add material to a highly pressurized (osmotically) shell without bursting. The basic mechanism for growth is actively driven dislocations plowing through the shell in the circumferential direction. These motor-driven defects introduce new material (MreB filaments) into the shell but generate stress concentrations surrounding the moving defects. Motivated by the large deformations inherent in bacterial growth, we develop a nonlinear continuum mechanics model with actively driven dislocations to describe the growth of the cell wall. Using numerical simulations, we study the interaction of stress fields that arise as these filaments are added to the existing peptidoglycan mesh. Furthermore, we investigate how the growth mechanics are affected by fluctuations in turgor pressure, and the presence of heterogeneities and defects in the cell wall that can form during an osmotic shock or antibiotic treatment.

2:54PM C66.00003: Limitations on Tissue Shape Control by Mechanical Feedback* ALEXANDER GOLDEN (Presenter), Physics, Boston University, DAVID K LUBENSKY, University of Michigan — How size and shape of living tissues are controlled is a fundamental question of developmental biology. What are the mechanisms that can produce correct sizes? How does size control relate to shape control? We investigate how size and shape control interact in a model of growth control in the *Drosophila* wing disc epithelium, which appears to achieve a robust final size. In particular, we study the capacity of mechanical feedback models to control not only tissue size, but tissue shape. We develop an analytic model capable of integrating mechanical feedback on tissue growth into an elastic theory. This allows us to make precise claims about the limitations of shape control by mechanical feedback, and demonstrate how these limitations derive from underlying elastic principles.

*NSF DMR-1056456

3:06PM C66.00004: Inflationary Embryology and the Statistical Physics of Noisy Tissue Growth* OJAN KHATIB DAMAVANDI (Presenter), DAVID K LUBENSKY, University of Michigan — Tissue growth is fundamental to biology and is noisy. Noise has important implications for morphogenesis and tissue integrity, yet a basic theoretical description of noisy tissue growth has been lacking. Growth nonuniformity leads to a build-up of mechanical stresses, and many tissues respond to stress by modulating their growth. Then, how does the interplay between noise and stress feedback affect tissue growth, and what can we predict about the statistical properties of experimentally accessible quantities? We model the tissue as a continuum, elastic sheet undergoing exponential growth with mechanical feedback and find that the density-density correlations show power-law scaling in space. In anisotropic growth, the standard deviation in clone sizes is comparable to the mean, in contrast to the isotropic case where relative variations in clone size vanish at long times. The high variability in clone statistics observed in anisotropic growth is due to the presence of two soft growth modes, which generate no stress. Our work analyzes the simplest model of noisy growth of elastic tissues. It thus both introduces a new class of nonequilibrium growth models and represents a first step towards understanding specific biological contexts.

3:18PM C66.00005: Biophysically Inspired Morphometrics SALEM AL MOSLEH (Presenter), GARY P. T. CHOI, MAHADEVAN, John A. Paulson School Of Engineering And Applied Sciences, Harvard University — Motivated by the quest to understand shape changes in biology, both in a developing organism and over evolutionary time scales, we develop a computational framework for analyzing geometric shape changes between surfaces embedded in three dimensions. Our approach allows us to simultaneously solve the problem of registration and the morphing of shapes onto each other using biophysically inspired distance functions. We then discuss how this framework can be used to analyze shape changes in such instances as planar wings and human faces.
3:30PM C66.00006: Dynamic Morphoskeleton  MATTIA SERRA (Presenter), Harvard University, SEBASTIAN STREICHAN, UCSB, L MAHADEVAN, Harvard University — During embryonic development, cells undergo large-scale motion generating tissues rearrangement, which ultimately defines the final shape of the embryo. While developmental biology has identified several genes driving local cellular processes, the interplay between cell-intrinsic and external stresses is fairly less understood because several local mechanisms are still unknown or hard to measure. By contrast, with the significant advances in live imaging techniques, it is now possible to fully track cell trajectories. Using ideas from nonlinear dynamics, we propose a rigorous objective kinematic framework for analyzing cell motion, which uncovers the underlying dynamic morphoskeleton, i.e. the centerpieces of cell trajectory patterns in space and time. The dynamic morphoskeleton provides a quantitative tool for comparing different morphogenetic phenotypes, quantifying the impact of genetic and physical manipulations, studying cell fate, and overall bridging the gap between bottom-up and top-down modeling approaches. We illustrate our results on a Drosophila gastrulation dataset obtained by in toto light-sheet microscopy.

3:42PM C66.00007: Morphology analysis based on information theory  VASYL ALBA (Presenter), MADHAV MANI, RICHARD CARTHEW, Northwestern University, JAMES CARTHEW, The University of British Columbia — We used machine vision and information theory approach to address a question of quantitative description of the morphological traits in biological systems. We used a population of fruit flies that was under developmental pressure to demonstrate the potential of the newly developed method. In particular, we changed diet and temperature to increase morphological variation.

3:54PM C66.00008: Activity driven buckling in early steps of organogenesis*  FRANCESCO SERAFIN (Presenter), SURAJ SHANKAR, BENJAMIN LOEWE, Syracuse University, BORIS I SHRAIMAN, MARK BOWICK, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, M. CRISTINA MARCHETTI, Physics Department, University of California Santa Barbara — Morphogenesis, the complex process by which the shape of organs and organisms emerges from cell organization, intertwines chemical and physical processes. In many situations, 3D biological structures are achieved through targeted active folding processes of 2D tissue layers. An example is the process of lumen formation – the buckling, folding and invagination of a planar cell sheet that leads to the formation of a hollow cavity enwrapped by a polarized epithelium. In this talk, starting with an active elastic continuum description of a cellular tissue layer of finite thickness, we derive an effective 2D model that includes contractility and cell division. We show that the model can account for the buckling instability at the onset of lumen formation. We find that traction localizes contractile stresses at the boundary of the tissue, while cell division induces an in-plane outward pressure. These two competing effects destabilize the initial planar state forcing the tissue to buckle.

*This work was supported by the NSF grants DMR-1609208, DMR 1720256 (iSuperSeed) and PHY-1748958 (KITP) and by the Simons Foundation Targeted Grant in the Mathematical Modeling of Living Systems Number 342354.

4:06PM C66.00009: Active junctions as a pathway to stress generation in morphogenesis*  SILKE HENKES (Presenter), ILYAS DJAFER-CHERIF, Mathematics, University of Bristol, LUKE COBURN, ICSMB, University of Aberdeen, GUILLERMO SERRANO-NAJERA, KEES WEIJER, RASTKO SKNEPNEL, SLS, University of Dundee — During gastrulation, and other development stages like germ band extension, epithelial cell sheets spontaneously organise to exert contractile mechanical forces, resulting in convergence-extension flow. Current models assume different types of chemical signalling based pre-patterning of the junctions, leading to both tension and flow. Here we present a model of self-amplifying contractile cell sheets that posits a myosin-dependent junction contractility with a tension-dependent feedback loop. This active mechanics model leads to the spontaneous formation of tension chains with both isotropic characteristics and directionality in the presence of an applied stress. We discuss the necessary and sufficient ingredients for the local mechanics to generate chains, and then focus on the flow that results from the activated junctions. We find that disordered flow arises spontaneously, and characterize the conditions for convergence-extension flow using small active cell groups embedded in a passive matrix.

4:18PM C66.00013: Coordination of epithelial cells during morphogenesis. MATTHIAS HÄRING (Presenter), Max Planck Institute for Dynamics and Self-Organization, PRACHI RICHA, JÖRG GROSSHANS, Universitätsmedizin Göttingen, FRED WOLF, Max Planck Institute for Dynamics and Self-Organization — Despite a long-standing effort to uncover the physical principles governing animal morphogenesis, the knowledge of embryonic tissue mechanics remains elusive. We address the physical aspects of embryonic tissue mechanics using fruit fly gastrulation as a model. During this process, a subset of cells in the ventral part of the embryo constrict on one side and subsequently invaginate into the interior of the embryo, thereby causing the embryonic surface to form a furrow. To determine the mechanism of tissue shape change during gastrulation, we have developed a toolbox of biophysical methods that allow accurate quantification of material tissue properties in live fruit fly embryos. Specifically, we have developed magnetic tweezeers exploiting either fluorescent magnetic microspheres or ferrofluid droplets, as well as flexible cantilevers microfabricated from PDMS, allowing highly quantitative measurements of the rheological properties in the early fly embryo. Our measurements directly translate into a predictive theory that explains key aspects of tissue dynamics during fruit fly gastrulation. Specifically, our model explains the marked anisotropy of tissue constriction in the initial phase of gastrulation as well as the mechanism of tissue invagination during the subsequent phase.

4:30PM C66.00010: Physical Aspects of Drosophila gastrulation. KONSTANTIN DOUBROVINSKI (Presenter), Biophysics, MPI-KS, AKANKSHA JAIN, PAVEL TOMANČAK, Tomancak, MPI-CBG, STEPHAN W GRILL, Biophysics, TU Dresden — Gastrulation is a critical step during the development of multicellular organisms in which a single-layered tissue folds into a multi-layered germ band. This shape change is characterized by tissue folding and large-scale tissue flow. The myosin-dependent forces that underlie this process have been increasingly investigated; however, thus far, the possible interaction between the moving tissue and the rigid shell surrounding the embryo has been neglected. Here, we present our quantitative findings on the physical mechanisms governing gastrulation in the red flour beetle, Tribolium castaneum. We investigated the forces expected within the tissue given the myosin distribution observed by multi-view light-sheet microscopy and discovered that an additional external force must be counteracting this tissue-intrinsic contractility. We then identified that a specific part of the tissue tightly adheres to the outer rigid shell. This attachment is mediated by a specific integrin whose knock-down leads to a complete loss of the counter-force. Moreover, in the fruit fly Drosophila melanogaster, knock-down of another integrin leads to a severe twist of the germ band, suggesting that the integrin-mediated interaction between tissue and vitelline envelope may be conserved in insects.

4:30PM C66.00011: External forces generated by the attachment between blastoderm and vitelline envelope impact gastrulation in insects. STEFAN MÜNESTER (Presenter), Biophysics, TU Dresden, ALEXANDER MIETKE, Biophysics, MPI-KS, AKANKSHA JAIN, PAVEL TOMANČAK, Tomancak, MPI-CBG, STEPHAN W GRILL, Biophysics, TU Dresden — Gastrulation is a critical step during the development of multicellular organisms in which a single-layered tissue folds into a multi-layered germ band. This shape change is characterized by tissue folding and large-scale tissue flow. The myosin-dependent forces that underlie this process have been increasingly investigated; however, thus far, the possible interaction between the moving tissue and the rigid shell surrounding the embryo has been neglected. Here, we present our quantitative findings on the physical mechanisms governing gastrulation in the red flour beetle, Tribolium castaneum. We investigated the forces expected within the tissue given the myosin distribution observed by multi-view light-sheet microscopy and discovered that an additional external force must be counteracting this tissue-intrinsic contractility. We then identified that a specific part of the tissue tightly adheres to the outer rigid shell. This attachment is mediated by a specific integrin whose knock-down leads to a complete loss of the counter-force. Moreover, in the fruit fly Drosophila melanogaster, knock-down of another integrin leads to a severe twist of the germ band, suggesting that the integrin-mediated interaction between tissue and vitelline envelope may be conserved in insects.

4:42PM C66.00012: Optogenetic control of contractile tissue forces during Drosophila morphogenesis. MARISOL HERRERA PEREZ (Presenter), KAREN E. KASZA, Columbia University — Epithelial tissues undergo dramatic changes in shape during development. These changes are driven in large part by contractile forces generated by the actomyosin cytoskeleton of cells. In addition to physically shaping cells and tissues, mechanical forces can act as cues to influence cell behavior and could help coordinate cell behaviors across multicellular tissues. A major obstacle to dissecting the mechanisms of how mechanical forces shape tissues has been the lack of tools for precise manipulation of forces in vivo. To address this, we have developed a collection of optogenetic tools to locally and systematically modulate actomyosin contractility in the Drosophila embryo. With these tools, we have demonstrated local, light-gated myosin recruitment, and changes in myosin localization patterns across tissues. Using these tools in combination with live confocal imaging and quantitative images analysis, we find that inducing contractile forces in small groups of cells in an epithelial tissue can deform and influence cell behaviors across the tissue in the developing embryo. These studies are shedding light on the roles of mechanical cues in coordinating cell behaviors in multicellular tissues during development.

4:42PM C66.00013: Coordination of epithelial cells during morphogenesis. MATTHIAS HÄRING (Presenter), Max Planck Institute for Dynamics and Self-Organization, PRACHI RICHA, JÖRG GROSSHANS, Universitätsmedizin Göttingen, FRED WOLF, Max Planck Institute for Dynamics and Self-Organization — Epithelial cells are capable of sensing and reacting to the forces and movements of their neighbours. We fully quantify the dynamics of epithelial tissue using a novel high-throughput image analysis pipeline based on deep neural networks. Inspired by graph theory, we decompose cell-cell interactions into three distinct coupling types. With this approach, the epithelium can be represented by a planar graph of cell couplings whereby cells are interpreted as vertices and junctions between cells as edges. Utilizing graph-theoretic measures, we compare wild type tissue and mutants with impaired signal transduction capabilities revealing significant differences in e.g. composition of coupling types and spatial distributions. In contrast to the wild type, tension in those mutants is anisotropically distributed, indicating that local cell-cell coordination through mechano-sensing is essential for the function of an epithelium as force-generating tissue.
5:06PM C66.00014: Cell-cell adhesion in tissue mechanics and morphogenesis  XUN WANG, KAREN KASZA (Presenter), Mechanical Engineering, Columbia University — During development, simple epithelia reorganize into tissues with complex form and structure. Tissue reorganization during morphogenesis can be rapid. In Drosophila, cell rearrangements in the embryonic epithelium double the length of the body axis in 30 minutes. Adhesion at cell-cell contacts, mediated by junctional proteins, and contractile tension, generated by actomyosin, are thought to be key machineries controlling epithelial tissues. However, it remains unclear how the balance between adhesion and tension determines epithelial structure and mechanics. To gain insight, we are systematically modulating the balance between adhesion and tension in vivo. E-cadherin is a primary component of cell-cell adhesions. Using multiple approaches, we increase or decrease E-cadherin levels relative to wild type and use confocal imaging to study the effects on cell shapes and movements. We find that modulating adhesion influences cell shapes prior to the onset of axis elongation as well as cell rearrangement rates during elongation. We will discuss how our results compare to vertex model predictions. These systematic, quantitative experimental studies of tissue mechanics in vivo are an essential step in building models of morphogenesis.

5:18PM C66.00015: Superstretching epithelial sheets  ERNEST LATORRE-IBARS, Institute for Bioengineering of Catalonia (IBEC), SOHAN KALE, Polytechnic University of Catalonia, XAVIER TREPAT, Institute for Bioengineering of Catalonia (IBEC), MARINO ARROYO (Presenter), Polytechnic University of Catalonia — During morphogenesis, cell monolayers need to change their shape in various ways. For instance, cell monolayers undergo very large stretching during blastocyst hatching in mammalian embryos. In this talk, I will discuss a mechanism by which epithelial tissues can withstand extreme stretches without significantly increasing tissue tension, which would otherwise compromise tissue integrity [1]. I will describe how, under applied tension, epithelial cells can adopt two “metastable” states, one in a barely stretched state, and one in a superstretched state. This phase coexistence allows tissues to further stretch at constant tension by switching cells into the super-stretched phase, in close analogy with the phenomenology of superelasticity exhibited by NiTi alloys or by intermediate filaments. In epithelial monolayers, this phenomenology has an active origin that depends on cytoskeletal dynamics. I will present experimental evidence of epithelial active superelasticity, a theoretical model explaining it and bridging from cytoskeletal dynamics to emergent material behavior, and will discuss the implications during morphogenesis.

Monday, March 4, 2019 2:30 PM - 5:30 PM

Session C67 APS/SPS: Undergraduate Research III  BCEC 050 - Brad Conrad, American Institute of Physics - Tag(s): Undergraduate

2:30PM C67.00001: Neuronal dynamics on patterned substrates measured by fluorescence microscopy*  JOAO MARCOS VENSI BASSO (Presenter), CRISTIAN STAII, Physics and Astronomy, Tufts University — Geometrical features are known to be very important in neuronal growth and the formation of neuronal networks. We present experimental and theoretical investigations of axonal growth and dynamics for neurons cultured on patterned surfaces. We utilize fluorescence microscopy to image the axonal dynamics and show that these substrates impart a strong directional bias to neuronal growth. We model axonal dynamics using a general stochastic model and use this framework to extract key dynamical parameters. These results provide novel insight into how geometrical cues influence neuronal growth and represent important advances toward bioengineering neuronal growth platforms.

*Tufts Faculty Research Award
ANDREA CAPA SALINAS (Presenter), JESUS VELASQUEZ, PEI-CHUN HO, Physics, California State University, Fresno — When a temperature gradient is imposed at the ends of a conducting material, a voltage will be generated on this material. This phenomenon is known as the Seebeck effect and is characterized by the Seebeck coefficient. Thermopower, or Seebeck coefficient measurements, can provide a deeper understanding of the properties of a sample, its normal state behavior, and help progress on applications, such as thermoelectric generators, cooling systems, and temperature measurement devices. The samples of interest for thermopower measurements in our lab are filled-skutterudite compounds, for they exhibit thermoelectric effects. For this purpose, a thermopower measurement probe was designed and its resolution tested using Nickel 201 alloy and platinum samples. It was concluded that the device provides measurements within 3% error in the 100K-300K range. However, measurements below 100K must be improved, since current data indicates measurements are limited by the operating range of the type-T thermocouple used. Thus, future improvement will consist of adding a Cernox thermometer on the hot platform to account for a more accurate temperature difference at low temperatures.

*Research at CSU-Fresno is supported by NSF DMR-1506677.

GREGORY PRICE (Presenter), Chemistry and Physics, Augusta University, UMESH KUMAR, Physics and Astronomy, University of Tennessee, KENNETH C STIWINTER, Chemistry and Physics, Augusta University, STEVEN JOHNSTON, Physics and Astronomy, University of Tennessee, TRINANJAN DATTA, Chemistry and Physics, Augusta University — Resonant inelastic x-ray scattering (RIXS) is a novel spectroscopic method for probing charge and spin excitations in quantum magnets. In one dimension, where quantum fluctuations are most prominent, a system of interacting electrons can support fractionalized spinless charge excitations (holons) and chargeless spin excitation (spinons). Currently, X-ray spectroscopic techniques such as RIXS can excite the O K-edge core electrons of correlated quantum magnets to probe the physical nature of the above mentioned spin-charge separated state. Using exact diagonalization we investigate the O K-edge RIXS response of the one dimensional antiferromagnetic spin chain compound with nearest and next-nearest neighbor hoppings. We also study the spin-anisotropic version of the same model. Interaction of the core electrons with the X-rays generate multi-spinon excitations in the RIXS spectrum, for example in strontium copper oxide. We find that the RIXS spectrum of the $t_1-t_2-J$ model with spin anisotropy presents a rich source of physical information, including allowing us to identify microscopic pathways for how the quantum spin fluctuations control the appearance of the four spinon excitations observed in the isotropic O K-edge spectrum.

EMILY SUTHERLAND (Presenter), QUE HUONG NGUYEN, Physics, Marshall University — We report a theoretical research on Wannier-Frenkel hybrid exciton in a semiconductor nanorod coated by an organic shell.

There are two kinds of excitons in solids: the Frenkel exciton in molecular and organic materials and the Wannier-Mott exciton in semiconductors. The two kinds of excitons have very different and complementary properties. In heterostructure combining of semiconductors and organic materials with exciton energies close to each other, the coupling between them will form a hybridization state having complimentary properties of both kinds of excitons.

Our model considers a system consisting of a semiconductor nanorod coated by a thin shell of an organic material. At the surface of the nanorod, due to a dipole-dipole interaction a hybridization exciton state will be formed. The electronic structures, the energies, wave function as well as dispersion relations of the new hybrid exciton state will be obtained, depending on the size and the parameters of the rod and the materials. We also investigate the effect of applying an external electric field on the hybrid excitons.

ALEXANDER GLICKFIELD (Presenter), GONZALO ORDONEZ, Butler University — The Friedrichs model consists of an interaction between the discrete states of a quantum system (say, a set of atoms) and a set of continuous states. The interaction produces a resonance, resulting in complex eigenenergies. The resonance appears as a pole of the analytic continuation of the reduced resolvent corresponding to the interacting Hamiltonian. As the imaginary component approaches 0, the eigenstate's lifetime becomes infinite, forming a bound state in the continuum. We solve for a set of parameters that generates multiple resonances with infinite lifetime within the model.
3:30PM C67.00006: Static and dynamic properties of a one-dimensional spin-1/2 system*  
AVIVA SHOOMAN (Presenter), LEA SANTOS, Yeshiva University — We study the static properties and the dynamics of a quantum system described by a one-dimensional spin-1/2 model with nearest neighbor couplings. We analyze the eigenvalues and the eigenstates of this model with different chain sizes and different boundary conditions. From this analysis, we are able to anticipate how fast the excitations should spread over the chain. The more delocalized the eigenstates are, the faster the excitations should move along this chain. Next, we study the evolution of the system numerically and confirm our predictions. All our Mathematica codes are available upon request.

3:42PM C67.00007: Charge Density Wave States in CeTe2  
BURHAN AHMED (Presenter), BISHNU SHARMA, MANOJ SINGH, BONING YU, Clark University, PHILIP WALMSLEY, IAN R FISHER, Stanford University, MICHAEL C BOYER, Clark University — Charge density wave (CDW) states are formed in some, typically low-dimensional, materials below a transition temperature, T_{CDW}. The transition of a material into a CDW state leads to the formation of a periodic charge modulation, a periodic lattice modulation, and the opening of an energy gap. While CDW states exist in many condensed matter systems, there is much to be known about the driving-mechanisms for these states as well as how these states coexist with other phases such as superconductivity. Here we present our work using scanning tunneling microscopy (STM) to study CDW states in CeTe2, a rare-earth ditelluride with a CDW transition well over room temperature. In particular, we will present our work on quantifying nanoscale strain in CeTe2 in an effort to better understand the local properties of the CDW states we observe.

3:54PM C67.00008: Development and characterization of an improved wireless centrifuge force microscope using acrylate microspheres and silicon nitride membranes*  
LOGAN FAIRGRIEVE-PARK (Presenter), TRISTAN STARK, DAVID FORTIN, Department of Physics, University of Alberta, AMY AU, Ross Sheppard High School, MICHAEL WOODSIDE, NOEL Q HOFFER, MARK FREEMAN, Department of Physics, University of Alberta — Centrifuge force microscopy allows for multiple concurrent single molecule measurements which cannot be achieved using more traditional experimental platforms. By altering the design of a wireless centrifuge force microscope (CFM) created at the University of Albany [1], we have developed an improved model. By upgrading the integrated single board computer to a Rock64 (Pine Microsystems Inc.) with a USB 3 connector we can achieve higher image transfer rate. Additionally, we describe a novel technique for CFM calibration. By adhering acrylate microspheres of multiple sizes to a silicon nitride membrane (Norcada) [2], we are able to quantify membrane displacement as a function of centripetal force. This technique could be extended to other CFMs as a method for calibration of the centrifuge and optics. Upon completion of the experimental use of the CFM, it will be integrated into a senior undergraduate physics lab course at the University of Alberta.

*We gratefully acknowledge funding from the University of Alberta Teaching and Learning Enhancement Fund, the Faculty of Science, and the Canada Foundation for Innovation.
4:06PM C67.00009: Surface Species in Graphene Liquid Cells for Transmission Electron Microscopy* NATHAN ROSEN Mann (Presenter), LOPA BHATT, ARUNACHALA NUTALAPATI, SOOMIN PARK, JAKE R JOKISAARI, MARK SCHLOSSMAN, ROBERT KLIE, Physics, University of Illinois at Chicago — The behavior of nanoparticles in liquid is important to a wide variety of fields, from medical to environmental. The aggregation of such particles is an important factor for nanoparticle removal during processes such as water purification. However, due to their size, nanoparticles in solution are difficult to characterize directly by optical or x-ray based methods. An effective method to observe nanoparticles in liquid is using the scanning transmission electron microscope(STEM) combined with graphene-based liquid cells(GLC).

The preparation of GLC’s usually requires wet chemical etching steps which often leave surface species on the etched graphene. This may change the properties of the water-graphene interface depending on the chemicals used for the etching process, and the surface species produced from the reactions. In this contribution we examine the presence of such species using a combination of STEM, energy dispersive x-ray analysis(EDX), and Raman spectroscopy to analyze the molecular species present at the graphene interface in the GLC’s and how certain surface species affect liquid cells containing gold nanoparticles.

*Supported by the Chancellor’s Undergraduate Research Award. Made use of instruments in the Electron Microscopy Service at Research Resources Center, UIC.

4:18PM C67.00010: Using the "EasySpin" toolbox in MATLAB to model the magnetism of clusters and chains* ORLANDO TREJO (Presenter), MARK MEISEL, Dept. of Physics and NHMFL, University of Florida, ERIK CIZMAR, Dept. of Condensed matter, Institute of Physics, P.J. Šafárik University — The “EasySpin” toolbox [1], which runs within MATLAB software, was designed as an analysis tool of EPR spectra. Yet, the 4.5 version of the toolbox was used to generate algorithms that allowed the isothermal magnetization and temperature-dependent magnetic susceptibility of clusters to be modelled [2,3]. Now, the 5.2 version contains library functions that allow these magnetic properties to be calculated. The first step was to compare the results of the new version with the published work [2,3]. Next, the magnetic response of [Mn₃O(O₂PPh₂)₃(mpko₃)] [4] was simulated with “EasySpin”, and these results will be discussed. Ultimately, the goal is to simulate the low-field, temperature-dependent, magnetic susceptibility reported for an S = 1, one-dimensional spin chain, [Ni(HF₂)(3-Clpy)₄]BF₄ [5] with nearest-neighbor interactions, J, and single-ion anisotropy, D. These results will be presented for chain lengths of at least 7 spins.

*NSF via DMR-1708410 (MWM) and DMR-1644779 (NHMFL).

4:30PM C67.00011: Switching of biaxial synthetic antiferromagnets: a micromagnetic study* MICHAEL ACKERMANN (Presenter), SATORU EMORI, Department of Science, Virginia Tech — We simulate the switching behavior of nanoscale synthetic antiferromagnets, inspired by recent experimental progress in spin-orbit-torque switching of crystal antiferromagnets. The synthetic antiferromagnet consists of two ferromagnetic thin films with in-plane biaxial anisotropy and interlayer exchange coupling, which leads to enhanced stability against external field perturbations compared to single-layer ferromagnets. Switching between the orthogonal easy axes is enabled by current-induced Rashba spin-orbit fields from the opposite surfaces of the synthetic antiferromagnet. The use of the field-like spin-orbit torque allows for faster switching with increased Gilbert damping, without a significant detrimental increase of the threshold switching current density. Our results point to the potential of these model systems, based on simple ferromagnetic metals, to mimic antiferromagnetic device physics.

Implementation of a microwave readout for scanning superconducting quantum interference devices (SQUIDs)*

RACHEL RESNICK (Presenter), JUSTIN OH, Cornell University, FARSHAD FOROUGHI, JAN-MICHAEL MOL, RWTH Aachen University, ALEXANDER B JARJOUR, DAVID LOW, Cornell University, JOHN ROBERT KIRTLEY, Stanford University, HENDRIK BLUHM, RWTH Aachen University, KATJA NOWACK, Cornell University — In scanning superconducting quantum interference device (SQUID) microscopy a SQUID is rastered close to the surface of a sample to obtain images of the sample's magnetic properties. In this talk we will discuss a microwave readout for scanning SQUIDs that incorporate an on-chip capacitor as reported in [1]. In this case, the SQUID acts as a flux-dependent inductor, that forms an LC resonant circuit with the on-chip capacitor. The phase and amplitude of microwaves reflected by this circuit encode changes in magnetic flux. We will present our progress towards implementing this microwave readout and characterizing the SQUID noise performance at mK temperatures. The microwave readout holds the promise to both increase our flux sensitivity to below 100nPhi_0/sqrt(Hz) and our measurement bandwidth to several hundreds of MHz [1].

*This work was supported by the Cornell Center for Materials Research with funding from the NSF MRSEC program (DMR-1719875). The SQUIDs used in this study were developed under an NSF IMR-MIP contract, Award No. 0957616.

Optimizing a cryogen-free measurement system for measurement of single electron devices

LETICIA DAMIAN (Presenter), JUSTIN K PERRON, California State University San Marcos, San Marcos, Ca 92069 — Single electron devices (SEDs) are electronic devices capable of isolating individual electrons along a conducting path. This ability has many proposed applications including their use in metrology, and quantum information science. Recently our lab has installed a cryogen-free dilution refrigeration system for the purpose of investigating SEDs and their use in these applications. In this talk I will describe our efforts in optimizing the electrical measurement setup of this system. Our primary metric for optimization is electron temperature, a limiting factor in measurements of this type.

Kinetic Separation of Hydrogen Isotopes in Metal-Organic Frameworks*

KATHARINE RIGDON (Presenter), NAIYUAN (JAMES) ZHANG, STEPHEN FITZGERALD, Oberlin College — Deuterium is a valuable hydrogen isotope with applications in NMR, nuclear power, and as a medical tracer. It constitutes less than 0.02% of naturally occurring hydrogen and is challenging to isolate. Current industrial separation techniques, which rely on tiny differences in the isotopes' chemical behavior, are expensive and energy intensive. Recently a new approach based on difference in the confined isotopes' zero-point energy has emerged. While these "quantum sieving" methods exhibit higher selectivity, many practical obstacles remain for them to replace the standard chemical approach. I will present data on a kinetics based separation within highly porous pellets of metal-organic frameworks (MOF). Mass spectroscopy with isotope mixtures shows breakthrough times that differ by more than three minutes. While these results are obtained at liquid nitrogen temperature, it is expected that planned experiments with the MOF known as Cu-MFU-4l should produce similar time differences at room temperature.

*NSF grant # CHE-1565961

Quantitative Imaging of Cytoskeletal Filaments of C17.2 Cells

JAY MAGERS (Presenter), JULIA HUTSKO, Physics, Susquehanna University, SABRINA JEDLICKA, SWETHA CHANDRASEKAR, Material Science, Lehigh University, SLAVA V. ROTKIN, Material Research Institute, Penn State, MASSOOMA PIRBHAI, Physics, Susquehanna University, LISA SCHNEIDER, Math and Computer Science, Salisbury University — The ability of cells to resist deformation, to transport intercellular cargo and to change shape during movement depends on the cytoskeletal filaments. Recent work has demonstrated that internal and external stimuli can affect these filaments and thus cellular behavior. Therefore, it is important to understand how to quantitatively extract data about the network of filaments and their changes. This research focuses on the modeling of the cytoskeletal networks to create a catalogue of them. While many cell analysis programs already exist, most are complex to use and are designed to analyze multiple types of cells and situations with limited customization in the program's analysis. Therefore, in order to obtain a more specialized analysis, different programming languages were explored in order to develop a custom analysis method. Several custom program were developed primarily utilizing the Python image analysis library OpenCV and MATLAB. This talk will explore the actin structures in C17.2 neural stem cells and compare the different programs' methods and capability to segment individual cells then calculate their fluorescent density.

Monday, March 4, 2019 2:30 PM - 4:54 PM

2:30PM C69.00001: The Universe as a Quantum Computer* [Invited] SETH LLOYD (Presenter), Massachusetts Institute of Technology — Every elementary particle carries with it bits of information that describe its type, charge, mass, position, and velocity. Every time two or more particles interact, that information is transformed and processed. The universe computes; and it computes in a way that is governed by the laws of quantum mechanics. The computational nature of the universe has nontrivial implications for its history, including how complex structures are generated, and the future of these structures. This talk discusses the implications of quantum information processing for the history and future of the universe.

*This work was funded by NSF

3:06PM C69.00002: Does This Ontological Commitment Make Me Look Fat? A Defense of Many-Worlds [Invited] SEAN CARROLL (Presenter), Caltech — The Everettian or Many-Worlds formulation of quantum mechanics features the simplest and most straightforward set of concepts and equations, but comes at the cost of the non-uniqueness of our observed part of reality. I will give a brief introduction to this approach, and discuss both a set of misguided objections and some true challenges. Among the true challenges are the issue of structure (how do complicated aspects of observed reality emerge from an austere vector in Hilbert space?) and probability (why are probabilities given by amplitudes squared if every outcome happens on some branch of the wave function?).

3:42PM C69.00003: The Relational Interpretation of Quantum Mechanics [Invited] CARLO ROVELLI (Presenter), Aix-Marseille University — The Relation Interpretation of Quantum Mechanics is a refinement of textbook “Copenhagen” quantum mechanics, which is receiving increasing attention. It does not assume an absolute split of the world into “quantum system” and “classical observer”; it rather assumes that any physical system can play either role. It avoids the “many worlds” of some Everettian interpretations, the un-observable entities of Bohmian interpretations, as well as the un-observed dynamical collapse of physical-collapse theories. The prices to pay is to accept that all physical quantities are relational, in the sense in which velocity is relational in classical mechanics: it expresses a relation between a system another system. I shall illustrate this understanding of quantum theory in detail and compare it with different and similar ways of viewing quantum mechanics.

4:18PM C69.00004: Quantum theory of the classical: quantum jumps, Born’s Rule and objective classical reality via quantum Darwinism [Invited] WOJCIECH ZUREK (Presenter), Los Alamos National Laboratory — The emergence of the classical from the quantum substrate is a long-standing conundrum. I will describe three insights into the transition from quantum to classical based on recognition of the role of the environment [1]. I will first derive preferred sets of states that define what exists -- our everyday classical reality. They arise as a result of breaking of the unitary symmetry of the Hilbert space resulting from the conflict between linearity of quantum evolutions and nonlinearities inherent in the process of amplification -- of replicating information. This accounts for quantum jumps and the emergence of the preferred pointer states consistent with those obtained via environment-induced superselection, (einselection), but is accomplished without the usual tools of decoherence. Pointer states determine what can happen -- define events -- without appealing to probabilities. Therefore, Born’s Rule can now be deduced from entanglement-assisted invariance, or envariance -- a symmetry of entangled quantum states. Envariance also provides new basis for statistical physics, allowing one to deduce thermodynamics from symmetries of entanglement -- that is, without the need for ensembles [2]. Information flows accompanying decoherence explain how the perception of objective classical reality arises from the quantum substrate: the effective amplification they represent accounts for the objective existence of the einselected states of macroscopic quantum systems through redundancy of their records in the environment -- through quantum Darwinism [1].

Session E01 DCMP: Electronic Structures of Weyl Semimetals and Topological Insulators BCEC 106 - Andrew Weber, Donostia International Physics Center

8:00AM E01.00001: Evolution of the Electronic Structure of MoTe2 under Pressure YAJIAN HU (Presenter), YUK TAI CHAN, KWING TO LAI, KIN ON HO, XIAOYU GUO, KING YAU YIP, SWEE KUAN GOH, Physics, The Chinese University of Hong Kong, YUJI AOKI, TATSUMA D. MATSUDA, Department of Physics, Tokyo Metropolitan University — Transition metal dichalcogenides have recently been heavily studied owing to their intriguing physical properties such as extremely large magnetoresistance (MR) in WTe2 and MoTe2. Further interests are attracted when they are predicted as candidates of type-II Weyl semimetals. Moreover, as both WTe2 and MoTe2 host superconductivity, this opens up the possibility of topological superconductivity.

In this work, we present the magneto-electronic transport study of MoTe2 under pressure. We did the magneto-resistance measurement with magnetic field up to 14 T and temperature down to 30 mK. The large MR and the Hall coefficient decrease rapidly with increasing pressure. Beyond 10 kbar, where the $T_d$ phase is completely suppressed and the superconducting transition temperature $T_c$ is significantly enhanced, the Hall coefficient becomes very small and saturated. We will discuss the evolution of Fermi surface across the temperature-pressure phase diagram. The electronic structure study would help us investigate the ground state and superconductivity of MoTe2.
**8:12AM E01.00002:** Crystal structure and electronic structure of non-centrosymmetrical trigonal PtBi₂*

WENXIANG JIANG (Presenter), FENGFENG ZHU, PING LI, HAIYANG MA, HAOHUA SUN, ZHONGQIANG YANG, CANHUA LIU, DANDAN GUAN, JINFENG JIA, WEIDONG LUO, DONG QIAN, Department of Physics and Astronomy, Shanghai Jiao Tong University — Electronic structure of single crystalline y-PtBi2 is studied by angle-resolved photoemission spectroscopy (ARPES). It is proposed by theoretical calculation that the stable structure of y-PtBi2 should be non-centrosymmetric. ARPES measurement gives powerful evidences in this paper that different band structures between two types of cleaved surface are clearly observed. Bulk and surface bands are characterized through systematically photon dependent measurement. The bulk band dispersions agree well with the first-principle calculation except Rashba shaped surface states. The topography studied by STM also confirms the existence of two different cleaved surfaces. Besides, some efforts has been made to demonstrate the existence of triply degenerate point fermions.

**8:24AM E01.00003:** Spin-Resolved Electronic Response to the Phase Transition in MoTe₂*

ANDREW WEBER (Presenter), Donostia International Physics Center, PHILIPP RÜSSMANN, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, NANN XU, Swiss Light Source, Paul Scherrer Institute, STEFAN MUFF, MAURO FANCIULLI, ARNAUD MAGREZ, PHILIPPE BUGNON, HELMUTH BERGER, Institute of Physics, École Polytechnique Fédérale de Lausanne, NICHOLAS C PLUMB, MING SHI, Swiss Light Source, Paul Scherrer Institute, STEFAN BLUEGEL, PHIVOS MAVROPOULOS, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, J. HUGO DIL, Institute of Physics, École Polytechnique Fédérale de Lausanne — The Weyl semimetal MoTe₂ is studied by spin- and angle-resolved photoemission spectroscopy across the centrosymmetry-breaking structural transition temperature of the bulk. A three-dimensional spin-texture is observed in the bulk Fermi surface in the low temperature, noncentrosymmetric phase that is consistent with first-principles calculations. The spin texture and two types of surface Fermi arc are not completely suppressed above the bulk transition temperature. The lifetimes of quasiparticles forming the Fermi arcs depend on thermal history and lengthen considerably upon cooling toward the bulk structural transition. The results indicate that a new form of polar instability exists near the surface when the bulk is largely in a centrosymmetric phase.

**8:36AM E01.00004:** Investigation of the magnetic Weyl semimetal candidate Co₃Sn₂S₂ by ARPES.*

ILYA BELOPOLSKI (Presenter), TYLER COCHRAN, Princeton University, ENKE LIU, YU-HSIN SU, Max Planck Institute for the Chemical Physics of Solids, JIAJIN YIN, GUOQING CHANG, SONGTIAN SONIA ZHANG, Princeton University, ZURAB GUGUCHIA, Paul Scherrer Institut, CLAUDIA FELSER, Max Planck Institute for the Chemical Physics of Solids, ZAHID HASAN, Princeton University — Topological phases in magnetic materials are a topic of current interest in the community. Recently, the kagome-lattice ferromagnet Co₃Sn₂S₂ was predicted to be a Weyl semimetal, while transport showed an exceptionally large anomalous Hall angle. Motivated by these exciting results, we use synchrotron ARPES to study single crystal Co₃Sn₂S₂. We observe a strong photon energy dependence consistent with out-of-plane $k_z$ dispersion, even at moderate VUV photon energies. We compare our ARPES results with DFT and find a general match, with typical disagreement of ~ 0.1 eV. To address this disagreement, we perform muon/neutron scattering on Co₃Sn₂S₂ to better understand the magnetic state experimentally. We comment on progress using our muon/neutron results to match DFT to ARPES and evaluating possible changes in the predicted Weyl phase and other topological indices. Our results suggest that the search for topological magnets might benefit from an iterative approach building on muon/neutron measurements of the magnetic state, DFT and ARPES.

8:48AM E01.00005: Surface resonances of topological origin in bcc iron*  OLEG YAZYEV (Presenter), DANIEL GOSÁLBEZ MARTÍNEZ, GABRIEL AUTÉS, Ecole Polytechnique Fédérale de Lausanne (EPFL), Switzerland — Chiral band degeneracies are ubiquitous in the band structures of systems with broken inversion or time-reversal symmetries. While in Weyl semimetals such degeneracies are isolated near the Fermi level, the broadly defined notion of topological metal implies the presence of disconnected Fermi surface sheets characterized by non-zero Chern numbers. Bcc iron is an archetypal example of ferromagnetic metal with two non-trivial Fermi surface electron pockets along the direction parallel to the magnetization [1]. In this work, we investigate the surface-state signatures of the topological nature of these Fermi surface pockets. We find that the (110) surface presents arc-like resonances attached to the non-trivial electron pockets. These Fermi arc resonances are due to two chiral degeneracies, a type-I elementary Weyl point and a type-II composite (Chern number ±2) Weyl point, located at slightly different energies. We further show that such surface resonances can be controlled by the orientation of magnetization, and can eventually be eliminated following a topological phase transition.

*We acknowledge support by the NCCR Marvel.

9:00AM E01.00006: Sharp Orientation-dependent Quantum Oscillations in HoPtBi  CONNOR RONCAIOLI (Presenter), PRATHUM SARAF, YUN SUK EO, HYUNSOO KIM, JOHNPIERRE PAGLIONE, University of Maryland, College Park — Rare-earth platinum and palladium-bismuthides have been host to rich phenomenon in the search for topological states and Weyl semimetals. YPtBi in particular is host to a spin-split fermi surface which hosts a spin-3/2 superconducting state. In this study we expand this investigation to HoPtBi, a magnetic analog to YPtBi with an AFM ground state and a paramagnetic state above 1.2K. We present orientation-dependent measurements of quantum oscillations in HoPtBi and find a strong orientation dependence near the crystallographic [110] direction very similar to, but phenomenologically distinct from the behavior of YPtBi.

9:12AM E01.00007: Observation of surface Dirac dispersion in transition metal dipnictides*  GYANENDRA DHAKAL (Presenter), MD MOFAZZEL HOSEN, University of Central Florida, WEI-CHI CHIU, BAHADUR SINGH, Department of Physics, Northeastern University, KLAUSS DIMITRI, University of Central Florida, BAOKAI WANG, Department of Physics, Northeastern University, FIROZA KABIR, CHRISTOPHER SIMS, SABIN REGMI, University of Central Florida, HSIN LIN, Institute of Physics, Academia Sinica, DARIUSZ KACZOROWSKI, Institute of Low Temperature and Structure Research, Polish Academy of Sciences, ARUN BANSIL, Department of Physics, Northeastern University, MADHAB NEUPANE, University of Central Florida — The experimental discovery of Dirac and Weyl Fermions, quasi-particles existing in low energy excitation in condensed matter physics, has paved a new avenue of research interests in condensed matter physics. Recently, the Lorentz-invariance breaking Weyl semimetallic state has been reported in MoP2 and WP2. Arsenic counterparts of these compounds, which also harbor high magnetoresistance, demand the detailed study to investigate the possible semimetallic state possessed by them. Here, we discuss our angle-resolved photoemission spectroscopy (ARPES) and first-principles calculations results on the electronic structures of MoAs2 and WAs2, which reveal the presence of a surface Dirac cone. Our systematic electronic structures analysis reveals the termination dependent electronic structure in these compounds. Our study offers the opportunity to study the various quantum phase transitions within this family.

*This work is supported by the Air Force Office of Scientific Research under Award No. FA9550-17-1-0415 and the startup fund from UCF (M.N.).

9:24AM E01.00008: ARPES measurements on Dirac nodal-line semimetal candidate TiRhAs  HANG LI (Presenter), DAYU YAN, CONGCONG LE, BINBIN FU, YOUGUO SHI, HONG DING, TIAN QIAN, Chinese Academy of Sciences — In the family of topological materials, a new Dirac nodal-line (DNL) semimetal TiRhAs was recently predicted by first-principles calculations. Unlike most of DNL semimetals, TiRhAs has a single nodal ring residing near the Fermi level with no interference from other bands, which makes that the carriers in TiRhAs are entirely contributed by nodal-line fermions. Moreover, the calculations show that the hybridization gap induced by SOC is negligible in TiRhAs. Therefore, TiRhAs can be regarded as a hydrogen-atom-like DNL semimetal. By the soft X-ray ARPES, we systemetically studied the band structure of TiRhAs and observed a single nodal ring at kx=0 plane in BZ.
9:36AM E01.00009: Observation of Yamaji Magic Angles in Bismuth Nanowires*  TITO HUBER (Presenter), Chemistry, Howard University, Washington DC 20059, ALBINA NIKOLAEVA, LEONID KONOPKO, Academy of Sciences, Chisinau, Moldova, MD-2028 — Experimental studies that probe the surface of bulk bismuth as a composite of topological insulator edges and hinges on the surface of bulk Bi are lacking. We present angle-dependent transverse magnetoresistance (TMR) oscillation measurements of small diameter (50 nm) bismuth nanowires where electronic transport is dominated by the surface, rather than the bulk in the core of the nanowire, because of quantum confinement. We find that the TMR of the surface states in our nanowires exhibits peaks for a sequence of nanowire rotation angles that strongly suggest an interpretation in terms of Yamaji magic angles. Magic angles are observed in layered and other low-dimensional conductors with weak interplanar coupling that are amenable to be described by an open, corrugated, Fermi surface. In contrast to surface states, bulk bismuth does not display magic angles since the Fermi surface is closed. We will discuss our interpretation of surface states of bismuth and the main Fermi surface parameters that we observe: orientation of the Fermi surface, Fermi wavevector, and coupling strength.

*We acknowledge support by NSF-CIQM 1231319 and by The Keck Foundation.

9:48AM E01.00010: Topological Line-Like Bound States in the Continuum* MANABU TAKEICHI (Presenter), SHUICHI MURAKAMI, Tokyo Institute of Technology — Bound states in the continuum (BIC) have been studied mainly in optics. Recently, electronic BIC have been proposed. They appear as points in the momentum space and are protected topologically by the Chern number. In this study, we propose a new type of BIC protected by the winding number, which is one of the topological invariants. These BIC appear as lines in the momentum space, and are realized in a multilayer model consisting of honeycomb-lattice layers. We show band structure and spatial localization of the BIC in this model. The wavenumbers at which the BIC appear can be explained in terms of topology in the momentum space.

10:00AM E01.00011: Scanning tunneling spectroscopy studies of the topological states in the Dirac metal Hf$_2$Te$_2$P TIMOTHY BOYLE (Presenter), ANTONIO ROSSI, PETER CARLSON, MOIRA K MILLER, JINGTAI ZHAO, MORGAN WALKER, VALENTIN TAUFOUR, INNA VISHIK, EDUARDO H DA SILVA NETO, University of California, Davis — Recent angle-resolved photoemission spectroscopy experiments and theoretical calculations indicate the existence of multiple Dirac states in the topological material Hf$_2$Te$_2$P [1]. In this study we use scanning tunneling spectroscopy (STS) to measure the electronic band structure of the material. Using STS as a direct probe of the real-space local density of states, we identify quasiparticle interference patterns that allow us to measure the topological surface states. The results will be discussed in the context of density functional theory calculations that predict multiple topological states below and above the Fermi energy.

Since the establishment of topological insulators, a lot of interest has turned to finding systems that combine topology with strong electron correlations. This led Dzero et al. to propose that Kondo insulators, materials that open a band gap by mixing local and itinerant states of opposite parity, should fall into this category [1]. The effort spurred by this proposal has advanced the state of knowledge on SmB6, the leading candidate for a topological Kondo insulator [2]. The question of its topology, however, remains unanswered.

The apparently contradictory results from different experimental techniques form major obstacle to resolving this issue. In this paper we tackle one of these apparent contradictions: Researchers using scanning tunneling microscopy [3,4] have reached different conclusions on the surface terminations than those using photoemission spectroscopy [5]. By combining both techniques we find the results from these methods can be reconciled, a conclusion that will help settle this topical issue.

In this work, we explore surface states of nonsymmorphic semimetals with lifted band degeneracy at the symmetry points. HfSiS, a typical Dirac nodal-line semimetal with the nonsymmorphic symmetry exhibits a Rashba-type spin-split surface state. In this regard, we explore the Rashaba surface states which draw an analogy to the topological materials, where the spin and orbital entanglement takes place. We have performed spin- and angle-resolved photoemission spectroscopy experiment on HfSiS and ZrSiS single crystals with \( p \)-polarized and \( s \)-polarized light. The observed variation in the intensity distribution upon changing the light polarization tells us that the surface states along the M-X-M line are mainly composed of \( d_{z^2} \) orbitals, and change into \( d_{xy} \) along the G-X-G line. Combining the observed spin polarizations with the result of the slab calculation, we have concluded that the surface bands surrounding the X point exhibit a quite anisotropic spin and orbital texture. Our findings provide a new way of light manipulation by controlling the spin structure in materials which is important for future applications.
10:48AM E01.00015: Interaction of coherent phonons with spin-orbit coupled surface states*  JONATHAN SOBOTA (Presenter), SLAC National Accelerator Laboratory, HADAS SOIFER, Stanford University, PATRICK S KIRCHMANN, SLAC National Accelerator Laboratory, ZHIXUN SHEN, Stanford University — Spin-polarized electronic states form at the surface of materials due to the combination of spin-orbit coupling and broken inversion symmetry. This phenomenon was first established for Shockley states at the surface of noble metals such as gold, and more recently, has been recognized as a central mechanism responsible for the formation of topologically non-trivial states. Given the fundamental significance of these states, as well as their potential role in spintronics applications, it is important to understand their interaction with collective excitations of the crystal lattice.

Here we use time- and angle-resolved photoemission spectroscopy (trARPES) to investigate electron-phonon coupling in a model system: the Rashba-split surface state of the semimetal Antimony (Sb). The simplicity of the structure permits us to coherently excite all zero-momentum optical modes of the crystal, and study their coupling to both bulk and surface electronic states. In addition, this material provides an ideal platform for testing coherent control schemes, as well as exploring excitation mechanisms for finite-momentum phonon modes. We will discuss our results in the context of similar measurements on topological insulators.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E02 DMP DCOMP: Dielectric & Ferroic Oxides -- Optically Induced Properties and Optical Measurements 8CEC 107A - Dennis Meier

8:00AM E02.00001: Ultrafast photoinduced transient strain in BiFeO3 thin film probed by x-ray free electron laser diffraction  HYEONJUN LEE (Presenter), YOUNGJUN AHN, SAMUEL MARKS, Department of Materials Science and Engineering, University of Wisconsin-Madison, ERIC C LANDAHL, Department of Physics, DePaul University, JOONYOUNG LEE, TAYEON KIM, SANJITH UNITHRATTIL, JI YOUNG JO, School of Materials Science and Engineering, Gwangju Institute of Science and Technology, SEHWAN CHEON, SUNAM KIM, Pohang Accelerator Laboratory,, Pohang Accelerator Laboratory,, CAROLINA ADAMO, Department of Applied Physics, Stanford University, DARRELL G. SCHLOM, Department of Materials Science and Engineering, Cornell University, HAIDAN WEN, X-ray Science Division,, Argonne National Laboratory, PAUL G EVANS, Department of Materials Science and Engineering, University of Wisconsin-Madison — Photoinduced structural effects provide an emerging method for manipulating the crystal structure of polar perovskites and for eventual ultrafast control of phenomena such as ferroelectricity and magnetism. Studies of the dynamics of the strain generation and relaxation after photoexcitation can provide fundamental insight into the origin of these photoinduced phenomena. Experiments probing a 35 nm thick BiFeO3 thin film using an x-ray free electron laser (XFEL) providing 100 fs time resolution show that a transient lattice expansion can be produced by intense ultrafast optical excitation. The diffraction employed an x-ray fluence below the BiFeO3 damage threshold. Optical excitation induced a shift of the BiFeO3 002 reflection to lower wavevector by up to 0.8% within 9 ps. Temporal oscillations of the scattered intensity were observed over a wide range of wavevectors, equivalent to several thickness fringes. The diffraction matched the longitudinal acoustic (LA) sound velocity indicates that an impulse propagated into the film in a manner consistent with kinematical calculations. The predicted intensity at 5 ps is not predicted accurately, which may indicate that there is a more complex distribution of the initial stress than is expected from the optical absorption profile.

8:12AM E02.00002: Ultrafast optical control of ferroelectric polarization via resonant magnon excitation*  HARICHARAN PADMANABHAN (Presenter), YAKUN YUAN, Pennsylvania State University, ALEXANDER MELVILLE, Massachusetts Institute of Technology, DARRELL G. SCHLOM, Cornell University, VENKATRAMAN GOPALAN, Pennsylvania State University — Optical control of order parameters in condensed matter is of great interest in fundamental as well as applied science. In the context of ferroic materials, controlling ferroic degrees of freedom using ultrafast optical pulses could pave the way towards ultrafast switches and devices that work on femtosecond timescales. Attempts to achieve this by direct excitation of ferroic modes have not been completely successful, necessitating other novel strategies.

In this work, we demonstrate a transient suppression of the ferroelectric polarization in the prototypical multiferroic BiFeO3 by resonant excitation of a magnon coupled to the ferroelectric mode. Ultrafast pump-probe measurements using a second harmonic generation probe reveal that the suppression and recovery of the polarization occur at a femtosecond timescale. Furthermore, we observe that the zero polarization transient state can be stabilized by tuning the domain structure of the lattice, increasing its lifetime by one order of magnitude.

*DOE Grant No. DE-SC0012375
8:24AM E02.00003: Reversible optical control of multiferroicity in BiFeO$_3$ thin films  YI-DE LIOU, National Cheng Kung University, Tainan 70101, Taiwan, YEN-LIN HUANG, National Chiao Tung University, Hsinchu 30010, Taiwan, RYAN THOMAS HART, University of Texas at Arlington, Arlington, TX 76019, USA, YUAN-CHIH WU, National Cheng Kung University, Tainan 70101, Taiwan, RAJESH V CHOPDEKAR, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, VALANOOR NAGARAJAN, University of New South Wales, Sydney, 2052, Australia, YING-HAO CHU, National Chiao Tung University, Hsinchu 30010, Taiwan, YI-CHUN CHEN, National Cheng Kung University, Tainan 70101, Taiwan, YE CAO, University of Texas at Arlington, Arlington, TX 76019, USA, JAN-CHI YANG (Presenter), National Cheng Kung University, Tainan 70101, Taiwan — Nowadays, increasing technology interest has focused on the optical control of non-volatile functional units. In this work, we present the deterministic switching/modulation of the ferroelectric and (anti)ferromagnetic orders at ambient temperature through laser illumination.

With well-tuned laser illumination, the local temperature of illuminated region increases, resulting in a significant flexoelectric field at the boundaries of illuminate and non-illuminated region. The induced flexoelectric field is then adopted to modulate the local ferroelectricity of BiFeO$_3$ thin film, generating a wide spectrum of tunable domain structures. To verify the role of flexoelectric effect, phase field simulation is processed to simulate the correlation between the as-grown and light induced domain architecture. Due to the fact that BiFeO$_3$ thin film has its ferroelectricity coupled strongly with inherent antiferromagnetism/ferromagnetism, the optical modulation of ferroelectric order gives rise to corresponding alteration of the antiferromagnetism/ferromagnetism as well. Furthermore, we show that the domain conductivity and piezoresponse enhancement could also be turned on and off via laser illumination.

8:36AM E02.00004: Prediction of photo-induced phase transitions and coherent optical phonon generation in BaTiO$_3$*  FANGYUAN GU (Presenter), Department of Materials, Imperial College London, ÉAMONN MURRAY, PAUL TANGNEY, Department of Physics and Department of Materials, Imperial College London — We investigate the effects of above band gap ultrafast laser pulses on the lattice dynamics and structural properties of the prototypical perovskite, BaTiO$_3$, using electronic structure methods and atomistic simulations. We use a constrained density functional method to study the local changes induced by ultrafast laser excitation. Our work shows a reduction in the ionicity due to electrons being returned by O anions to Ti cations. We calculate the dependences of phonon frequencies and equilibrium structures on excited carrier density and find that moderate levels of photo-excitation reduces the polarization, coherently excites and softens optical phonons of A1 symmetry, and lowers the local barriers to ferroelectric domain reversal. We use our first-principles calculations to fit atomistic potentials and study structural changes on significantly longer time-scales. Our results suggest that pump-probe spectroscopy could be used to induce a purely-displacive transition to higher symmetry phase at low temperature and to study the decay of coherent optical phonons. Our findings may also provide guidance to the design of optically controlled devices.

*Supported by EPSRC grants EP/L015579/1, EP/P020194/1.

8:48AM E02.00005: Optically Induced Nanoscale Domain Transformation in Low-Strain BaTiO$_3$ Thin Films YOUNGJUN AHN (Presenter), ANASTASIOS PATERAS, HYEON JUN LEE, JOONKYU PARK, Department of Materials Science & Engineering, University of Wisconsin - Madison, Madison, Wisconsin 53706, USA, SILVIA DAMERIO, ARNOUD EVHERHARDT, Zernike Institute for Advanced Materials, University of Groningen, Nijenborgh 4, 9747 AG Groningen, The Netherlands, ANTHONY DICIARA, HAIDAN WEN, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, BEATRIZ NOHEDA, Zernike Institute for Advanced Materials, University of Groningen, Nijenborgh 4, 9747 AG Groningen, The Netherlands, PAUL G EVANS, Department of Materials Science & Engineering, University of Wisconsin - Madison, Madison, Wisconsin 53706, USA — Above-bandgap ultrafast optical excitation provides the means to extend the current state of understanding of polarization domain phenomena and the relationship between electronic dynamics and mesoscale transformation. We report a time-resolved synchrotron x-ray diffraction study of a BaTiO$_3$ film grown on a NdScO$_3$ substrate in which an optically induced domain transformation is observed. The key experimental feature is an optically induced change in the intensities and reciprocal space positions of the diffuse scattering patterns arising from aa*/ca* and ca$_1$/ca$_2$ domain configurations. Following above-bandgap optical excitation, the diffuse scattering intensity of the aa*/ca* domains increases within 1 ns while that of the ca$_1$/ca$_2$ domains decreases. The change in intensities indicates a transformation from the ca$_1$/ca$_2$ to the aa*/ca* domain configuration. The transformation is accompanied by polarization rotation toward the out-of-plane direction, which has the same time dependence as the intensity variation. The degree of the polarization rotation varies depending on the optical fluence and is different for the two domain configurations. The results show that the mechanism of the domain transformation is associated with the polarization rotation induced by the optical excitation.
9:00AM E02.00006: Photostrictive characteristics in Perovskite Strontium Iridate Thin Films  YI-DE LIOU (Presenter), Physics, National Cheng Kung University, WEN-YEN TZENG, Electrophysics, National Chiao Tung University, HENG-JUI LIU, Materials Science and Engineering, National Chung Hsing University, CHIH WEI LUO, Electrophysics, National Chiao Tung University, YI-CHUN CHEN, Physics, National Cheng Kung University, YING-HAO CHU, Materials Science and Engineering, National Chiao Tung University, JAN-CHI YANG, Physics, National Cheng Kung University — Photostrictive effect depicts a direct light-matter interaction that exhibits a reversible mechanical deformation in a material under light illumination. In this work, we investigate the giant visible-light-induced deformation of orthorhombic perovskite SrIrO$_3$ (SIO), taking advantages of its sizable crystal field and high absorption across the visible spectrum at room temperature. By using highly structural sensitive in-situ Raman spectroscopy, the red-shift behaviors of all the optical phonons of SIO were observed as the increase of light intensities. The corresponding local strain states were analyzed by means of the phonon deformation potential theory, which unveils the giant photostrictive behavior in SIO thin films. The fast response time is also discovered by ultra-fast pump probe spectroscopy. We found that SIO shows significant photostriction properties compared to conventional semiconductors, polymers and perovskite oxides. The strong photostrictive effect, fast response time and superior stability of SIO at room temperature pave a promising route towards new applications and multifunctionalities of photon-driven devices.

9:12AM E02.00007: Coherent Phonons and Magnons in Hetero-Epitaxial BTO-BFO Films and Nano-rods*  BRENDEN A MAGILL (Presenter), RATHSARA R HERATH MUDIYANSELAGE, GITY KHODAPARAST, JOSEPH A SPENCER, JOHN BURTON, KIARA MCMILLAN, MIN GYU KANG, HAN-BYUL KANG, Virginia Tech, SHASHANK PRIYA, Virginia Tech/Penn State, JADE HOLLEMAN, STEPHEN A MCCGILL, Florida State/NHMFL — The desire to create monolithic multifunctional devices has driven significant research toward exploring multiferroics, where the coupling between electric, magnetic, optical, and structural order parameters can provide added functionality. In this study, we utilize time resolved responses of (1-x)BaTiO$_3$(x)BiFeO$_3$, x = 0.725 epitaxial films grown on LSMO with STO substrate and the BTO-BFO nanorods grown on Pt with Si as the substrate to reveal several coherent dynamics. We probed the dynamics of photo-excited carriers in several films and nanorods to obtain information on the time scale of different relaxation process, including coherent phonon and magnon dynamics. The ability to generate and manipulate the time resolved, phononic, and magnonic degrees of freedom in materials with external optical, electric, and magnetic fields promises to usher in a new era of revolutionary.

9:24AM E02.00008: Terahertz optical diode effect in multiferroics FeZnMo$_3$O$_8$ and BaCoSiO$_4$*  SHUKAI YU (Presenter), Tulane University, BIN GAO, JAE WOOK KIM, ALEMAYEHU S. ADMASU, XIANGHAN XU, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, XING ZHU, MICHAEL K. L. MAN, JULIEN MADÉO, KESHAV M DANI, Femtosecond Spectroscopy Unit, Okinawa Institute of Science and Technology Graduate University, DIYAR TALBAYEV, Tulane University — We present a terahertz (THz) spectroscopic study of multiferroic FeZnMo$_3$O$_8$ and BaCoSiO$_4$. THz optical diode effect (ODE) is observed in both compounds. Two mechanisms for the ODE will be discussed in terms of symmetry. The ODE in FeZnMo$_3$O$_8$ is due to the toroidal moment which is the vector of cross product of polarization and magnetization. When the light is travelling along toroidal moment, the propagation of light is nonreciprocal if we flip the propagation direction. While the propagation of light in BaCoSiO$_4$ which has magneto-chiral structure is also nonreciprocal. For both of materials, the magnetic excitation plays a key to ODE. Magnetic dipole active magnetic excitation which is from electron spin resonance between the eigenstates of single-ion anisotropy Hamiltonian produces giant ODE in paramagnetic FeZnMo$_3$O$_8$ where the material doesn't have long range magnetic ordering. However, the magnetic excitation in BaCoSiO$_4$ generates weaker ODE in ferrimagnetic phase. We will discuss the resonant enhancement of the THz optical diode effect in both materials due to terahertz-frequency spin excitations.

9:36AM E02.00009: Acoustic study of ferroelectric phase transitions, from bulk materials to thin films.* ROBERT MECH (Presenter), BETZAI DA BERRIOS, OLEKSIY SVITELSKI, Gordon College, GARY PENNINGTON, RAJESWARI M KOLAGANI, GRACE YONG, Towson University, LYNN A BOATNER, Oak Ridge National Lab — The purpose of this project is to investigate how elastic properties of ferroelectric materials change when dimensionality of the specimen is reduced. Measurements done using ultrasound phase-sensitive pulse-echo technique. Ultrasound frequency ~50 MHz, length of pulses ~1us, pulse frequency ~ 10 kHz. We start investigation with bulk ferroelectric KTa0.92Nb0.08O3 crystal, exploring propagation of ultrasound waves as the crystal undergoes ferroelectric transitions spontaneously and in the presence of electric field with strength from 100 V/cm up to 2 kV/cm. The speed and attenuation of sound are both sensitive to the changes in the crystal. The observed behavior can be understood in terms of a mixed model that includes elements of soft-mode and disorder to order mechanisms of the transitions. The obtained data will be applied for understanding behavior of ferroelectric films.

*This work was partially supported by NSF DMR awards # 1709282 and 1709781.

9:48AM E02.00010: Controlling Distinguishable Ferroelectric States with Pulsed Electric Fields FRED FLORIO (Presenter), RAVISHANKAR SUNDARARAMAN, JIAN SHI, YANG HU, Rensselaer Polytechnic Institute — Ferroelectric materials are of increasing interest for novel computing paradigms such as neuromorphic computing, which require a large number of distinguishable states that can be set and read out in a controllable way. Achieving this necessitates a deeper understanding of polarization dynamics and their interplay with material grains and boundaries, down to the nanoscale. Using large ensembles of phase field simulations, we investigate domain switching dynamics under different field conditions for realistic device and grain size distributions. With statistical analyses and machine-learning approaches on these simulation results, we identify relationships between electric field pulse patterns and polarization states as a function of grain distributions, and quantify the capacity for realistic ferroelectric materials to be poled into a multitude of distinguishable states.

10:00AM E02.00011: Subtle structural distortions in LiOsO3 observed using optical second harmonic generation JUN-YI SHAN (Presenter), ALBERTO DE LA TORRE, NICHOLAS LAURITA, Department of Physics, California Institute of Technology, LIUYAN ZHAO, Department of Physics, University of Michigan, CAMERON DASHWOOD, Department of Physics, California Institute of Technology, DANIL0 PUGGIONI, Department of Materials Science and Engineering, Northwestern University, KAZUNARI YAMAURA, Research Center for Functional Materials, National Institute for Materials Science, YOUGUO SHI, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, JAMES M RONDINELLI, Department of Materials Science and Engineering, Northwestern University, DAVID HSIEH, Department of Physics, California Institute of Technology — LiOsO3 is a metal that undergoes a non-polar to polar structural phase transition upon cooling below a critical temperature Tc ~ 140 K, which is unusual because the presence of itinerant carriers is usually incompatible with ferroelectric-like structural distortions. To explore the microscopic mechanism of this phase transition, we performed angle-of-incidence dependent optical second harmonic rotational anisotropy measurements on LiOsO3 single crystals. We observe subtle distortions in the paraelectric phase above Tc and I will discuss their implications for an order-disorder versus a displacive picture of the polar phase transition.

10:12AM E02.00012: Optical nonlinearity and the anharmonicity of oxides ALI HAMZE (Presenter), ALEXANDER DEMKOV, University of Texas at Austin — Integration of crystalline oxides on silicon is one of the most promising ways to continue enhancing the performance and functionality of silicon-based technology. Oxide integration offers access to new physical phenomena not present in current semiconductor platforms to make use of in devices. In this work, we discuss one such phenomenon, the Pockels effect (also known as the linear electro-optical effect), and its connection with crystal anharmonicity. The Pockels effect describes the linear change in a material’s index of refraction in response to an applied electric field, and as such, is only present in non-centrosymmetric crystals. Anharmonic crystals with soft phonon modes can have enormous Pockels responses, and anharmonicity often manifests itself via large thermal expansion. However, one does not imply the other. Highly anharmonic crystals like BaTiO3 (and, under strain, SrTiO3) do exhibit large Pockels effect, while the even more anharmonic LiB3O5 does not. We will discuss the relationship between the thermal expansion, anharmonicity and the electro-optical effect.
10:24AM E02.00013: Raman scattering study of lattice and electronic excitations in Ce₂O₃**

ASTHA SETHI (Presenter), JOHN SLIMAK, University of Illinois at Urbana-Champaign, TARAS KOLODIAZHNYI, National Institute of Materials Science, S. LANCE COOPER, University of Illinois at Urbana-Champaign — The giant magnetodielectric effect exhibited by Ce₂O₃ near Tₙ suggests the presence of strong electron-lattice coupling effects. To clarify the microscopic details of these effects, we present a temperature and magnetic field dependent Raman scattering study of the lattice and electronic excitations in Ce₂O₃. Two crystal field excitations (CFEs) are observed at low temperatures, corresponding to transitions within the crystal-field-split J=5/2 manifold. We provide evidence that electron-phonon coupling is significantly enhanced at low temperatures, leading to a mixing of electronic and phononic states. The magnetic field-dependence of these coupled excitations provide insight into the microscopic mechanism associated with magnetodielectric behavior in Ce₂O₃.

**Research was supported by the National Science Foundation under Grant NSF DMR 1800982.

10:36AM E02.00014: Raman Study of Crystal Field Excitations and Soft Modes in Pr₂O₃*

JOHN SLIMAK (Presenter), ASTHA SETHI, University of Illinois at Urbana-Champaign, TARAS KOLODIAZHNYI, National Institute for Materials Science, Japan, S. LANCE COOPER, University of Illinois at Urbana-Champaign — The rare earth sesquioxides constitute an interesting class of materials because of the diverse ways in which lattice degrees of freedom interact with f-electrons. Several members of this class of materials exhibit unit cell doubling, as is the case with La₂O₃ at high pressures, or magnetodielectric effects, such as Ce₂O₃ at low temperatures, however Pr₂O₃ has only been only minimally investigated under high pressures or high fields. We report a preliminary Raman scattering study of the phonon and crystal field excitations Pr₂O₃ as functions of temperature and magnetic field. We observe significant softening of an A1g phonon that may be indicative of an incipient structural distortion that cannot be accessed at ambient pressures. Two crystal field excitations (CFEs) are also observed at low temperatures, and we observe splitting and evidence of electron-phonon coupling effects associated with the lowest CFE under an applied magnetic field. We discuss the relevance of these results to the possibility of a pressure-dependent structural change for Pr₂O₃.

*Research was supported by the National Science Foundation under Grants NSF DMR 1800982 and NSF DMR 1464090.

10:48AM E02.00015: Direct Measurements of the Atomic Displacements Related to the Ferroelectric Transition in Sn₂P₂S₆*

SIZHAN LIU (Presenter), HAN ZHANG, New Jersey Institute of Technology, SANJIT GHOSE, Brookhaven National Laboratory, SUYIN GRASS WANG, YU-SHENG CHEN, Argonne National Laboratory, DEAN R EVANS, Air Force Research Lab - WPAFB, TREVOR TYSON, New Jersey Institute of Technology — The Sn₂P₂S₆ is known to be ferroelectric and is one of the few Sn based ferroelectric (FE) systems which have been discovered. The true nature of the onset of the electric polarization has not been previously correlated with the changes in atomic structure. We have conducted structural measurements on multiple length scales as a function of temperature. In addition the structural results are compared to the low frequency phonons obtained from Raman scattering measurements. A complete model of the polar state of this system is developed.

Session E03 DCMP: Novel Transport in Topological Systems

8:00AM E03.00001: Ultrafast Photocurrents in the Weyl Semimetal TaAs

NICHOLAS SIRICA (Presenter), RA’ANAN TOBEY, Los Alamos National Laboratory, LINGXIAO ZHAO, GENFU CHEN, BING XU, RUN YANG, institute of physics chinese academy of sciences, BING SHEN, Physics and Astronomy, university of california los angeles, DZMITRY A. YAROTSKI, PAMELA BOWLAN, STUART TRUGMAN, JIAN-XIN ZHU, Los Alamos National Laboratory, YAOMIN DAI, School of Physics, Nanjing University, ABUL K AZAD, Los Alamos National Laboratory, ANTOINETTE TAYLOR, ROHIT P PRASANKUMAR, Los Alamos National Laboratory — We investigate polarization-dependent, ultrafast photocurrents in the Weyl semimetal TaAs using terahertz (THz) emission spectroscopy. Our results reveal that highly directional, transient photocurrents are generated along the non-centrosymmetric c-axis regardless of incident light polarization, while helicity-dependent photocurrents are excited within the ab-plane. This is consistent with both the bulk photovoltaic effect and the circular photogalvanic effect observed in direct photocurrent experiments, and provides additional insight into their microscopic origin by way of the dynamical information gained from the emitted THz waveform.
8:12AM E03.00002: Elastic gauge fields and zero-field 3D quantum Hall effect in hyperhoneycomb lattices* SANG WOOK KIM (Presenter), BRUNO UCHOA, University of Oklahoma — We derive the elastic gauge fields that emerge from lattice deformations in the hyperhoneycomb lattice, a three-dimensional structure with trigonally connected sites. In its semimetallic form, this lattice is a nodal-line semimetal with a closed loop of Dirac nodes. Using strain engineering, we find the strain fields that create nearly uniform 3D Landau level quantization. In the 3D quantum anomalous Hall phase, we show that the elastic Hall viscosity is \( \eta_H = \frac{\beta^2 \sqrt{3}}{16\pi a^3} \), where \( a \) is the lattice constant.

*S.W.K. and B.U. acknowledge NSF CAREER Grant No. DMR-1352604 for support.

8:24AM E03.00003: Proximal Anomalous Hall Effect in Ferromagnetic Insulator/Bulk-insulating BiSbTeSe2 Heterostructures* SHIHUA ZHAO (Presenter), HAIMING DENG, City College of New York, DANIEL RHODES, JAMES HONE, Columbia University, MARCIN KONCZYKOWSKI, Ecole Polytechnique, AGNIESZKA WOLOS, University of Warsaw, LIA KRUSIN-ELBAUM, City College of New York — Realization of Quantized Anomalous Hall Effect in topological insulators (TIs) thus far has been limited to ultra-thin MBE films of Cr- or V-doped (Bi,Sb)2Te3. In this system the disorder of the dopant landscape may limit the quantization temperature range in which the chiral channels can be observed. The alternative is to obtain proximal ferromagnetism in a 3D TI by creating a trilayer sandwich comprising ferromagnetic insulator (FMI) on the top and bottom surfaces of a TI. Here we report on the trilayer structure comprising bulk-insulating TI BiSbTeSe2 (BSTS) sandwiched between a two-dimensional van der Waals ferromagnetic insulator Cr2Ge2Te6 (CGT) grown using Bridgeman method. The structure was assembled in the inert-gas glovebox to prevent oxidation and contamination of the interface. h-BN capping was used to protect CGT against degradation in air. The out-of-plane magnetization of CGT down to thicknesses of 18 nm was confirmed by exfoliating it directly atop our custom-designed Hall microsensor chips. The enhancement of proximal magnetism obtained by (1) the optimal thickness of BSTS, (2) using pressure to obtain a better interfacial coupling, and (3) by electrostatic gating to the Dirac gap will be discussed.

*NSF DMR-1312483-MWN, NSF DMR-1420634, NSF HRD-1547830

8:36AM E03.00004: Nodal Arc in Disordered Dirac Fermions: Connection to Non-Hermitian Band Theory* MICHAL PAPAJ (Presenter), HIROKI ISOBE, LIANG FU, Massachusetts Institute of Technology — We show that Dirac fermion systems in two dimensions generally exhibit disorder-induced nodal arc replacing the nodal point and tilted Dirac cone, provided that the two components of the Dirac fermion correspond to two distinct orbitals unrelated by symmetry. This result is explicitly demonstrated using renormalization group analysis in a disordered Dirac model that we introduce, where the disorder potential acts differently on the two orbitals. As we show by numerical simulations and self-consistent Born approximation calculation, this drives the system into a new strongly disordered phase.

*This work was supported by the David and Lucile Packard Foundation.

8:48AM E03.00005: Interacting Dirac Semimetals* RUI-XING ZHANG (Presenter), Department of Physics, University of Maryland, SHENG-JIE HUANG, Department of Physics, University of Colorado, Boulder, JIABIN YU, Department of Physics, The Pennsylvania State University — The experimental discovery of three dimensional (3d) Dirac semimetals has opened up a new world of symmetry protected gapless state with non-trivial topological properties. While most existing studies have focused on the free fermion descriptions, we will show that interaction effects will significantly change the topological classification of Dirac semimetals. With the help of the dimensional reduction technique, we explicitly show that 3d Dirac semimetals protected by C_n rotation symmetries, such as Cd3As2 and Na3Bi, can be adiabatically connected to a gapped 3d axion insulator and gapless 1d axion strings in a symmetric way. This construction demonstrates that the anomaly nature of 3d Dirac semimetals is one dimensional. We further show that the non-interacting classification of a 3d Dirac semimetal generally reduces from Z to its Z_n subgroup in the presence of strong interactions. Our work lays the theoretical foundation for strongly interacting topological semimetals and paves the way for their future material realizations.

*RXZ acknowledges the JQI Postdoc Fellowship of University of Maryland. SJH acknowledges support from the U.S. Department of Energy, Office of Science, Basic Energy Sciences (BES) under Award number DE-SC0014415.
9:00AM E03.00006: Influence of Landau levels in the phonon dispersion of Weyl semimetals* PIERRE RINKEL, Universite de Sherbrooke, PEDRO LOPES, Physics, University of British Columbia, ION GARATE (Presenter), Universite de Sherbrooke — Discovered in high-energy physics, the chiral anomaly has recently made way to materials science by virtue of Weyl semimetals (WSM). Thus far, the main efforts to probe the chiral anomaly in WSM have concentrated on electronic phenomena. Nevertheless, recent theoretical works [1,2] have studied signatures of the chiral anomaly in the dynamics of lattice vibrations, to first order in the external magnetic field. In this work, we generalize those earlier results to magnetic fields of arbitrary strength by incorporating the influence of Landau levels in the phonon spectra. We predict a hybridization between plasmons and optical phonons that becomes potentially observable at high magnetic fields, and we identify fingerprints of chiral Landau levels in the sound velocity.

*This research has been funded by the Natural Sciences and Engineering Research Council of Canada, the Fonds de Recherche du Québec - Nature et Technologies, and Canada's First Research Excellence Fund.

9:12AM E03.00007: Anomalous off-diagonal thermal response in Mn$_3$Ge LIANGCAI XU, XIAOKANG LI, XIUFANG LU, Wuhan National High Magnetic Field Center and School of Physics, Huazhong University of Science and Technology, CLEMENT COLLIGNON, Laboratoire de Physique Et Etude des Matériaux, ESPCI Paris, ALASKA SUBEDI, Centre de Physique Theorique, Ecole Polytechnique, BENOIT FAUQUE, Laboratoire de Physique Et Etude des Matériaux, ESPCI Paris, ZENGWEI ZHU (Presenter), Wuhan National High Magnetic Field Center and School of Physics, Huazhong University of Science and Technology, KAMRAN BEHNIA, Laboratoire de Physique Et Etude des Matériaux, ESPCI Paris — We present a study of anomalous transverse response in non-collinear antiferromagnet Mn$_3$Ge down to sub-Kelvin temperature. Special attention is paid to the amplitude and temperature dependence of the anomalous Lorenz ratio $L^A_{ij} = \kappa^A_{ij} / T \sigma^A_{ij}$ relative to the Sommerfeld value. The contrast with Mn$_3$Sn [1] provides crucial information in the ongoing effort to identify the k-space location of the Weyl points. We also present measurements of the anomalous Ettingshausen and the anomalous Nernst effects in order to verify the Bridgman relation, a consequence of Onsager reciprocity.

9:24AM E03.00008: Localized Plasmons in One Dimensional Topological Systems ZHIHAO JIANG (Presenter), ROELOF E GROENEWALD, MALTE ROESNER, STEPHAN WOLFGANG HAAS, University of Southern California — One dimensional topological systems (the Schrieffer-Su-Hegger model and the generalized Aubry-André-Harper model) support strongly localized electronic states in the topologically nontrivial phases. In this work, we study plasmon modes in these systems by calculating the real space dielectric function within the random phase approximation. We observe localized plasmon modes in the electron energy loss spectra. In the topologically nontrivial sectors, these localized plasmon modes are shown to originate from the localized electronic edge states by separating the full polarization into contributions from pure bulk transitions without localized electronic states and edge-bulk transitions involving localized electronic states. We also show that the Coulomb interaction plays a role of delocalizing plasmons due to its long-range property. Therefore, the localization of plasmon modes is less strong than the localized electronic states obtained from non-interacting tight binding models.

9:36AM E03.00009: μ-ARPES studies of few-layer WTe2* ANTONIO ROSSI (Presenter), University of California, Davis, CHRIS JOZWIAK, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, Lawrence Berkeley National Lab, SENG HUAT LEE, RONALD DEAN REDWING, KEVIN DRESSLER, The Pennsylvania State University, INNA VISHIK, University of California, Davis — WTe2 exhibits a wide variety of physics in its bulk and monolayer regimes including two different topological phases, non-saturating magnetoresistance, and superconductivity under pressure or gating. We will present micro-ARPES studies on bulk and few-layer WTe2, which connect microscopic electronic structure to observations from transport experiments. Doping-dependence, spatial inhomogeneity, and layer-dependence of electronic structure and interactions will be discussed.

*This research used resources of the Advanced Light Source, which is a US Department of Energy Office of Science User Facility under contract no. DE-AC02-05CH11231. A portion of the work was supported by NSF cooperative agreement DMR-1539916.
9:48AM E03.00010: “Glide-resolved selection rules for scanning-tunneling microscopy; application to Black Phosphorus and Zirconium(III) Chloride” JUNG PYO HONG (Presenter), BENJAMIN WIEDER, ZHIJUN WANG, Physics, Princeton University, MICHAEL ZALETEL, Physics, University of California at Berkeley, ANDREI B BERNEVIG, Physics, Princeton University — Recently Queiroz et al. predicted that the Bloch bands of nonsymmorphic crystals can exhibit novel selection rules in their quasiparticle interference (QPI) pattern, characterized by a quasi-Brillouin Zone (BZ) periodicity of extinction patterns in the momentum transfer channel. Here, we focus on glide reflection symmetry—i.e. the combined operation of mirror reflection and in-plane half-integer lattice translation—to quantitatively realize ‘glide-resolved QPI (gQPI) selection rules’ on 2D minimal tight-binding models respecting the symmetries of layer group pma2 (LG 24), considering the limits of both strong and negligible spin-orbit coupling (SOC). We numerically compute the lattice- and energy-resolved local density of states (LDOS) in the presence of a local impurity and demonstrate the existence of quasi-BZ periodicity in the momentum-space LDOS. We propose Zirconium(III) Chloride and Black Phosphorus, whose monolayers respect pma2, as material candidates for the observation of gQPI in the presence and absence of SOC, respectively. By utilizing Topological Quantum Chemistry and density functional theory to construct tight-binding models, we find numerical evidence for gQPI in these materials, which can potentially be detectable through scanning-tunneling microscopy (STM).

10:00AM E03.00011: Purely Rotational Symmetry-Protected Topological Crystalline Insulator α-Bi₄Br₄ CHUANG-HAN HSU (Presenter), Department of Physics, National University of Singapore, TAY-RONG CHANG, XIAOTING ZHOU, Department of Physics, National Cheng Kung University, QIONG MA, NUH GEDIK, Department of Physics, Massachusetts Institute of Technology, ARUN BANSIL, Department of Physics, Northeastern University, VITOR PEREIRA, Department of Physics, National University of Singapore, LIANG FU, SUYANG XU, Department of Physics, Massachusetts Institute of Technology, HSIN LIN, Institute of Physics, Academia Sinica — Recent theoretical advances have proposed a new class of topological crystalline insulator (TCI) phases protected by rotational symmetries. Distinct from topological insulators (TIs), rotational symmetry-protected TCIs are expected to show unique topologically protected boundary modes: First, the surface normal to the rotational axis features "unpinned" Dirac surface states whose Dirac points are located at generic \( k \) points. Second, due to the "higher-order" bulk boundary correspondence, a 3D TCI also supports 1D helical edge states. Despite the unique topological electronic properties, to date, purely rotational symmetry-protected TCIs remain elusive in real materials. Using first-principles band calculations and theoretical modeling, we identify the van der Waals material α-Bi₄Br₄ as a TCI purely protected by rotation symmetry. We show that the α-Bi₄Br₄'s (010) surface exhibits a pair of unpinned topological Dirac fermions protected by the two-fold rotational axis. These unpinned Dirac fermions show an exotic spin texture highly favorable for spin transport and a band structure consisting of van Hove singularities due to Lifshitz transition.

10:12AM E03.00012: Modeling Image Potential States on Topological Semimetal Antimony Surface* HAIMEI ZHANG (Presenter), Wellesley College, JIANFENG GE, YANG HE, Harvard University, YAU CHUEN YAM, University of British Columbia, PENGCHENG CHEN, Princeton University, JENNIFER HOFFMAN, Harvard University — Topological materials host protected surface states with locked spin and momentum degrees of freedom that are predicted to give rise to exotic excitations such as Majorana fermions and magnetic monopoles. The topological semimetal antimony (Sb) offers a pristine platform in which to search for these excitations. Here we present scanning tunneling spectroscopy (STS) studies of Sb at high energy where quantized image potential states form due to the binding between the tunneling electron and the polarized surface. We fit the energies of these quantized states using a one-dimensional model based on the image potential on metal surfaces, the electric field applied between tip and sample, and the work functions of both tip and sample materials. The model fits well with the experimental data as a function of tip-sample voltage and distance. The study of these image potential states allows exploration of the image charge geometry necessary to realize a magnetic monopole.

*Experiments were supported by National Science Foundation DMR-1410480, and data analysis was supported by the Science and Technology Center for Integrated Quantum Materials under NSF DMR-1231319.
10:24AM E03.00013: pnictide square net materials with reduced symmetry, the rare earth diantimonides: electronic structure and topology  MATTEO MICHIARDI (Presenter), Quantum Matter Institute, University of British Columbia, FABIAN ARNOLD, Physics and Astronomy, Aarhus University, ELIA RAZZOLI, Quantum Matter Institute, University of British Columbia, KARL F. FISHER, Department of chemistry, Aarhus University, VAITHHEESWARAN GANAPATHY, Andvanced Center for Research in high energy materials, Hyderabad University, GIORGIO LEVY, FABIO BOSCHINI, ILYA ELFIMOV, Quantum Matter Institute, University of British Columbia, BO B IVERSEN, Department of chemistry, Aarhus University, PHILIP HOFMANN, Physics and Astronomy, Aarhus University, ANDREA DAMASCELLI, Quantum Matter Institute, University of British Columbia — With the discovery of Dirac fermions, much research effort has been put into finding the structural elements that can generate Dirac-like degeneracies in the electronic band structures [1]. It was discovered that some layered materials can host planar square nets of group IV-V elements within their lattice. Analogously to graphene, these square nets possess a 2-atom basis and feature wide Dirac bands. Most of the known layered compounds that retain the electronic properties of the net, such as (Sr,Ca)MnBi2 and ZrSiS, crystallize in a tetragonal structure, and exhibit a Dirac semimetal or nodal line phase that can host a rich plethora of electronic and magnetic quantum properties [2]. In this talk we will show a new variety of square net semimetals whose structure breaks the 4-fold symmetry, the rare earth di-antimonides. These materials crystallize in the orthorhombic group Cmca reducing the overall symmetry of the system. We employed ARPES and DFT calculations on the series precursor, LaSb2, to study its electronic structure. We will discuss the effect that the symmetry reduction has on the electronic properties, on the Dirac states, as well as its interplay with spin-orbit coupling.

10:36AM E03.00014: de Haas-van Alphen effect of correlated Dirac states in kagome metal Fe3Sn2*  LINDA YE (Presenter), Massachusetts Institute of Technology, MUN KEAT CHAN, ROSS MCDONALD, National High Magnetic Field Laboratory, LANL, DAVID E GRAF, National High Magnetic Field Laboratory, Florida State University, MIN GU KANG, Massachusetts Institute of Technology, JUNWEI LIU, Hong Kong University of Science and Technology, TAKEHITO SUZUKI, RICCARDO COMIN, LIANG FU, JOSEPH CHECKELSKY, Massachusetts Institute of Technology — We report the study of the de Haas-van Alphen effect in the ferromagnetic kagome metal Fe3Sn2, where massive Dirac electronic states have been identified by spectroscopic means [1,2]. Through magneto-quantum oscillations we observe two quasi-2D Fermi surfaces that are consistent with the quasi-2D double Dirac cone structures. Moreover, these Fermi surfaces appear to change following the rotation of the soft ferromagnetic moment, implying a strong coupling of the Dirac states with the ferromagnetic order through spin-orbit coupling. Finally, these observations establish the bulk nature of the Dirac bands and offer unique insight into lattice-borne topological electronic states. These results are summarized in arxiv/1809.11159 [3].

10:48AM E03.00015: Topological insulator materials for advanced nonlinear in-chip plasmonic devices  YINXIAO XIANG (Presenter), CHENHUI YAN, LIAN LI, CHENG CEN, Physics and Astronomy, West Virginia University — Topological insulator (TIs) has fascinating nonlinear optical properties that are inaccessible in classical materials. We report extraordinarily large third harmonic generation (THG) signal from telecom wavelength incidences in Bi2Se3 and Sb2Te3 grown by molecular beam epitaxy (MBE). Nonlinear optical measurements performed in samples with different thicknesses and stoichiometries are combined with angle-resolved photoemission spectroscopy (ARPES) characterizations to elucidate the nature of the giant THG signals. Moreover, by integrating with nanoscaled plasmonic devices on top of TIs, the strong plasmonic field enhancement further enables us to produce controllable nonlinear optical functionalities with very low input energy threshold. Our findings demonstrate a great potential for a new class of topological materials based on-chip nonlinear photonic devices.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM
Session E04 DMP: Dirac/Weyl Semimetals -- Materials Prediction I  BCEC 107C - Arun Bansil - Tag(s): Focus
8:00AM E04.00001: Weyl Points Enabled by Three-dimensional Flat Band*  YINONG ZHOU (Presenter), KYUNG-HWAN JIN, HUAQING HUANG, Department of Materials Science and Engineering, University of Utah, ZHENGFEI WANG, University of Science and Technology of China, FENG LIU, Department of Materials Science and Engineering, University of Utah — Topological flat band (FB) has attracted much interest because it exhibits a range of exotic quantum phases. Here, we discover yet another novel physical manifestation arising from three-dimensional (3D) FB but absent for 2D FB. We show that in the presence of spin-orbit coupling, magnetization of 3D FBs induces a transition from a 3D topological insulator (TI) into a Weyl semimetal, while for a 2D FB a transition from a 2D TI into a Chern insulator is known previously. The Weyl semimetal so formed may contain only a minimum of two Weyl points. The formation of Weyl points by symmetry breaking of highly degenerate 3D FBs is distinctively different from the conventional mechanism by symmetry breaking of a Dirac point. We demonstrate this unusual 3D-FB-enabled Weyl state first in a pyrochlore lattice model using tight-binding method and then in a real material Sn2Nb2O7 using first-principles calculations. The main features of the resulting Weyl points are analyzed with respect to symmetry, topological invariant and surface state. The Weyl fermions associated with FB may open new frontiers in the research of topological physics and materials.

*DOE-BES (Grant No. DE-FG02-04ER46148). CHPC. DOE-NERSC.

8:12AM E04.00002: Probing Hydrodynamic Materials from First Principles*  JENNIFER COULTER (Presenter), PRINEHA NARANG, Harvard University — In the hydrodynamic regime of transport, momentum-conserving scattering dominates momentum-relaxing processes such as Umklapp, defect, and boundary scattering so that momentum is quasi-conserved and electron flow obeys the formalism of hydrodynamics. In light of recent experimental evidence of hydrodynamic transport in PdCoO2, WP2, and PtSn4, understanding the specifics of microscopic scattering processes in these materials is of fundamental interest. In order to provide a more comprehensive perspective of experimentally observed hydrodynamic phenomena, we use first-principles methods including calculations of electron-phonon coupling to evaluate a number of different scattering lifetimes, the electrical and thermal conductivities, and optical properties of these materials. Through our ab initio framework, we aim to to probe the microscopic properties of the recently experimentally observed hydrodynamic solids and study the interplay between topological physics and ultrafast dynamics in these materials.

*JC acknowledges the DOE Computational Science Graduate Fellowship (CSGF) (DE-FG02-97ER25308) and that this work was supported by the DOE Photonics at Thermodynamic Limits Energy Frontier Research Center (EFRC) under grant #DE-SC0019140.

8:24AM E04.00003: Catalogue of Topological Electronic Materials  TIANTIAN ZHANG (Presenter), YI JIANG, ZHIDA SONG, Institute of physics, Chinese Academy of Sciences, HE HUANG, YUQING HE, Computer Network Information Center, Chinese Academy of Sciences, ZHONG FANG, HONGMING WENG, CHEN FANG, Institute of physics, Chinese Academy of Sciences — Topological electronic materials are new quantum states of matter hosting novel linear responses in the bulk and anomalous gapless states at the boundary, and are for scientific and applied reasons under intensive research in physics and in materials sciences. Here we introduce an effective, efficient and fully automated algorithm in obtaining the topological invariants for all non-magnetic materials that are known to human, based on recently developed principles that allow for exhaustive mappings between the symmetry representation of occupied bands and the topological invariants. Equipped with this method we have scanned through a total of 39519 materials available in structural databases, and found that as many as 8056 of them are actually topological (8889 if spin-orbital coupling is neglected). These are further catalogued into classes of 5005 topological semimetals, 1814 topological insulators and 1237 topological crystalline insulators, most of which are new to human knowledge. All the results are available and searchable at http://materiae.iphy.ac.cn/; and for each topological material, we have plotted the band structure as well as the local density of states, shown on the same website.

8:36AM E04.00004: Topological crossings in magnetic space groups  DARSHAN G. JOSHI (Presenter), Max-Planck-Institute for Solid State Research, Stuttgart, Germany, YANG-HA0 CHAN, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei 10617, Taiwan, ANDREAS P SCHNYDER, Max-Planck-Institute for Solid State Research, Stuttgart, Germany — Non-symmorphic symmetry is known to enforce topological crossings in crystals. Using the elementary band irreducible representations non-trivial crossings in the form of hour-glass or accordian spectrum have been discovered in certain space groups. Here we extend such an analysis to a wider domain of magnetic space groups (MSGs). We show that the magnetic co-representations (coreps), which are derived from the non-magnetic irreducible representations, can be used to detect non-symmetric symmetry enforced topological crossings in MSGs. We demonstrate this with two examples, where we find magnetic Weyl points and hour-glass dispersions. DFT band-structure calculation of corresponding magnetic materials confirms our findings. Furthermore, we compute the surface states and discuss other experimental consequences of the hourglass dispersion in magnetic materials.
8:48AM E04.00005: Chemical Principles of Topological Semimetals* [Invited] LESLIE SCHOOP (Presenter), Chemistry, Princeton University — Chemical principles can be a powerful tool for predicting, understanding and synthesizing new topological materials. In this talk I will introduce these concepts. A common practice in solid state chemistry is to connect structural motifs with properties. In this spirit, I will focus on a common structural motif, a square-net arrangement of atoms. I will explain how simple chemical rules, for example electron counting or geometrical considerations, such as atomic distances, can be used for identifying topological semimetals in such compounds. By connecting the crystal structure to the electronic properties, we can define a tolerance factor, solely based on atomic distances, which separates square-net-based nodal line semimetals from other trivial compounds. The talk is largely based on these two references [1,2].

*This research was partially supported by NSF through the Princeton Center for Complex Materials, a Materials Research Science and Engineering Center DMR-1420541, and by a MURI grant on Topological Insulators from the Army Research Office, grant number ARO W911NF-12-1-0461.

9:24AM E04.00006: Comparative first-principles study of a prototypical Dirac semimetal by GGA and SCAN meta-GGA energy functionals WEI-CHI CHIU (Presenter), Department of Physics, Northeastern University, BAHADUR SINGH, SZU-NUS Collaborative Center and International Collaborative Laboratory of 2D Materials for Optoelectronic Science \& Technology, Engineering Technology Research Center for 2, JOHANNES NOKELAINEN, Department of Physics, Lappeenranta University of Technology, CHENLIANG SU, SZU-NUS Collaborative Center and International Collaborative Laboratory of 2D Materials for Optoelectronic Science \& Technology, Engineering Technology Research Center for 2, HSIN LIN, Institute of Physics, Academia Sinica, BERNARDO BARBIELLINI, Department of Physics, School of Engineering Science, Lappeenranta University of Technology, ARUN BANSIL, Department of Physics, Northeastern University — Density functional theory is widely used to study topological properties of materials, limitations of the underlying exchange-correlation functionals notwithstanding. In this connection, the recently constructed strongly-constrained-and-appropriately-normed (SCAN) meta-GGA exchange-correlation functional has shown significant improvements in many classes of materials. Here we discuss SCAN-based electronic properties of the prototypical Dirac semimetal Na\(_3\)Bi and compare our results with those based on the commonly used generalized gradient approximation (GGA). In particular, SCAN yields a spin-orbit coupling driven topological phase transition from the normal insulator to Dirac semimetal state in contrast with the GGA results. SCAN produces Dirac-node locations, Fermi velocities and s-band shift around the \(\Gamma\) point that are in better accord than the GGA predictions with the corresponding experimental results.

9:36AM E04.00007: A Monopole Mining Method for High Throughput Screening Weyl Semimetals VSEVOLOD IVANOV (Presenter), SERGEY SAVRASOV, University of California, Davis — Although topological invariants have been introduced to classify the appearance of protected electronic states at surfaces of insulators, there are no corresponding indexes for Weyl semimetals whose nodal points may appear randomly in the bulk Brillouin Zone (BZ). Here we use a well–known result that every Weyl point acts as a Dirac monopole and generates integer Berry flux to search for the monopoles on rectangular BZ grids that are commonly employed in self–consistent electronic structure calculations. The method resembles data mining technology of computer science and is demonstrated on locating the Weyl points in known Weyl semimetals. It is subsequently used in high throughput screening several hundreds of compounds and predicting a dozen new materials hosting nodal Weyl points and/or lines.
Chiral crystals are materials whose lattice structure with a well-defined handedness due to the lack of inversion, mirror, or other roto-inversion symmetries, which represent a broad, important class of quantum materials. Yet, the topological properties of chiral crystals have still remained largely uncharacterized. Here, we show that Kramers-Weyl fermions are a universal topological electronic property of chiral crystals with spin-orbit coupling (SOC). Unlike conventional Weyl fermions, they appear at time-reversal-invariant momenta. By combining our analysis with the results of previous works, we further determine that all point-like nodal degeneracies in nonmagnetic chiral crystals with relevant SOC carry nontrivial Chern numbers. Using this theory, we identify representative chiral materials in 33 of the 65 chiral space groups in which topological chiral fermions are relevant to low-energy physics. Among all the materials, RhSi family exhibit the ideal topological band structures with longest Fermi arcs and nontrivial energy windows.

Fermi arcs in topological chiral crystals

The telltale trademarks of a Weyl semimetal are the topologically protected Fermi arc surface states. While these surface states have been demonstrated in conventional Weyl semimetals (for instance, the TaAs family), they should also be present in the recently proposed unconventional Weyl semimetals. However, there is still a lack of candidate materials for experimental exploration. In this talk, we comment on a number of chiral crystals in space group No. 198, as platforms for expanding the list of Fermi arc materials. Notably, RhSi, CoSi, CoGe, RhGe, AlPd, AlPt, BaPtP, and BaPtAs constitute promising candidate materials. Indeed, these compounds should exhibit the longest possible Fermi arcs, spanning across the entire surface Brillouin zone. These predictions are closely tied to the maximally separated 4-fold and 6-fold unconventional chiral fermions that have recently been predicted in this class of compounds. We further comment on experimental progress and the current challenges in using ARPES to observe a chiral Weyl semimetal phase with Fermi arcs in these materials.

Work at Princeton was supported by the US DOE under Basic Energy Sciences programme (grant number DOE/BES DE-FG-02-05ER46200) and the Gordon and Betty Moore Foundation (GBMF4547/Hasan).

Pr$_2$Ir$_2$O$_7$: when Luttinger semimetal meets Melko-Hertog-Gingras spin ice state

In quantum materials with multiple flavors of degrees of freedom (DOF), the interplay between them leads to intriguing phenomena and allows the mutual control. Here we study band topology and engineering from the interplay between local moments and itinerant electrons in pyrochlore iridates. For metallic Pr$_2$Ir$_2$O$_7$, the Ir 5d conduction electrons interact with the Pr 4f local moments via the f-d exchange. While the Ir electrons form a Luttinger semimetal, the Pr moments can be tuned into an ordered spin ice with a finite ordering wavevector, dubbed Melko-Hertog-Gingras (MHG) state, by varying Ir and O contents. We point out that the Pr Ising order generates an internal field that reconstructs the Ir bands. Besides the broad existence of Weyl nodes, we predict that the magnetic translation of the Pr MHG state protects the Dirac band touching at certain time reversal invariant momenta for the Ir bands. We propose the magnetic fields to control the Pr magnetism and indirectly influence the Ir electrons. Our prediction can be immediately tested in ordered Pr$_2$Ir$_2$O$_7$ samples. Our theory constitutes a nontrivial and realistic example for the interplay between itinerant electrons and local moment in three dimensions, and shed lights on hybrid quantum materials with multiple flavors of DOF.
Optically-Controlled Orbitronics on a Triangular Lattice

VO TIEN PHONG (Presenter), ZACHARIAH ADDISON, University of Pennsylvania, SEONGJIN AHN, HONGKI MIN, Physics and Astronomy, Seoul National University, RITESH AGARWAL, EUGENE JOHN MELE, University of Pennsylvania

Orbital polarization of a Bloch state in a crystal can endow a band structure with nontrivial geometry and manifest itself in unique responses to applied fields. We study this for an on-site orbital multiplet on a 2D primitive triangular lattice where orbital degeneracies are lifted by propagation on a Bravais lattice. The model contains fully orbitally-derived band structure degeneracies including a line-node required by the perpendicular mirror symmetry and two types of point degeneracies protected by PT symmetry.

Crucially, and in contrast to the well-studied analogous problem on the honeycomb lattice, here point degeneracies with opposite winding numbers are generically offset in energy which enables the activation of anomalous transport responses using readily-implemented spatially-uniform local potentials. We demonstrate this by calculation of an anomalous charge Hall effect activated by coherently coupling to a circularly polarized optical field and an orbital Hall effect describing an orbital angular momentum current directed perpendicular to an applied in plane electric field.

Chiral Vortical and Gyrotropic Effects in Weyl Semimetals

ZHAO HUANG (Presenter), PAVAN HOSUR, University of Houston

The chiral anomaly is the source of various interesting phenomena for chiral fermions, and especially in Weyl semimetals which contain chiral fermions as low energy excitations. For example, a magnetic field leads to a longitudinal current flow in the absence of electric fields, well known as the chiral magnetic effect. Since the Coriolis force behaves like a Lorentz force in many ways, one expects an axial current induced by rotation for chiral fermions. This is known as the chiral vortical effect. This effect has attracted a lot of attention in nuclear physics for its possible consequences for heavy ion collisions [1]. In this work, we theoretically explore the possibility of the chiral vortical effect in Weyl semimetals. In particular, we argue that naively rotating a Weyl semimetal is not the correct way to induce the chiral vortical effect. Instead, one must rotate the chiral fluid of electrons relative to the background lattice. The latter can be achieved via an electric field with a non-zero curl, and is otherwise known as the gyrotropic effect.

Prediction of Weyl semimetal, AFM topological insulator, nodal line semimetal, and Chern insulator phases in Bi$_2$MnSe$_4$

SUGATA CHOWDHURY (Presenter), KEVIN GARRITY, FRANCESCA TAVAZZA, Materials Measurement Laboratory, National Institute of Standards and Technology

Three dimensional materials with strong spin-orbit coupling and magnetic interactions represent an opportunity to realize a variety of rare and potentially useful topological phases. In this work, we use first principles calculations to show that the recently synthesized material Bi$_2$MnSe$_4$ displays a combination of band inversion and magnetic interactions, leading to several topological phases. In bulk form, the ferromagnetic phase of Bi$_2$MnSe$_4$ is either a nodal line or Weyl semimetal, depending on the direction of the spins. When the spins are arranged in a layered antiferromagnetic configuration, the combination of time reversal plus a partial translation is a new symmetry, and the material instead becomes an antiferromagnetic topological insulator. However, the intrinsic TRS breaking at the surface of Bi$_2$MnSe$_4$ removes the typical Dirac cone feature, allowing the observation of the half-integer quantum anomalous Hall effect (AHC). Furthermore, we show that in thin film form, for some thicknesses, Bi$_2$MnSe$_4$ becomes a Chern insulator with a band gap of up to 58 meV. This combination of properties in a stoichiometric magnetic material makes Bi$_2$MnSe$_4$ an excellent candidate for displaying robust topological behavior.

Session E05 DMP: Topological Superconductivity: TMD, Quantum Wells

BCEC 108 - Vidya Madhavan, Univ of Illinois - Urbana - Tag(s): Focus
Quantum spin Hall state in monolayer 1T'-TMDCs*  

SHUJIE TANG (Presenter), SIMES, Stanford University — Quantum spin Hall (QSH) insulator, also known as 2D topological insulator (TI), hosts quantized helical edge state, which is a superior candidate to construct artificial 1D superconductor utilizing the superconductivity proximity effect. Among the rapidly developing 2D TI family, group VI transition metal dichalcogenides (TMDCs) in 1T' structural phases are unique in their van der Waals layered structure, which can be easily integrated into vertical heterostructures. Bottom-up synthesis of monolayer 1T'-TMDCs (WTe2, WSe2 and MoTe2) on graphitized SiC substrate were achieved using molecular beam epitaxy. Together with theoretical calculation and ARPES measurement, the characteristic signatures of QSH states such as band inversion and bulk gap opening have been confirmed in 1T'-WTe2 and WSe2 [1, 2]. Scanning tunneling spectroscopy (STS) measurements further provide evidence for the robust edge states reside in the bulk gap. It is also found that, although conduction and valence band degeneracy is lifted in 1T'-MoTe2, the spin-orbital coupling is not strong enough to further separate them, leaving 1T'-MoTe2 a semimetal [3].

9:00AM E05.00004: Observation of Superconductivity in Few-layers WTe₂ Induced by Normal Contacts**

ARTEM KONONOV (Presenter), GULIBUSITAN ABULIZI, ANDREAS BAUMGARTNER, Department of Physics, University of Basel, KEJIAN QU, JIAQIANG YAN, DAVID GEORGE MANDRUS, Materials Science and Engineering, The University of Tennessee, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, CHRISTIAN SCHONENBERGER, Department of Physics, University of Basel — WTe₂ is a material possessing topological properties both as a bulk crystal and single layer. In the former case, it is a type-II Weyl semimetal and in the latter a quantum spin Hall state. Recent reports showing the possibility to induce superconductivity in WTe₂ by proximity to a bulk superconductor or by electrostatic gating make it a promising platform for topological superconductivity and quantum computation. Here we report on a novel mechanism of inducing superconductivity within few-layers of WTe₂ by normal metal contacts. In transport measurements we find that the induced superconductivity is highly anisotropic in magnetic field and survives up to 7 Tesla in in-plane field. Superconducting transport persists over μm distances at temperatures up to 1 Kelvin. Our results could provide insight to the superconducting state in WTe₂ and its topological nature.

9:12AM E05.00005: Proximity-induced superconductivity with sub-gap anomaly in type-II Weyl semimetal WTe₂

QIAO LI (Presenter), School of Physics, Nanjing University — Tungsten ditelluride (WTe₂) is one of the material candidates in the family of type-II Weyl semimetals, exhibiting many exotic properties, such as anisotropic chiral anomaly. Due to the intrinsic topological band structure and tilted Weyl cone in WTe₂, it has been predicted that unconventional superconducting properties will emerge when WTe₂ enters to superconducting phase. In this work, we report the observation of superconductivity in the type-II Weyl semimetal WTe₂ based on WTe₂/NbSe₂ heterostructure induced by proximity effect. We find a long coherence length along c axis of WTe₂. Furthermore, we observe anomalous oscillations of the differential resistance spectrum during the transition from superconducting to normal state. Theoretical calculations indicate that the stage change in the differential resistance spectrum can be associated with anomalous density of states in superconducting state and reveals that such a sub-gap anomaly is the intrinsic property of WTe₂ in superconducting state induced by the proximity effect. Our findings can enrich the understanding of superconductivity mechanism in type-II Weyl semimetal and pave the way for their future applications in topological quantum computing.

9:24AM E05.00006: Quantum transport in MoTe₂ and WTe₂ topological monolayers

XIRUI WANG (Presenter), KENJI YASUDA, YAFANG YANG, SANFENG WU, TAKEHITO SUZUKI, LIN ZHOU, JING KONG, JOSEPH CHECKELSKY, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — There has been growing interest in the study of 2D topological quantum states. Recent experiments established monolayer WTe₂ as a 2D topological insulator, which also becomes a superconductor via gating. This has triggered a lot of excitement in studying a wide range of topological properties of monolayer WTe₂ and its cousins, such as MoTe₂. We will report our investigations on the quantum transport behavior of monolayer WTe₂ and MoTe₂ in nano-fabricated devices, in the direction of searching for topological superconductivity.

9:36AM E05.00007: Procedural Determination of Novel Stoichiometric Topological Superconductors through Surface and Pressure Effects

ABHISHEK ALLAMSETTY (Presenter), Thomas Jefferson High School for Science and Technology — Topological superconductors have attracted great interest as a groundbreaking platform to allow for fault-tolerant quantum computing and overcome the limitations of classical processors defined by Moore’s law. In this paper, we discover eight novel topological superconductors, ABX₂ (A=Bi, In; B=Nb, Ta; X=Se, S) and propose a new systematic method to realize topological superconductors by combining of transition metal dichalcogenides with spin-orbit post-transitional elements. These eight compounds are bulk superconductors with intrinsic topological surface states and can be realized without any tampering, a coveted quality for topological superconductors. Utilizing density functional theoretical calculations, we determined topological surface states and bulk superconductivity from the electronic band structures of our compounds. In addition, we demonstrated the robust nature of our materials under high-pressure conditions, as their non-trivial topology and superconductivity were maintained. Our eight novel compounds hold great promise towards the practical realization of fault-tolerant quantum computers through their ability to eliminate the longstanding problem of quantum decoherence within quantum computational systems.
9:48AM E05.00008: Enhancing Superconductivity in Indium Arsenide Quantum Well Heterostructures* ANDREW SAYDJARI (Presenter), MICHAEL KOSOWSKY, ANDREW T PIERCE, Physics, Harvard University, JOSEPH YUAN, KAUSHINI WICKRAMASINGHE, Physics, New York University, JAVAD SHABANI, AMIR YACOBY, Physics, Harvard University — Hybrid superconductor-semiconductor heterostructures containing indium arsenide quantum wells combine strong spin-orbit effects, s-wave superconductivity, and arbitrary lithographic confinement. This platform facilitates both study of induced superconductivity in the quantum well and topological states in quasi-one-dimensional systems. While epitaxial aluminum provides transparent contact to the quantum well, aluminum cannot sustain large magnetic fields (>1 T) required to explore many topological effects. Further, the small (150 µeV) superconducting gap of aluminum can complicate detection and inhibit manipulation of states required for applications to topological quantum computing. In this work, we present a method of coupling niobium-based superconductors to indium arsenide quantum wells to supplement the critical magnetic field and superconducting gap in this platform. Experimental progress on fabrication of superconductor-semiconductor-superconductor (SNS) junctions and quantum point contacts will be presented.

10:00AM E05.00009: Multi-terminal Josephson effect in epitaxial InAs/Al superconductor/semiconductor devices I: current-biased measurements HANHO LEE (Presenter), NATALIA PANKRATOVA, ROMAN KUZMIN, KAUSHINI WICKRAMASINGHE, University of Maryland, College Park, ALEX LEVCHENKO, MAXIM VAVILOV, University of Wisconsin-Madison, JAVAD SHABANI, New York University, VLADIMIR MANUCHARYAN, University of Maryland, College Park — Junctions of more than two topological superconductors are typically required for implementing braiding operations on Majorana fermions [1]. Here we report the first realization of 3- and 4-terminal Josephson junctions fabricated from a Majorana-compatible hybrid InAs/Al epitaxially-grown heterostructure [2]. We observed several novel phenomena: interaction of intersecting supercurrents, multi-terminal Fraunhofer effect in a magnetic field, and out-of-equilibrium multiple Andreev reflections (MAR) at bias voltages far exceeding the gap of Al. The data in a large number of channels regime can be modeled using random matrix circuit theory of superconducting transport. Progress towards realizing the phase-control of zero-energy quasiparticle states, predicted in such structures in the absence of Zeeman fields [3,4,5], will be discussed.

10:12AM E05.00010: Multi-terminal Josephson effect in epitaxial InAs/Al superconductor/semiconductor devices II: phase-biased measurements NATALIA PANKRATOVA (Presenter), HANHO LEE, ROMAN KUZMIN, KAUSHINI WICKRAMASINGHE, University of Maryland, College Park, ALEX LEVCHENKO, MAXIM VAVILOV, University of Wisconsin-Madison, JAVAD SHABANI, New York University, VLADIMIR MANUCHARYAN, University of Maryland, College Park — Junctions of more than two topological superconductors are typically required for implementing braiding operations on Majorana fermions [1]. Here we report the first realization of 3- and 4-terminal Josephson junctions fabricated from a Majorana-compatible hybrid InAs/Al epitaxially-grown heterostructure [2]. We observed several novel phenomena: interaction of intersecting supercurrents, multi-terminal Fraunhofer effect in a magnetic field, and out-of-equilibrium multiple Andreev reflections (MAR) at bias voltages far exceeding the gap of Al. 10:24AM E05.00011: Probing Spin-Orbit Coupling in InAs/Al SQUIDs* WILLIAM ANDREW MAYER (Presenter), SICHAO YU, Physics, New York University, KAUSHINI WICKRAMASINGHE, Physics, University of Maryland, College Park, JOSEPH YUAN, Physics, New York University, NARAYAN MOHANTA, ALEX MATOS ABIAGUE, Physics, Wayne State University, IGOR ZUTIC, Physics, University at Buffalo, The State University of New York, JAVAD SHABANI, Physics, New York University — InAs/Al epitaxial heterostructures allow for transparent semiconductor/superconductor interfaces to study superconducting proximity effect, particularly in Josephson junctions. A superconducting quantum interference device (SQUID) constructed from such junctions opens the possibility of studying current-phase relations in these materials systems. One distinct property of this system is the gate-tunability where each junction can be depleted, effectively turning off the current in that junction. This allows for detailed analysis of the supercurrent properties not previously possible in a single device. The second important feature of this system is the presence of spin-orbit coupling in InAs, whose strength is gate-tunable. We study the SQUID signal as we tune the spin-orbit coupling in each arm using independent gate voltages. The comparison between experimental data and theoretical simulation suggests that spin-orbit coupling can be detected in SQUID signal. This direct probe of spin-orbit coupling in proximitized systems represents an important tool to study systems which potentially host Majorana fermions.

10:36AM E05.00012: Induced superconductivity in InSb 2DEGs CHUNG-TING KE (Presenter), CHRISTIAN M. MÖHLE, FOLKERT DE VRIES, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands, CANDICE THOMAS, SARA METTI, CHARLES R GUINN, Department of Physics and Astronomy and Station Q Purdue, Birck Nanotechnology Center, Purdue University, West Lafayette, Indiana 47907, USA, RAY KALLAHER, GEOFFREY C. GARDNER, Microsoft Quantum at Station Q Purdue, Birck Nanotechnology Center, Purdue University, West Lafayette, Indiana 47907, USA, MICHAEL MANFRA, Department of Physics and Astronomy and Station Q Purdue, Birck Nanotechnology Center, Purdue University, West Lafayette, Indiana 47907, USA, SRIJIT GOSWAMI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, 2600 GA Delft, The Netherlands — Superconductor-semiconductor hybrid systems are promising candidates to create Majorana zero modes (MZMs). Using a semiconductor two-dimensional electron gas (2DEG) could allow one to create complex networks required for Majorana qubit schemes. In this regard, InSb 2DEGs stand out due to their large g-factor, strong spin-orbit coupling, and low disorder. We integrate such high-quality 2DEGs with NbTiN to create Josephson junctions (JJs), thus providing the first demonstration of induced superconductivity in InSb 2DEGs. Remarkably, the supercurrent persists over several microns and shows distinct signatures of ballistic transport. Applying an in-plane magnetic field produces a revival of the supercurrent due to a Zeeman induced 0-π transition, where the transition field scales linearly with the junction length. Moreover, we show that this transition can be tuned in-situ using gate voltages, which allows us to map out the free energy landscape of the JJ as a function of density and magnetic field. Our experiments are consistent with the expected behavior of 0-π transitions in ballistic JJs and are an important step toward creating robust MZMs in 2DEG-based π-junctions.

10:48AM E05.00013: Transport phenomena in epitaxial Al / InAs heterostructures with strong spin-orbit coupling in the presence of in-plane magnetic fields* MICHAEL KOSOWSKY (Presenter), ANDREW SAYDJARI, ANDREW T PIERCE, Physics, Harvard University, HECHEN REN, Physics, California Institute of Technology, KAUSHINI WICKRAMASINGHE, JOSEPH YUAN, JAVAD SHABANI, Physics, New York University, AMIR YACOBY, Physics, Harvard University — Two-dimensional electron gas (2DEG) systems with strong spin-orbit coupling (SOC) and induced s-wave superconductivity are predicted to realize topological superconductivity when in the presence of in-plane magnetic fields. A major obstacle in studying these systems arises due to the tendency of magnetic fields to suppress superconductivity. By growing epitaxial aluminum on top of an InAs quantum well heterostructure, it is possible to create a high-transparency interface between the superconductor and the 2DEG. This interface results in induced superconductivity that is comparable with the true aluminum superconducting gap, thereby sustaining larger in-plane fields than achieved by ex situ aluminum deposition. Here, we discuss the devices that we have fabricated to explore this exciting system, as well as present initial millikelvin measurements studying Josephson phenomena in the presence of varying in-plane and perpendicular magnetic fields.

*The device fabrication and measurements are supported by the NSF DMR-1708688 and by the STC Center for Integrated Quantum Materials under NSF DMR-1231319. The material growth was supported by NSF-DMR-1836687.

Tuesday, March 5, 2019 8:00 AM - 10:48 AM

Session E06 DCMP: Electronic States in Se Chalcogenides: Including Excitonic Behavior
BCEC 109A - Johnpierre Paglione, University of Maryland, College Park
8:00AM E06.00001: Response of FeSe to in-plane anisotropic strain* CLIFFORD HICKS (Presenter), JACK BARTLETT, ALEXANDER STEPPKE, Max Planck Institute for Chemical Physics of Solids, SUGURU HOSOI, Osaka University, TAKASADA SHIBAUCHI, Tokyo University, ANDREW MACKENZIE, Max Planck Institute for Chemical Physics of Solids — By affixing thin single crystals of FeSe to rigid sample carriers and then applying uniaxial stress to the carrier, we apply in-plane uniaxial strains of up to ~0.7% to FeSe. Above the structural transition temperature $T_s$, anisotropic strain drives partial polarization of the nematic order, and a corresponding strong resistive anisotropy [1, 2]. However the resistive anisotropy saturates rapidly as strain is applied, and the resistivity then varies nonmonotonically for compressions above ~0.3%. Below $T_s$, the extrinsic contribution to the resistance from twin boundaries can be identified. The twin boundaries are weakly pinned and can be partially annealed, allowing the intrinsic elastoresistivity below $T_s$ to be resolved.

*Max Planck Society

8:12AM E06.00002: Nonequilibrium dynamics of local lattice distortions in FeSe TATIANA Konstantinova (Presenter), Lijun Wu, Milinda Abeykoon, Cedomir Petrovic, CMPMSD, Brookhaven National Laboratory, Xijie Wang, SLAC, Yimei Zhu, Aifeng Wang, CMPMSD, Brookhaven National Laboratory — The role of the lattice in unique properties of iron-based superconductors, such as electronic nematicity, is still unclear. This rises an interest in investigating the local structure modifications during the phase transitions in these materials. We report the study of the local crystal structure of FeSe and its connection to electronic nematicity using ultrafast electron diffraction, x-ray diffraction, and transmission electron microscopy. The study reveals the local distortions in form of iron dimers, ordered within nanometer-sized domains. The observed nonequilibrium lattice dynamics implies sensitivity of the lattice distortions to the nematic order parameter.

8:24AM E06.00003: Character of excitonic insulator phase in a transition metal dichalcogenide 1T-TiSe$_2$. JIN MO BOK (Presenter), HAN-YONG CHOI, Sungkyunkwan University — We revisit the question of the transition metal dichalcogenide 1T-TiSe$_2$ charge density wave (CDW) state being an excitonic insulator. The BCS-like CDW gap equation with statically screened Coulomb interaction was employed to calculate the transition temperature ($T_c$) as a function of the energy gap. Realistic dispersions for one hole band centered at $\Gamma$ and three electron bands at M points in two-dimensional periodic hexagonal lattice were considered to model the TiSe$_2$. The obtained $T_c$ (~240K) is comparable to measured one for monolayer (~232K), and $T_c$ suppression as a function of doping concentration and pressure are reproduced by controlling chemical potential and energy gap. We discuss possibility of the 1T-TiSe$_2$ CDW state originating from exciton condensation through the calculated $T_c$, ARPES intensity and density of states.

8:36AM E06.00004: Intrinsic Insulating Ground State in Transition Metal Dichalcogenide TiSe$_2$. DANIEL CAMPBELL (Presenter), CHRIS ECKBERG, PETER ZAVALIJ, JOHNPIERRE PAGLIONE, University of Maryland, College Park — TiSe$_2$ has received significant research attention over the past four decades, in large part due to the uniqueness of its charge-ordered state. Different techniques can suppress the charge density wave transition, vary low temperature resistivity by orders of magnitude, and stabilize magnetic or superconducting states. This talk will present the results of a new synthesis method whereby samples were grown in an argon gas environment at elevated pressures up to 180 bar. Above 100 K, properties (including those of the 200 K CDW) are unchanged from prior reports. However, a hysteretic resistance region beginning around 80 K, accompanied by insulating low temperature behavior, is distinct from anything previously observed. This new feature suggests that pressure growth may allow access to a nonmetallic ground state in a material long speculated to be an excitonic insulator.
Folded superstructure and degeneracy-enhanced band gap in the weak-coupling charge density wave system 2H–TaSe₂

YIWEI LI (Presenter), Department of Physics, University of Oxford, United Kingdom, JUAN JIANG, School of Engineering & Applied Science, Yale University, USA, HAIFENG YANG, School of Physical Science and Technology, ShanghaiTech University, People's Republic of China, DHARMALINGAM PRABHAKARAN, Department of Physics, University of Oxford, United Kingdom, ZHONGKAI LIU, School of Physical Science and Technology, ShanghaiTech University, People's Republic of China, LEXIAN YANG, Department of Physics and Collaborative Innovation Center of Quantum Matter, Tsinghua University, People's Republic of China, YULIN CHEN, Department of Physics, University of Oxford, United Kingdom — Using high-resolution angle-resolved photoemission spectroscopy (ARPES), we have mapped out the reconstructed electronic structure in the commensurate charge-density-wave (CDW) state of quasi-two-dimensional transition metal dichalcogenide 2H–TaSe₂. The observation of the fine structure near Brillouin zone (BZ) center supplements the picture of Fermi surface folding in the 3×3 CDW state. In addition to the anisotropic CDW band gaps that energetically stabilize the system at the Fermi level in the first-order lock-in transition, we found band reconstruction at high binding energy, which can be well explained by the hybridization between main bands (MBs) and folded bands (FBs). Furthermore, in contrast to the perfectly nested quasi-one-dimensional system, triple-nesting-vector-induced CDW FBs increase the degeneracy of the band crossing and thus further enlarge the magnitude of band gap at certain momentum-energy positions. The visualization and modeling of CDW gaps in momentum-energy space reconcile the long-lasting controversy on the gap magnitude and suggests a weak-coupling Peierls physics in this system.

Observation of anomalous electron relaxation in optically excited 1T-TaSe₂

YINGCHAO ZHANG (Presenter), XUN SHI, WENJING YOU, ZHENSHENG TAO, Department of Physics and JILA, University of Colorado, Boulder, KAI ROSSNAGEL, MICHAEL BAUER, Institute of Experimental and Applied Physics, Kiel University, HENRY C KAPTEYN, MARGARET MARY MURNANE, Department of Physics and JILA, University of Colorado, Boulder — Ultrafast light pulses can drive materials far from their equilibrium states and is a powerful approach for manipulating their states. In this work, we present a series of anomalous behaviors observed in the electron relaxation in the charge density wave (CDW) material 1T-TaSe₂. After exciting the material with a femtosecond laser pulse, we measure the temporal evolution of the band structure and electron temperature. We observe a band oscillation that is coherently coupled to the CDW amplitude mode. Meanwhile, the hot electron temperature relaxes anomalously fast, and very different from that predicted by the widely-used N-temperature model. Moreover, this anomaly shows a critical change at the laser fluence corresponding to the ultrafast phase transformation to a new long-lived metastable state. These results offer a rare opportunity for better understanding of the coherent electron-phonon coupling.

Spinon Fermi Surface in a Cluster Mott Insulator Model on a Triangular Lattice and Possible Application to 1T-TaS₂

WENYU HE (Presenter), XIAO YAN XU, Hong Kong University of Science and Technology, GANG CHEN, Department of Physics, Fudan University, KAM TUEN LAW, Hong Kong University of Science and Technology, PATRICK LEE, Department of Physics, Massachusetts Institute of Technology — 1T-TaS₂ is a cluster Mott insulator on the triangular lattice with 13 Ta atoms forming a star of David cluster as the unit cell. We derive a two-dimensional XXZ spin-1/2 model with a four-spin ring exchange term to describe the effective low energy physics of a monolayer 1T-TaS₂, where the effective spin-1/2 degrees of freedom arises from the Kramers degenerate spin-orbital states on each star of David. A large scale density matrix renormalization group simulation is further performed on this effective model and we find a gapless spin liquid phase with a spinon Fermi surface at a moderate to large strength region of the four-spin ring exchange term. All peaks in the static spin structure factor are found to be located on the“2kF” surface of a half-filled spinon on the triangular lattice. Experiments to detect the spinon Fermi surface phase in 1T-TaS₂ are discussed.
distortion associated with the formation of the EI state allows bidirectional electronic dynamics in quantum solid material. In this talk, we will present the electronic evidence of quenching the bandgap, TNS is believed to realize the pure excitonic insulator state, free from the complications of coexisting density-many-body gap, as well as a coherent amplitude-like response observed in optical pump-probe data. Due to its direct optical band gap $E_g = 160$ meV. At the same time, the gap gradually fills from the high-frequency side with significant spectral weight from above-gap states. This transfer of spectral weight can be interpreted as predominant incoherent hopping of charge carriers along the Ta-Ni chains in the orthorhombic phase and as evidence for near-zero-gap behavior at high temperature. A phonon centered at 4.71 meV in both the $a$- and $c$-axis response suggests that the monoclinic distortion associated with the formation of the EI state allows bidirectional $a$-plane activity of the $B_{1u}/B_{3u}$ modes.

9:36AM E06.00009: Terahertz spectroscopy of excitonic insulator candidate Ta$_2$NiSe$_5$  
ROBERT DAWSON (Presenter), TIMOFEI LARKIN, MARC HOEFFNER, TOMOHIRO TAKAYAMA, MASAKI YAMAMOTO, HIDENORI TAKAGI, BERNHARD KEIMER, ALEXANDER BORIS, Max Planck Institute for Solid State Research — An excitonic insulator (EI) is a correlated-electron state in which excitons condense into an insulating ground state in analogy with the condensation of Cooper pairs in a superconductor. A handful of EI candidates have been proposed, but to date experimental verification of such a state has not been conclusively found. Recent transport and specific heat measurements have placed Ta$_2$NiSe$_5$ as the leading EI candidate with $T_c = 326$ K. Here we present measurements of the terahertz and far-infrared optical conductivity of Ta$_2$NiSe$_5$, which show that at temperatures far below $T_c$ a thermally-activated Drude peak gradually develops inside the optical band gap $E_g^{op} = 160$ meV. At the same time, the gap gradually fills from the high-frequency side with significant spectral weight from above-gap states. This transfer of spectral weight can be interpreted as predominant incoherent hopping of charge carriers along the Ta-Ni chains in the orthorhombic phase and as evidence for near-zero-gap behavior at high temperature. A phonon centered at 4.71 meV in both the $a$- and $c$-axis response suggests that the monoclinic distortion associated with the formation of the EI state allows bidirectional $a$-plane activity of the $B_{1u}/B_{3u}$ modes.

9:48AM E06.00010: Cooperative Exciton-Phonon Bose-Einstein Condensation in an Excitonic Insulator*  
EDOARDO BOLDINI (Presenter), Department of Physics, Massachusetts Institute of Technology, YAO WANG, Department of Physics, Harvard University, ALFRED ZONG, CHANGMIN LEE, DEBANJAN CHOWDHURY, Department of Physics, Massachusetts Institute of Technology, YANGFAN LU, Department of Physics, University of Tokyo, TOMOHIRO TAKAYAMA, HIDENORI TAKAGI, Max Planck Institute for Solid State Research, EUGÈNE DEMLER, Department of Physics, Harvard University, NÜH GEDIK, Department of Physics, Massachusetts Institute of Technology — The excitonic insulator is an exotic phase of matter in which excitons spontaneously form and collectively undergo Bose-Einstein condensation. Recently, increasing evidence has shown that this ground state is stabilized in the layered transition metal chalcogenide Ta$_2$NiSe$_5$ (TNS). Distinctive signature of exciton condensation is the pronounced flattening of the valence band top with decreasing temperature, signaling the opening of an additional many-body gap, as well as a coherent amplitude-like response observed in optical pump-probe data. Due to its direct bandgap, TNS is believed to realize the pure excitonic insulator state, free from the complications of coexisting density-wave orders or strong coupling to other degrees of freedom. Here, we reveal that a cooperative exciton-phonon mechanism lies instead at the origin of the condensate in TNS. Specifically, we use time- and angle-resolved photoemission spectroscopy to show that the vibrational degrees of freedom play a crucial role in the photoinduced melting of the exciton Bose-Einstein condensate. Our results open new routes towards the selective manipulation of the excitonic insulating state via specific modes of the crystal lattice.

10:00AM E06.00011: Time- and Angle-Resolved Photoemission Study on the Excitonic Insulator Candidate Ta2NiSe5  
WENTAO ZHANG (Presenter), School of Physics and Astronomy, Shanghai jiao Tong University — Ultra-high resolution laser-based time- and angle-resolved photoemission is a unique technique in probing the momentum resolved ultrafast electronic dynamics in quantum solid material. In this talk, we will present the electronic evidence of quenching the excitonic insulating state and a hidden semimetallic state upon excited by a strong infrared laser pulse in the excitonic insulator candidate Ta2NiSe5.
10:12AM E06.00012: Exciton Mott transition revisited*  
DANIELE GUERCI (Presenter), MASSIMO CAPONE, MICHELE FABRIZIO, International School for Advanced Studies — The dissociation of excitons into holes and electrons in photoexcited semiconductors, despite being one of the first recognized examples of a Mott transition, still defies a complete understanding, especially regarding the character of the transition, which is first order in some cases and second order in others. We tackle this issue by a recently proposed and very powerful variational technique, which extends the conventional Gutzwiller variational wavefunction and has been named ghost Gutzwiller wavefunction (g-GA). The results that we present [1] are in accordance with experiments and allow identifying the key parameter that controls the nature of the transition: the magnitude of the exciton binding energy.

10:24AM E06.00013: A Description of Phases with Induced Hybridisation at Finite Temperatures*  
DENIS GOLOSOV  
(Presenter), Department of Physics and the Resnick Institute, Bar-Ilan University, Ramat-Gan 52900, Israel — In an extended Falicov-Kimball model, an excitonic insulator phase can be stabilised at zero temperature. With increasing temperature, the excitonic order parameter (interaction-induced hybridisation on-site, characterised by the absolute value and phase) eventually becomes disordered, which involves fluctuations of both its phase and (at higher T) its absolute value. In order to build an adequate mean field description, it is important to clarify the nature of degrees of freedom associated with the phase and absolute value of the induced hybridisation, and the corresponding phase space volume. We show that a possible description (including the phase space integration measure) is provided by the on-site density matrix parametrisation. In principle, this allows to describe both the lower-temperature regime where phase fluctuations destroy the long-range order, and the higher temperature crossover corresponding to a decrease of absolute value of the hybridisation relative to the fluctuations level. This picture is also expected to be relevant in other contexts, including the Kondo lattice model.

*This work was supported by the Israeli Absorption Ministry.

10:36AM E06.00014: Gutzwiller Molecular Dynamics Simulation using Second-Moment Approximation  
PEDROM ZADEH (Presenter), GIA-WEI CHERN, University of Virginia — Molecular dynamics (MD) simulations are crucial to modern computational physics, chemistry, and material science, especially when combined with potentials derived from density-functional theory. However, even in state of the art MD codes, the on-site Coulomb repulsion is only treated at the self-consistent Hartree-Fock level. This standard approximation may miss important effects due to electron correlations. The recently developed Gutzwiller molecular dynamics (GMD) method provides a feasible approach for realistic correlated materials [1]. The Gutzwiller variational method captures the essential physics of correlated electron systems, and is much faster than, for example, the dynamical-mean field theory approach. In its current implementation, however, the GMD method is limited to small system sizes mainly due to the heavy computational cost of solving the renormalized electron Hamiltonian at every time-step. Here we demonstrate significant improvement of the GMD efficiency using the second-moment approximation. Importantly, we show that this approximation still captures the main features of the correlation-induced metal-insulator transition.

Session E07 DCMP: Correlated Chains and Ladders  
BCEC 109B - Satya Kushwaha, Los Alamos National Laboratory
Here we explore the non-equilibrium steady-state of an XY spin chain in a transverse magnetic field coupled at its ends to magnetic thermal reservoirs. We generalize the phase diagram to non-equilibrium conditions obtained by applying a magnetization bias to the reservoirs.

Upon increasing the bias we observe a discontinuous jump of the magnetic order parameter that coincides with a divergent correlation length. While the first observation is a signature of a first-order transition, in equilibrium, the second arises only for continuous transitions. Thus, our findings show that out-of-equilibrium conditions allow for novel critical phenomena not possible at equilibrium. Moreover, for steady-states with a non-vanishing conductance, the entanglement entropy at the zero temperature was found to have logarithmic corrections that differ from the well-known equilibrium case.

*The authors acknowledge support by NSFC China, FCT Portugal, and National Key R&D Program of the MOST of China.

8:12AM E07.00002: Estimates of the Quantum Fisher Information in the $S = 1$ Anti-Ferromagnetic Heisenberg Spin Chain with Uniaxial Anisotropy* 

JAMES LAMBERT (Presenter), ERIK SORENSEN, McMaster University — The quantum Fisher information has relevance to quantum metrology and as an entanglement measure. We focus on the $S = 1$ anti-ferromagnetic Heisenberg model with uniaxial anisotropy. Quantum Monte Carlo techniques are used to determine low temperature correlations from which the quantum Fisher information can be estimated within the single mode approximation. The quantum Fisher information is compared to the quantum variance for the staggered magnetization operators in the transverse direction and inequalities between the quantum Fisher information, the quantum variance and the full variance are discussed.

Both the quantum and full variance as well as the quantum Fisher information are examined at finite temperatures above the isotropic point and at the quantum critical point for the Haldane-Néel transition. A finite size scaling study of the quantum Fisher information is performed at the quantum critical point and used to confirm the Ising nature of the Haldane-Néel transition.

8:24AM E07.00003: Reduced density operators of finite-sized Heisenberg XXZ chains* 

BOHAN LU (Presenter), ALEXANDER SEIDEL, Physics, Washington University — In quantum many-body physics, reduced density operators play a central role in revealing the properties of a given system. We elaborate on this by studying finite size Heisenberg XXZ chains in the presence of periodic boundary conditions. As pointed out by F. Verstraete and J. Cirac, the admissible (2-site) local density matrices form a convex set determined by compatibility with translational invariance. The density matrices of ground states of translationally invariant nearest-neighbor Hamiltonians will define the boundary of this set. It is hard to determine this boundary without actually solving for many-body ground states, as knowledge of it would give immediate access to ground state energies of a rich class of models. Here we present studies on the size dependence of this mysterious boundary manifold. We also discuss non-analyticities of the boundary characterizing quantum phase transitions in the thermodynamic limit.

*I am grateful for the financial support made possible by the Greg Delos Summer Fellowship.
8:36AM E07.00004: Localization in a t − J type ladder with translational symmetry  RONGYANG SUN (Presenter), Institute for Advanced Study, Tsinghua University, ZHENG ZHU, Department of Physics, Massachusetts Institute of Technology, ZHENG-YU WENG, Institute for Advanced Study, Tsinghua University — An explicit spatial localization of a hole is shown in a two-leg t-J ladder in the presence of a staggered chemical potential, which still retains translational symmetry, by density matrix renormalization group method. Delocalization can be recovered in following cases, in which either the hidden phase string effect is turned off or a finite next-neighbor hopping $t'$ is added to sufficiently weaken the phase string effect. In particular, two holes are always delocalized by forming a mobile bound pair in contrast to the localized single holes, pointing to a novel pairing mechanism of strong correlation nature.

8:48AM E07.00005: Flexible magnetism in flexible crystals*  ELISE KENNY (Presenter), ANTHONY C JACKO, BEN J POWELL, School of Mathematics and Physics, The University of Queensland — We predict that the elastically flexible crystal, $[\text{Cu(acac)}_2]$ [1], contains quasi-one-dimensional magnetic interactions that change dramatically when the crystal is bent. In the unbent crystal, all interchain interactions are doubly frustrated – geometrically and by the equipoise of antiferromagnetic and ferromagnetic interactions in the two planes perpendicular to the chains. We parametrize a Heisenberg model for the unbent and bent crystal from broken-symmetry density functional theory [2], revealing that the intrachain exchange interaction is an order of magnitude larger than the interchain exchange interactions. We calculate the three dimensional Néel temperature, $T_N$, from the chain random phase approximation (CRPA) [3], which reveals that $[\text{Cu(acac)}_2]$ is an almost perfect Tomonaga-Luttinger liquid (TLL) with a $T_N$ that increases by approximately 175 orders of magnitude when the material is bent. This is a proof of principle demonstration that magnetic properties can be significantly altered by bending flexible crystals.

9:00AM E07.00006: Ladder-like optical conductivity in the spin-fermion model*  LAURA CLASSEN (Presenter), CMPMSD, Brookhaven National Laboratory, NEIL ROBINSON, Institute for Theoretical Physics, University of Amsterdam, ALEXEI TSVELIK, CMPMSD, Brookhaven National Laboratory — In the nested limit of the spin-fermion model for the cuprates, 1D-type physics in the form of half-filled two-leg ladders emerges. We show that the RG flow of the corresponding ladder is towards the dMott phase, a gapped spin-liquid with short-ranged d-wave pairing correlations, and reveals an intermediate SO(5)xSO(3) symmetry. We use the results of the RG in combination with a memory-function approach to calculate the optical conductivity of the spin-fermion model in the high-frequency regime, where processes within the hotspot region dominate the transport. For finite temperature, we determine the resistivity in the zero-frequency limit. We argue that Umklapp processes play a major role. Our results show an approximate linear temperature dependence of the resistivity and a conductivity that follows a non-universal power law, qualitatively consistent with experiment.

*This project has received funding from the Alexander-von-Humboldt foundation (L.C.), the European Union's Horizon 2020 research and innovation program under grant agreement No 745944 (N.J.R) and the U.S. Department of Energy, Office of Basic Energy Sciences, Contract No. DE-SC0012704 (A.M.T., LC).

9:12AM E07.00007: Spectrum of Dissipative Ising Chain  JIAN WANG (Presenter), SUDIP CHAKRAVARTY, physics and astronomy, University of California, Los Angeles — This paper extends the (0+1)D spin-boson problem to its (1+1)D version, a dissipative Ising Chain. Monte Carlo simulation and analytic continuation methods are used to explore its phase and dynamics. We find that, the quasi-particle excitation picture is destroyed, when the dissipation strength is greater than a critical value.

9:24AM E07.00008: Single-component fermion chain: emergent mode and liquids of bound states  YUCHI HE (Presenter), Physics, Carnegie Mellon University, BINBIN TIAN, DAVID PEKKER, ROGER MONG, Physics and Astronomy, University of Pittsburgh — We study the formation of bound states in a single-component Fermi chain with attractive interactions. The phase diagram, computed from DMRG (density matrix renormalization group), shows not only a superfluid of paired fermions (pair phase) and a liquid of fermion triplets (trion phase), but also a phase (2M phase) with two gapless modes. We argue based on our numerical data, that the single, pair, and trion phases are descendants of the 2M phase with a 2-component (“emergent”) Tomonaga-Luttinger liquid theory description.
We thus introduce and study interacting Majorana chains with $N = 1$ SUSY [3]. The Hamiltonian is defined by the square of a supercharge with a parameter, which is constructed solely by Majorana fermions. In the parameter space of the model, we find a particular point at which SUSY is unbroken and the ground states can be obtained analytically. We also find that SUSY is restored in the thermodynamic limit for modest values of the parameter. We prove, for large enough parameter values, that the system exhibits spontaneous SUSY breaking. We also prove the existence of NG fermions associated with this SUSY breaking, the dispersion of which is found to be cubic in momentum.

9:48AM E07.00010: Majorana-Hubbard Ladders  ARMIN RAHMANI (Presenter), Western Washington University, DMITRY PIKULIN, Microsoft Station Q, IAN AFFLECK, The University of British Columbia — Models of interacting Majorana modes may be realized in vortex lattices in superconducting films in contact with topological insulators and may be tuned to the strong interaction regime by adjusting the chemical potential. Extending the results on one- and two-dimensional Majorana-Hubbard models, here we study two- and four-leg ladders using both field theory and the (density-matrix renormalization group (DMRG)) methods, finding a phase diagram largely consistent with that proposed for the two-dimensional model on the square lattice.

10:00AM E07.00011: Ising ferromagnet to valence bond solid transition in a one-dimensional spin chain-analogies to deconfined quantum critical points*  SHENGHAN JIANG (Presenter), OLEXEI I MOTRUNICH, Caltech — We study a 1D system that shows many analogies to proposed 2D deconfined quantum critical points. Our system is a translationally invariant spin-1/2 chain with on-site $Z_2 \times Z_2$ symmetry and time reversal symmetry. It undergoes a direct continuous transition from a ferromagnet (FM), where one of the $Z_2$ symmetries and the time reversal are broken, to a valence bond solid (VBS), where all on-site symmetries are restored while the translation symmetry is broken. The other $Z_2$ symmetry remains unbroken throughout, but its presence is crucial for both the direct transition and the characterization of the VBS phase. The transition has a description in terms of either two domain wall species that "fractionalize" the VBS order parameter or in terms of partons that "fractionalize" the FM order parameter. The two descriptions are dual to each other. We also find an exact reformulation of the transition that leads to a simple field theory description that explicitly unifies the two order parameters, which can be interpreted as a new parton approach that encodes the two order parameters in instantons.

DONGHWAN KIM (Presenter), Department of Physics, Pohang University of Science and Technology, KYUNG-TAE KO, Max Planck POSTECH center for Complex Phase Materials, YOUNGHAK KIM, Department of Physics, Pohang University of Science and Technology, YOON SEOK OH, Department of Physics, Ulsan National Institute of Science and Technology, JAE-HOON PARK, Max Planck POSTECH center for Complex Phase Materials — A minor canted component of antiferromagnetic order below $T_N \sim 30.5$ K of NiTe$_2$O$_5$ was investigated by the soft x-ray resonant scattering on Ni $L_3$ edge. It is a $S=1$ (Ni$^{2+}$) magnetic insulator composed of edge shared NiO$_6$ one dimensional chains along b axis with four Ni atoms per period. The nearly 90° superexchange path between two adjacent Ni stabilizes intra-chain ferromagnetic order along b axis, which is ordered antiferromagnetically between adjacent chains. A detailed analysis on the azimuthal and polarization dependence of the (010) structural forbidden peak reveals that the resonant peak is a result of interference between the anisotropic tensor susceptibility and the magnetic resonant scattering amplitude from ‘up-down-down-up’ minor canted moment in ac plane. The non-collinear spin structure is related to the distortion of Ni-O-Ni bonding to induce non-zero Dzyaloshinskii-Moriya interaction, and rather large spin-orbit coupling of Ni 3d orbital.

This work was supported by Max Planck POSTECH/Korea Research Initiative, Study for Nano Scale Optomaterials and Complex Phase Materials (2016K1A4A4A01922028), through National Research Foundation (NRF) funded by MSIP of Korea.

SAMUEL DETMER (Presenter), ANJAN SOUMYANARAYANAN, MICHAEL YEE, YANG HE, Harvard University, MARTHA GREENBLATT, Chemistry and Chemical Biology, Rutgers University, NIGEL HUSSEY, Physics, University of Bristol, JENNIFER HOFFMAN, Harvard University — The marked deviation from Fermi liquid behavior for the quasi-one-dimensional (1D) purple bronze Li$_{0.9}$Mo$_6$O$_{17}$ (LMO) has been observed both by bulk transport and by surface-sensitive spectroscopic probes, and has generated much theoretical interest. Here we present spectroscopic scanning tunneling microscope (STM) images of 1D ‘chains’ on the surface of LMO. We find that the Coulomb suppression of tunneling around the Fermi energy is inhomogenous on the nanometer length scale, which necessitates a revision of the existing model of Luttinger-liquid-like behavior that was based on spatially-averaged spectroscopic techniques. We further report that chains of varying length exhibit resonances at varying energies, and we discuss the implications of this phenomenon for modeling the surface structure of LMO as a 1D quantum system.

KHAGENDRA ADHIKARI (Presenter), KEVIN BEACH, University of Mississippi — The dynamical behavior of many-particle systems is characterized by the lifetime of quasi-particles or excitations. Observables of any non-conserved quantity decay exponentially, but those of a conserved quantity relax to equilibrium with a power law ($t \sim 1/\Delta - L^z$). Such decay processes are associated with a dynamical exponent (e.g., $z = 1$ for the ballistic spread of quasi-particles and $z = 2$ for diffusion) that relates the spread of correlations in space and time. We present numerical results for the Fredkin model—a quantum spin chain with an unusual three-body interaction term—which exhibits a dynamical exponent $z \approx 3$. We discuss our efforts to make a reliable, quantitative estimate of $z$ and to explain the very slow dynamics in terms of a random walk executed by the excitation in Monte Carlo time.

SHINTARO TAKAYOSHI (Presenter), Max Planck Institute for the Physics of Complex Systems, THIERRY GIAMARCHI, Department of Quantum Matter Physics, University of Geneva — Localization caused by disorder has a long history of study since the pioneering work of Anderson. Recently many-body localization (MBL) has been intensively studied in the field of both condensed-matter and statistical physics. Considering the detection of MBL in experiments, it is an important task to investigate on the behavior of physical quantities, especially dynamical ones, in interacting disordered systems. We study the dynamical spin conductivity in XXZ antiferromagnets with random magnetic field. We start from the XX models, which is equivalent to the free fermion system, and then include an Ising interaction. The ground state of easy-plane XXZ chains is gapless Luttinger liquid, and the system is localized by disorder when the Luttinger parameter satisfies $K<3/2$. We calculate dynamical spin conductivity numerically using the technique of Chebyshev matrix product states. We investigate this quantity in the low and high frequency region, and the behavior is power law in both regions. The power depends on the strength of Ising interaction in the high frequency region.

8:00AM E08.00001: Nanocalorimetric Evidence for Nematic Superconductivity in Sr0.1Bi2Se3*  KRISTIN WILLA, ROLAND WILLA, KOK WEE SONG, Materials Science Division, Argonne National Laboratory, GENDA GU, RUIDAN ZHONG, JOHN A. SCHNEELOCH, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, ALEXEI E KOSHELEV, WAI-KWONG KWOK, ULRICH WELP (Presenter), Materials Science Division, Argonne National Laboratory — Spontaneous rotational-symmetry breaking in the superconducting state of doped Bi2Se3 has attracted significant attention as an indicator for topological superconductivity. High-resolution calorimetry of single-crystal Sr0.1Bi2Se3 provides unequivocal evidence of a twofold rotational symmetry in the superconducting gap by a bulk thermodynamic probe, a fingerprint of nematic superconductivity. The extremely small specific heat anomaly resolved with our high-sensitivity technique is consistent with the material’s low carrier concentration proving bulk superconductivity. The large basal-plane anisotropy of Hc2 is attributed to a nematic phase of a two-component topological gap structure η = (η1, η2) and caused by a symmetry-breaking energy term δ(|η1|² - (|η2|²)Tc. A quantitative analysis of our data excludes more conventional sources of this two-fold anisotropy and provides the first estimate for the symmetry-breaking strength δ ~ 0.1.

8:12AM E08.00002: μSR and Magnetometry Study of the Type I Superconductor BeAu*  JAMES BEARE (Presenter), MATTHEW NUGENT, MURRAY N WILSON, McMaster University, ETERI SVANIDZE, Max Planck Institute for Chemical Physics of Solids, YIPENG CAI, McMaster University, ALFRED AMON, ANDREAS LEITHE-JASPER, Max Planck Institute for Chemical Physics of Solids, ZIZHOU GONG, ZURAB GUGUCHIA, Columbia University, YURI GRIN, Max Planck Institute for Chemical Physics of Solids, YASUTOMO J UEMURA, Columbia University, GRAEME LUKE, McMaster University — We present Muon Spin Rotation and Relaxation (μSR) measurements as well as demagnetisation corrected magnetometry measurements on polycrystalline samples of the noncentrosymmetric superconductor BeAu. From μSR measurements in a transverse field we find that BeAu is a rare Type I superconducting alloy. To account for demagnetising effects in magnetometry measurements we produced an ellipsoidal sample for which we could calculate the demagnetising factor and found results comparable with our μSR measurements. From both sets of measurements we have constructed a phase diagram from 30 mK to Tc ≈ 3.25K. We also studied the effect of hydrostatic pressure and find that 450 MPa decreases Tc by 44 mK, comparable to the change seen in several elemental type I superconductors.

*We would like to acknowledge funding from the Natural Sciences and Engineering Research Council of Canada as well as the Canadian Institute for Advanced Research

8:24AM E08.00003: Direct evidence of multi-band superconductivity in Mo8Ga41*  ANSHU SIROHI (Presenter), Indian Institute of Science Education and Research, Mohali, SURABHI SAHA, Indian Institute of Science, Bangalore, PRAKRITI NEHA, Jawaharlal Nehru University, New Delhi, SHEKHAR DAS, Indian Institute of Science Education and Research, Mohali, SATYABRATA PATNAIK, Jawaharlal Nehru University, New Delhi, TANMOY DAS, Indian Institute of Science, Bangalore, GOUTAM SHEET, Indian Institute of Science Education and Research, Mohali — Mo8Ga41, a member of the family of endohedral gallide cluster compounds shows superconductivity with relatively large Tc of 9.8 K as compare to the other members in this family. In order to study the superconducting phase of Mo8Ga41 a number of experiments have been employed and it was shown that this compound manifests unusually high electron-phonon coupling leading to a large ∆/kBTc ratio and an indication of multi-gap superconductivity was also found. In this talk, from the direct measurement of the superconducting energy gap measured by Scanning Tunneling Spectroscopy (STS), I will show that Mo8Ga41 is a two-gap superconductor like MgB2 with the superconducting energy gaps of magnitude 0.85 meV and 1.6 meV respectively. Evolution of superconducting energy gaps with temperature and magnetic field demonstrates the conventional nature of both of the gaps as per the BCS prediction. In addition, through the band structure calculations, we have also identified the bands responsible for the two respective gaps and also shows that only two specific Mo sites in an unit cell contribute to superconductivity. Magnetic field dependent STS experiments further suggest that the interband coupling is weak in Mo8Ga41, as in case of MgB2.

*Department of Science and Technology, India
8:36AM E08.00004: Evidence of a structural quantum critical point in \((\text{Ca}_{x}\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}\) from a lattice dynamics study* YIU WING CHEUNG (Presenter), YAJIAN HU, Department of Physics, The Chinese University of Hong Kong, MASAKI IMAI, YASUAKI TANIOKU, HIBIKI KANAGAWA, JOICHI MURAKAWA, KODAI MORIYAMA, Department of Chemistry, Kyoto University, WEI ZHANG, KWING TO LAI, Department of Physics, The Chinese University of Hong Kong, KAZUYOSHI YOSHIMURA, Department of Chemistry, Kyoto University, MALTE GROSCH, Cavendish Laboratory, University of Cambridge, KOJI KANEKO, Materials Sciences Research Center, Japan Atomic Energy Agency, SATOSHI TSUTSUI, Japan Synchrotron Radiation Research Institute, SWEE KUAN GOH, Department of Physics, The Chinese University of Hong Kong — The nonmagnetic quasiskutterudite \((\text{Ca}_{x}\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}\) represents a precious system to explore the interplay between structural instabilities and superconductivity by tuning the Ca concentration \(x\) [1-3]. We performed inelastic x-ray scattering to probe the phonon spectrum of \((\text{Ca}_{x}\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}\) for various calcium contents. We detected a complete phonon softening at the \(M\) point when approaching the structural transition temperature from above. Intriguingly, at \(x = 0.85\), the energy squared of the soft mode at \(M\) extrapolates to zero at \((-5.7 \pm 7.7)\) K, providing the first compelling microscopic evidence of a structural quantum critical point (QCP) in \((\text{Ca}_{x}\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}\). The observed phonon softening around the \(M\) point provides the essential ingredient for realizing strong-coupling superconductivity near the structural QCP [4].

8:48AM E08.00005: Singlet superconductivity in single-crystal NiBi\(_3\) superconductor* GEJIAN ZHAO, Southern University of Science and Technology, Institute for Quantum Science and Engineering and Department of physics, XINXIN GONG, PENGCHAO XU, Department of Physics, Fudan University, BOCHAO LI, ZHIYU HUANG, Arizona State University, XIAOFENG JIN, Department of Physics, Fudan University, XIANG-DE ZHU, High Magnetic Laboratory, Chinese Academy of Sciences, TINGYONG CHEN (Presenter), Arizona State University — Verification of triplet superconductors (SCs), especially those that can carry spin angular momentum, is essential for understanding fundamental mechanism of unconventional superconductivity as well as important applications in quantum computing and spintronics. But singlet and triplet SCs have similar macroscopic properties, an ideal experiment would be to directly measure the spin states of Cooper pairs. In this work, Andreev reflection spectroscopy with unpolarized and highly spin-polarized currents has been utilized to study an intermetallic single-crystal SC NiBi\(_3\). Magnetoresistance at zero bias voltage of point contacts shows the occurrence and suppression of Andreev reflection by unpolarized and polarized current, respectively. The gap value, its symmetry and temperature dependence have been determined using an unpolarized current. The spin state in the NiBi\(_3\) sample is determined to be antiparallel using a highly spin-polarized current. The gap value \(2D/k_B T\), gap symmetry and its temperature dependence, combined with the antiparallel spin state show that the bulk NiBi\(_3\) is a singlet \(s\)-wave superconductor.

*The work was supported as part of SHINES, an EFRC center funded by the U. S. Department of Energy, Office of Science, Basic Energy Science, under award SC0012670.

9:00AM E08.00006: Magnesium Diboride Thin Film Cavity Fabricated by Hybrid Physical Chemical Vapor Deposition XIN GUO (Presenter), WENURA K WITHANAGE, JAY R. PAUDEL, Department of Physics, Temple University, ALIREZA NASSIRI, Argonne National Laboratory, XIAOXING XI, Department of Physics, Temple University — Magnesium diboride (MgB\(_2\)) is considered as a potential material for superconducting radio frequency cavities. MgB\(_2\) thin film fabricated on an inner surface of the Cu cavity will allow for a higher operational temperature because of the higher transition temperature of MgB\(_2\) and the high thermal conductivity of Cu. Using the hybrid physical chemical vapor deposition (HPCVD) technique, a uniform MgB\(_2\) coatings were achieved on the inner wall of the 3 GHz Cu cavity. The quality of the films were characterized on small Cu samples which were mounted at different selected locations of the cavity. Preliminary RF result for the MgB\(_2\) thin film cavity will be presented.
9:12AM E08.00007: The extraordinary superconductivity of commercial niobium-titanium wire at extreme pressures  
LILING SUN (Presenter), JING GUO, GONGCHANG LIN, SHU CAI, Institute of Physics, CAS, CHUANYING XI, CHANGJIN ZHANG, High Magnetic Field Laboratory, CAS, WANSHUO SUN, QIULIANG WANG, Institute of Electrical Engineering, CAS, QI WU, Institute of Physics, CAS, YUHENG ZHANG, High Magnetic Field Laboratory, CAS, TAO XIANG, Institute of Physics, CAS, ROBERT CAVA, Princeton University — We report the observation of extraordinary superconductivity in a pressurized commercial niobium-titanium alloy wire. We demonstrate that its zero-resistance superconductivity persists from ambient pressure to pressures as high as 261.7 GPa, a pressure that falls within that of the outer core of the earth, establishing the record where a superconducting state continuously survives. At such high pressures the superconducting transition temperature (Tc) has increased from ~9.6 K to ~19.1 K and the critical magnetic field (Hc2) at 1.8 K from 15.4 T to 19 T, setting new records for both Tc and Hc2 among all the known transition element alloy superconductors, all, remarkably, in spite of a 45% volume shrinkage. The behavior is quite different from what is seen in copper oxide and iron pnictide superconductors, whose superconducting transition temperatures are quite sensitive to subtle changes in the lattice structure. Our results therefore not only provide fresh information on the remarkable properties of this commercial superconductor, but also pose a substantial challenge for models of a phenomenon as “well understood” as conventional electron-phonon coupled superconductivity.

9:24AM E08.00008: Field-induced large resistance peak in superconducting niobium thin films deposited on surface reconstructed SrTiO3 substrate  
AKHILESH SINGH (Presenter), TSUNG-CHI WU, UDDIPTA KAR, Institute of Physics, Academia Sinica, Nankang, Taipei, 11529, Taiwan, WEI-CHENG LEE, Department of Physics, Applied Physics and Astronomy, Binghamton University, Binghamton, New York 13902, USA, WEI-LI LEE, Institute of Physics, Academia Sinica, Nankang, Taipei, 11529, Taiwan — It is known that oxygen vacancies in SrTiO3(STO) can result in surface reconstructions (SR), giving rise to a metallic surface and unusual surface phonon modes. Few earlier works have demonstrated intriguing phenomena of a huge superconducting transition temperature enhancement in a monolayer FeSe on SR-STO substrate, where its intrinsic mechanism remains debatable. In this work, we constructed a phase diagram of SR-STO with surface structures of, where SR-STO samples were prepared via thermal annealing in ultra-high vacuum followed by low energy electron diffraction analysis. Thin Nb films with different thicknesses (t) were deposited on the SR-STO. The detail studies on the magnetotransport and superconducting properties of the Nb(t)/SR-STO films revealed a large positive magnetoresistance, and a pronounced resistance peak occurred near the onset of the resistive superconducting transition in the presence of a large magnetic field. Remarkably, amplitude of the resistance peaks increases with increasing fields, reaching a value of nearly 340 % of the normal state resistance at 12 T. Such resistance peaks were not observed for the control samples of Nb(t)/STO and Nb(t)/SiO2. Possible mechanisms of the large field-induced resistance peak will be discussed.

9:36AM E08.00009: Effects of dimensionality and magnetic correlations on superconducting properties of MoCo thin films  
TOMAS POLAKOVIC (Presenter), Physics Division, Argonne National Laboratory, TERENCE BRETZ-SULLIVAN, JOHN E. PEARSON, J SAMUEL JIANG, ANAND BHATTACHARYA, AXEL F HOFFMANN, Materials Science Division, Argonne National Laboratory, GORAN KARAPETROV, Department of Physics, Drexel University, VALENTYN NOVOSAD, Materials Science Division & Physics Division, Argonne National Laboratory — The ability to precisely control superconducting transition within a narrow range of temperatures is crucial for many applications in cryogenic detectors. One way of achieving this is by utilizing magnetic impurities in superconductors. We present a systematic study of the effect of Co dopant on superconducting Molybdenum thin films prepared by sputtering from alloyed targets over a broad range of impurity concentrations and film thicknesses. Electric and magnetic measurements show strong dependence of the critical temperature on Co concentration, as well as presence of Kondo effect that vanishes as the film thickness is reduced. In addition to the pair-breaking effect due to magnetic impurities, we also explore the trend of Tc reduction with decreasing film thickness, generally attributed to the reduction of the superconducting order parameter on the surfaces.

Kenichi Kaminaga (Presenter), WPI-AIMR, Tohoku Univ., Daichi Oka, Graduate School of Science, Tohoku Univ., Tetsuya Hasegawa, Graduate School of Science, University of Tokyo, Tomoteru Fukumura, WPI-AIMR, Tohoku Univ. — We report effects of carrier density and epitaxial strain on superconductivity in rock-salt lanthanum monoxide (LaO) epitaxial thin film [1]. Electron carrier doping via introducing oxygen vacancies resulted in a dome-shaped $T_c$ as a function of carrier density. In addition, epitaxial strain influenced significantly the $T_c$ despite its highly symmetric rock-salt structure. $T_c$ was raised up to 5.2 K in tensilely strained thin film on LaAlO$_3$ substrate, in contrast with $T_c$ of at most 4.5 K in compressive strained film on YAIO$_3$ substrate. [1] K. Kaminaga et al., J. Am. Chem. Soc. 140, 6754 (2018).

Chi-Tie Liang (Presenter), Guan-Ming Su, Ankit Kumar, Chau-Shing Chang, Ching-Chen Yeh, Bi-Yi Wu, Dinesh Patel, Physics, National Taiwan University, Yen-Ting Fan, Sheng-Di Lin, Electronics Engineering, National Chiao Tung University, Lee Chow, Physics, University of Central Florida — In this work, we present experimental evidence for the Berezinskii–Kosterlitz–Thouless (BKT) transition in an atomic-scale aluminum nanofilm grown on a GaAs substrate by molecular beam epitaxy (MBE). Such a MBE-grown Al film has a higher superconducting critical temperature and a larger critical magnetic field compared to those of bulk Al. In a 4-nm-thick Al film, our results show that $V/I^2$ can occur in both the low-voltage (the BKT transition temperature $T_{BKT} = 1.97$ K) and high-voltage ($T_{BKT} = 2.17$ K) regions where $V$ and $I$ correspond to the voltage across the device and the driving current, respectively. By fitting our data to the vortex/anti-vortex model and a model based on dynamical scaling, we unequivocally determine that $T_{BKT} = 2.17$ K in our nanofilm. Our new experimental results suggest that when one uses the temperature for which $V/I^2$ to determine $T_{BKT}$, great care has to be taken as one also needs to fit one's data to both dynamical scaling and vortex/anti-vortex models.

Catalin Martin (Presenter), Eng. Physics, Ramapo College of NJ, Ali S. M. Radmanesh, Advanced Materials Research Institute and Department of Physics, University of New Orleans, Yanglin Zhu, Zhiqiang Mao, Physics and Engineering Physics, Tulane University, Leonard Spinu, Advanced Materials Research Institute and Department of Physics, University of New Orleans — Using the combination of a tunnel diode oscillator (TDO) and a commercial dilution refrigerator, we measured temperature dependent magnetic penetration depth $\lambda(T)$ in single crystals of YPdBi and TbPdBi, down to temperatures as low as 0.1 K. We found that penetration depths of both compounds do not show exponential temperature dependence and saturation at low temperatures, as expected for conventional BCS superconductors. Instead, in both materials, the penetration depth can be described by a power law $\lambda(T) = A \times T^n$. The coefficient A was found to be about 50% smaller in TbPdBi, but the exponents are very similar, $n = 2.76 \pm 0.04$ in YPdBi and $n = 2.6 \pm 0.3$ in TbPdBi, respectively. Our results suggest unconventional superconductivity in both YPdBi and TbPdBi.

**10:24AM E08.00013: Effect of magnetic field on short-range antiferromagnetic correlations in the filled skutterudite Pr$_{1-x}$Eu$_x$Pt$_4$Ge$_{12}$**

RAM ADHIKARI (Presenter), PENGTAO SHEN, DOM LAL KUNWAR, Kent State University, INHO JEON, M BRIAN MAPLE, Physics, University of California, SanDiego, MAXIM DZERO, CARMEN CRISTINA ALMASAN, Kent State University — We have investigated the effects of Eu substitution through thermodynamic measurements on the superconducting filled skutterudite Pr$_{1-x}$Eu$_x$Pt$_4$Ge$_{12}$ in an applied magnetic field H. A heat capacity Schottky anomaly is present over the whole doping range. For the samples with x > 0.5, these peaks shift to lower temperature with increasing applied magnetic field H, hence they reveal the antiferromagnetic (AFM) ordering of the Eu moments, as the AFM transition is suppressed by H. The heat capacity peaks in the samples with x ≤ 0.5 shift to higher temperatures with increasing magnetic field. These latter Schottky peaks are a result of Zeeman splitting by internal magnetic field due to short-range AFM correlations of random magnetic moments of nearing Eu sites, thus increases with Eu concentration x. In low H, the Schottky gaps show a non-linear relationship with H as the magnetic moments become weakly magnetized. In the case of a high applied H, the magnetic moments of Eu sites become completely aligned along H. Thus, Increasing H will not increase further the magnetization, hence the Schottky gaps are a linear function of the external field H.

**10:36AM E08.00014: Increase in Birr and reduction of anisotropy of MgB2 with Dy2O3/C co-doping**

MIKE SUMPTION (Presenter), Ohio State University — In this study a series of Dy$_2$O$_3$/C co-doped MgB$_2$ bulks and strands were fabricated. The C – doping level was fixed at 2.0 mol% for all the MgB$_2$ strands. The transport and magnetic properties of MgB$_2$ strands was systematically investigated in terms of Dy$_2$O$_3$ doping level over a wide temperature range. Compared to C-doped-only MgB$_2$ strand, the Dy$_2$O$_3$/C co-doped MgB$_2$ strands have higher transport $J_{ct}$ at 4.2 K. The improved transport $J_{ct}$ – $B$ performance results from the fact that Dy$_2$O$_3$ doping can further improve the anisotropy and flux pinning strength of C-doped MgB$_2$ strand. TEM results of REO doped sample showed nano-size inclusions (20 – 100 nm) present both inside MgB$_2$ grains and on grain boundaries. In-field resistivity measurement (up to 28 T) was performed from 4-40 K. The Bc2 values extracted from both resistivity and magnetic measurements were unchanged by Dy2O3 additives. However, the irreversibility field Bk was increased in response to Dy2O3 doping suggesting a decrease in the anisotropy. The Bk increase, about 1 T between 4-35 K, is of particular interest at higher temperatures (20-30 K).

**10:48AM E08.00015: Superconductivity and phase diagram in a transition metal doped Zr$_5$Ge$_3$ compound**

XIAOYUAN LIU (Presenter), SHENG LI, VARUN ANAND, BING LV, University of Texas at Dallas — Systematic doping studies have been carried out to search for superconductivity in the transition metal doped Zr$_5$Ge$_3$ system at different sites. Superconductivity is only discovered with Pt doping at Ge site with $T_c$~2.8K and remain absent with other transition metal doping such as Y, Cr, Ir, and Pd at other different sites. Coincidental with our previous findings in the Zr$_5$Ge$_3$-$x$Ru$_x$ system, it appears that the induced superconductivity is not only site-selective (only at Ge site) but also dopant selective (only with Pt and Ru dopants). The bulk superconductivity in Zr$_5$Ge$_{3-x}$Pt$_x$ has been investigated through resistivity, magnetization, and heat capacity measurements. The superconducting phase diagram of Pt doped Zr$_5$Ge$_{3-x}$Pt$_x$ is also proposed.

8:00AM E09.00001: Superconductivity in Chevrel phases  GIANNI PROFETA (Presenter), GIOVANNI MARINI, Physical and Chemical Sciences, University of L'Aquila, ANTONIO SANNA, Max Planck Institute — Chevrel phases is a class of interesting materials discovered more than 40 years ago including more than 100 examples. They are ternary compounds of general stoichiometry M_xMo_6X_8 (X = chalcogen and M=metal) and many of them show interesting superconducting properties with critical temperatures as high as 15K and high critical magnetic fields (around 50 Tesla).

We present the results of the prediction of the superconducting phase in Chevrel compound, PbMo_6S_8, within the SuperConducting Density Functional Theory (SCDFT), a first-principles theory of the superconducting phase which does not rely on any semi-empirical parameter.

We successfully predict the critical temperature of PbMo_6S_8 at ambient conditions highlighting the role of phase instability, electron-phonon coupling with different intra-molecular and inter-molecular phonon modes and the fundamental role of repulsive electron-electron interaction, treated from first-principles. The evolution of the superconducting critical temperature as a function of the external pressure results in excellent agreement with available experiments.

Despite the interesting physical and chemical properties of Chevrel phases their fundamental explanation was still lacking: SCDFT opens way to systematic investigation of this large class of compounds.

8:12AM E09.00002: New magnetic phases and the absence of superconductivity in doped Hematophanite, Pb_4Fe_3O_8Cl*  ALEX HOJEM (Presenter), JAMES WAMPLER, IVAN SCHULLER, Department of Physics and Center for Advanced Nanoscience, University of California, San Diego — We searched for new magnetic and superconductivity phases in the hematophanite system [1], Pb_4Fe_3O_8Cl, which has structural similarities to some cuprates [2]. To enhance the potential number of subphases we synthesized inhomogeneous samples via powder metallurgy and explored electron and hole doping of both Pb, with Ga and Bi, and Fe, with Mn and Co. We used magnetic field modulated microwave spectroscopy [3], as well as vibrating sample magnetometry, to identify magnetic phase transitions as a function of temperature. Crystallographic phase information is obtained via x-ray diffraction and Rietveld refinement. We observe that in both the Ga and Co doped systems we induce multiple magnetic phase transitions that correspond to various subphases present in our samples. Although many magnetic phases were created in these samples there is no indication of the presence of a new superconducting phase above 4 K.

8:24AM E09.00003: Discovery of a new strong-coupling superconductor Y_7Ru_4InGe_12 by indium flux*  JINKE BAO (Presenter), DANIEL BUGARIS, KRISTIN WILLA, ULRICH WELP, DUCK YOUNG CHUNG, MERCOURI KANATZIDIS, Materials Science Division, Argonne National Laboratory — Compounds containing rare earth, transition metal and germanium elements can exhibit interesting phenomena such as charge density wave, complex magnetism and superconductivity. Using indium flux makes it possible to synthesis new compounds under a relative low temperature. Here we discovered a new superconductor Y_7Ru_4InGe_12 with T_c ~ 5.8 K grown from the indium flux, which is confirmed by resistivity, magnetization and specific heat measurements. It is a type-II superconductor and its upper critical fields are estimated to be 5.4 and 2.7 T along and perpendicular to the c axis, respectively. The estimated mean free path along the c axis is ~ 29 Å, much smaller than the superconducting coherence length ~ 172 Å, putting it in a dirty limit regime. The specific heat jump of this superconductor ΔC/γeT_c = 2.4 is much larger than the BCS theoretical value 1.43, pointing to a strong-coupling scenario. A new polymorphism of LuRuGe and several trials to synthesize isostructural compounds of Y_7Ru_4InGe_12 by replacing the rare earth elements will also be presented in this talk.

8:36AM E09.00004: Superconducting SrSnP with Strong Sn-P Antibonding Interaction: Is the Sn Atom Single or Mixed Valent? XIN GUI (Presenter), Department of Chemistry, Louisiana State University, ZUZANNA SOBCZAK, Department of Solid State Physics, Gdansk University of Technology, TAY-RONG CHANG, Department of Physics, National Cheng Kung University, XITONG XU, SHUANG JIA, International Center for Quantum Materials, Peking University, TOMASZ KLIMCZUK, Department of Solid State Physics, Gdansk University of Technology, WEIWEI XIE, Department of Chemistry, Louisiana State University — The large single crystals of SrSnP were prepared using Sn self-flux method. SrSnP crystallizes in the CaGaN structure type with space group $P4/nmm$ (S.G.129, Pearson symbol tP6). A combination of magnetic susceptibility, resistivity, and heat capacity measurements confirms the bulk superconductivity with $T_c = 2.3(1)$ K in SrSnP. According to the X-ray photoelectron spectroscopy (XPS) measurement, the assignments of Sr$^{2+}$ and P$^{3-}$ are consistent with the chemical valence electron balance principles. Moreover, it is highly likely that Sn atom has only one unusual oxidation state. First-principles calculations indicate the bands around Fermi level are hybridized among Sr-$d$, Sn-$p$, and P-$p$ orbitals. The strong Sn-P and Sr-P interactions pose as keys to stabilize the crystallographic structure and induce the superconductivity, respectively. The physics-based electronic and phononic calculations are consistent with the molecular viewpoint. After including the spin-orbit coupling (SOC) into the calculation, the band degeneracies at G-point in the first Brillouin zone (BZ) split into two bands, which yield to the van Hove singularities around Fermi level.

8:48AM E09.00005: Superconductivity and Sn-Mössbauer spectra of the antiperovskite oxide $\text{Sr}_{3-x}\text{SnO}$* ATSUTOSHI IKEDA (Presenter), Department of Physics, Kyoto University, Japan, SHINJI KITAO, Institute for Integrated Radiation and Nuclear Science, Kyoto University, Japan, SHUN KOIBUCHI, MOHAMED OUDAH, Department of Physics, Kyoto University, Japan, IGOR MARKOVIC, School of Physics and Astronomy, University of St Andrews, UK, JAN NIKLAS HAUSMANN, SHINGO YONEZAWA, Department of Physics, Kyoto University, Japan, MAKOTO SETO, Institute for Integrated Radiation and Nuclear Science, Kyoto University, Japan, YOSHITERU MAENO, Department of Physics, Kyoto University, Japan — We recently reported bulk superconductivity in the antiperovskite oxide $\text{Sr}_{3-x}\text{SnO}$, with a possibility of topological nature. We investigate the evolution of superconducting properties with the nominal Sr deficiency $x$. In all superconducting samples, two superconducting phases with $T_c \approx 5$ K and 1 K appear concurrently that originate from $\text{Sr}_{3-x}\text{SnO}$. Mössbauer spectroscopy reveals an unusual Sn$^{4+}$ ionic state in both stoichiometric and superconductive samples. In addition to the main absorption peak, we observe a satellite peak attributable to the Sn sites with nearest-neighbor Sr deficiencies. The intensities of these two peaks exhibit a rather different temperature dependence, possibly reflecting different environment of the lattice vibrations. These results clarifying the Sr deficiency dependence of the normal and superconducting properties of the antiperovskite oxide $\text{Sr}_{3-x}\text{SnO}$ will promote future work on this class of materials.

9:00AM E09.00006: Palladium Dependent Superconductivity in the $\text{Nb}_2\text{Pd}_x\text{Se}_5$ System* JENNIFER NEU (Presenter), YOU LAI, DAVID E GRAF, National High Magnetic Field Laboratory, DAVID SINGH, University of Missouri, RYAN BAUMBACH, THEO SIEGRIST, National High Magnetic Field Laboratory — Single crystals of $\text{Nb}_2\text{Pd}_x\text{Se}_5$ across the range $0.68<x<0.95$ were grown with the objective of studying the superconducting properties as a function of Pd stoichiometry. Electrical conductivity measurements down to 0.4K indicate a Pd-concentration dependent dome of superconductivity in this system. Here we discuss the crystal growth method, structural characterization, and the evolution of the superconducting properties within the accessible range of Pd stoichiometries.

*NSF DMR-1606952, NHMFL NSF DMR 1677449, DOE DE-SC0019114 and the State of Florida
9:12AM E09.00007: Highly reproducible superconductivity in K-doped triphenylbismuthine and tris(2/4-methylphenyl)bismuthine*  ZHONGBING HUANG (Presenter), Physics, Hubei University, REN-SHU WANG, JIA CHENG, Materials Science, Hubei University, XIAO-LIN WU, HUI YANG, Physics, Hubei University, YUN GAO, Materials Science, Hubei University, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research, Shanghai — To search for new organic superconductors, we perform a systematic study on the magnetic and electrical properties of K-doped triphenylbismuthine and tris(2/4-methylphenyl)bismuthine, which are successfully synthesized by a two-step method - ultrasound treatment and low temperature annealing. The combination of dc and ac magnetic measurements show that one hundred percent of synthesized samples exhibit superconductivity at 3.5 K and/or 7.2 K for triphenylbismuthine, and at 3.6 K for tris(2/4-methylphenyl)bismuthine. The observed superconductivity is strongly supported by the resistivity measurements. Both calculated electronic structures and measured Raman spectra indicate that superconductivity is realized by transferring electron from potassium to carbon atom. Our study opens an encouraging window for the search of organic superconductors in organometallic molecules.

*We acknowledge financial support from the National Natural Science Foundation of China under Grants Nos. 11574076, 11674087, and 91221103.

9:24AM E09.00008: Structures and charge transfer in metal-doped aromatic hydrocarbons  GUO-HUA ZHONG (Presenter), Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research, HAI-QING LIN, Beijing Computational Science Research Center — Organic based compounds were suggested as candidates for high temperature or room temperature superconductors since the electrons can interact with much higher excitation energy than the phonon energy in these materials. Recently, the discovery of superconductivity in aromatic hydrocarbons seemingly supports the above idea suggested by Little and Ginzburg. Chen et al reported that the Tc exceeds 120 K in K-doped p-terphenyl. This result clearly shows that organic compounds are potential room-temperature superconductors. However, the structural characteristics of metal-doped aromatic hydrocarbons and the charge transfer from metal to organic molecule have always been puzzled. Here we report these research results by employing the first-principles calculations. In this work, we will present the atomic positions in metal (K, Al, Ga, and In)-doped aromatic hydrocarbons and the distribution and the number of transferred charge, as well analyze the relation between them and electronic structures. The results is meaningful to understand this superconductivity in this kind of materials.

9:36AM E09.00009: Signatures of two-gap superconductivity in epitaxial La(Pt_xSi_1-x)_2 films*  JIAN LIAO (Presenter), Department of Physics, University of Texas at Dallas, Richardson, TX, 75080, YUNBO OU, Plasma Science and Fusion Center and Francis Bitter Magnet Laboratory, MIT, Cambridge, MA, 02139, JAGADEESH MOODERA, Department of Physics, MIT, Cambridge, MA, 02139, XIAOYAN SHI, Department of Physics, University of Texas at Dallas, Richardson, TX, 75080 — Symmetry plays an important role in superconductivity. In noncentrosymmetric superconductors, the pairing state might become a mixture of spin-singlet and spin-triplet components due to the anti-symmetric spin-orbit coupling (ASOC), which is “protected” by the lack of an inversion center. This mixing can further lead to two-gap physics. We investigated the transport properties of various La(Pt_xSi_1-x)_2 thin films grown by molecular beam epitaxy (MBE), where the inversion symmetry and spin-orbit coupling strength are tunable by varying the Pt concentration x. For certain x, magnetoresistance shows a two-step transition at finite temperatures below Tc, and the upper critical field is well described by a two-band model. Furthermore, the current-voltage characteristics, along with the differential resistance measurements, reveal a two-gap structure in magnetic fields up to 1 T. These observations indicate the multi-gap superconductivity in La(Pt_xSi_1-x)_2 films.

*This work was supported by UT Dallas research enhancement funds, National Science Foundation (NSF-DMR 1700137), Office of Naval Research (N00014-16-1-2657), and Center for Integrated Quantum Materials (DMR-1231319).
Phase separation at the dimer-superconductor transition in Ir$_{1-x}$Rh$_x$Te$_2$* RUNZE YU, SOHAM BANERJEE, HECHANG LEI, MILINDA ABEYKOON, CEDOMIR PETROVIC, ZURAB GUGUCHIA, EMIL BOZIN (Presenter), Brookhaven National Laboratory — The detailed evolution of the local atomic structure across the (x, T) phase diagram of Ir$_{1-x}$Rh$_x$Te$_2$ superconductor (0≤x≤0.3, 10K≤T≤300K) is obtained from high-quality x-ray total scattering data using the atomic pair distribution function method. The observed hysteretic thermal structural phase transition from a trigonal to a triclinic dimer phase for low Rh content emphasizes the intimate connection between the lattice and electronic properties. For superconducting samples away from the dimer/superconductor boundary, structural transition is absent and the local structure remains trigonal down to 10 K. In the narrow range of compositions close to the boundary structural phase separation is observed, suggestive of weak first-order character of the Rh-doping induced dimer-superconductor quantum phase transition. Samples from this narrow range show weak anomalies in electronic transport and magnetization, hallmarks of the dimer phase, as well as superconductivity albeit with incomplete diamagnetic screening. The results imply competition of the dimer and superconducting orders.

*Work at Brookhaven National Laboratory was supported by US DOE-BES under Contract No. DE-SC0012704.

Angle-Resolved Photoemission Spectroscopy Study of Planar Nickelate Pr$_4$Ni$_3$O$_8$ HAOXIANG LI (Presenter), XIAOQING ZHOU, KYLE GORDON, University of Colorado, Boulder, HONG ZHENG, JUNJIE ZHANG, JOHN MITCHELL, Material Science Division, Argonne National Lab, DANIEL DESSAU, University of Colorado, Boulder — Planar nickelates share the similar crystal structure and 3d electron configuration with high $T_c$ cuprate materials, and thus can be considered as a potential proxy for cuprate physics as well as a possible candidate for hosting high-temperature superconductivity. A previous study has shown that Pr$_4$Ni$_3$O$_8$, a metallic material in the planar nickelate family, has a pronounced orbital character of $dx^2-y^2$ near the Fermi energy [1], which is a signature of the cuprate electronic structure. Here we present the first angle-resolved photoemission spectroscopy study of Pr$_4$Ni$_3$O$_8$. Consistent with the electron counting, planar nickelate Pr$_4$Ni$_3$O$_8$ shows a non-gapped Fermi surface that resembles the one in the heavily over-doped cuprate. A detailed comparison of the ARPES result shows more similarity in the electronic structure. Our observations demonstrate that planar nickelate Pr$_4$Ni$_3$O$_8$ material can be a potential test ground for the study of cuprate physics.

Isotope effect in the layered bismuth chalcogenide (BiCh$_2$-based) superconductor* KAZUHISA HOSHI (Presenter), YOSHIKAZU MIZUGUCHI, YOSUKE GOTO, Physics, Tokyo Metropolitan University — We have investigated the selenium isotope effect on $T_c$ in the layered bismuth chalcogenide (BiCh$_2$-based) superconductor LaO$_{0.6}$F$_{0.4}$Bi(S,Se)$_2$ using $^{76}$Se and $^{80}$Se. For all examined samples, the Se concentration, which is linked to the superconducting properties, is successfully controlled within x = 1.09–1.14 in LaO$_{0.6}$F$_{0.4}$BiS$_2–x$Se$_x$. From the transition temperature estimated from the magnetization and electrical resistivity measurements, we found that the changes in $T_c$ between $^{76}$Se and $^{80}$Se were apparently smaller than that expected from phonon-mediated pairing mechanism. The estimated isotope effect exponent $\alpha_{Se}$ is close to zero (-0.04 $\leq \alpha_{Se}$ $\leq$ +0.04) [1]. Our results may indicate that the pairing in LaO$_{0.6}$F$_{0.4}$Bi(S,Se)$_2$ is not mediated by phonons, which is consistent with recent theoretical and experimental studies suggesting that unconventional pairing mechanisms are essential for the BiCh$_2$-based superconductor. We will show the recent results on sulfur isotope effect on the BiS$_2$-based superconductors.

*We thank O. Miura and R. Higashinaka for their experimental support and K. Kuroki for his fruitful discussion.
MENDELEEV'S PERIODIC TABLE and SUPERCONDUCTIVITY: Here it is pointed out that, like chemical properties, elemental metals in the same column of the table and in one headed by a nonmagnetic metal typically have similar Tc's. GORDON RIBLET (Presenter), Microwave Development Laboratories — In the first and second columns of the periodic table, headed by lithium and beryllium, none of the 5 alkali metals or 5 alkaline earth metals is a superconductor (see the table on p. 356 of the 5th edition of Kittel). Of the many rare earth metals in the third column only lanthanum is a superconductor. In the fourth and fifth columns, headed by titanium and vanadium, all three metals in each column is a superconductor. In the fourth column Tc's vary between .37 K and .56 K. In the fifth column Tc's are an order of magnitude higher with niobium having the highest at 9.2 K. Skipping over the next few columns headed by magnetic metals we arrive at the column of the precious metals. None of the these is a superconductor. Once again in the next column headed by zinc all three elemental metals are superconductors. Mercury's Tc of 4.2 K is higher than Zn(.8 K) and Cd(.6 K) perhaps due to it's low melting point(-40 C). This brings us to the last column headed by a metal in this case aluminum. All 4 elemental metals are superconductors. Ga(1.1 K) has the lowest Tc while In(3.4 K) has the highest. Of the 5 light elemental metals in the top two rows of the periodic table only aluminum is superconducting! Why? In time will it become possible to calculate its Tc accurately from first principles?

Signature of Nematic Superconductivity in Cu4Bi2Se3: Ginzburg-Landau Theory with External Stress* PYE TON HOW (Presenter), SUNGKIT YIP, Institute of Physics, Academia Sinica — Cu4Bi2Se3 displays superconductivity[1]. It garners considerable interest because Bi2Se3 is a topological insulator. Evidence of two-fold anisotropy suggests that the superconducting phase may be nematic[2, 3]. However, the upper critical field Hc2 also appears two-fold anisotropic[3], and this actually contradicts the nematic hypothesis[4]. A pre-existing "pinning field" could break the symmetry explicitly[4], but then this casts in doubt the interpretation of any two-fold anisotropy. We study the Ginzburg-Landau theory of a nematic order parameter coupled to external stress as a pinning field. We classify possible phase diagrams, and indicate experimental signatures that might distinguish, in a pre-existing pinning field, a true nematic phase from an isotropic phase.

Session E10 DMP DCOMP: Fe-based Superconductors -- Bulk FeSe

Laser ARPES on Orbital Origin of Extremely Anisotropic Superconducting Gap in FeSe Superconductor* CONG LI (Presenter), DEFA LIU, JIANWEI HUANG, Institute of Physics, Chinese Academy of Sciences, BIN LEI, Department of physics, University of Science and Technology of China, LE WANG, XIANXIN WU, QIANG GAO, YUXIAO ZHANG, XU LIU, YONG HU, LIN ZHAO, SHAOULONG HE, GUODONG LIU, XIAOLI DONG, XIAOWEN JIA, YOUGUO SHI, JIANGPING HU, TAO XIANG, Institute of Physics, Chinese Academy of Sciences, XIANHUI CHEN, Department of physics, University of Science and Technology of China, ZUYAN XU, CHUANGTIAN CHEN, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences, XINGJANG ZHOU, Institute of Physics, Chinese Academy of Sciences — We have carried out high resolution laser-based angle-resolved photoemission (ARPES) measurements on bulk FeSe superconductor (Tc=8~9K). We will report direct observation of highly anisotropic Fermi surface and extremely anisotropic superconducting gap in the nematic state of the FeSe superconductor. We find that the low-energy excitations of the entire hole pocket at the Brillouin zone center are dominated by the single dzx orbital. The superconducting gap exhibits an anticorrelation relation with the dzx spectral weight near the Fermi level. These observations provide new insights in understanding the orbital origin of the extremely anisotropic superconducting gap in the FeSe superconductor and the relation between nematicity and superconductivity in the iron-based superconductors.

STM studies of Iron-based Superconductor FeSe$_{0.5}$Te$_{0.5}$

ZHENDA GU, CIDAYA MADHAVAN, Department of Physics, University of Illinois Urbana Champaign — Recent studies on the iron-based superconductor, FeSe$_{0.5}$Te$_{0.5}$ have suggested that it is in a topologically non-trivial phase and harbors topological surface states. When these states are gapped by proximity effect, Majorana bound states are expected in the vortex cores, which have been confirmed by STM. In this work we present STM studies of both the vortex core states as well as boundary states in FeSe$_{0.5}$Te$_{0.5}$. Our data provide supporting evidence for the existence of Majorana modes in this system.

*The work was supported by the National Science Foundation and the Department of Energy. The STM component was made possible through the NSF Award DMR-1610143 while the data analysis was funded by the DOE Scanned Probe Division under the Award Number DE-SC0014335.

Itinerant approach to magnetic neutron scattering of FeSe: effect of orbital selectivity

ANDREAS KREISEL (Presenter), Faculty of Physics and Earth Sciences, Universität Leipzig, BRIAN M. ANDERSEN, Niels Bohr Institute, University of Copenhagen, PETER HIRSCHFELD, Univ of Florida - Gainesville — Recent STM experiments and theoretical considerations have highlighted the role of interaction-driven orbital selectivity in FeSe, and its role in generating the extremely anisotropic superconducting gap structure in this material. We study the magnetic excitation spectrum resulting from the coherent quasiparticles within the same renormalized random phase approximation approach used to explain the STM experiments, and show that it agrees well with the low-energy momentum and energy dependent resonance measured by inelastic neutron scattering experiments. We find a correlation-induced suppression of (π,π) scattering due to a small quasiparticle weight of states of d$_{xy}$ character [1]. We compare predictions for twinned and untwinned crystals, and predict in particular a strongly (π,0)-dominated susceptibility at low energies in untwinned systems. These results will be discussed in comparison to recent inelastic neutron scattering on detwinned FeSe.

The same description of the coherent quasiparticles is used to make further predictions of physical observables in FeSe such as the magnetic penetration depth which has recently been examined in detail by μSR experiments [2].

Pressure-induced tetragonal magnetic order in FeSe

ANDREAS KREYSSIG (Presenter), Ames Laboratory, Iowa State University, Dept. of Physics and Astronomy, Ames; ANNA E. BÖHMER, Ames Laboratory, Iowa State University, Ames; Karlsruhe Institute of Technology, Karlsruhe, KARUNAKAR KOTHAPALLI, Ames Laboratory, Iowa State University, Ames; King University, Bristol, WAGEEFA T JAYASEKARA, JOHN M. WILDE, BING LI, Ames Laboratory, Iowa State University, Dept. of Physics and Astronomy, Ames, AASHISH SAPKOTA, Ames Laboratory, Iowa State University, Ames; Brookhaven National Laboratory, Brookhaven, BENJAMIN G. UELAND, Ames Laboratory, Iowa State University, Dept. of Physics and Astronomy, Ames, PINAKI DAS, Ames Laboratory, Iowa State University, Ames; Argonne National Laboratory, Argonne, YUMING XIAO, WENLI BI, JIYONG ZHAO, ESEN ALP, Advanced Photon Source, Argonne National Laboratory, Argonne, SERGEY L. BUD’KO, PAUL C. CANFIELD, ROBERT J. MCQUEEN, ALAN I. GOLDMAN, Ames Laboratory, Iowa State University, Dept. of Physics and Astronomy, Ames — We present a microscopic study of magnetism and lattice distortion on FeSe single crystals by high-energy x-ray diffraction and time-domain Mössbauer spectroscopy over wide temperature and pressure ranges. The magneto-structural ground state can be tuned by pressure from a paramagnetic state with an orthorhombic lattice distortion through a strongly coupled magnetically ordered and orthorhombic state to a magnetically ordered state without an orthorhombic lattice distortion. Close to the reported maximum of the superconducting critical temperature, the orthorhombic distortion suddenly disappears and FeSe remains tetragonal down to the lowest temperature measured. Analysis of the structural and magnetic order parameters suggests an independent origin of the structural and magnetic ordering phenomena, and their cooperative coupling leads to the similarity with the canonical phase diagram of iron pnictides.

8:48AM E10.00005: Relationship between Superconductivity and Antiferromagnetic Fluctuations in FeSe$_{0.9}$S$_{0.1}$ under Pressure Studied by $^{77}$Se NMR

Khusboo Rana (Presenter), Ames Lab & Dept of Physics and Astronomy, Iowa State University, Paul Wiecki, Anna Boehmer, Institut für Festkörperphysik, Karlsruhe Institute of Technology, Sergey Budko, Paul Canfield, Yuji Furukawa, Ames Lab & Dept of Physics and Astronomy, Iowa State University — Magnetic fluctuations and/or nematic fluctuations are considered to be candidates for the pairing mechanism in unconventional superconductors such as iron pnictide superconductors. Quite recently nuclear magnetic resonance (NMR) measurements revealed strong correlation between superconductivity and antiferromagnetic (AFM) fluctuations despite being near a nematic quantum critical point in FeSe$_{1-x}$S$_x$ [1]. To understand the quantitative relationship between superconductivity and magnetic fluctuations, we carried out $^{77}$Se NMR on the optimally doped FeSe$_{0.9}$S$_{0.1}$ under pressure. In this presentation, we will report the NMR results, especially temperature dependence of nuclear spin lattice relaxation rate under different pressures. Upon analyzing the new together with the previous data [1, 2] we will discuss the relationship between AFM fluctuations and superconductivity in the system.

*This work is supported by the USDOE, Basic Energy Sciences, Division of Materials Sciences and Engineering, under Contract No. DE-AC02-07CH11358

9:00AM E10.00006: Evidence for time-reversal symmetry breaking in the superconducting state of FeSe

Kohei Matsura (Presenter), Takaaki Takenaka, Yuichi Sugimura, Takasada Shibauchi, University of Tokyo, Kohtaro Yamakawa, Qi Sheng, Zurab Guguchia, Yasutomo J Uemura, Columbia University, Yipeng Cai, Graeme Luke, McMaster University, Shengli Guo, Licheng Fu, Zhenlong NING, Zhejiang University, Guoqiang Zhao, Guangyang Dai, Chaoqing Jin, Institute of Physics, Chinese Academy of Sciences — The iron-based superconductor FeSe has attracted special attention because it uniquely has a pure nematic phase without a magnetic ordering. It is considered as a key material for investigating the influence of nematicity on superconductivity. The superconducting state inside the nematic phase also has unique properties, and it has been recently proposed that the superconducting order parameter breaks the time-reversal symmetry near the nematic twin boundaries. The lifting of superconducting gap nodes due to twin boundaries has been observed in scanning tunneling spectroscopy and angle-resolved photoemission spectroscopy, which is consistent with the induced imaginary component. However, these measurements of the gap structure provide only indirect evidence for time-reversal symmetry breaking (TRSB), and thus the observation of spontaneous internal magnetic field generated by TRSB is indispensable. Here we report on the zero-field muon spin rotation ($\mu$SR) measurement, which is one of the most sensitive magnetic probes, in high-quality single crystals of FeSe. We find that the relaxation rate starts to grow just below $T_c$ (=9 K). This indicates that weak but finite internal magnetic field is induced in the superconducting state, providing strong evidence for TRSB state in FeSe.

9:12AM E10.00007: Superconductivity and magnetism of S-doped FeSe with a high $T_c$ (≈25-30K) studied via $^{77}$Se-NMR measurements under pressure

Naoki Fujiwara (Presenter), Takanori Kuwayama, Kyoto University, Kohei Matsura, Yuta Mizukami, University of Tokyo, Shigeru Kasahara, Yuji Matsuda, Kyoto University, Takasada Shibauchi, Yoshiya Uwatoko, University of Tokyo — 12%-S doped FeSe system has a high $T_c$ of 25-30 K class under a pressure of 3.0 GPa. We have succeeded in investigating its microscopic properties for the first time via $^{77}$Se-NMR measurements under pressure. We measured the relaxation time ($T_1$), the Knight shift, and the AC susceptibility under pressures up to 3.0 GPa. Unexpectedly, the antiferromagnetic (AFM) fluctuation measured from $1/T_1 T$ at the optimal pressure was strongly suppressed compared to the AFM fluctuation at ambient pressure, despite that the optimal pressure is close to the phase boundary of the AFM phase induced at a high pressure region. In addition, we revealed that the SC phase at an applied field of 6 T exhibited a remarkable double-dome structure in the pressure-temperature phase diagram, unlike the SC phase at zero field. These phenomena are explained by a pressure-induced Lifshitz transition, a topological changes in Fermi surfaces under pressure. The strong AFM fluctuation at ambient pressure is attributable to a hidden AFM quantum critical point.

*The NMR work is supported by JSPS KAKENHI Grant Number JP18H01181 and a grant from Mitsubishi Foundation.
Scaling of the superconducting gap with orbital character in FeSe

LUKE RHODES (Presenter), Department of Physics, Royal Holloway University of London, MATTHEW WATSON, School of Physics and Astronomy, University of St. Andrews, AMIR HAGHIGHIRAD, Institute for Solid State Physics, Karlsruhe Institute of Technology, DANIIIL EVTUSHINSKY, Institute of Physics, Ecole Polytechnique Federale Lausanne, MATTHIAS ESCHRIG, Department of Physics, Royal Holloway University of London, TIMUR KIM, Diamond Light Source — It is often hypothesized that superconductivity in the iron-based superconductors is mediated by a spin-fluctuation pairing mechanism, however direct evidence of this pairing is challenging to obtain. Here we present a high-resolution angle-resolved photoemission spectroscopy (ARPES) study on the three-dimensional superconducting gap of FeSe. We observe a direct scaling between the $d_{xz}$ orbital weight at the Fermi level and the size of the superconducting gap at both the hole and electron pockets. Suggesting that superconducting pairing is mediated by strong, local Coulomb interactions.

We then present an ARPES-derived tight binding model which quantitatively takes into account all the features present in the nematic phase of FeSe; including spin-orbital coupling, nematic ordering, and most crucially the incoherence of an electron pocket. Using this model, we show that the calculated momentum dependence of the superconducting gap, assuming spin-fluctuation mediated superconductivity, directly reproduces the experimental results.

These findings provide both experimental and theoretical support for spin-fluctuation mediated superconductivity in FeSe.

Ultra-long quasiparticle relaxation times in the superconducting state of FeSe

GRAHAM BAKER (Presenter), JAMES DAY, SHUN CHI, RYAN P DAY, RUIXING LIANG, WALTER HARDY, DOUGLAS BONN, University of British Columbia — We report on measurements of the in-plane microwave conductivity of FeSe in the superconducting state. Our measurements were performed from 0.5 to 20 GHz and from 1.2 to 10 K by means of bolometric broadband microwave spectroscopy. In this frequency range, we are sensitive to the charge dynamics of thermally excited quasiparticles. We observe a dramatic narrowing in the conductivity spectra below $T_c$, corresponding to a rapid suppression of quasiparticle scattering. Using a phenomenological model, we extract a temperature-dependent quasiparticle relaxation rate $\Gamma$ from the conductivity, which can be understood as the sum of two contributions. The contribution to $\Gamma$ from inelastic scattering has an exponential temperature dependence. This implies that the excitation spectrum responsible for the inelastic scattering of quasiparticles is electronic in origin and gapped below $T_c$. The contribution to $\Gamma$ from elastic scattering is consistent with Born-limit scattering from a dilute concentration of impurities. At 1.2 K, the quasiparticle relaxation rate reaches a value corresponding to a mean free path greater than 100 $\mu$m.

Anisotropic Vortex Pinning in Single Crystal FeSe

IRENE ZHANG (Presenter), LOGAN BISHOP-VAN HORN, JOHANNA PALMSTROM, JOHN ROBERT KIRTLEY, YUSUKE IGUCHI, IAN R FISHER, KATHRYN ANN MOLER, Stanford University — Iron-based superconductors are known for their complex interplay between magnetic, nematic, and superconducting order. FeSe is an iron-based superconductor with a structural transition at 90 K without the appearance of magnetic ordering. The lack of magnetic order allows us to probe the superconducting transition of an iron-based superconductor from a purely nematic phase. We study single crystal FeSe using a scanning SQUID microscope that has both a field coil to apply a local magnetic field and a pickup loop to measure the vortex response. We model the effect of the SQUID geometry on vortex motion in an anisotropic pinning potential and find that SQUID orientation has a significant effect. Our initial findings suggest that the pinning potential anisotropy aligns with twin domain boundaries produced by the structural transition. We also check for correlation between spatial variation in diamagnetic response and anisotropy. These studies will help elucidate whether the relationship between nematic and superconducting order in these materials is competing or enhancing.

10:00AM E10.00011: Quantum vortex core and missing pseudogap in the multi-band BCS-BEC-crossover superconductor FeSe

TETSUO HANAGURI (Presenter), RIKEN CEMS, SHIGERU KASAHARA, Dept of Physics, Kyoto Univ., JAKOB BOKER, ILYA EREMIN, Theoretische Physik III, Ruhr-Univ. Bochum, TAKASADA SHIBAUCHI, Dept. Adv. Mat. Sci., Univ. Tokyo, YUJI MATSUDA, Dept of Physics, Kyoto Univ. — The iron-based superconductor FeSe is considered to be in the BCS-BEC crossover regime where the superconducting gap is comparable to the Fermi energy. We performed spectroscopic-imaging scanning tunneling microscopy to search for spectroscopic signatures of the BCS-BEC crossover. The large superconducting-gap to Fermi-energy ratio may yield well separated discrete bound states in the vortex core, as well as a pseudogap above the superconducting transition temperature due to preformed Cooper pairs. We found a signature of the discrete vortex bound states but could not detect the pseudogap. We argue that these conflicting observations can be resolved if multi-band nature is taken into account.

*This work was supported by KAKENHI (Grant Nos. 15H02106, 15H05852, 16H04024, 18H01177, and 18H05227) and by the joint DFG-ANR Project (No.ER463/8-1) and DAAD PPP USA Grant No.N57316180.

10:12AM E10.00012: Superconductivity fluctuation in FeSe investigated by magnetic torque measurement using optical interference

HIDEYUKI TAKAHASHI, Kobe University, FUYUKI NABESHIMA, RYO OGAWA, Department of Pure and Applied Sciences, University of Tokyo, EIJJI OHMICHI, HITOSHI OHTA, Kobe University, ATSUTAKA MAEDA (Presenter), Department of Pure and Applied Sciences, University of Tokyo — We investigated the superconducting fluctuation (SCF) in FeSe by a magnetic torque measurement. This material has a large ratio of the superconducting gap to Fermi Energy, and is proposed to be located in BCS-BEC crossover regime [1]. In our method, the absolute value of the cantilever displacement can be measured with high resolution by detecting the interference intensity of the Fabry-Perot type cavity formed between the cantilever and the optical fiber. We observed SCF signal originating from the surviving vortex liquid state, whose onset temperature increases up to above 1.5 Tc in high magnetic field. Its contribution to the magnetic torque is about 0.5 % of that of the total sample magnetization at 10 K and 10 T. These features are totally different, both qualitatively and quantitatively, from those of the signal observed in the previous torque magnetometry study using a piezoresistive cantilever[1], while similar to what reported in cuprate superconductors [2]. Therefore, we conclude that SCF in FeSe is not anomalous and it can be understood in the same framework as other superconductors using Ginzburg number.

Session E11 DMP DCOMP FIAP: Defects in Semiconductors -- Oxides BCEC 152 - Leonard Brillson, Ohio State University - Tag(s): Focus

8:00AM E11.00001: Electronic states in electron-doped rare-earth nickelates from first principles*[Invited] MICHELE KOTIUGA (Presenter), Rutgers University, New Brunswick — Correlation effects in transition metal based materials give rise to many interesting and exotic properties. The rare-earth nickelates, with a rich composition-phase diagram, are no exception. Doping rare-earth nickelates can lead to electron localization, introducing defect states that are unlike typical shallow or deep donor states familiar in conventional semiconductors. We present first-principles density-functional-theory-based calculations of rare-earth nickelates, with a focus on lanthanum nickelate and samarium nickelate, in which we add electrons to the material. Here, we investigate doping concentrations on the order of one electron per formula unit with the goal of changing the orbital occupation and triggering a phase transition, akin to the phase control seen with strain modulation. We carry out calculations where a uniform compensating background charge (jellium*) has been added to maintain charge neutrality when electrons are added, as well as supercell configurations with defects that electron dope the system, and superlattices where an electron is transferred at interfacial layers. In particular, we explore the effects of intercalated hydrogen and lithium as well as oxygen vacancies in samarium nickelate as well as lanthanum nickelate/strontium iridate superlattices. In comparing these calculations, we find the jellium-background calculations capture the changes to the electronic structure seen with the explicit inclusion of defects and interfaces. The resulting changes to the electronic structure, intimately linked to structural changes, cannot be understood with a rigid shift of the states: the bands are reorganized and the character of the gap is fundamentally altered. This class of doping effects introduces a new knob to turn in the field of materials design.

*We acknowledge financial support from Office of Naval Research Grant N00014-17-1-2770
8:36AM E11.00002: Energy Band Gap Tuning based on Ag doped LaFeO3 Nano-porous*  WAFAA AZOUZI (Presenter), Physics Department, Mohammed V University -Rabat, HICHAM LABRIM, DERS, Centre National de l’Energie, des Sciences et des Techniques Nucléaires / Rabat, MOHAMMED BENAÏSSA, Physics Department, Mohammed V University -Rabat — porous lanthanum ferrite LaFeO3 has been elaborated with wet chemical method. We have employed both DFT simulation and Rietveld refinement to understand deeply the complex optical behavior accurate in synthesized Nano-powders [1], with different amount of silver as dopant, and also evaluate the stoichiometry-optical properties relationship in this insulator oxide. It found that all samples, with different gap value depending on the silver concentration, exhibit a p-type semiconductor with a direct gap in the visible light spectrum. The results showed that lanthanum defects present in the synthesized samples improve optical absorption [2] in the visible range comparing with bulk calculated spectrum making it potentially useful in solar photovoltaic application.

8:48AM E11.00003: The role of hydrogen in the persistent photoconductivity of SrTiO3*  ZHIQIANG ZHANG (Presenter), Physics and Astronomy, University of Delaware, ANDERSON JANOTTI, Department of Materials Science & Engineering, University of Delaware — Strontium titanate (STO) is a perovskite oxide with an indirect bandgap of 3.25 eV at room temperature. It has been often used as substrate to grow other materials, and it is the basis of widely reported perovskite heterostructures that show high-density two-dimensional electron gas. Recently, an extremely long persistent photoconductivity (PPC) at room temperature has been observed in annealed strontium titanate single crystals upon illumination with sub-gap light [M. C. Tarun, F. A. Selim, and M. D. McCluskey, Phys. Rev. Letters, 111, 187403 (2013)]. Annealed studies indicate the importance of hydrogen impurities as well as oxygen vacancies to induce PPC. We use electronic structure calculations based on density functional theory (DFT) to investigate possible mechanisms behind the PPC effect. We present results of defect formation energies, defect-related absorption, and defect migration barriers, in an attempt to identify the defect associated with the observed PPC in STO. The results are combined to explain the experimental observations, and we further generalize the model to predict similar effects in other oxide like TiO2 and BaTiO3.

9:00AM E11.00004: Characterization and modulation of oxygen vacancy defects in metal/SrTiO3-δ Schottky heterojunctions  HAOMING JIN (Presenter), XIAOCHEN ZHU, ARTHUR F HEBARD, University of Florida — Strontium titanate, SrTiO3-δ (STO), can be made semiconducting and even metallic using high temperature anneals by introducing oxygen vacancy defects (δ > 0). Controlled thermal anneals with various temperatures and durations are employed to create specific defect profiles near the STO surfaces. Thermal sublimation or e-beam evaporation technique is then used to apply gold (Au) contact electrodes to the thermally treated STO substrates and create Schottky junctions. The presence of the oxygen vacancy defects strongly alters the electrical properties of these junctions as measured by transport, capacitance and low frequency noise. Our comparative study of these Schottky Au/STO junctions reveals that (i) the concentration of oxygen vacancy defects increases at the higher annealing temperature (ii) an improved spatial distribution/uniformity of defects is obtained by either lengthening the annealing duration or raising the annealing temperature. We show that the electrical characterizations of Schottky junction discussed here can serve as a useful tool to probe defects near the interfaces of novel materials and unravel information that is not easily accessed by other approaches.
9:12AM E11.00005: Doping in perovskite stannates* SANTOSH KC (Presenter), University of California, Santa Barbara, CA 93106, USA, LEIGH WESTON, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, CHRIS VAN DE WALLE, University of California, Santa Barbara, CA 93106, USA — The perovskite stannates (A\text{SnO}_3; A = Ba, Sr, Ca) are being actively explored for potential applications as transparent conducting oxides (TCOs) and in oxide electronics. To realize this potential, doping needs to be controlled. Using first-principles hybrid density functional calculations, we have performed comprehensive investigations of La donors as well as various types of defects. We examine the impact on doping as a function of growth conditions and impurity concentrations. For native defects, we investigate not only vacancies but also antisites. Trends among the various materials in the family (BaSnO3, SrSnO3, and CaSnO3) are analyzed. Our results identify optimum growth conditions for high n-type doping and identify defects that are most likely to impact device properties.

*Work supported by ONR.

9:24AM E11.00006: The Effects of Excess Charge Carriers in BiVO4* IFLAH LARAIB (Presenter), MARCIANO ALVES CARNEIRO, ANDERSON JANOTTI, Materials Science and Engineering, University of Delaware — Research on photoelectrochemical (PEC) performance of BiVO4 has gained momentum in the past few decades due to the potentially low cost solar-to-hydrogen conversion pathway provided by using this material as a PEC cell anode. While this material exists in four different phases, it is only its monoclinic phase doped with n-type carriers that exhibits significant PEC activity. These carriers typically involve hydrogenation, which supposedly introduces hydrogen interstitial and oxygen vacancy defects in the lattice. In this work, we use density functional theory calculations to explore the effects of excess n-type carriers on the structure and electronic properties of BiVO4, focusing on the most prominent tetragonal and monoclinic phases, and link it to its enhanced photo activity and possible carrier localization through electron small-polaron formation. The obtained results are compared to previous calculations and available experimental findings.

*This work was supported by the National Science Foundation Faculty Early Career Development Program DMR-1652994.

9:36AM E11.00007: Role of Point Defects in Enhancing the Conductivity of BiVO4 HOSUNG SEO, Department of Physics and Department of Energy Systems Research, Ajou University, YUAN PING (Presenter), Department of Chemistry and Biochemistry, University of California Santa Cruz, GIULIA GALLI, The Institute for Molecular Engineering, University of Chicago — Bismuth vanadate (BiVO4) is a promising photoanode for solar-to-fuel photocatalytic applications, and it has been extensively studied in recent years. However, the microscopic mechanism underlying the observed changes in electronic conductivity due to oxygen vacancies and nitrogen dopants remains unclear. Here, we combine electronic structure calculations at the hybrid density functional theory (DFT) level with constrained DFT, and we elucidate the role of defects in enhancing the transport properties of the material [1]. We show that at low temperature, oxygen vacancies give rise to deep levels within the fundamental gap of BiVO4; however even as deep levels, oxygen vacancies can act as effective n-dopants and polaronic charge carriers, due to their favorable position in energy relative to polarons in the pristine bulk. In addition, we show that N atoms can be easily introduced in n-doped BiVO4 and that the presence of substitutional nitrogen affects the formation energy of polarons, effectively contributing to an increase of the carrier mobility in the material. Our results reconcile apparently conflicting experiments and they may provide a foundation for polaronic defect engineering for photoanodes oxides. [1] H. Seo et al, Chem. Mater.

Computational Study of LiGaO₂ Electron Paramagnetic Resonance Spectra of Li and Ga Vacancies

DMITRY SKACHKOV (Presenter), WALTER R L LAMBRrecht, Case Western Reserve University — LiGaO₂ is an ultra-wide-band-gap material with a wurtzite-like crystal structure and band gap of 5.3 eV. Electron paramagnetic resonance (EPR) experiments on irradiated samples of this material were recently published by Lenyk et al. (J. Appl. Phys. 124, 135702, 2018). In the present work, density functional theory (DFT) calculations are carried out of the Ga and Li vacancies using the DFT+U approach in the charge states which carry an unpaired spin. In both vacancies the p-hole is located on one oxygen atom adjacent to the vacancy. Apical O and basal plane O are considered. The magnetic resonance parameters of the defects are determined using the Gauge Including Projector Augmented Wave (GIPAW) method. The EPR spectra of VGa²⁻ is characterized by a quasi-isotropic superhyperfine interaction with one Ga nucleus and for the apical O spin gives a g-tensor with maximum oriented along b axis. For VLi⁰ there is a quasi-isotropic superhyperfine interaction with two Ga nuclei and the g-tensor maximum is along c for the basal plane O spin. Both of these are in agreement with experiment but we predict also the g-tensors for the other possible localization of the spins. The energy ordering and transition levels for the different models will be discussed.

Towards bipolar tin monoxide: revealing unexplored dopants

JOSE FLORES LIVAS (Presenter), MIGLE GRAUZINYTE, STEFAN A C GOEDECKER, University of Basel — The advancement of transparent electronics, one of the most anticipated technological developments for the future, is currently inhibited by a shortage of high performance p-type semiconductors. Recent demonstration of tin monoxide as a successful transparent p-type thin film transistor and the discovery of its potential for ambipolar doping, suggests that tin monoxide -- an environmentally friendly earth-abundant material -- could offer a solution to this challenge. With the aim of enhancing the electronic properties, an extensive search for useful dopant elements was performed. Substitutional doping with the family of alkali metals was identified as a successful route to increase the concentration of acceptors in SnO and over ten shallow donors, that to the best of our knowledge have not been previously contemplated, were discovered. During this talk I will present a detailed analysis of the most promising n-/p-type dopants -- offering new insights into the design of an ambipolar SnO. If synthesized successfully, such a doped ambipolar oxide could open new avenues for many transparent technologies.

Experimental and computational evidence of defect centres in amorphous titanium dioxide and their confluence in resistive switching

DIP DAS (Presenter), ARABINDA BARMAN, Department of Physics, Shiv Nadar University, ANIL KUMAR SINHA, AD-XRD Lab, Indus-2 Synchrotron Utilization Division, Raja Ramanna Center for Advanced Technology (RRCAT), MUKUL GUPTA, SIMS Lab, UGC-DAE Consortium for Scientific Research, D. M. PHASE, Beamline Lab, UGC-DAE Consortium for Scientific Research, RAHUL SINGHAL, Department of Physics, Malaviya National Institute of Technology, SERGEI ZVYAGIN, High Magnetic Field Laboratory, Helmholtz-Zentrum Dresden-Rossendorf (HZDR), PRIYA JOHARI, ALOKE KANJILAL, Department of Physics, Shiv Nadar University — This work identifies dominant defect centres in amorphous titanium dioxide (a-TiO₂) films and their role in resistive random access memories with the help of combined experimental and theoretical studies. X-ray absorption spectroscopy reveals a significant decrease in peak splitting between t₂g and e₈ sub-bands at the Ti-L edge, which is attributed to lower valence of Ti-ions. Deconvolution of the Ti-2p X-ray photoelectron spectrum also suggests the existence of Ti³⁺ state along with oxygen vacancies in a-TiO₂. Further, the role of oxygen vacancies as intrinsic electron trapping centres in such system is recognized by low-temperature electron paramagnetic resonance measurements. The same has been verified using ab-initio density functional theory based simulations for a-TiO₂ phase, generated using ab-initio molecular dynamics simulations. The partial charge density and Bader charge analysis were done, in particular, to manifest the localized character of the excess electrons ejected during the creation of oxygen vacancies. Such electronic localisations facilitate local high conducting regions in the amorphous matrix, which in turn leads to forming free resistive switching behaviour in Pt/a-TiO₂/Pt devices.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E12 DMP: Devices from 2D Materials -- Sensors
8:00AM E12.00001: Graphene and Black Phosphorus Infrared Photodetectors* [Invited]  FENGNIAN XIA (Presenter), QIUSHI GUO, BINGCHEN DENG, XIAOLONG CHEN, Yale Univ — In this talk, we will discuss latest development on infrared photodetectors based on graphene and black phosphorus. We will first cover graphene plasmon-enhanced mid-infrared photodetectors in which the detection leverages the bolometric effect in graphene nanoribbons. Then we will review the infrared detection properties of black phosphorus. Gated tunable black phosphorus photodetectors will also be presented, in which the bandgap of black phosphorus is tuned for the light detection up to the wavelength of around 8 μm. Finally we will compare the performance of infrared photodetectors based on graphene and black phosphorus and discuss their possible applications.

*National Science Foundation, Office of Naval Research and Air Force Office of Scientific Research

8:36AM E12.00002: A fast, sensitive, room-temperature graphene nanomechanical bolometer*  ANDREW BLAIKIE (Presenter), DAVID MILLER, BENJAMIN J ALEMAN, University of Oregon — Bolometers are a powerful and vital means of detecting light in the IR to THz frequencies, and have been adopted for applications ranging from astronomy to thermal imaging. As uses diversify there is an increasing demand for faster, more sensitive room-temperature bolometers. To this end, graphene has generated interest because of its vanishingly small heat capacity and its intrinsic ultra-broadband absorption, properties that would allow it quickly detect low levels of light of nearly any color. Yet, it is challenging to operate a traditional electrical graphene bolometer at room temperature due to its weakly temperature-dependent resistivity and high thermal conductivity. Our method overcomes these challenges with a simple approach that employs suspended graphene as a nanomechanical bolometer, where absorbed light is detected as shift in its mechanical resonance frequency. We report on the measured sensitivity and response bandwidth of these graphene nanomechanical bolometers, which compare favorably to the state-of-the-art. Furthermore, we model the response of these devices and discuss a path to reach femtowatt sensitivity at room temperature.

8:48AM E12.00003: Transient and Flexible Photodetectors  SHIH-YAO LIN, GOLAM HAIDER, YU-MING LIAO, CHEN-YOU SU (Presenter), YANG-FANG CHEN, Physics, National Taiwan University — With the rapid development of technology, electronic devices have become omnipresent in our daily life as they have brought much convenience in human activity. Side-by-side, electronic waste has become a global environmental burden creating an ever-growing ecological problem. The transient device technology in which the devices can physically disappear completely in different environmental conditions has attracted widespread attention in recent years owing to its emerging application potential spanning from biomedical to military use. In this work, we demonstrated the first attempt for a dissolvable ecofriendly flexible photodetector using a hybrid of graphene and chlorophyll on a PVA substrate. The whole device can physically disappear in aqueous solutions in a time span of ~30 min, while it shows a photoresponsivity of ~200 A W−1 under ambient conditions. The high carrier mobility of graphene and strong absorption strength of a green photon harvesting layer, chlorophyll, result in the photocurrent gain of the device as high as 103 with subsecond response time under the illumination of red light. The newly designed photodetector shown here yields zero waste with a minimum impact on the environment, which is very useful for the development of the sustainability of our planet.

9:00AM E12.00004: Electromechanical resonators based on h-BN graphene heterostructures  ROHIT KUMAR (Presenter), DERIC W SESSION, HARRISON PAAS, RYUICHI TSUCHIKAWA, VIKRAM DESHPANDE, University of Utah — The exceptional robustness, stability, ultra-low weight, and high tunability are some of the most intriguing attributes of 2D atomically thin crystals like graphene, MoS2 to name a few. These remarkable properties make them promising candidates for a new generation of nanoelectromechanical systems (NEMS). Many microelectromechanical (MEMS) sensors used today employ two or more layers of different materials; however, the area of 2D heterostructure based NEMS has not been explored much. In this study, we discuss the fabrication and characterization of circular heterostructure resonators based on hexagonal boron nitride (h-BN) and graphene stacks. The stacks are electrically actuated and measured using the vector network analyzer (VNA) from room temperature down to cryogenic temperatures. h-BN graphene provides a flat and clean interface and resonators are tunable with gate voltage. The temperature dependence of strain induced in resonators of different thicknesses will be discussed.
Graphene-enabled and directed nanomaterial placement from solution for large-scale device integration*

MICHAEL ENGEL, IBM Research - Brazil, DAMON FARMER, IBM Research - USA, JAIONE TIRAPU AZPIROZ, IBM Research - Brazil, JUNG-WOO T. SEO, JOOHOOON KANG, Department of Materials Science and Engineering and Department of Chemistry, Northwestern University, PHAEDON AVOURIS, IBM Research - USA, MARK HERSAM, Department of Materials Science and Engineering and Department of Chemistry, Northwestern University, RALPH KRUPKE, Institute of Nanotechnology, Karlsruhe Institute of Technology, MATHIAS B STEINER (Presenter), IBM Research - Brazil — In this presentation we report on a process for electric-field assisted placement of nanomaterials from solution using large-scale graphene layers having patterned nanoscale deposition sites. The patterned graphene layers are prepared via either transfer or synthesis on standard substrates, then are removed once nanomaterial deposition is completed, resulting in material assemblies with nanoscale resolution that cover surface areas larger than 1mm². In order to demonstrate the universality of this approach, we have assembled representative zero-, one-, and two-dimensional semiconductors at predefined substrate locations and integrated them into nanoelectronic devices. Finally, we explore the scaling behavior of this approach for integration of high performance nanoelectronic devices.

Chemical Vapor Sensing with Transition Metal Dichalcogenides via Photoluminescence Modulation

AUBREY HANBICKI (Presenter), PAUL MICHAEL CAMPBELL, United States Naval Research Laboratory, SAUJAN SIVARAM, NRC Postdoc at Naval Research Laboratory, ANDREW KUSTERBECK, Nova Research Inc., VIET NGUYEN, R. ANDREW MCGILL, KATHLEEN MCCREARY, BEREND JONKER, ENRIQUE COBAS, F. KEITH PERKINS, United States Naval Research Laboratory, ADAM FRIEDMAN, Laboratory for Physical Sciences — Two-dimensional transition metal dichalcogenides (TMDs) such as MoS₂ and MoSe₂ are promising materials for chemical vapor sensing applications. Their potential includes straightforward fabrication, readily available materials, and good selectivity, sensitivity, and speed of response. Another attractive aspect is that they have been shown to detect chemical vapors and gases in several ways. More commonly, sensors have been fabricated based on the chemiresistive device properties. Here, however we will discuss our recent studies implementing TMD sensors using the optical properties, in particular the photoluminescence (PL) as the core element of the sensor. We examine the PL of MoSe₂ while it is exposed to strong electron donor gases such as triethylamine. There is a fast and significant decrease in the PL upon exposure with PL reduction by as much as 75% during exposure. When the vapor is turned off, the PL quickly recovers indicating fast adsorption/desorption of the analyte. We compare the temporal response and sensitivity of the PL with that of the electrical change in conductivity and analyze the data in terms of possible applications to chemical vapor sensing of chemicals relevant to nerve gas and explosive sensing. This work was supported by core programs at NRL.

Raman enhancement of blood constituent proteins using graphene

SHENGXI HUANG (Presenter), Pennsylvania State University, RISHIKESH PANDEY, University of Connecticut School of Medicine, ISHAN BARMAN, Johns Hopkins University, JING KONG, MILDRED DRESSELHAUS, Massachusetts Institute of Technology — Raman spectroscopy has drawn considerable attention in biomedical sensing due to the promise of label-free, multiplexed and objective analysis along with the ability to gain molecular insights into complex biological samples. However, its true potential is yet to be realized due to the intrinsically weak Raman signal. Here, we report a simple, inexpensive and reproducible signal enhancement strategy featuring graphene as a substrate. Taking key blood constituent proteins as representative examples, we show that Raman spectra acquired from biomacromolecules can be reproducibly enhanced when these molecules are placed in contact with graphene. In particular, we demonstrate that hemoglobin and albumin display significant, but different, enhancement with the enhancement factor depending on the Raman modes, excitation wavelengths and analyte concentrations. This technique offers a new strategy for label-free biosensing owing to the molecular fingerprinting capability, signal reliability, and simplicity of the enhancement method.
Effect of oxygen adsorption on electron transport in few-layer InSe FETs

ARVIND SHANKAR KUMAR (Presenter), Case Western Reserve University, RAJESH KUMAR, RAMAN SANKAR, FANGCHENG CHOU, National Taiwan University, XUAN GAO, Case Western Reserve University — The oxidation effect in 2D chalcogenides is a well-known problem in 2D materials. We investigate the adsorption of oxygen molecules on the surface of few layer InSe FETs through transconductance and time dependent conductance measurements. We observe a positive shift of threshold voltage when few-layer InSe FET devices are exposed to oxygen (corresponding to a reduction in electron density in the order of $10^{12} \text{ cm}^{-2}$ for an oxygen pressure of 60 Torr) which is partially reversible through applying gate stress. Time dependent measurements show a drop in conductivity up to a factor of 5 when exposed to 5 Torr of oxygen gas, over the time scale of the order of 1000 seconds. From these results, we characterize the oxygen sensing response of few-layer InSe devices, and discuss the implications on the underlying binding interaction between oxygen molecules and InSe. Nitrogen exposure, on the other hand, did not yield appreciable change in InSe FET’s characteristics.

Broadband and high responsivity graphene-based photodetectors by engineering atomic-layer-deposition dielectric films

HO VINH (Presenter), YIZHOU WANG, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech, MICHAEL P. COONEY, NASA Langley Research Center, VINH Q NGUYEN, Department of Physics and Center for Soft Matter and Biological Physics, Virginia Tech — Ability to covert light of graphene occurs in an ultra-broadband spectral range from violet to mid-infrared region, making graphene as desirable photodetectors for various technology applications in imaging, sensing, spectroscopy and telecommunication. However, the low responsivity of graphene photodetectors about 10 mA/W, due to the ultra-fast recombination of photocarriers, limits their potential applications. Here, we have engineered the interface between graphene and atomic-layer-deposited dielectric films to introduce trapping centrals supporting the highly light reactive of photodetectors. Our graphene-based photodetectors have showed a high sensitivity up to $2 \times 10^5 \text{ A/W}$ together with a fast response time in a broadband spectral at room temperature.

*The authors gratefully acknowledge the financial support of this effort by IRAD and ESTO programs from NASA Langley Research Center’s Office of Chief Technologist.

Electronic Detection of Oxygen Adsorption and Size-Specific Doping of Few-Atom Gold Clusters on Graphene

SHUANGLONG LIU (Presenter), University of Florida, JEROEN SCHEERDER, VYACHESLAV ZHARINOV, KU Leuven, NICOLAS RECKINGER, JEAN-FRANÇOIS COLOMER, University of Namur, JORIS VAN DE VONDEL, EWALD JANSSENS, KU Leuven, HAI-PING CHENG, University of Florida — Graphene has potential application as sensor due to its sensitivity to adsorbed particles. Few-atom clusters are promising candidates as adparticles on graphene. In this joint experimental and computational work, we investigate size-selected gold clusters with 3 and 6 atoms adsorbed on graphene field-effect transistors and their interaction with molecular oxygen. We find that the doping level of graphene significantly depends on the cluster size, in the absence or presence of oxygen molecules. Furthermore, the doping of 3-atom gold cluster decorated graphene changes sign from n- to p-doping upon oxygen adsorption, directly evidencing electron transfer to the oxygen molecules and hence their activation. As such, graphene promises to be a valuable platform to investigate and exploit size-dependent cluster properties. The presentation covers mainly the theoretical aspects of the work, namely density functional theory (DFT) based simulations of adsorption site, adsorption energy, atomic configuration, and electronic structure.

*This work is supported by the KU Leuven Internal Research Fund C14/17/080. H.-P. C. acknowledges the US DOE/BES DE-FG02-02ER45995 for supporting the computational work. Part of the study received funding from the European Union H2020 program, project No 649953.

HYEONDEOK SHIN (Presenter), YE LUO, ANOUAR BENALI, Argonne National Laboratory, YONGKYUNG KWON, Physics, Konkuk University — Diffusion Monte Carlo (DMC) calculations were performed for an accurate description of the nature of the $O_2$ adsorption on a single layer graphene. We investigated the stable orientation of $O_2$ as well as its equilibrium adsorption distance and energy for a specific adsorption site. At equilibrium adsorption distances, an $O_2$ was found to prefer a horizontal orientation, where the O-O bond is parallel to the graphene surface, to the vertical orientation. However, the vertical orientation is favored at the $O_2$-graphene distance shorter than the equilibrium distance, which could be understood by their steric repulsion. Contrary to previous DFT calculations, our DMC calculations show that the most energetically-stable adsorption site for $O_2$ is not the center of a hexagonal ring but the midpoint of a C-C bond. The $O_2$ adsorption energy at a bridge site was estimated to be 0.135(4) eV, which is in good agreement with the recently-reported experimental value [1]. Finally, we have found that $O_2$ is very diffusive on the surface of graphene with the diffusion barrier along a bridge-hollow-bridge path being as small as $\sim 10$ meV.

10:36AM E12.00012: Reproducible fabrication of graphene field effect transistors for detection of CA1

NARENDRA KUMAR (Presenter), Physics, Boston College, ANDREW WEBER, Giner Inc., MASON GRAY, Physics, Boston College, JUAN C. ORTIZ-MARQUEZ, Biology, Boston College, CAMERON RICHARD DESMOND, MATTHEW CATALANO, Physics, Boston College, AVNI ARGUN, Giner Inc., TIM VAN OPJNEN, Biology, Boston College, KENNETH BURCH, Physics, Boston College — The ultra-sensitivity of graphene field effect transistors (GFETs) to any chemical or biological interaction on the surface makes them a potential candidate for miniaturized label free biosensors. The reproducibility and stability remain key challenges for GFETs based biosensors as they are also sensitive to environment and chemicals used during fabrication. In this work, the reproducible GFET devices were fabricated inside a glove box in argon environment using monolayer graphene. The fabricated devices showed the charge neutrality point (CNP) of 0±10V in the back gate mode while ~0.5V in top liquid gate mode using Pt wire as pseudo reference electrode. Finally, the fabricated devices were utilized for detection of carbonic anhydrase 1 (CA1) in phosphate buffer solution (PBS) as well as CA1 spiked diluted human saliva samples using RNA aptamer as probes. I will discuss the various limits of detection and sensitivity to non-specific targets.

10:48AM E12.00013: Fabrication of lithographic and self-organized graphene ribbons grown on SiC

BIYI WU (Presenter), NIST, Natl Taiwan Univ, YANFEI YANG, ALBERT RIGOSI, JIUNING HU, HSIN-YEN LEE, MATTIAS KRUSKOPF, HANBYUL JIN, RANDOLPH E ELMQUIST, NIST, CHI-TE LIANG, Natl Taiwan Univ — It has been shown that the edge properties play an important role in transport in narrow ribbons. In this work, we prepare two types of graphene ribbons within a few hundred nm by vastly different fabrication techniques to discuss the edge effects. The first type of samples is made by electron-beam lithography and conventional RIE etching processes. Strong negative magnetoresistance (MR) behavior is observed due to the consequence of disorder in the edge structure (e.g. chemical dopants, the resolution of e-beam lithography and so on). The second type of ribbons on SiC is self-organized, and grown “naturally” (i.e., similar to the way large-area monolayer graphene can be prepared by high-temperature Si sublimation [1]), which guarantees cleaner and more uniform edges. At low magnetic fields, the MR curve shows evidence for weak localization due to intervalley scattering from the sharp edges. With increasing magnetic field, quantum transport described by boundary scattering in the quasi-ballistic regime can be observed [2]. The scattering mechanism of self-organized ribbons is totally different from that of the etched one due to the edge effects.

Session E13 DMP: 2D Materials (General) -- Growth, Mostly CVD/T
8:00AM E13.00001: Interaction of Two-Dimensional Transition Metal Dichalcogenides on Different Substrates and Nanostructures*  
ANDREW GREENSPON (Presenter), John A. Paulson School of Engineering and Applied Sciences, Harvard University, QINGQING JI, Research Laboratory of Electronics, Massachusetts Institute of Technology, MENA N GADALLA, DANQING WANG, NIAMH MULHOLLAND, John A. Paulson School of Engineering and Applied Sciences, Harvard University, JING KONG, Research Laboratory of Electronics, Massachusetts Institute of Technology, EVELYN L HU, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Two-dimensional transition metal dichalcogenides (2D TMDs) are 2D semiconductors that hold promise for a variety of optoelectronic devices, especially by harnessing the valley degree of freedom. Growth of 2D TMDs on different substrates and nanostructures provides enormous opportunities in engineering ultra-thin devices with tailored optical emission properties. We characterize the optical differences when the 2D TMD molybdenum disulfide (MoS2) is grown via chemical vapor deposition on the substrates silicon dioxide on silicon, gallium nitride (GaN), and silicon carbide (SiC). Changes in the spacing and relative intensity of the E12g and A1g Raman peaks suggest differences in the microstructure of the grown MoS2 or its interaction with the substrate. Additionally, we characterize the interaction between MoS2 and optical cavities patterned onto GaN and SiC. Preliminary results show brighter MoS2 exciton photoluminescence and shifted emission peaks on the optical cavities compared to the bulk substrate of each. We also show first results attempting to couple MoS2 emission to the resonant modes of these optical cavities.

8:12AM E13.00002: The effect of multi-step Cu surface oxidization on growth of single crystal graphene by low pressure chemical vapor deposition*  
SAJITH WITHANAGE (Presenter), THARANGA NANAYAKKARA, BINUKA GUNAWARDANA, C. RASADI MUNASINGHE, U. KUSHAN WIJEWARDENA, RASANGA SAMARAWEERA, ANNIKA KRISA, RAMESH MANI, Physics & Astronomy, Georgia State University — There has been much recent interest in the growth large area single crystal graphene flakes as an approach for overcoming the relatively low carrier mobility and the multigrain structure observed in Chemical Vapor Deposition (CVD) graphene. [1] One approach for growing large-sized single crystal graphene by CVD, [2] involves limiting the nucleation density of graphene on the copper foil surface that is often used as a catalyst for the growth of CVD graphene. Here, we report the results of a study of CVD growth of graphene following surface modification of the copper foil by oxidizing the copper foil at different stages of the growth process. Thus, we detail the effect of copper surface oxidization at different steps of the growth for controlling the nucleation on the size and the quality of relatively large sized single crystal graphene flakes. The graphene layers are characterized by various methods and the results of the study are reported.

8:24AM E13.00003: Tempered Dewetting of Metal Films: A platform for networked 2D crystal membranes*  
JOSE FONSECA VEGA (Presenter), JAMES CLIFFORD CULBERTSON, MAXIM ZALALUTDINOV, CORY D CRESS, JEREMY T ROBINSON, United States Naval Research Laboratory — The controlled dewetting and recrystallization of metal films with two-dimensional (2D) crystal over-layers enables the formation of highly textured metallic films, together with a network of metallic pores and suspended 2D crystal membranes. Mechanically-exfoliated and chemical-vapor deposited (CVD-grown) 2D crystals (e.g., graphene, h-BN, and transition-metal dichalcogenides (TMDs)) were transferred on top of metallic thin films on SiO2/Si substrates to modify the dewetting and recrystallization dynamics. After heat treatment, metal films capped with 2D crystals become textured and form pores that can span up to 60% of the planar surface area, depending on annealing conditions and 2D crystal quality. The network of suspended membranes was found to have significantly different optical and electronic properties than the supported regions. For example, enhancement in photoluminescence of nearly three orders of magnitude and spatial surface potential variations up to 300 mV. The process capabilities are exemplified through a series of heterostructures of different metal/2D crystal materials where the resulting properties highlight the influence of the networked topography.

8:36AM E13.00004: From Synthesis to Quantum Properties of Novel 2D Layers*

JOSHUA ROBINSON (Presenter), Pennsylvania State University — Quantum materials (QMats) are prime candidates for next-generation energy-efficient technologies, such as topological quantum computing, quantum sensing, and neuromorphic computing. 2D materials offer to drastically advance our ability to synthesize, characterize, and control QMats at the atomic scale. With graphene being the first of its kind, there are now many recent breakthrough phenomena in 2D materials, including 2D magnets (e.g. CrI3), superconductors (e.g. 2D-Ga, NbSe2), and quantum emitters (e.g. WSe2, hBN), that continue to intrigue the scientific world. Quantum phenomena needed to drive disruptive Quantum Leap technologies often require integrating dissimilar materials such as superconductors and topological insulators (SC/TI) for topological superconductivity and quantum computing; (anti)ferromagnets coupled to complex oxides for correlation-driven devices beyond Moore's Law; or coherent coupling of localized spins in SiC to magnons (magnets) and Cooper pairs (superconductors) for transduction of quantum information. In this talk I will discuss our pioneering work in confinement heteroepitaxy (CHet), which decouples the growth of disparate constituent materials, thereby enabling a new platform for creating artificial quantum lattices (AQLs) with atomically sharp interfaces and designed properties. As a specific example, we synthesize plasmonic layers and 2D-superconductors combined with topological insulators to demonstrate the first “2D” topological insulator, which opens up avenues for enabling a virtual “legoland” of hybrid quantum materials.

*Funding for this work comes from NSF, Northrop Grumman, NIST, and the Semiconductor Research Corporation.

TODD BRINTLINGER (Presenter), United States Naval Research Laboratory, TOMOJIT CHOWDHURY, BENJAMIN O STEPHENS, THOMAS J KEMPA, Chemistry, Johns Hopkins University — We characterize MoS2 nanoribbons grown using a catalyst-free vapor phase synthesis that relies on pre-treatment of a bare Si surface. This growth method leads to the spontaneous formation of long ‘nanoribbons,’ with typical diameters of 100 nm and lengths greater than 10 µm. Despite their high aspect ratio and inherent flexibility, the nanoribbons are robust upon handling and are self-supporting, rendering them stable during transfer to support structures to allow electron microscopy. We use scanning electron microscopy to characterize the ribbon morphology and aberration-corrected scanning transmission electron microscopy to identify the phase, composition, and atomic structure of the samples. We identify that the MoS2 nanoribbons (1) are predominantly 2H-phase, (2) display a ‘sawtooth’ edge structure with corrugations on the order of 2–5 nm, (3) fold to give very low radii of curvature, and (4) contain occasional nanometer-scale triangular inclusions. Intriguingly, these high aspect ratio nanoribbons exhibit a PL peak that is blue-shifted significantly relative to that of as-synthesized and transferred 2-dimensional MoS2 sheets.

*The authors acknowledge funding from the Office of Naval Research (Naval Research Laboratory Basic Research Program).

9:24AM E13.00006: Strong interlayer coupling and layer-dependent bandgap in 2D layered PdSe2 synthesized by chemical vapor deposition

LI-SYUAN LU (Presenter), HUI-YU CHENG, GUAN-HAO CHEN, Department of Electrophysics, National Chiao Tung University, CHIA-HAO CHEN, TZU-HUNG CHUANG, DER-HSIN WEI, National Synchrotron Radiation Research Center (NSRRC), MING-YANG LI, CHIH-PIAO CHUU, LAIN-JONG LI, Corporate Research and Chief Technology Office, Taiwan Semiconductor Manufacturing Company (TSMC), WEN-HAO CHANG, Department of Electrophysics, National Chiao Tung University, — Two-dimensional (2D) noble metal dichalcogenides, such as PtS2 or PdSe2, have attracted much attention due to their remarkable layer-dependent electronic structures and superior electrical properties for device applications. However, most of the demonstrated experiments thus far are based on mechanical exfoliations from bulk crystals. Here, we demonstrate that highly crystalline and air stable PdSe2, from bilayer up to few layers, can be synthesized by chemical vapor deposition. The atomic ratio and the lattice structure of PdSe2 have been confirmed by x-ray photoemission and polarization-resolved Raman spectra. Low-frequency Raman measurements of breathing vibration modes reveal the strong interlayer coupling, which can also be used for identifying the layer numbers [1]. Based on absorption measurements, we observed a strongly layer-dependent bandgap, which shows a gap shrinkage up to 0.5 eV with the increasing layer number from bilayer to 7 layers. The dramatically layer-dependent bandgap shrinkage is also consistent with the calculated energy gap based on density functional theory.[2]

9:36AM E13.00007: Synthetic Metal-Semiconductor Junctions of Transition Metal Disulfides*  WEI SUN LEONG (Presenter), QINGQING JI, NANNAN MAO, Electrical Engineering and Computer Science, Massachusetts Institute of Technology (MIT), YIMO HAN, Applied and Engineering Physics, Cornell University, HAOZHE WANG, Electrical Engineering and Computer Science, Massachusetts Institute of Technology (MIT), AARON J GOODMAN, Chemistry, Massachusetts Institute of Technology (MIT), CONG SU, YUNFAN GUO, PIN-CHUN SHEN, ZHENFEI GAO, Electrical Engineering and Computer Science, Massachusetts Institute of Technology (MIT), DAVID ANTHONY MULLER, Applied and Engineering Physics, Cornell University, WILLIAM A TISDALE, Chemical Engineering, Massachusetts Institute of Technology (MIT), JING KONG, Electrical Engineering and Computer Science, Massachusetts Institute of Technology (MIT) — Transition metal dichalcogenides (TMDs), a group of 2D materials with diverse electronic properties, are ideal candidates to build atomically thin electronics. Although critical components of an electronic device based on TMDs, such as insulator-semiconductor and semiconductor-semiconductor junctions, have been demonstrated, there is limited experimental realization of TMD-based metal-semiconductor junctions to date. Here, we report a two-step chemical vapor deposition (CVD) strategy that enables the synthesis of high-quality solely TMD-made metal-semiconductor lateral junctions. Remarkably, we discover a novel growth behavior in such lateral TMD heterojunctions: MoS2 was found to nucleate from the vertexes of multilayered VS2 flakes and evolve into monolayer polycrystals, rather than the edge epitaxy observed in other TMD lateral junctions. Furthermore, we demonstrate that lattice coherency across the lateral junction is not a necessity for low-resistance contacts, as our VS2-MoS2 junctions manifest contact resistance as low as 500 Ωµm and a Schottky barrier height as small as 30 meV, both among the best values reported to date for contacts to 2D TMDs. This work opens up a new avenue for all-2D-based synthetic electronics.

*AFOSR FATE MURI, Grant No. FA9550-15-1-0514

9:48AM E13.00008: Scaling a van der Waals quantum Hall semiconductor  KAI YUAN (Presenter), RUOYU YIN, XIAOSONG WU, YU YE, LUN DAI, School of Physics, Peking University — Indium selenide (InSe), a two-dimensional (2D) layered semiconductor material, have attracted much attention recently due to their high mobility and fascinating physical properties. Nevertheless, the preparation of few-layer InSe is limited to mechanical exfoliation which hinders their potential in the future applications. Recently reports of few-layer InSe synthesized via chemical vapor deposition (CVD) method failed to maintain high mobility characteristics of InSe. Here, we explored the controlled one-step synthesis of 2D InSe nanoflakes with chemical vapor transport (CVT) by appropriately slowing down the growth rate. Diverse growth routes were developed by using different transport agents. As-grown InSe nanoflakes with thickness down to monolayer was successfully obtained. Atomic-resolution ADF-STEM imaging revealed the high quality of the as-synthesized InSe nanoflakes. Encapsulated by BN at both sizes, the electrical transport of our InSe nanoflakes shows excellent performance with carrier mobilities larger than 1000 cm²V⁻¹s⁻¹ at room temperature and 5000 cm²V⁻¹s⁻¹ at 1.5 K, enabling us further observe the quantum Hall effect. This is the first time that a quantum Hall effect was observed in as-grown 2D semiconductor materials.

10:00AM E13.00009: Theoretical insight into the mechanism for spontaneous vertical growth in ReS2*  ANTHONY YOSHIMURA (Presenter), DEBJIT GHOSHAL, TUSHAR GUPTA, Rensselaer Polytechnic Institute, ANDREW HOUSE, New Jersey Institute of Technology, SWASTIK BASU, YANWEN CHEN, TIANMENG WANG, YANG YANG, WENJIA SHOU, Rensselaer Polytechnic Institute, JORDAN A. HACHTEL, JUAN CARLOS IDROBO, Oak Ridge National Laboratory, TOH-MING LU, Rensselaer Polytechnic Institute, SAGNIK BASURAY, New Jersey Institute of Technology, VINCENT MEUNIER, SUFEI SHI, NIKHIL KORATKAR, Rensselaer Polytechnic Institute — While vertical growth can be observed in some transition metal dichalcogenides (TMDs) under special conditions, vertical growth of rhenium disulfide (ReS2) is unique in that it is thermodynamically favorable over horizontal growth regardless of substrate. In this study, we use density functional theory (DFT) to shed light on the mechanism that initiates vertical growth in ReS2 to explain its substrate-independence. We propose that ReS2 growth has two stages. First, ReS2 grows parallel to the substrate, in a manner similar to that of conventional TMDs. However, as a growing ReS2 flake reaches a critical diameter, spontaneous vertical growth is nucleated at points near the flake’s center. At these sites, an additional Re atom binds to a cluster of “pinched” Re atoms, leaving an under-coordinated S atom protruding out of the ReS2 plane. This S atom is “reactive” and readily binds to free Re and S atoms, initiating growth in a direction perpendicular to the ReS2 surface. The resulting vertical ReS2 arrays possess high surface-to-volume ratios and can therefore accommodate a broad range of applications including surface enhanced Raman spectroscopy, field emission, and solar-based disinfection of bacteria.

10:12AM E13.00010: Stoichiometric Control of Structural Phases in Two-Dimensional NbS2 Nanoflakes* AMANDA COUGHLIN (Presenter), WENCao YANG, ZHEN LI, SHIXIONG ZHANG, Indiana University Bloomington — Two-dimensional transition metal dichalcogenides (TMDs) are known to exist in multiple structural phases (1T, 2H, and 3R etc.) each with distinct physical properties. The ability to tune the crystal structures in a controlled manner provides an effective route to engineer the respective properties and is therefore of significant technological importance. In this study, we use NbS2 nanoflakes as an example to demonstrate the control of structural phases in layered TMDs by tuning their stoichiometry. The as-grown NbS2 has a rhombohedral 3R phase which can be readily transformed into another structure via a simple annealing process. By varying the annealing conditions, we realize several different structural phases as identified by Raman spectroscopy. The reversibility and the underlying mechanism of phase transformations are also studied.

10:24AM E13.00011: Spectroscopic Characterization of Colloidally Synthesized, Anisotropic 2D SnS ADAM BIACCHI, BRIAN ALBERDING, SON T. LE, SUGATA CHOWDHURY, JOSEPH HAGMANN, SUJITRA POOKPANRATANA, CURT A RICHTER, EDWIN HEILWEIL, ANGELA HIGHT WALKER (Presenter), National Institute of Standards and Technology — Solution routes afford scalable means of manufacturing size-, shape-, and composition-controlled nanoscale electronic materials. We have developed solution routes to monodisperse 2D semiconductor SnS nanostructures, an easily processable and cost-efficient alternative to exfoliation and gas-phase deposition techniques. These colloidal chemistries afford two distinct SnS morphologies: nanoribbons and square nanosheets. The uniformity and morphology of the nanocrystals were verified using TEM, SEM, AFM, and optical microscopy. A spectroscopic investigation of the inherent structural and electronic properties of nanocrystals showed the α-SnS polymorph adopts a layered orthorhombic crystal structure, isostructural with black phosphorus. These 2D crystals are anisotropic, with in-plane atoms adopting the armchair configuration along one axis and zigzag in the orthogonal direction. Detailed polarization-, wavelength- and temperature-dependent Raman spectroscopy provide key insight into the crystallographic details and low-frequency phonon behavior. Back-gated devices fabricated from individual crystals reveal electronic transport information and four-point probe methods show the anisotropic conductivity resulting from a black phosphorus-like bonding arrangement found in 2D SnS.

10:36AM E13.00012: Engineering Defect Transition-Levels through van der Waals Heterostructure* AKASH SINGH (Presenter), Materials Research Centre, Indian Institute of Science, Bangalore 560012, India, AADITYA MANJANATH, Institute of Chemistry, Indian Institute of Science, Bangalore 560012, India, ABHISHEK KUMAR SINGH, Materials Research Centre, Indian Institute of Science, Bangalore 560012, India — Tuning the defect transition levels in 2D semiconductors without significantly altering the integrity of the materials remains one of the most difficult challenges. Among the 2D materials, monolayer MoS2 is considered as a front-runner for device applications, does not have a single intrinsic shallow defect, thereby limiting its applications. We demonstrate that the deep defect levels created by a cation vacancy in a monolayer of MoS2, can be tuned to a shallow level by forming the van-der-Waals heterostructure of it with a monolayer of WS2, while maintaining their structural and compositional integrity intact. In result, the deep defect levels are shallowed by nearly 4(V-1Mo) and 2(V-1W) times, respectively, compared to their monolayer counterparts. The overall change in dielectric constant rescales the defect transition levels in a heterostructure. Our finding has the potential to revolutionize the doping strategy of the 2D materials and could pave the way for 2D electronics.

Session E14 DCMP: Graphene: Transport Properties BCEC 153C - Dongying Wang, Ohio State University
8:00AM E14.00001: Fermi surface anisotropy of graphene measured by ballistic transport experiments on antidot lattice samples  RYUTA YAGI (Presenter), TAKUSHI OKA, RYOYA EBISUOKA, TAIKI HIRAHARA, AdSM, Hiroshima Univ., KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science (NIMS) — Monolayer graphene and bilayer graphene have strikingly different properties. One such difference is the shape of the Fermi surface. Although anisotropic band structures can be detected in optical measurements, they have so far been difficult to detect in transport experiments on two-dimensional materials. Here we describe a ballistic transport experiment using high-quality graphene that revealed Fermi surface anisotropy in the magnetoresistance. The shape of the Fermi surface is closely related with the cyclotron orbit in real space. Electron trajectories in samples with triangular lattices of holes depend on the anisotropy of the Fermi surface. We found that this results in the magnetoresistance which are dependent on crystallographic orientation of the antidot lattice, which indicates the anisotropic Fermi surface of bilayer graphene which is a trigonally-warped circle in shape. While in monolayer, shape of magnetoresistance was approximately independent of the orientation of antidot lattice, which indicates that the Fermi surface is a circle in shape.

8:12AM E14.00002: Universal voltage scaling due to self-averaging of quantum corrections in graphene  NARGESS ARABCHIGAVKANI (Presenter), Department of Physics, University at Buffalo, The State University of New York, RATCHANOK SOMPHONSANE, Department of Physics, King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand, HARIHARA RAMAMOORTHY, GUANCHEN HE, JUBIN NATHAWAT, SHENCU YIN, JONATHAN P BIRD, Department of Electrical Engineering, University at Buffalo, State University of New York, BILAL BARUT, Department of Physics, University at Buffalo, The State University of New York, MIAO ZHAO, ZHI JIN, High-Frequency High-Voltage Device and Integrated Circuits Center, Institute of Microelectronics of Chinese Academy of Sciences, JONAS FRANSSON, Department of Physics and Astronomy, Uppsala University — The differential conductance of graphene is shown to exhibit a zero-bias anomaly at low temperatures, arising from a suppression of the quantum corrections due to weak localization and electron interactions. A simple rescaling of these data, free of any adjustable parameters, shows that this anomaly exhibits a universal, temperature independent form. According to this, the differential conductance is approximately constant at small voltages (V<kBT/e), while at larger voltages it increases logarithmically with the applied bias, reflecting a quenching of the quantum corrections. For theoretical insight into the origins of this behavior, we formulate a model for weak-localization in the presence of nonlinear transport. According to this, the voltage applied under nonequilibrium induces unavoidable dephasing, arising from a self-averaging of the diffusing electron waves responsible for transport. By establishing the manner in which the quantum corrections are suppressed in graphene, our study will be of broad relevance to the investigation of nonequilibrium transport in mesoscopic systems in general. This includes systems implemented from conventional metals and semiconductors, as well as those realized using other two-dimensional semiconductors and topological insulators.

8:24AM E14.00003: Uniform doping of graphene close to the Dirac point by polymer-assisted assembly of molecular dopants  YUNG PARK (Presenter), Physics and Astronomy, Seoul National University & University of Pennsylvania, HANS HE, KYUNG HO KIM, SERGEY KUBATKIN, SAMUEL LARA-AVILA, Microtechnology and Nanoscience, Chalmers University of Technology — Tuning the charge carrier density of two-dimensional (2D) materials by incorporating dopants into the crystal lattice is a challenging task. An attractive alternative is the surface transfer doping by adsorption of molecules on 2D crystals, which can lead to ordered molecular arrays. However, such systems, demonstrated in ultra-high vacuum conditions (UHV), are often unstable in ambient conditions. Here we show that air-stable doping of epitaxial graphene on SiC-achieved by spin-coating deposition of 2,3,5,6-tetrafluoro-tetracyano-quino-dimethane (F4TCNQ) incorporated in poly(methylmethacrylate)-proceeds via the spontaneous accumulation of dopants at the graphene-polymer interface and by the formation of a charge-transfer complex that yields low-disorder, charge-neutral, large-area graphene with carrier mobilities ~70,000cm²V⁻¹s⁻¹ at cryogenic temperatures. The assembly of dopants on 2D materials assisted by a polymer matrix, demonstrated by spin-coating wafer-scale substrates in ambient conditions, opens up a scalable technological route toward expanding the functionality of 2D materials.

In conventional semiconductors, the exciton bound state (arising from the attractive Coulomb interaction between electrons and holes) can be successfully analyzed by the effective mass approximation based on the lowest-order parabolic dispersion relation at band extrema. However, parabolic dispersion is by no means the only possible outcome endowed by a periodic lattice potential, especially in two dimensional electronic materials, where weak inter-subband matrix elements suppress otherwise strong band repulsion across a forbidden gap, resulting in nonparabolic ‘Mexican hat’ or ‘caldera’-shaped bands, in which “effective mass” is ill-defined. Focusing on electrostatically-biased bilayer graphene as an example where quartic (and higher) dispersion terms are necessary, we present a semi-analytic theory used to investigate the properties of ground and excited excitonic states. This includes determination of the exciton binding energy and wavefunctions, which are further used to analyze the relative oscillator strengths and magnetic moments (g-factors) that can be directly compared to recent experimental measurements.

9:24AM E14.00008: Breakdown of the law of reflection at a disordered graphene edge* ELIAS WALTER, Faculty of Physics, LMU Munich, TOMAS ÖRN ROSDAHL, ANTON AKHMEROV (Presenter), Kavli Institute of Nanoscience, Delft University of Technology, FABIAN HASSLER, Institute for Quantum Information, RWTH Aachen — The law of reflection states that smooth surfaces reflect waves specularly, thereby acting as a mirror. This law is insensitive to disorder as long as its length scale is smaller than the wavelength. Monolayer graphene exhibits a linear dispersion at low energies and consequently a diverging Fermi wavelength. We present proof that a charge-neutral disordered graphene boundary results in a diffusive electron reflection even when the electron wavelength is much longer than the disorder correlation length. Using numerical quantum transport simulations, we demonstrate that this phenomenon can be observed as a nonlocal conductance dip in a magnetic focusing experiment.

9:36AM E14.00009: Ultrafast Valley polarization in gapped graphene SEYYEDEH AZAR OLIAEIMOTLAGH (Presenter), VADYM APALKOV, MARK I STOCKMAN, Georgia State University — We study numerically the ultrafast valley polarization in gapped graphene that can be accessed and controlled by a single cycle of a circularly polarized intense pulse. The amplitude of the pulse is about 0.5 V/\AA and its duration is 5 fs. Depending on the polarization of the pulse, right or left handed, one valley, K or K', is significantly populated, resulting in significant residual valley polarization of gapped graphene. The unequal valley population in the reciprocal space is due to topological resonance, which is caused by the mutual cancellation of the topological and dynamic phases. The ultrafast valley polarization, generated in gapped graphene-like materials, can be used in ultrafast quantum memory devices.

9:48AM E14.00010: All-Electronic Thermal Transport With Nonlocal Noise Thermometry in Graphene JONAH WAISSMAN (Presenter), ARTEM V TALANOV, YOUNG JAE SHIN, DANIAL HAEI NAJAFABADI, Harvard University, MARINE ARINO, HUGO BARTOLOMEI, Physics, ENS Paris, PHILIP KIM, Harvard University — Ever since the measurements of Wiedemann and Franz in 1853, thermal transport has played a central role in condensed matter physics. Thermal conductance can help pinpoint neutral modes such as spin waves, non-Fermi liquid states such as hydrodynamic states and Luttinger liquids, and topological degrees of freedom such as Majorana modes. In this context, van der Waals materials now offer a rich landscape of interacting, symmetry-broken, and topological states of matter enhanced by their low dimensionality, yet thermal transport has remained a difficult probe to realize for few-atom thick materials and for many of the most delicate electronic ground states. Here, we demonstrate a new technique to achieve all-electronic thermal transport in a van der Waals material. We use graphene as a sensitive electronic heater and thermometer by implementing a new type of nonlocal noise thermometry. We show that the technique allows us to accurately extract the electronic thermal conductance of a bridge between two graphene thermometers. This new probe now allows us to study a wide array of symmetry-broken and topological states in van der Waals materials through their heat transport properties.

10:00AM E14.00011: Studying the effects of strain in graphene using a MEMS device and electronic transport measurements at low temperatures* PAUL ANDERSON (Presenter), Physics and Astronomy, California State University Long Beach, YIFAN HUANG, Mechanical and Material Engineering, University of Nebraska Lincoln, SARA QUBBAJ, Physics and Astronomy, California State University Long Beach, QIN ZHOU, Mechanical and Material Engineering, University of Nebraska Lincoln, CLAUDIA OJEDA-ARISTIZABAL, Physics and Astronomy, California State University Long Beach — Different theoretical studies have motivated experiments on strained graphene, predicting exotic behaviors such as superconductivity or the induction of gauge fields that act effectively as large magnetic fields. Up to now the study of strain in graphene has been limited to the use of substrates where wrinkles or bubbles create strain or to the use of flexible substrates that create strain when they are bent. Here we present preliminary electronic transport experiments at low temperatures on a suspended graphene where strain is applied through a sophisticated micro-electro-mechanical systems (MEMS). We observe features in the magnetoresistance that change as strain is imposed to the sample, possibly showing the effects of the superposition of a magnetic field and a time reversal symmetric pseudo-magnetic field.

10:12AM E14.00012: Conductivity and Mobility of Substitutionally Disordered Graphene under the Coherent Potential Approximation*  JACOB ROBBINS (Presenter), JORGE OSVALDO SOFO, Pennsylvania State University — We calculate the DC electrical conductivity and carrier mobility of graphene with randomly distributed impurities of boron, nitrogen, and/or carbon vacancies. Conductivity and mobility are found at the linear response level with the Kubo-Greenwood formula [1,2]. Disorder is treated in a mean field approximation, namely the Coherent Potential Approximation (CPA) [3]. Our results show a decrease in mobility for increasing disorder, which agrees with experiments on nitrogen doped graphene [4]. The CPA also captures localized states around the Dirac point whenever vacancies are included. Any amount of carbon vacancies also induce a significant decrease in conductivity, even in the presence of the softer scattering centers, boron and nitrogen. This reduction in conductivity agrees with experiments on graphene with vacancies induced by a helium ion beam [5].

10:24AM E14.00013: Ballistic Transport of Epitaxial Graphene Nanoribbons on SiC  YUE HU (Presenter), YIRAN HU, DOGUHAN DENIZ, School of Physics, Georgia Institute of Technology, VLADIMIR PRUDKOVSKYI, Institut Neel/CNRS-Univ. Grenoble Alpes, JEAN-PHILIPPE TURMAUD, School of Physics, Georgia Institute of Technology, JAMES GIGLIOTTI, School of Materials Science and Engineering, Georgia Institute of Technology, LEI MA, TICNN, Tianjin University, CLAIRE BERGER, Institut Neel/CNRS-Univ. Grenoble Alpes, WALT A. DE HEER, School of Physics, Georgia Institute of Technology — Exceptional ballistic transport was observed in sidewall epitaxial graphene nanoribbons on SiC (SWGNRs) at room temperature [1]. These objects are of fundamental interest as they provide a direct access to charge neutral graphene with excellent transport properties. Here, beyond sidewalls, we fabricate epitaxial graphene nanoribbons on different crystal faces on SiC, including Si-face and non-polar facets. We introduce amorphous carbon as contact pads and high temperature annealing to reduce the edge roughness of ribbons and the contamination from resist residue. Then we discuss transport measurement and magnetoresistance results of graphene nanoribbons on Si-face as well as on non-polar SiC facets, which might reveal the nature of the ballistic channels in SWGNRs.

10:36AM E14.00014: Electron-phonon Cerenkov instability in graphene revealed by global and local noise measurements*  BO DWYER (Presenter), Harvard University, JAVIER D SANCHEZ-YAMAGISHI, Physics, University of California Irvine, TROND I ANDERSEN, JOAQUIN RODRIGUEZ NIEVA, Harvard University, KARTIEK AGARWAL, Princeton University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, EUGENE DEMLER, PHILIP KIM, HONGKUN PARK, MIKHAIL LUKIN, Harvard University —

Understanding and controlling non-equilibrium electronic phenomena is an outstanding challenge in science and engineering. Graphene presents a particularly interesting system for studying such effects because its high mobility means electrons may be accelerated very far out of equilibrium. We find that when fully encapsulated graphene is driven with a sufficiently high DC current, the drift velocity of the electrons exceeds the phase velocity of sound. This results in population inversion of the electronic system and stimulated emission of phonons becomes the dominant scattering process. This phonon Cerenkov effect leads to a runaway growth of certain phonon modes in the direction of momentum flow. Using NV centers as local noise probes, we map the exponential spatial growth of the phonon population by measuring the resulting local current fluctuations. Additionally, we measure a significantly altered global noise spectrum and AC conductivity at GHz frequencies, both of which are well described by stimulated emission of acoustic phonons. Since the amplified phonons are primarily in the THz range, the observation of a phonon Cerenkov effect in graphene is a first step towards realizing an on-chip generator of THz sound and radiation.

Elastic response of the electron fluid in intrinsic graphene: The collisionless regime

JULIA LINK (Presenter), Simon Fraser University, DANIEL E. SHEEHY, Louisiana State University, BORIS N. NAROZHNY, JOERG SCHMALIAN, Karlsruhe Institute of Technology — The elastic response of an electron fluid at finite frequencies is defined by the electron viscosity $\eta(\omega)$. We determine $\eta(\omega)$ for graphene at the charge neutrality point in the collisionless regime, including the leading corrections due to the electron-electron Coulomb interaction. We find interaction corrections to $\eta(\omega)$ that are significantly larger if compared to the corresponding corrections to the optical conductivity. In addition, we find comparable contributions to the dynamic momentum flux due to single-particle and many-particle effects. We also demonstrate that $\eta(\omega)$ is directly related to the nonlocal energy-flow response of graphene at the Dirac point. The viscosity in the collisionless regime is determined with the help of the strain generators in the Kubo formalism. Here, the pseudospin of graphene describing its two sublattices plays an important role in obtaining a viscosity tensor that fulfills the symmetry properties of a rotationally symmetric system.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E15 DMP GMAG: 2D Materials (Semiconductors) -- Magnetism

BCEC 154 - Wenzhuo Wu, Purdue University

8:00AM E15.00001: Tunneling through Charge transfer heterostructure of CrI$_3$

TULA PAUDEL (Presenter), EVGENY YTSYMBAL, University of Nebraska - Lincoln — Two dimensional ferromagnetic insulator CrI$_3$ have attracted a lot of attention because of its interesting properties including tunneling magnetoresistance in a Van der Waals heterostructure. Using the first-principles methods, we calculate the spin-dependent transport through a CrI$_3$-based tunnel junction and find that the tunneling current is 100% spin polarized. In zero bias regime, switching between the ferromagnetic and antiferromagnetic configurations of CrI$_3$ leads to the tunneling magnetoresistance of 9800%. The transmission is mediated by the states located at the k-points away from the high symmetry points in the Brillouin zone and modulated by the distribution of the k-dependent decay states in the barrier. When biased, both the spin polarization and tunneling magnetoresistance are enhanced. This behavior persists even when the CrI$_3$ barrier is as thin as two monolayers. Our calculations open up the possibility achieving 100% spin polarized current using conventional metallic electrodes, thereby broadening design space beyond 2D Van der Walls heterostructures.

8:12AM E15.00002: Interplay between interlayer exchange and stacking in CrX$_3$ (X = Cl, Br, I)$^*$

CLAUDIA CARDOSO (Presenter), QuantaLab, International Iberian Nanotechnology Laboratory, Portugal, DAVID SORIANO, Institute for Molecules and Materials, Radboud University, the Netherlands, JOAQUIN FERNANDEZ-ROSSIER, QuantaLab, International Iberian Nanotechnology Laboratory, Portugal — The study of few-layer crystals with ferromagnetic (FM) order is a natural follow-up of the recent discovery of FM order in stand alone 2D crystals. And as a result, the study of the structural and magnetic interlayer interactions. Here we address the case of CrX$_3$ (X = Cl, Br, I). All of them display FM order within the layers but have different interlayer interactions. The interlayer exchange in bulk CrCl$_3$ is antiferromagnetic (AFM), whereas for CrBr$_3$ and CrI$_3$ is FM. In contrast, few-layers CrBr$_3$ and CrI$_3$ present an AFM interlayer coupling. [1] Moreover, the bulk systems undergo a crystallographic phase transitions with temperature and there is evidence of an strong interplay between the crystallographic and magnetic degrees of freedom, both for the bulk and the few layer systems. [2] In this study, we address the interplay between stacking and interlayer exchange coupling for CrX$_3$ 2D crystals using first-principles calculations and an effective interlayer coupling model. Our results shed light on the magnetic behavior of the CrX$_3$ bulk and 2D crystals.

$^*$We acknowledge FEDER project NORTE-01-0145-FEDER-000019 and the FCT grant UTAP-EXPL/NTec/0046/20177

8:24AM E15.00003: Probing interlayer magnetism and magnons in two-dimensional chromium trihalides

BOWEN YANG (Presenter), HYUN HO KIM, GEORGE NICHOLS, FRANCOIS SFIGAKIS, University of Waterloo, CHENGHE LI, SHANGJIE TIAN, Renmin University of China, DAVID CORY, GUOXING MIAO, University of Waterloo, HECHANG LEI, Renmin University of China, ADAM TSEN, University of Waterloo — We study CrX$_3$ (X = I, Br, Cl) in the atomically thin limit by incorporating them in vertical tunnel junctions with graphene electrodes. In this device geometry, we are able to characterize the interlayer magnetic coupling, tunnel magnetoresistance, magnetic anisotropy, as well as magnon excitations. I will discuss the results of these studies and show how the magnetic properties of 2D CrX$_3$ are modified when changing the halogen atom.

770 of 3305
Raman spectroscopy studies of spin waves in two-dimensional CrI$_3$*  
WENCAN JIN (Presenter), University of Michigan, HYUN HO KIM, University of Waterloo, ZHIPENG YE, Texas Tech University, SWEN LI, University of Michigan, POUYAN REZAIE, FABIAN S DIAZ, SAAD SIDDIQ, ERIC S WAUER, Texas Tech University, BOWEN YANG, University of Waterloo, CHENGHE LI, SHANGJIE TIAN, Renmin University of China, KAI SUN, University of Michigan, HECHANG LEI, Renmin University of China, ADAM W TSEN, University of Waterloo, RUI HE, Texas Tech University, LIUYAN ZHAO, University of Michigan — The long-range magnetic order in the two-dimensional (2D) limit at finite temperatures has recently been demonstrated in a honeycomb Ising ferromagnet CrI$_3$. It has triggered tremendous interest in 2D magnet-based applications. To achieve a complete understanding of the 2D magnetic phase, a direct measurement of the magnetic excitations, i.e., spin waves, or magnons, is pressingly in need. In this talk, we will present the experimental evidence of spin waves in the 2D honeycomb ferromagnet, CrI$_3$. Using polarized micro-Raman spectroscopy, we have identified two branches of zero-momentum spin waves in 2D CrI$_3$ with exceptionally high frequencies in the THz range, as compared to those of the conventional ferromagnets. By tracking the layer thickness dependence of both spin waves, we further show that both are surface magnons, and their lifetimes remain an order of magnitude longer than their temporal period down to the monolayer limit.

Magneto-optical Kerr effect in two-dimensional diluted magnetic transition metal dichalcogenide semiconductors*  GONÇALO CATARINA (Presenter), JOAQUIN FERNANDEZ-ROSSIER, QuantaLab.  

In this talk, I will present a theory to model the Kerr angle for two-dimensional transition metal dichalcogenide semiconductors, such as MoS2, doped with a small density of magnetic atoms. The model Hamiltonian describes the band carriers within the effective gapped Dirac theory, accounting for spin-orbit and spin-valley coupling [1]. The magnetic impurities are described within a mean-field virtual crystal approximation, leading to a band-dependent spin splitting of the spectrum [2]. We find that the transverse optical susceptibility is non-zero, leading to a finite Kerr angle, when the exchange-induced splitting in the valence and conduction bands are different. We consider the case when there are no free carriers in the bands, as well as the n-doped and p-doped regimes.

*We acknowledge financial support from FCT for the P2020-PTDC/FIS-NAN/4662/2014 project. J. F.-R. acknowledges financial support from FCT for the UTAP-EXP/NTec/0046/2017 project.

Magnetism and Distortions in Transition-Metal Dioxide Layers: On the Quest for Intrinsic Magnetic Semiconductor Layers*  FAUSTINO AGUILERA-GRANJA, Instituto de Fisica, Universidad Autonoma de San Luis Potosi, 78000 San Luis Potosi, Mexico, ANDRES AYUELA (Presenter), Donostia International Physics Center, Centro de Física de Materiales-MPC CSIC-UPV/EHU, 20018 San Sebastian, Spain — Future nanoscale technological applications in spintronics require research on two dimensional materials with combined semiconductor and magnetic properties. We investigate transition metal dioxides in the form of layers, and report on the structural and electronic properties of selected late transition metal d-elements. With half-filled d states, the MnO2 and TcO2 layers are magnetic semiconductors, and for side d-elements the CrO2 and FeO2 layers become half-metals. These magnetic materials in 2D must be synthesized in order to assess their usefulness in future electronic and spintronic devices.

*The Spanish Ministry of Economy and Competitiveness under Grant No. FIS2016-76617-P (MINECO/FEDER).

Diversified Magnetoelectric Coupling in 2D Multiferroic Materials  QING YANG (Presenter), MENGHAO WU, Huazhong University of Science and Technology — Multiferroic materials with coupled magnetism and ferroelectricity, even though scarcely exist in nature, are highly desirable for efficient “electric writing + magnetic reading”. Currently, the polarization and magnetization of traditional multiferroics with strong magnetoelectric coupling are all too weak for practical applications. Here we show first-principles evidences that strong magnetoelectric can be realized in a series of 2D multiferroics: in some intercalated bilayer systems, their “mobile” magnetism can be controlled by ferroelectric switching upon external electric field, exhibiting either “on” state with spin-selective and highly p-doped channels, or “off” state insulating for both spin and electron transport, which renders efficient electrical writing and magnetic reading; vertical polarization can be maintained against depolarizing field, rendering high-density data storage possible. In some 2D systems, the magnetization can be switched by 90 or even 180 degree upon ferroelectric switching.

10:00AM E15.00011: Negative Parabolic Magnetoresistance due to Electron-Electron Interactions in a Disordered 2D Electron Gas in InSe* KASUN PREMASIRI (Presenter), Case Western Reserve University, RAJESH KUMAR, RAMAN SANKAR, FANGCHENG CHOU, National Taiwan University, XUAN GAO, Case Western Reserve University — Magnetotransport measurements serve as a multifarious tool in understanding various phenomena involved in electron transport, among which the prevalence of the electron-electron interaction (EEI) represents a key aspect with its unique magnetoresistance (MR) signatures. Semiconductor-heterostructure-based, two-dimensional electron gases (2DEGs) have been extensively studied to extract information about the EEI. Two-dimensional (2D) materials may provide more insight into the EEI, possessing an array of materials with extreme versatility in electronic properties. We report negative parabolic MR due to the EEI in a 2DEG formed in InSe, which is a 2D monochalcogenide semiconductor. In this system, we study the EEI in the regime of $\omega_c\tau<1$, which is relatively unexplored. A logarithmic relationship between the EEI and the temperature is observed confirming the contribution from the EEI to the MR. We also compare the strength of the observed EEI with other conventional systems such as Si metal-oxide semiconductor field-effect transistors and GaAs quantum wells.

*X. G. thanks NSF (grant number: DMR-1607631) for funding the project.

10:12AM E15.00012: Ferromagnetism created from non-ferromagnetic vdW heterostructures CHENG GONG (Presenter), University of California, Berkeley, PEIYAO ZHANG, TENZIN NORDEN, Physics, University at Buffalo, State University of New York, QUANWEI LI, ZHEN GUO, University of California, Berkeley, APOORVA CHATURVEDI, School of Materials Science and Engineering, Nanyang Technological University, ARMAN NAJAFI, Physics, University at Buffalo, State University of New York, SHOUFENG LAN, XIAOZE LIU, YUAN WANG, University of California, Berkeley, HAO ZENG, Physics, University at Buffalo, State University of New York, HUA ZHANG, School of Materials Science and Engineering, Nanyang Technological University, ATHOS PETROU, Physics, University at Buffalo, State University of New York, XIANG ZHANG, University of California, Berkeley — Intrinsic long-range ferromagnetic order has recently been discovered in two-dimensional atomic crystals. However, the prospect of 2D magnets remains largely hindered by the scarcity of 2D ferromagnets with limited diversity in magnetic attributes. In this context, creative ways to bring forth ferromagnetism from non-ferromagnetic 2D materials are attractive and profitable for both fundamental physics and device applications. In this talk, I will show you the possibility of such creation based on our magneto-optical study of vdW heterostructures and discuss the underlying material physics. Our work paves the new path to harvest 2D ferromagnetism.

10:24AM E15.00013: Electrically tunable magnon bands in two-dimensional magnets* MOHAMMAD MUSHFIQUR RAHMAN (Presenter), AVINASH RUSTAGI, YONG CHEN, PRAMEY UPADHYAYA, Purdue University — Magnons, namely quanta of spin waves-coherent excitations of magnetically ordered medium-are considered as promising carriers of spin information for classical [Nat. Phys. 11, 453 (2015)] and quantum [npj Quantum Info. 3, 28 (2017)] information processing. For these applications, the ability to electrically reconfigure the bandstructure of magnons, can open novel opportunities to create dynamic magnon crystals and multifunctional high frequency, logic and quantum devices [Journal of Phys. D: Appl. Phys.50, 24 (2017)]. In this work, we propose a novel platform to realize electrically tunable magnon bands, namely recently discovered two-dimensional (2-D) magnets [Nature 546, 270(2017)]. For this purpose, we utilize the efficient electrical control of spin-spin interactions within bilayer Chromium Iodide [Nature Mat. 17, 406 (2018)] to numerically demonstrate electrically controlled sub-Terahertz magnons. This study opens the possibility of using van der Waal magnets and their heterostructures for high frequency magnon spintronics applications.

*We acknowledge NSF grant DMR-1838513.

10:36AM E15.00014: Raman phonon spectra from CrI3 atomic layers* RUI HE (Presenter), ZHIPENG YE, GAIHUA YE, ERIC S WAUER, FABIAN S DIAZ, DAVID TAUZIN, Texas Tech University, HYUN HO KIM, BOWEN YANG, ADAM TSEN, University of Waterloo, HYUN HO KIM, XIAOFENG QIAN, Texas A&M University, WENCAN JIN, LIUYAN ZHAO, University of Michigan — CrI3 has recently been demonstrated to be an Ising ferromagnet whose magnetization retains even in a single monolayer below Curie temperature. Here we report our recent Raman studies on bulk and monolayer/few-layer CrI3. Temperature-dependent Raman studies are performed to scrutinize structural phase transition and magnetic phase transition. We determine the symmetries of the phonon modes using polarized Raman spectroscopy and first-principles theoretical calculations. Our results show that Raman selection rule no longer holds in degraded CrI3 samples.

*Supported by NSF CAREER Grants No. DMR-1760668, DMR- 1753054, and DMR-1749774.
Giant excitonic and magneto-optical responses in two-dimensional ferromagnets* MENG WU
(Presenter), ZHENGLU LI, TING CAO, STEVEN G. LOUIE, University of California, Berkeley — The magneto-optical (MO) effects, such as the magneto-optical Kerr effect (MOKE) and the Faraday effect, have been intensively investigated in a variety of magnetic materials serving as a highly sensitive probe for electronic and magnetic properties. Recent experiments using MOKE have discovered a few two-dimensional (2D) magnets, and demonstrated their rich magnetic behaviors. In particular, a giant Kerr response has been measured in monolayer and few-layer CrI3. However, by far, the microscopic origin of such MO signals is still unknown, because the essential spin-orbit coupling and excitonic effects are beyond the capability of existing first-principles methods. With newly developed GW and GW-BSE methods, we show that the exceedingly large optical and MO responses in ferromagnetic monolayer CrI3 arise from the strongly bound exciton states consisting of spin-polarized electron-hole states. With a realistic experimental setup, we find that the substrate configuration and excitation frequency strongly shape the MO signals. Our first-principles results are in good agreement with recent experiments on CrI3.

*This work was supported by NSF (No. DMR-1508412 and No. EFMA-1542741), and by the U.S. DOE (No. DE-AC02-05CH11231). Computational resources were provided by XSEDE and NERSC.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E16 DMP: Transport in Nanostructures -- Nanoscale Transport I BCEC 155 - Han Htoon, Los Alamos National Laboratory - Tag(s): Focus

Nanostructured gold thermocouple for photodetection* MAHDIYEH ABBASI (Presenter), Electrical and Computer Engineering, Rice university, CHARLOTTE I EVANS, Physics and astronomy, Rice university, XIFAN WANG, Material science, Rice university, LONGJI CUI, DOUGLAS NATHELSON, Physics and astronomy, Rice university — The Seebeck coefficient of a metal depends on the energy-dependent electrical conductivity, which in turn depends on the energy-dependent electron mean free path and the material band structure. At the nanoscale, when the geometric size is comparable with mean free path of the electrons, single metal thermocouples can be fabricated by changing the material geometry across the thermocouple. By using plasmonically-resonant structures, different device geometries and sizes can be used for wavelength sensitive light detection. We will present preliminary experimental data and simulations of single metal gold nanostructures with different geometries that are plasmonically active with IR laser illumination. We will discuss how these devices can be used for photodetection and discuss future applications for these measurements.

*The authors acknowledge support from NSF-1704625.

Shot-Noise Measurements of Waveguides with Attractive Electron-Electron Interactions* MUQING YU (Presenter), YUN-YI PAI, LEENA AGGARWAL, University of Pittsburgh, HYUNGWOO LEE, JUNGWOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — Mesoscopic devices created at oxide interfaces, such as the LaAlO3/SrTiO3 heterostructure [1], exhibit a wide range of exotic behavior that is linked to a strong electron-electron interaction. Electron pairing without superconductivity [2] involves transport of charge-2e carriers and higher-order “Pascal” phases with charge \( n \) \( e \) \( (n>2) \), have been identified in quantum transport measurements. One way to gain further insight to these phases would be to verify the existence of quantized charge by measuring shot noise. Here we describe experimental efforts to reveal shot-noise characteristics in electron waveguide devices whose electronic phases can be tuned between paired and unpaired state via tuning of magnetic field and chemical potential. These shot noise measurements have the potential to confirm the charge of these exotic electron liquid phases and provide insight into their phase diagrams.

8:24AM E16.00003: Observation of 450 GHz surface acoustic waves in suspended polycrystalline films by use of time-resolved resonant soft X-ray scattering* PHOEBE TENGDIN, DMITRIY ZUSIN, JOSHUA L KNOBLOCH, Physics, University of Colorado, ANATOLY SHABALIN, STJEPAN HRKAC, NELSON HUA, Physics, University of California, San Diego, YAROSLAV KVASHNIN, Physics and Astronomy, Uppsala University, SHEENA PATEL, Physics, University of California, San Diego, TIANMIN LIU, Physics, Stanford University, JUSTIN SHAW, National Institute of Standards and Technology Boulder, HANS T. NEMBACH, JILA, University of Colorado, Boulder, DANIEL J HIGLEY, Physics, Stanford University, WILLIAM F SCHLOTTER, ALEX REID, SLAC, RAHUL NANDKISHORE, Physics, University of Colorado, OLLE ERIKSSON, Physics and Astronomy, Uppsala University, LOIC LE GUYADER, European XFEL, ERIC FULLERTON, Electrical and Computer Engineering, University of California, San Diego, OLEG SHPYRKO, Physics, University of California, San Diego, MARGARET MARY MURNANE, HENRY C KAPTEYN, JILA, University of Colorado, Boulder, HERMANN DÜRR, Physics and Astronomy, Uppsala University, THOMAS SILVA (Presenter), National Institute of Standards and Technology Boulder — We have used ultrafast optical pumping to generate nanoscale surface acoustic waves (SAWs) from 200 to 450 GHz, 10-50 nm wavelengths, in metallic films on SiN membranes. Our measurement demonstrates a novel soft X-ray elastic scattering mechanism that probes the coupling of the electronic and phononic degrees of freedom on a [Co90Fe10(0.6 nm)/Ni(0.2 nm)]x50 multilayer. The samples have an average grain size of 30 nm and a rms roughness of 1 nm. This nanostructured surface topography allows optical coupling to the in-plane SAW. In a transmission soft X-ray scattering geometry, with circular polarized X-rays tuned to the Ni L3 edge, we observe a prominent charge scatter ring with a radius of approximately 0.2 nm⁻¹. After optical pumping with fluences ranging from 24-27 mJ/cm², SAWs appeared as ripples on the charge scatter ring that oscillate at ps timescales. We use Brillouin light scattering (BLS) and modeling to identify the SAW as a dilation mode with an in-plane velocity of 5.6 km/s. Surprisingly, the SAW lifetime peaks sharply at q = 0.25 nm⁻¹ (300 GHz), with a value greater than 60 ps, suggestive of a minimum in the SAW correlation length in the case of 2-d localization.

*Support by DOE/BES X-Ray Scattering Program Awards No. DE-SC0002002, DE-SC0018237, and DE-FOA-0001664

8:36AM E16.00004: Phonon Localization in Heat Conduction MARIA N. LUCKYANOVA, JONATHAN MENDOZA, Massachusetts Institute of Technology, HONG LU, University of California, Santa Barbara, BAI SONG (Presenter), Department of Mechanical Engineering, Massachusetts Institute of Technology, SHENXIE HUANG, JIAWEI ZHOU, MINGDA LI, Massachusetts Institute of Technology, YONGQI DONG, HUA ZHOU, Argonne National Laboratory, JOSEPH A GARLOW, LIJUN WU, Brookhaven National Laboratory, BRIAN KIRBY, ALEXANDER GRUTTER, National Institute of Standards and Technology, ALEXANDER PURETZKY, Oak Ridge National Laboratory, YIMEI ZHU, Brookhaven National Laboratory, MILDRED DRESSELHAUS, Massachusetts Institute of Technology, ARTHUR C GOSSARD, University of California, Santa Barbara, GANG CHEN, Massachusetts Institute of Technology — The departure from diffusive phonon thermal transport has been extensively observed via a reduction in thermal conductivity in nanostructures. Such non-diffusive behavior has been largely explained with classical size effects, ignoring the wave nature of phonons. Here, we report localization behavior in phonon heat conduction due to multiple scattering and interference of broadband phonon waves, observed through measurements of the thermal conductivities of GaAs/AlAs superlattices with ErAs nanodots randomly distributed at the interfaces. Near room temperature, the measured thermal conductivities increased with increasing number of superlattice periods and eventually saturated, indicating a transition from ballistic to diffusive transport. At low temperatures, the thermal conductivities of the samples with ErAs dots first increased and then decreased with an increasing number of periods, signaling phonon wave localization. This Anderson localization behavior is also validated via atomistic Green’s function simulations. The observation of phonon localization in heat conduction is surprising due to the broadband nature of thermal transport. This discovery suggests a new path forward for engineering phonon thermal transport.
profiles for desired performance of integrated semiconductor architectures. The ML framework will facilitate the development of inverse design approach to engineer interface algorithms. Our model has shown remarkable ability to predict band structures and Onsager transport coefficients of large nanostructures. The algorithm is trained on inexpensive ~200 DFT calculations of SixGe1-x substitutional alloys, by algorithms to predict electronic structure and transport of non-ideally fabricated multilayered thin film Si/Ge systems with large number of configurational degrees of freedom. In this study, we employ machine learning (ML) dimension approaches nanoscale. Ab initio methods become expensive and infeasible to predict electronic properties of broad range of applications. The contact interfaces between these components dictate performance, especially as device components are being aggressively inserted into semiconductor architectures to perform operations at high rates, for a mean free path in a network of cavities.

This departure from Casimir’s linear scaling law can be understood in terms of the geometry dependence of the phonon Casimir radiation and wavelength-dependent Rayleigh scattering. We exploit this definition to understand heat transport in newly synthesized silicon metalattices, which consist of a finely controlled, three-dimensional arrangement of nanometer-sized cavities in crystalline silicon. Through computational simulation and experimental validation, we show that the heat conductivity of metalattices exhibits a minimum as a function of the cavity diameter at constant porosity. We establish that the constants of proportionality linearly depend on SL and to determine the parameters to optimize electronic transport and therefore, thermoelectric performance of short period SL.

*This work is funded by DARPA (DSO).

9:00AM E16.00006: Controlling hot-electron thermalization in nanoscale materials*  
SRIDHAR SADASIVAM, MARIA CHAN, PIERRE DARANCET (Presenter), Argonne National Laboratory — Non-equilibrium energy transfer between hot electrons and phonons plays an important role in the design and operation of photovoltaic and nanoelectronic devices. In this talk, I will show how symmetries in low dimensional materials can impact electron-phonon coupling and the timescale of “hot” electron thermalization. Using a recently-developed first-principles Boltzmann transport equation framework accounting for electron-phonon and phonon-phonon interactions [1], I will show this effect can be used to control hot electron dynamics and phonon bottlenecks for experimentally-synthesized low-dimensional devices. In particular, I will show how such non-equilibrium dynamics can be controlled by external gate potentials.

*Use of the Center for Nanoscale Materials, an Office of Science user facility, was supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

9:12AM E16.00007: Machine Learning Electronic Transport Properties of Multilayered Semiconductor Nanostructures*  
SANGHAMITRA NEOGI (Presenter), ARTEM PIMACHEV, University of Colorado, Boulder — Computing components are being aggressively inserted into semiconductor architectures to perform operations at high rates, for a broad range of applications. The contact interfaces between these components dictate performance, especially as device dimension approaches nanoscale. Ab initio methods become expensive and infeasible to predict electronic properties of systems with large number of configurational degrees of freedom. In this study, we employ machine learning (ML) algorithms to predict electronic structure and transport of non-ideally fabricated multilayered thin film Si/Ge nanostructures. The algorithm is trained on inexpensive ~200 DFT calculations of SixGe1-x substitutional alloys, by exploiting the relationship between local atomic environments and electronic properties. The predictor variables are obtained with Voronoi tessellation approach and the response variables are calculated with decision tree regression algorithm. Our model has shown remarkable ability to predict band structures and Onsager transport coefficients of large non-ideal superlattices. The ML framework will facilitate the development of inverse design approach to engineer interface profiles for desired performance of integrated semiconductor architectures.

*The project is funded by the DARPA (DSO).

9:24AM E16.00008: Ballistic length scale of heat transport in the subwavelength limit  
WEINAN CHEN (Presenter), DISHA TALREJA, Materials Science and Engineering Department, Pennsylvania State University, HIU YAN CHENG, Department of Chemistry, Pennsylvania State University, GERALD D MAHAN, VINCENT HENRY CRESPI, Department of Physics, Pennsylvania State University, JOHN BADDING, Department of Chemistry, Pennsylvania State University, VENKATRAMAN GOPALAN, ISMAILA DABO, Materials Science and Engineering Department, Pennsylvania State University — We present a comprehensive study of phonon ballistic length scale using a Casimir–Rayleigh model of heat transport. This model incorporates temperature-dependent Casimir radiation and wavelength-dependent Rayleigh scattering. We exploit this definition to understand heat transport in newly synthesized silicon metalattices, which consist of a finely controlled, three-dimensional arrangement of nanometer-sized cavities in crystalline silicon. Through computational simulation and experimental validation, we show that the heat conductivity of metalattices exhibits a minimum as a function of the cavity diameter at constant porosity. This departure from Casimir’s linear scaling law can be understood in terms of the geometry dependence of the phonon mean free path in a network of cavities.
In contrast to established work that use the diffuse surface scattering of phonons as the physical mechanism to reduce the thermal conductivities, in this talk we show that the largest reduction of thin film heat conduction is achieved via specular surface scattering. Our results create new opportunities for heat conduction manipulation since smooth surfaces – in contrast to rough surfaces – can be more effective on suppressing thin film phonon heat conduction.

9:48AM E16.00010: Coupling of Boron Dipyrromethene Dye Excitons to Plasmonic Surface Lattice Resonances in Aluminum Nanodisk Arrays

ROBERT COLLISON (Presenter), City University of New York, JACOB TREVINO, Chemeleon Inc., VINOD M MENON, STEPHEN O'BRIEN, City University of New York — When plasmonic metal nanoparticles are arranged in extended, one- or two-dimensional periodic arrays, the localized surface plasmon resonances (LSPRs) of the individual particles will couple radiatively to form a collective, propagating photonic-plasmonic mode known as a surface lattice resonance (SLR). Currently, SLRs and their potential applications in photonic devices, such as solar cells and light-emitting diodes, are growing topics of interest in the literature. In particular, the interaction of propagating, delocalized SLRs with the highly localized excitons of organic dye molecules is being investigated, and exotic phenomena such as the Bose-Einstein condensation of polaritons composed of dye excitons coupled to SLRs was recently reported(1). We report on the fabrication of SLR-supporting arrays of aluminum nanodisks on glass, and the coupling of these SLRs to dye excitons via coating of the arrays with dye-doped poly(methyl methacrylate). In particular, the interaction of the SLRs with boron dipyrromethene (BODIPY) dyes is examined, and the resulting effects, including angle-dependent fluorescent emission and enhancement of energy transfer between two different BODIPY dyes, are reported.

*NSF, CREST IDEALS

10:00AM E16.00011: Terahertz Spectroscopy of Metallic Single-Wall Carbon Nanotubes

HENRY WLADKOWSKI (Presenter), Physics and Astronomy, University of Wyoming, SHASHANK RAM NANDYALA, Electrical and Computer Engineering, University of Wyoming, JEFFREY FAGAN, NIST - Natl Inst of Stds & Tech, JON M PIKAL, Electrical and Computer Engineering, University of Wyoming, WILLIAM RICE, Physics and Astronomy, University of Wyoming — Optically generated, Coulombically bound electron-hole pairs, known as excitons, are rarely observed in metals due to strong electrostatic screening. However, in quantum-confined systems, such as one-dimensional (1D) single-wall carbon nanotubes (SWCNTs), screening effects are suppressed giving rise to exciton-dominated optical spectra in both semiconducting and metallic SWCNTs. Because of the difficulty of creating highly isolated 1D metallic environments, these metallic excitons are poorly studied. Here, we use terahertz absorption of single-chirality enriched SWCNTs at low temperatures to examine collective phenomena in 1D. We prepared, single-chirality (5,5) metallic and enriched (6,5) semiconducting SWCNTs in high-purity using aqueous two-phase extraction and characterized these fractions by optical methods. Enriched SWCNTs were immersed in a broadly transparent polymer matrix which preserved SWCNT individualization for cryogenic measurement. Using terahertz time-domain spectroscopy, we observed low-frequency plasmon absorption in metallic SWCNTs across a broad temperature range. This work provides the foundation for in-depth study of excitonic and plasmonic phenomena in single-chirality SWCNTs.

*HVW and WDR acknowledge support from the UW School of Energy Resources.

10:12AM E16.00012: Fabrication and characterization of nanoscale devices using Local anodic oxidation technique

HYEWON DU (Presenter), TAEKWANG KIM, SOMYEONG SHIN, SEONYEONG KIM, MINHO SONG, HANSUNG KIM, DAIN KANG, SUNAE SEO, Physics, Sejong Univ. — Graphene is one of the most promising materials as a flexible transparent electrode because of its high transparency and ultrahigh carrier mobility. Up to now, there are a number of methods to pattern graphene for application as electrodes. A commonly used patterning method is a combination of lithography and plasma etching, which causes undesired graphene defects during the etching process. Attempts to develop a patterning method that can simplify the fabrication process with minimal degradation is still a challenge. Here, we applied an electrochemical process based on Atomic force microscopy (AFM), Local anodic oxidation (LAO) technique, to define graphene electrodes with minimized graphene defect by eliminating the etching process. In addition, it is easy to manufacture a short channel device because the AFM tip has a nanometer order radius. This technique paves the way for the fabrication of organic-based devices where it is difficult to fabricate with short channels.
This talk will present recent highlights from our research on two-dimensional (2D) materials. Results span from fundamental measurements and simulations, to applications taking advantage of unusual 2D material properties. We measured record velocity saturation in graphene [1], and the thermal properties of graphene nanoribbons [2]. We have also grown monolayer 2D semiconductors by CVD over large areas, including MoS$_2$ [3], WSe$_2$, MoSe$_2$ [4], and multilayer MoTe$_2$ and WTe$_2$ [5]. ZrSe$_2$ and HfSe$_2$ have native high-K dielectrics ZrO$_2$ and HfO$_2$, which are of key technological relevance [6]. Improving electrical contacts [7], we demonstrated 10 nm transistors using monolayer MoS$_2$, with the highest current reported to date (>400 µA/µm), near ballistic limits [8]. Current density in such 2D devices is ultimately limited by self-heating and phonon scattering [9], in part due to the weak van der Waals bonds between 2D materials and their environment, which lead to a large thermal resistance of this interface [10]. On the other hand, we exploited this weak interface to improve energy efficiency in phase-change memory [11], and we tuned it by Li intercalation, demonstrating MoS$_2$-based thermal transistors [12]. These studies reveal fundamental limits and some applications of 2D materials, taking advantage of their unique properties.

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E17 DCOMP: Matter in Extreme Environments: Novel Approaches to Pressure and Synthesis

8:00AM E17.0001: Matter in Extreme Environments: Materials synthesis and crystallography at extreme pressure - revealing some remarkable materials properties [Invited] NATALIA DUBROVINSKAIA (Presenter), LEONID DUBROVINSKY, University of Bayreuth — During last decades, the impact of high-pressure studies on fundamental physics and chemistry, and especially on Earth and planetary sciences, has been enormous. Modern science and technology rely on the vital knowledge of matter which is provided by crystallographic investigations. The most reliable information about crystal structures of solids and their response to alterations of pressure and temperature is obtained from single-crystal diffraction experiments. Advances in diamond anvil cell (DAC) techniques, designs of double-stage DACs, and in modern X-ray instrumentation and synchrotron facilities have enabled structural research at multimegabar pressures.

We have developed a methodology for performing single-crystal X-ray diffraction experiments in double-side laser-heated DACs and demonstrated that it allows the crystal structure solution and refinement, as well as accurate determination of thermal equations of state above 200 GPa at temperatures of thousands of degrees. Application of this methodology resulted in discoveries of novel compounds with unusual chemical compositions and crystal structures, uncommon crystal chemistry and physical properties. It has been successful in investigations of various classes of solids - elemental materials, oxides, carbides, borides, carbonates, nitrides, and silicates. In this contribution we will report the results of our single-crystal diffraction studies of phase relations in the Fe-O system, transition metals carbonates, silicates, and nitrides at simultaneous high pressures and high temperatures. Perspectives of materials synthesis and crystallography at extreme conditions will be outlined.
8:36AM E17.00002: Investigation of Pressure Induced Formation of Diamondene* LUIZ GUSTAVO PIMENTA MARTINS (Presenter), Massachusetts Institute of Technology, DIEGO LOPEZ, Physics, Federal University of Minas Gerais, MATEUS MATOS, Physics, Federal University of Ouro Preto, LEORA EVE DRESSELHAUS-COPPER, Lawrence Livermore National Laboratory, ROBERTO MOREIRA, MARIO SERGIO MAZZONI, Physics, Federal University of Minas Gerais, JING KONG, Massachusetts Institute of Technology, LUIZ GUSTAVO CANCADO, Physics, Federal University of Minas Gerais — Pressure is a convenient thermodynamic parameter for obtaining new materials that cannot be synthesized under ambient conditions. For instance, theoretical calculations show that when two layers of graphene are compressed at high-pressures in the presence of specific chemical groups, they can be turned into a 2D diamond called diamondene: a ferromagnetic semiconductor with spin-polarized bands. Efforts to experimentally demonstrate this structure are in the initial stages, yet we have already obtained robust results [1]. In this initial work, we obtained indirect evidence of diamondene formation at room temperature by compressing two layers of graphene using water as a pressure transmitting medium (PTM) in a diamond anvil cell (DAC). The phase transition was identified by measuring the G band dispersion with laser energy as a function of pressure. We will report our progress in investigating this phase transition with new experimental evidences.

8:48AM E17.00003: X-Ray Diffraction Crystallization Studies on a Zr-Based Bulk Metallic Glass under High-Pressure and High-Temperature* KATHRYN HAM (Presenter), YOGESH KUMAR VOHRA, University of Alabama at Birmingham, ROSTISLAV HRUBIAK, CURTIS KENNY-BENSON, HPCAT, The Advanced Photon Source, Argonne National Laboratory, ANDREW WERESZCZAK, Materials Science and Technology Division, Oak Ridge National Laboratory — X-ray diffraction crystallization studies were conducted on bulk metallic glass, Zr_{58.5}Cu_{15.6}Ni_{12.8}Al_{10.3}Nb_{2.8}. Each sample was compressed using a Paris-Edinburgh Press at Beamline 16-BM-B, HPCAT, of the Advanced Photon Source, and heated to 800°C. MgO was used as a pressure standard for this experiment, and two constant heating rates, 2.9°C/min and 6.0°C/min were investigated. A heating rate dependence was seen in the crystallization temperature, with a faster heating rate corresponding to a higher crystallization temperature for the full pressure range tested.

9:00AM E17.00004: Graphene as a Diffusion Barrier in High-Temperature Electronics* LAURA BRANDT (Presenter), Physics and Electrical Engineering & Computer Science, University of California, Berkeley, ANANTH SARAN YALAMARTH, Mechanical Engineering, Stanford University, PETER F. SATTERTHWAITE, SAM VAZIRI, SAVANNAH BENBROOK, ERIC POP, Electrical Engineering, Stanford University, DEBBIE G. SENESKY, Aeronautics & Astronautics Engineering, Stanford University — The development of high-temperature semiconductor technology for use in applications such as power plants, nuclear reactors, and on hot planets like Venus (~460°C) is severely limited by the failure of essential metal contacts in otherwise thermally robust devices. This failure, which manifests as bubbling on the metal contact, is thought to be due to inter-diffusion of metal and semiconductor layers. To test this hypothesis, we constructed a monolayer graphene barrier to see if bubble formation would be reduced. Auger electron spectroscopy was used to characterize the inter-diffusion of material layers in Pd/AlGaN/GaN and Pd/Graphene/AlGaN/GaN Schottky diodes subjected to thermal treatments over a range of temperatures from 100 to 450°C. Graphene was shown to stop bubble formation in high-temperature metal contacts up to 425°C, supporting the inter-diffusion hypothesis and demonstrating promise for use on, for example, the planet Mercury (where temperatures range from approximately -180 to 430°C).

*This work was supported by the National Science Foundation (NSF) Engineering Research Center for Power Optimization of Electro-Thermal Systems with cooperative agreements ECC-1449548, and made use of the Stanford Nano Shared Facilities, NSF grant ECCS-1542152.
MEZOUAR, ESRF — The upper pressure achievable in the conventional Diamond Anvil Cell (DAC) had been limited to approximately 400 GPa since the early 2000s. We show that by sculpting the diamond anvil tip into a toroidal shape with a ratio of 1:3, the maximum pressure can be extended toward the terapascal pressure range. Measurements similar to standard DACs are possible in terms of precision, reproducibility, sample dimensions and type of materials from gas to solids and with any atomic number. Our toroidal-DAC design will be compared to other innovative schemes recently proposed to extend the pressure limit of the DAC, such as the double-stage DAC.

**9:17AM E17.00005: In Situ Solid State Laser Refrigeration at GPa Pressures**

**ABBBIE GANAS (Presenter), ANUPUM PANT, XIAOJING XIA, ELENA DOBRETSOVA, PETER PAUZAUSKIE, University of Washington — Solid state laser refrigeration can cool a host lattice through the emission of anti-Stokes upconverted photons from rare-earth dopant ions. Recently, laser refrigeration has also been demonstrated in condensed phases, including liquid water using single-beam laser tweezers. Laser refrigeration within a diamond anvil cell would allow researchers to explore in situ temperature-dependent properties of materials without external hardware. To date, laser refrigeration at extreme pressures has not yet been demonstrated. Here, we demonstrate the cooling of 10^9 Yb^{3+}:LiYF_4 (Yb:YLF, I_{41}/a space group) micro-crystals at elevated pressures in a diamond anvil cell. In addition, we investigate the impact of a scheelite to fergusonite phase transition on laser refrigeration at pressures >10.5 GPa. Varying the irradiance of a 1020nm continuous wave laser shows that Yb:YLF can be effectively cooled with a linear dependence on laser irradiances. Cooling temperatures are quantified using a ratiometric thermometry approach involving a Boltzmann fit to f-f transitions from the Yb^{3+} ions that occur between the Stark levels within the 2F_{5/2} and 2F_{7/2} manifolds.

**9:24AM E17.00006: Magnetometry and Stress Tomography in Diamond Anvil Cells using Nitrogen Vacancy Centers**

**PRABUDHYA BHATTACHARYYA (Presenter), SATCHE HSIEH, THOMAS MITTIGA, BRYCE H KOBRIN, FRANCISCO MACHADO, CHONG ZU, Physics, University of California, Berkeley, THOMAS SMART, Earth and Planetary Science, University of California, Berkeley, TIM HOEHN, NICHOLAS Z RUI, Physics, University of California, Berkeley, MEHDI KAMRANI, Aerospace Engineering, Iowa State University, SOONWON CHOI, Physics, University of California, Berkeley, VIKTOR V. STRUZHKIN, Geophysical Laboratory, Carnegie Institute of Washington, VALERY LEVITAS, Aerospace Engineering, Iowa State University, RAYMOND JEANLOZ, Earth and Planetary Science, University of California, Berkeley, NORMAN YAO, Physics, University of California, Berkeley — The Nitrogen Vacancy (NV) center in diamond has emerged as a promising candidate for the nanoscale sensing of temperature, strain, electric and magnetic fields. The integration of NV-based sensing into diamond anvil cells (DAC), a workhorse of high pressure science, offers a means not only for making spatially resolved measurements of relevant sample properties but also for monitoring the stress distribution in the diamond anvil itself. Compared to conventional high pressure probes, key advantages of NV sensing include diffraction limited spatial resolution (~1 um) and versatility, thus enabling exploration of novel phases of matter and the transitions between them, with pressure as a tuning parameter. Additionally, imaging the stress distribution inside DACs can provide insight into the mechanical failure of anvils and inform improvements in anvil design. We describe two main results: 1) we generate a layer of NVs near the tip of the diamond anvil and use DC magnetometry to study pressure-driven magnetic phase transitions and 2) using a carefully applied bias magnetic field we map the tensorial stress distribution within the diamond anvil itself.

**9:36AM E17.00007: Sterically Controlled Solid-State Mechanochemistry Under Hydrostatic Pressure**

**HAO YAN (Presenter), Stanford University, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago, WENDY MAO, Stanford University, NICHOLAS A MELOSH, Materials Science and Engineering, Stanford University, ZHIHUN SHEN, Stanford University — Mechanical stress can modify the energy landscape of chemical reactions and enable new reaction pathways. Mechanochemical mechanisms under tensile stress have been extensively studied in one-dimensional polymers. However, bond activation has not been possible with hydrostatic pressure in three-dimensional solids. Here we show that mechanochemistry through isotropic compression is possible by molecularly engineering structures that translate macroscopic isotropic stress into molecular-level anisotropic strain. We engineer molecules with mechanically heterogeneous components consisting of a compressible mechanophore and incompressible ligands. In these ‘molecular anvils’, isotropic stress leads to anisotropic deformation of the compressible mechanophore and activating bonds. We combine experiments and computations to demonstrate hydrostatic-pressure-driven redox reactions in crystalline metal-organic chalcogenides, where bending of bond angles or shearing of adjacent chains activates the metal-chalcogen bonds. These results reveal an unexplored mechanism and enable new possibilities for high-specificity mechanosynthesis.

**9:48AM E17.00008: The toroidal diamond anvil cell for detailed measurements under extreme static pressures.**

**PAUL LOUBEREY (Presenter), AGNES DEWAELLE, FLORENT OCCELLI, OLIVIER MARIE, CEA de Bruyeres-le-Chatel, MOHAMED MEZOUAR, ESRF — The upper pressure achievable in the conventional Diamond Anvil Cell (DAC) had been limited to approximately 400 GPa since the early 2000s. We show that by sculpting the diamond anvil tip into a toroidal shape with a Focussed Ion Beam, the maximum pressure can be extended toward the terapascal pressure range. Measurements similar to standard DACs are possible in terms of precision, reproducibility, sample dimensions and type of materials from gas to solids and with any atomic number. Our toroidal-DAC design will be compared to other innovative schemes recently proposed to extend the pressure limit of the DAC, such as the double-stage DAC.
10:00AM E17.00009: Toroidal diamond anvils for static compression experiments beyond 5 megabar* ZSOLT JENEI (Presenter), EARL F O'BANNON, SAMUEL T WEIR, HYUNCHAE CYNN, MAGNUS J LIPP, WILLIAM J EVANS, NICK E TESLICH, Lawrence Livermore Natl Lab, YUE MENG, JESSE SMITH, HPCAT, Advanced Photon Source, ANL — The diamond anvil cell has been around for over 50 years and has been the primary tool for routinely studying materials up to pressures of ~3 Mbar. Experiments over 4 Mbar with in situ pressure determination have been reported, however these reports are scarce. This indicates that these experiments are challenging, and that the success rate of these experiments is quite low. However, critical for developing accurate fundamental physics and chemistry models, with possible applications in modeling interiors of large planets. In this presentation I will show that focused ion beam crafted toroidal single-crystal diamond anvils with ~9.0 μm culets are capable of producing pressures over 5.0 Mbar. The toroidal surface prevents gasket outflow and provides a means to stabilize the central culet. We have reached a maximum pressure of ~6 Mbar using Re as in-situ pressure marker, a pressure regime typically accessed only by double-stage diamond anvils and dynamic compression platforms.

10:12AM E17.00010: Single Crystal X-ray Diffraction in Laser Heated DACs LEONID DUBROVINSKY (Presenter), Bayreuth University — Until recently, all DAC-laser-heating systems were stationary and could not be used for single-crystal structural studies aimed not only at determining lattice parameters, but also at structural refinements, which require measuring X-ray diffraction intensities and at least partial rotation of the DAC during experiments with monochromatic radiation. The beam of a stationary laser enters the cell at a fixed angle, so that the rotation leads to departure of the crystal from the focus position and scattering the powerful laser light in arbitrary directions by the diamond anvils that might be dangerous.

In order to overcome this problem we have developed a portable laser heating system and diamond anvils with round tables (DARTs) and implemented them in our experiments at various diffraction beamlines (ID15 and ID27 at ESRF, and P02 at PETRA III). The performance and potential of this approach have been demonstrated in simultaneous high-pressure and high-temperature powder and single-crystal diffraction studies of chemical and phase relations in transition metals oxides, carbides, hydrides, carbonates, and silicate perovskites.

10:24AM E17.00011: Carbon-based clathrates* TIMOTHY STROBEL (Presenter), Carnegie Institution for Science — Clathrate structures are found throughout nature in tetrahedral systems including water, silicates, silicon, germanium, tin and even colloids. Given similarities in bonding, it is natural to presume the existence of clathrate frameworks based on carbon, but attempts to prepare these materials have been unsuccessful thus far. If synthesized, these materials are expected to exhibit diamond-like mechanical properties due to the nature of covalent bonding, as well as strong electron-phonon coupling that could lead to high superconducting transition temperatures. We develop a stabilization principle based on the substitution of boron within the polyhedral carbon cages. Using this approach, we predict and synthesize the first carbon-based clathrate comprised of truncated octahedral C12B12 cages that trap Sr atoms in the "type-VII" structure. The mechanical properties, electronic structure and superconducting properties of this material will be discussed, as well as the potential for different structures and compositions within this new family of carbon-based materials.

Session E18 DCOMP DCMP DAMOP: Machine Learning Quantum States I BCEC 156B - Yizhuang You, Harvard University - Tag(s): Focus

8:00AM E18.00001: Learning quantum states with generative models [Invited] JUAN CARRASQUILLA (Presenter), Vector Institute — The technological success of machine learning techniques has motivated a research area in the condensed matter physics and quantum information communities, where new tools and conceptual connections between machine learning and many-body physics are rapidly developing. In this talk, I will discuss the use of generative models for learning quantum states. In particular, I will discuss a strategy for learning mixed states through a combination of informationally complete positive-operator valued measures and generative models. In this setting, generative models enable accurate learning of prototypical quantum states of large size directly from measurements mimicking experimental data.
8:36AM E18.00002: Machine Learning Holography in Neural Network Renormalization Group  
HONGYE HU (Presenter), University of California, San Diego, SHUO-HUI LI, LEI WANG, Institute of Physics, Chinese Academy of Sciences, YIZHUANG YOU, University of California, San Diego — Previously, people have shown the close relations between renormalization group (RG) with both deep learning and holographic duality, and how holographic geometry can emerge from deep learning the entanglement feature of a quantum many-body state. Inspired by those, we propose any boundary conformal field theory can be mapped into its holographic bulk to an operator level. In our framework, renormalization group is constructed as a hierarchical unsupervised generative model. Coarse graining direction can be viewed as an emergent direction, and it pushes boundary field theory configurations to bulk field configurations. The inverse coarse graining direction generates boundary field configurations from bulk noises. The goal is to construct optimal RG that makes bulk variables as uncorrelated as possible. The leftover of correlations between bulk variables can be used to define measure of distance in the bulk. We studied two dimensional interacting bosonic system as a boundary field theory. RG network is trained to find the effective bulk field theory and we observed the emergence of hyperbolic geometry (AdS3 spatial geometry) as we tuned system towards critical point.

8:48AM E18.00003: Study of phi-4 theories with deep learning methods*  
ZHONG YUAN LAI (Presenter), XIAOPENG LI, Department of Physics, Fudan University — Field theories find wide applications from characterization of scattering processes in particle physics, to analysis of statistical models, to description of critical phenomena in condensed matter. One key problem in using field theories is to perform non-perturbative calculations, which is crucial in various places, but has remained an open question. In this talk I will present our recent work combining field theoretical and deep learning methods to systematically account for non-perturbative aspects. In calculating Green's functions, nonperturbative Feynmann diagrams are automatically taken into account in our approach. I will present applications of this new approach to phi-4 field theories in one and two dimensions. Our approach potentially offers a generic solver for nonperturbative field theory calculations, of relevance to a broad context.

9:00AM E18.00004: Analytic continuation by combining sparse modeling with the Pade approximation  
YUICHI MOTOYAMA (Presenter), KAZUYOSHI YOSHIMI, ISSP, University of Tokyo, JUNYA OTSUKI, Tohoku University, HIROSHI SHINAOKA, Saitama University — Numerical methods based on the imaginary-time path-integral such as the path-integral Monte Carlo method are powerful tools to investigate a quantum many-body system both at absolute zero and finite temperatures. For example, these can calculate the imaginary-time Green's function directly, and other important quantities such as spectrum function can be transformed from this by the analytic continuation (AC) or by solving the Lehmann representation as an integral equation. In practice, however, this transformation is unstable against noise of the imaginary-time Green's function.

Several methods have been developed to solve this problem so far. The noise reduction by the sparse modeling (SpM) is one of them. In this method, we transform basis by the singular matrices of the integral kernel and truncate noisy components in the new basis by the sparse modeling. However, this truncation introduces an unphysical oscillation to the obtained spectrum as a systematic error.

In this study, we have improved SpM method by combining it with AC by the Pade approximation. AC by the Pade approximation gives a stable and smooth spectrum in low frequency region, which can be used to make the SpM spectrum smooth and high accuracy.

9:12AM E18.00005: A machine learning approach to excited states of quantum many-body systems*  
DOUGLAS HENDRY (Presenter), ADRIAN FEIGUIN, Northeastern University — We present a variational Monte Carlo method for determining dynamical properties and the spectral function of quantum many-body systems. Restricted Boltzmann machines (RBMs) are used to encode the Green's function of the system. First, the ground state wave function is calculated using a standard variational approach. The dynamical correlation function is then obtained by solving two linear systems of equations. We present a variational Monte Carlo approach to do so. This process has to be repeated for each value of frequency and momentum, but it can be easily parallelized. We illustrate it with applications to the Heisenberg model in one and two dimensions. Results show remarkable agreement with exact calculations on small systems and demonstrate that RBMs can also faithfully represent excited states.

*National Science Foundation
9:24AM E18.00006: Machine Learning Spatial Geometry from Entanglement Features YIZHUANG YOU (Presenter), UCSD — Motivated by the close relations of the renormalization group with both the holography duality and the deep learning, we propose that the holographic geometry can emerge from deep learning the entanglement feature of a quantum many-body state. We develop a concrete algorithm, call the entanglement feature learning (EFL), based on the random tensor network (RTN) model for the tensor network holography. We show that each RTN can be mapped to a Boltzmann machine, trained by the entanglement entropies over all subregions of a given quantum many-body state. The goal is to construct the optimal RTN that best reproduce the entanglement feature. The RTN geometry can then be interpreted as the emergent holographic geometry. We demonstrate the EFL algorithm on 1D free fermion system and observe the emergence of the hyperbolic geometry (AdS3 spatial geometry) as we tune the fermion system towards the gapless critical point (CFT2 point).

9:36AM E18.00007: Machine learning many-body localization: Search for the elusive nonergodic metal XIAO LI (Presenter), YI-TING HSU, DONG-LING DENG, University of Maryland — The many-body localization transition in isolated quantum systems with a single-particle mobility edge is an intriguing subject that has not yet been fully understood. In particular, whether a nonergodic metallic phase associated with a many-body mobility edge exists or not is under active debate. In this Letter, we construct a neural network classifier to investigate the existence of the nonergodic metallic phase in a prototype model using many-body entanglement spectra as the sole diagnostic. We find that such a classifier is able to identify with high confidence the nonergodic metallic phase existing between the many-body localized and the thermal phase. Our neural network based approach shows how supervised machine learning can be applied not only in locating phase boundaries, but also in providing a way to definitively examine the existence of a novel phase whose existence is unclear.

9:48AM E18.00008: Machine learning of condensed-matter phases with physical interpretability MING HAN (Presenter), ZONGHUI Wei, ERIK LUIJTEN, Northwestern University — Nature displays a vast variety of phase transitions. Detecting and quantifying these often requires creative design of order parameters, which are strongly system dependent. Thanks to recent advances in machine learning (ML), it is now possible to identify phase behavior by directly analyzing atomistic configurations via modern pattern-recognition techniques. Whereas these ML approaches are universal and robust, they often suffer from the lack of physical interpretability. Here we introduce a new ML scheme, which distinguishes different condensed-matter phases by autonomously recognizing order parameters. When applied to two-dimensional Ising models, our method can accurately predict the Curie and Néel temperatures and capture the corresponding critical phenomena by recognizing ferro- and antiferro-magnetizations, respectively. Going beyond these prototypical test cases, we analyze the nonequilibrium polymeric sol-gel transition, locating not only the transition temperature, but also discovering two classes of underlying collective behavior, the condensation and network-formation modes. Compared to existing MLs, our method offers physical insights as well as high training efficiency.

10:00AM E18.00009: Interpretable Machine Learning Study of Many-Body Localization Transition in Disordered Quantum Spin Chains* WEI ZHANG (Presenter), Boston College, LEI WANG, Institute of Physics Chinese Academy of Sciences, ZIQIANG WANG, Boston College — We develop, train, and apply a support vector machine (SVM) to study the phase transition between many-body localized and thermal phases in a disordered quantum Ising chain. We use the labeled probability density of eigenstate wavefunctions in the deeply localized and thermal regimes at two different energy densities as the training set. We find that the trained SVM is then able to predict the whole phase diagram. The obtained phase boundary qualitatively agrees with previous work using entanglement entropy to characterize these two phases. We further analyze the decision function of the SVM to interpret its physical meaning and find that it is analogous to the inverse participation ratio in the many-body configuration space. Our findings demonstrate the ability of the SVM to capture potential quantities that may characterize the many-body localization phase transition. The qualitative agreement of phase boundary obtained by SVM and by scaling entanglement entropy motivates further exploration of the relation between these two different quantities in connection to many-body localization.

Analytic continuation via “domain-knowledge free” machine learning*  HONGKEE YOON (Presenter), JAE-HOON SIM, MYUNG JOON HAN, Department of Physics, KAIST — We present a machine-learning (ML) approach to a long-standing issue in quantum many-body physics, namely, analytic continuation. This notorious ill-conditioned problem of obtaining spectral function from Green's function has been a focus of new method developments for past decades. Here we demonstrate the usefulness of modern ML techniques including convolutional neural networks and the variants of stochastic gradient descent optimizer. ML continuation kernel is successfully realized without any ‘domain-knowledge’, which means that any physical ‘prior’ is not utilized in the kernel construction and the neural networks ‘learn’ the knowledge solely from ‘training’. The outstanding performance is achieved for both insulating and metallic band structure. Our ML-based approach not only provides the more accurate spectrum than the conventional methods in terms of peak positions and heights, but is also more robust against the noise which is the required key feature for any continuation technique to be successful [1]. Furthermore, its computation speed is $10^4$–$10^5$ times faster than maximum entropy method.

Monte Carlo Renormalization Group for Systems with Quenched Disorder*  YANTAO WU (Presenter), ROBERTO CAR, Princeton University — We extend to quenched disordered systems the variational scheme for real space renormalization group calculations that we recently introduced for homogeneous spin Hamiltonians. When disorder is present our approach gives access to the flow of the renormalized Hamiltonian distribution, from which one can compute the critical exponents if the correlations of the renormalized couplings retain finite range. Key to the variational approach is the bias potential found by minimizing a convex functional in statistical mechanics. This potential reduces dramatically the Monte Carlo relaxation time in large disordered systems. We demonstrate the method with applications to dilute Ising, random field Ising and short-range spin glass models, on the two-dimensional square lattice.

*We acknowledge support from DOE Award DE-SC0017865.

Session E19 DAMOP: Precision Many Body Physics IV  BCEC 156C - Tigran Sedrakyan, University of Massachusetts Amherst - Tag(s): Focus

Quantum Transport in Strongly Interacting Fermi Gases* [Invited]  MARTIN ZWIERLEIN (Presenter), Massachusetts Institute of Technology — Transport is the defining property of states of matter, but often the most difficult to understand. Strongly interacting Fermi gases are especially challenging, despite their ubiquitous presence across many fields of physics. Experiments on ultracold fermionic atoms allow the direct measurement of transport properties in ideal model systems where the hamiltonian is precisely known while transport properties are difficult to calculate theoretically. In this talk I will present transport measurements on two strongly interacting Fermi systems, the unitary Fermi gas and the Fermi-Hubbard gas, both realized in uniform box potentials. In the unitary gas, we excite first and, in the superfluid regime, also second sound waves and demonstrate a quantum limited sound diffusivity given by $\hbar c$ over the particle mass. The first and second sound diffusivities give direct access to the thermal conductivity and the viscosity of the gas. For the Fermi-Hubbard gas, realized under a quantum gas microscope, we measure spin diffusion and spin conductivity in the Mott insulator at half filling. For strong interactions, spin diffusion is driven by super-exchange and doublon-hole-assisted tunneling, and strongly violates the quantum limit of charge diffusion. The technique developed in this work can be extended to finite doping, which can shed light on the complex interplay between spin and charge in the Hubbard model.

8:36AM E19.00002: Spectra of heavy polarons and molecules coupled to a Fermi sea* DIMITRI PIMENOV (Presenter), Ludwig Maximilian University of Munich, MOSHE GOLDSTEIN, Tel Aviv University — We study the spectrum of an impurity coupled to a Fermi sea (e.g., minority atom in an ultracold gas, exciton in a solid) by attraction strong enough to form a molecule/trion. We introduce a diagrammatic scheme which allows treating a finite mass impurity while reproducing the Fermi edge singularity in the immobile limit. For large binding energies the spectrum is characterized by a semi-coherent repulsive polaron and an incoherent molecule, which is the lowest-energy feature in the single-particle spectrum. The previously predicted attractive polaron seems not to exist for strong binding.

8:48AM E19.00003: Energy and short-range correlations of Bose Polarons in the strong coupling regime* CARSTEN ROBENS (Presenter), ZOE YAN, YIQI NI, ALEXANDER YU CHUANG, MARTIN ZWIERLEIN, Massachusetts Institute of Technology — The concept of the Bose polaron quasiparticle originates in Landau’s description of a crystal’s conduction electron which deforms the surrounding ionic lattice. Despite the conceptual simplicity of the Bose polaron – i.e. an impurity dressed by a surrounding bosonic bath – this quasiparticle poses remarkable challenges for both theoretical and experimental physicists. These challenges arise at strong interaction strengths where a multitude of bosons can simultaneously interact with the impurity thereby forming a complicated many-body state. We here report on the first creation of an ensemble of Bose polarons – comprised of fermionic 40K impurities immersed in a 23Na Bose Einstein condensate – in local equilibrium and in the strongly interacting regime. Using radio frequency ejection spectroscopy, we measure the Bose polaron ground-state energy and short-range correlations as a function of temperature across a variety of interaction strengths by tuning an interspecies magnetic Feshbach resonance. We further study collective oscillations between the BEC and the impurities, demonstrating strong dissipation of the impurities’ momentum at the transition from collisionless to hydrodynamic regime.

*Gordon and Betty Moore Foundation, National Science Foundation (NSF), AFOSR - MURI, ARO

9:00AM E19.00004: Polaron mobility in the \`\`beyond quasiparticles" regime* ANDREY MISHCHENKO (Presenter), Center for Emerging Matter Science (CEMS), RIKEN — In a number of physical situations, from polarons, to non-Fermi liquids, to Dirac liquids, one often faces a problem of computing particle mobility/conductivity when conditions for applicability of the kinetic equation approach are violated. The corresponding \`\`beyond quasiparticles" (or \`\`overdamped") regime is formally identified as a state in which an inelastic scattering time (computed formally within the standard perturbative approach) is exceeding the typical thermal energy of quasiparticles. We employ the Diagrammatic Monte Carlo method to study mobility of Frohlich polarons in the overdamped regime and find two effects: a substantial delay in developing an exponential law at temperatures below the optical mode frequency, and a mobility minimum at T close to optical ode frequency. Both effects should be taken into account in interpreting mobility data in materials with strong electron-phonon coupling.

*This work was funded by the ImPACT Program of the Council for Science, Technology and Innovation (Cabinet Office, Government of Japan).
9:12AM E19.00005: The contact of the Fermi gas at unitarity*  SCOTT JENSEN (Presenter), Yale University, CHRISTOPHER GILBRETH, Central Washington University, YORAM ALHASSID, Yale University — The unitary Fermi gas is a strongly correlated system with a short-range interaction that saturates the upper bound on the modulus of the two-particle s-wave scattering amplitude. It is characterized by an infinite scattering length and sits in the middle of the BCS-BEC crossover. The contact of this system is a quantity that describes short-range pairing correlations and appears in the high momentum tail of the momentum distribution and the static structure factor, as well as in the high-frequency tail of the shear viscosity spectral function. There have been a number of recent calculations and important experimental advances towards determining the contact for the unitary Fermi gas. We present results for the temperature dependence of the contact at unitarity using finite-temperature auxiliary-field quantum Monte Carlo (AFMC) methods on the lattice. Our calculations are carried out within the canonical ensemble with multiple filling factors and extrapolated to the continuum limit. We compare our results with other theoretical calculations and with experiment.

*This work was supported in part by the U.S. DOE grant Nos. DE-FG02-91ER40608 and DE-FG02-00ER41132.

9:24AM E19.00006: Signatures of pairing in the free energy of the unitary Fermi gas at finite temperature*  CHRISTOPHER GILBRETH (Presenter), Physics, Central Washington University, SCOTT JENSEN, YORAM ALHASSID, Physics, Yale University — The pseudogap regime in cold atomic Fermi gases is characterized by pairing correlations occurring above the critical temperature without the presence of superfluidity. Although this regime is easily understood to exist when there is a deep bound state in the two-particle system, its existence when there is only a zero-energy resonance, i.e., in the unitary limit of infinite scattering length, is much more difficult to verify. An accurate understanding requires precise theoretical and experimental methods at finite temperature, as well as investigating multiple observables. We discuss new quantum Monte Carlo calculations for the free energy of the unitary gas at finite temperature and their implications for pseudogap physics. In particular, we present new results for the even-odd staggering of the free energy based on canonical ensemble calculations.

*Supported in part by the US Department of Energy Grant No. DE-FG02-00ER41132.

9:36AM E19.00007: Spin Transport in a Mott Insulator of Ultracold Fermions*  MATTHEW A NICHOLS, Massachusetts Institute of Technology, LAWRENCE CHEUK, Harvard University, MELIH OKAN, THOMAS HARTKE (Presenter), ENRIQUE MENDEZ, HAO ZHANG, Massachusetts Institute of Technology, EHSAN KHATAMI, San Jose State University, MARTIN ZWERLEIN, Massachusetts Institute of Technology — Understanding transport in strongly interacting Fermi systems is among the most pressing but difficult tasks of many-body physics. The Fermi-Hubbard model serves as a prototypical example of a strongly correlated fermionic quantum system, and is believed to hold the key to high-temperature superconductivity. However, the transport properties in the various regions of its phase diagram are far from understood. We realize the Fermi-Hubbard model using a gas of fermionic atoms in an optical lattice, confined in a homogeneous box trap. In this setting, we study spin and charge transport using a quantum gas microscope, able to resolve individual atoms. In particular, at half filling, the charge degree of freedom is frozen, while spins are still able to move. Spin transport is induced by applying a spin-dependent magnetic field gradient. We observe spin dynamics which are diffusive in nature, and obtain the spin conductivity and spin diffusivity. These findings can be compared to existing theoretical approaches, such as the numerical-linked-cluster expansion (NLCE).

*This work was supported by the NSF, AFOSR, ONR, and the Gordon and Betty Moore Foundation.

9:48AM E19.00008: Excitation spectrum of dipolar Bose gases*  YOUSSEF KORA (Presenter), MASSIMO BONINSEGNI, University of Alberta — We investigate the excitation spectrum of a dipolar Bose gas in the low temperature limit across the superfluid-supersolid-crystal transition. At sufficiently low temperatures, a system of aligned dipolar bosons will undergo a quantum phase transition by tuning the range of the repulsive two-body potential. In one limit, the phase of the system is that of a classical crystal of filaments. At the other limit, the system experiences quantum melting into a superfluid phase. In the intermediate regime, the system exists in a supersolid state. We use Quantum Monte Carlo techniques to compute imaginary time correlation functions at the different regions of the phase diagram, and we use the method of Maximum Entropy to extract the dynamical structure factor, which is then used to obtain the excitation spectrum and its evolution throughout the phase diagram.

*This work was supported by the Natural Sciences and Engineering Research Council of Canada.
10:00AM E19.00009: Bose liquid in checkerboard antiferromagnet  
HAIYUAN ZOU (Presenter), Tsung-Dao Lee Institute, Shanghai Jiao Tong University, FAN YANG, School of Physics, Beijing Institute of Technology, WEI KU, Tsung-Dao Lee Institute & School of Physics and Astronomy, Shanghai Jiao Tong University — The frustrated $J_1$-$J_2$ antiferromagnet model on the checkerboard lattice, known as the two-dimensional analog of the pyrochlore lattice, provides a perfect platform for dimensional crossover effect due to competition between the two exchange constants $J_1$ and $J_2$. Using recently developed tensor network algorithm based on Projected Entangled Simplex States (PESS), we obtain a line degenerate bose liquid state without magnetic order on the whole range of $J_2 > J_1$ for both XY and Heisenberg antiferromagnetic limit. The degenerate liquid state is stable even when small anisotropy on $J_1$ bond is introduced and the interaction enhance the robustness of the bose liquid behavior.

10:12AM E19.00010: Impenetrable SU(N) fermions in one-dimensional lattices  
YICHENG ZHANG (Presenter), Department of physics, Pennsylvania State University, LEV VIDMAR, Department of Theoretical Physics, J. Stefan Institute, MARCOS RIGOL, Department of physics, Pennsylvania State University — We study SU(N) fermions in the limit of infinite on-site repulsion between all species. We focus on states in which every pair of consecutive fermions carries a different spin flavor. Since the particle order cannot be changed (because of the infinite on-site repulsion) and contiguous fermions have a different spin flavor, we refer to the corresponding constrained model as the model of distinguishable quantum particles. We introduce an exact numerical method to calculate equilibrium one-body correlations of distinguishable quantum particles based on a mapping onto noninteracting spinless fermions. In contrast to most many-body systems in one dimension, which usually exhibit either power-law or exponential decay of off-diagonal one-body correlations with distance, distinguishable quantum particles exhibit a Gaussian decay of one-body correlations in the ground state, while finite-temperature correlations are well described by stretched exponential decay. We also study the dynamics of distinguishable quantum particles after geometric quantum quenches.

10:24AM E19.00011: Efficient exact diagonalization of the n-body reduced density matrix*  
HATEM BARGHATHI (Presenter), ADRIAN DEL MAESTRO, University of Vermont — The n-body reduced density matrix provides an alternate description of a quantum-many body system that can offer considerable compression over the wavefunction while providing access to observables and correlation functions. In this talk, we present an efficient algorithm for its construction and exact diagonalization in a system of N interacting particles. In one spatial dimension, we simplify computations by exploiting translational, reflection and particle-hole symmetries. We illustrate the method by calculating the maximal particle entanglement entropy constructed from the N/2-particle reduced density matrix in the ground state of up to 13 interacting fermions on 26 sites.  

*This work was supported in part by the NSF under Grant No. DMR-1553991. Computations were performed on the Vermont Advanced Computer Core supported in part by NSF Grant No. OAC-1827314.

10:36AM E19.00012: Prethermalization and Thermalization in Generic Isolated Quantum Systems*  
KRISHNANAND MALLAYYA (Presenter), MARCOS RIGOL, Department of Physics, Pennsylvania State University, WOJCIECH DE ROECK, Instituut voor Theoretische Fysica, KULeuven — Prethermalization has been extensively studied in systems close to integrability. We propose a more general, yet simpler, setup for this phenomenon. We consider a possibly nonintegrable-reference dynamics, weakly perturbed so that the perturbation violates at least one conservation law of the reference dynamics. We argue then that the evolution of the system proceeds via intermediate (generalized) equilibrium states of the reference dynamics. The motion on the manifold of equilibrium states is governed by an autonomous equation, flowing towards global equilibrium in a time of order $g^2$, with $g$ the perturbation strength. We also describe the leading corrections to the time-dependent reference equilibrium state, in general of order $g$. The theory is well-confirmed by numerical calculations relying on the numerical linked cluster expansion.  

*NSF Grant No. PHY-1707482, PHY-1748958
Evolution of two-time correlations in strongly correlated dissipative systems: aging and hierarchical dynamics*

STEFAN WOLFF (Presenter), JEAN-SEBASTIEN BERNIER, HISKP, University Bonn, DARIO POLETTI, Science and Math Cluster and EPD Pillar, Singapore University of Technology and Design (SUTD), AMENEH SHEIKHAN, Department of Physics, Shahid Beheshti University, CORINNA KOLLATH, HISKP, University Bonn — In recent years, considerable experimental efforts have been devoted to dynamically generate complex states and monitor their evolution. Despite remarkable advances, the theoretical principles behind the non-equilibrium dynamics of strongly correlated quantum matter are still far from being fully understood. In particular, very few studies have sought to clarify the influence of environmental couplings on the propagation of correlations. We attempt here to fill this gap. To do so, we extend quasi-exact time-dependent matrix product state techniques to simulate the evolution of two-time correlations in the XXZ spin-1/2 model in contact with an environment causing local dephasing on all sites. We find this system to display hierarchical and aging dynamics. The latter dynamical regime is characterized by a breakdown of time-translation invariance, a slow non-exponential relaxation of two-time correlations and the presence of dynamical scaling.

Time-dependent density-functional approaches for excitons: the pros and cons of long-range corrected exchange-correlation kernels*

CARSTEN ULLRICH (Presenter), University of Missouri — Time-dependent density-functional theory (TDDFT) is, in principle, more efficient than the Bethe-Salpeter equation for calculating the optical properties of semiconductors and insulators. However, finding accurate exchange-correlation (xc) kernels for describing excitons is quite challenging: standard local and semilocal approximations lack the proper long-range behavior and do not produce bound excitons. This talk presents a systematic assessment of a class of long-range corrected (LRC) xc kernels which have shown promise for excitonic effects. It is found that no existing LRC kernel is capable of simultaneously producing good optical spectra and quantitatively accurate exciton binding energies for both semiconductors and insulators. We discuss strategies to improve the TDDFT treatment of excitons via semiempirical LRC xc kernels and screened hybrid approaches.

Exact exchange-correlation kernels for optical spectra

MIKE ENTWISTLE (Presenter), REX W GODBY, Physics, University of York — Time-dependent density-functional theory (TDDFT) is in principle a powerful technique for simulating the time-evolution of systems of interacting electrons. Whilst TDDFT has had notable successes, the usual adiabatic functionals within the linear response regime can fail badly when applied to problems such as optical absorption spectra. By reverse-engineering numerically exact calculations of the ground and excited many-body states, and response functions, of prototype one-dimensional systems, we obtain the exact exchange-correlation kernel $f_{xc}(x,x',\omega)$ for each system. We explore the properties of these exact xc kernels, and suggest how common approximations may be improved.
8:48AM E20.00003: Accelerating excited-state calculations in NanoGW using an interpolative separable density fitting method*  WEIWEI GAO (Presenter), JAMES CHELIKOWSKY, University of Texas at Austin — The NanoGW package implements some of the most widely used methods for calculating excited-state properties, including time-dependent density function theory (TDDFT), GW approximation, and Bethe-Salpeter equation in the single-particle orbital basis. Solving Casida's equation of TDDFT and performing GW/BSE calculations with NanoGW involve the computation of many electron-repulsion integrals. We will discuss the implementation of the interpolative separable density fitting (ISDF) method, a new density-fitting method [1] with $O(N_{\text{atom}}^3)$ computational complexity, in NanoGW. With ISDF method, we can reduce the number of electron-repulsion integrals from $O(N_{\text{atom}}^4)$ to $O(N_{\text{atom}}^2)$.

9:00AM E20.00004: Floquet theory for the electronic stopping of projectiles in solids*  NICOLO' FORCELLINI (Presenter), EMILIO ARTACHO, Physics, University of Cambridge — The problem of electronic stopping is traditionally approached and understood in the context of linear response theory[1], or a full non-linear theory for jellium[2]. First-principles quantitative simulations using time dependent density functional theory show reasonably predictive accuracy but remain computationally expensive and do not provide a clear, intuitive understanding of the stopping processes. We propose here a general (single-particle) stationary theory for the electronic excitation in crystalline solids by a constant-velocity projectile. It is based on the Floquet formalism for time-periodic systems[3], exploiting the system discrete translational space-time invariance. A change to the projectile's reference frame allows for a generalization of the treatment in Ref. [2], permitting a full study of the stopping in strong coupling for any crystalline system. Non-trivial effects such as the low-velocity threshold effect can be analyzed and understood in this framework.

9:12AM E20.00005: Electronic stopping of protons in anisotropic weakly bound materials*  JESSICA F. K. HALLIDAY, Cavendish Laboratory, University of Cambridge, PERE ALEMANY, IQTC-UB, Universidad de Barcelona, EMILIO ARTACHO (Presenter), Cavendish Laboratory, University of Cambridge — Ions shooting through condensed matter dissipate their kinetic energy by transferring it to the target's electrons and nuclei. At high velocities (above 1% of the speed of light) the stopping is mostly electronic, in a highly non-equilibrium, non-adiabatic process. First-principles simulations of such processes have been quite successfully performed in the last decade for varied systems. Here we present results for electronic stopping power for protons in graphite and ideal crystalline polyethylene, anisotropic systems with strong bonding in two dimensions and weakly bound in the other dimension, and vice-versa, respectively. They are based on time-dependent density-functional theory in real time, and using a basis of atomic orbitals (LCAO) within the SIESTA program. Results of the effect of trajectory orientation and impact parameter will be presented, displaying a transition from electronic-structure dependence at low velocity, to a regime at higher velocities in which the particle density along the projectile's path dominates. A reformulation of the TD-LCAO formalism and its implications for numerical simulations will be also presented.

9:24AM E20.00006: Electronic excitations in proton-irradiated ice via Real-Time TDDFT†

DANIEL MUÑOZ-SANTIBURCIO (Presenter), EMILIO ARTACHO, CIC nanoGUNE — Describing the interaction of water ice with highly energetic particles at the atomistic/electronic scale is of great importance to understand many astrophysical/chemical processes taking place in interstellar dust, comets, asteroids and satellites exposed to such particles present in solar wind, cosmic rays or strong magnetospheres.

Here I will show the results of Real-Time Time-Dependent-DFT calculations where the irradiation of ice with highly energetic protons is simulated in real time via Ehrenfest MD. This allow us not only to precisely compute the energy absorbed by the target and to follow the electronic excitations, but also to obtain an intuitive picture of which kind of electrons in the system (either ‘lone pairs’ or ‘bonding pairs’ electrons) are more likely to get excited, ultimately leading to ionization of the ice target. The influence of factors such as the trajectory and energy of the incoming proton will be also disclosed.

†This project has received funding from the European Union’s Horizon 2020 research and innovation programme under the Marie Sklodowska-Curie grant agreement No 748673. We acknowledge PRACE for awarding us access to MareNostrum at Barcelona Supercomputing Center (BSC), Spain.

9:36AM E20.00007: Electronic stopping power from time-dependent density-functional theory in Gaussian basis

IVAN MALIYOV (Presenter), FABIEN BRUNEVAL, JEAN-PAUL CROCOMBETTE, Saclay Nuclear Research Centre — Irradiation damage in condensed matter has been identified as central to nuclear materials, electronics, nuclear medicine. The interaction between an irradiating ion and a target material is measured by the stopping power, defined as the energy transfer from the projectile to the material per penetration distance. The most important ionic energy loss channel occurs through electronic excitations. This work is devoted to the ab initio calculations of the electronic stopping power.

We have developed a real time TDDFT approach based on MOLGW code for finite systems [1]. Using localized Gaussian basis has numerous advantages, such as the cheap account of core electrons, the simple implementation of the hybrid functionals, the tunable basis accuracy and overall low computational cost.

With our tool, we explore the bulk limit, how to properly average over the impact parameters so to obtain the experimental random electronic stopping power. We perform calculations for several metallic targets and for different ionic projectiles to evaluate the so-called Barkas effect [2] and to study the wake electronic density behind the projectile.

9:48AM E20.00008: Charge equilibration and electronic stopping for self-irradiated silicon*

CHENG-WEI LEE (Presenter), ANDRE SCHLEIFE, University of Illinois at Urbana-Champaign — Charged energetic particle radiation has technological interest in applications including nuclear energy, outer space, medicine, and fundamental research. As a result of irradiation, damage, including point defects, forms and ultimately determines the material properties. Therefore, understanding the underlying interactions between charged particles and a material from first principles is important. Recently, we investigated heavy (silicon) projectiles traversing crystalline bulk silicon and found a pronounced dependence of electronic stopping on the initial projectile charge state. This effect was not observed for light projectiles impacting metal or semiconductor targets. To understand this, we analyze the dynamics of charge equilibration, influence of the impact parameter, and contributions of core and valence electrons to electronic stopping. We observe that the equilibrium charge state of the Si projectile depends on the impact parameter and ultimately dominates electronic stopping. We also predict that this effect should be observable experimentally for large-Z projectiles of different charge, on hyper-channeling trajectories, e.g. in a thin film.

Office of Naval Research (N00014-18-1-2605)
10:00AM E20.00009: Vicinage effects in the stopping power of molecular hydrogen in aluminum*  EDWIN QUASHIE (Presenter), XAVIER ANDRADE, ALFREDO A. CORREA, Quantum Simulation Group, Lawrence Livermore National Laboratory — Using time-dependent density functional theory (TDDFT) we calculate the electronic stopping power of the hydrogen molecule, H₂, projectile in aluminum over a wide range of velocities where we take into account the effect of the drag dynamics of excited electrons. The electronic excitations determine the stopping power and also a change the interatomic forces of the molecule during the trajectories.

We observed that the stopping power strongly depends on the orientation of the H₂ molecule and differs significantly from the stopping of He and (twice) the stopping of H. The position of the maximum stopping changes from \( \nu = 1.3 \) a.u. for H to \( \nu = 1.8 \) a.u. for H₂ projectiles. We also study the effect of the interatomic forces and equilibrium distances as a function of the projectile velocity, allowing us to make a prediction of the behavior of the molecule during the stopping process. Our results agree with the available experimental results for the stopping of H₂ molecules in aluminum thin films and allows us to understand those results.

10:12AM E20.00010: Negative Differential Conductivity in Semiconductors from First Principles*  RAFI ULLAH (Presenter), XAVIER ANDRADE, ALFREDO A. CORREA, Lawrence Livermore Natl Lab — The negative differential conductivity (NDC) in gas-discharge tubes had been known long before [1] it was discovered in solids [2]. It was the discovery of NDC in semiconductors that invoked renewed interest in this area and opened it to applications in electronics [3]. Recently NDC has been observed in a quantum gas of neutral atoms [4]. It has been observed and predicted in different physical systems, including in normal metals [5], but the underlying physics is very different in each of those systems. In semiconductors it is mainly attributed to the electron transfer between different energy sub-bands. The transport phenomena in general and the NDC in semiconductors in particular is non-linear in nature and can not be accurately described by linear response theories. We have used time dependent density functional theory to compute the NDC in GaAs, a prototypical semiconductor. It is one of the first materials in which NDC was observed and widely used in NDC based applications.

*Prepared by LLNL under Contract DE-AC52-07NA27344

10:24AM E20.00011: Exchange and correlation effects in finite-temperature TDDFT*  JOHN REHR (Presenter), JOSHUA KAS, University of Washington — We discuss the finite-temperature (FT) generalization of time-dependent density functional theory (TDDFT) [1]. Formally the theory is analogous to that at temperature \( T = 0 \). In the local density approximation, the FT exchange-correlation kernel \( f_{xc}(T,n) \) can again be expressed as a density derivative of the exchange correlation potential \( d v_{xc}(T,n)/dn \), where \( n = N/V \) is the electron number density. An approximation for the TDDFT kernel \( f_{xc}(T,n) \) is obtained from the FT generalization of the retarded cumulant expansion applied to the homogeneous electron gas [2]. Results for \( f_{xc} \) and for the FT loss function are shown for a wide range of temperatures and densities, including the warm dense matter regime with temperatures of order \( T_F \), the electron degeneracy temperature. The FT cumulant Green’s function approach also yields a physical interpretation of the exchange and correlation contributions to the theory.

*Supported by DOE Office of Science BES Grant DE-FG02-97ER45623
10:36AM E20.00012: Real time-TDDFT study of thermal and non-thermal lattice dynamics depending on laser pulse-width*  
YOSHIYUKI MIYAMOTO (Presenter), National Institute of Advanced Industrial Science and Technology — In this work, I will discuss lattice dynamics of α-quartz conducted by femtosecond laser by performing the real-time TDDFT Ehrenfest dynamics with use of plane-wave basis set, TM type pseudopotentials, and adiabatic LDA functional. The α-quartz was expressed by a slab model with hydrogen termination. The distribution of kinetic energy for silicon and oxygen atoms was found to be nearly equal under shining the femtosecond laser with full-width of half-maximum (FWHM) 100 fs, wave length 800 nm, and fluence 10 J/cm². It is therefore concluded that this pulse width gave thermal dynamics on the lattice. By fixing the wave length and fluence of the femtosecond laser, the lattice dynamics with shorter FWHM was examined and non-equal distribution of kinetic energies among silicon and oxygen atoms was found. Furthermore, shorter pulse with FWHM=10 fs conducted ablation. I will discuss the physics behind this phenomenon.

*This work is based on results obtained from a NEDO project “Development of advanced laser processing with intelligence based on high-brightness and high-efficiency laser technologies” (TACMI project).

10:48AM E20.00013: Non-linear effects in core photoemission from Real-time TDDFT.*  
MARILENA TZAVALA (Presenter), JOSHUA KAS, JOHN REHR, Physics, University of Washington, LUCIA REINING, LSI, Ecole Polytechnique, Paris — In core photoemission spectroscopy a photon is absorbed and a core electron is emitted into the continuum, leaving behind a core hole. The remainder of the system responds to screen the core hole, significantly affecting the spectrum. State-of-the-art many-body perturbation theory (MBPT) methods such as the GW and the cumulant expansion are usually evaluated in the linear-response approximation. This requires a weak core hole; if this is not the case, one needs to go beyond linear response. This can be carried out with a non-linear cumulant derived in a MBPT framework, and evaluated from a real-time time-dependent density functional theory (TDDFT) approach. We discuss the application of this method with calculations carried out with an extension of our RT-Siesta code [1] for systems with d- and f valence electrons.

Session E21 DCOMP DCMP GSNP: Advances in Computational Methods for Statistical Physics and Their Applications  
BCEC 157B - Ying Wai Li, Oak Ridge National Laboratory - Tag(s): Focus

8:00AM E21.00001: Parallel approaches to long-time atomistic simulations: decomposition, replication, and speculation* [invited]  
DANNY PEREZ (Presenter), Los Alamos National Laboratory — Molecular Dynamics (MD) is a workhorse of computational materials science. Indeed, MD can in principle be used to obtain any thermodynamic or kinetic quantity for a given interatomic potential. This enviable quality however comes at a steep computational price, limiting the system sizes and simulation times that can be achieved in practice. While the size limitation can be efficiently addressed with massively parallel implementations of MD based on spatial decomposition strategies, the same approach cannot extend the timescales much beyond microseconds. This is a significant issue, as this implies that the constant increase in the computing power delivered by leadership-scale machines cannot be leveraged to make long-time predictions.

In this talk, I discuss additional parallelization strategies, namely replication and speculation, that can be used to address the timescale limitation of MD for systems that evolve through rare transitions, concentrating primarily on the Parallel Trajectory Splicing (ParSplice) method and its recent developments. Using as an example the evolution of the shape of metallic nanoparticles, we show how, taken together, these ideas can significantly extend the simulation space accessible to MD in a way that can unlock the potential of current massively-parallel computing platforms.

*This research was supported by the Exascale Computing Project (17-SC-20-SC), a collaborative effort of two U.S. Department of Energy organizations (Office of Science and the National Nuclear Security Administration) responsible for the planning and preparation of a capable exascale ecosystem, including software, applications, hardware, advanced system engineering, and early testbed platforms, in support of the nation's exascale computing imperative.
8:36AM E21.00002: Advanced computational methods for an accurate thermodynamic description of the paramagnetic state of magnetic materials from first principles  
DAVIDE GAMBINO (Presenter), BJORN ALLING,  
Department of Physics, Chemistry and Biology (IFM), Linköping University — In the past years, procedures to calculate from first principles the (Gibbs) free energy of a system with arbitrary accuracy have been established, starting in general from a simplified model and then calculating the full free energy with the use of statistical sampling techniques. These methods have been proven powerful for many materials; however, when it comes to magnetic materials at finite temperature, the system becomes more complex to be treated with ab initio techniques because of the indirect influence of magnetism on several equilibrium properties, besides its explicit contribution to the free energy.  
To improve the description of magnetic materials in the high temperature paramagnetic phase from first principles, we develop a method [Physical Review B 98, 064105 (2018)] to perform structural relaxations in the paramagnetic phase based on the disordered local moment (DLM) model, and we apply it to the case of a vacancy and a C interstitial in bcc Fe, bcc Fe$_{1-x}$Cr$_x$ random alloys, and defects in CrN. We also apply the recently developed atomistic spin dynamics-ab initio molecular dynamics approach [Physical Review Letters 121, 125902 (2018)] to defect free bcc Fe at the Curie temperature to prove the feasibility of free energy calculations on this system.

8:48AM E21.00003: Coupled spin dynamics and ab initio molecular dynamics approach for paramagnetic materials  
IRINA STOCKEM (Presenter), Department of Physics, Chemistry, and Biology (IFM), Linköping University, ANDERS BERGMAN,  
Department of Physics and Astronomy, Materials Theory Division, Uppsala University, ALBERT GLENSK, Laboratory of Computational Science and Modeling, Institute of Materials, École Polytechnique Fédérale de Lausanne, BLAZEJ GRABOWSKI, FRITZ KÖRMANN, TILMANN HICKEL, JÖRG NEUGEBAUER, Computational Materials Design, Max-Planck-Institut für Eisenforschung GmbH, BJORN ALLING, Department of Physics, Chemistry, and Biology (IFM), Linköping University — Magnetic semiconductors like YMnO$_3$[1] and CrN [2] show an anomalous temperature dependence of the thermal conductivity in their paramagnetic phase: A strong suppression is observed right above the magnetic transition, followed by an almost constant conductivity at higher temperatures.  
At high temperature lattice vibrations and spin fluctuations occur simultaneously. As local effective moments still exist above the magnetic transition temperature, they interact with each other and with the lattice vibrations.  
By treating both lattice vibrations and spin fluctuations in a combined atomistic spin dynamics (ASD) – ab initio molecular dynamics (AIMD) approach, we are able to ascribe this experimentally observed effect to a mutual and dynamic spin-lattice coupling [3]. This coupling shows a strong influence on the phonon life times right above the magnetic transition.

9:00AM E21.00004: Full spin modeling and efficient mapping of the high dimensional Hamiltonian in Dy$_2$Ti$_2$O$_7$  
ANJANA SAMARAKOON (Presenter), Neutron Scattering Division, Oak Ridge National Laboratory, DAVID TENNANT, Materials Science and Technology Division, Oak Ridge National Laboratory, CRISTIAN BATISTA, Department of Physics, University of Tennessee, QIANG ZHANG, FENG YE, Neutron Scattering Division, Oak Ridge National Laboratory, HAIDONG ZHOU, Department of Physics, University of Tennessee, MARKUS EISENBACH, National Center of Computational Sciences, Oak Ridge National Laboratory, KIPTON BARROS, Theoretical Division, Los Alamos National Laboratory, SÁNTIAGO GRIGERA, School of Physics and Astronomy, University of St Andrews, YING WAI LI, National Center of Computational Sciences, Oak Ridge National Laboratory, ZHILING DUN, Department of Physics, University of Tennessee — Precise modeling of a material is a key to understand its underlying interactions and physics but also revealing the competing phases in the nearby interaction space. Highly frustrated systems are important due to the richness in physics and diversity of phases including spin liquids with exotic topological states they display.  
Here, we present a machine learning workflow to fit multi-experimental datasets to find an optimal Hamiltonian while undertaking phase classification and extracting information about the topography around the region of interest. Experimental data from a spin-ice material, Dy$_2$Ti$_2$O$_7$ including diffuse neutron scattering, heat capacity, and susceptibility are utilized. This approach is shown to provide the best model in an efficient and effective way but also is powerful at planning the best experimental strategies.
9:12AM E21.00005: Digital Alchemy Applied to Molecular Dynamics  JAMES PROCTOR (Presenter), University of Michigan, Ann Arbor, MI, GREG VAN ANDERS, Queen's University, Kingston, ON, Canada, SHARON GLOTZER, University of Michigan, Ann Arbor, MI — Recently, colloidal and nanoparticle synthesis techniques have grown in scope more quickly than the capacity to populate relevant phase diagrams, challenging the predictive ability of computer simulation. Meeting this challenge suggests the development of new techniques that simultaneously explore the dynamics of particles’ canonical degrees of freedom, and particle attributes. Here, we describe a Molecular Dynamics implementation of the “Digital Alchemy” framework. This framework extends statistical ensembles to include variation in “alchemical” degrees of freedom describing particle attributes. We apply alchemical Molecular Dynamics simulations to particles interacting via a Lennard-Jones-Gauss potential, and show that several previously known crystal structures, including a quasicrystal, exhibit stable behavior in this alchemically extended design space, allowing for optimization and exploration.

9:24AM E21.00006: Exploring the Early Stages of Corrosion with ab initio Adaptive Kinetic Monte Carlo Simulations of Non-Equilibrium Oxides  MICHAEL WATERS (Presenter), JAMES M RONDINELLI, Materials Science and Engineering, Northwestern University — The early stages of corrosion in Ni-alloys are dominated by kinetically favorable, non-equilibrium layers comprising normally immiscible oxides. The ionic transport across these highly defective layers mediates their continued growth and the oxidation the substrate alloy. While at longer time scales, the phase segregation of the non-equilibrium layer into thermodynamically stable phases is key to long term passivation of the alloy. In order to simulate the atomistic kinetics on such long-time scales in a natural manner, we employ the state-of-the-art ab initio adaptive kinetic Monte Carlo method. We detail our key findings in regards to the importance of correlation and magnetic order.

9:36AM E21.00007: Removing Lattice Constraints from Lattice Protein Models: A Wang-Landau Study  ALFRED FARRIS (Presenter), University of Georgia, DANIEL T. SEATON, Harvard University, DAVID P LANDAU, University of Georgia — We apply Wang-Landau sampling [1] to the continuum analogue of the hydrophobic-polar (HP) lattice protein model [2] to study the effects of lattice constraints on generic folding behavior in coarse-grained protein models. The continuum version is inspired by the AB polymer model [3], but incorporates potentials chosen specifically to mimic those of the lattice protein case. In this study, we compare and contrast thermodynamics during the folding process of the continuum model to the original HP lattice protein model for sequences mapped from Crambin, a 46 amino acid plant protein. We find that the folding processes for both of these coarse-grained models are quite similar, with major structural transitions occurring at almost the same temperatures. The continuum model hints at a small, additional structural transition not seen in the lattice case; the exact nature of this rearrangement is currently under investigation.

9:48AM E21.00008: Ensemble Monte Carlo Growth simulations of polymers in confined environments  GRAZIANO VERNIZZI (Presenter), Siena College (Loudonville, NY), TRUNG NGUYEN, Northwestern University (Evanston, IL), HENRI ORLAND, CEA Saclay (Gif-sur-Yvette Cedex, France), MONICA OLVERA DE LA CRUZ, Northwestern University (Evanston, IL) — We apply a recent Ensemble Monte Carlo Growth algorithm to sample the microcanonical density of states of polymers in confined geometries. The main advantage of computing the entropy directly, is that it allows to locate and characterize phase transitions accurately, while circumventing problems associated with long time scales. However, when the accessible phase space is restrained, such as in geometrically confined polymers, entropic forces exerted on the confining walls lead to changes in several statistical mechanical properties of the polymers. We test the performance of the microcanonical ensemble Monte Carlo growth algorithm for confined interacting self avoiding walks. We discuss also how to extend the model to include electrostatic interactions.
10:00AM E21.00009: Model Amyloid Protofibrils Simulated with Replica-Exchange Wang-Landau  MATTHEW S. WILSON (Presenter), GUANGJIE SHI, DAVID P LANDAU, Center for Simulational Physics, University of Georgia, THOMAS WUEST, Scientific IT Services, ETH Zurich, FRIEDERIKE SCHMID, Institute of Physics, Johannes Gutenberg University — As neurological diseases associated with toxic peptide aggregates emerge, the research of aggregate and fibril formation has become a prominent, yet extremely challenging problem. The ability to form an amyloid state has been posited as a general feature of peptide systems, and is considered in this study by simulating a collection of coarse-grained, generic model peptides. The H0P model\(^1\) adds an additional neutral polarity group to the classic hydrophobic-polar (HP) model\(^2\), and is used for simplicity and efficiency. With the replica-exchange Wang-Landau (REWL) algorithm and an efficient trial move set\(^3\), the density of states is determined for multiple interacting model peptides. We observe the formation of fibrillar structures in two continuous transitions that separate three phases: dissolved peptides, disordered oligomers, and crystalline aggregate structures. Additional structural observables are calculated in a post-simulation production run to further study the physical behavior during the observed transitions.

10:12AM E21.00010: Conformational mechanics for polymers doubly-grafted to a homogeneous substrate\(^*\)  SHENGMING ZHANG (Presenter), MICHAEL BACHMANN, Department of Physics and Astronomy, University of Georgia — Studies of linear polymer structures with their two ends anchored at a planar substrate can help to provide insights into conformational properties of biologically active systems such as myosin and kinesin. We thoroughly investigated the conformational phases of a coarse-grained flexible homopolymer model with both ends of the chain grafted to a homogeneous attractive substrate by means of parallel tempering computer simulations. For bonded monomers, we employed the FENE potential, whereas the nonbonded interaction was described by the Lennard-Jones potential. The monomer-substrate attraction was modeled using an integrated Lennard-Jones potential. Specific energetic and structural quantities were measured and used as indicator functions for the characterization of the conformational phases in this system. Based on these results, we constructed the temperature versus end-to-end separation pseudo-phase diagram. We identified unique crystalline and icosahedral solid phases in addition to a globular liquid and two geometric gas-like phases.

\(^*\)NSF Grant No. DMR-1463241

10:24AM E21.00011: Framework to track Order-Disorder Transitions - From Particles to Block Copolymers\(^*\)  ANKITA MUKHTYAR (Presenter), FERNANDO A ESCOBEDO, Cornell University — Block copolymers self-assemble into a variety of phases with highly regular patterns, depending on the ordering of molecules. Paramount to understanding and controlling this “order” is to have good “order parameters”, variables used to track changes in the system as it transitions from disorder to order. Molecular dynamics is used to simulate the growth of minimalistic versions of the lamella, cylinder and gyroid phases from an isotropic liquid using a binary nanoparticle mixture model. Based on the correlation of bonding symmetries between a particle and its neighbors, local order parameters are developed and used to track the formation and growth of specific geometric motifs along the transition pathway. They are then modified to study similar transitions in coarse-grained models of polymers and oligomers, namely the assembly of a linear symmetric diblock copolymer into the lamellar, and a branched bolaamphiphile into the single diamond phase. The framework also finds use in the estimation of free-energy barriers for such ordering transitions. These calculations are yet to be reported in literature for such systems and require the use of novel variants of nucleus-size pinning and umbrella sampling techniques.

\(^*\)Funding support from NSF award DMR-1609997 is gratefully acknowledged.
10:36AM E21.00012: Noise reduction and automated molecule detection in atomistic diffusion calculations of correlated systems

NICOLA MOLINARI, IAN LEIFER (Presenter), YU XIE, BORIS KOZINSKY, Harvard University — When using molecular dynamics to compute diffusion coefficients for correlated systems, the fully correlated analysis of molecular trajectories leads to very noisy estimates because it is based on the center of mass motion rather than motion of individual atoms. We propose a new method that systematically reduces the noise in the diffusion constant calculation. By assuming that the underlying correlation structure of a system is the same for the entire trajectory, we leverage the information learned from the well-converged short-time position-position correlation matrix to reduce the noise at longer times. The proposed method allows to significantly decrease the uncertainty of diffusivity estimates and works for both non-bonded and bonded correlation scenarios. In the latter case we are able to identify automatically the diffusing degrees of freedom of the system, i.e. identify the molecular species. Furthermore, we demonstrate that using our method the estimation of the diffusion constant is never worse than the widely-adopted center-of-mass approach.

10:48AM E21.00013: Scaling relations for the continuum limit from collisions between nanoclusters and rough surfaces*

ERIC SWITZER (Presenter), ANIKET BHATTACHARYA, University of Central Florida — Nanoclusters have wide ranges of applications for their unique size-dependent properties. We report molecular dynamics simulation studies of the coalescence of small clusters with each other and with heterogeneous surfaces, as well as bouncing and fragmentation of clusters. Specifically, we study collisions of dust particles consisting of silica and water molecules and study the aftermath immediately following the collisions. We vary cluster sizes from 10 – 1000 nm containing 1000 – 100,000 particles with an aim to derive scaling relations for the elastic limit so that the extracted elastic parameters for the extrapolated continuum models can be used to study clusters of much larger sizes beyond the scope of simulation studies.

8:00AM E22.00001: Physics-Based Machine Learning Models for Discovery of Novel Scintillator Chemistries

GHANSHYAM PILANIA (Presenter), CHRISTOPHER R. STANEK, BLAS PEDRO UBERUAGA, Los Alamos National Laboratory — Applications of inorganic scintillators—activated with lanthanide dopants, such as Ce—are found in diverse fields. As a strict requirement to exhibit scintillation, the 4f ground state and 5d1 lowest excited state levels induced by the activator must lie within the host bandgap. This talk will discuss a new machine learning (ML) based screening strategy that relies on a high throughput prediction of the lanthanide dopants’ ground and excited state energy levels with respect to the host valance and conduction band edges for efficient chemical space explorations to discover novel inorganic scintillators. Using a set of perovskite oxides and elpasolite halides as examples, it will be demonstrated that the developed approach is able to (i) capture systematic chemical trends across host chemistries and (ii) effectively screen promising compounds in a high-throughput manner. While a number of other application-specific performance requirements need to be considered for a viable scintillator, the present scheme can be a practically useful tool to systematically down-select the most promising candidate materials in a first line of screening for a subsequent in-depth investigation.
8:12AM E22.00002: Finding Novel Fast Ionic Conductors Using Combined Techniques from Density Functional Theory and Materials Informatics*  RANDY JALEM (Presenter), Center for Green Research on Energy and Environmental Materials & Global Research Center for Environment and Energy based on Nanomaterials Science (GREEN), National Institute, KENTA KANAMORI, ICHIRO TAKEUCHI, Computer Science, Nagoya Institute of Technology (NiTech), Japan, YOSHITAKA TATEYAMA, Center for Green Research on Energy and Environmental Materials & Global Research Center for Environment and Energy based on Nanomaterials Science (GREEN), National Institute, MASANOBU NAKAYAMA, Life Science and Applied Chemistry, Nagoya Institute of Technology (NiTech), Japan — Computational new material search is an ongoing hot topic for research in various fields of applications. In here, we show our works related to efficient computational methods for finding novel fast ionic conductors for potential use in solid-state batteries. One topic deals with our proposed search framework based on a Bayesian optimization algorithm with a kernel definition that is general for high dimension of material descriptors, coupled to a DFT method to calculate ion migration energy barriers (Eb) over chemical search spaces of oxides (Eb as a search criterion) (Sci. Rep. 2018, 8, 5845). The next part shows our formulation of descriptors for crystalline solids which are derived from literature data and real feature values from atom-centered Voronoi partitioning (STAM 2018, 19, 231). We validated the scheme in terms of machine learning of various DFT-calculated properties such as cohesive energy, material density, electronic band gap energy, and convex hull decomposition energy.

*This research has been supported by National Institute for Materials Science (NIMS), NIMS “Materials research by Information Integration” Initiative (MI2I), and JST-PRESTO program.

8:24AM E22.00003: Crystal structure prototype database based on machine learning classification of existing inorganic material structures*  SHULIN LUO (Presenter), BANGYU XING, JIAN LV, LIJUN ZHANG, College of Materials Science and Engineering, Jilin University — Combining high-throughput calculations with database construction and data mining offers opportunities for computational material scientists to discover new materials. Candidate materials considered in high-throughput calculations are usually from chemical substitution or structure variation based on known crystal structures. So, knowledge of crystal structure prototypes is vital for the validity of high-throughput calculations. We herein built a high quality crystal structure prototype database with the aid of machine learning classification of existing inorganic materials structures. The structure data were classified by the hierarchical clustering approach and the state-of-the-art structure fingerprinters including the bond order parameters and the smooth overlap of atomic positions were used for structure characterization. The database can generate sub-databases dynamically based on new criteria. We have integrated the database into the in-house developed infrastructure of JUMP/2, a python framework for materials discovery via high-throughput calculations, aiming at creating an automatic and high-performance computational materials discovery platform.

*Work at Jilin University is supported by National Natural Science Foundation of China under Grant Nos. 61722403 and 11674121.

8:36AM E22.00004: Development of linearly independent descriptor generation method for sparse and interpretable modeling in materials science*  HITOSHI FUJII (Presenter), National Institute for Materials Science, TETSUYA FUKUSHIMA, Institute for NanoScience Design, Osaka university, TAMIO OGUCHI, Institute of Scientific and Industrial Research, Osaka university — In recent years, researches using techniques of machine-learning have been considerably activated in the field of materials science and we focus on research for empirical law discovery to elucidate a mechanism of physical properties of target materials. We propose linearly independent descriptor generation method for increasing the expression capability of linear regression model without generating any multicollinearity and strong near-multicollinearity which are a major problem in linear regression analysis. Our method is expected to be an essential preprocessing technique for sparse and interpretable modeling in materials science.

*Materials research by Information Integration Initiative (MI2I) project of the Support Program for Starting Up innovations Hub from Japan Science and Technology Agency (JST)
At 8:48 AM E22.00005: Important descriptors and descriptor groups of Curie temperatures of rare-earth transition-metal binary alloys

HIORI KINO (Presenter), National Institute for Materials Science — We analyze Curie temperatures of rare-earth transition metal binary alloys with machine learning method. In order to select important descriptors and descriptor groups, we introduce newly developed subgroup relevance analysis and adopt the hierarchical clustering in the representation. We execute the exhaustive search and illustrate that our approach indeed leads to the successful selection of important descriptors and descriptor groups. It helps us to choose the combination of the descriptors and to understand the meaning of the selected combination of descriptors.

*This work was partly supported by PRESTO and by the "Materials Research by Information Integration" Initiative (M2I) project of the Support Program for Starting Up Innovation Hub, both from the Japan Science and Technology Agency (JST), Japan; by the Elements Strategy Initiative Project under the auspices of MEXT; and also by MEXT as a social and scientific priority issue (Creation of New Functional Devices and High-Performance Materials to Support Next-Generation Industries; CDMSI) to be tackled by using a post-K computer. The calculations are partly carried out on Numerical Materials Simulator at NIMS.

At 9:00 AM E22.00006: Supervised learning and prediction of electronic properties: Discovery and Design of Materials and Interfaces for back-end-of-line interconnects

GANESH HEGDE (Presenter), HARSONO SIMKA, CHRIS BOWEN, Advanced Logic Lab, Samsung Semiconductor Inc, Austin, TX, USA — Supervised machine learning based techniques have found notable success in the recent past in the fields of atomic structure prediction and interatomic potential generation. Such techniques, however, have not found similar success in the prediction of non-local electronic-structural quantities such as electronic transmission and total density of states.

In this work, we present approaches to accurately predict a range of electronic structure properties - from Hamiltonian Matrix elements, electronic transmission to density of states - using supervised learning. Training and test data is obtained from open materials databases and from tailored first-principles Density Functional Theory simulations of materials and material interfaces.

The key role played by structural and electronic descriptors and their impact on the accuracy of predictions is discussed. The use of simulation-based proxies for material properties accessible through experiment is also discussed.

Finally, recent progress on the discovery and design of conductor and barrier materials for back-end-of-line interconnect using supervised learning is presented.

At 9:12 AM E22.00007: Machine-Learning-Assisted Accurate Band Gap Predictions of Functionalized MXene

ARUNKUMAR RAJAN (Presenter), AVANISH MISHRA, SWANTI SATSANGI, RISHABH VAISH, ABHISHEK KUMAR SINGH, Indian Institute of Science — MXene is a recent addition to the ever-growing family of 2D-materials, promising for optical, electronic, energy storage and photocatalytic applications. Utilizing statistical learning-based approach, we electronically characterize this vast class of materials by predicting their band gaps with GW level accuracy. Using a classification model, MXene having finite band gaps are filtered out and few of them are selected to build a machine learning model. The model is built by correlating the easily available elemental and computed properties as features with respect to calculated GW band gaps of selected MXene. Depending upon feature combinations, Gaussian process regression method resulted in optimized model yielding low root-mean-squared-error of 0.14 eV, which can be employed to estimate the accurate GW band gaps of tens of thousands of MXenes [1,2] within minutes. Our results demonstrate that machine learning model can bypass band gap underestimation problem of local and semi-local functionals used in DFT calculations, without subsequent correction using time-consuming GW approach.

9:24AM E22.00008: Accelerating inorganic discovery with meta-calculation filtering via a decision classifier
CHENRU DUAN (Presenter), Chemistry, Chemical engineering, Massachusetts Institute of Technology, JON PAUL JANET, Chemical Engineering, Massachusetts Institute of Technology, ADITYA NANDY, Chemistry, Chemical engineering, Massachusetts Institute of Technology, FANG LIU, HEATHER J KULIK, Chemical Engineering, Massachusetts Institute of Technology — Machine learning (ML) has the capacity to revolutionize materials discovery with accurate property estimation at negligible computational cost. Still, most discovery workflows require computationally-demanding simulation to generate data to feed in an ML model. However, two key challenges remain at the stage of data generation: i) materials may not form a stable complex and ii) calculations may fall outside the domain of applicability of the chosen method. Usually, these two failure modes can only be detected after calculations finished, leading to a massive waste of computational resources. To address this problem, we trained a classifier to estimate the success rate of a calculation directly from topological, heuristic features prior to simulation. Inspired by the data distribution in the latent space, we designed a model confidence metric specifically for classification tasks, lowering the risk of terminating jobs that are actually fruitful. A dynamical classifier that utilizes the information generated during simulation is also developed, which directs the on-the-fly decision of whether to abandon an in-progress calculation. Our classifiers are useful in dataset generation with first-principles calculations to accelerate the ML-driven design of novel inorganic materials.

ROHIT BATRA (Presenter), School of Materials Science and Engineering, Georgia Institute of Technology, GHANSHYAM PILANIA, BLAS PEDRO UBERUAGA, Los Alamos National Lab, RAMAMURTHY RAMPRASAD, School of Materials Science and Engineering, Georgia Institute of Technology — Cost versus accuracy trade-offs are frequently encountered in materials science, where a particular property of interest can be measured at different levels of accuracy or fidelity. Naturally, the most accurate measurement is also the most resource-intensive, while the inexpensive quicker alternatives tend to be noisy. In such situations, machine learning strategies, such as multi-fidelity information fusion (MFIF), can be employed to fuse information accessible from sources with varying levels of fidelity, and allow for accelerated property predictions. In this work, we use a dataset consisting of dopant formation energies of 42 dopants in hafnia—each studied in six different hafnia phases—computed at two levels of fidelity. The performance of traditional single fidelity (SF) and three MFIF models, namely, Δ-learning, low-fidelity as a feature, and multi-fidelity (MF) co-kriging are compared. We find that the MF based learning scheme not only outperforms the traditional SF machine learning methods, such as Gaussian process regression, but also provides an accurate, inexpensive and flexible alternative to other MFIF strategies. The learning approach is expected to be general and can be readily applied to a much wider spectrum of materials discovery and optimization problems.

9:48AM E22.00010: Machine Learning for Energetic Material Detonation Performance
BRIAN BARNES (Presenter), US Army Research Laboratory — We present advances in accurate, extremely rapid prediction of detonation performance for energetic molecules. These models may be integrated into a larger effort for high-throughput virtual screening or rapid pre-screening of molecules before any hazardous synthesis is attempted. Our workflow utilizes (a) a reference dataset generated from quantum mechanical calculations and a thermochemical code, (b) a cheminformatics approach to molecular descriptors, and (c) neural network and kernel-based algorithms for nonlinear regression. This data-driven approach leverages modern “machine learning” techniques for prediction of molecular properties. We create models to predict detonation velocity and detonation pressure. Molecules evaluated are CHNO-containing organic molecules drawn from GDB datasets, and known explosives. Usefulness of a variety of feature descriptors (e.g. Morgan fingerprints), are compared. Kernel and activation functions, hyperparameter optimization, and relative accuracy of models are discussed. Algorithms evaluated include neural networks, least absolute shrinkage and selection operator regression (“Lasso”), random forest regression, and Gaussian process regression. The Python workflow for automated dataset generation and analysis is also discussed.
10:00AM E22.00011: Machine learning study of two-dimensional magnetic materials*  TREVOR DAVID RHONE (Presenter), WEI CHEN, SHAAN DESAI, AMIR YACOBY, EFTHIMIOS KAXIRAS, Harvard University — When the dimensionality of an electron system is reduced, new behavior emerges. This has been demonstrated in GaAs quantum Hall systems since the 1980’s, and more recently in van der Waals (vdW) materials. We discuss the behavior of electrons in reduced dimensions with a focus on their spin properties. We study vdW materials with intrinsic magnetic order, materials at the forefront of physics research. We use materials informatics (machine learning applied to materials science) to study the magnetic and thermodynamic properties of vdW materials. Crystal structures based on monolayer Cr2Ge2Te6, of the form A2B2X6, are studied using density functional theory (DFT) calculations and machine learning tools. Magnetic properties, such as the magnetic moment are determined. The formation energies are also calculated and used to estimate chemical stability. We show that machine learning, combined with DFT, provides a computationally efficient means to predict properties of two-dimensional (2D) magnets. In addition, data analytics provides insights into the microscopic origins of magnetic ordering in 2D. This novel approach to materials research paves the way for the rapid discovery of chemically stable 2D magnets.

10:12AM E22.00012: Stochastic Discovery of Variance Mechanisms in Heterogeneous Dielectric Coatings  VENKATESH MEENAKSHISUNDARAM (Presenter), DAVID YOO, ANDREW GILLMAN, UES, Inc, JAMES DENEAULT, UTC, NICHOLAS GLAVIN, PHILIP BUSKOHL, Air Force Research Laboratory — Microscale spatial and material heterogeneities in 3D printed electrical devices present significant challenges to predictable electrical performance and device reliability. Dielectric particles are often added to dielectric inks to tailor the macro level permittivity of printed dielectric substrates and coatings. However, the combined role of particle morphology, discrete spatial arrangement and material properties on variance is difficult to distinguish experimentally, due to the large parameter space of processing variables and electrical sensitivity to local heterogeneities. We address this challenge by combining a finite element capacitor model with a neural network guided genetic algorithm (GA) to optimize the volume fraction, particle size and permittivity distributions of dielectric particles to identify systems with high capacitance variance. Classification-based machine learning techniques were also applied to the GA-created database to extract correlations between the spatial/material distributions of the dielectric particles and the capacitance variance. Collectively, the study provides a useful framework to correlate electrical performance with both macro- and microstructural variation sources, which is key to accelerating the development of 3D printing materials.

10:24AM E22.00013: Ligand Optimization for the Spin-Lattice Coupling of Single-Molecule Magnets Mn3  JIE GU (Presenter), WILLIAM PERRY, MAHER YAZBAK, DIANTENG CHEN, Department of Physics and the Quantum Theory Project, University of Florida, MARK E. TURIANSKY, University of California, Santa Barbara, HAI-PING CHENG, XIAOGUANG ZHANG, Department of Physics and the Quantum Theory Project, University of Florida — Single molecule magnets (SMM) exhibit a pseudo-multiferroicity which arises from structural changes that occur during spin state transitions. This spin-lattice coupling leads directly to magnetocapacitance which may also allow the spin state of the ground state to be tuned via strain. We propose that this tuning can be performed via replacement of the ligands which surround the SMM core atoms, and we attempt to search for a ligand which maximizes the spin-lattice coupling in the SMM Mn3 as a test case. We use density functional theory (DFT) calculations, Bayesian optimization, and slightly modified atomic environment vectors (AEVs) to perform the search. These techniques are employed in order to minimize the cost of searching through a large number of candidate ligands from the PubChem database. Following this procedure, we have obtained evidence that the spin-lattice coupling can be affected through a judicious choice of ligand.

10:36AM E22.00014: Identification of stable Cu-Pd-Ag nanoparticles using neural network interatomic potentials  SAMAD HAJINAZAR (Presenter), ERNESTO D. SANDOVAL, AIDEN J. CULLO, ALEKSEY KOLMOGOROV, Binghamton University — A neural network potential constructed with a stratified training scheme available in the MAISE package [1,2] has been used to find low-energy structures of elemental, binary and ternary Cu-Pd-Ag clusters. The efficiency of the employed unbiased global ground state evolutionary search for elemental nanoparticles was improved by co-evolving clusters across a range of sizes. We systematically compared the stability of the clusters found with the neural network model against previously reported structures found with the Gupta potential. Predictions made with the neural network show a consistent improvement in nanoparticle stability at the density functional theory level.

Tuesday, March 5, 2019 8:00 AM - 10:48 AM
8:00AM E23.00001: How do interactive physics learning environments foster Intellectual Humility (IH)?

MEAGAN SUNDSTROM (Presenter), FABIANA CARDETTI, University of Connecticut — Students often enter the physics classroom with intuitive conceptions drawn from real life experiences or former coursework, and may be hesitant or reluctant to forego these mindsets in favor of formally instructed knowledge. The goal of introductory physics courses is not only to teach and expose students to new content, but also to cultivate students' abilities to reason through and derive content knowledge through personal inquiry. This scientific process necessitates one's abilities to be open-minded in terms of hearing evidence that contradicts his or her personal opinion, to be willing to discard any original misconceptions in the face of such alternative evidence, and to identify and pay appropriate attention to one's academic limitations. Such a mindset is indicative of the quality of Intellectual Humility (IH), defined as "the owning of one's limitations." In the present study, we utilize IH surveys, reflections, conceptual knowledge assessments, and classroom observations collected for both a traditional, lecture-style physics course and an interactive environment, problem-solving based physics course. We will present our findings from the study as we attempt to examine the role of interactive learning environments in fostering IH in physics through collaboration.

8:12AM E23.00002: In-class use of clickers and clicker tests improve learning and enable instant feedback and retests via automated grading

SNEHALATA KADAM (Presenter), NANCY BURNHAM, Physics Department, Worcester Polytechnic Institute, ERIN DESILVA, Dartmouth College — An audience response system ("clickers") was gradually incorporated into introductory physics courses at Worcester Polytechnic Institute during the years 2011-14. Clickers were used in lectures, as a means of preparing for labs, and for collection of exam data and grading. Average student grades were 13.5% greater, as measured by comparing exam results with a previous year. Student acceptance of clickers was high, ranging from 66% to 95%, and grading time for exams was markedly reduced, from a full day to a few hours for approximately 150 students. The streamlined grading allowed for a second test on the same material for the students who failed the first one. These improvements have the immediate effects of engagement, learning, and efficiency, and ideally, they will also provide an environment in which more students will succeed in college and their careers.

*The authors are grateful to the continual and cheerful support of both the Academic Technology Center and the Morgan Teaching and Learning Center at WPI. We warmly thank Fred Hutson for proof-reading a draft of the manuscript.

ERIN DUFFY (Presenter), KINSEY BAIN, Department of Chemistry, Michigan State University, LYDIA BENDER, Department of Physics, Kansas State University, MARCOS DANIEL CABALLERO, Department of Physics and Astronomy, Michigan State University, JAMES T LAVERTY, Department of Physics, Kansas State University, STUART HOLDEN TESSMER, Department of Physics and Astronomy, Michigan State University, MELANIE M COOPER, Department of Chemistry, Michigan State University — In 2013, Michigan State University (MSU) launched an interdisciplinary project to transform introductory courses across chemistry, biology, and physics to three-dimensional learning (3DL) environments. As part of this effort, we have developed an observation protocol (the 3-Dimensional Learning Observation Protocol, or 3DLOP) to measure the extent to which instructors and students engage in scientific practices, disciplinary core ideas, and crosscutting concepts (the three dimensions) during class time. Simply put, the 3DLOP differs from other classroom observation protocols in that it does not only measure how active a class is, but rather, it measures how rich the activity is. Using the 3DLOP on videos of instructors, our goal is to measure the change in the amount of 3DL in gateway courses pre- and post-transformation. Protocol development and initial findings from using the 3DLOP on physics lecture courses will be discussed.

*This material is based upon work supported by the National Science Foundation under Grant No. 1725520.
8:36AM E23.00004: Exploring the relationship between students' online LMS performance and attitudes in an intro physics course  
MICHELLE TOMASIK (Presenter), Physics, MIT, ANINDYA ROY, Open Learning, MIT — Many educational institutions have adopted a variety of online learning platforms to offer online content. As students use these learning platforms, they leave behind digital footprints. We can construct a better understanding of students' behaviors and practices if we complement this observational clickstream dataset with other data sources -- such as the data obtained from survey instruments. In this project we combine CLASS (Colorado Learning Attitudes about Science Survey)[1] results with the online learning activities on the MITx platform (a modified version of the edX platform[2]) for an on-campus introductory physics course at MIT. CLASS is a validated and popular survey instrument, which probes students' problem-solving sophistication, confidence and their conceptual understanding, among other categories. From the edX platform, we get a detailed record of students' problem-solving efforts, and the use of posted video resources. By combining these datasources and tying them to their overall course performance, we get improved insight into student behavior and motivation that could inform the course-design process and the science of teaching and learning.

8:48AM E23.00005: Calculus-based Physics students' understanding on vectors: a comparison between engineering students and life-science students*  
DIEGO VALENTE (Presenter), XIAN WU, University of Connecticut — Students' understanding of vector concepts affects their learning outcome of introductory physics courses. We administered a research-based vector survey to test how well students understood eight essential vector concepts. Students from two calculus-based physics course sequences were recruited: engineering students from a traditional physics for engineers course sequence and life-sciences students from a general physics with calculus course. We found that even though engineering students outperformed life-sciences students, these two groups of students had difficulties answering 2D vector subtraction, dot product and cross product questions correctly. We have also analyzed whether dressing a vector problem with physical context affected student performance in the vector survey and have found that physical context had a stronger impact on the questions with lower student performance than on questions where students performed better: adding a physical context made students do worse in the 2D vector subtraction question, while for questions evaluating the dot product and the cross product, adding physical context improved student performance on these questions.

*The authors acknowledge funding from the Center for Excellence in Teaching and Learning at the University of Connecticut.

9:00AM E23.00006: Transforming the introductory physics laboratory using Jupyter Notebooks*  
EMILY WALL (Presenter), CADE SCHURZ, PAUL NAKROSHIS, University of Southern Maine — Many colleges and universities have large introductory physics lectures and a correspondingly large number of laboratory sections that are taught using a cookbook style laboratory wherein students typically gather data in one week and turn in the report the next, with no opportunity to revise or revisit the experiment. A recent article by Natasha Holmes and Carl Wieman in Physics Today (Physics Today 71, 1, 38 (2018); https://doi.org/10.1063/PT.3.3816) concluded that the standard introductory lab section did not have any measurable positive effect on student's learning in lecture. Armed with the results of their work, we have begun the process of transforming our introductory laboratory by piloting an experimental section to focus on the process of doing science, and modelling reproducible research principles by using python-based Jupyter Notebooks to analyze data and write lab reports. We will report on the results of this trial, including student learning, attitudes, and a comparison to a non-reformed section. This talk will be presented by the two upper level physics Learning Assistants that were instrumental in the design and implementation of this introductory laboratory reform.

*Funding for this project comes from the University of Southern Maine Learning Assistant Program.
9:12AM E23.00007: The power of physics to demonstrate the physics of power  SAAMI SHAIBANI (Presenter), Instruction Methods, Academics & Advanced Scholarship — The promise of nuclear fusion as a viable means of generating electricity remains elusive, even after more than half a century of effort. One reason for this lies in a low level of public awareness of the enormous potential of fusion, whereas greater awareness might lead to appropriate pressure on policymakers to cause an increase in funding. Educational resources developed to help encourage societal participation include material originally designed for the classroom[1], which is extended here by a new construct involving the D-T reaction. Use of this tool identifies how so much (energy) is available from so little (fuel), and an instructional approach to present the solution is also described. The definitive nature of the methodology produces successful student learning and it is readily adaptable to reach a broader audience in the public arena. A concomitant benefit of this strategy is the addition of another scenario to the library of real-world events[2-5], which are vastly superior to standard textbook problems but which are still accessible with standard principles.

9:24AM E23.00008: Primetime learning: collaborative and technology-enhanced studying with genuine teacher presence  PEKKA KOSKINEN (Presenter), Department of Physics, University of Jyväskylä, JONI LÄMSÄ, Department of Education, University of Jyväskylä, JUSSI MAUNUKSELA, Department of Physics, University of Jyväskylä, RAJJA HÄMÄLÄINEN, Department of Education, University of Jyväskylä, JOUNI VIIRI, Department of teacher education, University of Jyväskylä — While physics education research has introduced several effective instructional strategies, most of them still rely on traditional teacher roles, depend on the presence of classrooms, and cling to a summative assessment. Here we summoned all the lessons learned from science education research and developed a new, practical, and transformational instructional strategy, the primetime learning model.(1) We devised the model by organizing the basic elements of active learning into a theory-based four-step study process. The model is based on collaborative and technology-enhanced learning, on versatile formative assessment without a final exam, and on genuine teacher presence through intimate meetings between students and teachers. We piloted the model on two university physics courses on thermodynamics and optics and observed persistent student activity, improved retention, enjoyable learning experience, and robust learning outcomes. The model suits particularly well for courses that, in addition to the teaching subject itself, focus on teaching balanced study routines and strengthening social integration.

9:36AM E23.00009: Replacing traditional final exams with project-building in advanced undergraduate physics classes  PRATHEESH JAKKALA (Presenter), Illinois College — This paper presents the implementation of project-building replacing traditional final exams in advanced undergraduate physics classes at a small liberal arts college. Students from 'Circuits' class and 'Dynamics' class built projects using the concepts learnt throughout the semester. Projects for Circuits class were built in teams of three and projects for Dynamics class were built by individual students. Majority are original projects. A total of 18 students built 11 projects. Students were required to present their findings, conclusions and data in a scientific paper format and an oral presentation. Students were presented with challenging and open-ended real-life problems. This paper also presents the learning outcomes, and how students successfully used the classroom concepts to solve the challenging real-life problems. This paper also presents the details of all the students projects under consideration.

9:48AM E23.00010: Introducing the strong nuclear interaction and many-body physics in undergraduate quantum mechanics  BRANDON INSCOE (Presenter), JARRETT LANCASTER, High Point University — The standard treatment of spin in undergraduate quantum mechanics provides all the essential ingredients for introducing a number of exciting and contemporary topics which are of great interest to the condensed-matter and high-energy physics community but which are also rarely addressed in a meaningful way at the undergraduate level. Specifically, the color charge of quantum chromodynamics possesses a structure which is quite similar to the electron's spin degree of freedom. By considering a system of three color charges at fixed positions with Heisenberg-like interactions, one is able to construct a toy model of a baryon with tunable interaction strength in which the color charge components exhibit dynamics similar to those of interacting spin components. The system of three particles leads naturally to an exploration of three-body interactions, which are highly relevant to quantum chromodynamics. Moreover, the overall approach to investigating the system's nontrivial dynamics provides a digestible introduction to the technique of exact diagonalization in a novel, few-body quantum system. VPython is used to visualize the emergent dynamics, providing an interesting demonstration which is appropriate for a course on modern physics.
**10:00AM E23.00011: Modernizing the Undergraduate Dynamics Curriculum**  
DAVID NOLTE (Presenter), Purdue University  
— The best parts of physics are the last topics that our students ever see. These are exciting topics like the bending of light by black holes, traffic on the World Wide Web, or the synchronization of global economies. A new method for teaching upper-division mechanics provides an introduction to modern dynamics by generalizing state-space and metric-space approaches at a mathematically accessible level. Given the growing importance of dynamical systems in science and technology, this approach gives students an up-to-date foundation for their future careers, embedding topics of modern dynamics—chaos, synchronization, network theory, neural networks, evolutionary change, econophysics and relativity—within the context of traditional physics founded on Lagrangian and Hamiltonian physics. The goal is to modernize the teaching of junior-level dynamics, responsive to a changing society, while retaining the core traditions and common language of the physics of dynamics.

**10:12AM E23.00012: A program to encourage underrepresented high school students to study STEM through hands-on University-level research experience: its impact, how we did it, and what we learned**  
TREVOR GRANDPRE (Presenter), Science Education, Graduate Division, University of California, Berkeley, MIGUEL DAAL, Physics, UC Santa Barbara, KAYLEIGH A CASSELLA, DA AN, Science Education, Graduate Division, University of California, Berkeley, DANIELLE H SPELLER, Physics, Yale University, BERNARD SADOULET, RACHEL WINHELD, MATTHEW CHOW, FRANK WANG, ALVARO A LOYA VILLALPANDO, Science Education, Graduate Division, University of California, Berkeley, ARRAN TJ PHIPPS, Physics, Stanford University, TAMMIE VISINTAINER, Science Education, Graduate Division, University of California, Berkeley — Since 2007, we have offered a course that pairs small groups of ninth grade high schoolers from historically underrepresented backgrounds with graduate student researchers from STEM disciplines to complete a five week long summer research project of the graduate students' design. Our course, 'Topics in Current Research', is located at UC Berkeley and administered with the SMASH Academy, a Bay Area non-profit. In this presentation, we detail the structure of the course; discuss lessons learned in its administration; and, present findings from 10 years of data collected from the high school and graduate students showing, among other things, that after participating in the program high schoolers were more likely to feel like they belonged in STEM and more likely to consider it for a career. We hope that this program will serve as a model and motivation for other institutions to do something similar.

*This work is supported in part by the National Science Foundation Particle Astrophysics/Underground Physics Program, under Grant Number PHY-1408597.

**10:24AM E23.00013: Observation of relativistic corrections to Moseley’s law at high atomic number**  
DUNCAN C WHEELER, EMMA BINGHAM (Presenter), MICHAEL WINER, JANET MARIE CONRAD, SEAN ROBINSON, Department of Physics, Massachusetts Institute of Technology — Transitions between low-lying electron states in atoms of heavy elements lead to electromagnetic radiation with characteristic discrete energies between about 0.1 keV and 100 keV (x rays). Moseley’s law is an empirical relation, described in 1914, that supported predictions of the Bohr model of the atom. It predicts that the energy of these x rays scales as $Z^2$ while also identifying the atomic number $Z$ as the measure of nuclear charge. The foundational nature of Moseley’s experiment has led to popularity in undergraduate advanced laboratory physics subjects. We report observations of deviations from Moseley’s law in the K-alpha x-ray emission of 13 elements from $Z = 29$ to $Z = 92$. While the deviations follow the square-law predictions of the Bohr model fairly well at low Z, they become larger with increasing Z. We find that relativistic models of atomic structure are necessary to fit the full range of elements observed ($p = 0.23$ for the relativistic Bohr model). As has been argued by previous authors, measurements of relativistic deviations from Moseley's law are pedagogically valuable at the advanced lab level and accessible with modern but modest apparatus. Here, we show this value can be extended by using higher Z elements, where the effects are more dramatically observable.

**10:36AM E23.00014: In-situ differential thermal analysis and crystal growth**  
YURI JANSSEN (Presenter), KEMAR DUDLEY, Department of Physics, Farmingdale State College — Differential thermal analysis (DTA) can give valuable information on melting and freezing of mixtures that are used for flux or solution growth of single crystals for materials research, and increasing the success rate of crystal growth attempts. DTA is especially valuable as a tool for undergraduate research involving crystal growth, as it can quickly give a realistic and easy-to-understand picture at what is happening inside a growth crucible as it is hiding the cooling crystal-growth mixture from view. In the past, we have performed DTA in a dedicated instrument, with small crucibles containing exactly the same composition as the larger growth crucible in the larger growth furnace. Recently, we have started to perform in-situ DTA inside the growth furnace and on as-prepared growth samples, quickly improving crystal growth performed by undergraduate students with limited time dedicated to lab, and, moreover, on very inexpensive equipment. Here, we will present first results on these developments, and provide an outlook at possible enhancements of this in-situ technique, used by undergraduate students.

*Funding was provided by the Office of the Provost of Farmingdale State College.

8:00AM E24.00001: Measuring Electromagnetic and Gravitational Responses of Photonic Landau Levels* [Invited]
NATHAN SCHINE (Presenter), University of Chicago — Topology describes global properties insensitive to local perturbation or manipulation. Mathematical examples include knots in strings, where no manipulation of a closed loop besides cutting it can change its knottedness, and the genus (number of handles) of a closed surface, where no smooth deformation can change its number of handles. Topological materials have recently become a distinct focus in condensed matter physics, appearing famously in the quantum Hall effect and topological insulators.

Synthetic materials in which the constituent particles are photons trapped in an optical resonator offer an exciting platform on which to study topological materials. Recent efforts have realized broad control over the single-photon Hamiltonian, including a strong synthetic magnetic field for photons, and strong photon-photon interactions. In this talk, I will present how a nonplanar resonator can harbor a quantum Hall system in curved space. I will then discuss measurements of three distinct topological indices, offering insight onto their physical meaning and application. We measure the Chern number via real-space local projectors: non-reciprocal products of transmission amplitudes reveal an Aharanov-Bohm phase associated with a non-zero Chern number. Two additional topological invariants, the mean orbital spin and chiral central charge, are encoded in the variation of the local density of states near a singularity of spatial curvature, revealing a complex interplay between geometry and topology. I will conclude with a view towards the experimental introduction of interactions and the role these invariants play in characterizing topological phases of matter.

8:36AM E24.00002: Dynamically Generated Synthetic Electric Fields for Photons* PETR ZAPLETAL (Presenter), University of Cambridge, STEFAN WALTER, FLORIAN MARQUARDT, Max Planck Institute for the Science of Light, Staudtstrasse 2, 91058 Erlangen, Germany — Static synthetic magnetic fields give rise to phenomena including the Lorentz force and the quantum Hall effect even for neutral particles, and they have by now been implemented in a variety of physical systems. Moving towards fully dynamical synthetic gauge fields allows, in addition, for backaction of the particles’ motion onto the field. If this results in a time-dependent vector potential, conventional electromagnetism predicts the generation of an electric field. Here, we show how synthetic electric fields for photons arise self-consistently due to the nonlinear dynamics in a driven system. Our analysis is based on optomechanical arrays, where dynamical gauge fields arise naturally from phonon-assisted photon tunneling. We study open, one-dimensional arrays, where synthetic magnetic fields are absent. However, we show that synthetic electric fields can be generated dynamically. The generation of these fields depends on the direction of photon propagation, leading to a novel mechanism for a photon diode, inducing nonlinear unidirectional transport via dynamical synthetic gauge fields.

8:48AM E24.00003: A polarization-selective cavity inside a hollow-core optical fiber* JEREMY FLANNERY (Presenter), BEHROOZ SEMNANI, MICHAL BAJCSY, University of Waterloo — We fabricate and characterize a polarization-selective cavity inside a hollow-core optical fiber by attaching photonic-crystal (PC) membranes acting as metasurface mirrors to the end faces of a segment of such fiber. These slabs are comprised of a thin film of a dielectric material (silicon nitride) perforated with a pattern of holes where the reflective properties are dictated by the type and dimensions of the hole pattern. By breaking the x-y symmetry of the photonic crystal pattern using a rectangular lattice of elliptical holes, the mirrors become polarization-selective, i.e., the mirrors are highly reflective for one linear polarization and almost fully transparent for the orthogonal polarization. The holes of the PC slab allow injection of gasses into the hollow core of the fiber, which would not be possible if the fiber was capped with a dielectric stack mirror. The polarization selectivity is also a unique feature not possible with conventional mirrors.

This novel type of polarization dependent fiber-integrated cavity can enhance quantum optics schemes with atomic ensembles relying on cavity field and single-pass field with the ensemble by choosing the appropriate polarizations of the fields.

9:00AM E24.00004: Quantum Noise Free Thermal Noise Measurements of a Fabry-Perot Cavity  TORREY CULLEN (Presenter), Physics, Louisiana State University — As gravitational wave measurements become more sensitive, they will start to be limited by quantum back action noise. Because effects like quantum radiation pressure noise have been previously measured, the next step is to remove these effects from measurement in a process called back action cancellation. Our system, consisting of a Fabry Perot cavity with a microfabricated movable mirror, is used to demonstrate cancellation of quantum back action. We first verify the presence of this back action by measuring the light in reflection of the cavity. The cancellation is then performed by splitting the transmitted light from the cavity, sending it to two photo detectors, and cross correlating the outputs. By showing that the cross correlated output and previous measurements of thermal noise are the same, we confirm that these quantum effects have been eliminated from the measurement (because thermal noise is the next limiting noise source). These cancellations demonstrate a significant step towards the reduction of quantum radiation pressure noise effects in aLIGO and future generation detectors.

9:12AM E24.00005: Multimode Cavity Optomechanics in superfluid Helium droplets*  ANDREA AIELLO (Presenter), Marquardt's division, Max Planck Institute for the Science of Light — The “minimal” optomechanical system consists in an optical cavity with a vibrating end mirror. There is, in this case, one optical mode coupled via radiation-pressure force to one mechanical mode [1]. Recently, it was proposed a novel optomechanical system based upon millimeter-size droplets of liquid Helium magnetically levitated in vacuum where the droplet serves both as optical and mechanical resonator [2]. The optical resonances are given by the whispering-gallery modes of light and the mechanical resonances by the vibrational surface modes. These about $10^3$ resonances ranges from $2\pi \times 23$ Hz to $2\pi \times 219$ kHz [3].

In this presentation we illustrate the principal unusual characteristics of the multimode dynamics [4] of the optically excited Helium droplet and we present some preliminary results about nonlinear effects.

*This project has received funding from the European Unions Horizon 2020 research and innovation programme under grant agreement No 732894 (Hybrid Optomechanical Technologies)

9:24AM E24.00006: Towards two spin-mechanical hybrid quantum systems  EMMA ROSENFELD (Presenter), JAN GIESELER, AARON N KABCENELL, ARTHUR D SAFIRA, MARTIN SCHUETZ, MIKHAIL LUKIN, Harvard University — Hybrid quantum systems combine complimentary phenomena to enable breakthroughs in quantum mechanics, information processing, and simulation - from preparation of non-thermal states of mechanical objects, to quantum buses for long-distance entanglement of qubits. A particular hybrid quantum system with such potential can be achieved by combining the spins with a magnetic mechanical oscillator. Creating such a platform with high cooperativity is both desirable and challenging to implement: we need a large resonator zero-point motion and magnetic field gradient to maximize the coupling, while both the resonator and spin are isolated from the environment.

To address this challenge, we investigate two mechanical resonators, each of which are coupled to a spin: (i) high-Q nanobeam SiN resonators and (ii) levitated mechanical oscillators. In both cases, the small mass results in a large zero-point motion, and the geometry reduces coupling to the environment, thereby minimizing dissipation. For the spin, we use a nearby nitrogen-vacancy (NV) center defect in diamond, which features long coherence times. In this talk, we demonstrate progress towards these hybrid systems, each of which could open doors to unexplored regions of parameter space in the physics of quantum optics.
THIBAUD RUELLE, MARTINO POGGIO, FLORIS BRAAKMAN (Presenter), University of Basel — In recent years, techniques have been developed to realize concave mirror templates on the tips of optical fibers. These can be used to define tunable open-access Fabry-Perot microcavities with high finesse. The combination of spectral tunability, high finesse, intrinsic fiber coupling and uniquely small dimensions offered by these optical cavities has led to their widespread adoption in the cavity quantum electrodynamics (CQED) community and to a lesser extent in the optomechanics community.

We realize mirror templates on the tips of optical fibers using a single-shot CO2 laser ablation procedure. We perform a systematic study of the influence of the pulse power, pulse duration, and laser spot size on the radius of curvature, depth, and diameter of the mirror templates. We find that these geometrical characteristics can be tuned to a larger extent than has been previously reported, and notably observe that compound convex-concave shapes can be obtained. This detailed investigation should help further the understanding of the physics of CO2 laser ablation processes and help improve current models. We additionally identify regimes of ablation parameters that lead to mirror templates with favorable geometries for use in cavity quantum electrodynamics and optomechanics.

TIRTH SHAH (Presenter), Physics, Friedrich Alexander Universität Erlangen Nurnberg, VITTORIO PEANO, CHRISTIAN BRENDEL, Max Planck Institute for the Science of Light, OSKAR PAINTER, Applied Physics, California Institute of Technology, HANNES PFEIFER, FLORIAN MARQUARDT, Max Planck Institute for the Science of Light — We present the design of and numerical simulations for an on-chip optomechanical device that supports helical vibrations and allows all-optical excitation and read-out thereof. The device is based on a so-called optomechanical crystal, i.e. a nanostructure that supports both mechanical and optical bulk band gaps. The optomechanical crystal of interest is a patterned silicon slab. The pattern of holes has been engineered to give rise to i) topologically distinct domains separated by a domain wall of chosen shape supporting a broadband mechanical helical edge state, ii) high quality factor optical cavities that are localized close to the domain wall and display a good coupling to the helical states. As usual in optomechanics, the optomechanical coupling can be boosted by driving the optical cavities using a laser. This allows the excitation and the high-precision read out of the helical vibrations propagating along the domain wall.

*Tirth Shah acknowledges support from the European Union's Horizon 2020 Programme for Research and Innovation under grant agreement No. 722923 (Marie Curie ETN - OMT).

VICTOR BITTENCOURT (Presenter), VERENA FEULNER, SILVIA VIOLA-KUSMINSKIY, Max Planck Institute for the Science of Light — Cavity optomagnonics is an emergent field where photons couple to elementary magnetic excitations in solid state systems. For optical photons, the coupling is parametric and the magnetic material is both the optical cavity and the host of the magnetic excitations (magnons). These systems are promising for integration in hybrid quantum platforms. In this context, we propose a magnon heralding protocol to generate a magnon Fock state by detecting a cavity photon. We analyze the constraints imposed by the magnonic decay rate and by the strength of the optomagnonic coupling. We show that the detrimental thermal effects can be overcome by initially actively cooling the magnon mode. We discuss the feasibility of the proposed protocol for state of the art YIG cavity optomagnonic systems.

*The authors acknowledge the support from the Max Planck Gesellschaft through an independent Max Planck Research Group
10:12AM E24.00010: Faddeev-Kulish Asymptotic States in Cold Atom Quantum Physisorption on 2D Materials
SANGHITA SENGUPTA (Presenter), Physics, Institut quantique de l’Université de Sherbrooke — Theories with long-range interactions like QED or perturbative gravity exhibit severe infrared divergences in their scattering rates due to the emission of infinitely many soft quanta. Remarkably, a low-energy condensed matter analogue of this infamous infrared problem in QED is realized in a hybrid system of cold atoms coupled to a vibrating elastic membrane. We focus on the atom-phonon coupling of the vibrating membrane and provide procedures to address the infrared divergences. Our methods include non-perturbative techniques that can be broadly categorized into two schemes: (1) inclusion of emission of infinitely many soft-phonons and (2) dressing of asymptotic states which is similar in essence to the Faddeev-Kulish treatment of the infrared divergences in QED. We provide results for both the schemes in the spirit of the well-known exact solution of the independent boson model and discuss the validity of the results corresponding to the different scales of the infrared. In particular, we present the results of our resummation procedures for the physisorption rate of cold atomic hydrogen as function of membrane sizes and temperature.

10:24AM E24.00011: Cavity Superconductor-Polaritons
ANDREW ALLOCCA (Presenter), ZACHARY RAINES, JONATHAN CURTIS, VICTOR GALITSKI, University of Maryland, College Park — Following the success of realizing exciton-polariton condensates in cavities, we examine the hybridization of cavity photons with the closest analog of excitons within a superconductor, states called Bardasis-Schrieffer modes. Though these modes do not typically couple linearly to light, one can engineer a coupling with an externally imposed supercurrent, leading to the formation of hybridized Bardasis-Schrieffer-polariton states, which we obtain both as poles of the bosonic Green's function and through the derivation of an effective Hamiltonian picture for the model. These new excitations have nontrivial overlap with both the original photon states and d-wave superconducting fluctuations. We conjecture that their condensation could produce a finite d-wave component of the superconducting order parameter -- an $s\pm id$ superconducting state.

10:36AM E24.00012: Cavity superconductor Higgs-polaritons
ZACHARY RAINES (Presenter), ANDREW ALLOCCA, VICTOR GALITSKI, University of Maryland, College Park — Motivated by the dramatic success of cavity exciton-polariton physics we consider the formation of a polariton from cavity photons and the amplitude mode of a disordered superconductor. Enabled by the recently predicted and observed supercurrent-induced coupling between these excitations we find that significant hybridization between cavity photons and Higgs excitations in a quasi-2D superconductor can occur. We analyze the character and damping of the hybrid modes.

10:48AM E24.00013: Investigating Light-Matter Interactions Through the Coupling of Single Emitters to Bowtie Nanoantennas
NATHAN KIMMITT (Presenter), ESTHER A WERTZ, Rensselaer Polytechnic Institute — Metallic nanoparticles, which confine light into very small volumes and greatly enhance fields, have many exceptional and tunable optical properties. Nanodimers known as bowtie nanoantennas are known to have strong field enhancements and confinement to the gap between the triangles. However, due to intrinsic ohmic losses, obtaining strong coupling between an emitter and the cavity remains an issue. In this study, to elucidate the effects of the nanometric positioning of the emitter, we employ super-resolution single-molecule fluorescence techniques to study the effects of detuning, polarization, orientation, nanometer gap size, and adhesion layer have on the fluorescence properties of the dye, as well as the trapping dynamics of the system. A clear set of optimal parameters has been found, aided by finite element simulations, hinting towards obtaining the maximal coupling for single emitters in this geometry.

Session E25 DAMOP DCMP: Disorder and Localization in AMO Systems I: Time Crystals, Diffusion, Quantum Chaos 8CEC 160A - Anushya Chandran, Boston University - Tag(s): Focus
Discrete time crystals in long-range interacting systems

NORMAN YAO (Presenter), University of California, Berkeley — A generic periodically driven, isolated system will absorb energy until it looks, locally, like an infinite-temperature state. However, when the drive frequency is large compared with the local energy scales of the system, then the system can only absorb energy from the drive by spreading it out over many excitations. Consequently, heating occurs very slowly, and there is a long-lived quasi-steady state - a so-called "pre-thermal" state - in which ordered phases of matter can occur. In this context, I will describe how long-range interactions can stabilize pre-thermal time-translation symmetry breaking in one dimensional systems (even in the absence of disorder). I will begin by motivating a new definition for light-cones in power-law interacting quantum systems and using this definition, I will prove that long-range, pre-thermal time crystals naturally exhibit exponentially long lifetimes. Finally, an experimental realization of a one dimensional, pre-thermal time crystal in trapped atomic ions will be discussed.

NMR observations of discrete time crystalline signatures in an ordered crystal of ammonium dihydrogen phosphate

ROBERT BLUM (Presenter), JARED ROVNY, SEAN BARRETT, Physics, Yale University — The discrete time crystal (DTC) is a recently-described phase of driven quantum systems that breaks the discrete time translation symmetry of its drive. If the Hamiltonian has period T, the signature of a DTC is a response of period nT that is robust to "error" in the drive. Two experiments recently reported this signature in trapped ions [1] and in diamond NV centers [2]. We present signatures of DTC order [3,4] in an NMR system of 31P spins in an oriented crystal of ammonium dihydrogen phosphate (ADP), a clean sample with multiple dipolar-coupled spin species (1H, 31P, 14N). By varying the pulse angle θ and delay time τ of the DTC pulse sequence, we observe robust DTC oscillations across a much greater range in (θ, τ) than has been observed in earlier experiments [1,2], both with and without 1H decoupling.

Beyond discrete time crystal signatures: hidden coherence, causes of decay, and the first "discrete time crystal echo"

JARED ROVNY (Presenter), ROBERT BLUM, SEAN BARRETT, Physics, Yale University — The phase structure of driven quantum systems can include exotic phenomena, including the recently-described discrete time crystal (DTC). The key signature of a DTC is a response with period nT (n=2,3,...) for drive period T, even when the drive is imperfect. Two experiments recently demonstrated this signature, one in trapped ions [1] and the other in diamond NV centers [2]. We have shown this signature in an NMR system of 31P spins on a crystal lattice, with little to no disorder [3,4]. We study the decay of the DTC oscillations, with two main results. First, we use a novel "DTC echo" sequence to demonstrate that the decay is caused in part by coherent evolution. Second, we demonstrate that the observed decay for perfect pi pulses (ε = 0) can be produced by the action of the internal Hamiltonian during the pulses.
9:00AM E25.00004: Spatial-Translation-Induced Discrete Time Crystals  KAORU MIZUTA (Presenter), KAZUAKI TAKASAN, Department of Physics, Kyoto University, MASAYA NAKAGAWA, CEMS, RIKEN, NORIO KAWAKAMI, Department of Physics, Kyoto University — Time crystals, where time translation symmetry is spontaneously broken, are novel phases of matters in that they are proved to exist only in nonequilibrium[1]. In particular, time crystals in Floquet systems, called discrete time crystals (DTCs), have attracted much interest because of theoretical developments[2] and recent experimental realization[3].

In many of conventional DTCs, symmetry operation and its symmetry breaking are utilized [2], but only on-site symmetries are focused on. Therefore, we propose new DTCs named "spatial-translation-induced DTCs"(STI-DTCs), which is realized by spatial translation and its symmetry breaking[4]. By focusing on spatial translation symmetry, STI-DTCs have notable properties which do not exist in conventional DTCs - high controllability of DTC orders and nontrivial oscillation of local transport. We have also proposed a new way to realize DTCs in quantum circuits as an experimental platform.

9:12AM E25.00005: Quantum diffusion in the strong tunneling regime*  NISARGA PAUL (Presenter), ARIEL AMIR, Harvard University — We discuss the dynamics of a quantum-mechanical wavepacket in a noisy environment (i.e., time-dependent disorder), modeled using a tight-binding Hamiltonian. It has been found that the fluctuating environment may give rise to diffusive behavior (rather than Anderson localization, which occurs for time-independent disorder). We develop a new approach to this problem by considering the dynamics as arising from multiple Landau-Zener crossing events. We find the conditions for the validity of the approach, and use it to calculate how the diffusion constant depends on the noise. The analytical results are corroborated numerically. The results may be applicable to exciton diffusion in photosynthesis and electronic transport in solid-state physics.

9:24AM E25.00006: Quantum-Spin Diffusion Driven by Ergodic and Non-Ergodic Finite Spin Baths  WALTER HAHN (Presenter), VIATCHESLAV DOBROVITSKI, TU Delft, QuTech — We investigate spin diffusion driven by a finite quantum spin bath in a system accessible for solid-state NMR experiments; namely polycrystalline L-alanine. The direct spin transport within the subsystem consisting of dipolar coupled carbon spins is suppressed due to disorder given by different Larmor frequencies. Spin diffusion is, therefore, governed by the surrounding network of proton spins-1/2. This proton network consists of strongly coupled groups which are weakly interacting among each other. By means of numerical simulations, we model realistic solid-state NMR experiments. We show that nearby proton spins govern the local magnetic field for carbon spins, while the farther proton spins determine dynamics within the proton bath. In particular, the farther proton spins provide ergodicity in the proton bath and, thereby, drastically change the spin diffusion in the carbon subsystem. We also consider deuterated alanine with all proton spins-1/2 replaced by deuteron spins-1. For deuterated L-alanine, we show that the local magnetic fields created by deuterons is insufficient to allow for spin diffusion due to the small magnetic dipole moment of deuterons. Instead, spin diffusion is governed by the spin-lattice relaxation of deuteron spins on much larger time scales.

9:36AM E25.00007: Signatures of Quantum Chaos in Classically Non-Chaotic Systems  EFIM ROZENBAUM (Presenter), University of Maryland, College Park, LEONID BUNIMOVICH, School of Mathematics, Georgia Institute of Technology, VICTOR GALITSKI, University of Maryland, College Park — One of the original goals in the field of quantum chaos was to establish a correspondence between the dynamics of chaotic classical systems and their quantum counterparts. The general issue is that quantum-mechanical interference washes out classical chaos after a very short (logarithmic) time, and the correspondence breaks down. Recently, out-of-time-ordered correlator, a universal tool to study quantum chaos, has received a lot of attention due to its versatility and natural interpretation. We use this diagnostic to show that a new kind of drastic disagreement can occur between quantum and classical counterparts of the same model. Remarkably, quantum mechanics appears capable of playing the opposite to its usual role. In particular, it brings chaos to a family of classically non-chaotic systems, where on the quantum side, we demonstrate the Lyapunov-like exponential growth of OTOC.
9:48AM E25.00008: The longest-lived current in a quantum chaotic spin chain  ARNOLD K. MONG (Presenter), DAVID HUSE, Princeton University — To explore issues of numerically capturing dissipative dynamics in closed many-body quantum systems, we have studied the relaxation of nonconserved current operators in a certain quantum chaotic spin chain. The Hamiltonian is a translationally-invariant spin-1/2 chain with nearest-neighbor XY interactions and a tilted field that breaks the conservation of total Z magnetization. We look at an infinite chain and examine the relaxation of all “current” operators that have total momentum zero and are odd under spatial inversion. The relaxation is via operator spreading; a unitary flow in operator space from simple short Pauli strings to long (and thus nonlocal) Pauli strings. To approximate this numerically, we limit the length of the Pauli strings and introduce an artificial nonunitary damping that acts only on the longest Pauli strings that we keep, and solve exactly for the longest-lived current operator in this approximation. We find that there is a regime of this artificial damping where we obtain a good approximation to the correct unitary dynamics, while in other regimes the artificial damping causes a blockage of the proper unitary flow in operator space and, as a result of this “bad plumbing”, gives incorrect results.

10:00AM E25.00009: Quantum Chaos for the Unitary Fermi Gas from the Generalized Boltzmann Equations  PENGFEI ZHANG (Presenter), Tsinghua University — we study the chaotic behavior of the unitary Fermi gas in both high and low temperature limits by calculating the Quantum Lyapunov exponent defined in terms of the out-of-time-order correlator. We take the method of generalized Boltzmann equations derived from the augmented Keldysh approach. At high temperature, the system is described by weakly interacting fermions with two spin components and in the low temperature limit, the system is a superfluid and can be described by phonon modes. By comparing these to existing results of heat conductivity, we find that $D \ll v^2 \tau_L$. We argue that this is related to conservation laws for such systems with quasi-particles.

10:12AM E25.00010: Chaos and integrability in experimentally accessible all-to-all spin models*  GREGORY BENTSEN, Stanford University, THOMAS SCAFFIDI, VIR BULCHANDANI (Presenter), IONUT-DRAGOS POTIRNICHE, University of California, Berkeley, MONIKA SCHLEIER-SMITH, Stanford University, EHUD ALTMAN, University of California, Berkeley — In recent years, models of disordered fermions with random, all-to-all couplings have emerged as prime candidates for studying the limit of strong chaos in quantum mechanical systems. However, such models are prohibitively difficult to realize experimentally. By contrast, spin models with random, all-to-all couplings can be engineered in the context of cavity QED and could provide an opportunity to probe strongly interacting, disordered physics in the laboratory. We show that the class of models most naturally realized in this system has the unusual property of possessing two integrable points in its phase diagram. We construct the integrals of motion explicitly and propose a method to directly measure their characteristics in the experiment. This scheme raises the possibility of tuning the system between classical and quantum physics on the one hand, by varying the effective spin per site, and between integrable and chaotic physics on the other, by varying the effective cavity interactions.

10:24AM E25.00011: Scrambling in the Dicke model*  YAHYA ALAVIRAD (Presenter), SEYED ALI HOSSEINI LAVASANI, University of Maryland, College Park — The scrambling rate $\lambda_L$ associated with the exponential growth of out-of-time-ordered correlators can be used to characterize quantum chaos. Here we use the Majorana Fermion representation of spin $1/2$ systems to study quantum chaos in the Dicke model. We take the system to be in thermal equilibrium and compute $\lambda_L$ throughout the phase diagram to leading order in $1/N$. We find that the chaotic behavior is strongest close to the critical point. At high temperatures $\lambda_L$ is nonzero over an extended region that includes both the normal and super-radiant phases. At low temperatures $\lambda_L$ is nonzero in (a) close vicinity of the critical point and (b) a region within the super-radiant phase. In the process we also derive a new effective theory for the super-radiant phase at finite temperatures. Our formalism does not rely on the assumption of total spin conservation.

Quantum inverse freezing and mirror-glass order* THOMAS IADECOLA (Presenter), MICHAEL SCHECTER, Joint Quantum Institute and Condensed Matter Theory Center, University of Maryland — It is well known that spontaneous symmetry breaking in one spatial dimension is thermodynamically forbidden at finite energy density. Here we show that mirror-symmetric disorder in an interacting quantum system can invert this paradigm, yielding spontaneous breaking of mirror symmetry only at finite energy density and giving rise to "mirror-glass" order. The mirror-glass transition, which occurs via the energetic activation of a finite density of emergent Ising degrees of freedom, is enabled by many-body localization and appears to occur simultaneously with the localization transition. This counterintuitive manifestation of localization-protected order can be viewed as a quantum analog of inverse freezing, a phenomenon that occurs, e.g., in certain models of classical spin glasses.

*We acknowledge support from the Laboratory for Physical Sciences and Microsoft. T.I. acknowledges a JQI postdoctoral fellowship.

Out of Time Ordered Correlators in the Random Field XX Spin Chain* JONATHON RIDDELL (Presenter), ERIK SORENSEN, Physics and Astronomy, McMaster University — We study out of time order correlations, $C(x,t)$ and entanglement growth in the random field XX model with open boundary conditions using the exact Jordan-Wigner transformation to a fermionic Hamiltonian. For any non-zero strength of the random field this model describes an Anderson insulator. Two scenarios are considered: A global quench with the initial state corresponding to a product state of the Néel form, and the behaviour in a typical thermal state at $\beta=1$. As a result of the presence of disorder the information spreading as described by the out of time correlations stops beyond a typical length scale, $\xi_{\text{OTOC}}$. For $|x|<\xi_{\text{OTOC}}$ information spreading occurs at the maximal velocity $v_{\text{max}}=J$ and we confirm predictions for the early time behaviour of $C(x,t)-t^2|x|$.

Session E26 DQI: Driven and Dissipative Superconducting Circuits BCEC 160B - Shyam Shankar, Yale Univ

Observation of the parity-time symmetry breaking transition in a dissipative superconducting qubit* MAHDI NAGHILOO (Presenter), MARYAM ABBASI, Physics, Washington University in St. Louis, YOGESH N JOGLEKAR, Physics, Indiana University-Purdue University Indianapolis (IUPUI), KATER MURCH, Physics, Washington University in St. Louis — Non-Hermitian systems that exhibit parity-time (PT) symmetry have been recently studied in electrical, optical, and mechanical classical systems revealing applications in non-reciprocal devices and sensing. While questions have remained as to whether PT-symmetric systems are realizable in the quantum regime due to the role of quantum noise in amplifiers, the topological features associated with PT-symmetric Hamiltonians are shared by dissipative systems with selective losses, which can be realized at the quantum level. We employ bath engineering techniques to realize a non-Hermitian Hamiltonian that has effective PT symmetry for a superconducting circuit. We use quantum state tomography to observe the PT symmetry breaking transition as manifested in the evolution of both diagonal and off-diagonal elements of the qubit density matrix.

8:12AM E26.00002: An experimental implementation for stabilizing Schrödinger cat states in a Kerr nonlinear resonator - Basic concepts* NICHOLAS FRATTINI (Presenter), ALEXANDER GRIMM, SHANTANU O. MUNDHADA, SHRUTI PURI, STEVEN TOUZARD, Applied Physics, Yale University, MAZYAR MIRRAHIMI, INRIA Paris and Yale University — Schrödinger cat states of microwave light based on superpositions of coherent states in a superconducting resonator can be used as error-protected qubits as well as auxiliary systems for fault-tolerant quantum computation. It has recently been shown that such states can be stabilized by applying a two-photon drive to a Kerr nonlinear resonator. In this talk, we will give an introduction on this type of qubit and its potential uses in quantum computation before discussing an experimental implementation. Our system is based on a modified, low-anharmonicity, transmon qubit. Instead of a Josephson junction, we use a Superconducting Nonlinear Asymmetric Inductive eLement (SNAIL) providing us with both three- and four-wave-mixing terms. This simultaneously implements the required nonlinearity and gives us access to a strong two-photon drive. We will report on the details of this implementation and present our progress towards the realization of this stabilization scheme. Part one of this two-part presentation will introduce the basic concept of this qubit and its uses in quantum information.

8:36AM E26.00004: Directional Quantum State Transfer by Dissipation I – Conceptual Overview* CHEN WANG (Presenter), JEFFREY GERTLER, University of Massachusetts Amherst — Quantum state transfer from an information-carrying qubit to a receiving qubit is ubiquitous for quantum information technology. In a closed quantum system, this task requires precisely-timed control of coherent qubit-qubit interactions that are intrinsically reciprocal. Here, breaking reciprocity by dissipation in an open system, we propose a type of cascaded quantum systems where a quantum state can be spontaneously transferred between stationary qubits without time-dependent control. We show that the minimum system dimension for transferring one qubit of information in this way is 3x2 (between one physical qutrit and one physical qubit), plus one auxiliary reservoir. We discuss general requirements and strategies for such autonomous quantum state transfer as well as its connection with autonomous quantum error correction. We further discuss physical implementation schemes, with our experimental progress in a superconducting circuit QED platform to be described in a following presentation.

**8:48AM E26.00005: Directional Quantum State Transfer by Dissipation II – Implementation in Circuit QED**

JEFFREY GERTLER (Presenter), CHEN WANG, Physics, University of Massachusetts Amherst, XIAOWEI DENG, Physics, University of Massachusetts Amherst and Southern University of Science and Technology, China — Dissipation is a remarkable resource in quantum information processing that can be used to stabilize and manipulate quantum states or manifolds. Here we utilize dissipation to implement an autonomous technique for quantum state transfer, with built-in directionality, that eliminates the need for time dependent external control. We report experimental progress towards this state transfer in a 3D superconducting circuit QED system between a three-level transmon (Alice) and a coaxial storage cavity (Bob). The quantum state is irreversibly transferred from Alice to Bob via dissipation of a coupled axillary transmon reservoir, activated by two four-wave mixing processes produced by off-resonant drives. Using virtual states of the reservoir to compensate for unwanted dispersive frequency shift, we show that quantum coherence can be maintained throughout the dissipative process, leading to high-fidelity state transfer which is limited by inherent qubit/cavity decoherence.

*This research was supported by the U.S. Air Force Office of Scientific Research and the U.S. Army Research Office.

**9:00AM E26.00006: Reconstructing Josephson Current-Phase Relations with Intermodulation Spectroscopy**

SHAN JOLIN (Presenter), THOMAS WEISSL, RICCARDO BORGANI, DAVID HAVILAND, Nanostructure Physics, KTH Royal Institute of Technology — When driving with multiple tones, a nonlinear system will give rise to intermodulation, or frequency mixing. Two drive tones placed near a nonlinear resonance produces a comb of intermodulation products. We present a method based on matrix inversion to reconstruct the nonlinearity from a measurement of this comb [1, 2]. We apply this method to a microwave frequency comb generated from a Nb-coplanar waveguide resonator with Josephson weak-links. This method is useful for accurate characterization of nonlinearities in superconducting quantum circuits.

*The authors acknowledge financial support from Knut and Alice Wallenberg Foundation.

**9:12AM E26.00007: Dissipation-free non-Hermitian physics using quantum parametric amplifiers**

YUXIN WANG (Presenter), AASHISH CLERK, Institute for Molecular Engineering, University of Chicago — There has been considerable interest in driven-dissipative systems governed by non-Hermitian effective Hamiltonians. These systems can exhibit a range of unusual phenomena, such as the spontaneous breaking of parity-time (PT) symmetry [1], and chiral effects associated with encircling exceptional points [1]. Quantum versions of these effects are however often compromised by their dissipative nature. Here, we show that many of these non-Hermitian effects can be realized in a completely non-dissipative setting, by exact unitary mappings to parametrically-driven bosonic setups. Applications of these mappings include enhanced quantum sensing using exceptional points, and chiral switching based on encircling of exceptional points. Our approach could be implemented experimentally using superconducting quantum circuits, or in optomechanical systems.

**9:24AM E26.00008: Driven Kerr resonators: new regimes of solvability and quantum bistability**

DAVID ROBERTS (Presenter), Physics, University of Chicago, AASHISH CLERK, Institute for Molecular Engineering, University of Chicago — The driven Kerr resonator is one of the most iconic solvable models in cavity QED [1]. When subject to two-photon (parametric) driving it can exhibit bistability, something that has been exploited in several recent experiments in circuit quantum electrodynamics and proposals for protected quantum memories [2, 3]. Here, we develop a more physically transparent method for finding analytic solutions to driven Kerr resonators. This allows us to solve for a wider class of systems than in previous work, and also allows us to derive closed-form expressions for steady-state Wigner functions. More intriguingly, our approach also uncovers a new class of previously-overlooked points of quantum bistability in the resonator's phase diagram. Our work could open up new avenues for using nonlinear driven superconducting quantum circuits as quantum processors.

Motivation and modelization*  JAYAMEENAKSHI VENKATRAMAN (Presenter), XU XIAO, CLARKE SMITH, Applied Physics, Yale University, ZAKI LEGHTAS, Centre Automatique et Systèmes, Mines ParisTech, LUCAS VERNEY, QUANTIC, INRIA, Paris, MAZYAR MIRRAHIMI, QUANTIC, INRIA, Paris; YQI, Yale University, SHYAM SHANKAR, Applied Physics, Yale University, IOAN-MIHAI POP, Physics, Karlsruhe Institute of Technology, MICHEL H. DEVORET, Applied Physics, Yale University — The transmon is ubiquitous in circuit QED experiments due to its remarkable coherence properties and simplicity of design and fabrication. However, when strongly driven at microwave frequencies, the transmon exhibits various kinds of instabilities. Floquet-Markov theory indeed predicts such instabilities. Shunting the transmon with a linear inductance qualitatively changes the potential seen by the phase, thus increasing the device stability under certain conditions. We call the resulting qubit the inductively-shunted transmon (IST) to distinguish it from the RF SQUID. Comparison of driven transmons and ISTs with different implementations offers insights in eliminating these instabilities, and also sheds light on the fundamental problem of chaos in a strongly driven dissipative quantum system. This talk will focus on the motivation and modelization.

9:48AM E26.00010: Quantum Electrodynamic Modeling of Superconducting Circuits* [Invited]  HAKAN TURECI (Presenter), Princeton University — The demand for rapid and high-fidelity execution of initialization, gate and read-out operations casts tight constraints on the accuracy of quantum electrodynamic modeling of superconducting integrated circuits. Attaining the required accuracies requires reconsidering our basic approach to the quantization of the electromagnetic field in spatially inhomogeneous waveguides and the notion of normal modes. I will discuss a computational framework based on the Heisenberg-Langevin approach to address these fundamental questions. This framework allows the accurate determination of the quantum dynamics of a superconducting qubit in an arbitrarily complex electromagnetic environment infinite in extent, for any coupling strength and any degree of openness. This includes the regime of overlapping resonances and the “ultra-strong coupling” regime. I will also discuss the effectiveness of this computational approach in meeting the demands of present-day quantum computing research.

This work has been carried out with Moein Malekakhlagh, Alex T. Petrescu and Saeed Khan.

10:36AM E26.00012: Bistability and Critical Slowing Down in Superconducting Circuits  PAUL BROOKES (Presenter), University College London, GIOVANNA TANCREDI, Chalmers University of Technology, THEMIS MAVROGORDATOS, Stockholm University, ANDREW D PATTERTON, JOSEPH RAHAMIM, MARTINA ESPOSITO, PETER LEEK, University of Oxford, ERAN GINOSSAR, University of Surrey, MARZENA HANNA SZYMANSKA, University College London — We carry out an experimental and numerical examination of bistability and critical slowing down in the strongly driven non-linear regime of circuit QED. The system under study is a 3D microwave cavity coupled to a transmon qubit. By measuring the response of the cavity to a step function drive pulse, we see that in the bistable regime the time required for the system to reach equilibrium is far longer than both the cavity and qubit relaxation times. We observe that this equilibration time saturates at high drive powers. Through careful modelling we are able to attribute this saturation to phase noise of the transmon. In addition we demonstrate that the equilibration time is highly sensitive to the temperature of the cavity.
Sizeable photon-photon interactions in networks of nonlinear oscillators enable the study of strongly correlated photons in non-equilibrium quantum many-body systems. We present a system composed of two superconducting resonators, coupled nonlinearly by a superconducting quantum interference device (SQUID). By applying a parametrically modulated magnetic flux we control the linear photon hopping rate between the two resonators and its ratio with the cross-Kerr rate. When increasing the hopping rate we observe a fully controllable crossover in the spatial correlations of the photonic fields of the two resonators, from photon self-ordering to delocalization of photons. The presented parametric coupling scheme is intrinsically robust to frequency disorder and may therefore prove useful for realizing larger-scale resonator arrays, and in turn facilitate active control of extended correlated quantum gases for the purpose of emulating other less accessible quantum systems.

Session E27 DQI DQI: Quantum Machine Learning I BCEC 160C - Daniel Kyungdeock Park, KAIST - Tag(s): Focus

8:00AM E27.00001: Improved Training of Quantum Boltzmann Machines
ERIC ANSCHUETZ (Presenter), YUDONG CAO, Zapata Computing — Quantum Boltzmann machines (QBMs) are a natural quantum generalization of restricted Boltzmann machines (RBMs) that, at least under numerical simulation, perform better than their classical counterparts in learning generic data distributions. However, training QBMs using gradient-based methods requires sampling observables in quantum thermal distributions, a problem that generically is NP-hard. In this work, we find that the locality of the gradient observables that must be sampled gives rise to an efficient sampling method based on the Eigenstate Thermalization Hypothesis (ETH), and thus an efficient method for training QBMs on quantum devices. Furthermore, we demonstrate a hybrid gradient-based/black box optimization procedure that outperforms strictly gradient-based training methods.

8:12AM E27.00002: Measurement-based adaptation protocol with quantum reinforcement learning
LUCAS LAMATA (Presenter), University of the Basque Country, FRANCISCO ALBARRÁN-ARRIAGADA, JUAN CARLOS RETAMAL, Universidad de Santiago de Chile, ENRIQUE SOLANO, University of the Basque Country — Machine learning employs dynamical algorithms that mimic the human capacity to learn, where the reinforcement learning ones are among the most similar to humans in this respect. On the other hand, adaptability is an essential aspect to perform any task efficiently in a changing environment, and it is fundamental for many purposes, such as natural selection. Here, we propose an algorithm based on successive measurements to adapt one quantum state to a reference unknown state, in the sense of achieving maximum overlap. The protocol naturally provides many identical copies of the reference state, such that in each measurement iteration more information about it is obtained. In our protocol, we consider a system composed of three parts, the "environment" system, which provides the reference state copies; the register, which is an auxiliary subsystem that interacts with the environment to acquire information from it; and the agent, which corresponds to the quantum state that is adapted by digital feedback with input corresponding to the outcome of the measurements on the register. F. Albarrán-Arriagada, J. C. Retamal, E. Solano, and L. Lamata, Phys. Rev. A 98, 042315 (2018).
8:24AM E27.00003: Improving training of Boltzmann machines with error corrected quantum annealing* RICHARD LI (Presenter), DANIEL A LIDAR, University of Southern California — Boltzmann machines, a class of machine learning models, are the basis of several deep learning methods that have been successfully applied to both supervised and unsupervised machine learning tasks. Quantum annealing may help lead to future advances in the development of these learning algorithms, but its usefulness is determined in part by the effective temperature. We have applied nested quantum annealing correction (NQAC) to do unsupervised learning with a small bars and stripes (BAS) dataset, and to a coarse-grained MNIST dataset, which consists of black-and-white images of hand-written integers, to do supervised learning. For both datasets, we demonstrate an effective temperature reduction with NQAC that leads to an increase in learning performance. We also find better performance overall with longer annealing times and offer some interpretation of the results based on comparison to simulated quantum annealing (SQA) simulations.

8:36AM E27.00004: Opportunities and Challenges in Quantum-Assisted Machine Learning [Invited] ALEJANDRO PERDOMO (Presenter), Rigetti Computing — With quantum computing technologies nearing the era of commercialization and quantum advantage, machine learning (ML) is promising as one of the promising "killer" applications. Despite significant effort, there has been a disconnect between most quantum ML proposals, the needs of ML practitioners, and the capabilities of near-term quantum devices towards a conclusive demonstration of a meaningful quantum advantage in the near future. In this talk, we provide concrete examples of intractable ML tasks that could be enhanced with near-term devices. We argue that to reach this target, the focus should be on areas where ML researchers are struggling, such as generative models in unsupervised and semi-supervised learning, instead of the popular and more tractable supervised learning tasks. We focus on hybrid quantum-classical approaches and illustrate some of the key challenges we foresee for near-term implementations.

9:12AM E27.00005: Quantum generative adversarial learning in a superconducting quantum circuit HU LING, Tsinghua University, SHUHAO WU, USTC, WEIZHOU CAI, YUWEI MA (Presenter), XIANGHAO MU, YUAN XU, HAIYAN WANG, YIPU SONG, DONG-LING DENG, Tsinghua University, CHANG-LING ZOU, USTC, LUYAN SUN, Tsinghua University — Generative adversarial learning is one of the most exciting recent breakthroughs in machine learning—a subfield of artificial intelligence that is currently driving a revolution in many aspects of modern society. It has shown splendid performance in a variety of challenging tasks such as image and video generations. More recently, a quantum version of generative adversarial learning has been theoretically proposed and shown to possess the potential of exhibiting an exponential advantage over its classical counterpart. Here, we report the first proof-of-principle experimental demonstration of quantum generative adversarial learning in a superconducting quantum circuit. We demonstrate that, after several rounds of adversarial learning, a quantum state generator can be trained to replicate the statistics of the quantum data output from a digital qubit channel simulator, with a high fidelity (98.8% on average) that the discriminator cannot distinguish between the true and the generated data. Our results pave the way for experimentally exploring the intriguing long-sought-after quantum advantages in machine learning tasks with noisy intermediate-scale quantum devices.

9:24AM E27.00006: Noncommutative Boltzmann Machines* MARK NOVOTNY (Presenter), Mississippi State University — Building on the 2018 paper on quantum Boltzmann Machines (qBM) by Amin et al [1], the concept of noncommutative Boltzmann Machines (ncBM) is introduced. ncBM contain qBM as a subset, but can be viewed, for example, as machine learning with superoperators. In particular, we study ncBM with the Liouvillian superoperator, and show the negative phase of machine learning becomes easy to calculate in a particular limit. Both Bernoulli data sets [1] and quantum dragon datasets [2] are utilized for both generative and discriminative learning. Possibilities of using near-term adiabatic quantum annealing machines for ncBM will be discussed.

9:36AM E27.00007: Hybrid quantum-classical schemes for generative adversarial learning: HQGANs*  JHONATHAN ROMERO (Presenter), Harvard University, ALAN ASPURU-GUZIK, University of Toronto, Department of Chemistry, and Computer Science — Quantum computing and machine learning are two fast-growing research areas. Recently, these two areas have been merged into the field of quantum machine learning (QML), seeking to find ways in which quantum computers can offer advantages at solving machine learning problems over classical computers. Here, we propose to use quantum computers to learn models that mimic observed data distributions, a type of task known as generative learning, by substituting neural networks with variational quantum circuits in the generative adversarial networks (GANs) framework. GANs are statistical models that learn to sample from an observed data distribution by looking at individual samples. They consist of two neural networks, known as the discriminator and the generator, competing against each other in a minimax game. We propose a hybrid-quantum classical scheme that trains two variational quantum circuits, playing the role of discriminator and generator, to perform the same task on classical data. The proposed hybrid quantum GANs (HQGANs) might benefit machine learning by improving the ability to model more complex data distributions and could offer a new niche of applications for near-term quantum computers.

9:48AM E27.00008: Variational circuits for machine learning with near-term devices  MARIA SCHULD (Presenter), University of KwaZulu-Natal and Xanadu — Variational circuits are parameter-dependent quantum algorithms that can be optimized for a certain task. One approach in quantum machine learning is to interpret these circuits as machine learning models that can be trained to generalise from data. Such models are often referred to as variational quantum classifiers. This talk will focus on various issues around this approach, for example how to think about the power of variational quantum classifiers, how we can train them and what they might be good for.

10:00AM E27.00009: Quantum Manifold Learning Algorithms for Dimensionality Reduction  XI HE (Presenter), LI SUN, XIAOKAI HOU, XIAOTING WANG, University of Electronic Science and Technology of China — Manifold learning is a kind of method which discusses the machine learning problems under the manifold hypothesis. It assumes that the sampled high-dimensional data actually comes from the embedding of some low-dimensional manifold structure. Manifold learning has wide range of applications in dimensionality reduction and data visualization. In the field of manifold learning, two most representative and commonly used algorithms are isometric mapping and locally linear embedding. Using techniques of quantum computing, we research out two quantum algorithms in correspondence to them. Compared with corresponding classical algorithms, the two quantum algorithms proposed in this paper can be implemented on a quantum computer with quantum speed-up. Quantum isometric mapping provides at least quadratic acceleration and quantum locally linear embedding takes logarithmic resources. In addition, we attempt to find out a common process to deal with quantization of manifold learning algorithms.

10:12AM E27.00010: Differentiable Quantum Circuits and Generative Modeling*  JINGUO LIU (Presenter), LEI WANG, Institute of Physics, Chinese Academy of Sciences — We present a fresh approach to quantum machine learning by using quantum circuits as probabilistic generative models. The proposed QCBM overcomes the challenging problem in training implicit density models with discrete outputs in deep learning. The key component of our gradient-based learning algorithm is to measure the gradient of the two sample test loss function on a quantum computer unbiasedly and efficiently. With the inspiration of matrix product state, we are able to train a Born machine to generate intermediate-scale images with number of qubits much less than pixel numbers. We demonstrate the generative power of these learning schemes with our new Julia quantum circuit simulator Yao.jl [1]. With Yao.jl, one can simulate quantum machine learning models, quantum optimization algorithms and quantum chemistry problems efficiently and easily. We combined our framework with state of art machine learning framework like Zygote.jl, aiming for quantum software 2.0: "Automatic Differentiable Quantum Circuits".

10:24AM E27.00011: Machine-learned QCVV for distinguishing single-qubit noise*  
TRAVIS SCHOLTEN (Presenter), T. J. Watson Research Center, IBM, YI-KAI LIU, NIST, KEVIN YOUNG, Sandia National Laboratories, ROBIN BLUME-KOHOUT, Center for Computing Research, Sandia National Laboratories — We investigate the use of machine learning (ML) algorithms for developing new QCVV protocols. ML algorithms learn approximations to functions that relate experimental data to some property of interest. As an example, we show ML algorithms can successfully learn separating surfaces for distinguishing coherent and stochastic noise affecting a single qubit. The performance of various ML algorithms depends strongly on the geometry of experimental data (in this case, data from gate set tomography experiments). We show performance can be boosted by hyperparameter tuning and feature engineering.

10:36AM E27.00012: Quantum optical neural networks for next generation quantum information processing*  
GREGORY R STEINBRECHER, Research Laboratory of Electronics, Massachusetts Institute of Technology, JONATHAN OLSON (Presenter), Zapata Computing, DIRK R. ENGLUND, JACQUES CAROLAN, Research Laboratory of Electronics, Massachusetts Institute of Technology — Physically motivated quantum algorithms for specific near-term quantum hardware will likely be the next frontier in quantum information science. Here, we show how many of the features of neural networks for machine learning can naturally be mapped into the quantum optical domain by introducing the quantum optical neural network (QONN). Through numerical simulation and analysis we train the QONN to perform a range of quantum information processing tasks, including protocols for quantum optical state compression, reinforcement learning, and black-box quantum simulation. Our results indicate QONNs are a powerful design tool for quantum optical systems and a promising architecture for next generation quantum processors.

Yale Univ - Tag(s): Focus

8:00AM E28.00001: Quantum dynamics and fluctuating Hamiltonians: controlling many-body decoherence  
AURELIA CHENU (Presenter), AVADH SAXENA, Los Alamos National Laboratory, ADOLFO DEL CAMPO, University of Massachusetts — Beating decoherence and dissipation is a core problem to develop quantum computation and quantum technologies. While tailoring the environment-system coupling has been proposed as a solution, techniques to engineer the required many-body decoherence in the laboratory remain to be developed. Instead, the stochastic fluctuations naturally present on any platform can be harnessed as a resource to tailor the dynamics. I will present a versatile scheme for the quantum simulation of the open dynamics of a many-body system embedded in an environment to which it couples via arbitrary many-body interactions. This approach exploits current technology for digital and analog quantum simulation of unitary dynamics harnessing noise as a resource, and can be readily implemented in various quantum experimental platforms such as trapped ions, superconducting circuits and cold atoms, thus finding widespread applications in quantum simulation and computation, quantum chemistry and biology.
Gradient-based optimal control of open systems using quantum trajectories and automatic differentiation* MOHAMED ABDELHAFEZ (Presenter), DAVID SCHUSTER, University of Chicago, JENS KOCH, Northwestern University — We present a gradient-based optimal-control technique for open quantum systems that utilizes quantum trajectories. Using trajectories allows for optimizing open systems with less computational cost than the regular density matrix approaches. In addition, we propose an improved sampling algorithm to minimize the required number of trajectories needed per optimization iteration. Together with employing stochastic gradient descent techniques, this reduces the complexity of optimizing realistic open quantum systems. Our optimizer harnesses automatic differentiation to provide flexibility in optimization and to suit the different constraints and diverse parameter regimes of real-life experiments. The optimizer is utilized in a variety of applications to demonstrate how the use of quantum trajectories significantly reduces the computation complexity while achieving a multitude of simultaneous optimization targets. Demonstrated targets include high state transfer fidelities despite dissipation, and maximizing the readout fidelities of a qubit while maintaining the quantum non-demolition nature of the measurement and allowing for subsequent fast resonator reset.

Dissipative self-interference and robustness of continuous error-correction to miscalibration VICTOR ALBERT (Presenter), Caltech, KYUNGJOO NOH, Yale, FLORENTIN REITER, Harvard — We derive an effective equation of motion within the steady-state subspace of a large family of Markovian open systems (i.e., Lindbladians) subject to perturbations of their Hamiltonians and system-bath couplings [1]. We derive a set of conditions under which competing dissipative processes destructively interfere, producing no dissipation within the steady-state subspace. Due to the mildness of the conditions, such destructive interference turns out to be much more generic than expected. For quantum error-correction, these effects imply that continuously error-correcting Lindbladians are robust to calibration errors, including miscalibrations consisting of operators undetectable by the code. A similar interference is present in more general systems if one implements a particular Hamiltonian drive, resulting in a coherent cancellation of dissipation. On the opposite extreme, instead of suppressing dissipation, we provide a simple implementation of universal Lindbladian simulation.

A Quantum Law of Requisite Variety* DAVIDE GIROLAMI (Presenter), Los Alamos National Laboratory — The Law of Requisite Variety was the first attempt to quantify the ability of a controller to shield information-processing systems against error sources. It was then rediscovered in classical control theory, complexity science and computational mechanics. I here extend it to the quantum domain, establishing information-theoretic limits to the controllability of open quantum systems in terms of the resources available to the controller, quantum coherence and correlations. I also introduce a measure of controllability to capture the influence exerted on a system by a controlling device. I verify the result by implementing a control protocol in the IBM 5-qubit chip "ibmqx4".

*Los Alamos National Laboratory, project 20180702PRD1

Conditions allowing error correction in driven qubits* ROBERT THROCKMORTON (Presenter), University of Maryland, College Park — We consider a qubit that is driven along its logical z axis, with noise along the z axis in the driving field Ω proportional to some function f(Ω), as well as noise along the logical x axis. We establish that whether or not errors due to both types of noise can be canceled out, even approximately, depends on the explicit functional form of f(Ω) by considering a power law form, f(Ω) ∝ Ω^k. In particular, we show that such cancellation is impossible for k = 0, 1, or any even integer. However, any other odd integer value of k besides 1 does permit cancellation; in fact, we show that both types of errors can be corrected with a sequence of four square pulses of equal duration. We provide sets of parameters that correct for errors for various rotations and evaluate the error, measured by the infidelity, for the corrected rotations versus the naive rotations. We also consider a train of four trapezoidal pulses, which take into account the fact that there will be, in real experimental systems, a finite rise time, again providing parameters for error-corrected rotations that employ such pulse sequences. Our dynamical decoupling error correction scheme works for any qubit platform as long as the errors are quasistatic.

*This work is supported by the Laboratory for Physical Sciences.
9:00AM E28.00006: Parametrically-mediated Dissipative Entanglement Generation  EMERY DOUCET (Presenter), Physics and Applied Physics, University of Massachusetts Lowell, FLORENTIN REITER, Physics, Harvard University, LEONARDO M RANZANI, Raytheon BBN Technologies, RAYMOND SIMMONDS, JOSE AUMENTADO, NIST - Boulder, ARCHANA KAMAL, Physics and Applied Physics, University of Massachusetts Lowell — Dissipative state preparation provides a powerful alternative to traditional gate-based state preparation protocols. Rather than generating the desired state through a sequence of unitary operations, dissipative protocols engineer always-on interactions with the environment such that the system autonomously converges to the desired state. Such an approach allows improved robustness to initialization errors and decoherence. Nonetheless, dissipative state preparation methods realized thus far have the limitation that the preparation time and error are anti-correlated, meaning that accurate preparation requires long stabilization times. In this talk, I will present a novel scheme which makes use of parametric qubit-qubit and qubit-resonator interactions to avoid this issue. This scheme allows high-fidelity preparation of arbitrary maximally-entangled two-qubit states with stabilization times in the few hundred nanosecond range. Uniquely, it also enables continuous in-situ control of the target state in a specified parity manifold. I will discuss the robustness of the scheme to experimental imperfections and qubit decoherence, and an implementation which is readily achievable with current circuit-QED technology.

9:12AM E28.00007: To catch and reverse a quantum jump mid-flight* [Invited]  ZLATKO MINEV (Presenter), SHANTANU O. MUNDHADA, SHYAM SHANKAR, PHILIP REINHOLD, Applied Physics, Yale University, RICARDO GUTIERREZ, The Dodd-Walls Centre for Photonic and Quantum Technologies, Department of Physics, University of Auckland, ROBERT SCHOELKOPF, Applied Physics, Yale University, MAZYAR MIRRAHIMI, QUANTIC, INRIA Paris, HOWARD J CARMICHAEL, The Dodd-Walls Centre for Photonic and Quantum Technologies, Department of Physics, University of Auckland, MICHEL H. DEVORET, Applied Physics, Yale University — Quantum physics differs fundamentally from classical physics in that the measurement of a quantity cannot always give certain results, even in the ideal case where both the preparation and the measurement of the system is perfect. This idea is epitomized in the phenomenon of quantum jumps, first hypothesized by Bohr in his description of the radiation emitted by an excited hydrogen atom, and now routinely observed in the laboratory on a single quantum entity. Quantum jumps are fundamentally random: the time at which they occur cannot be predicted. However, modern measurement theory stipulates that it is possible to obtain an advance warning signalling the imminent occurrence of jump, before its full completion. Consequently, it is possible to reverse the jump if it is initiated by a coherent drive. We have successfully caught and reversed jumps by implementing the indirect QND measurement of a superconducting artificial atom that undergoes a transition from its ground state G to a dark state D. This is achieved by monitoring the occupancy of an auxiliary bright level B coupled to G through a Rabi drive. Our experimental results, in agreement with the predictions of quantum trajectory theory with essentially no adjustable parameters, provide new ground for the exploration of real-time intervention techniques in the control of quantum systems, such as early detection of error syndromes for computation and sensing. More generally, our results provide support to the point of view that a single system under continuous, efficient observation is characterized by a time-dependent wave-function inferred from the record of previous measurement outcomes, and whose meaning is that of an objective, generalized degree of freedom.

9:48AM E28.00008: Adaptive Rotating-Wave Approximation for Driven Open Quantum Systems* BRIAN BAKER (Presenter), Department of Physics and Astronomy, Northwestern University, ANDY C. Y. LI, Fermi National Accelerator Laboratory, NICHOLAS IRONS, Department of Physics and Astronomy, Northwestern University, NATHAN D EARNEST, The James Franck Institute and Department of Physics, University of Chicago, JENS KOCH, Department of Physics and Astronomy, Northwestern University — In this talk, I will present a numerical method to approximate the long-time asymptotic solution \( \rho_{\infty}(t) \) to the Lindblad master equation for an open quantum system under the influence of an external drive. The proposed scheme uses perturbation theory to rank individual drive terms according to their dynamical relevance, and adaptively determines an effective Hamiltonian. In the constructed rotating frame, \( \rho_{\infty} \) is approximated by a time-independent, nonequilibrium steady-state. This steady-state can be computed with much better numerical efficiency than asymptotic long-time evolution of the system in the lab frame. I will illustrate the use of this method by simulating recent transmission measurements of the heavy-fluxonium device, for which ordinary time-dependent simulations are severely challenging due to the presence of metastable states with lifetimes of the order of milliseconds.

10:00AM E28.00009: Exploring topological features of a dissipative qubit near an exceptional point* MARYAM ABBASI (Presenter), MAHDI NAGHILLOO, Physics, Washington University in St. Louis, YOGESH N JOGLEKAR, Physics, Indiana University-Purdue University Indianapolis (IUPUI), KATER MURCH, Physics, Washington University in St. Louis — We study the behavior of a single dissipative qubit which is described by a non-Hermitian Hamiltonian that has effective space-time reflection (PT) symmetry. We use quantum state tomography to observe the PT-symmetry breaking transition as we cross the exceptional point by varying the coupling strength between the two quantum states. By changing the detuning of the coupling, we probe the topological features associated with encircling the exceptional point. In addition, we introduce a time-modulated coupling strength where the resulting Floquet Hamiltonian provides a richer phase diagram where the PT broken phase can occur for dissipations levels that are much smaller than the PT symmetry threshold in the static case. Here we observe multiple transitions breaking and restoring the PT-symmetric phase.

10:12AM E28.00010: Experimental repetitive quantum channel simulation WEIZHOU CAI (Presenter), HU LING, XIANGHAO MU, YUWEI MA, YUAN XU, HAIYAN WANG, YIPU SONG, Tsinghua University, CHANG-LING ZOU, University of Science and Technology of China, LUYAN SUN, Tsinghua University — Universal control of quantum systems is a major goal to be achieved for quantum information processing, which demands thorough understanding of fundamental quantum mechanics and promises applications of quantum technologies. So far, most studies concentrate on ideally isolated quantum systems governed by unitary evolutions, while practical quantum systems are open and described by quantum channels due to their inevitable coupling to environment. Here, we experimentally simulate arbitrary quantum channels for an open quantum system, i.e. a single photonic qubit in a superconducting quantum circuit. The arbitrary channel simulation is achieved with minimum resource of only one ancilla qubit and measurement-based adaptive control. By repetitively implementing the quantum channel simulation, we realize an arbitrary Liouvillian for a continuous evolution of an open quantum system for the first time. Our experiment provides not only a testbed for understanding quantum noise and decoherence, but also a powerful tool for full control of practical open quantum systems.

10:24AM E28.00011: Measurement-induced phase transition in the dynamics of entanglement BRIAN SKINNER (Presenter), Massachusetts Institute of Technology, JONATHAN RUHMAN, Bar-Ilan University, ADAM NAHUM, Oxford University — We study the dynamics of quantum entanglement in a many-body system that undergoes unitary evolution punctuated by projective measurements. We show that when these measurements occur randomly with a finite rate per degree of freedom, there is a critical measurement rate that separates "entangling" and "disentangling" phases. The entangling phase is characterized by a linear growth of the entanglement entropy with time that leads to volume-law entanglement, while in the disentangling phase the entanglement entropy takes a constant, area-law value. We demonstrate this dynamical transition using numerics and a mapping to classical percolation that becomes exact in certain limits.

10:36AM E28.00012: Controlling the dynamics across a quantum phase transition* ADOLFO DEL CAMPO (Presenter), LUIS PEDRO GARCIA-PINTOS, DIEGO TIELAS, FERNANDO GÓMEZ-RUIZ, University of Massachusetts Boston — When a quantum phase transition is crossed in finite time, critical slowing down leads to the breakdown of adiabatic dynamics and the formation of topological defects. The average density of defects scales with the quench rate following a universal power-law predicted by the Kibble-Zurek mechanism (KZM). The scaling theory of phase transitions can however be used to determine the full counting statistics of topological defects, beyond the KZM. Knowledge of the distribution of topological defects provides new insights into the breakdown of adiabaticity. In addition, the quantum critical dynamics can be controlled. One approach relies on quantum monitoring via continuous quantum measurements. A second approach is based on local driving of the phase transition. We shall present theoretical and experimental progress based on these approaches.

Quantum Tracking Control of Molecular Rotor Orientation is Singularity-free

ALICIA MAGANN (Presenter), TAK-SAN HO, HERSCHEL A RABITZ, Princeton University — Quantum tracking control aims to identify applied fields to steer particular observable expectation values along desired paths in time. The fields can be identified by inverting the underlying dynamical equations for the observables. However, fields found in this manner are often plagued by undesirable singularities. In this talk I will consider a planar molecular rotor and derive singularity-free expressions for the fields that steer the expectation value of the rotor's orientation along desired trajectories in time. Simulations will be presented that utilize two orthogonal control fields to drive the orientation of the rotor along a series of designated tracks.

Stability of an accelerated hydrodynamic discontinuity

DANIIL ILYIN, WILLIAM GODDARD, California Institute of Technology, SERGEI I. ANISIMOV (Presenter), Landau Institute for Theoretical Physics, Russia, SNEZHANA ABARZHI, Univ of Western Australia — While looking from a far field, we analyze the evolution of an accelerated discontinuity separating ideal incompressible fluids of different densities. We develop and apply a general matrix method and identify a new hydrodynamic instability that occurs when the acceleration magnitude exceeds a critical threshold value. The flow dynamics conserves mass, momentum and energy in the fluid bulk and at the interface, has potential velocity fields in the fluid bulk, and is shear-free at the interface. The interface stability is set by the interplay of inertia and buoyancy. Surface tension also stabilizes the dynamics by a distinct mechanism. The growth rate and the flow fields' structure of the unstable dynamics depart substantially from those of other interfacial hydrodynamic instabilities, thus suggesting new opportunities for stabilization, diagnostics, and control of the interfacial dynamics.

*The work is supported by the University of Western Australia (AUS), the California Institute of Technology (USA), and the National Science Foundation (USA).

Detonation Initiation in Type Ia Supernovae

GABRIEL CASABONA (Presenter), University of Massachusetts Dartmouth, PRITOM MOZUMDAR, Physics, UC Davis, UMass Dartmouth, ROBERT FISHER, University of Massachusetts Dartmouth — Type Ia supernovae play a crucial role as standardizable candles for cosmology, but their stellar progenitors remain mysterious. Underlying this mystery is a crucial physical process: the mechanism of detonation initiation in Type Ia supernovae. Early suggestions for detonation initiation, based upon a detonation initiation mechanism originally proposed by Zel'dovich, cannot apply in the highly-turbulent conditions prevalent in major Type Ia supernova channels, in which the burning is disrupted into the distributed burning regime. We demonstrate, for the first time, using both analytic estimates and three-dimensional numerical simulations, how a carbon detonation may arise in a realistic three-dimensional turbulent electron-degenerate flow. We term this new mechanism turbulently-driven detonation. The turbulently-driven detonation initiation mechanism leads to a wider range of conditions for the onset of carbon detonation than previously thought possible, with important ramifications for SNe Ia models.

A Numerical Study of the Richtmyer–Meshkov Instability in a Relativistic Fluid using Multi-Directional Riemann Solvers and High-Order WENO Schemes

JAMIE TOWNSEND (Presenter), LÁSZLÓ KÓNÖZSY, KARL JENKINS, Cranfield University — The present work focuses on relativistic hydrodynamic (RHD) simulations of the Richtmyer–Meshkov (RM) instability in 2D and assesses the performance of different numerical schemes. The RM instability is known to occur in various high-energy phenomena such as supernovae detonations and relativistic jets. The RHD equations are solved using the finite volume method (FVM) via a third-order TVD Runge–Kutta scheme for time integration and WENO reconstructions for spatial discretization. The effect of the imposed Riemann solver is studied via the comparative use of a Rusanov, HLL, and HLLC Riemann solver. A novel multi-directional approach has been used in which all fluxes have been computed by taking into account information propagation from all spatial directions. In particular, we investigate the linear growth-rate of the instability under a parameter space consisting of positive and negative Atwood numbers and varying shock-speed for a perfect gas. The growth-rate in the linear regime has been reported to peak in the mildly relativistic limit. We aim to shed light on the numerical influence and predictive capability of computational modelling relativistic fluids.

*Fully-funded studentship provided by the Centre for Computational Engineering Sciences, Cranfield University.
8:36AM E29.00004: Evaluation of the turbulence velocity skewness factor in a detonation-turbulence interaction
SARAH HUSSEIN (Presenter), FRANK K LU, Mechanical and Aerospace Engineering, University of Texas at Arlington — In physical and computational studies of turbulence, the velocity skewness factor is a property of interest quantifying the development of the turbulence. Tavoularis (1978) defined the velocity skewness for fully-developed turbulence as a negative ratio of the average partial derivative of streamwise velocity with respect to the axial position, \( S(u,x) \). This definition is used in the direct numerical simulation of homogeneous isotropic turbulence. The skewness factor, in this study, is evaluated for a turbulent fluid flow as it interacts with a detonation wave. The analysis extends the long-standing definition to include the variation of the transverse velocities in all three Cartesian spatial coordinates. The skewness components are evaluated and compared to assess significance in a detonation-turbulence interaction.

8:48AM E29.00005: Correlating ocean vertical transport and surface coherent structures
ARAVIND HARILAL MEENAMBIKA (Presenter), MICHAEL ALLSHOUSE, Mechanical Engineering, Northeastern University — Vertical transport in the upper ocean impacts the transport of nutrients, surface mixing, and the ocean energy budget. Observing regions of significant vertical transport has proven to be difficult since vertical velocities in the ocean are often orders of magnitude smaller than horizontal velocities. What is available, however, is HF radar and satellite altimetry, which provide ocean surface velocities. While an Eulerian analysis of this field can yield some information, Lagrangian coherent structures prove to be more robust to noisy observational data. We correlate these structures on the surface to vertical transport below the surface. In particular, we compute the finite-time Lyapunov exponent (FTLE) field from just the surface velocity and compare this with the FTLE field for a full three-dimensional analysis and the corresponding vertical subduction. These correlations are tested on a high-fidelity simulation of a sheared submesoscale flow.

9:00AM E29.00006: Vegetation-generated turbulence in combined wave-current canopy flows
JIARUI LEI (Presenter), HEIDI NEPF, Massachusetts Institute of Technology — Laboratory experiments are conducted in combined waves and current to measure turbulence structure and intensity in arrays of wooden cylinders, a model for submerged rigid aquatic vegetation. For dense canopies, drag leads to velocity reduction within canopy. The velocity gradient at the top of canopy generates a shear layer which results in coherent vortices traveling downstream. The canopy-scale vortices control the transport of mass and momentum and penetrate into the canopy with a length of \( \delta_e \). In pure current, near-bed TKE (turbulent kinetic energy) is elevated as turbulence is transported from the shear region to the bed. TKE increases as the vortices develop downstream. In combined wave-current conditions, the turbulence within canopy is mainly set by the waves as the mean current is small compared to wave velocity. The near-bed turbulence is not significantly elevated by the shear-generated vortices and can be predicted using existing empirical model of stem-generated turbulence. As the ratio of wave velocity to current speed increases, the shear layer diminishes and \( \delta_e \), as well as the magnitude of Reynolds stress, decreases. In pure waves, no shear layer is observed and stem-generated turbulence dominates the turbulence structure and intensity within canopy.

9:12AM E29.00007: Electron Contribution in Mirror mode Instability in Quasi-linear Regime
NAILA NOOREEN (Presenter), Forman Christian College — The solar wind is characterized by proton temperature anisotropies. The plasma compression generates the perpendicular anisotropy, which may lead to the mode instability for high beta situation. In the present paper the mirror mode instability is discussed in the framework of simplified and reduced quasi-linear kinetic theory, which includes the contribution of electrons. It is found that the linear growth rate associated with the electron mirror mode can be much higher than that the proton mirror mode, and the electron mirror instability operates over a range of carrying out the quasi-linear analysis, it is shown that for the proton mirror instability. However, upon carrying out the quasi-linear analysis, it is shown that for the high initial growth rate does not necessarily imply dynamical importance, since the saturated magnetic field intensity associated with electron mirror instability is extremely low and that the influence on the particle temperature is minimal. The present finding shows that under some circumstances, the dynamical consequences of a system cannot simply be estimated on the basis of the linear prediction alone and that nonlinear analysis must be taken into account.
KEQING XIA (Presenter), Department of Mechanics and Aerospace Engineering, Southern University of Science and Technology, KAI LEONG CHONG, GUANG-YU DING, The Chinese University of Hong Kong — We study numerically the dynamical and structural properties of columnar vortices in rotating Rayleigh-Bénard convection. Our results show that the vortices form clustered structures with a characteristic length scale when their density becomes sufficiently large. Dynamically, their motion is ballistic in short time scale and crosses over to diffusive in longer time scale. We further found that the ratio of the Brownian time scale for vortex diffusion and the relaxation time scale given by the normal stress among vortices may be the key parameter that determines the structural formation of vortices.

SAMAR ALQATARI (Presenter), Mechanical Engineering, Massachusetts Institute of Technology, THOMAS ERIK VIDEBÆK, Physics, University of Chicago, IRMGARD BISCHOFBERGER, ANETTE E. HOSOI, Mechanical Engineering, Massachusetts Institute of Technology, SIDNEY ROBERT NAGEL, Physics, University of Chicago — A hydrodynamic instability can develop at the interface between a denser fluid placed atop a less dense one. We investigate this Rayleigh-Taylor instability between two miscible liquids in a confined Hele-Shaw geometry. Surprisingly, we find that the typically unstable interface between the dense and less-dense liquids is stabilized below a critical confinement, set by the gap spacing of the Hele-Shaw cell. This critical confinement shows power law scaling with the difference in densities between the liquids. We also discuss the dependence of the characteristic wavelength of the instability on fluid parameters and the gap spacing. Our measured wavelength in this confined geometry deviates strongly from theoretical predictions for unconfined systems, suggesting an important effect of geometry on the onset of the instability.

RYAN MCKEOWN (Presenter), Harvard University, RODOLFO OSTILLA MONICO, University of Houston, ALAIN JACK PUMIR, ENS Lyon, MICHAEL PHILLIP BRENNER, SHMUEL RUBINSTEIN, Harvard University — The turbulent cascade, or the means by which the energy of a flow is conveyed from large to small scales, is governed by the interactions between vortices over many scales. In order to better understand the mechanisms that govern the close-range interactions between vortices, we experimentally examine the head-on collision of two vortex rings. By seeding the vortex rings with fluorescent dye and imaging their collision with a high-speed scanning laser sheet, we visualize the breakdown dynamics of the flow in full 3D. For weak collisions at low Reynolds numbers, the colliding rings stretch radially, develop long-wavelength perturbations, and reconnect into a tiara of secondary vortex rings. Conversely, for violent collisions at high Reynolds numbers, the rings rapidly develop short-wavelength perturbations as they stretch radially before erupting into a turbulent cloud of fine-scale vortex filaments. Initiated by these instabilities, the colliding vortices break down through various distinct processes and lead to the generation of small-scale flow structures. Thus, the close-range interactions of the colliding vortices could provide new insights into the mechanistic underpinnings of the turbulent cascade.

LU ZHU (Presenter), LI XI, Department of Chemical Engineering, McMaster University — Study of turbulent vortices in DNS relies heavily on visual inspection, anecdotal observations, and intuitive arguments. Quantitative analysis is limited by the lack of computational tools for the objective detection and extraction of vortex structures. Despite much progress in the development of vortex identification criteria (which shows the vortices without distinguishing their individualities), vortex tracking requires a separate step and existing techniques only targeted quasi-linear vortices. In this study, a new tracking algorithm is proposed which propagates along the vortex axis-lines and iteratively search for new directions for growth. It is the first tracking method designed for general three-dimensional vortices. The method is tested in transient flow fields with specific vortex types as well as DNS. A new procedure is also proposed that classifies vortices into commonly-observed shapes, including quasi-streamwise vortices, hairpins, hooks, and branches, based on their axis-line topology. This new method is then applied to both viscous and viscoelastic turbulent channel flows for analyzing the distribution of vortex size, shape, and location. Introducing polymer additives suppresses vortex lift-up process and fundamentally change the vortex regeneration dynamics.
10:12AM E29.00012: Realization of Confined Turbulence Through Multiple Vortex Ring Collisions* TAKUMI MATSUZAWA (Presenter), NOAH P MITCHELL, STEPHANE PERRARD, WILLIAM T. M. IRVINE, University of Chicago — We report a method to generate a steady, localized blob of turbulence by colliding multiple vortex rings successively. Our system supplies vorticity to a turbulent region through vortex rings, which enables us to create controlled turbulent flows far from boundaries. The state of turbulence can be controlled by altering properties of the injected rings. We present spatial structures and turbulence characteristics of the blobs by varying strength, size and shape of the vortex rings. This novel method provides an ideal system to study both generation and decay of turbulence absent from any boundary effects.

*The authors gratefully acknowledge financial support from the U.S. Army Research Office through Grant No. W911NF-18-1-0046.

10:24AM E29.00013: Numerical Analysis of Iron-Zeolite Based Emission Control Device for Two-Wheelers NAFEES AHMAD (Presenter), MEHUL VARSHNEY, ANCHAL VARSHNEY, SS ALAM, Aligarh Muslim University — The present work involves numerical simulation of a novel emission control device (Indian Patent Publication Number: 41/2018) for about 30 million two-wheeled vehicles running on Euro3/BS III norms without a catalytic converter across the Asia Pacific. The governing equations for turbulent fluid flow and species transport with eddy dissipation and PDF models have been solved on commercial package FLUENT® to predict the behavior of oxides of nitrogen (at different engine loads) in presence of Iron-Zeolite. Substrates of Iron Zeolites with high viscous resistance provide ample residence time for adsorption of exhaust gas molecules and reduction of inorganic oxides. The findings show that the concentration of harmful oxides of Nitrogen in exhaust gases gets reduced by approximately 50% by conversion to harmless nitrogen gas. Furthermore, the geometry is optimized in a way to ensure invariance in standard speed-torque characteristics of the engine by generating negligible back pressure. The device provides an optimal business and environmental solution by controlling emissions through extremely cheap and innovative Iron-Zeolite at places where ultra-expensive Platinum/Palladium/Rhodium based catalysts are not feasible.

8:00AM E30.00001: Polymer Physics Prize Talk Break —

8:06AM E30.00002: Soft ionic diodes formed at the interface of ionic liquid networks* [Invited] RYAN HAYWARD (Presenter), University of Massachusetts Amherst — Soft elastic materials capable of conducting ionic charge carriers offer numerous opportunities for the design of new classes of highly deformable electronic devices. Our group has recently studied the formation of ionic ‘diodes’ at the interface between two single-ion conducting elastomers with oppositely signed charge carriers formed by polymerization and crosslinking of ionic liquid monomers. We characterize the properties of these interfaces using a variety of techniques, in particular AC impedance spectroscopy, and show that they act as stretchable rectifying junctions based on capacitive, rather than electrochemical, effects. Further, such soft ionic diodes possess a number of potentially useful characteristics, including strain sensitive electrical signals and reversibly switchable electro-adhesion. Finally, we have explored templating methods to generate high surface area ionic diodes, which are expected to yield further improvements in properties.

Neutron Spin Echo Insight into Dynamic Networks Formed by Ionomers

DVORA PERAHIA (Presenter), Chemistry, Physics, Clemson University, SIDATH WIJESINGHE, Chemistry, UNC Chapel Hill, MANJULA SENANAYAKE, SUPUN S. MOHOTTALALAGE, CHATHURIKA KOSGALLANA, Chemistry, Clemson University, PIOTR ADAM ZOLNIERCUZUK, Jülich Centre for Neutron Science at SNS, ORNL, Oak Ridge, TN

Association of ionic groups strongly affects the rheology of ionomers in melts and in solutions. The constraint arises from formation of ionic clusters affects the macroscopic dynamics. While the network is constrained, the chains remain dynamic on the length scale of the network mesh. Using NSE we probe chain dynamics in networks formed by polystyrene sulfonate (PSS) as the physical crosslinks are perturbed by addition of ethanol. Solutions of 20Wt% PSS, 11,000 g/mol (PD=1.02) with 3 and 9% mole sulfonation were studied. S(q,t) measured across a broad temperature range, was analyzed in terms KWW and characteristic times extracted. At length scales that correspond to the ionic domains, the motion is constrained in both solvents; however, ethanol enhances the dynamics. While the ionic domains expand, the dynamics remain restricted, pointing to formation of "ionic clouds" where the ionic clusters are swollen with alcohol, but remain segregated, retaining the physical crosslinks of the network. At smaller dimensions, the dynamics becomes significantly faster and no differences are observed as ethanol was added. Increasing the temperature results in equal acceleration of the motion across all q values, indicative of retaining the dynamic, swollen, physical crosslinks.

Solvent Polarity Effects on Segmental Dynamics in Ionic Polymer Networks: Quasi Elastic Neutron Scattering Study

SUPUN SAMINDRA MOHOTTALALAGE (Presenter), SIDATH WIJESINGHE, MANJULA SENANAYAKE, CHATHURIKA KOSGALLANA, Department of Chemistry, Clemson University, Clemson, SC, United States., NARESH OSTI, Oak Ridge National Laboratory, Oak Ridge, TN, United States., DVORA PERAHIA, Department of Chemistry/Department of Physics, Clemson University, Clemson, SC, United States.

Incorporating ionic groups into polymers drives formation of physical networks that affect the dynamics of the macromolecules. Here, using quasi elastic neutron scattering (QENS), segmental dynamics of slightly sulfonated (3mol%) polystyrene (PSS) networks formed in cyclohexane, a non-polar environment and a theta solvent for PS was studied, followed by tracking the polymer motion as the association of the sulfonated groups is disrupted by ethanol. Specifically, a 10%(w/w) PSS in cyclohexane/ethanol solutions was studies in the q range of 0.3 Å⁻¹ to 1.3 Å⁻¹ corresponding to 5 Å⁻²1 Å. The relaxation times and segmental motion were extracted from a Kohlrausch-Williams-Watts (KWW) analysis. As expected for PSS in cyclohexane, the dynamics is constrained at larger dimensions but the polymer remains mobile on smaller length scales. Addition of less than 5%(v/v) of ethanol is enough to release the constrains. Surprisingly however, further increase in ethanol results in decrease in segmental motion. This reduction could be attributed to overall plasticization of the polymer in presence of ethanol.

Dynamics of Ionomer Networks Studies by Pulse Field Gradient (PFG) NMR

SHALIKA D. K. MEEDIN (Presenter), MANJULA SENANAYAKE, SUPUN S. MOHOTTALALAGE, CHATHURIKA KOSGALLANA, Department of Chemistry, Clemson, SC, 29634, United States, Clemson University, DVORA PERAHIA, Department of Chemistry, Clemson, SC, 29634, United States, Clemson University, Department of Physics, Clemson, SC, 29631, United States, Clemson University — Ionomer networks are formed in solutions at extremely low concentrations. Tuning these networks offers a means to control the structures that remain trapped as the solvents evaporate to form membranes. Here, we probe the diffusion of the polymers and the solvents in networks formed by polystyrene sulfonate (PSS) by pulse field gradient NMR. The diffusion of the polymer reflects the properties of the network and that of the solvent. Specifically, PSS networks with sulfonation levels of 0, 3 and 9 mole % were studied in toluene and cyclohexane neat and mixed with ethanol. Toluene is a good solvent for polystyrene and cyclohexane is a theta solvent at room temperature. We find that with increasing sulfonation levels, both the polymer and the solvent motions decrease in both solvents. Regardless of sulfonation level, the diffusion of PSS is almost same in cyclohexane and toluene at room temperature. With increasing temperature, the diffusion of all components increases in both solvents however it is more pronounced in cyclohexane. The solvents diffuse faster than the polymers but follow similar trends. While perturbing the ionic clusters affect the overall network dynamics, the polar solvent also affects the hydrophobic network rigidity.

DOE funding DE-SC0019284
9:48AM E30.00006: Solvent Effects on the Structure of Sulfonated Polystyrene Networks* CHATHURIKA KOSGALLANA (Presenter), SIDATH WIJESINGHE, MANJULA SENANAYAKE, SUPUN S. MOHOTTALALAGE, Department of Chemistry, Clemson University, Clemson, SC, United States, LILIN HE, Oak Ridge National Laboratory, Oak Ridge, TN, United States, DVORA PERAHIA, Department of Chemistry/Department of Physics, Clemson University, Clemson, SC, United States — Driven by ionic association, ionomers form dynamic sparse networks in solutions at extremely low ionic content. Here we probe the factors that affect the structure of these types of networks formed by lightly sulfonated polystyrene (PSS) using small angle neutron scattering (SANS). Measurements were carried out in 0.25-10Wt% PSS in toluene/ethanol solutions, across a broad temperature range. In toluene, a good solvent for the PS, the SANS patterns consist of a broad signature at intermediate q, attributed here to an average network mesh size, determined by the distance between ionic physical crosslinks. At low q, a network characteristic upturn is observed. With increasing concentrations, the characteristic dimension, calculated from Rg of a Gaussian chain, decreases by ~1nm due to increasing cluster size and numbers. The long-range correlations of ~20nm, were captured by the Beacuge model. The PS chains assume an overall Gaussian configuration around the ionic clusters. Surprisingly, while the long-range correlations diminish with addition of ethanol, the mesh size decreases. While the ionic clusters become less defined, the PS chains are concurrently affected, assuming a more constrained chain configuration.

*DOE DE-SC0019284

10:00AM E30.00007: Dissipative Particle Dynamics Computational Modeling of Structurally Tailored and Engineered Macromolecular (STEM) Gels TAO ZHANG (Presenter), SANTIDAN BISWAS, ANNA CHRISTINA BALAZS, University of Pittsburgh — Structurally tailored and engineered macromolecular (STEM) gels are polymer networks containing latent initiator sites available for post synthesis modifications, with the networks acting as a backbone grafted with secondary polymer side chains. Here we use dissipative particle dynamics (DPD) simulations to study the mechanical response of the modified STEM gels under compression. We observe lower compressional modulus of the networks after adding secondary side chains and the mechanical properties are tunable by varying the grafting density and side chain length. To gain insight into the microscopic origin of observed mechanical behaviors, we measure the chain entanglements density, conformational entropy change, and conduct 3D structural domain analysis during the compression process. Furthermore, we show that attaching the initiator sites to the primary networks through labile links allows the links to break/rearrange, and thus relieves local stress concentrations.

10:12AM E30.00008: Internal Fracture in Tough Double Network Hydrogels Revealed by Various Modes of Stretching THANH-TAM MAI (Presenter), Kyoto Institute of Technology, TAKAHIRO MATSUDA, TASUKU NAKAJIMA, JIAN PING GONG, Hokkaido University, KENJI URAYAMA, Kyoto Institute of Technology — The cyclic stretching measurements in various geometries including uniaxial, planar, unequal and equal biaxial extension, reveal the distinctive features of the internal fracture in the double network (DN) hydrogels. The modulus reduction, dissipated energy (D), dissipation factor (Δ, the ratio of dissipated energy to input strain energy) in each loading-unloading cycle are evaluated as a function of the imposed maximum elongation (λi,m) in i-direction (i=x,y) in each cycle. The modulus reduction and Δ depend on the stretching mode when compared at the same λx,m, but each of them exhibits a universal relation independently of the stretching mode when the magnitude of left Cauchy-Green deformation tensor is used as a variable. In contrast, Δ in filled elastomers shows the corresponding universal relation when the first strain invariant is used as a variable (Mai et al., Soft Matter 13, 1966–1977, 2017). The difference in governing variable indicates that the influence of the cross-effect of strains (λλj; ij =x,y,z and i ≠ j) on the dissipation factor is pronounced in the DN gels whereas it is minimal in the filled elastomers. (Mai et al., Macromolecules 51, 5245–5257, 2018)
10:24AM E30.00009: Design and Control of Finite Conformational Changes in Mechanical Networks* JASON KIM (Presenter), DANIELLE BASSETT, University of Pennsylvania — Conformational changes in physical networks play a crucial role in many systems, enabling error correction in DNA replication, cooperativity in hemoglobin, and mechanical capacities in metamaterials. Important work has begun to delineate the relationship between network structure and instantaneous conformational change. However, these efforts have failed to address finite conformations, which are critical for the successful function of most physical networks. Here we establish a simple framework for the design and control of mechanical spring networks in 2 and 3 dimensions. Specifically, for a set of nodes with arbitrarily specified initial and final positions, we characterize all bipartite networks with zero energy at these positions, demonstrate transitions between these positions, and design multi-stable networks for information storage. Finally, we use hysteresis and bi-stability to design networks demonstrating cooperativity.

10:36AM E30.00010: Quantifying force-induced bond dissociation in metal-coordinate gels under steady shear flow* IRINA MAHMAD RASID (Presenter), BRADLEY DAVID OLSEN, NIELS HOLTEN-ANDERSEN, Massachusetts Institute of Technology — The dynamic nature of the bonds in associating polymer networks has led to its use in the design of tough and self-healing hydrogels. While the ability of the materials to regain its original stiffness after a recovery period has been documented, such data provides no information on the molecular level processes occurring as the network is damaged, and subsequently as it heals. In this work, the non-linear response of a model associative network, consisting of linear side-functionalized chains, with nickel-terpyridine complexation as the crosslinking group was investigated. With a custom-built setup, force-induced bond dissociation was quantitatively measured through fluorescence measurements, as the network was strained under steady shear. The measured fraction of dissociated bonds is compared to predictions of several models from transient network theory.

10:48AM E30.00011: The Dynamics of Bulk Polymers with Metal-ligand Coordination Crosslinking* JOY ZHANG (Presenter), YUVAL VIDAVSKY, MEREDITH SILBERSTEIN, Cornell University — The dynamics of polymer networks consisting of metal-ligand coordination as crosslinks have been widely studied in solution and gel systems. However, understanding the dynamics of bulk polymers with metal-ligand coordination crosslinking remains a challenge because it is hard to decouple the polymer relaxation and association/dissociation of the dynamic bonds. To address this problem, we carefully designed both the polymer structure and the intramolecular dynamic bond in the system. A series of copolymers containing ethyl acetoacetate ligands have been synthesized by RAFT polymerization. The ethyl acetoacetate ligands can form coordination complexes with different metal ions (Ni(II), Cu(II), and Zn(II)) and act as reversible crosslinks. We investigated the dynamic responses of these polymer networks by rheometer and DMA. These lightly crosslinked networks have behavior that varies both with choice of metal and quantity of metal, thereby revealing the kinetic differences due to the metal-ligand coordination bonds in bulk polymers. We show that these non-covalent dynamic bonds in the bulk polymer networks play an important role in determining their mechanical properties.

Tuesday, March 5, 2019 8:00 AM - 10:48 AM

Session E31 DCP GMAG: Design and Control of Molecular Magnets (QIS2) BCEC 203 - Mark Pederson, United States Department of Energy - Tag(s): Focus
8:00AM E31.00001: The power of molecular chemistry in nanoscale materials research: from quantum physics properties to water oxidation catalysis [Invited] GEORGE CHRISTOU (Presenter), Department of Chemistry, University of Florida — Molecular chemistry brings many powerful advantages to the study of nanoscale materials of various kinds, and this area of 'molecular nanoscience' is therefore a rapidly growing field. The advantages include monodisperse (single-size) products and a monolayer shell of organic ligands that imparts solubility and crystallinity, allowing structural characterization of molecular crystals to atomic resolution by X-ray crystallography. The ligands can usually also be modified as desired, allowing tuning of redox properties and atom/isotope labelling (²H, ¹⁹F, etc.) for studies in the solid state and solution, such as NMR spectroscopy. In the molecular nanomagnetism arena, these advantages have been absolutely crucial in the study of single-molecule magnets (SMMs), molecules that function as individual ultra-small nanomagnets. They have greatly assisted the synthesis and study of numerous SMMs, leading to discovery of new quantum physics phenomena important to new 21st century technologies, such as exchange-biased quantum tunneling of the magnetization vector and quantum superposition states. Giant (~4 nm) SMMs have also bridged the gap between the 'top-down' world of traditional magnetic nanoparticles and the 'bottom-up' world of molecular nanomagnets. Recently we have developed controlled ways to form supramolecular [Mn₃]ₙ oligomers of 2 or more linked Mn₃ SMMs to study the resulting quantum properties, introduced by the weak inter-SMM exchange coupling, in more detail, including in solution for the first time. Some of our larger magnetic molecules, such as [Mn₁₂O₁₂(O₂CR)₁₆(H₂O)₄] and others, can be described as a small piece of metal oxide within an organic shell, and recent work has established that they can also function as homogeneous electrocatalysts for water oxidation to O₂ gas with low overpotentials. A selection of these materials and studies will be described.

8:36AM E31.00002: Controlling Anisotropy in the Presence of Magnetic Coupling in Molecular Magnets* [Invited] JEFFREY RINEHART (Presenter), JEREMY HILGAR, MAXIMILIAN BERNBECK, AARON BUTTS, Chemistry and Biochemistry, University of California, San Diego — The control of magnetic anisotropy and magnetic coupling are crucial to the design of devices utilizing molecular materials for both spintronic and quantum information processing. Generally, theoretical models and synthetic approaches exist for optimizing these parameters independently to a very high degree. However, design principles for either orthogonal or synergistic, predictable control of anisotropy and coupling are far more complex. This presentation will focus on our efforts to address the challenge of designing molecules that can effectively preserve the orientation and magnitude of their anisotropy upon introducing coupling interactions that necessarily alters the local crystal field.

*We thank the Office of Naval Research Young Investigator Award N00014-16-1-2917 for supporting this research.

9:12AM E31.00003: Magnetic properties of actinide complexes from first principle calculations. [Invited] HÉLÈNE BOLVIN (Presenter), Université Toulouse 3, LCPQ-IRSAMC — Magnetic properties of actinides are often analyzed using models devoted to lanthanides. But due to the higher covalency of the former, those models are not adequate and a more precise description of the complexes is necessary in order to get the full understanding of those properties. The calculation of the magnetic properties of open-shell 5f molecules is a challenge for the methods of quantum chemistry: actinide complexes have many low lying configurations, spin-orbit effects are important and correlation effects must be taken into account. The first principle SO-CASPT2 method gives results that compare well to experimental data and permits to analyze the different contributions to the magnetic properties.

On monomers, calculations enable to
- determine crystal field parameters
- analyze the effect of covalency
- scrutinize the contributions above the LS coupling scheme.

On dimers, they permit to
- analyze the magnetic coupling between the two magnetic centers
- propose Spin Hamiltonians which permit to model the magnetic behavior of those complexes
9:48AM E31.00004: Theoretical Investigation of Actinides Based Single Molecule Magnets  CARLO ALBERTO GAGGIOLI (Presenter), LAURA GAGLIARDI, Department of chemistry, University of Minnesota — Single molecule magnets (SMMs) are highly appealing for reducing the length scale of magnetic materials that have potential applications in information storage and spin electronics.\(^1\) SMMs show slow relaxation of the magnetization of purely molecular origin. The actinides elements are promising for the design of SMMs and examples have emerged.\(^2\)

In this contribution, the electronic structure of plutonium based SMMs\(^3\) have been computationally examined by means of multiconfigurational calculations. A modified ligand has also been studied in order to modify the electronic properties.\(^4\)

We are currently investigating other actinide-based SMMs, namely \(\text{[Np(COT)2]}\)\(^5\) and \(\text{AmFe}_2\).\(^6\) We are also analyzing the inclusion of dynamical correlation by means of multiconfiguration pair-density functional theory (MC-PDFT),\(^7\) a new method developed in our group. These results will be discussed.

10:00AM E31.00005: Self-interaction effects in the density functional description of iron(II) spin-crossover molecules  TORSTEN HAHN (Presenter), SEBASTIAN SCHWALBE, JULIA RICHTER, Theoretical Physics, Technical University Freiberg — Spin-crossover metal complexes are one of the paradigmatic examples of magnetic molecular materials showing switching and bistability at the molecular level. Octahedral Fe\(^{2+}\) molecules are particularly interesting as they often exhibit such a spin-crossover transition. Many efforts were made to assess the performance of density functional theory for such systems. However an exchange-correlation functional able to account accurately for the energetic of the various possible spin-states has not been identified yet.

We present results on different Fe\(^{2+}\) ions using self-interaction corrected semilocal exchange-correlation functionals \([1,2,3]\) within the FLO-SIC DFT framework and we focus on the energy differences between the various spin states. Further we compare our data to high level quantum chemical calculations.

10:12AM E31.00006: Molecular Geometries of Fe (II) Spin-Crossover Complexes  BRIAN FINNEY (Presenter), BESS VLAISAVLJEVICH, University of South Dakota — Spin-crossover (SCO) complexes are a class of inorganic compounds in which external stimuli facilitate a change in geometry and spin state from a diamagnetic low spin state to a paramagnetic high spin state or vice versa. Due to this bistability, they are an important class of molecules for new energy technologies and molecular electronics\(^1\). The multiconfigurational nature and large number of electrons of these molecules make it difficult to provide accurate theoretical descriptions of the electronic structure. To date, density functional theory (DFT) has been the foundation for the study of these complexes' geometries\(^2\). Recent advances in computing has made it now possible to produce geometries with methods beyond DFT.

Octahedral Fe(II) (d\(^6\)) molecules are among the most well studied of this class of compound. Here, an accurate description of the multiconfigurational electronic structure of several Fe(II) SCO complexes using the CASPT2 method is presented. The convergence of geometry with respect to active space and basis set size as well as differences with the traditional DFT approach and the refined CASPT2 structures are noted.

10:24AM E31.00007: Coupled-Cluster Valence Bond Theory for Exact Treatment of Spin-Fluctuation  JOONHO LEE (Presenter), DAVID SMALL, MARTIN HEAD-GORDON, College of Chemistry, University of California, Berkeley — We present a valence bond approach for treating spin-fluctuation called coupled-cluster valence bond (CCVB). In particular, we will discuss the three-pair extension of CCVB, CCVB+i3, and its application to spin-frustrated systems such as molecular magnets. CCVB+i3 can describe spin-fluctuation exactly without invoking neither an exponential wall nor spin contamination. We also discuss a future direction on including charge-fluctuation into this model.
Molecular Magnetism and Quantum Information  MARK PEDERSON (Presenter), United States Department of Energy — Quantum Information Science and instrumentation for next-generation computing, information, and other fields is evolving quickly into an interdisciplinary field that intersects strongly with the missions, interests and portfolios of basic energy sciences. The fundamental research in chemical physics, quantum chemistry, inorganic chemistry, and magnetism is strongly synergistic with applications such as sensing, navigation, communications, simulation and computing. Researchers in these fields must play a role in enabling and understanding manipulation of uniquely quantum phenomena that arise from the entanglement of electrons, spins, and low-energy excitations in actual molecular systems. This talk will summarize emerging possibilities for chemical sciences based upon DOE Basic-Energy-Sciences rountable reports. It will focus on activities targeting the fundamental design, manipulation, or addressing of molecular-scale quantum-chemical qubits, the use of early quantum processors for chemical simulation, and synergistic prospects for the near-term quantum- systems and algorithms research supported by BES. To address the aims of this focused session, specific contact to the chemistry, magnetism, and optical response of molecular magnets and organic poly-radicals will be featured.

Tuesday, March 5, 2019 8:00 AM - 10:12 AM

Session E32 DCP: Time-dependent and Time-independent Approaches (B) BCEC 204A - Tucker

Towards the calculation of multidimensional vibrational spectra* [invited] KENNETH RUUD (Presenter), Hylleraas Centre for Quantum Molecular Sciences, Department of Chemistry, UiT The Arctic University of Norway — Great advances are being made in the experimental realization of multiphoton spectroscopy, such as the experimental confirmation of four- and five-photon absorption in the visible energy range as well as two-dimensional Raman spectra.

The complexity of these nonlinear processes means, however, that computational studies are important for unraveling the full information content of the experimentally recorded spectra. Furthermore, many of the unique responses that can be observed in multidimensional vibrational spectroscopies are directly related to electric and/or mechanical anharmonicities. These methods therefore provide a unique window into molecular vibrational responses that would otherwise be difficult to disentangle from the dominant harmonic contributions.

In this presentation, I will in particular focus on the evaluation of the vibrational response functions that determine a wide class of multidimensional vibrational spectroscopies. Our approach takes as its starting point the Liouville equation, from which a sum-over-states expression for the response function at the appropriate order for an in principle arbitrary number of incident laser pulses is derived. The vibrational contributions to these response functions are determined recursively and the results are evaluated for a general setup of polarization vectors and time-ordering of the incident lasers. For selected numbers of independent variables (i.e. frequencies or frequency differences/sums in the IR range), the program generates spectra of the appropriate dimensionality.

I will provide some illustrations of the code to different multidimensional vibrational spectra. I will also present a benchmark study of the accuracy of density functional theory for the calculation of harmonic and fundamental vibrational frequencies.

8:36AM E32.00002: Anharmonicity and vibrational coupling from ab-initio molecular dynamics* [invited] NADIA REGA

(Presenter), Department of Chemical Sciences, University of Napoli Federico II — We discuss on going advances in developing methods based on ab-initio molecular dynamics to simulate and understand vibrational dynamics, with focus on anharmonicity and vibrational coupling. This achievement is essential to understand at molecular level photoinduced processes on fast and ultrafast scale (femtoseconds to picoseconds). To this aim, we adopt time resolved vibrational analysis designed to follow equilibrium and transient vibrational dynamics extracted from ground and excited state trajectories.[1-5] We present results obtained for charge transfer complexes and photochromic reactions. We also discuss perspectives, limits and future challenges of these methods.

9:12AM E32.00003: UV Photodissociation Dynamics of Bromoform Studied by Ultrafast Inner-Shell Transient Absorption Spectroscopy* HAN WANG (Presenter), BENJAMIN W TOULSON, MARIO BORGWARDT, OLIVER GESSNER, Chemical Sciences Division, Lawrence Berkeley National Laboratory, DAVID PRENDERGAST, Molecular Foundry, Lawrence Berkeley National Laboratory — Small bromoalkanes have been the focus of multiple studies owing to the importance of bromine chemistry in the atmosphere as bromine is ~60 times more destructive towards stratospheric ozone than chlorine. Here we study the photochemistry of the low-lying electronically excited states of bromoform (CHBr3). To understand the physical mechanism of UV-induced C-Br bond breaking, fewest switches surface hopping (FSSH) calculations are performed to simulate the dynamics of CHBr3 after photon excitation. Using intermediate geometries and electronic structures from the FSSH simulation, XUV absorption spectra are calculated with the linear-response time-dependent DFT method for comparison with femtosecond time-resolved inner-shell absorption measurements. The combined theoretical-experimental study indicates that C-Br bond scission proceeds on a timescale of ~30-40 fs, followed by continued electronic interaction between the departing Br atom and the remaining CHBr2 fragment on an ~80-90 fs timescale. The study demonstrates how photochemical processes may be probed through a combination of ultrafast XUV/X-ray transient absorption spectroscopy, excited state molecular dynamics simulations, and core-level near-edge XUV/X-ray absorption calculations.

9:24AM E32.00004: Probing Ultrafast Dissociation Dynamics of Pentafluorobenzene Cation (C₆F₅H⁺) with Electrons* MING-FU LIN (Presenter), XIAOZHE SHEN, SLAC National Accelerator Laboratory, PEDRO NUNES, Department of Physics and Astronomy, UNIVERSITY OF NEBRASKA–LINCOLN, JIE YANG, RENKAI LI, STEPHEN WEATHERSBY, SLAC National Accelerator Laboratory, ROB PARRISH, TODD MARTINEZ, Department of Chemistry, Stanford University, MARTIN CENTURION, Department of Physics and Astronomy, UNIVERSITY OF NEBRASKA–LINCOLN, THOMAS JACOB ARCANGELO WOLF, XIJIE WANG, MICHAEL MINITTI, SLAC National Accelerator Laboratory — Real-time observation of a structural change of photoexcited molecular ion is important to understand the fundamental reaction mechanism. Here, we use mega-electronvolt ultrafast electron diffraction technique (MeV-UED) to directly construct a molecular movie of photogenerated pentafluorobenznen cation. The molecular cation was produced by multiphoton ionization of C₆F₅H at 269 nm. This cation dissociates into fragment ions within ~10 ps time scale through statistical internal energy redistribution prior to the following bond dissociation and ring opening. Parit distribution function (PDF) analysis allows us to pin down the specific chemical bond dissociation process in this unimolecular dynamics.

*The UED work was performed at SLAC MeV- UED, which is supported in part by the DOE BES SUF Division Accelerator & Detector R&D program, the LCLS Facility, and SLAC under contract Nos. DE-AC02-05-CH11231 and DE-AC02-76SF00515.
9:36AM E32.00005: State-resolved thermal reaction rate from ring-polymer surface hopping* XUECHENG TAO (Presenter), PHILIP SHUSHKOV, THOMAS MILLER, Caltech — Employing the recently developed isomorphic Hamiltonian framework for including nuclear quantum effects in mixed quantum-classical non-adiabatic dynamics, [J. Chem. Phys., 148, 102327 (2018)] we present a flux-side formulation of state-resolved thermal reaction rates for ring-polymer surface hopping. The method is shown to be robust and straightforwardly implemented, and numerical results reveal that RPSH in the isomorphic Hamiltonian framework leads to excellent dividing-surface independence, due to improved preservation of the path-integral statistics. The method is further applied to investigate F+H2 reactive scattering with an ab initio multi-level potential energy surface and its effectiveness is demonstrated with preliminary results.

9:48AM E32.00006: Mapping of the Excited State Potential Energy Surface during Molecular Photo-isomerization to Control Chemical Reactions RACHEL GLENN (Presenter), Michigan State, Virginia Tech — We present a new perspective of light matter interaction with molecules. When using shaped pulses, we explain fundamentally how our understanding of absorption and dispersion changes. We show how the phase of the pulse can change an absorption line-shape to a dispersion-like line-shape. Contrary to conventional belief, we show that the first-order polarization is sensitive to the phase of the electric field. We show that by performing single pulse experiments that it is possible to "map" out the propagation of the wave packet in the excited state potential energy surface. In addition, we describe how to measure the momentum dependent lifetime of the wave packet through a conical intersection. We use these fundamental ideas to answer the question of finding an optimum coherent pulse(s) that will maximize the formation of a desired chemical species.

10:00AM E32.00007: Modeling Molecular Spectra with Interpretable Atomistic Neural Networks* MICHAEL GASTEGGER (Presenter), KRISTOF T SCHÜTT, HUZIEL SAUCEDA, KLAUS-ROBERT MÜLLER, Technical University of Berlin, ALEXANDRE TKATCHENKO, University of Luxembourg — Deep neural networks are emerging as a powerful tool in quantum chemistry, combining the benefits of high-level electronic structure methods with excellent computational efficiency. The recently developed SchNet model provides an accurate description of molecules and materials across chemical compound space, as well as easy access to energy conserving force fields [1]. Here, we demonstrate that the modular nature of deep models can also be exploited to enhance their versatility and offer insights beyond the basic relationships learned by the network. First, we adapt existing architectures to model different spectroscopic quantities, such as molecular infrared spectra [2]. Going beyond the simple prediction of properties, we then explore modifications of SchNet in the form of latent features. Although these variables are inferred, they correspond to readily interpretable physical concepts, such as molecular charge distributions [3].

Tuesday, March 5, 2019 8:00 AM - 11:00 AM

Session E33 FIAP: Devices for Biological Applications and Biological Materials BCEC 204B - Alan Johnson, Univ of Pennsylvania
8:00AM E33.00001: Laser-activated Polymer Devices for Intracellular Delivery  WEILU SHEN (Presenter), ERIC MAZUR, School of Engineering and Applied Physics, Harvard University, STEFAN KALIES, Institut für Quantenoptik, Gottfried Wilhelm Leibniz Universität Hannover, MARINNA MADRID, School of Engineering and Applied Physics, Harvard University, ALEXANDER HEISTERKAMP, Institut für Quantenoptik, Gottfried Wilhelm Leibniz Universität Hannover — A challenge in the biomedical field to advancing fundamental studies of biologically interesting molecules for clinical use is the direct delivery into the cytoplasm in an efficient way. Established methods such as electroporation and viral transduction each come with respective strengths and weaknesses that fit different application needs. We present a delivery method that combines 11-ns laser pulses of 1064 nm wavelength and polymer substrates to create transient pores in cells. These polymer devices are low-cost, biocompatible, and have simple fabrication techniques. Adherent cells are grown on the substrates, and pores only form on the cells in localized regions excited with the laser pulses, allowing spatial selectivity. The medium surrounding the cell contain the cargos, and they diffuse into the cell before the transient pores self-seal. We are able to deliver membrane-impermeable cargos of sizes up to 40 kDa. We obtained efficiencies of up to 40% with viabilities of 60% for calcein green in HeLa and Panc-1 cells. Scanning electron microscopy and optical profilometry are used to study the substrate surface morphology. This laser-activated polymer device can deliver important material directly into cells, furthering the field of nanomedicine in a cost-effective manner.

8:24AM E33.00003: A high-sensitivity 16-channel magnetic sensor for magnetocardiographic experiments*  YOUNG JIN KIM (Presenter), IGOR M SAVUKOV, Los Alamos National Laboratory — Multichannel parallel magnetic measurements are required for various applications in many fields such as neuroscience and biomedical research. We recently constructed a portable, low-cost, high-sensitivity 16-channel magnetic sensor for magnetocardiography (MCG) applications. The sensor is based on a high-sensitivity atomic magnetometer (AM) with a novel configuration of nearly parallel pump and probe laser beams. The AM-based 16-channel magnetic sensing is realized in a single module by using a single large rubidium vapor cell, two broad laser beams, and a 16-channel photodiode matrix, leading projected 10-fold reduction of the cost of sensors. For MCG experiments with the sensor, its main components except lasers are located inside a magnetically shielded room. We describe the basic principle and the design of the 16-channel magnetic sensor. We also present human heart signals directly recorded by the sensor.

*This work was supported by the U. S. DOE through the Los Alamos National Laboratory LDRD program.

8:36AM E33.00004: Detection of Biofilm Infections in Human Fluid Samples using DNA-Functionalyzed Carbon Nanotube Vapor Sensors*  EMILIE BENSON (Presenter), CHRISTOPHER KEHAYIAS, ALAN T JOHNSON, University of Pennsylvania — Human fluid samples collected from individuals suffering from various biofilm-related infections were analyzed using single-stranded DNA-functionalized carbon nanotube (ssDNA-CNT) vapor sensors. Fluids from infected individuals were collected and categorized by infection type: staph infections and non-staph infections. The samples were placed in individual flasks that were heated in a water bath, and a vapor handling system was used to sequentially deliver the headspace of the samples to an array of CNT devices configured as an “electronic nose”. Each array comprised up to 100 sensors, with each sensor functionalized with one of ten unique sequences of ssDNA, thereby yielding a ten-dimensional output response characteristic of the volatile odor signature of the samples. The resulting data space was dimensionally reduced using linear discriminant analysis (LDA), resulting in a differentiation of staph versus non-staph data clusters.

*This work was supported by the Kleburg Foundation.
8:48AM E33.00005: Triggered gelation of microfluidic polymer droplets to identify and isolate viable antigen-specific immune cells* BRENDA DEVENEY (Presenter), JULIE BROUCHON, JOHN HEYMAN, YUAN YUAN, DAVID A WEITZ, Harvard University — The isolation of antigen-specific immune cells is fundamental to the study of autoimmune diseases and to the development of effective immunotherapies, yet practical technologies for doing so are lacking. We present here a new method for the triggered gelation of polymeric microfluidic assay droplets that enables the isolation of viable antigen-specific T-cells in microfluidic devices. Specifically, T-cell/target cell pairs are coencapsulated in liquid droplets prior to droplet conversion into gel microspheres compatible with fluorescence activated cell sorting. We aim to use this platform to perform high-throughput cell-cell interaction assays and isolate individual immune effector cells together with their cognate target cells for future immunotherapy development.

*This is work is supported by AmfAR.

9:00AM E33.00006: Emergence of quantized vortices in microfluidic devices* JEREMIAS GONZALEZ (Presenter), BIN LIU, Physics, UC Merced — Structured vortices in microfluidic flows are often associated with suspensions of active matter that move in a collective fashion. For instance, vortical flows at microscales have been observed in bacterial swarms, with their forming mechanisms attributed to the self-propulsion of individuals and the cell-cell interactions. Here, we demonstrate that an array of microscale vortices can emerge purely due to the geometry and dimensionality in a steady flow. Specifically, we show that a chain of vortices can be induced in a rectangular cavity that is sheared under a steady flow. Interestingly, these vortices have an intrinsic aspect ratio, with their numbers quantized by the length of the cavity. We also elucidate that such intrinsic flow structures can be generalized to a wide class of confining geometries, indicating a fundamental mechanism of vortex formation in microscale flows.

*The authors thank the support of National Science Foundation NSF, CREST: Center for cellular and Biomolecular Machines (NSFHRD1547848).

9:12AM E33.00007: Graphene Probes for Detecting Electrical Activity of Individual Synapses* YUCHEN ZHANG (Presenter), RUI WANG, MINGJIAN SHI, BRYSON BREWER, LIJIE YANG, DONNA WEBB, DEYU LI, YAQIONG XU, Vanderbilt University — Complex neural circuits connected by billions of neurons with trillions of synapses require techniques that map the electrical activity of neural networks with extraordinary temporal and spatial resolution to decipher the underlying mechanisms for multiple aspects of neuroscience. By combining graphene transistors with scanning photocurrent microscopy, we can detect the local electrochemical environment changes induced by electrical activity of individual synapses of primitive hippocampal neurons, enabling us to estimate extracellular potential variations of individual synapses during depolarization. The ultrafast nature of graphene photocurrent response allows decoding of the activity patterns of individual synapses with sub-millisecond temporal resolution. As such, our new neurotechnology will offer promising potential for recording the electrical signals of a large population of synapses in neural networks.

*This work was supported by the National Institutes of Health (1R01EY027729, 1R21EY026176, and 1R21NS095323) and the National Science Foundation (ECCS-1055852 and 1810088, CBET-1264982, and BIO-1450897). Device Fabrication was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.

9:24AM E33.00008: Development of a Mass Spectrometer for Sequencing Single Protein Molecules* BENJAMIN WIENER (Presenter), NICHOLAS DRACHMAN, Brown University, MATHILDE LEPOTTEVIN, Chemistry, École normale supérieure, WILLIAM MAULBETSCHE, OLIVER G ISIK, DEREK STEIN, Brown University — I will describe a new nanopore-based mass spectrometer designed to sequence proteins. The instrument will combine a nanopore ion source capable of extracting ionized amino acids directly from solution into a vacuum chamber using electric fields[1] with a magnetic sector for separation by charge-to-mass ratio. The mass-separated ions will travel into an array of channeltron-style detectors capable of continuously monitoring the full mass range of interest and tagging each detected ion with its precise arrival time. In addition, our design features tunable hardware which will allow us to precisely align and adjust the position of our ion source to achieve the detection efficiency necessary for sequencing.

*We acknowledge support from Oxford Nanopore Technologies.
Microfluidic calorimetric immunosensor: experimental results and COMSOL simulations of heat transfer in microchannel

SAIF MOHAMAD ISHRAQ BARI, LOUIS REIS, GERGANA NESTROVA (Presenter), Louisiana Tech University — Recent years have witnessed significant progress in the development of detection technologies for lab-on-a-chip immunoassays that provide increased sensitivity and specificity. The calorimetric technique allows the detection of reactions that are not compatible with other methods. Optimization of thermal transport through the microchannel relates to increasing sensitivity and high-throughput of sample analysis. This study presents the design and fabrication of calorimetric immunosensor for quantification of TNF-α. The impact of channel height (100μm, 500μm, 1000μm), lower channel wall thickness (170μm, 500μm, 1000μm), and MEMS materials (PDMS, glass) were simulated using COMSOL Multiphysics® to investigate the effect of these parameters on the heat transfer within the microchannel. Computational analysis indicates that reducing the channel height and the thickness of the lower channel wall results in an increased temperature difference. The simulations results were validated experimentally in a microfluidic immunosensor with an integrated antimony/ bismuth thermopile for quantification of TNF-α. The accuracy of the developed technology was validated using conventional ELISA.

Detection of Early-Stage Ovarian Cancer using DNA-Decorated Carbon Nanotube Vapor Sensors

CHRISTOPHER KEHAYIAS (Presenter), EMILIE BENSON, ALI GHORASHI, WILLIAM WATKINS, ALAN T JOHNSON, University of Pennsylvania — We propose an “electronic nose” technology based on arrays of carbon nanotube field-effect transistors (CNT-FETs) as a minimally invasive diagnostic for ovarian cancer. We measured the real-time electrical response of the sensor arrays to volatile organic compounds (VOCs) in the headspace of blood plasma samples collected from 21 patients with malignant ovarian cancer (six of whom had early-stage cancer), 16 patients with benign ovarian lesions, and 21 age-matched healthy subjects. Sensor arrays comprised 100 CNT-FETs, where each device was functionalized with one of ten different sequences of single-stranded DNA, providing a ten-dimensional output for each sample tested. A linear discriminant analysis tool was used to dimensionally reduce the ten-dimensional data space. A machine-learning package was then used to classify samples as malignant, benign, or healthy based on a training subset of the data, leading to correct classification of 88% of the samples in the test set. Moreover, all early-stage samples were correctly classified as malignant. This signifies a promising step towards a reliable diagnostic for ovarian cancer in the early stage, when standard therapeutic procedures are highly effective.

Prediction of crystal structure and study of transport and optoelectronic properties of NH2 substituted trans-stilbene derivative: A new promising ambipolar organic semiconductor

DWAIPAYAN CHAKRABORTY (Presenter), PRIYA JOHARI, Shiv Nadar University — Organic Semiconductor (OS) is an emerging class of energy materials, for its several advantages over its inorganic counterpart, such as large area, flexibility, low cost and most importantly their environment friendly manufacturing process. This class of materials can start a new electronic era, if their charge transport properties can be improved. Computational designing and study of new semiconducting organic molecules has come up as a great support in this regard. In this effort, we therefore rationally designed a promising Donor(D)-π-Acceptor(A) type molecule NNDM-NH2, a trans-stilbene derivative. We first calculated the molecular properties of this newly designed molecule and found important characteristics of molecule to exhibit high charge carrier mobility in solid. Further, on predicting its crystal structure and calculating the corresponding properties, we found that this new organic semiconductor owns a high charge carrier mobility of \(~ 2.11 \text{ cm}^2/\text{Vs}\) for hole and \(~ 0.64 \text{ cm}^2/\text{Vs}\) for electron, together with desirable electronic and optical properties. Thus, revealing NNDM-NH2 as a potential candidate for the application in opto-electronic devices. In addition, it has found to have remarkable non linear optical (NLO) properties.

We acknowledge Shiv Nadar University for funding.
**10:12AM E33.00012: XAS signature of ferroelectricity in Croconic Acid**  
FUJIE TANG (Presenter), PRATIKKUMAR H DHU Vad, Temple University, XUANYUAN JIANG, University of Nebraska, Department of Physics and Astronomy, MEHMET TOPS AKAL, DEYU LU, Brookhaven National Laboratory, Center for Functional Nanomaterials, XIAOSHAN XU, University of Nebraska, Department of Physics and Astronomy, XIFAN WU, Temple University — Molecular ferroelectrics (FE) based on ordering hydrogen bonds have potentially high electric polarization and ordering temperature compared with the conventional oxide FE materials. In particular, croconic acid (C₅O₅H₂) has a FE polarization of 26 μC/cm², in which the polar mode is strongly coupled to the intermolecular proton transfer. We applied X-ray absorption spectroscopy (XAS), a characterization technique that is sensitive to local structural and chemical properties, to probe the hydrogen bond structures of the croconic acid. First-principles simulations were used to interpret oxygen K-edge XAS features of croconic acid. The calculated XAS spectra semi-quantitatively agree with the three main experimental features at ~531.2 eV, 533.6 eV and 541.1 eV, respectively. The electron excitations in the two low-energy spectral features are found to be closely associated with the proton transfer, which gives rise to the FE polarization and can be recognized as a spectral signature of the FE in the croconic acid.

**10:24AM E33.00013: Conformation of DNA in periodic temperature gradient created by plasmonic heating**  
RYOKO SHIMADA (Presenter), HITOMI SAKAI, Japan Women's University — Different molecules in mixed solutions can be separated from each other along a temperature gradient. This phenomenon, so-called Soret effect, is quite important for molecular manipulation in various research fields. Among various techniques, plasmonic heating from periodic metal domains is one of the effective ways to create a periodic temperature gradient for observation of the Soret effect. In this work, we utilized the plasmonic heating from periodic silver (Ag) domains under emission of blue light (400 – 440 nm) to create the periodic temperature gradient (with a large amplitude of ~ 0.5 K/mm), thereby attempting to observe the Soret effect of DNA mixed in polyethylene glycol (PEG) solutions. The DNA molecules, labeled with fluorescent dyes, were concentrated in high temperature zones, confirming the positive Soret effect. In addition, for large DNA molecules (~166 Kbp), the conformation appeared to be distorted possibly because of the microscopic Soret effect within the molecule. Details of this observation will be discussed on site.

**10:36AM E33.00014: Excess heat capacity measurement of nano/bio-materials by photo-thermal conversion calorimetry**  
XING LI (Presenter), CHIA-CHING CHANG, Department of Biological Science and Technology, National Chiao Tung University, Taiwan, DAR-BIN SHIEH, CHENG-YANG TSAI, Institute of Oral Medicine, National Cheng Kung University, Taiwan — Photothermal therapy in medical care including cancer is gradually being valued. We modified Thermal activity monitor to measure the heat generated by the photothermal reaction of nanoparticles. The thermal Activity Monitor is a freestanding multichannel microcalorimeter. We use this system to measure the photothermal reaction excess heat and calculate the specific heat of the photothermal nanoparticles. Furthermore, We can calculate the elevated net temperature. In addition, this method can also measure the excess heat generated by various nanoparticles and proteins excited by laser at a specific wavelength. According to this result, we can accurately know the thermal reaction effect of the nanoparticles to achieve better treatment.

**10:48AM E33.00015: Para-phenylenediamine crosslinked alginate gels and their mechanical properties**  
ROSA MARIA BADANI PRADO (Presenter), RANGANA WIJAYAPALA, SANTANU KUNDU, Chemical Engineering, Mississippi State University — Alginate hydrogels are widely applicable in bioengineering and pharmaceutical applications due to their biocompatibility. Conventionally, calcium ions are used to crosslink alginate chains. However, gel modulus decreases in physiological solutions due to ion exchange with the medium, leading to a deterioration of their microstructure. This can be overcome by replacing the crosslinking calcium ions with covalent bonds. Here, we investigate chemically crosslinked alginate hydrogels using para-phenylenediamine (PPD) as a crosslinker. PPD binds the carboxylic groups present in β-D-mannuronic acid and α-L-guluronic acid residues of alginate chains. The gel modulus is tuned by changing polymer and crosslinker concentrations. These gels show higher moduli and are more brittle as compared to ionic alginate gels for the same crosslinker concentration. A comparison of mechanical properties with respect to the ionic alginate gels will be presented.

**Session E34 GMED: Radiation Detection and Monitoring in Medical Imaging and Therapy**

BCEC 205A - Wojciech Zbijewski, Johns Hopkins University - Tag(s): Invited

838 of 3305
Recent advances in medical imaging include the development of large-area flat-panel x-ray detectors for radiography, fluoroscopy, mammography, and cone-beam CT as well as multi-detector and photon counting systems for diagnostic CT. Such advances have enabled new capabilities (for example, improved spatial resolution and reduced radiation dose) and propelled a revolution in 3D imaging systems over the last two decades. Quantitative understanding of the performance of various detector technologies - and optimizing their performance for a particular clinical application - benefits tremendously from mathematical models of imaging performance, including analytical models of spatial resolution, noise, and detective quantum efficiency. Such models give insight on the performance of each element of the imaging chain in terms of its spatial-frequency-dependent transfer characteristics. In turn, these characteristics can be related to the performance of a particular imaging task by considering spatial-frequency-dependent signal and noise with respect to the spatial-frequencies associated with performance of a particular task - i.e., "task-based" models. Such analysis has provided a foundation for imaging chain optimization (including scintillator thickness, pixel pitch, and electronic readout noise) and helped to accelerate the development of new imaging systems for 2D (projection) and 3D (volumetric) imaging systems for a variety of applications in medical diagnosis and interventional guidance. In this presentation, we review the essentials of such task-based models of imaging performance, study examples of model-based design of new imaging systems, and consider future challenges in modeling of nonlinear imaging systems.

Session E35 DQI: Exchange-Based Spin Qubits BCEC 205B - Pascal Cerfontaine, RWTH Aachen University - Tag(s): Focus

8:00AM E35.00001: Spin qubits made of quantum dots and donors in silicon [Invited] PATRICK HARVEY-COLLARD (Presenter), Sandia National Laboratories — In this talk, I will present our recent work on control and readout of electron spin qubits in silicon MOS. Valley splitting is an issue that can induce control variability or limit readout fidelity. We show how this splitting is tunable in MOS devices [1], and introduce a shell-filling trick to overcome potential readout challenges. Readout fidelity has lagged behind that of control. We demonstrate that an enhanced latching mechanism can be used to improve the signal and lifetime of the spin-blockade readout while preserving its speed, achieving single-shot readout fidelities of > 99.86% [2]. The best spin qubit in the solid state is the nuclear spin of donors, but it is difficult to couple it to other qubits. We show coherent coupling of a donor to a quantum dot, a milestone for nuclear spin quantum computing [3]. We also study spin-orbit interaction for electrons in silicon quantum dots. We show that it is sufficiently large to drive a singlet-triplet qubit, allowing universal control without external elements [4]. We study the mechanisms behind this interaction and find three different effects [5]. Our work identifies crystallographic and magnetic field anisotropies that can be used to enhance or suppress these effects.

Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International, Inc., for the DOE's National Nuclear Security Administration under contract DE-NA0003525. The views expressed in the article do not necessarily represent the views of the DOE or the U.S. Government.

8:36AM E35.00002: Decoherence of a donor-dot hybrid qubit in Si* JOHN TRUONG (Presenter), XUEDONG HU, University at Buffalo, The State University of New York — A recent proposal for a scalable donor-based quantum computer scheme promises excellent coherence properties and fast qubit couplings [1]. The system consists of two types of qubits per donor: a flip-flop qubit consisting of the electron and nuclear spins, and a charge qubit of the donor electron tunneling between the donor and an interface quantum dot. The proposal identifies a parameter regime where flip-flop qubit dephasing due to electrical noise is strongly suppressed.

We study the decoherence properties of the flip-flop qubit when positioned near this sweet spot. In particular, we study the effect of charge noise that is coupled to the flip-flop qubit via the dependence of the hyperfine interaction and the electron gyromagnetic ratio on the charge qubit state. We find that zero frequency noise is indeed suppressed at the sweet spot. In the meantime, finite-frequency contributions from the qubit coupling to the excited charge states come into play at shorter time scales, although their effects average out over longer times. We also explore the decoherence dependence on external control parameters such as the applied magnetic field and tunnel coupling between the donor and dot.

Probing exchange interaction for gate-defined double quantum dots

PATRICK BETHKE (Presenter), JARA-FIT Institute Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, MICHAEL A WOLFE, Department of Physics, University of Wisconsin, Madison, ROBERT P. G. MCNEIL, Niels Bohr Institute, University of Copenhagen, ARNE LUDWIG, ANDREAS D. WIECK, Lehrstuhl für angewandte Festkörperphysik, Ruhr-Universität Bochum, HENDRIK BLUHM, JARA-FIT Institute Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University — The exchange interaction $J$ is vital for gating in electron-spin qubits. Therefore, understanding its behavior is crucial for high-fidelity gating, especially at low $J$ where an inability to turn it off completely may impact the fidelity of parallel qubit operations. Historically, the exchange interaction (controlled via detuning $\varepsilon$ between dots) measured in experiment, $J(\varepsilon) \propto \exp(-\varepsilon/\varepsilon_0)^{1-2}$, has deviated from Hubbard-based predictions, $J(\varepsilon) \propto 1/|\varepsilon|$.

We present measurements of $J$ down to values below 1MHz by controlling the nuclear magnetic field gradient $\Delta B_z$ in a GaAs double quantum dot. When $\Delta B_z$ becomes comparable to $J$ the visibility of the S-T0 precession is reduced. Fitting the relation between oscillation amplitude and frequency allows the extraction of $J(\varepsilon)$. In combination with Ramsey-like experiments we measure $J(\varepsilon)$ over three orders of magnitude.

Our results can be reproduced by a microscopic model including excited states in each dot and state-dependent tunnel coupling. Some parameters in the Hamiltonian, e.g. ground-state tunneling, excited-state tunneling, S-T0 splitting, can be measured independently and are found to be reasonably consistent with the model.

Computational modeling of exchange splitting in Si/SiO₂ double quantum dots

HARSHAD SAHASRABUDHE (Presenter), Department of Physics and Astronomy, Purdue University, West Lafayette, IN, RAJIB RAHMAN, School of Physics, University of New South Wales, Sydney, Australia — One and two qubit operations have been demonstrated using electrons trapped in quantum dots at the interface of isotopically purified Si/SiO₂ materials. We present a computational study of Si/SiO₂ based double quantum dot qubits which could help in scaling the device design. Exchange splitting between the lowest singlet and triplet states, which plays an important role in two qubit operations, is calculated using the full configuration interaction (FCI) method. The single electron wavefunctions used in FCI are calculated using 20-band $sp^3d^5s^*$ tight binding (TB) Hamiltonian, which accurately represents the conduction-band X valley and spin orbit coupling in quantum dots. The electrostatic potential needed in TB is calculated using self-consistent effective-mass Schroedinger-Poisson (S-P) simulations on finite element meshes resembling the actual device geometry. Energy spectrum of S-P and TB simulations shows a good match at low detuning between the dots. At high detuning close to the (1,1)-(0,2) transition, where the two qubit operations take place, higher X-valleys along x, y and z axes are found to play a role in the exchange splitting, which could impact the response to charge noise.

Achieving A High Fidelity Controlled-NOT Gate Between A Pair Of Exchanged-Coupled Silicon Double-Quantum-Dot Hybrid Qubits

YUAN-CHI YANG (Presenter), MARK G FRIESEN, SUSAN COPPERSMITH, University of Wisconsin - Madison — It has been shown that operating qubits by varying exchange couplings while operating at sweet spots against detuning noise can improve gate fidelities. For double-quantum-dot hybrid qubits, this requires keeping the system in the large-detuning regime where dephasing is greatly suppressed. Here we show that, in a pair of exchange-coupled double-quantum-dot hybrid qubits, it is possible to exploit the large-detuning regime to achieve a sizeable exchange interaction between the qubits while suppressing leakage and dephasing, yielding a high-fidelity controlled phase gate with a gate time less than 1 ns. We find that the fidelity of a CNOT gate can be above 99.9%, in the presence of charge noise typical for semiconductor devices.

*This work has been supported in part by ARO (W911NF-17-1-0274), the University of Wisconsin-Madison, and the Vannevar Bush Faculty Fellowship program sponsored by the Basic Research Office of the Assistant Secretary of Defense for Research and Engineering and funded by the Office of Naval Research through grant N00014-15-1-0029. The views and conclusions contained in this work are those of the authors and should not be interpreted as representing the official policies, either expressed or implied, of the Army Research Office (ARO), or the U.S. Government.
MAXIMILIAN RUSS (Presenter), Department of Physics, University of Konstanz, JASON R PETTA, Department of Physics, Princeton University, GUIDO BURKARD, Department of Physics, University of Konstanz — We propose a quadrupolar exchange-only (QUEX) spin qubit that is highly robust against charge noise and nuclear spin dephasing, the dominant decoherence mechanisms in quantum dots [1]. Building on ideas developed for the exchange-only qubit [2], the hybrid qubit [3], and the exchange-only singlet-only spin qubit [4], the QUEX qubit consists of four electrons trapped in three quantum dots, and operates in a decoherence-free subspace to mitigate dephasing due to nuclear spins. To reduce sensitivity to charge noise, the qubit can be completely operated at an extended charge noise sweet spot that is first-order insensitive to electrical fluctuations. Due to on site exchange mediated by the Coulomb interaction, the qubit energy splitting is electrically controllable and can amount to several GHz even in the “off” configuration, making it compatible with conventional microwave cavities. A symmetric readout and initialization protocol can be used to perform fast and high fidelity measurements.

*RResearch was sponsored by Army Research Office grant W911NF-15-1-0149.

JONNE KOSKI (Presenter), ANDREAS LANDIG, PASQUALE SCARLINO, Department of Physics, ETH Zurich, MAXIMILIAN RUSS, Department of Physics, University of Konstanz, DAVID VAN WOERKOM, CHRISTIAN REICHL, WERNER WEGSCHEIDER, Department of Physics, ETH Zurich, GUIDO BURKARD, Department of Physics, University of Konstanz, ANDREAS WALLRAFF, THOMAS IHN, KLAUS ENSSLIN, Department of Physics, ETH Zurich — The implementation of circuit quantum electrodynamics (cQED) allows coupling of distant qubits by microwave photons hosted in on-chip resonators. Typically, the qubit-photon interaction is realized by coupling the photons to the electrical dipole moment of the qubit. A recent proposal [1] suggests storing the quantum information in the quadrupole moment of an electron in a triple quantum dot. This type of qubit is expected to have an improved coherence since the qubit does not have a dipole moment and is consequently better protected from electric noise. We report the experimental realization of such a quadrupole qubit hosted in a triple quantum dot in a GaAs/AlGaAs heterostructure. A high-impedance microwave resonator is capacitively coupled to the middle of the triple dot to realize interaction with the qubit quadrupole moment. We demonstrate strong quadrupole qubit-photon coupling with a qubit-photon coupling strength of $g / 2\pi \approx 130$ MHz and a qubit decoherence rate of $\gamma_2 / 2\pi \approx 30$ MHz. Furthermore, we observe improved coherence properties of the qubit when operating in the parameter space where the dipole coupling vanishes.

GUO XUAN CHAN (Presenter), XIN WANG, City University of Hong Kong — The relatively weak coupling between spin states in spin qubits has spurred a revival of interest in charge qubits, which promises stronger coupling between multiple charge qubits due to stronger long-range Coulomb interaction. Among the proposed charge qubits, charge quadrupole (CQ) qubit is suggested to provide a relatively robust quantum computation by virtue of the logical bases residing in a decoherence free subspace such that leakage state decouples from the manifold [1]. Conventionally, CQ qubit is realized with an electron residing in a lateral triple quantum dot device, yet any fluctuation in tunneling and detuning control causes significant leakage. We propose a strategy to mitigate such destructive coupling by simply implementing the CQ qubit in a triangular triple quantum dot, where the tunneling between the two dots on the edge strongly suppresses leakage, eliminating the need of complex pulse sequences. The reduction of leakage is demonstrated from molecular orbital calculation, in corporation with numerical simulations.

10:00AM E35.00009: A High-Fidelity Gateset for Exchange-Coupled Singlet-Triplet Qubits

RENE OTTEN (Presenter), PASCAL CERFONTAINE, JARA-FIT Institute Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, MICHAEL A WOLFE, Department of Physics, University of Wisconsin, Madison, HENDRIK BLUHM, JARA-FIT Institute Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University — A key ingredient for a quantum computer is the accurate manipulation of qubits in order to generate high-fidelity gates. For S-T0 qubits in semiconductor quantum dots, which allow purely electric control with moderate bandwidth requirements, single-qubit gates with fidelities above the error correction threshold were demonstrated, whereas two-qubit operations have not reached the required fidelity [1-2]. Here, we numerically optimize a complete two-qubit gate set under realistic experimental constraints, exploiting exchange coupling while also accounting for capacitive coupling. We obtain fidelities of 99.9% for GaAs, while about 99.99% are achieved with vanishing magnetic field noise as in Si. We suppress leakage to $10^{-5}$ by choosing high inter-qubit magnetic field gradients.

For optimized parallel single-qubit gates, we find that inter-qubit capacitive coupling needs to be considered to avoid undesired entanglement, but is mitigated by interleaved operation. Realistic levels of residual inter-qubit exchange coupling are compensated for by our gates.

We will also report on progress of the realization of such gates in a GaAs device with two exchange-coupled S-T0 qubits.

10:12AM E35.00010: Fast high-fidelity entangling gates in Si double quantum dots

FERNANDO CALDERON-VARGAS (Presenter), GEORGE BARRON, XIUHAO DENG, EDWIN BARNES, SOPHIA ECONOMOU, Virginia Tech — High-fidelity two-qubit gates remain a challenge for spin qubits in quantum dots, partly due to the exchange coupling’s sensitivity to charge noise and relatively longer gate times. Here we show that, by using simple smooth pulses to control the amplitude of the oscillating magnetic field, entangling gates locally equivalent to control-NOT and control-Z gates can be implemented in times as low as 26 ns and with fidelities up to 99.99%. Moreover, we provide the particular single-qubit gates necessary to make the two-qubit gates exactly equal to the CNOT and CZ gates.

*This work is supported by the Army Research Office (W911NF-17-0287).

10:24AM E35.00011: Robust implementation of one-qubit gates despite always-on exchange coupling in silicon double quantum dots

UTKAN GUNGORDU (Presenter), JASON PAUL KESTNER, University of Maryland, Baltimore County — In a silicon two-qubit device, bandwidth constraints on exchange coupling and limitations on ESR power are important obstacles for the realization of strictly local gates, which are themselves necessary components of robust non-local gating schemes [1]. Here we show that, even in the presence of an exchange coupling stronger than one-qubit Rabi frequencies, spins can be addressed separately to implement a particular class of one-qubit gates optionally surrounded by exchange gates, and the crosstalk between them can be eliminated stroboscopically. We also show how to make such gates robust against quasistatic charge- and hyperfine-noise.

*This research was sponsored by the Army Research Office (ARO), and was accomplished under Grant Number W911NF-17-1-0287.

10:36AM E35.00012: Adiabatic two-qubit gates of capacitively coupled quantum dot hybrid qubits

ADAM FREES (Presenter), University of Wisconsin - Madison, JOHN GAMBLE, Quantum Architectures and Computation Group, Microsoft Research, MARK G FRIESEN, SUSAN COPPERSMITH, University of Wisconsin - Madison — Semiconductor quantum dot qubits have progressed greatly over the past several years, with two-qubit gates realized by several groups. So far, the fidelities reported for these gates are still below the error correction threshold. Here, we model a system consisting of two capacitively-coupled quantum dot hybrid qubits, and optimize the adiabatic electrical pulses used to entangle these qubits. We find a simple pulse that yields a CZ gate with greater than 99% fidelity in the presence of a quasistatic charge noise distribution with standard deviation 1 µeV. Further, we introduce the concept of a "dynamical sweet spot" which can be used to develop pulses that decrease the infidelity by a factor of >5.

10:48AM E35.00013: Minimal non-orthogonal gate decomposition for qubits with limited control*  XIAOMING ZHANG (Presenter), City University of Hong Kong, JIANAN LI, Department of Physics, Southern University of Science and Technology, XIN WANG, City University of Hong Kong, MAN-HONG YUNG, Shenzhen Institute for Quantum Science and Engineering and Department of Physics, Southern University of Science and Technology — How an arbitrary unitary transformation can be decomposed into minimum number of elementary rotations, subject to particular physical constraints, is a fundamental and practical question. Here, we consider two important scenarios. The first one is when rotation axes are allowed to vary in a range of a plane, which corresponds to the Singlet-Triplet (ST) qubit in quantum-dot systems; the second one is when rotation axes can only along two fixed directions, corresponding to the Exchange-Only (EO) qubits. For both scenarios, we provide the criteria for determining the minimal number of pieces and explicit gate construction procedure for each unitary gate. Our results analytically explain the four-gate decomposition of EO qubits, previously determined numerically by Divincenzo et al. Moreover, our approaches can reduce both gate time and gate fidelity dramatically for ST qubits, compared with Ramon sequence and its variant.

Session E36 DBIO: Physics of the Cytoskeleton Across Scales I  BCEC 205C - Megan Valentine, University of California, Santa Barbara - Tag(s): Invited

8:00AM E36.00001: Controlling Epithelial Cell Shape [Invited]  MARGARET GARDEL (Presenter), University of Chicago — I will discuss my lab's recent work to study the biophysical mechanisms regulating control of cell shape in epithelial tissue. In particular, we have used optogenetics to locally regulate Rho activity at cell junctions to uncover how local Rho pulses drive junction contraction and stabilization via a ratcheting mechanism. We find that at short timescales, Rho activation drives junction contraction that reverses upon Rho reduction. Sustained RhoA activity shows a similar initial rapid contraction followed by a slow contractile phase. Upon removal of RhoA activation, the junction does not fully recover back to its original length, similar to junctional ratcheting observed in vivo. We find that this ratchet is dependent on both trans E-cadherin interactions and Formin activity. To understand these data, we model junction length in response to variable tension. In contrast to existing vertex models, our data argues that a junction has a rest length that is determined by the force-dependent junctional remodeling under acute periods of tension. This model then predicts that the slow contractile phase will eventually saturate to limit the amount of junction length changes and this is indeed what we see experimentally. We can overcome this saturation by inducing multiple activation periods, recapitulating junctional ratcheting seen in vivo. Altogether, these data provide insight into the underlying molecular and biophysical mechanisms of junction length changes seen in development.

8:36AM E36.00002: Posttranslational modification of microtubule mechanics* [Invited]  LOREN HOUGH (Presenter), Department of Physics and BioFrontiers Institute, University of Colorado, Boulder, TAVIARE L HAWKINS, Department of Physics, University of Wisconsin, La Crosse, KATHRYN P. WALL, Department of Biochemistry and BioFrontiers Institute, University of Colorado, Boulder, HAROLD HART, Department of Physics, University of Wisconsin, La Crosse — Microtubules are built from tubulin dimers, which contain an intrinsically disordered C-terminal tail that makes up approximately 4% of the mass of a dimer. These tails coat the microtubule surface, and affect microtubule bending (the persistence length) and binding of other proteins. C-terminal tails are post-translationally modified by addition of chains of glycine or glutamate residues. We have developed methods for purifying tubulin with distinct levels of these modifications to study how tail modification affects microtubule behavior. We combine nuclear magnetic resonance spectroscopy with fluorescence measurements of the microtubule bending rigidity to determine the atomic and mechanical effects of varying post-translational modifications. Remarkably, we find that posttranslational modification that adds a small number of additional residues to the tubulin tail can lead to increase the microtubule persistence length by almost 50%.

9:12AM E36.00003: Active Stresses and Stress Relaxation in Cytoskeletal Networks* [Invited] FRED C. MACKINTOSH (Presenter), Department of Chemical and Biomolecular Engineering, Rice University — Living systems must operate out of thermodynamic equilibrium at the molecular scale. This lack of equilibrium results in directed fluxes through chemical states or phase space, corresponding to violations of the principle of detailed balance at the molecular scale. We explore consequences of such active, nonequilibrium dynamics at the meso and macro scales, with particular emphasis on cytoskeletal networks, which are driven by a variety of internal stresses. These stresses are often due to molecular motors, such as myosin that generates tension in the actin networks. These stresses can result in active remodeling of the networks and self organization of stress, particularly in networks near marginal stability. Active processes can also govern stress relaxation in such networks, through treadmilling and severing of filaments. We show how severing can lead to a surprising molecular weight independent relaxation in actin gels. We also show how transient crosslinking, together with prestress can lead to very slow, glassy relaxation in actin gels. Moreover, transient nonequilibrium (un)binding can also generate contractile stress in the absence of molecular motors.

9:48AM E36.00004: Dynamics and mechanics of actin cytoskeleton networks in vitro and in cellulo* [Invited] OLIVIA DU ROURE (Presenter), JULIEN HEUVINGH, PMMH UMR 7636, CNRS ESPCI Paris, PIERRE BAUÉR, Hospital, Institut Curie, Paris, REDA BELBAHRI, PMMH UMR 7636, CNRS ESPCI Paris, ALPHÉE MICHELOT, IBDM UMR 7288, CNRS AMU, VALENTIN LAPLAUD, PMMH UMR 7636, CNRS ESPCI Paris, MATTHIEU PIEL, UMR 144, Institut Curie, Paris, ANA-MARIA LENNON-DUMENIL, U932, Institut Curie, Inserm — Actin is a protein which self-assembles into highly dynamic filaments organized, within the cells, in different kinds of structures: bundled, crosslinked, contractile or branched networks. Actin interacts with a large number of partners either regulating the meshwork dynamics (polymerization, depolymerization and contractility) or the meshwork architecture (bundling, branching or crosslinking proteins). The architecture dictates the mechanics of the network and combines to its dynamic properties to enable the cell to achieve essential processes like migration, deformation or integration of external signals. I will show in this talk how we take advantage of the self-assembly of magnetic micro-particles to study simultaneously dynamic and mechanical properties of different actin networks. Results on actin cortex directly in living cells as well as on in vitro Arp2/3 actin networks resembling the ones at play in lamellipodia or in endocytosis will be discussed.

*This work benefited from the support of the French Agence Nationale de la Recherche (ANR) under the grant MuScActin (ANR-15-CE13-0004), of ITMO Cancer (VL, PhD fellowship), and of ERC grant SegregActin (ERC-StG-2014 638376).

10:24AM E36.00005: What can we learn from self-organization for the understanding of the spatio-temporal dynamics of the cytoskeleton* [Invited] EBERHARD BODENSCHATZ (Presenter), ALEXEI KREKOV, MARCO TARANTOLA, HSIN-FANG HSU, Max Planck Institute for Dynamics and Self-Organization, CARSTEN BETA, University of Potsdam — The response of the actin cytoskeleton to external chemical stimuli plays a fundamental role in numerous cellular functions. One of the key players that governs the dynamics of the actin network is the motor protein myosinII. Here we report on experiments and modeling on the interplay between myosinII and filamentous actin in Dictyostelium discoideum. In chemotactically competent cells, upon uniform stimulation with the chemoattractant cAMP, myosinII is first released from the cortical region and then translocated back to the cortex with a time delay relative to the rapid increase of cortical actin. After the initial release of myosinII, the freshly formed filamentous actin pushed the membrane outward resulting in a change of cell morphology. By comparing with myosinII-null cells, we found that in the last stage of the cell response the coupling between myosinII and actin determines contraction dynamics. I shall also report on our approaches using phase field modeling.

8:00AM E37.00001: NMR Investigation of the Breathing Kagome Lattice in Li$_2$In$_{1-x}$Sc$_x$Mo$_3$O$_8$  AIME VERRIER
(Presenter), MARIAM EL-AMINE, XAVIER BAZIER-MATTE, Institut Quantique, Université de Sherbrooke, HAIDONG ZHOU, RYAN P
SINCCLAIR, University of Tennessee, JEFFREY QUILLIAM, Institut Quantique, Université de Sherbrooke — We report $^7$Li NMR
measurements on Li$_2$In$_{1-x}$Sc$_x$Mo$_3$O$_8$ at concentrations $x=0$, 0.6 and 1. The results are compared with those of other groups
on the end members of the series [1] and with previous work using muon spin rotation ($\mu$SR) [2]. The sample dependence
and the effects of pressure on the NMR spectra and on the temperature dependence of the spin-lattice relaxation will be
discussed, as well as their implications for possible spinon excitations in the spin liquid regime at intermediate Sc
concentration.

(2018).

8:12AM E37.00002: Thermal transport properties of S = 1/2 Cd-kapellasite  MASATOSHI AKAZAWA (Presenter), HAYATO
DOKI, KAORI SUGII, MASAAMI SHIMOZAWA, MINORU YAMASHITA, HYUN-YONG LEE, NAOKI KAWASHIMA, RYUTARO
OKUMA, ZENJI HIROI, ISSP, University of Tokyo, JUNG HOON HAN, Sungkyunkwan University — In recent years the thermal Hall
effect has gained a great interest as an important signature of the topology. This effect has been observed in
paramagnetic phase of kagome antiferromagnets, volborthite and Ca-kapellasite [1]. These thermal Hall conductivities ($\kappa_{xy}$)
are shown to be well reproduced by Schwinger-boson mean field theory by tuning the Dzyaloshinskii-Moriya
interaction D and the exchange energy J as fitting parameters. In this talk, we report further evidence supporting the
agreement between the experiment and theory from thermal Hall measurements in Cd-kapellasite CdCu$_3$(OH)$_6$(NO$_3$)$_2$H$_2$O
which has a smaller J/k$_B$ ~ 45 K than that of Ca-kapellasite. We find not only that $\kappa_{xy}$ of Cd-kapellasite is also well
reproduced by the theory, but also that the peak temperature in $\kappa_{xy}$ is shifted to a lower temperature with a larger value in
$\kappa_{xy}$ as expected by the theory. The good scaling of these kagome materials strongly indicates that a kagome

Goethe Universität Frankfurt am Mai, THEO SIEGRIST, National High Magnetic Field Laboratory — Barlowite (Cu$_4$(OH)$_6$FBr)
and claringbullite (Cu$_4$(OH)$_6$FCl) are atacamite minerals related to the quantum spin liquid (QSL) candidate herbertsmithite
ZnCu$_3$(OH)$_6$Cl$_2$, the popular S = ½ antiferromagnet with a geometrically perfect kagome lattice. The kagome lattices of
claringbullite and barlowite are stacked perfectly on top of one another and show promise as QSL candidates.
Experiments suggest that at room temperature both materials have a hexagonal crystal structure with P6$_3$/mmc symmetry and
undergo temperature-dependent phase transitions. Ab-initio density functional theory calculations were performed to
explain these structural phase transitions. The transitions are likely influenced by the presence of defects, so it is expected
that the transition temperature varies from sample to sample and will be different for crystals grown by different
methods.

ARASH AKBARI-SHARBAF (Presenter), Institut Quantique and Département de Physique, Université de Sherbrooke, RYAN P. SINCLAIR, Department of Physics and Astronomy, University of Tennessee, AÎMÉ VÉRRIER, DJAMEL ZIAT, Institut Quantique and Département de Physique, Université de Sherbrooke, HAIMDONG ZHOU, Department of Physics and Astronomy, University of Tennessee, XUEFENG SUN, Department of Physics, Hefei National Laboratory for Physical Sciences at the Microscale, JEFFREY QUILLIAM, Institut Quantique and Département de Physique, Université de Sherbrooke — A promising approach to understanding the complexities of experimental quantum spin liquid candidates is to search for a way to tune the microscopic Hamiltonian and study changes in the resulting magnetic phases. In this talk I will present recent developments in a new class of highly tunable Mo$_3$O$_{13}$ cluster Mott insulators. This family of materials can be viewed as a breathing kagome lattice (BKL) of Mo ions, where the corner-sharing up and down triangles have two different sizes. In the compounds Li$_2$In$_{1-x}$Sc$_x$Mo$_3$O$_8$ the breathing parameter ($\lambda$) changes non-monotonically with Sc concentration ($x$), tuning the system from an antiferromagnetic Mott insulator for large $\lambda$, to a quantum spin liquid for small $\lambda$.[1]. For large breathing parameter electrons become confined on the small triangles forming spin-1/2 Mo$_3$ clusters on a triangular lattice with antiferromagnetic exchange coupling between them, leading to long range antiferromagnetic order. On the other hand, for small breathing parameter electrons are no longer confined to individual Mo$_3$ clusters but can tunnel between adjacent clusters, leading to a novel long range plaquette charge order (PCO) [2]. Our thermodynamic and muon spin rotation ($\mu$SR) measurements, suggest that the PCO coincides with a high degree of spin frustration and leads to a quantum spin liquid ground state, with gapless spinon excitations. The tunability of these materials can be extended to lower and higher breathing parameter in several related Mo-oxide materials, revealing additional quantum spin liquids and even ferromagnetism.

9:12 AM E37.00005: Pressure and doping effects on the low-field anomalous magnetism in kagome Co$_3$Sn$_2$S$_2$  
HUNG-CHENG WU (Presenter), Texas Center for Superconductivity, University of Houston, Texas 77204, USA, PO-JUNG SUN, DONG-JIE HSIEH, Department of Physics, National Sun Yat-sen University, Kaohsiung, 80424, Taiwan, D CHANDRASEKHAR KAKARLA, Center of Crystal Research, National Sun Yat-sen University, Kaohsiung, 80424, Taiwan, CHING-WU CHU, Texas Center for Superconductivity, University of Houston, Texas 77204, USA, HUNG-DUEN YANG, Department of Physics, National Sun Yat-sen University, Kaohsiung, 80424, Taiwan — Polycrystalline samples Co$_3$Sn$_2$S$_{2+x}$ (0 ≤ x ≤ 0.34) and (Co$_{1-x}$M$_x$)$_3$Sn$_2$S$_{2.26}$ (M = Ni and Fe, 0 ≤ x ≤ 0.05) have been synthesized using solid-state-reaction and characterized by X-ray diffraction (XRD) and electron probe microanalyzer (EPMA). Basically, we are able to reproduce the phase diagram (so-called A' phase) as previously reported with negligible sample dependent effect. Furthermore, following the similar procedure and analysis, a so-called A' phase within phase can be sketched in H-T phase diagram of Co$_3$Sn$_2$S$_2$. Under the effects of external high-pressure and chemical substitutions, the anomalous magnetisms (A and A') in low magnetic field show a significant change. The possible origin of the field-induced A' phase could be ascribed to the non-collinear skyrmion-like phenomena. These striking findings provide a new candidate in spin-frustrated systems to explore the complexity of magnetic-field-induced magnetism.

9:24 AM E37.00006: Spin dynamics in the antiferromagnetic Heisenberg model on a pyrochlore slab  PREETHA SAHA (Presenter), DEPEI ZHANG, GIA-WEI CHERN, University of Virginia — Unconventional magnetic states such as spin liquids and spin glasses continue to attract the interest of researchers in magnetism. Recently, considerable effort has been focused on understanding their dynamical signatures.[1-2]. We present our study on deterministic spin precession dynamics using energy conserving Landau-Lifshitz equation on a geometrically frustrated magnet. The lattice constitutes of a triangular arrangement of bipyramids with classical antiferromagnetic Heisenberg interaction. Such a lattice structure is realized in frustrated SrCr$_9$Ga$_{2.9}$P$_{0.19}$[SCGO(p)] compounds [3]. Monte Carlo simulations are used to thermalize the system, which is then used as the initial state for the dynamical studies. We explore the temperature, wave vector and frequency dependence in the dynamical structure factor and the corresponding time dependent correlation functions of the model. Dynamics simulations is further used to estimate the extent to which transport of spin excitations in the lattice conform with phenomenological concept of spin diffusion.

9:36AM E37.00007: Chiral superconductivity with full Bogoliubov Fermi surface in a doped Kagome spin-liquid state.* FAN YANG (Presenter), Beijing Institute of Technology, YIFAN JIANG, Stanford University, HONG YAO, Tsinghua University — We employ a large-scale variational Monte-Carlo simulation to investigate the lightly doped t-J model on the Kagome lattice. We propose several new variational states which smoothly connect to the previously studied uniform 0-flux or U(1) π-flux states. By comparing the energies of a variety of trial-states at several system-sizes, we find that the state with lowest energy is a chiral superconducting state with full Bogoliubov Fermi surface, which can be analogous to the Fulde-Ferrell-Larkin-Ovchinnikov state. The physical properties of this new state and the experimental consequences of the existence of Bogoliubov Fermi surface in this superconducting state are discussed.

*Supported by NSFC under the grant No.11674025, 11334012

9:48AM E37.00008: A single-layer infinite projected entangled-pair state study of the chiral antiferromagnetic Heisenberg model on Kagome lattice* REZA HAGHSHENAS (Presenter), DONNA SHENG, SHOUSHU GONG, California State University, Northridge — In this talk, we present the study of the chiral antiferromagnetic Heisenberg model on Kagome lattice by using the infinite projected entangled-pair state ansatz. We discuss how to develop an efficient optimization algorithm in the framework of the single-layer tensor network with reduced computation cost O(D^9), where D is the so-called bond dimension of local tensors. We show that the algorithm is stable, providing accurate results similar to previous double-layer tensor network ansatz. We compare the extracted phase diagram with previous DMRG study and additionally show that only for strong chiral couplings the correlation length, extracted from the transfer matrix, reaches a fixed value for the largest bond dimensions, representing a gaped chiral state.

*This research is supported by the Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, under Contract No. DE-AC02-76SF00515 through SLAC National Accelerator Laboratory

10:00AM E37.00009: Magnetic clustering in frustrated Heisenberg magnets TOMONARI MIZOGUCHI (Presenter), Department of Physics, University of Tsukuba, LUDOVIC JAUBERT, University of Bordeaux, RODERICH MOESSNER, Max-Planck-Institut fur Physik komplexer Systeme, MASAFUMI UDAGAWA, Department of Physics, Gakushuin University — Fractionalization is one of the fundamental properties of magnets with nontrivial topological character. For example in spin ice, fractionalized degrees of freedom take the form of magnetic monopoles which serve as elementary excitations with a conserved quantum number, their magnetic charge. Recently, it has been pointed out that the clustering of such topological charges leads to characteristic patterns in static structure factors, which we named half moons, distinct form the pinch points that serve as indicators of a Coulomb phase.

In this presentation, we present a theory of clustering of spins in a more general framework. For this purpose, we employ J1-J2-J3 Heisenberg models on kagome and pyrochlore lattices. By investigating the magnetic structure factor with a large-N approximation, we find that the pinch points turn into different characteristic patterns, namely half moons and stars. Those are the sign of the clustering of spins in the real space whose structures are similar to that in the Ising models. We also reveal by solving the Landau-Lifshitz equation that the characteristic patterns are also found in the dynamical structure factor, indicating that those patterns serve as a clue to find clustering states through inelastic neutron scattering spectra.

10:12AM E37.00010: Phases of the Chiral-Heisenberg Kagome Antiferromagnet* JACKSON PITTS (Presenter), Univ of California - Riverside, FINN BUSSSEN, Univ Cologne, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems, Dresden, SIMON TREBST, Univ Cologne, KIRILL SHTENGEL, Univ of California - Riverside — The ground state degeneracy of the classical kagome Heisenberg antiferromagnet (KHAFM) is remarkably similar to that of the kagome chiral model (KCM) whose Hamiltonian consists of the scalar spin chiralities on the triangles of the lattice. However, models containing both types of interactions have reduced degeneracies. If chiral terms are introduced uniformly, the v3×v3 state lifts from the ground state manifold, but if they are introduced with staggered sign, the q=0 state is excluded instead. Only once the Heisenberg terms are entirely eliminated are states of both types again ground states. This has drastic effects on the order-by-disorder mechanism that drives coplanar ordering in the KHAFM. Our Monte Carlo simulations demonstrate a more discriminating selection effect in the intermediate models. Furthermore, even in the case of the pure KCM, only the v3×v3 structure is observed. We explain this by counting the soft modes of the KCM’s ground states. Only states of v3×v3 structure have sufficient populations of soft modes to drive the system to order. Due to an extra degeneracy of the KCM this structure exists on a large set of states forming a classical spin liquid.

A mechanism for thermal Hall effect in Mott insulating spin liquid

YONGHAO GAO (Presenter), GANG CHEN, Fudan University — We study the origin of thermal Hall effect from the spinon transport in a U(1) spinon metal. The external magnetic field, that polarizes the spins, effectively generates an internal U(1) gauge flux for the spinons and twists the spinon motion through the antisymmetric interaction. Such a mechanism for Lorentz force generation differs fundamentally from the induction of the internal U(1) gauge flux in the weak Mott insulating regime from the charge fluctuations. We apply this understanding to the specific cases of spinon metals in Kagome lattice and hyperkagome lattice. We carry out a numerical calculation of the thermal Hall conductivity within the linear response theory and discuss the relevance with the thermal transport measurement in Kagome materials volborthite and kapellasite.
8:12AM E38.00002: Mapping of a thin-film ferromagnet to electrodynamics: quantum statistics of vortices

SHU ZHANG (Presenter), SAYAK DASGUPTA, MICHAEL BJERNGAARD, OLEG TCHERNYSHYOV, Johns Hopkins University — We consider a field-theoretic description of a thin-film ferromagnet with easy-plane anisotropy. The system can be mapped to the electrodynamics theory in (2+1)-dimensional space-time. The low-energy description is the familiar Maxwell electrodynamics. Spin waves become electromagnetic waves, whereas vortices turn into particles whose electric charge equals the vortex number n. A careful analysis of the high-energy theory reveals that these particles also carry a magnetic flux equal to the net spin of the vortex core $S_z$. Braiding two identical vortices yields an Aharonov-Bohm phase $\exp(2\pi i n S_z)$, which may lead to a nontrivial quantum statistics of vortices.

8:24AM E38.00003: Mapping of a thin-film ferromagnet to electrodynamics: emission of spin waves by vortices

MICHAEL BJERNGAARD (Presenter), SAYAK DASGUPTA, SHU ZHANG, OLEG TCHERNYSHYOV, Johns Hopkins University — We consider a field-theoretic description of a thin-film ferromagnet with easy-plane anisotropy. An extension of the well-known duality with electrostatics in 2-dimensional space to (2+1)-dimensional spacetime maps this system to a theory of electrodynamics. The low-energy description is the familiar Maxwell electrodynamics. Spin waves become electromagnetic waves, whereas vortices turn into particles whose electric charge equals the vortex number. This analogy allows us to compute the emission of spin waves by a rotating vortex-antivortex pair. Energy dissipation from this process becomes noticeable when the pair separation decreases below a characteristic length scale of order $a^{-1/2}R$, where $R$ is the radius of the vortex core and $a$ is the Gilbert constant.

*The research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02-08ER46544.

8:36AM E38.00004: Calculation of nonlinear susceptibility in magnetic systems

YURIY SIZYUK (Presenter), PETER P. ORTH, Physics and Astronomy, Iowa State University — Coherent nonlinear optical spectroscopy has been a successful tool to probe interactions between excitations in NMR and semiconductor experiments. Recent advances of optical experiments in the terahertz range allows the realization of similar measurements for localized magnetic systems. Anticipating this, we are calculating nonlinear magnetic susceptibilities for well known models, such as the transverse field Ising model, and Kitaev honeycomb model. The information about the magnetic excitations can then be used as a probe to experimentally identify complex, yet elusive magnetic ground states, such as quantum spin liquids.

8:48AM E38.00005: Energy-momentum tensor of a ferromagnet

SAYAK DASGUPTA (Presenter), OLEG TCHERNYSHYOV, Johns Hopkins University — The energy-momentum tensor provides valuable information about a physical system. Deriving this quantity for a ferromagnet runs into a conceptual difficulty associated with the presence of gyroscopic forces, which are represented by spin Berry-phase terms in the Lagrangian. Their gauge dependence and lack of rotational symmetry lead to paradoxes. E.g., the adiabatic spin torque exerted on a domain wall by a spin-polarized current is either missing or contains unphysical glitches, depending on the gauge choice. It is therefore desirable to derive a gauge-invariant and rotationally symmetric version of the energy-momentum tensor. We achieve this by using the gauge-invariant and symmetric Wess-Zumino action for spins at the expense of introducing an extra dimension, with the ferromagnet living on its boundary. The energy-momentum tensor defined in this (d+2)-dimensional spacetime yields correct physical answers.

9:00AM E38.00006: A measurable form of Bell's correlation of spin currents across a double dot in the Kondo regime

RUI SAKANO (Presenter), ISSP, University of Tokyo, AKIRA OGURI, YUNORI NISHIKAWA, Physics, Osaka city university, EISUKE ABE, Spintronics Research Center, Keio university — We investigate Bell-state correlations of quasiparticle pairs that are excited within nonlinear current through a double dot in the Kondo regime. Using the renormalized perturbation expansion in the residual interaction of the local Fermi liquid, we calculate an asymptotically exact form of Bell's correlation at low energies. We find that the exchange interaction of the double dot violates Bell's inequality. We especially suggest a measurable form of Bell's inequality that is given by correlations of the full current across the double dot. We illustrate the exchange interaction dependence of upper limits of the suggested Bell's correlation in the quantum theory and the hidden variable theory, using the numerical renormalization group calculation.

9:12AM E38.00007: Evolution of magnetic Dirac bosons in a Kagome lattice* DANIEL BOYKO (Presenter), University of North Florida, ALEXANDER BALATSKY, Institute for Material Science, Los Alamos National Laboratory, AVADH SAXENA, Theoretical Division - T4, Los Alamos National Laboratory, JASON HARALDSEN, University of North Florida — We examine the magnetic properties and spin dynamics of Dirac nodes in a Heisenberg kagome lattice. Using linear spin theory, the phase diagrams and the evolution of exchange interactions in various magnetic configurations of the Kagome lattice are numerically calculated and produce spin waves that contain bosonic Dirac and Weyl points. Through the frustration of the magnetic geometry, we see a connection to the symmetry properties of the kagome lattice and the various antiferromagnetic configurations, where further study of external frustrations from a magnetic field, temperature, and anisotropy may reveal a controllability of the exchange interactions and nodal points.

*Institute for Materials Science at Los Alamos National Laboratory.

9:24AM E38.00008: How many tunable parameters to attain a spin degeneracy between Landau levels? CHONG WANG (Presenter), DUAN WENHUI, Tsinghua University, LEONID GLAZMAN, ARIS ALEXANDRADINATA, Yale University — The spin degeneracy of Landau levels is generically lifted by the Zeeman interaction, and also by the spin-orbit coupling in non-centrosymmetric solids. In the absence of any crystalline point-group symmetry, such a spin degeneracy can only be found by tuning three real parameters; we have exhaustively identified all symmetry classes of solids for which this number is reduced from three. In particular, only one parameter is needed in the presence of rotational symmetry; this parameter may be the magnitude or orientation of the field, or the bias voltage in tunneling spectroscopy. Signatures of single-parameter tunability include: (i) a smooth crossover between period-doubled and -undoubled quantum oscillations in the low-temperature Schubnikov-de Haas effect, and (ii) "magic angle" magnetoresistance oscillations. Case study is discussed for the Rashba-Dresselhaus two-dimensional electron gas subject to an arbitrarily oriented magnetic field.

9:36AM E38.00009: Implementation and application of a real-space pseudopotential method for calculating magnetocrystalline anisotropy* MASAHIRO SAKURAI (Presenter), JAMES CHELIKOWSKY, University of Texas at Austin — We present a real-space pseudopotential method for calculating magnetocrystalline anisotropy within relativistic density-functional theory. Our formalism is implemented in our real-space pseudopotential code, PARSEC, which is explicitly designed for an efficient implementation on a parallel computing platform (Phys. Rev. Materials 2, 084411 (2018)). We demonstrate that our formalism works well for prototypical transition-metal compounds, such as YCo5 and Mn2Ga, yielding an accurate magnetization and a magnetocrystalline anisotropy constant consistent with previous work. We also use our method to explore possible candidate materials for rare-earth-free permanent magnets. We find that ZrCo5 compounds can provide moderate magnetocrystalline anisotropy and sufficient work is supported by the National Science Foundation (NSF), DMREF-1729202. HPC resources were provided by the Texas Advanced Computing Center (TACC).saturation magnetization (Phys. Rev. Materials 2, 084410 (2018)).

*Our work is supported by the National Science Foundation (NSF), DMREF-1729202. HPC resources were provided by the Texas Advanced Computing Center (TACC).

9:48AM E38.00010: Strain control of the Néel vector in L10-type Mn-based antiferromagnetic materials: a first principles study* IN JUN PARK (Presenter), ROGER LAKE, University of California, Riverside — Mn-based antiferromagnetically ordered L10-type crystals such as MnIr, MnRh, MnNi, MnPd, and MnPt are of interest for possible electronic or spintronic applications. We used first-principles calculations to study the effect of strain on the magnetic anisotropy of those materials. The strain is applied along one axis (a) of the basal plane, and the structure and lattice vectors in the other two directions (b,c) are fully relaxed. We found that by applying strain, the direction of the Néel vector can be rotated by 90° for all materials. For MnIr, MnRh, MnNi, and MnPd, the Néel vector rotates within the basal plane. The sign of the effect, whether compression along the a-axis leads to a parallel or perpendicular Néel vector, depends on the specific material. MnPt is unique among this material family, since, at zero strain, its Néel vector lies along the c-axis, and strain along the a-axis rotates it into the basal plane.

*This work was supported as part of the Spins and Heat in Nanoscale Electronic Systems (SHINES) an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award #DE-SC0012670.
10:00AM E38.00011: First-principles calculations of magneto-optical Kerr effect in high Neel temperature antiferromagnetic Metals*  KRITHIK PUTHALATH (Presenter), Physics, University of Illinois at Urbana-Champaign, KISUNG KANG, ANDRE SCHLEIFE, Materials Science and Engineering, University of Illinois at Urbana-Champaign — Recent developments in spintronics have suggested the use of high Neel temperature antiferromagnetic (AFM) materials in memory devices due to their vanishing stray fields and robust magnetic structure for ultra-fast spin dynamics in the terahertz regime. In particular, the optical response of these magnetic materials via the Kerr effect (MOKE) provides an excellent method to probe surface magnetization and elucidate the AFM state under external magnetic fields. In this work, we use first-principles density functional theory calculations to obtain the fully relativistic dielectric tensor to predict MOKE signals for Cr$_2$As, Mn$_2$As, Fe$_2$As, MnPt and Mn$_2$Au under external magnetic fields. We further corroborate experimental measurements by obtaining the magnetic susceptibility from first principles using a spin-tilting method. Finally, we explore the implications of applying external magnetic bias in AFMs by interpreting the electronic band structure and its evolution with respect to spin-orbit coupling and magnetization, to better understand the origins of the predicted MOKE signals.

10:12AM E38.00012: Geometrical indicators for magnetism in Pt clusters*  ROBERTO D'AGOSTA (Presenter), University of the Basque Country, CONO DI PAOLA, FRANCESCA BALETT, Physics, King's College London — With "There is plenty of room at the bottom", Feynman points at the nanoscale where new phenomena take place, in particular when the behaviour of "a few" influences "many" particles. In particular, in nanoparticle physics, the lack of periodicity stabilises isomers whose morphology is impossible in crystalline bulk. At the same time, the physical properties of a mono-metallic nanocluster depend strongly on its shape and size. For example, catalytic properties rely on the presence of specific and diverse adsorption sites. By playing with size and shape of the nanocluster, we modify its properties towards tailored applications. We show that magnetism arising in nano-sized Pt objects is due to an effect present in the second coordination shell [1]. We demonstrate how magnetism is affected by the surrounding environment in the case of small Pt-nanoclusters embedded in zeolite pores [2]. Hopefully, we can identify geometrical indicators that help in designing clusters.

Session E39 GMAG DMP: Magnetic Nanostructures and Nanoparticles BCEC 207 - Katrin Schultheiss, Helmholtz-Zentrum Dresden-Rossendorf - Tag(s): Focus
8:00AM E39.00001: Topological Magnetic Writing: Controlling the magnetic state of nanostructures∗ [Invited] JACK C GARTSIDE, DAAN M ARROO, ALEXANDER VANSTONE, LESLEY COHEN, WILL BRANFORD (Presenter), Physics, Imperial College London — Networks of magnetic nanostructures are of broad interest from novel data storage and computation to magnonic crystals. One family of nanomagnetic arrays, characterized by strong and frustrated magnetic interactions are the artificial spin ices (ASI).1 ASI structures have provided vast amounts of physical insight in recent years in part due to their ability to model complex systems and exhibit exotic phenomena such as ‘magnetic monopole’-like states.2 The power of these networks stems from the extraordinary number of unique microstates, even in systems comprising relatively few nanostructures. However, magnetic nanoarrays in general, and ASI structures in particular, have yet to realise their full potential as the majority of microstates remain inaccessible due to the rudimentary state-writing tools currently available. An experimental means to prepare all potential microstates has huge implications, including realising ASI as a tunable-bandgap magnonic crystal3 or reconfigurable neural-network4. We present a novel MFM-tip based state writing technique,5 building on our previously demonstrated domain-wall injection process.6 It requires no global fields and is applicable to all nanostructure architectures, providing control over the spin-configuration and access to every possible microstate. We demonstrate our method via realisation of several exotic and thus-far unobserved states, unachievable via global field-protocols: ‘magnetic monopole-defect’ chains and the spin-crystal ground state of kagome ASI.

*The work was funded by Leverhulme Trust Research Project Grant RPG-2017-257

8:36AM E39.00002: Enhanced interaction strength in perpendicular artificial spin ice arrays∗ SUSAN KEMPINGER (Presenter), YU-SHENG HUANG, PAUL EDWARD LAMMERT, Pennsylvania State University, MICHAEL VOGEL, JOHN E. PEARSON, AXEL F HOFFMANN, Argonne National Lab, VINCENT HENRY CRESPI, Pennsylvania State University, PETER E SCHIFFER, Yale University, NITIN SAMARTH, Pennsylvania State University — Perpendicular implementations of artificial spin ice are appealing as a custom designed, frustrated system due to the optical accessibility of the magnetic components. This allows for complete microstate characterization in situ with an applied field using magneto-optical Kerr effect microscopy. We have fabricated arrays of lithographically patterned, single-domain Pt/Co multilayer islands. Studies on this system thus far have been limited by the weak interactions between islands that fit the constraints necessary for optical accessibility. New samples fabricated with a permalloy underlayer show an enhancement in correlation and allow for studies beyond the weakly interacting regime. We study both the quasi-dynamic hysteresis and demagnetized states of these systems to gain an understanding of how the coupling is affected by the soft underlayer.

*This project was funded by the US Department of Energy, Office of Basic Energy Sciences, Materials Sciences and Engineering Division under Grant No. DE- SC0010778

8:48AM E39.00003: Role of Lattice Defects in Artificial Spin Ice Studied with Coherent X-ray Scattering and XMCD-PEEM∗ XIAOQIAN M CHEN (Presenter), Lawrence Berkeley National Laboratory and University of Kentucky, BARRY W FARMER, JUSTIN WOODS, LANCE DE LONG, Physics, University of Kentucky, SUJOY ROY, ALS, Lawrence Berkeley National Laboratory, JEFFREY T HASTINGS, Electrical and Computer Engineering., University of Kentucky — Magnetically frustrated materials are unable to satisfy all competing interactions simultaneously. The introduction of a small defect in such a system can completely alter the ground state. We used coherent x-ray scattering and XMCD-PEEM to investigate the role of lattice defects in artificial spin ice. We observed reduced blocking temperature and the broadening of the phase coexistence region with increased doping. In addition, we observed defect pinnings of superdomain walls in a nontrivial manner as the temperature is varied through the transition.

*This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences under Award Number DE-SC0016519.
From ordering piles of sand [1] to comprehending the human mind [2], spin glass systems continue to inspire theorists and experimentalists alike. Artificial nanomagnet fabrication [3] offers a unique opportunity to directly visualize the dynamics of glassy systems. However, spin glass phases have only been discovered at finite temperature in systems embedded in dimensions greater than or equal to 3 [1,4]. In this study we fabricate Nanomagnet arrays such that the network of their interactions possesses an effective dimension [5] higher than 2. Dubbed the Bethe glass, this is first finite temperature spin glass embedded in two dimensions. Using XMCD [6] the time scale free relaxation of magnetic moments is filmed in real space, directly observing the supermetric qualities of [1] spin glass. Further, the effective dimension is varied to show the tunability of glass properties.

The fabrication of three-dimensional (3D) magnetic nanostructures is currently a central topic in nanomagnetism [1]. Ferromagnetic nanowires (NWs) and nanotubes (NTs) are potential candidates for magnetic data storage, logic and sensing, and Focused Electron Beam Induced Deposition (FEBID) could play a crucial role in the fabrication of these architectures [2].

We have developed a new approach to grow core-shell heterostructures by FEBID [3], obtaining Co@Pt and Fe@Pt NWs, and Co NTs [4]. In addition, annealing treatments of Co NWs have been found to increase metal purity, crystallinity and magnetic induction [5].

Furthermore, we report on the fabrication of Magnetic Force Microscopy (MFM) tips by FEBID, showing great performance. Tailored Co and Fe MFM tips have been tested, both in ambient conditions and liquid environment, getting outstanding mechanical stability, resolution and sensitivity [6,7]. In particular, Fe tips with a 7 nm-wide sharp end exhibit low sample-tip magnetic interaction, which has been useful to measure complex magnetic states such as skyrmions [7].

We have observed asymmetric electrical transport in macroscopic samples of artificial magnetic honeycomb lattice of Permalloy having ultra-small elements with length scales of sub - 10nm to 30nm. The unidirectional enhancement of conductivity, analogues to a semiconductor diode, is dependent on thickness of the Permalloy as well as the order of honeycomb and can persist up to room temperature. The Permalloy honeycomb lattice exhibit very small rectification voltage and power dissipation compared with semiconductor diodes, which could have strong implication for spintronics. We will present detailed investigation done on the system and shed some light on the possible mechanism behind the asymmetric transport phenomena.

*The research at MU is supported by the US Department of Energy, Office of Basic Energy Sciences under grant no. DE-SC0014461.
10:00AM E39.00007: Field and current control of the electrical conductivity of an artificial two-dimensional honeycomb lattice* YIYAO CHEN (Presenter), BROCK T SUMMERS, ASHUTOSH DAHAL, Department of Physics and Astronomy, University of Missouri, VALERIA LAUTER, Neutron Scattering Division, Neutron Sciences Directorate, Oak Ridge National Laboratory, GIOVANNI VIGNALE, DEEPAK K SINGH, Department of Physics and Astronomy, University of Missouri — The conductivity of a neodymium-based artificial honeycomb lattice undergoes dramatic changes upon application of magnetic fields and currents. We attribute these changes to a redistribution of magnetic charges that are formed at the vertices of the honeycomb due to the non-vanishing net flux of magnetization from adjacent magnetic elements. We suggest that the application of a large magnetic field or a current causes a transition from a disordered state, in which magnetic charges are distributed at random, to an ordered state, in which they are regularly arranged on the sites of two interpenetrating triangular Wigner crystals.

*The research at MU is supported by DOE, Office of Basic Energy Sciences under grant no. DE-SC0014461.

10:12AM E39.00008: Dynamic hysteresis loops of iron oxide nanoflowers ZOE BOEKELHEIDE (Presenter), JACKSON MILLER, Lafayette College, CORDULA GRÜTTNER, micromod Partikeltechnologie GmbH — Iron oxide nanoparticles have many potential applications in biomedicine, including magnetic hyperthermia and magnetic particle imaging. These applications depend sensitively on the magnetization ($M$) of the particles under a rapidly oscillating applied field $H$. The internal structure of nanoparticles strongly affects the magnetic behavior. Iron oxide nanoflowers, particles composed of several small crystallites fused together with an irregular surface, are promising for magnetic hyperthermia due to their large loss power [1]. We present dynamic measurements of $M(H)$ at 230 kHz for iron oxide nanoflowers. The nanoflowers were synthesized by a polyol method described previously [2]. The cores are 22 ± 9 nm and are coated in dextran (synomag®-D). The particles are suspended in H$_2$O at 14.2 mg(Fe)/mL. The resulting $M(H)$ curves show linear behavior (open ellipsoidal loops) at low fields, transitioning to nonlinear behavior at a field of 6 kA/m. These results show directly the magnetic reversal behavior of iron oxide nanoflowers in the linear and nonlinear regimes, and will help guide applications of these particles.

10:24AM E39.00009: Room temperature ferromagnetic MnCr2O4 spinel chromite nanoparticles EDUARDO MARTÍNEZ-TERÁN (Presenter), RAJU BARAL, HARIKRISHNAN NAIR, AHMED EL-GENDY, University of Texas, El Paso — MnCr2O4 spinel is a non-collinear ferrimagnet with transition temperature around 43 K. By means of reducing the particle size to nanoscale regime, the magnetic behavior changes to long-range ferromagnetic order and the transition temperature shifts to above 400 K. MnCr2O4 nanoparticles were synthesized successfully using supercritical conditions of liquid. Changing the reaction conditions, in particular, increasing the reaction time leads to reducing the particles size as well as increasing the magnetic properties of the formed MnCr2O4 nanoparticles. Crystal structures of the synthesized bulk and their nano-sized candidates were investigated using XRD revealing the same spinel cubic symmetry Fd-3m. Morphology of all samples has been identified using SEM yielding average size of 535±75 nm for bulk sample and 223±50, 195±40, 172±30, 148±27 nm for nanoparticles prepared at reaction time of 2, 4, 6, and 8 hours respectively. The results yield room temperature ferromagnetic behavior at 300 K with magnetization of 6.5, 8.4, 10.8, 17 emu/g, for 223±50, 195±40, 172±30, 148±27 nm respectively. The obtained results confirm the role of reducing the particles size in enhancing the magnetic properties and open new route to probe the ferroelectricity as well as multiferroicity of this system.

10:36AM E39.00010: Coercivity Distributions in BiFeO3 nanoparticles* EDWIN RAMOS (Presenter), ALEXANDER CARDONA, JUAN RAMIREZ, Department of physics, University of the Andes — We study the effect of distribution of coercivities with the calcination temperature, using the first order reversal curves (FORC) treatment in BiFeO3 nanoparticles prepared by sol-gel method. We varied the calcination temperature in order to control the NP size. XRD measurements suggest that at lower temperatures (450°C and 550°C) the BFO NPs are single phase. At higher temperatures an impurity phase at higher appears with magnetic contribution. The FORC treatment was built as a linear combination for each temperature value. The coercivity distributions were obtained extracting the central ridge of the resultant FORC diagrams and contrasted with magnetization as a function of magnetic field measures. These results evidence a decreasing in the coercivity average that we associate to a decrease of magnetic domain size; then, suggesting a transition from single domain to superparamagnetic particles.

Magnetically controlled geometry of flexible ferromagnetic rings

KOSTIANTYN YERSHOV (Presenter), Leibniz Institute for Solid State and Materials Research, IFW Dresden, D-01171 Dresden, Germany, DENIS D. SHEKA, Taras Shevchenko National University of Kyiv, 01601 Kyiv, Ukraine, VOLODYMYR P. KRAVCHUK, Leibniz Institute for Solid State and Materials Research, IFW Dresden, D-01171 Dresden, Germany, AVADH SAXENA, Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, YURI GAIIDIDEI, Bogolyubov Institute for Theoretical Physics of National Academy of Sciences of Ukraine, 03143 Kyiv, Ukraine — We propose a minimal extension of the anisotropic Heisenberg model in order to describe flexible magnetic wires (rings) [1]. Flexible ferromagnetic wires are spin-chain magnets, in which the magnetic and mechanical subsystems are coupled. The coupling between the magnetic and mechanical subsystems is driven by uniaxial anisotropy with the easy-axis oriented along the tangential direction. First, we show that depending on the magnetic and elastic parameters and the size of the system one can obtain two different states: the onion state with the quasi-uniform magnetization is typical for small enough rings, while the vortex state with the magnetization oriented tangential to the wire is preferable for large systems. Second, we demonstrate that according to the system symmetry there can appear normal modes with zero frequency (i.e. zero modes) on the background of equilibrium states. [1] Yu. Gaididei et al, arXiv:1809.10622 (2018).

Session E40 GMAG DMP: Magnetic Excitations in Oxides

8:00AM E40.00001: Optical signatures of a 3D electronic liquid crystal in Cd2Re2O7 [invited] DAVID HSIEH (Presenter), Physics, California Institute of Technology — In the presence of strong interactions, the fluid of mobile electrons in a metal can spontaneously break the point group symmetries of its underlying host lattice, forming an electronic analogue of a classical liquid crystal. The experimental discovery of 2D electronic liquid crystals (ELCs) was first made nearly 20 years ago in semiconductor heterostructures and has since been reported in many other systems including the copper- and iron-based high-temperature superconductors. However whether or not a 3D version of an ELC can exist has remained unclear. In this talk, I will present signatures of a 3D ELC in the strongly spin-orbit coupled metallic pyrochlore Cd2Re2O7 detected using ultrafast coherent phonon spectroscopy and a recently developed spatially-resolved nonlinear optical polarimetry technique.

8:36AM E40.00002: Nature of magnetic excitations in the spin-1/2 triangular antiferromagnet Ba3CoSb2O9 in applied magnetic field* LUWEI GE (Presenter), School of Physics, Georgia Institute of Technology, QING HUANG, Department of Physics and Astronomy, University of Tennessee, Knoxville, TAO HONG, Oak Ridge National Laboratory, HAILONG ZHOU, Department of Physics and Astronomy, University of Tennessee, Knoxville, JIE MA, Department of Physics and Astronomy, Shanghai Jiao Tong University, MARTIN MOURIGAL, School of Physics, Georgia Institute of Technology — Ba3CoSb2O9 is one of the very few experimental realizations of the spin-1/2 triangular antiferromagnets. Despite the model being extensively studied, a unified understanding of the compound’s zero-field magnetic excitations has not yet been achieved. Spin-wave theory up to 1/S correction clearly failed to describe the whole picture. However, whether this is indeed due to the intrinsic nature of the spin Hamiltonian remains debatable. Seeking more experimental evidence, we investigated the system’s field-induced states with inelastic neutron scattering, particularly in the low-field regime. While revealing some yet unexplained features, our results show some strong damping of the excitation branch around K point, consistent with the field-induced magnon decay scenario. Our results are expected to help obtain a better understanding of the system.

**8:00AM E40.00004: Non-Reciprocal Directional Dichroism of THz Radiation in Multiferroic Sr₂CoSi₂O₇**

JOHAN VIROK (Presenter), URMAS NAGEL, TOOMAS ROOM, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, DÁNIEL GERGELY FARKAS, Department of Physics, Budapest University of Technology and Economics and MTA-BME, Budapest, Hungary, PETER BALLA, Institute for Solid State Physics and Optics, Wigner Research Center for Physics, Hungarian Academy of Sciences, Budapest, Hungary, DÁVID SZALLER, Institute of Solid State Physics, Vienna University of Technology, Vienna, Austria, VILMOS KOCSIS, YUSUKE TOKUNAGA, YASUJIRO TAGUCHI, YOSHINORI TOKURA, RIKEN Center for Emergent Matter Science (CEMS), Wako, Japan, BENCE BERNÁTH, DMYTRO KAMENSKYI, High Field Magnet Laboratory (HFML-EMFL), Radboud University, Nijmegen, The Netherlands, ISTVAN KEZSMARKI, Experimental Physics 5, Center for Electronic Correlations and Magnetism, Institute of Physics, University of Augsburg, Augsburg, Germany, SANDOR BORDACS, KARLO PENC, Department of Physics, Budapest University of Technology and Economics and MTA-BME, Budapest, Hungary — Directional dichroism (DD) is the effect when material absorbs light beams travelling in opposite direction differently. At THz frequencies DD has been found in multiferroics with magnetic and charge order. In these materials the spin waves are coupled to the oscillations of electric polarization. A spin wave acquires electric dipole activity due to optical magnetoelectric (ME) coupling and therefore interacts with the electric component of the THz radiation in addition to magnetic component. We studied spin excitations in Sr₂CoSi₂O₇ below 2 THz between 3 and 100 K and in magnetic fields up to 30 T. Almost one-way transparency is seen in some spin wave modes. What is more, the DD increases above the Neel temperature (7 K) in high magnetic field. This is unusual in multiferroics but is explained by the ME coupling on a single spin site [1]. This study demonstrates that DD exists in multiferroics with the single spin site ME interaction even above the magnetic ordering temperature when sufficiently strong polarizing external magnetic field is applied [2].

**9:12AM E40.00005: Resonant inelastic x-ray scattering study the evolution of spin and charge excitations in La₂₋ₓCeₓCuO₄ combi-films**

JIAQI LIN (Presenter), JIE YUAN, Institute of Physics, Chinese Academy of Sciences, SCHMITT THORSTEN, Paul Scherrer Institute, KEJIN ZHOU, Diamond Light Source, KUI JIN, Institute of Physics, Chinese Academy of Sciences, XUERONG LIU, School of Physical Science and Technology, ShanghaiTech University — We present resonant inelastic x-ray scattering (RIXS) study of spin and charge excitations in La₂₋ₓCeₓCuO₄ combi-films. The doping level of the film changes continuously from one tip to the other, nominally x=0.10 to x=0.19. Doping dependence is accomplished by simply translating the film in a fine step along the doping gradient direction. We explored the evolution of spin and charge excitations from an optimal doped superconductivity at x=0.11 to an overdoped fermi liquid at x=0.18. As doping, the energy of both spin and charge excitations is hardening. For the width, the spin excitation is broadening, and the charge excitation becomes sharpening. In addition, we performed L and incident energy dependence measurements to examine the characteristics of two excitations. Spin excitation does not have L dependence nor incident energy dependence, while charge excitation has L dependence and slightly incident energy dependence. This indicates spin and charge excitations are not the two faces of the coin. Instead, spin and charge excitations are derived from short-range correlation and long-range Coulomb interaction, respectively.
polarization configuration $h_\omega \parallel c$ and $e_\omega \parallel b$ and observed a significant change in the spectrum between 80 K and 120 K ferroelectric phase below $T_C \approx 833$ K, there is a strong continuous change in phonon profiles involving the two non-mid-infrared spectral range. While up to 300 K our measurements are in agreement with known spectra, in the THz dielectric permittivity shows hysteresis between 80 K and 120 K that does not occur for any other orientations. In addition, we have observed a magnon with a frequency of 840 GHz at 10 K that red shifts with increasing temperature until 70 K. At which point, its spectral weight decreases rapidly, while at the same time a lower frequency magnon gains intensity. This behavior is only observed for $h_\omega \parallel c$ irrespective of the direction of the electric field of the THz pulse. These behaviors seem to be associated with the decrease in the population of the B magnetic phase and simultaneous increase in the population of the A phase around 100 K.

9:36AM E40.00007: Hysteresis of THz dielectric permittivity below $T_{\text{Neel}}$ in CaFe$_2$O$_4$*  

DANIEL HELIGMAN (Presenter), THUC MAI, Physics, Ohio State University, LUNYONG ZHANG, Laboratory for Pohang Emergent Materials and Max Plank POSTECH Center for Complex Phase Materials, Pohang University of Science and Technology, Pohang 790-784, Korea, JAE WOOK KIM, Physics and Astronomy, Rutgers University, SANG-WOOK CHEONG, Rutgers University, Physics and Astronomy, and Laboratory for Pohang Emergent Materials and Max Plank POSTECH Center for Complex Phase Materials, Pohang University of Science, ROLANDO VALDES AGUILAR, Physics, Ohio State University — CaFe$_2$O$_4$ is a quantum antiferromagnet that exhibits an interplay between two different magnetic phases below $T_{\text{Neel}} \sim 200$ K. We have analyzed the terahertz (THz) response of CaFe$_2$O$_4$ for the polarization configuration $h_\omega \parallel c$ and $e_\omega \parallel b$ and observed a significant change in the spectrum between 80 K and 120 K for frequencies above 900 GHz. The THz dielectric permittivity shows hysteresis between 80 K and 120 K that does not occur for any other orientations. In addition, we have observed a magnon with a frequency of 840 GHz at 10 K that red shifts with increasing temperature until 70 K. At which point, its spectral weight decreases rapidly, while at the same time a lower frequency magnon gains intensity. This behavior is only observed for $h_\omega \parallel c$ irrespective of the direction of the electric field of the THz pulse. These behaviors seem to be associated with the decrease in the population of the B magnetic phase and simultaneous increase in the population of the A phase around 100 K.

9:48AM E40.00008: H-ErMnO$_3$ electrodynamics from far-infrared emission, reflectivity, and absorption in the ferroelectric and paraelectric phases  

NESTOR MASSA (Presenter), CEQUINOR, CONICET- UNLP, La Plata, Argentina, LEIRE DEL CAMPO, CNRS-CEMHTI, Orléans, France, KARSTERN HOLLDACK, HZB, BESSY II, Berlin, Germany, VINH TA PHUOC, GREMAN, Tours, France, PATRICK ETCHEGUT, CNRS-CEMHTI, Orléans, France, PAULA KAYSER, CSEC-UE, Edinburgh, UK, JOSÉ ANTONIO ALONSO, ICMM-CSIC, Madrid, Spain — We report on the temperature evolution of ambient non-centrosymmetric hexagonal H-ErMnO$_3$ -P6$_3$cm-(Z=6) from 2 K to decomposition as seen in absorption, near normal reflectivity, and emission spectra in the THz to mid-infrared spectral range. While up to 300 K our measurements are in agreement with known spectra, in the ferroelectric phase below $T_C \sim 833$ K, there is a strong continuous change in phonon profiles involving the two non-equivalent Er sites and bipyramids tilting. Three weak but sharp lowest frequency-lower temperature hybrid modes also melt into the background at about $T_C$. In emission spectra, toward the paraelectric centrosymmetric (P6$_3$ /mmc, Z=2) phase, an optical conductivity mid-infrared intraband becomes distinctive. It peaks at ~5000 cm$^{-1}$ and has the energy and profile fingerprint of small polarons (bipolarons). Its intensity depends on electric dipole ordering. At 900 K, just above $T_C$, this pronounce band starts a continuous weakening shifting to lower frequencies up to the temperature triggering hopping conduction onset of decomposition. We propose that oxygen polarizability (partially delocalized 2p-electrons) is a main dynamical constituent for bipolarons in cooperative driven MnO$_5$ bipyramids and thus in spontaneous ferroelectric polarization.
Managing magnon transport properties in bulk magnetic oxides within mesoscopic Boltzmann methods*  
YANXIA WANG, TAO LIU, WEI WANG, YUHENG LI, JIANWEI ZHANG (Presenter), School of Physics Science and Engineering, Tongji University — The bulk transport properties of magnon in magnetic oxides layers demand precise physical understanding of magnon diffusion, scattering and relaxation processes. In this work, we invent a novel magnon Boltzmann equation from full quantum magnon Hamiltonian. With changing thickness of magnetic oxide film (YIG), our numerical results on magnon accumulation and current show there are two different processes in bulk magnon transport: diffusion region and relaxation region. Furthermore, we theoretically discover physical origin for decreasing of magnon diffusion length with increasing magnetic field $H$, it was only observed in previous experimental works. And since magnon relaxation closely related to many magnons scattering, a new spatial dependent draft field was introduced, similar to anisotropy, which was describing collective local motion of magnon. More importantly, our results show magnon current can be manipulated by varying of anisotropy in magnetic oxides, especially in strong anisotropic energy materials, such as NiFe$_2$O$_4$ or CoFe$_2$O$_4$. In this framework, we also provide the methods to adjust the magnon transport with applying gradient magnetic field and gradient $T$ field.

Spin Structure Models of YFeO$_3$ from THz Spectroscopy Study*  
KIRILL AMELIN (Presenter), URMAS NAGEL, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, RANDY FISHMAN, Materials Science and Technology Division, Oak Ridge National Lab, Oak Ridge, Tennessee, USA, YOSHIYUKI YOSHIDA, National Institute of Advanced Industrial Science and Technology, Tsukuba, Ibaraki, Japan, HASUNG SIM, KISOO PARK, JE-GUEN PARK, Department of Physics & Astronomy, Seoul National University, Seoul, Korea, TOOMAS ROOM, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia — In YFeO$_3$ iron spins $S=5/2$ arrange in an antiferromagnetic (AFM) canted state $\Gamma_4(G_a F_{c} A_{1b})$ well above room temperature. With four spins per unit cell, its spin structure is described by a combination of exchange interactions, Dzyaloshinskii-Moriya (DM) interactions, and single-ion anisotropies (SIA). Since only Fe ions have the non-zero magnetic moment, this compound is a perfect modelling system for spin interactions and a step towards understanding more complex materials, possibly those with multiferroic properties.

We measured absorption of THz radiation in single crystals at the temperature 3 K in magnetic fields up to $B = 17$ T. THz spectroscopy can measure two out of four spin wave (SW) modes in YFeO$_3$, those with zero-field energies 1.2 and 2.4 meV. Combining the $B$ dependence of the SW modes with earlier inelastic neutron scattering results, we were able to quantify the parameters of DM interactions and SIA more precisely than was previously possible. We then evaluated different models of the spin structure and determined the one that represents magnetic interactions most accurately.

Terahertz emission spectroscopy of YIG | topological insulator bilayers*  
EVAN JASPER (Presenter), Department of Physics, The Ohio State University, JOHN S JAMISON, Materials Science and Engineering, The Ohio State University, TIMOTHY PILLSBURY, ANTHONY R. RICHARDELLA, NITIN SAMARTH, Department of Physics and Materials Research Institute, Pennsylvania State University, ROBERTO MYERS, Materials Science and Engineering, The Ohio State University, ROLANDO VALDES AGUILAR, Department of Physics, The Ohio State University — Building on the demonstration of terahertz (THz) emission spectroscopy (TES) in metallic ferromagnet | normal metal heterostructures, recent works have now observed the THz emission from heterostructure bilayers of both yttrium iron garnet (YIG) | Pt and Co | Bi$_2$Se$_3$. We examine the energy dependence of the spin-charge conversion efficiency of THz emission in samples of a few quintuple layers of Bi$_2$Se$_3$ and (Bi$_{24}$Sb$_{76}$)$_2$Te$_9$ grown on YIG(100) and YIG(111) substrates. We excite the samples with ultrafast femtosecond light pulses of both 1.55 eV and 3.10 eV. At 1.55 eV, no electrons in YIG are excited above the band gap of 2.85 eV. When we double the photon energy to 3.10 eV, electrons in the YIG are excited into the conduction band. Since both photon energies emit THz radiation, we expect that in each case the mechanism of emission will be attributed to different effects. Specifically, with excitations of 1.55 eV, the spin current process should be predominately generated by the spin-Seebeck effect. With excitations of 3.10 eV, the generation of spin current should be dominated by the direct photoexcitation of spin-polarized charge carriers.

10:36AM E40.00012: Temperature dependent infrared spectroscopy on single crystals of YIG and Bi:YIG* RODICA MARTIN (Presenter), VALERIE AVENDANO, KEVIN SANTIAGO, CASEY KERKHOF, Physics and Astronomy, Montclair State University, IHOR SYDORYK, CATALIN MARTIN, Ramapo College — The insulating ferrimagnet yttrium iron garnet (YIG) has long been the material of choice for various optical and magneto-optical applications. Of particular interest is the use of YIG in optical isolators due to its large Faraday effect and good transparency over a broad spectral range in near/mid infrared. Bismuth doping has been shown to further increase the Faraday rotation. In this talk, we present temperature dependent (300 K to 4 K), broadband (10 meV to 3 eV) optical reflectance and transmittance on single crystals of YIG and Bi:YIG. We discuss the temperature dependence of vibrational modes in connection with magneto-optical properties, and assess the potential for using YIG and Bi:YIG in low temperature optical isolators.

Session E41 GMAG: Spin Hall effects BCEC 209 - Hailong Wang, Massachusetts Institute of Technology - Tag(s): Focus

8:00AM E41.00001: Unidirectional spin-Hall and Rashba–Edelstein magnetoresistance in topological insulator-ferromagnet layer heterostructures* [Invited] YANG LV (Presenter), Electrical and Computer Engineering, University of Minnesota, JAMES KALLY, Department of Physics, The Pennsylvania State University, DELIN ZHANG, Electrical and Computer Engineering, University of Minnesota, JOON SUE LEE, Department of Physics, The Pennsylvania State University, MAHDI JAMALI, Electrical and Computer Engineering, University of Minnesota, NITIN SAMARTH, Department of Physics, The Pennsylvania State University, JIANPING WANG, Electrical and Computer Engineering, University of Minnesota — The large spin–orbit coupling in topological insulators results in helical spin-textured Dirac surface states that are attractive for topological spintronics. These states generate an efficient spin–orbit torque on proximal magnetic moments. However, memory or logic spin devices based upon such switching require a non-optimal three-terminal geometry, with two terminals for the writing current and one for reading the state of the device. An alternative two-terminal device geometry is now possible by exploiting the recent discovery of the unidirectional spin Hall magnetoresistance in heavy metal/ferromagnet bilayers and unidirectional magnetoresistance in magnetic topological insulators. Here, we report the observation of such unidirectional magnetoresistance in a technologically relevant device geometry that combines a topological insulator with a conventional ferromagnetic metal. Our devices show a figure of merit (magnetoresistance per current density per total resistance) that is more than twice as large as the highest reported values in all-metal Ta/Co bilayers.

8:36AM E41.00002: Giant Spin Hall Effect in Magnetron sputtered W3Ta thin films* MOHSIN ZAMIR MINHAS (Presenter), ILYA KOSTANOVSKIY, STUART S PARKIN, MAZHAR NAWAZ ALI, Max Planck Institute for Microstructure Physics — The spin Hall effect (SHE), in non-magnetic (NM) metals with strong spin-orbit coupling (SOC) has received much attention due to potential technological applications like magnetic random-access memory (MRAM) and spin-logic devices. Large spin Hall angles (SHA, the ratio of $J_S/J_C$) have been observed in materials like Pt and β-W (a.k.a. W3W in the A15-structure), particularly when doped with oxygen reaching a peak value of 0.45. Recently, W3Ta (and other A15 compounds) was theoretically predicted to host an even larger intrinsic SHE than β-W, originating from the large spin Berry curvature of its electronic band structure. Here we present experimental results on magnetron sputtered W3Ta thin films, fabricated in Hall bar geometries using standard lithography and deposition techniques. The SHA was measured using ST-FMR on films of various thicknesses. Also, SHAs of various $W_{4-x}Ta_x$ compositions will be presented and compared with theoretical predictions.

Giant intrinsic orbital Hall effects in weakly spin-orbit coupled metals

DAEGEUN JO (Presenter), DONGWOOK GO, HYUN-WOO LEE, Department of Physics, Pohang University of Science and Technology — Recently, it was proposed that the intrinsic orbital Hall effect (OHE) can emerge from momentum-space orbital texture in centrosymmetric materials [1]. In searching for real materials with strong OHE, we investigate the intrinsic OHE in metals with small spin-orbit coupling (SOC) in face-centered cubic (Al, Mn, and Ni) and body-centered cubic structures (Li, V, Cr, and Mn). We find that these materials can have the giant orbital Hall conductivities (OHCs) $\sim 10^3 - 10^4 \,(h/e)(\Omega \text{cm})^{-1}$, which are comparable or larger than spin Hall conductivity (SHC) of Pt. We also show SHCs in these materials are sizable and the spin Hall angles may be of the order of 0.1, although SHCs are smaller than OHCs due to small SOC. We discuss implications on recent spin-charge interconversion experiments on materials having small SOC.

Ab initio calculation of intrinsic anomalous and spin Hall conductivity using localized pseudoatomic orbitals

JUWON OH (Presenter), HYOUNG JOON CHOI, Department of Physics, Yonsei University, Seoul 03722, Korea — For first-principles calculation of intrinsic anomalous Hall conductivity (AHC) and spin Hall conductivity (SHC), we implemented AHC and SHC formulas into the SIESTA code, which uses localized pseudoatomic orbitals to expand electronic wavefunctions. We calculate AHC from the Brillouin zone integration of the Berry curvature, and SHC by replacing a velocity operator in the AHC formula with a symmetrized product of spin and velocity operators. For AHC and SHC calculations, it is crucial to perform noncollinear-spin calculations including the spin-orbit coupling. We conduct AHC calculations of Fe, Co and SHC calculations of Pd, Pt and Ta. We compare our calculations with experimental results. We also investigate Berry curvature along high symmetry k points and the energy dependence of AHC and SHC.

Real-space Picture of the Intrinsic Anomalous Hall Effect

FEI XUE (Presenter), PAUL HANEY, National Institute of Standards and Technology — The intrinsic anomalous Hall effect is commonly expressed as the integral of Berry curvature in the reciprocal space. It has been shown that this intrinsic effect can also be computed in real space for systems which lack periodicity (e.g. finite or open systems). Motivated by this, we study a tight-binding toy model to show that the intrinsic anomalous Hall effect could be interpreted in terms of an electric field-induced change in the charge quadrupole moment. We additionally present a first-principle calculation of bcc Fe and demonstrate how the charge quadrupole moments changes in the presence of electric field. We also consider a real space interpretation of intrinsic anti-damping torques in a ferromagnet/heavy metal bilayer system.

Intrinsic spin Hall effect in nonmagnetic compounds

YANG ZHANG (Presenter), QIUNAN XU, Max Planck Institute for Chemical Physics of Solids, JAKUB ZELEZNY, TOMAS JUNGWIRTH, Institute of Solid State Physics, Czech Academy of Sciences, CLAUDIA FELSER, Max Planck Institute for Chemical Physics of Solids, JEROEN VAN DEN BRINK, Leibniz Institute for Solid State and Materials Research, YAN SUN, Max Planck Institute for Chemical Physics of Solids — The spin Hall effect (SHE), i.e., conversion of charge current to spin current without magnetic moment, has gained intensive interests over the last decade since the study of its intrinsic mechanism and the observation of it in experiments. Owing to its natural functions of spin current generation, detection, and manipulation, SHE meets the fundamental requirements for the spintronics. In this work, we performed an extensive study of the intrinsic SHE for all the existing non-magnetic materials, and provide an intrinsic SHC database including approximately 20000 compounds. From this database, we extracted a universal origin for strong SHE, the mirror symmetry protected nodal lines that are gapped out by spin-orbit coupling. This extensive study of intrinsic SHE in materials via numerical predictions offers a good platform to experimental design strong SHE, and it is helpful for the comprehensive understanding of the SHE via statistical analysis.

9:36AM E41.00007: Large spin Hall conductivity in Pt as measured with non-contact microwave spectroscopy
ANDREW BERGER (Presenter), Stanford Research Systems, ERIC EDWARDS, HANS T. NEMBACH, National Institute of Standards and Technology Boulder, ALEXY KARENOWSKA, Department of Physics, University of Oxford, MATHIAS WEILER, Walther-Meissner-Institut, OLOF KARISS, Department of Physics and Astronomy, Uppsala University, MARK KELLER, THOMAS SILVA, National Institute of Standards and Technology Boulder — By use of microwave spectroscopy, we have measured the spin Hall effect (SHE) and spin transparency in bilayers of Ni80Fe20/Pt. The method uses a phase-sensitive amplitude analysis of FMR spectra with unpatterned thin films that are proximate to, but not electrically connected with a coplanar waveguide [1]. Both SHE and iSHE are measured simultaneously, as mandated by Onsager reciprocity. The method does not require the samples to have an easy axis, nor knowledge of the precession angle. Damping is simultaneously measured, permitting self-consistent fitting of the SHE and spin pumping signals [2]. In agreement with previous reports [3], the spin transport efficiency between Ni80Fe20 and Pt is << 1, presumably due to interfacial spin memory loss. Also, the transparency is a strong function of deposition order, with a 3x reduction when Ni80Fe20 is grown on Pt. While the effective SHE signal and spin diffusion length are comparable to previous reports [4], substantial spin memory loss implies a larger value for the intrinsic SHE ratio of Pt (~ 0.4) than previously reported. 9:48AM E41.00008: Anisotropic and spin Hall magnetoresistance in FeRh/Pt bilayers* JOSEPH SKLENAR (Presenter), University of Illinois at Urbana-Champaign, HILAL SAGLAM, Materials Science Division, Argonne National Laboratory, JUNSEOK OH, GREG HAMILTON, University of Illinois at Urbana-Champaign, YI LI, Materials Science Division, Argonne National Laboratory, WEI ZHANG, Oakland University, MATTHEW GILBERT, University of Illinois at Urbana-Champaign, AXEL F HOFFMANN, Materials Science Division, Argonne National Laboratory, NADYA MASON, University of Illinois at Urbana-Champaign — We have sputtered epitaxial films of BCC FeRh with thicknesses between 7.5-35 nm on (100) MgO, capped with 5-nm Pt. Magnetometry and magnetotransport measurements indicate a first-order transition from ferromagnetic to antiferromagnetic order below room temperature. We have structured lithographically the films into Hall bars and nano-wires, such that the current is directed along different crystalline orientations. The angular-dependent magnetoresistance of all devices is measured in both the ferromagnetic and antiferromagnetic phase, and there is evidence for both intrinsic anisotropic magnetoresistance as well as spin Hall magnetoresistance contributing to the measured signal. In the antiferromagnetic phase we measure drastically different angular signals depending on whether the current is along the (100) or (110) direction.

10:00AM E41.00009: Spin hall effect in SrIrO3 measured by spin torque ferromagnetic resonance XIAOXI HUANG (Presenter), Department of Materials Science and Engineering, University of California, Berkeley, ARNOUD EVERHARDT, Materials Science Division, Lawrence Berkeley National Laboratory, MAHENDRA DC, School of Physics and Astronomy, University of Minnesota, CHRISTOPH KLEWE, Advanced Light Source, Lawrence Berkeley National Laboratory, R RAMESH, Department of Physics, University of California, Berkeley, JIANPING WANG, School of Physics and Astronomy, University of Minnesota — A lot of research focus on spin Hall effect for the use of spintronic devices has been put on heavy metals such as Pt and topological insulators but there is rare research on spin Hall effect in complex oxide systems with strong spin orbit coupling effects. Complex oxides such as SrIrO3 with strong spin orbit coupling effects have drawn considerable research interest. We have studied spin torque ferromagnetic resonance (ST-FMR) induced by spin Hall effect in SrIrO3. Spin Hall angle of SrIrO3 as large as 0.36 is determined by ST-FMR, which is almost the same order as Ta. More interestingly, as thickness of SrIrO3 increases, spin Hall angle of SrIrO3 increases, while resistivity decreases.
10:12AM E41.00010: Detecting end states of topological quantum paramagnets via spin Hall noise spectroscopy*
DARSHAN G. JOSHI, ANDREAS P SCHNYDER, Max Planck Institute for Solid State Research, SO TAKEI (Presenter), Queens College — We theoretically study the equilibrium spin current fluctuations and the corresponding charge noise generated by the inverse spin Hall effect (ISHE) in a metal with strong spin-orbit coupling deposited on top of a quantum paramagnet. It is shown that the charge noise power spectra measured along different spatial axes can directly probe the different spin components of the boundary dynamic spin correlations of the quantum paramagnet. We report the utility of this ISHE-facilitated spin noise probe as a tool to unambiguously detect topological phase transitions in an $S = 1/2$ quantum spin ladder that hosts a trivial ground state of singlet product states, but topologically protected fractional spin excitations localized at its ends. Our work demonstrates the general usefulness of ISHE-mediated spin noise spectroscopy for the detection of topological phases in quantum paramagnets.

10:24AM E41.00011: Electrical detection of Spin Hall effect in Tungsten films using a compact device geometry*
ARPITA MANDAL, SOUMIK AON, PARTHA MITRA (Presenter), Indian Institute of Science Education and Research, Kolkata — Direct detection of Spin Hall Effect (SHE) using electrical schemes continues to be an experimental challenge as there is no electrical voltage associated with the accumulation of electron spins of opposite signs at the edges of a standard Hall bar sample. We present a simple yet elegant measurement scheme that allows detection of spin accumulation using the well known concepts of non-local detection proposed by Johnson and Silsbee. We fabricated devices with pairs of voltage leads consisting of a ferromagnet (FM: Co or Py) and a normal metal (NM: Cu) suitably placed in contact with one of the spin accumulation edge of Tungsten (W) bar shaped films, so that other competing effects like ordinary Hall effect and magnetoresistance are minimised. We show that voltage difference measured between the FM and NM leads are a manifestation of the spin accumulation due to SHE. We present detailed temperature and magnetic field dependent study of the spin Hall conductivity extracted from the spin accumulation voltage.

10:36AM E41.00012: Temperature dependence of side-jump contribution to anomalous/spin Hall conductivities*
CONG XIAO (Presenter), Department of Physics, University of Texas at Austin, YI LIU, ZHE YUAN, The Center for Advanced Quantum Studies and Department of Physics, Beijing Normal University, SHENGYUAN YANG, Research Laboratory for Quantum Materials, Singapore University of Technology and Design, QIAN NIU, Department of Physics, University of Texas at Austin — The side-jump contribution to anomalous/spin Hall conductivities is conventionally understood to be a constant independent of both the scattering strength and density of scatterers, even though it depends on the type of scatterer. In this work, we reveal that the side-jump contribution due to electron-phonon scattering, the primary source of scattering in clean samples, can in fact acquire substantial temperature dependence when the temperature drops below the high-temperature classical regime of equipartition law. We demonstrate this phenomenon in an analytic model, supplemented by a first-principles calculation for pure Pt. Experimentally accessible high-purity Pt is proposed to be suitable for observing the predicted prominent variation of the spin Hall conductivity below 80 K.

Session E42 DQI: Applications of Noisy Intermediate Scale Quantum Computers II BCEC 210A
- Andras Gyenis, Princeton University - Tag(s): Focus
8:00AM E42.00001: Algorithm-Centric Error Mitigation*  ED YOUNIS (Presenter), Department of Electrical Engineering and Computer Sciences, University of California, Berkeley, WIM LAVRIJSEN, Computational Research Division, Lawrence Berkeley National Laboratory, KOUISHIK SEN, Department of Electrical Engineering and Computer Sciences, University of California, Berkeley, AYDIN BULUC, MIROSLAV URBANEK, WIBE A DE JONG, COSTIN IANCU, Computational Research Division, Lawrence Berkeley National Laboratory — We derive algorithm-specific error mitigation procedures for VQE. The core idea is to determine which part of a circuit contributes most to the final output error and then harden only these sub-circuits. Using simulation with gate level noise injection, our results indicate that VQE is most sensitive to errors on the source qubit of CNOT gates, and relatively insensitive to errors on any other qubits or single gates, irrespective of the noise distribution. We then devise an algorithm that attempts to increase the fidelity of qubits that appear as sources of CNOT gates. Given a circuit, we determine the qubits that appear in most CNOT gates (contribute most to error) and use ancilla qubits to mimic their operations (same state) and periodically switch between the original and ancilla qubit during circuit operation. Simulation results indicate that the technique is able to improve the quality of the solution from the quantum circuit. This is confirmed by experiments on the IBM hardware, where for a 4-qubit VQE with one ancilla qubit we observe fidelity improving from 46% to 52%.

8:12AM E42.00002: Implementation of Grover's quantum search algorithm with error mitigation at IBM Q computers  YULUN WANG (Presenter), ROBERT J HARRISON, PREDRAG KRSTIC, Institute for Advanced Computational Science, State University of New York at Stony Brook — We have constructed the quantum circuits for implementation of the N=4 qubits Grover algorithm at IBM Q quantum computers. The circuit efficiency was achieved by explicit use of the qubits topology, specific for the used machines. For comparison, we implemented the same approach for the 2 and 3 Grover's algorithms. While the classical simulation led to a high probability of finding the searched object, the running at the IBM Q quantum machine resulted to the search probability below the recognition. This was a consequence of the decoherence errors, which has grown with the number of the circuit elements. We have experimented with zero-noise extrapolation method as well as error correction codes to mitigate and correct the errors of the circuit, leading to improvements in the implemented search.

8:24AM E42.00003: Fundamental limitations for measurements in quantum many-body systems  THOMAS BARTHEL (Presenter), JIANFENG LU, Duke University — Dynamical measurement schemes are an important tool for the investigation of quantum many-body systems, especially in the age of quantum simulation. Here, we address the question whether generic measurements can be implemented efficiently if we have access to a certain set of experimentally realizable measurements and can extend it through time evolution. For the latter, two scenarios are considered (a) evolution according to unitary circuits and (b) evolution due to Hamiltonians that we can control in a time-dependent fashion. We find that the time needed to realize a certain measurement to a predefined accuracy scales in general exponentially with the system size – posing a fundamental limitation. The argument is based on the construction of ε-packings for manifolds of observables with identical spectra and a comparison of their cardinalities to those of ε-coverings for quantum circuits and unitary time-evolution operators. The former is related to the study of Grassmann manifolds.

Postponing the orthogonality catastrophe: efficient state preparation for electronic structure simulations on quantum devices*  
NORM TUBMAN (Presenter), CARLOS MEJUTO ZAERA, JEFFREY EPSTEIN, DIPTARKA HAIT, DANIEL LEVINE, WILLIAM HUGGINS, University of California, Berkeley, ZHANG JIANG, JARROD MCCLEAN, Ryan BABBUSH, Google, MARTIN HEAD-GORDON, BIRGITTA K WHALEY, University of California, Berkeley — Many proposals for efficiently simulating eigenstates of physical systems on quantum computers require that one can easily initialize wavefunctions with non-vanishing overlap on eigenstates of interest. Though there is now a large body of work exploring the costs of simulating electronic structure systems on a quantum computer, the challenge of preparing states with sufficient ground state support has so far been largely ignored. In this work we demonstrate that the adaptive sampling configuration interaction technique can be used to investigate the overlap issue. Using this technique, we find that easy-to-prepare single Slater determinants such as the Hartree-Fock state often have surprisingly robust support on the ground state for many applications of interest. For the most difficult systems, we introduce a method for preparation of multi-determinant states on quantum computers. We investigate several prominent applications of quantum simulations including organic molecules, transition metal complexes, the uniform electron gas, Hubbard models, and the quantum impurity models arising from embedding formalisms such as dynamical mean-field theory.

Testing, analysis, and refinement of the quantum Metropolis algorithm  
JONATHAN MOUSSA (Presenter), Molecular Sciences Software Institute — The classical Metropolis algorithm has been adapted into a quantum algorithm [Temme et al., Nature 471, 87 (2011)] with three important drawbacks: (1) long-time Hamiltonian evolution is needed for precise phase estimation of system energies, (2) many repetitions are needed to successfully reject a Metropolis update with a low failure rate, and (3) thermal-state observables are not measured during the thermalization process. We present a revised quantum Metropolis algorithm that partially mitigates these drawbacks as evidenced by a combination of numerical experiments and theoretical analysis.

Simulating strongly interacting fermionic systems in a quantum computer  
ALEXANDRE CHOQUETTE-POITEVIN (Presenter), Univeristé de Sherbrooke, PANAGIOTIS BARKOUTSOS, IBM Research - Zurich, AGUSTIN DI PAOLO, ALEXANDRE FOLEY, DAVID SENECHAL, Univeristé de Sherbrooke, IVANO TAVERNELLI, IBM Research - Zurich, ALEXANDRE BLAIS, Univeristé de Sherbrooke — Noisy intermediate-scale quantum computation has the potential to be useful for the quantum simulation of small fermionic systems using variational quantum algorithms (VQA). Applications of hybrid quantum-classical approaches provide proof that VQAs are robust against noise and can handle limited qubit connectivity. In this talk, we approach a class of strongly interacting fermionic Hamiltonians formulated in the variational cluster approach by means of VQAs. More precisely, we tackle the problem of a 1D lattice to study the Mott transition. This work is a first step towards quantum simulation of larger and higher-dimensional strongly interacting electronic systems.

End-to-end quantum chemistry simulations with reduced errors*  
MIROSLAV URBANEK (Presenter), WIM LAVRIJSEN, WIBE A DE JONG, Computational Research Division, Lawrence Berkeley National Laboratory — Error reduction through suppression, mitigation, or correction is essential to enable quantum chemistry applications on a larger number of qubits accessible in Noisy Intermediate-Scale Quantum (NISQ) computers. We focus on the development of quantum chemistry algorithms running within the hybrid classical-quantum Variational Quantum Eigensolver (VQE) approach. VQE has been successfully demonstrated on quantum computers with a small number of qubits, but its performance on larger systems is currently limited by various sources of experimental noise. Our target is to develop quantum algorithms and computational circuits that exploit various error mitigation and correction techniques for initialization, gate operations, and measurement. This is necessary to reduce errors introduced by experimental conditions in NISQ systems. We compare theoretical and simulation results with results obtained in experiments.

9:24AM E42.00008: Trotter Error Scaling with System Size in Quantum Simulations*  MATTHIAS TROYER (Presenter), Microsoft, NATALIE PEARSON, Theoretical Physics, ETH Zurich, DAVID POULIN, Université de Sherbrooke — A main concern when implementing digital quantum simulation on quantum computers or simulators is the number of gate operations required. The most common implementation uses the Trotter decomposition to map an arbitrary Hamiltonian onto realisable gates. However, the proven upper bounds on the error introduced using this method grows with the system size. In order to maintain the same accuracy this would imply that the time step has to shrink with system size, leading to a sharp increase in the number of gates required. We show empirically that for local Hamiltonians the error for local observables and their correlation functions is independent of system size. This results is obtained by simulating large one-dimensional quantum Ising model at and away from the critical point using a Trotter decomposition in imaginary time. We find that the Trotter errors saturate with increasing system size even at the critical points. We finally discuss long-range models and correlations in time.

9:36AM E42.00009: Improved optimization algorithm for use in variational quantum eigensolvers*  TITUS MORRIS (Presenter), Oak Ridge National Laboratory — Quantum algorithms for treating nuclear and electronic structure problems face a host of challenges in order to run successfully on both near-term and future fault tolerant quantum computers. For variation quantum eigensolvers (VQE), one such challenge is how to optimize parameters dictating the wavefunction efficiently i.e. with few function evaluations in the presence of noisy energy evaluation. This has typically been done with classic optimizers, but these will begin to pose problems as the parameter sets required to treat larger realistic systems grow. Here I present an algorithm that, at the cost of extra Pauli expectation values, allows for a faithful estimation of the parameter gradient of several classes of wavefunctions. I apply this algorithm to the treatment of the deuteron and H_2, and show that it gives a much faster convergence in terms of overall function evaluations when compared to classic optimizers, and this advantage increases with parameter set size. This presents a promising step forward in pushing for treating realistic systems with quantum computers.

*This material is based upon work supported by the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research (ASCR) quantum algorithms and testbed programs.

9:48AM E42.00010: Characterization of Training Circuits for Hybrid Quantum-Classical Algorithms*  SUKIN SIM (Presenter), Chemistry and Chemical Biology, Harvard University, PETER D. JOHNSON, Zapata Computing, Inc., ALAN ASPURU-GUZIK, Chemistry and Computer Science, University of Toronto — Performing useful computations with current and near-term quantum computers is becoming increasingly viable due to rapid advances in both algorithms and hardware. A class of algorithms that are promising candidates for demonstrating the utility of near-term quantum computers is the so called hybrid quantum-classical (HQC) algorithms. A common ingredient that plays a crucial role in the algorithmic performance of many HQC algorithms is the parametrized quantum circuit that is tuned to prepare quantum states relevant for (approximately) solving the problem of interest. Despite the importance of these circuits, they are often generated in the absence of a robust theoretical framework. In this work, we introduce several descriptors to characterize a set of parametrized circuits, including a measure of a circuit's expressibility and how it correlates with algorithmic performance. Ultimately, having a deeper understanding of the qualities associated with an effective parametrized circuit can lead to significant improvements in the overall development of HQC algorithms.

Error mitigation by symmetry verification on a variational quantum eigensolver*  

RAMIRO SAGASTIZABAL (Presenter), QuTech and Kavli Institute of Nanoscience, Delft University of Technology, XAVIER BONET-MONROIG, Lorentz Institute, Leiden University, MALAY SINGH, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, THOMAS E O’BRIEN, Lorentz Institute, Leiden University, MICHEL ADRIAAN ROL, CORNELIS CHRISTIAAN BULTINK, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, XIANG FU, QuTech and Quantum Computer Architecture Lab, Delft University of Technology, NANDINI MUTHUSUBRAMANIAN, ALESSANDRO BRUNO, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — Current efforts to increase the accuracy of quantum algorithms focus on the design and implementation of low-cost techniques to mitigate the impact of errors while avoiding fully-fledged error correction schemes. Both simple and comprehensive, variational quantum eigensolvers provide an excellent platform for exploring error and accuracy trade-offs. We present the implementation of our own low-cost error detection scheme, named symmetry verification (SV). We demonstrate an order of magnitude improvement in accuracy while solving the hydrogen molecule in a transmon quantum processor. Furthermore, by matching measurements to simulations, we report a breakdown of noise sources with which we quantify the error mitigating effects of SV and its limitations.

Rotationally Controlled Atomic Layer Heterostructures*  

EMANUEL TUTUC (Presenter), University of Texas at Austin — Heterostructures of atomic layers such as graphene, hexagonal boron-nitride, and transition metal dichalcogenides (TMDs) can serve as testbed for novel quantum phenomena in two-dimensions (2D). A key ingredient that can add a new dimension to the atomic layer heterostructures palette is the rotational control and alignment of different 2D layers. We review here an experimental technique that enables rotationally controlled heterostructures with accurate alignment of individual layer crystal axes [1]. We illustrate the applicability of this technique to the realization of tunable moiré patterns in twisted bilayer graphene [2], and rotationally aligned double layers of graphene [3], or TMDs [4] separated by a tunnel barrier, which display resonant, energy- and momentum-conserving tunneling in vertical transport. Rotationally aligned double bilayer graphene separated by a WSe2 tunnel barrier, designed to study equilibrium indirect exciton formation, display a strongly enhanced tunneling at low temperatures when the two graphene bilayers are populated with carriers of opposite polarity and equal density [5]. The enhanced tunneling at overall neutrality departs markedly from single-particle model calculations, and suggests the emergence of a many-body state with when electrons and holes of equal densities populate the two layers.

**8:36AM E43.00002: Strain-induced Pseudo-Magnetic Fields and flat band in Graphene** [Invited] YUHANG JIANG (Presenter), Department of Physics and Astronomy, Rutgers University, 136 Frelinghuysen Road, Piscataway, NJ 08855 USA — The discovery of free-standing 2D atomic layers ushered in a new era of materials whose properties can be shaped controlled and engineered by unconventional means such as strain, bend or twist. An externally imposed periodic potential breaks up the electronic band structure into a series of mini-bands which, under certain circumstances, become almost dispersionless. Such flat bands can occur naturally in the presence of a vector potential generated by a strain-induced periodic pseudo-magnetic field (PMF). Within these flat bands, the strongly suppressed kinetic energy favors the formation of interaction-driven exotic phases which can give rise to novel electronic properties. In this talk, I will present experimental results demonstrating two pathways to generate strain induced PMFs and flat bands. In the first method, a graphene membrane is supported and strained by a two-dimensional (2D) periodic array (~1mm) of Au nano-pillars grown on a hexagonal Boron Nitride (hBN) substrate. A direct measure of the local strain is achieved by scanning tunneling microscopy (STM) through the magnifying effect of the Moiré pattern formed against the hBN substrate. The strain-induced PMF (~10T) is obtained from the pseudo-Landau level spectra observed in scanning tunneling spectroscopy (STS). The second method utilizes the buckling transition of a compressed graphene membrane to generate a 2D periodic strain pattern. This produces spatially modulated PMFs with periods of order ~10nm and amplitudes exceeding 100T. Using STM, STS and numerical simulations we find that the pseudo-Landau levels associated with the strain-induced periodic PMF give rise to a flat-band at charge-neutrality, providing a pathway to engineering correlated phases by non-chemical means.  

**9:12AM E43.00003: Superconductivity in twisted graphene layers: electronic structure and interactions.** [Invited] FRANCISCO GUINEA (Presenter), Imdea Nanoscience, Madrid, Spain and School of Physics and Astronomy, University of Manchester, UK — A special feature of the states in the low energy bands of twisted graphene bilayers is that their charge distribution shows a significant momentum dependence. As a result, the filling of these bands leads to electrostatic potentials, which, in turn, modify the energy levels and the structure of the bands. The dependence of the band shape on the band filling can be described in terms of the emergence of new electron-electron interactions. We quantify and analyze these interactions, and discuss their relation with the observed superconducting and insulating states.

**9:48AM E43.00004: Transport in Twisted Bilayer Graphene at Extreme Angles** [Invited] PETER RICKHAUS (Presenter), Physics, ETH Zürich, JOHN WALLBANK, Centre for Ecology and Hydrology, Oxfordshire, SERGEY SLIZOVSKII, NRC Kurchatov Institute, Russia, RICCARDO PISONI, HISKE OVERWEG, YONGJIN LEE, MARIUS EICH, Physics, ETH Zürich, MING-HAO LIU, Department of Physics, National Cheng Kung University, Taiwan, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, Japan, KLAUS ENSSLIN, THOMAS IHN, Physics, ETH Zürich — Two misaligned layers of graphene exhibit intriguing transport properties that depend drastically on the twist angle. At very large twists, the system behaves similar to two decoupled graphene layers. Upon reduction of the angle, the graphene layers begin to couple, leading to a decrease in Fermi velocity. At a magical angle of 1.1°, superconductivity emerges [1]. Finally, at tiny twist angles, large regions of strongly coupled bilayer graphene dominate the transport. By gating, these regions can become insulating leading to a triangular network of topological channels [2]. An intriguing probe for transport phenomena in graphene consists in the formation of an electronic Fabry-Pérot interferometer [3,4]. P-n junctions serve as semi-transparent mirrors and exhibit relativistic phenomena such as Klein-tunneling and we discuss how they can be used to access the interesting physics twisted bilayer graphene at tiny [5] and at very large twist angles.

10:24AM E43.00005: Electrically tunable frustrated lattices and magnetism in twisted bilayer graphene* [Invited]
JOSE LADO (Presenter), ETH Zurich, ALINE RAMIRES, ICTP-SAIFR, Brazil, LUIS ALBERTO GONZALEZ-ARRAGA, IMDEA Nanoscience, Madrid, Spain, FRANCISCO GUINEA, IMDEA Nanoscience, Madrid, Spain and School of Physics and Astronomy, University of Manchester, UK, PABLO SAN-JOSE, ICMM-CSIC, Madrid Spain — Twisted graphene bilayers have become a powerful solid-state platform to realize a plethora of electronic states, stemming from the emergence of controllable moire superlattices and their electrical tunability. Here we theoretically show that twisted bilayer graphene is a versatile platform to realize tunable frustrated magnets, by realizing triangular and Kagome lattices of localized modes in two dramatically different regimes [1,2]. First, for rotation angles around 1.5 degrees, we show that the magnetic instabilities of the emergent triangular AA lattice can be electrically controlled [1]. In particular, we show that the ferromagnetic and antiferromagnetic ordering inside the AA regions can be electrically switched, giving rise to superlattice spin spirals in the emergent triangular moire superlattice. Second, we show that in the tiny angle regime of 0.2 degrees, an emergent Kagome lattice of localized modes can be electrically generated, stemming from an artificial gauge field created by the interlayer bias [2]. In particular, we show that the microscopic properties of these Kagome modes are controlled by the magnitude of the electrically generated gauge field, yielding a powerful solid-state platform to experimentally engineer a paradigmatic model of frustrated magnetism. These rich and electrically controllable frustrated lattices provide a potential route to experimentally explore frustrated magnetism and quantum spin liquid physics in twisted graphene bilayers.

Session E44 DCMP: New Developments in STM on Surfaces of Unconventional Superconductors and Related Systems BCEC 210C - Ilya Eremin, Ruhr University Bochum - Tag(s): Invited

8:00AM E44.00001: Determination of the superconducting gap sign by the phase referenced method: successful practice in cuprate and several iron based superconductors* [Invited] HAI-HU WEN (Presenter), Nanjing University — In many unconventional superconductors, the superconducting gap will change sign along the Fermi surface. The fundamental reason for this behavior is that the Cooper pairing may be established through a repulsive interaction, instead of the attractive interaction in phonon mediated pairing picture. However to detect this gap sign is not easy at all. The usual method for solving this problem is to measure the behavior of phase difference or supercurrent through a Josephson junction. However, this method seems not working well in systems with multi-Fermi pockets and with the same sign in individual pocket. Such circumstances happen in many iron based superconductors. In the superconducting state, quasi-particles (QPs) will be generated by thermal or pair breaking. These QPs with Bogoliubov dispersion are scattered from one momentum $k_1$ to another $k_2$ forming a standing wave with wave vector $q = k_1 - k_2$. All these standing waves interfere each other and form a particular pattern in the real space (QPI). By using STM we can measure these patterns. Through the Fourier transform on QPI patterns we can not only get the Fermi surface contour, but also obtain the gap feature, including the magnitude and sign for different $q$ vectors. This was called as the phase referenced QPI. Following this idea we have successfully detected the gap sign reversal in several iron based superconductors with and without the hole pockets. We can also directly visualize the d-wave gap in the typical cuprate superconductor Bi-2212.

8:36AM E44.00002: Pairing gap symmetry in optimally doped NaFeAs [Invited] ABHAY PASUPATHY (Presenter), Columbia University — TBD
9:12AM E44.00003: Lessons from modeling of tunneling spectroscopy on FeSe [Invited]  BRIAN ANDERSEN (Presenter), Niels Bohr Institute — Iron-based superconductors have been extensively studied both experimentally and theoretically over the last decade, with great progress in our understanding of these materials. Recent focus on FeSe has been centered on the connection between nematicity and superconductivity, and the possibility of enhancing Tc in monolayers on STO, or by pressure. In this talk, I will focus on two aspects of the theoretical study of tunneling spectroscopy on unconventional superconductors, 1) the physics of disorder generated local order, and 2) the understanding of recent scanning tunneling experiments mapping out the detailed spectroscopic features of FeSe by the Davis group at Cornell University. I will explain the recent evidence for orbital selective superconducting pairing, and the direct detection of orbital selective quasiparticles by quasi-particle interference. This highlights the correlated nature of FeSe, more specifically its Hund's metal nature with coexisting orbital-dependent coherent and incoherent low-energy states. I then proceed to discuss the theoretical modelling of these phenomena and the implications for our understanding of the magnetic properties of FeSe. This is relevant for understanding the origin of superconductivity in FeSe in particular, and in the iron-based superconductors in general.

Session E45 DCMP: Complex Oxide Surfaces, Interfaces, and Thin Films I BCEC 211 - David Lederman, UC Santa Cruz

8:00AM E45.00001: Mechanical strain-tuned magnetism and AFM Neel temperature by 90 K in PrVO3 thin films* WILFRID PRELLIER (Presenter), Laboratoire CRISMAT, CNRS/ENSICAEN/UNICAEN — The transition-metal oxides with ABO3 type perovskite structure show a strong coupling between spin-orbital and lattice degrees of freedom. Here, we present an experimental study of magnetic response to the residual strain in PVO thin films by growing PVO films on a variety of single crystal substrates and by varying PVO film thickness on a single crystal substrate. PrVO3 in bulk, being a strong antiferromagnet shows TN~ 130 K [1]. Our study reveals that the lattice distortion via misfit strain pave the way towards tuning the anti-ferromagnetic ordering temperature in PrVO3 thin films, resulting in a non-trivial evolution of the Neel temperature (TN) with substrate pseudo-cubic lattice parameter and PVO film thickness. We demonstrate that the strain produced via mechanical strain engineering, tune TN of PVO films in the range of 90 K. Moreover, we also show that PVO thin films show low temperature ferromagnetic behavior along with the insulating properties irrespective of the substrate. [1] Sage M H et. al. Phys. Rev. B 76 195102 (2007)

8:12AM E45.00002: Unusual Electronic Phase Separation Phenomena in Manganite Ultrathin Films  HONGYAN CHEN (Presenter), YANG YU, BAI YU, HANXUAN LIN, Fudan University, XIAOLONG LI, Chinese Academy of Sciences, HAO LIU, TIAN MIAO, YUNFANG KOU, Fudan University, YONGSHENG ZHANG, YAN LI, JIN TANG, Chinese Academy of Sciences, ZECHAO WANG, Tsinghua University, PENG CAI, YINYAN ZHU, ZHE WANG, Fudan University, ZHAOHUA CHENG, Chinese Academy of Sciences, XIAOYAN ZHONG, Tsinghua University, WENBIN WANG, Fudan University, XINGYU GAO, Chinese Academy of Sciences, RUQIAN WU, LIFENG YIN, JIAN SHEN, Fudan University — Ultrathin films often exhibit two-dimensional characteristics that are distinctly different from their bulk counterpart. In this work, we show an unusual behavior in La0.7Sr0.3MnO3 (LSMO) ultrathin films grown on SrTiO3 (001) (STO) substrate. Combining scanning tunneling microscopy and magneto-optical Kerr effect measurements, we have obtained the evolution of the magnetic state of the LSMO ultrathin films as a function of thickness. Strikingly, the LSMO ultrathin films are electronically phase separated in both lateral and vertical directions in thickness range between 4 and 7 unit cells. Specifically, the films are formed by 3 unit cell thick antiferromagnetic base layers, on top of which the layers consist of ferromagnetic metallic nanodisks in antiferromagnetic matrix. At 8 unit cells, an abrupt shear strain relief occurs by forming twinning patterns along [010] and [100] directions. After the shear strain is relieved, the whole films transform into a uniform ferromagnetic metallic state. Our observation reveals the richness of electronic and magnetic phases for strongly correlated systems even in their two-dimensional limit.
YOUNG MO KIM (Presenter), YOUJUNG KIM, JUYEON SHIN, KOOKRIN CHAR, Seoul National University — In order to identify the origin of the large conductance enhancement in the polar interface of LaInO$_3$/BaSnO$_3$, we studied the variation of the conductance enhancement in LaIn$_{1-x}$Ga$_x$O$_3$/BaSnO$_3$ interface. We found that the magnitude of the conductance enhancement decreased as Ga ratio increased and eventually completely disappeared in the case of LaGaO$_3$/BaSnO$_3$. The conductance of the interface, when present, reached its maximum values when LaIn$_{1-x}$Ga$_x$O$_3$ was about 4 unit cell thick, beyond which the conductance started to decrease slowly. Based on such findings, we developed a model for interface polarization in LIO, in which the polarization exists only in the 4 unit cell thick LIO near the interface. Such a model, when aided by 1D Poisson-Schrödinger equation, produces the $n_{2D}$ consistent with the experimental results. In addition, by introducing a deep donor density in LIO, we are able to fit the slow relaxation of the interface conductance. Our complete model, comprised of interface polarization in the 4 unit cell thick LIO and the resulting 2DEG state in BSO with 2 nm confinement length, also explains in a consistent way the entire experimental data of the recent doping dependence of the LIO/BSO interface conductance on both SrTiO$_3$ and MgO substrates.

Tuning the physical properties via Sr doping in the 4d transition metal oxide LaRhO$_3$ JUAN JIANG (Presenter), SANGJAE LEE, FREDERICK J WALKER, CHARLES H AHN, Applied Physics, Yale University — Perovskite transition metal oxides exhibit various novel properties due to the interactions of strongly correlated electrons. We discuss the physical properties of Rhodate thin film in this talk. We grow high quality La$_{1-x}$Sr$_x$RhO$_3$ thin films (up to $x=0.5$) on LaAlO$_3$ substrates by molecular beam epitaxy, and characterize their electrical and magnetic properties. Electrical anomalies and ferromagnetic signatures are observed. Strain effects are discussed, which might play a role in determine the physical properties of our thin films.

Modulation of manganite thin-film properties by strontium titanate excitons* CHI SIN TANG (Presenter), NUS Graduate School of Integrative Sciences & Engineering, National University of Singapore, XINMAO YIN, Department of Physics, National University of Singapore, LE WANG, Physical and Computational Sciences Directorate, Pacific Northwest National Laboratory, ANDREW THYE SHEN WEE, Department of Physics, National University of Singapore, JUNLING WANG, School of Materials Science and Engineering, Nanyang Technological University, ANDRIVO RUSYDI, Department of Physics, National University of Singapore — A comprehensive investigation of the optical, electronic and magnetic properties of La$_{0.7}$Sr$_{0.3}$MnO$_3$ films on SrTiO$_3$ (LSMO/STO) and other substrates is conducted using multiple experimental techniques. There is a significant difference in the optical properties of LSMO/STO even in the case of 87.2nm-thick LSMO/STO as compared to those of LSMO on other substrates. We observed interesting excitonic features in the LSMO/STO thin-film at ~4eV. This could be due to formation of anomalous charged excitonic complexes. Based on spectral-weight transfer analysis, anomalous excitonic effects from STO strengthen the electronic-correlation in LSMO films. This results in optical spectral changes related to intrinsic Mott-Hubbard properties in the manganite films. While lattice strain influences the optical properties of the LSMO thin-films, strong e-e and e-h interactions from the substrate play a significant role as well.

Thickness-dependent metal-to-insulator transition in La-doped SrTiO$_3$ thin films YEONGJAE SHIN (Presenter), CLAUDIA LAU, SANGJAE LEE, FREDERICK J WALKER, CHARLES H AHN, Department of Applied Physics, Yale — The electronic and structural properties of La-doped SrTiO$_3$ (LSTO) films grown by molecular beam epitaxy are studied as a function of film thickness and La doping. We demonstrate that electronic transport is highly affected by the insulating dead layers inside LSTO films, whose thickness depends on La doping. As the film thickness is reduced below the dead layer thickness, an abrupt metal-to-insulator transition occurs. We attribute the existence of insulating layers to the surface structure of LSTO. The reduced conductivity of LSTO films due to dead layers can be counteracted by growing additional capping layers on top of the LSTO surface, indicating the strong relationship between insulating dead layers and surface structure of LSTO films. Synchrotron-based X-ray scattering analysis is used to test this hypothesis. Our results emphasize the importance of surface structure studies for functional oxides in the thin film limit and provide a guiding principle to fabricate oxide nanoscale devices.
9:12AM E45.00007: Thickness-dependent oxygen octahedral distortions in perovskite thin films as an adaption to the heterointerface 
JENNIFER FOWLIE (Presenter), CÉLINE LICHTENSTEIGER, University of Geneva, MARTA GIBERT, University of Zurich, HUGO MELEY, University of Geneva, PHILIP WILLMOTT, Paul Scherrer Institut, JEAN-MARC TRISCONE, University of Geneva — Distortions of the oxygen octahedral network of ABO₃-type perovskites are one of the most common features that develop in oxide heterostructures as a response to the epitaxial strain imposed by the substrate. This behaviour, which can be characterised as rigid tilts and rotations of the octahedra themselves, is readily studied quantitatively by synchrotron x-ray diffraction at half-integer Bragg positions [1].

In this study, we analyse the thickness-dependence of the octahedral tilts and rotations of thin films of LaNiO₃. We find a striking difference between films grown on SrTiO₃ and LaAlO₃ substrates, which appears to stem not only from the difference in epitaxial strain state but also from the level of continuity at the heterointerface. In particular, the highly discontinuous LaNiO₃/SrTiO₃ interface causes a large variation in the octahedral network as a function of film thickness whereas the rather continuous LaNiO₃/LaAlO₃ interface seems to allow the immediate formation of a stable octahedral pattern corresponding to simply the applied biaxial strain from just a few unit cells.

The scope for structural engineering by exploitation of these interfacial effects is tangible.

9:24AM E45.00008: The spin texture in a SrTiO₃(111) two-dimensional electron gas 
PAN HE (Presenter), Department of Electrical and Computer Engineering, National University of Singapore, SIQBHAN MCKEOWN WALKER, Department of Quantum Matter Physics, University of Geneva, SHULEI ZHANG, Materials Science Division, Argonne National Laboratory, F. Y. BRUNO, Department of Quantum Matter Physics, University of Geneva, M. S. BAHRAMY, Quantum-Phase Electronics Center, The University of Tokyo, JONGMIN LEE, RAJAGOPALAN RAMASWAMY, KAIMING CAI, Department of Electrical and Computer Engineering, National University of Singapore, OLLE HEINONEN, Materials Science Division, Argonne National Laboratory, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri, FELIX BAUMBERGER, Department of Quantum Matter Physics, University of Geneva, HYUNSOO YANG, Department of Electrical and Computer Engineering, National University of Singapore — We report the observation of a bilinear magnetoelectric resistance (BMER) signal in the d-orbital two-dimensional electron gas (2DEG) at the SrTiO₃ (STO) (111) surface, demonstrating a spin-splitting. We show that our BMER measurements reveal a three-fold symmetric out-of-plane spin component that breaks the six-fold symmetry of the 2DEG subband dispersion, and an in-plane spin component locked perpendicularly to the momentum. By performing tight-binding supercell calculations based on the relativistic density functional theory of the STO bulk band structure, we find that this 3D spin texture is fully described by the effects of confinement of the STO t₂g conduction band in the (111) plane. We also show that the BMER can be substantially tuned through oxygen vacancy doping, electrostatic gating and temperature variation. Our findings highlight the untapped potential of SrTiO₃ (111) based 2DEGs as a playground for spintronic applications.

9:36AM E45.00009: Atomic-scale observation of large lattice bending and ferroelectric phase transition in freestanding BiFeO₃ thin films* 
DIANXIANG JI (Presenter), SONGJIA CAI, YIPENG ZANG, HAOLANG SUN, LU HAN, MIN GU, ZHENGBIN GU, PENG WANG, YUEFENG NIE, National Laboratory of Solid State Microstructures, College of Engineering and Applied Sciences, and Collaborative Innovation Center of Advanced Microstructures, Nanjing Univ, XIAOQING PAN, Department of Chemical Engineering and Materials Science and Department of Physics and Astronomy, University of California, Irvine, 916 Engineering Tower, Irvine, CA 92697, U — Novel electronic phases emerge in the growing family of two-dimensional (2D) materials, such as graphene and transition metal dichalcogenides. Recent realization of freestanding perovskite films could open the door to a rich spectrum of exotic 2D correlated phases. Moreover, the inherent flexibility at reduced dimensionality makes 2D materials more promising to achieve strong electromechanical coupling and novel functionalities. Here, using reactive molecular beam epitaxy and aberration-corrected transmission electron microscopy, we provide an atomic-scale demonstration of a large lattice bending in ionic crystals. In addition, a tetragonal phase was observed in bended freestanding BiFeO₃ films with a giant c/a of 1.3, which exceeds the largest reported value. Our work indicates that freestanding oxide perovskite is a promising platform to investigate electromechanical effects and their potential applications.

9:48AM E45.00010: Anomalous behaviour of phonon modes – Magnetic properties correlations in La$_{0.7}$Sr$_{0.3}$MnO$_3$/SrRuO$_3$ superlattices

ROSHNA S H (Presenter), P PADHAN, Indian Institute of Technology Madras, WILFRID PRELLIER, CRISMAT Laboratory, CNRS — Artificial superstructure of (111) oriented La$_{0.7}$Sr$_{0.3}$MnO$_3$ (LSMO)/SrRuO$_3$ (SRO) were grown on (111) oriented SrTiO$_3$ substrate using pulsed laser deposition. Microstructure quality and coherency of interafaces were studied using high resolution transmission electron microscopy. The growth epitaxy, crystalline quality, crystal structure and artificial bilayer periodicity of these superlattices were studied using x-ray diffraction. The cumulative strain in these superlattices was studied from the reciprocal space mapping (RSM). The RSM image of these superlattices indicates relaxation in some crystallographic directions. The magnetic exchange coupling at the interfaces of the LSMO-SRO has been investigated with the in-plane and the out-of-plane oriented magnetic field. The phonon mode anomaly of these superlattices were observed in the temperature dependent frequencies of the Raman lines. The observed peak at around 160 K and step like anomaly at around 350 K of the Raman peak frequencies provide strong evidence of magnetic phase transition of SRO and LSMO respectively. The observed anomalies in phonon modes in Raman scattering are discussed in terms of spin phonon coupling and delocalization of polaronic states in the vicinity of magnetic phase transition temperature of LSMO and SRO.

10:00AM E45.00011: Induced ferromagnetism due to oxygen vacancies at the YBa$_2$Cu$_3$O$_7$/SrTiO$_3$ Interface

KYRO BOOM, Department of Physics, University of North Florida, MI HE, EE MIN CHIA, Department of Physics and Applied Physics, Nanyang Technological University, JIAN-XIN ZHU, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, JASON HARALDSEN (Presenter), Department of Physics, University of North Florida — Complex oxide heterostructures provide a large playground of order parameters that can introduce a wide range of emergent phenomena. In the study, we set out to explain the emergent magnetic properties at the interface between YBa$_2$Cu$_3$O$_7$/SrTiO$_3$. Using density functional theory, we determined the electronic and magnetic properties for a simulated heterostructure with and without oxygen vacancies. It is shown that the sheer presence of the interface is not enough to produce a magnetic response. However, with the introduction of oxygen vacancies, we show that there is a shifting of the d orbital electron energies on the transition-metal atoms that induces a magnetic moment at the interface. This work details the effects of oxygen vacancies on complex oxide heterostructures, which has the ability to provide critical insight into future applications of oxide electronics.

10:12AM E45.00012: Mechanism of the irreversible back gate doping at the LaAlO$_3$/SrTiO$_3$ Interface

CHUNHAI YIN (Presenter), Huygens – Kamerlingh Onnes Laboratory, Leiden University, SANDER SMINK, MESA+ Institute for Nanotechnology, University of Twente, INGE LEERMAKERS, LUCAS TANG, High Field Magnet Laboratory (HFML-EMFL), Radboud University, NIKITA LEBEDEV, Huygens – Kamerlingh Onnes Laboratory, Leiden University, ULI ZEITLER, High Field Magnet Laboratory (HFML-EMFL), Radboud University, HANS HILGENKAMP, MESA+ Institute for Nanotechnology, University of Twente, JAN AARTS, Huygens – Kamerlingh Onnes Laboratory, Leiden University — The two-dimensional electron gas (2DEG) formed at the LaAlO$_3$/SrTiO$_3$ (LAO/STO) interface exhibits rich physical properties such as superconductivity and magnetism. Additionally, due to the large dielectric constant of STO, the 2DEG can be controlled by a back gate voltage ($V_G$). When applying $V_G$ to the system, a commonly observed phenomenon is that the sheet resistance follows an irreversible route when $V_G$ is swept first forward and then backward. The explanation as given by Biscaras et al. [1] is that the Fermi energy is close to the top of the quantum well (QW) and high mobility electrons escape the QW and get trapped in STO when the carrier density goes beyond a critical value. In this work, we study the mechanism of the irreversible field-effect doping by means of a back gate. By combining magnetotransport data and self-consistent Schroedinger-Poisson calculations, we come to a different picture. There is no critical carrier density for electron trapping but rather applying any positive $V_G$ triggers it. Moreover, the analysis shows that it is not the mobile charges which get trapped but that the additionally injected electrons immediately find defects. This appears to be a universal phenomenon in STO-based heterostructures.

**10:24 AM E45.00013: Influence of defects on surface morphology and electronic structure in BiVO₄**

WENNIE WANG (Presenter), Institute for Molecular Engineering, University of Chicago, MINGZHAO LIU, Center for Functional Nanomaterials, Brookhaven National Laboratory, KYOUNG-SHIN CHOI, Department of Chemistry, University of Wisconsin-Madison, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — Bismuth vanadate (BiVO₄) has several electronic properties that make it a promising candidate as a photoanode for water photocatalysis; these include strong absorption across much of the visible spectrum and a conduction band edge near the hydrogen evolution potential. However, charge transport and interfacial charge transfer have been reported to be limiting factors for PEC performance. Understanding the connections between surface morphology and PEC performance remains in its nascent stages, and building an accurate structural model is key. Here, we use density functional theory calculations to study the surface morphology and electronic structure of BiVO₄, and compare them with experiment. We investigate pristine surfaces and compare with those that have defects, and discuss the implications on PEC performance.

**10:36 AM E45.00014: Electronic Symmetry of La₀.₆₇Sr₀.₃₃MnO₃/SrTiO₃ Interfaces as a Function of Film Thickness**

JOEL E TAYLOR (Presenter), KUN ZHAO, MOHAMMAD SAGHAYEZHIAN, JIANDI ZHANG, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LOUIS H HABER, Department of Chemistry, Louisiana State University, Baton Rouge, E WARD PLUMMER, Department of Physics and Astronomy, Louisiana State University, Baton Rouge — Second harmonic generation (SHG) is a well known optical technique for probing electronic symmetry originating from regions of broken symmetries. For La₀.₆₇Sr₀.₃₃MnO₃/SrTiO₃ (LSMO/STO) buried interfaces, rotational anisotropic SHG is capable of characterizing interfacial electronic symmetry. Using film thickness and growth conditions to control the interface structure for LSMO/STO buried interfaces, induced changes in the electronic symmetry are detected with rotational anisotropic SHG. Data accumulated for LSMO/STO demonstrates thickness-dependent enhanced four-fold electronic symmetry patterns which are contrary to the measured C₄ᵥ electronic symmetry measured using atomically resolved electron microscopy and spectroscopy. Furthermore, the relative angles of the peak intensities between in-plane and out-of-plane polarization geometries varies with film thickness. Rotational anisotropy SHG of LSMO/STO thin films will be presented from <5 unit cell to 300+ unit cell LSMO/STO heterostructures.

*Supported by U.S. NSF through grant No. DMR-1504226. Thin films are grown by DoE grant No. DE-SC0002136.

**10:48 AM E45.00015: Decoupling carrier concentration and electron-phonon coupling in oxide heterostructures**

DEREK MEYERS (Presenter), Materials Science and Engineering, University of California, Berkeley, KEN NAKATSUKASA, Department of Physics and Astronomy, University of Tennessee, SAI MU, Department of Condensed Matter Physics and Materials Science, Oak Ridge National Laboratory, LIN HAO, JUNYI YANG, Department of Physics and Astronomy, University of Tennessee, YUE CAO, Materials Science Division, Argonne National Laboratory, GILBERTO F L FABBRIS, Advanced Photon Source, Argonne National Laboratory, HU MIAO, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, JONATHAN PELLICIALI, Department of Physics, Massachusetts Institute of Technology, DANIEL MCNALLY, MARCUS DANTZ, EUGENIO PARIS, Research Department Synchrotron Radiation and Nanotechnology, Paul Scherrer Institute, EVGUENIA KARAPETROVA, YONGSEONG CHOI, DANIEL HASKEL, Advanced Photon Source, Argonne National Laboratory, PADRAIC SHAFER, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, SCHMITT THORSTEN, Research Department Synchrotron Radiation and Nanotechnology, Paul Scherrer Institute, TOM BERLIJN, Center for Nanophase Materials, Oak Ridge National Laboratory, STEVEN JOHNSTON, JIAN LIU, Department of Physics and Astronomy, University of Tennessee, MARK DEAN, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — We present the results of resonant inelastic x-ray scattering at the O K-edge on superlattices of form nSrIrO₃/mSrTiO₃. Multiple phonon satellite peaks are observed corresponding to the 4th longitudinal optical mode of SrTiO₃ allowing direct extraction of the electron-phonon coupling strength. As the values of n and m are varied a systematic change in the relative intensity of the satellite features is observed indicating large changes to the electron-phonon coupling strength. In the absence of significant carrier doping this result shows the heterostructure morphology is able to independently tune this important interaction. Theoretical calculations indicate the Fröhlich mechanism dominates the electron-phonon coupling in these superlattices, with the reduced polarity and increased ε∞ driving the observed changes in the electron-phonon coupling.

Tuesday, March 5, 2019 8:00 AM - 10:48 AM
8:00AM E46.00001: Investigation of LaVO3/PrVO3 superlattices as geometric ferroelectrics  STEFANO GARIGLIO (Presenter), HUGO MELEY, University of Geneva, DUNCAN ALEXANDER, EPFL, PHILIPPE GHOSEZ, Université de Liège, JEAN-MARC TRISCONE, University of Geneva — Structural distortions in orthorhombic perovskite structures have been suggested as a source of ferroelectricity in layer-by-layer grown heterostructures of transition metal oxides. Here we explore the idea to achieve a multiferroic state by epitaxial growth in superlattices of LaVO3 and PrVO3. Heterostructures were synthesised by pulsed laser deposition and investigated by X-ray diffraction in order to determine the pattern of the oxygen octahedra. Cation polar distortions were measured by scanning tunnelling electron microscopy in order to confirm the prediction that superlattices with odd repetitions of LaVO3 and PrVO3 layers present a macroscopic ferroelectric state.

8:12AM E46.00002: Domain-wall ferroelectric tunnel junction with triple resistance states  MING LI (Presenter), LINGLING TAO, EVGENY Y TSYMBAL, University of Nebraska - Lincoln — The tunneling electroresistance (TER) effect in ferroelectric tunnel junctions (FTJs) has attracted interest due to potential applications in non-volatile memory devices. TER represents dramatic change in resistance of FTJ upon polarization reversal in ferroelectric barrier. A new type of TER's proposed, utilizing a head-to-head ferroelectric domain wall in La1-xSr_xMnO3(LSMO)/BaTiO3(BTO)/LSMO FTJ with the wall parallel to the plane. Domain wall state has higher conductance than uniformly polarized states, but is metastable and thus not reversible. This work, using first-principles DFT calculations, explores stability of the wall in this FTJ, by considering different La1-xSr_xO/TiO2 terminations at LSMO/BTO interfaces. Due to polar nature of the interface, appearance of the wall depends on doping level x. For x<0.4 domain wall state becomes global minimum, and DFT calculations demonstrate a triple-well energy profile with respect to net polarization. Using an electric field, the FTJ can be switched reversibly between domain wall and two uniformly polarized states. Using a phenomenological model based on Landau-Devonshire free energy and parameters obtained from DFT calculations, we analyze the hysteresis loops of this FTJ demonstrating the emergence of the triple resistance states.

8:24AM E46.00003: Design of a new polar metal via 6s lone pair electrons*  HANGHUI CHEN (Presenter), Physics, NYU Shanghai, YUEWEN FANG, Material Science and Engineering, Kyoto University — Polar metals are extremely rare because mobile electrons within a metal eliminate internal dipoles that may arise owing to asymmetric charge distributions. In this work we combine first-principles calculations and crystal structural search (CALYPSO) method to design a new polar metal. We show that an ordered double perovskite oxide BaBiTi2O6 undergoes a continuous transition from a high-temperature centrosymmetric P4/mmm structure to a low-temperature non-centrosymmetric Pmm2 structure. The material is conducting throughout the structural phase transition. The underlying mechanism is that the 6s lone-pair electrons in Bi3+ leads to polar instability and simultaneously donates electrons to empty Ti-d states, which results in conduction. Our work demonstrates that the lone-pair electrons are effective to induce polar instability in metals as they induce ferroelectric instabilities in insulators. This provides a robust design principle for new polar metals.

*We acknowledge financial support from NSFC.
8:36AM E46.00004: Dynamical Multiferroicity [Invited] NICOLA SPALDIN (Presenter), ETH Zurich — An appealing mechanism for inducing multiferroicity in complex oxides is the generation of electric polarization by a spatially varying magnetization that is coupled to the lattice through the spin-orbit interaction. Here, I will describe the reciprocal effect, in which a time-dependent electric polarization induces a magnetization, even in a material composed only of non-magnetic ions [1]. Two predicted consequences of dynamical multiferroicity will be illustrated using the example of strontium titanate as a model material: A Phonon Zeeman Effect, in which previously degenerate optical phonons split in the presence of a magnetic field, and a Quantum Critical Multiferroicity, manifesting as an anomalous magnetic susceptibility in the vicinity of the ferroelectric quantum critical point [2]. Finally, I will discuss possibilities for engineering and optimizing the behaviors using heteroepitaxial strain.

9:12AM E46.00005: Interface induced polar metals by multi-mode coupling* SAURABH GHOSH (Presenter), AAFREEN FATHIMA, Dept. of Physics and Nanotechnology, SRM Institute of Science and Technology, India, HANGWEN GUO, E WARD PLUMMER, Dept. of Physics and Astronomy, Louisiana State University, USA, SOKRATES T PANTELIDES, Dept. of Physics and Astronomy, Vanderbilt University, USA — Multi-mode coupling between various phonon modes in ABO3 perovskite oxides can be tuned by forming heterostructures, which can lead to precise control of their functionalities [1]. Considering the interest in ferroelectric properties in a metal i.e., in polar metals [2], an efficient way to induce ferroelectric-like (FEL) displacements in the centrosymmetric phase is by interface-induced coupling [3]. Here, using first-principles density functional theory (DFT) and DFT+U (static d-d Coulomb interaction) we have investigated (BaTiO3)m/(Metal)p/(BaTiO3)m' heterostructures [(m/p/m')= 6/3/7, 7/2/7, 7/1/8, m+p+m'= 16] to explore a new family of polar metals. We have chosen various metal blocks in a way that can represent a BTO/3dn/BTO system, where n= 1-6. We found that a FEL phase coupled with in-plane rotation of BO6 octahedra (a0a0c+) can be induced in the centrosymmetric ‘metal’ block when BaTiO3 is in the ferroelectric phase. The properties are found to depend strongly on the relative polarization direction of BTO units. [1]. S. Ghosh et. al. Phys. Rev. B. 92, 184112, (2015), [2] S. Ghosh et. al. Phys. Rev. Lett. 119, 177603 (2017), [3] H. Guo, PNAS, 114, E5062-E5069 (2017).

9:24AM E46.00006: Electrically-Tuned Strain Fields in a Ferroelectric/Ferromagnetic (PZT/LSMO) Heterostructure NELSON HUA (Presenter), University of California, San Diego, SYLVIA MATZEN, THOMAS MAROUTIAN, GUILLAUME AGNUS, University of Paris-Sud, MARTIN HOLT, Argonne National Laboratory, PHILIPPE LECOEUR, DAFINE RAVELOSONA, University of Paris-Sud, OLEG SHPYRKO, University of California, San Diego — Manipulating the magnetic properties of complex materials can be achieved by varying the temperature or composition (doping), but alternative methods like strain-induced modification of magnetic domains has been less explored. Nanostructures can accommodate larger values of strain, and can be applied using various epitaxial growth methods and dynamically altered by an external stimulus. Therefore, lattice strain can be used as a tuning parameter to modify magnetic properties on the nanoscale. To explore this possibility, we investigated the response from multiferroic materials that uses an intermediary strain field as a coupling mechanism. Specifically, we performed x-ray nanodiffraction to spatially resolve the coupled strain field between PZT and LSMO, a ferroelectric/ferromagnetic heterostructure, as a function of an applied electric field in the ferroelectric PZT layer. Our results reveal this interfacial strain transfer with 30nm spatial resolution and uncover the details of confined size effects associated with nanoscale structural domains.
Correlated oxides often exhibit the presence of intertwined phases of long-range order. The rare-earth nickelates (RNiO3) serve as a model transition metal oxide platform to understand and engineer the electronic structure of such phases. For several ‘strange’ metals whose properties cannot be described within the paradigm of conventional Fermi liquids, heterostructures incorporating such metals also have properties that are distinct from those found in similar structures based heterostructures resulting from the influences of dimensional confinement and interfacial coupling. We focus on the AF ground state in (NNO)m-(NdAlO3)n heterostructures: enhancement of AF domain dynamics and spin fluctuations in reduced dimensions appear to hinder spin ordering. We employ x-ray photon correlation spectroscopy (XPCS) measurements via coherent x-ray scattering of the heterostructures to elucidate dimensionality-driven spin dynamics. Speckle patterns arising from AF domains are investigated for different thickness of confined nickelate layers and their dynamics are studied across the charge and spin ordering transitions. This study demonstrates an approach to characterize dimensional effects on long-range order and the ability to control the AF domain configurations in oxide heterostructures.

Comparing Bulk and Layer Confined RNiO$_3$ to Disentangle Lattice and Electronic Effects in the Metal-Insulator Transition

ALEXANDRU BOGDAN GEORGESCU (Presenter), Center for Computational Quantum Physics, Flatiron Institute, NY, NY, 10010, OLEG E. PEIL, Materials Center, Leoben, Austria, ANKIT S DISA, Max Planck Institute, Hamburg, Germany, ANTOINE GEORGES, ANDREW MILLIS, Center for Computational Quantum Physics, Flatiron Institute, NY, NY, 10010 — The metal-insulator transition (MIT) of transition metal oxides is often associated with a simultaneous lattice and electronic symmetry breaking. We disentangle the effects of the electronic and lattice structure in the MIT of rare earth nickelates (RNiO$_3$) by comparing bulk and layer-confined NdNiO$_3$, using a combination of electronic structure and many-body methods[1,2,3]. We find that electronic confinement leads to an increase in the relative role of local interactions that favor an insulating symmetry-broken state. However, heterostructuring with another material leads to an increase in the lattice stiffness with respect to structural disproportionation caused by the interfacial octahedral coupling. Our work explains why nickelate heterostructures can have both a higher MIT temperature despite a weaker structural signature of the insulating state[4]. These results are of general relevance to the physics of transition-metal oxides.

Session E47 GERA: Energy Storage: Electrolytes and Ionic Conductors

BCEC 213 - Nancy Haegel, National Renewable Energy Laboratory

Nuclear Magnetic Resonance Investigation of Lithium Ion Transport in a Highly Conducting Solid Polymer Electrolyte: The Enabling Effect of High Salt Concentration

SAHANA BHATTACHARYYA (Presenter), Physics, CUNY Graduate Center, New York, NY 10016, MOINESHA GARAGA, STEVEN GARRY GREENBAUM, Physics and Astronomy, Hunter College of the City University of New York, New York, NY 10065, MATTHEW D WIDSTROM, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20740, PETER KOFINAS, Department of Chemical and Biomolecular Engineering, University of Maryland, College Park, MD 20740 — Solid polymer electrolytes based on poly(ethylene oxide) (PEO) for rechargeable lithium ion batteries significantly lack sufficiently high ionic conductivity for practical use at ambient temperature. Recent reports of high ionic conductivity and an expanded electrochemical window of aqueous electrolytes enabled by very high salt concentration (~20m) as well as earlier work on the “salt-in-polymer” concept have inspired this investigation of a solid PEO-salt-water system, where the dissolved salt (LiTFSI) concentration approaches its solubility limit and in combination with water association succeeds in inhibiting crystallization of the PEO matrix leading to higher conductivity. Room temperature ionic conductivity in these solid-like polymer electrolytes is about 2 mS-cm$^{-1}$, which is sufficiently high for battery application. Characterization of the ion transport process by NMR pulsed field gradient diffusion measurements ($^7$Li and $^{19}$F for the cation and anion, respectively) and electrochemical impedance spectroscopy demonstrate an acceptable degree of salt ion dissociation and a lithium transport number, i.e. the Li ionic fraction of the current, exceeding 0.6, which is unusually high for polymer electrolytes. Additional electrochemical testing results will also be presented.
Computational and experimental investigation of Na₄P₂S₆ as a promising solid electrolyte material for sodium metal batteries

YAN LI (Presenter), NATALIE A HOLZWARTH, Department of Physics, Wake Forest University, ZACHARY DAVID HOOD, Department of Materials Science and Engineering, MIT — Recent experiments¹ have shown that Na₄P₂S₆, prepared from a hydrated precursor Na₄P₂S₆·6H₂O by heating under vacuum to 175 deg. C, has good ionic conductivity and stability with respect to metallic Na anodes, suggesting its promise as a solid state electrolyte for Na ion batteries. Examining the experimental results, we have extended previous computational work² on this material to further understand its structural, conductivity, and interface properties. Of particular interest is the observation¹,³ that Na₄P₂S₆ crystallizes to form monoclinic crystals having the space group C2/m which is distinct from the hexagonal or trigonal structures⁴-⁶ analyzed for the related material Li₄P₂S₆. Computer modeling results suggest that the C2/m structure of Na₄P₂S₆ is stabilized by lattice vibrations.

First-principles prediction of potentials and space-charge layers in all-solid-state batteries

MICHAEL W. SWIFT (Presenter), YUE QI, Chemical Engineering and Materials Science, Michigan State University — As all-solid-state batteries (SSBs) develop as an alternative to traditional cells, a thorough theoretical understanding of driving forces behind battery operation is needed. We present a fully first-principles-informed model of potential profiles in SSBs and apply the model to the Li/LiPON/LiₓCoO₂ system. These profiles, especially the interface dipoles, yield valuable information about lithium distribution and transport and the nature of interfacial electrical double layers. The results suggest design rules to minimize interfacial lithium transport resistance and optimize device performance.

Structural Characterization of a Solid Electrolyte for 3D Microbatteries

DAVID CLARKSON (Presenter), MOUNESHA GARAGA, STEVEN GARRY GREENBAUM, Department of Physics & Astronomy, Hunter College of the City University of New York, MORAN LIFSHITZ, ELAZAR COHEN, DIANA GOLODNITSKY, School of Chemistry, Tel Aviv University — Three-dimensional (3D) microbatteries have gained attention as viable compact power sources with applications in wearable and implantable microelectronics, and IoT functions. A key innovation from our lab is electrophoretic deposition (EPD) of all thin-film layers, enabling conformal deposition of electrodes and solid electrolytes on complex-shape, high-aspect-ratio perforated silicon and polymer substrates. This leads to a large capacity gain per footprint area of battery, compared with wafer surface deposition.

Using EPD, we prepared a novel composite polymer-in-ceramic electrolyte composed of 87% lithium aluminum germanium phosphate (Li₁.₅Al₀.₅Ge₁.₅(PO₄)₃, LAGP), 13% polyethyleneimine (LAGP–PEI), saturated by LiI salt to produce high concentrations of mobile Li⁺ and I⁻ ions.

Solid state ⁶,⁷Li, ²⁷Al, and ³¹P magic angle spinning nuclear magnetic resonance (MAS NMR) measurements showed structural changes the LAGP-PEI-LiI composite compared with base LAGP material, including the conversion of about 1/3 of the crystalline compound into an amorphous phase containing both two-fold and three-fold coordinated P, and a change in the ratio of five-fold to six-fold coordinated Al. ⁷Li NMR diffusometry revealed faster Li ion diffusion in the LAGP-PEI-LiI composite than in base LAGP.
8:48AM E47.00005: Sol-gel synthesis of a Fe-doped cubic phase Li$_2$La$_3$Zr$_2$O$_{12}$ Solid State Electrolyte  
ANDRES VILLA PULIDO (Presenter), MAI TAN, ERNESTO MARINERO, School of Materials Engineering, Purdue University — Cubic Li$_2$La$_3$Zr$_2$O$_{12}$ (LLZO) exhibits high ionic conductivity, chemical stability and thermal stability and a high transference number. These characteristics make it a promising material for integration in solid state batteries. Doping LLZO with certain elements like bismuth, gallium, aluminum and tantalum increases the ionic conductivity and reduces the stabilization temperature of the cubic phase. In this work a sol-gel method is used to synthesize Fe-doped LLZO (Li$_{7-2x}$Fe$_x$La$_3$Zr$_2$O$_{12}$), wherein a low calcination temperature of 700°C in air is used. XRD is used to characterize the cubic phase and presence of other impurity phases. SEM is used to determine the microstructure of the powder and the prepared pellets with different Fe stoichiometric content. Electrochemical impedance spectroscopy is used to determine the bulk conductivity of the Fe-doped LLZO pellets. The low synthesis and calcination temperature combined with the high ionic conductivity (and other favorable characteristics of the LLZO garnet) make this synthesis method and material highly attractive for lithium-ion solid state batteries. Future work will involve fabrication of polymer composite electrolytes with this material, looking for positive synergy of polymer and garnet characteristics.

9:00AM E47.00006: Theoretical modelling of lithium environment in composite solid electrolyte batteries investigated through x-ray absorption near edge spectroscopy*  
EMILY BEEN (Presenter), FEIFEI SHI, Materials Science & Engineering, Stanford, SRI CHAITANYA DAS PEMMARAJU, SLAC, Stanford, YI CUI, Materials Science & Engineering, Stanford, THOMAS DEVEREAUX, SLAC, Stanford — Liquid electrolytes in conventional batteries are volatile, flammable, and cause many of the fires and explosions of lithium ion batteries. Moving to solid state electrolytes not only removes these instabilities but also suppress dendritic growth of lithium that can short a battery. Ion transport is a main limitation in these solid-electrolytes. Composite electrolytes made of nanostructured combinations of ceramics and polymers show promise to increase ion transport at the ceramic-polymer interface[1]. To investigate the mechanisms that preferentially transport lithium ions at this interface, x-ray absorption near edge spectroscopy (XANES) of lithium K-edge was performed experimentally and elucidated through theoretical simulation. The solid-electrolyte system investigated is lithium perchlorate (ClO$_4^-$) dissolved in poly(ethylene oxide) (PEO) in nanopores of anodized aluminum oxide. Simulation results explicate a complex relationship between the XANES edge shift and lithium environment, going beyond the preliminary expectation that coordination number of lithium with oxygen causes the XANES shift.

*This research is funded by U.S. Department of Energy, Stanford University, and SLAC National Accelerator Laboratory.

9:12AM E47.00007: Effects of solvent-salt charge-transfer complexes on oxidative stability of Li-ion battery electrolytes*  
ERIC FADEL (Presenter), Materials Science and Engineering, Massachusetts Institute of Technology, FRANCESCO FAGLIONI, Department of Chemical and Geological Sciences, University of Modena and Reggio Emilia, GEORGY SAMSONIDZE, Robert Bosch LLC Research and Technology Center, NICOLA MOLINARI, John A. Paulson School of Engineering and Applied Sciences, Harvard University, BORIS V MERINOV, WILLIAM GODDARD, Materials and Process Simulation Center, California Institute of Technology, JEFFREY C GROSSMAN, Materials Science and Engineering, Massachusetts Institute of Technology, JONATHAN P MAILOA, Robert Bosch LLC Research and Technology Center, BORIS KOZINSKY, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Electrochemical stability windows of multi-component electrolytes, both solid polymer and organic liquid, largely determine the operating regime limits of Li-ion batteries. In order to increase energy densities and lifetimes of batteries, new electrolyte materials need to be discovered and optimized which requires better understanding of their degradation and oxidation. Using computational tools, we present new insights into the oxidation mechanism that governs stability of multi-component polymer and liquid electrolytes. We find that explicitly including solvent molecules in the computation of the anion stability has a strong impact, and we show that this effect stems from electrostatic interactions between the molecules. Particularly, we find that across all chemistries studied, only one molecule in the system is oxidized. Building on this, we construct a model where two oxidation scenarios lead to different stability behaviors for the anion-solvent pairs, depending on their relative strength and geometry. This understanding of the microscopic details of oxidation allows one to formulate design rules and provides a good framework for screening electrolyte materials.

The Role of Ion Correlation on Transport Properties of Concentrated Ionic Liquids for Battery Electrolytes

Nicola Molinari (Presenter), Harvard University, Jonathan P Mailoa, Nathan Craig, Jake Christensen, Robert Bosch LLC, Boris Koziński, Harvard University — Recent pioneering work on Na batteries has drawn attention on ionic liquid electrolytes, yet most published works ignore the effects of ion-ion correlation. Using classical all-atom molecular dynamics and fully-correlated theory we highlight the drastic differences in fundamental understanding when using the systematically overlooked correlated approach. As a case study, we look at the promising Na/bis(fluorosulfonyl)imide (NaFSI) in room temperature ionic liquid N-propyl-N-methylpyrrolidinium/FSI. A previously undetected negative transference number emerges for sodium molar fractions lower than 0.2, effectively hinting to high degrees of ion-ion correlation that should not be dismissed. The spatial correlation is explored further by employing a variant of the single-linkage clustering algorithm. The approach we use enables us to explain the concentration-driven trends in ionic conductivity and transference numbers, and is generally able to correctly capture the transport physics of highly-correlated systems such as concentrated electrolytes.

First-Principles Replica Monte Carlo Sampling of Dopant Disorder in Solid Electrolyte

Shusuke Kasamatsu (Presenter), Osamu Sugino, Univ of Tokyo-Kashiwanoha — Oxides such as ZrO₂ and BaZrO₃ are promising candidates for the electrolyte material in medium to high-temperature solid oxide fuel cells. In these materials, aliovalent cation doping is used to introduce ionic defects which act as ionic charge carriers. Optimization of doping conditions is imperative for obtaining sufficient and stable ionic conductivity, but it is yet unclear how dopants are distributed in the material under various processing conditions and how the details of the distribution affect the total conductivity. Since the experimentally found optimal doping concentration can run up to 20%, the degrees of freedom in substitutional dopant placement is enormous (for example, choosing 10 substitutional sites out of 50 corresponds to 50C10~10 billion degrees of freedom). In this work, we harness the power of modern-day supercomputers and perform thermodynamic sampling of dopant placement in BaZrO₃ by directly combining first-principles calculations and the replica exchange Monte Carlo method. We show that dopant-carrier association decreases with increasing dopant concentration, in contrast to popular belief that association effects are responsible for conductivity decrease at high dopant concentrations.

Polyethylene oxide-Li₇La₃Zr₂O₁₂ composite solid-state electrolyte for advanced Li-ion batteries (LIBs)

Parisa Bashiri (Presenter), Prasada Rao Talakonda, Wayne State University, Vaman M Naik, University of Michigan Dearborn, Gholamabbas Nazri, Ratna Naik, Wayne State University — Recently, conformal solid-state polymer-based electrolytes have been considered as promising alternatives for liquid electrolytes in LIBs because of their fire safety and ease of fabrication in thin film form with desirable mechanical, thermal and high electrochemical stability. Several researchers have investigated polyethylene oxide (PEO) based films complexed with Li-salts, such as LiClO₄, as polymer electrolytes. However, these electrolytes exhibit low ionic conductivity (~10⁻⁶ - 10⁻⁷ S cm⁻¹) at room temperature due to high degree of crystallinity. This issue has been addressed by adding plasticizers such as ethylene carbonate (EC) or using inorganic fillers. We have studied PEO based polymer electrolyte with Li₇La₃Zr₂O₁₂ (LLZO) as an inorganic filler, which is also a Li-ion conductor. We show that the addition of LLZO (20 wt%) and EC (20 wt%) increases the ionic conductivity of PEO-LLZO composite electrolyte by an order of magnitude, lowers the activation energy from 0.6 eV to 0.5 eV, and maintains a high voltage stability (5 V). The results of electrochemical impedance spectroscopy, linear sweep voltammetry, and chronoamperometry measurements will be presented.

Investigate the mobility of Lithium-sulfur batteries via ab initio molecular dynamic with external force

Guoping Gao (Presenter), Lawrence Berkeley National Laboratory — Even though tremendous achievement has been made experimentally in the performance of Li-S battery, theoretical studies in this area are lagging behind due to the complexity of the Li-S systems. For this purpose, we have developed a new molecular dynamic method with external force applied on the Li atom to investigate the mobility. Our proposed computational framework not only opens a new avenue for understanding the key role played by solution and liquid electrolytes in Li-S battery, but also can be generally applied to other processes with liquids involved.
The development of safe high energy density rechargeable lithium (Li) ion batteries is crucial for meeting the goal of clean sustainable energy. A major limiting factor in these batteries is the electrolyte — organic liquids are typically flammable and have limited electrochemical stability while most solid electrolytes have lower ionic conductivity and limited stability. Here, we focus on design principles for ionic transport in multicomponent solid electrolytes, either artificially created or naturally generated at the electrode-electrolyte interface. General tradeoffs prevent single component solid electrolytes from achieving the desired properties simultaneously [1] but may be broken through a multicomponent system by a careful use of the phase boundaries through the generation of space charge regions [2], confinement, ion adsorption etc. Together with the descriptors for ionic conduction, our design principles will be supplemented by theoretical spectroscopy studies based on x-ray absorption and emission to assist in experimental validation of samples with the required composition.

8:00AM E48.00001: Enhancement of lift to drag ratio for a wing using thermal forcing ANchal VARshney, MeHuL VARshney (Presenter), MF Baig, Aligarh Muslim University — The aim is to enhance the lift to drag ratio produced by a wing with a cambered profile by thermal forcing its partial lower surface. Reynolds number is considered in the laminar regime. The efficacy of control technique has been checked at various Mach number and angle of attack. The overheat factor, which is the ratio of the temperature of the heated portion to free stream temperature has also been varied to study its role in the control technique. The governing equations of continuity, momentum, and energy have been solved using commercial package Fluent®. As of now, the proposed mechanism for the enhancement of lift to drag ratio is the increase in vorticity generation near the trailing edge because of the variation in viscosity. This brings about a net increase of circulation about the wing which results in higher lift. The other possible mechanism for the phenomenon is further being explored such that advancement in Micro-Air Vehicles technology can be done.

8:12AM E48.00002: Turbulent Drag Reduction on an Aircraft Wing MEHUL VARSHNEY (Presenter), MF BAIG, Aligarh Muslim University — The aim of the present work is to reduce the turbulent drag induced on a supercritical aircraft wing at commercial flight scale conditions of Reynolds number and Mach number by using jets installed on the upper and lower surface of the wing. The present method is an active technique of viscous drag reduction. To the best of author’s knowledge, no such control technique has been explored at such conditions. The analysis considers jets in the stream-wise and span-wise direction incorporated on suction and pressure surfaces of the wing which tend to form a pair of colliding-jets in the span-wise direction. The efficacy of the control technique has been checked for jets with various emerging mass flux and inclination angle of the streams. The governing equation of continuity, RANS (using Spalart Allmaras as turbulence model) and the energy have been solved numerically using the commercial package Fluent®. The mechanism behind the control technique is the lifting of the boundary layer which brings about a reduction in the skin-friction component of the drag and the cross-diffusion of the near-wall streaks which brings about a decrease in the turbulent kinetic energy and hence viscous drag. Role of vorticity variation will also be explored.

8:24AM E48.00003: Stable flight of meteors* PEJMAN SANAEI (Presenter), New York University - Courant Institute, MICHAEL JOHN SHELLERY, New York University - Courant Institute, Flatiron Institute, LEIF RISTROPH, New York University - Courant Institute — The atmospheric erosion of meteors is a splendid example of the reshaping of a solid object due to its motion through a fluid. Motivated by meteorite samples collected on Earth that suggest fixed orientation during flight—most notably the strikingly conical shape of so called oriented meteorite—here the hypothesis that such forms result from an aerodynamic stabilization of posture that may be achieved only by specific shapes, is explored. The laboratory- scale experiment is conducted for exploring systematic static stability tests on cones of varying apex angles in fast flows, and the resulting map of the orientational equilibria and their stability. A 2D mathematical model has been developed, and is compared with the experimental results. Armed with the simplified 2D model of oriented meteorites (with a conical shape), an isosceles triangle is considered in order to calculate its flow wake structure using free streamline theory and conclude that meteors are self-stabilizing in the sense that they seem to reshape themselves through erosion into a flight-stable form.

NSF CBET-1805506

8:36AM E48.00004: Vortex streets behind triangular objects ILDOO KIM (Presenter), Brown University — When a triangular object, instead of a circular object, is used to produce a vortex street, an exotic vortex arrangement is observed in addition to the commonly observed mushroom-like structure. The exotic structure is morphologically distinctive from the classical von Karman vortex street and is characterized by a thin layer of irrotational fluid that separates two rows of vortices. This structure appears when a dimensionless ratio between the thickness of the boundary layer and the size of the object is less than a certain value, which is measured to be 0.4 in our experiment. The experiment is modeled by a double shear layer profile, whose linear stability is solved numerically. The theoretical consideration shows a rough agreement with the measurement.
ALEXANDRE VILQUIN (Presenter), Laboratoire de Physique et Mécanique des Milieux Hétérogènes, VINCENT PAGNEUX, Université du Mans, AGNÉS MAUREL, PHILIPPE PETITJEANS, ESPCI — The vortex rings are torus-shaped vortices existing in many different situations in fluid mechanics. They are involved in the locomotion of numerous animals like birds and fish. The understanding of their formation process is essential to optimize the propulsion in engineering. They also play a major role for blood pumping in left ventricle and are considered as an index of cardiac health in the human heart. As proof of the phenomenon diversity, the presence of charged vortex ring with a quantized circulation has also been identified in superfluid helium.

The first part of this talk will give a short overview about interest and properties of the vortex rings. In a second part, I will present an experimental study on a semi vortex ring connected to a free surface, notably involved in the locomotion of water striders. This U-shaped object is here generated by the circular motion of a flat circular disc in water. Digital particle image velocimetry provides velocity fields and vortex properties. The formation process highlights not only the existence of a classical rolling up at the rear of the disk, but also a shedding phenomenon on the leading edge of the disc. The created small vortices affect final properties of the semi vortex ring.

POOJA CHOPRA (Presenter), DAVID A QUINT, AJAY GOPINATHAN, BIN LIU, University of California, Merced, CA, United States. — Transport through complex environments is paramount to microorganism propagation and survival. At the scale of a single bacterium, there can be environmental physical features that dramatically alter transport properties at the population level. In this work, we study the transportation of individual bacteria, here *Escherichia coli* (*E. coli*), through a lattice of micropillars which serve as structured obstacles with well-defined geometries. To fully account for single cell kinematics, we employ a 4D (3D+time) tracking microscope while imaging in the micropillar environment. Interestingly, we found that the micropillar arrays promote the dispersal of bacteria rather than serving as simple obstacles. We explore the mechanisms of such enhanced transport by studying the spatial dependence of the run-and-tumble statistics of *E. coli*, in part due to the hydrodynamic interactions between the bacteria and solid surfaces.

*The authors thank the support of National Science Foundation NSF, CREST: Center for cellular and Biomolecular Machines (NSF-HRD-1547848).

AMANDINE LECHANTRE (Presenter), University of Mons, ALEJANDRO RICO GUEVARA, University of California at Berkeley, PASCAL DAMMAN, University of Mons — Hummingbirds have a high metabolic rate requiring to feed on a very energetic resource: the nectar. For this purpose, they have developed a truly specialized nectar-feeding method. During the capture of the nectar, the hummingbird's bill goes into the corolla of the flower. Then the tongue is protruded out and plunges into the nectar. After the loading, the tongue retracts and is unloaded in the bill. The mechanism of the tongue's loading is still unresolved. At first, it was suggested that the tongue was composed of two thin tubes which was filled because of a capillary suction mechanism (Martin 1833, Scharnke 1931). But the morphological study of the tongue reveals that it is composed of two folded sheets and no closed tubes. In this talk, we will tackle the question: how a sheet can fold into a tube to capture viscous fluid. Several mechanisms were proposed: self-assembling capillary syphon (W. Kim et al. 2012) or elastic micropumps (A. R. Guevara et al. 2005). Based on elasto-capillary experiments and recording of living hummingbirds, the relevance of both models will be discussed.

GIUSEPPE PUCCI, IAN HO, DANIEL M HARRIS (Presenter), School of Engineering, Brown University — A body in motion tends to stay in motion but is often slowed by friction. We investigate the friction experienced by centimeter-sized bodies sliding on water. We show that their motion is dominated by skin friction due to the boundary layer that forms in the fluid beneath the body. We develop a simple model that considers the boundary layer as quasi-steady, and is able to capture the experimental behaviour for a range of body sizes, masses, shapes and fluid viscosities. We define a dimensionless sliding number as the ratio between the fluid inertia and the body inertia, which allows us to assess the regime of validity of our model. Furthermore, we demonstrate that friction can be reduced by modification of the body's shape or bottom topography. Our results are significant for understanding natural and artificial bodies moving at the air-water interface, and can inform the design of aerial-aquatic microrobots for environmental exploration and monitoring.

*The authors would like to thank the Brown OVPR Seed Award for partial support of this work. G. P. thanks the program CNRS Momentum for its support.
We study the effect of shape-polarity on the Stokesian sedimentation dynamics of particles by experiments in which isosceles triangles of varying apex angles are placed in a vertical plane and sedimented at low Reynolds number in a quasi-two-dimensional container. Unlike a nonpolar shape, the triangle rotates as it sediments - due to coupling between the orientational and translational degrees of freedom - and asymptotically approaches a stable configuration either pointing along or away from gravity [Jayaweera, Mason, J. Fluid Mech. 22 (1965)]. For small apex angles the triangle is stable with apex pointing down. As the apex angle is increased we find a transition at $\pi/3$ for which all orientations of the triangle are stable and for apex angles greater than $\pi/3$, the triangle is stable with apex pointing up. We understand the experimental results with a model of three stokeslets fixed to the vertices of a triangle. Adding polarity to the particles introduces an effective damping term in the equations of motion, thus making it not amenable to an effective Hamiltonian treatment constructed for apolar particles [R. Chajwa et. al. arXiv:1803.10269 (2018)].

*NM, AC acknowledge funding through NSF DMR 1507650.
9:00AM E49.00004: Mechanical Properties and Crazing Behavior in Model Polymer-Grafted Nanoparticle Thin Films*

JEFFREY ETHIER (Presenter), LISA HALL, William G. Lowrie Department of Chemical and Biomolecular Engineering, The Ohio State University — Thin films comprised of inorganic-organic polymer-grafted nanoparticles (PGNs) show promise for use in flexible electronics and high energy density materials. Recently, there has been significant interest in tuning the properties of the polymer-grafted layers to optimize entanglement formation between neighboring PGNs and improve mechanical performance. In this work, we show how graft density and polymer length affect inter-PGN entanglements and mechanical properties using coarse-grained molecular dynamics (MD) simulations. Specifically, we simulate twelve PGNs organized in a hexagonal spacing on a smooth, attractive surface. We rigidly attach the first monomer of every chain to the surface of a nanoparticle (using rigid body constraints) and model the polymers as bead-spring chains. We first quantify the number of interparticle entanglements between PGNs and show that moderate graft density particles have increased interparticle entanglements per chain and better mechanical toughness compared to high graft density particles in the melt state. We then cool the monolayer below the glass transition and compare the crazing behavior of PGN thin films to their analogous homopolymer thin films.

9:12AM E49.00005: Microscopic origins of caging and hyperdiffusive relaxations in hairy nanoparticle fluids*

[Invited]

LYNDEN ARCHER (Presenter), Cornell University — Nanocomposites formed from well-dispersed suspensions of solvent-free silica nanoparticles tethered with flexible polymers are known to exhibit jamming behavior due to interpenetrated chains in the confined space between nanoparticle cores. This talk discusses equilibration processes in such materials by means of small-angle X-ray scattering (SAXS), dielectric relaxation, and rheology measurements. In so doing the talk we explore the microscopic processes responsible for caging and show how cages emerge on the nanoparticle cores. The talk also considers consequences of caging, including hyperdiffusive particle dynamics and yielding. A simple microscopic model for caging and particle clustering is shown to explain both the yielding transition and onset of hyperdiffusive relaxations.

9:48AM E49.00006: Polymer-Grafted Nanoparticle (PGN) Assemblies: Supramolecular Dynamic Bonds for Enhanced Toughness*

ANDREW TIBBITS (Presenter), ALI JAWAID, JASON STREIT, LAWRENCE DRUMMY, RICHARD VAIA, Materials and Manufacturing Directorate, Air Force Research Laboratory — The targeted design of PGNs has significant ramifications in the design of scalable and tough coatings, flexible electronics, and functional inks. Studies of the nanomechanics of polystyrene grafted nanoparticles have shown a strong dependence of PGN architecture on plasticity. Nonetheless, toughness at high NP fraction is impeded by the inherently high entanglement molecular weight (MWe) of amorphous polymer grafts. The incorporation of supramolecular dynamic bonds (e.g. hydrogen bonding) into the canopy provides dynamic crosslinks that enhance viscoelasticity and dissipative processes at lower molecular weights. The modification of pendant olefins in poly(1,2-butadiene) with supramolecular dynamic bonds and subsequent grafting onto gold nanoparticles permits directed self-assembly into ordered superlattice structures at high core volume fraction (>30 vol%). The modular chemistry and grafting approach facilitates development of a comprehensive phase space correlating PGN architecture, dynamic bond strength and content, morphology, and nanomechanics to direct optimal engineered canopy designs to maximize robustness in PGN assemblies.

10:00AM E49.00007: Structure and dynamics of architecturally engineered all-polymer nanocomposites*

ERKAN SENSES (Presenter), Koc University, MADHUSUDAN TYGAI, ANTONIO FARAOE, NCNR, NIST — We present nanocomposites formed by using glassy star-shaped polymers as nanofillers and dispersing them in soft matrices. The resulting 'architecturally engineered' nanocomposites structurally reside between the linear homopolymer blends and the conventional polymer nanocomposites with solid fillers. We observed that the star polymers can induce reinforcement that can be as strong as that of solid nanoparticles, or softening depending on the compactness and concentration of the nanoparticles. We showed that the remarkable influence of filler architecture on the rheological properties can be traced back to the dynamical features at the segmental and the chain level which we investigated using neutron scattering over a wide range of time and lengths scales in the glassy and melt states of the nanocomposites. The local and segmental dynamics as well as chain-chain entanglements are all modified by polymer architecture, offering a novel approach for tuning the physical properties of all-polymer based composites.

10:24AM E49.00009: Deformation Mechanism of Mechanochromic Polymer Nanocomposites Fabricated by Self-Assembly of Colloidal Particles  
CHAO-HUNG CHENG (Presenter), SHUHEI NOZAKI, SHIORI MASUDA, NATTANEE DECHNARONG, Graduate School of Engineering, Kyushu University, KAZUTAKA KAMITANI, TOMOYASU HIRAI, KEN KOJIO, ATSUSHI TAKAHARA, Institute for Materials Chemistry and Engineering, Kyushu University — A novel polymer nanocomposite consisting of polymer-grafted nanoparticles have attracted great attention due to their properties of self-assembling to an ordered colloidal crystal structure. However, the deformation mechanism of this colloidal crystal has not been clarified yet. In this study, the structural evolution of a colloidal crystal with rubbery/glassy block copolymer-grafted silica particles (BCP-g-SiO$_2$) was investigated by in situ ultra small-angle X-ray scattering (USAXS) under deformation. Poly(butyl acrylate) (PBA) and poly (methyl methacrylate) (PMMA) were chosen as inner and outer layers of BCP-g-SiO$_2$, respectively. The heat-pressed film consisting of BCP-g-SiO$_2$ exhibited structural color due to the formation of photonic colloidal structure. The color changed under uniaxial stretching. The first order ring of USAXS pattern changed from circle to ellipsoid under elongation, indicating the lattice distance increased along the elongation direction but decreased in the direction perpendicular to elongation. Moreover, the BCP-g-SiO$_2$ with higher PBA ratio had larger transverse strain which was calculated from the $d$-spacing of the first order ring of structure factor, because the polymer layer was compressed more in the transverse direction under uniaxial stretching.

10:36AM E49.00010: Polymer-grafted Nanoparticle Membranes with Exceptional Gas Separation Performance*  
CONNOR BILCHAK (Presenter), SANAT KUMAR, CHRISTOPHER JAMES DURNING, Columbia University, YUCHENG HUANG, BRIAN C BENICEWICZ, Department of Chemistry and Biochemistry, University of South Carolina, JACQUES JESTIN, CEA/CNRS — There is considerable interest in developing novel gas separation membranes that improve on current, pure polymer-based technologies. Pure polymer grafted nanoparticle based membranes offer the exciting opportunity to tuneable small gas permeabilities but are still limited compared to current exotic polymers. Here, we discuss gas transport in GNP integrating small amounts of ungrafted polymer chains with judiciously chosen chain lengths. We find that the addition of homopolymer allows us to almost independently increase membrane gas selectivity, and thus exceed the Upper Bound representing the best currently available membrane materials. X-Ray and neutron scattering suggest that gas transport in GNP is spatially inhomogeneous with solutes bigger than a critical size being moved primarily through the interstitial spaces between the NPs, while small solutes are carried more homogeneously through the whole layer. High molecular weight free chains segregate into these interstitial regions and preferentially hinder large solute motion, thus greatly improving selectivity. Controllably manipulating transport in these inhomogeneous materials thus offers the opportunity to construct gas-separation membranes with exceptional performance.

8:00AM E50.00001: E50 POLYMER PHYSICS PRIZE BREAK  —
8:36AM E50.00002: Programming Emergent Chiral and Polar Symmetries with Saddle-Splay Elasticity  YU XIA  (Presenter), Chemical and Biological Engineering, Princeton University, ANDREW DEBENEDICTIS, Tufts University, DOUG J CLEAVER, Sheffield Hallam University, TIM ATHERTON, Tufts University, SHU YANG, University of Pennsylvania — Emergent chiral symmetries in liquid crystals (LCs) are usually achieved by symmetry breaking in close boundary confinements. Gaining precise control over the location, creation and manipulation of broken symmetries remains a formidable challenge. In this work, we achieve pre-programming of broken chiral symmetries in the nematic phase of two achiral LCs (5CB and 8CB) through a ubiquitous but oft-neglected property of LCs: the “saddle-splay” elasticity. Using combinations of lithographic patterning and selective surface functionalization, we create surface patterns with spatially defined geometry and precisely controlled surface chemistry. Through this, we characterize broken symmetry regimes on a variety of surface patterns, including arrays of circular, trefoil, and annulus posts, in which saddle splay-driven effects gain physical expression. In turn, we unlock the resultant director field patterns, and identify spontaneously broken symmetries within domains exhibiting chiral and polar regimes. By fine-tuning the patterning geometry, we then program the location, energy landscape, and means of manipulation of the symmetry breaking processes. As a result, we demonstrate a multi-state stable LC display device that can be switched at an extremely low voltage density (~0.5 V/µm).

8:48AM E50.00003: Twist-bend-like phases and elastic response of model bent-core liquid crystals*  JIALE SHI  (Presenter), Department of Chemical and Biomolecular Engineering, University of Notre Dame, HYTHEM SIDKY, Institute for Molecular Engineering, University of Chicago, JONATHAN WHITMER, Department of Chemical and Biomolecular Engineering, University of Notre Dame — Bent-core liquid crystals have recently attracted significant attention because of their novel mesostructure and the intriguing behavior of their elastic constants, which are strongly anisotropic and have an unusual temperature dependence. For instance, experiments report an abnormally low bend elastic constant, which dips near the nematic-twist-bend transition, and increases again as the transition is crossed; the molecular mechanisms responsible for these behaviors are unclear. Here, we utilize Density of States algorithms in Monte Carlo simulation applied to a bent-core variant of the Lebwohl-Lasher model to analyze the mechanism behind elastic response in this novel mesostructure and understand the temperature dependence of its Frank-Oseen elastic constants.

9:00AM E50.00004: Chiral helical nanofilament and nanocylinder phases and a new type of polymorphism in liquid crystals*  SASAN SHADPOUR (Presenter), AHLAM NEMATI, Advanced Materials & Liquid Crystal Institute, Kent State University, LIN LI, Department of Chemistry and Biochemistry, Kent State University, SAMANTHA WAKERLIN, JULIE VANEGAS, Advanced Materials & Liquid Crystal Institute, Kent State University, MIROSLAW SALAMONCZYK, CHENHUI ZHU, Advanced Light Source, Lawrence Berkeley National Laboratory, ANTAL ISTVAN JAKLI, TORSTEN HEGMANN, Advanced Materials & Liquid Crystal Institute, Kent State University — Helical nanofilaments, consisting of bundles of twisted smectic layers with a helical pitch of 200 nm, are formed by achiral bent-core liquid crystal (BC-LC) molecules due to an intralayer mismatch between top and bottom molecular halves relieved by local saddle-splay. Here, by introducing a chiral center to one of the sides of asymmetric BC-LCs (shorter side, called meta-side), we observed the first example of the polymorphism in liquid crystalline materials. They form a not heretofore helical microfilament (HF) phase upon rapid cooling and an oblique columnar upon slow cooling. Interestingly, another not reported morphology observed when the chiral center migrates to the longer para-side). In this case, the BC-LC molecules form layers that are rolled up into coaxial cylinders resulting in the formation of heliconical-layered nanocylinders (HLNCs). HLNCs form within 80-100 nm width and micrometer lengths. This optically active cylinders form feather-like structures, braid, and assemble into hollow structures totaling six levels of hierarchical self-assembly.

9:12AM E50.00005: Indication of a Twist-Grain-Boundary-Twist-Bend Phase of flexible bent-shape chiral dimers.*

MATTHEW MURACHVER (Presenter), AHLAM NEMATI, Chemical Physics Interdisciplinary Program, Kent State University, CARSON BULLOCK, Department of Physics, College of Wooster, ZACHARY SABATA, Department of Physics, University of Nebraska, Omaha, HAUMED RAHMANI, TETIANA VOROBIOVA, Chemical Physics Interdisciplinary Program, Kent State University, MIROSLAW SALAMONCZYK, Faculty of Chemistry, University of Warsaw, ALAIN IZADNEGHADAR, Advanced Precision Systems, SEYYED SALILI, Department of Physics & Astronomy, University of Pennsylvania, VICTORIA NORMAN, CHENHUI ZHU, Advanced Light Source, Lawrence Berkeley National Laboratory, TORSTEN HEGMANN, Chemical Physics Interdisciplinary Program, Kent State University, SAMUEL N SPRUNT, JAMES GLEESON, Department of Physics, Kent State University, ANTAL ISTVAN JAKLI, Chemical Physics Interdisciplinary Program, Kent State University — Flexible bent-core oligomers with odd-numbered methylene spacers exhibit a “twist-bend” nematic (NTB) phase characterized by a nanoscale heliconical pitch. We designed mixtures of achiral dimers, which exhibit the NTB phase, with a chiral additive. By differential scanning calorimetry, resonant soft X-ray scattering, polarized optical microscopy, and induced circular dichroism studies on condensed phases of these mixtures, we find, while in the nematic phase the micron-scale pitch of the additive-induced helical structure decreases with increasing additive concentration, in the N phase both the micron-scale and the nanoscale pitch of the ambidextrous spontaneous heliconical structure increase. At chiral additive concentrations above ~2% by weight, a new phase appears between the N* and NTB* phases, which we propose to be analogous to the twist-grain-boundary (TGB) phase of chiral smectics; we designate this new phase by TGBTB.

9:24AM E50.00006: Nano-confinement of chiral liquid crystals gives rise to exotic blue phases* VIVIANA PALACIO-BETANCUR (Presenter), Institute for Molecular Engineering, University of Chicago, JULIO C. ARMAS-PÉREZ, División de Ciencias e Ingenierías, Universidad de Guanajuato, JUAN P HERNANDEZ-ORTIZ, Departamento de Materiales y Minerales, Universidad Nacional de Colombia, JUAN DE PABLO, Institute for Molecular Engineering, University of Chicago — Blue phases (BPs) arise spontaneously in chiral liquid crystals (ChLCs) as a means to minimize the global free energy, by forming networks of defects with specific cubic symmetries. By confining BPs we introduce an approach to manipulate their structure through geometrical frustration. In this work, we present a new family of BPs by modeling ChLCs in toroidal and cylindrical cavities. The configurations are obtained following a theoretically-informed Monte Carlo relaxation of the free energy functional, which is described in the framework of the Landau-de Gennes formalism. We vary temperature and chirality to build phase diagrams and summarize the portfolio of chiral morphologies, which can be classified into twisted cholesterics, and BPs with helical and cubic symmetries. We also study the effects of surface anchoring and curvature to highlight the stability of these new phases. The formation of these new kind of morphologies offers interesting opportunities to direct the assembly of macromolecules and colloids at the nanoscale.

9:36AM E50.00007: Temperature Dependence of the Pitch in Chiral Lyotropic Chromonic Liquid Crystals* TIMOTHY OGOILLA, Kent State University, ROBERT PALEY, Swarthmore College, PETER COLLINGS (Presenter), Swarthmore College & University of Pennsylvania — Molecular chirality is a subtle symmetry-breaking operation, yet its presence can produce profound macroscopic effects. One example is the nematic phase of liquid crystals, in which the presence of molecular chirality causes the preferred direction of molecular orientation to rotate in helical fashion resulting in striking optical effects. The pitch of the helix is sensitive to many parameters, including the type of molecules, concentration of chiral molecules, and temperature. Most liquid crystals studied to date consist of molecules or strongly bonded molecular assemblies that are not affected by experimental conditions. One exception is a lyotropic chromonic liquid crystal (LCLC), in which the size of the assemblies depends strongly on concentration and temperature. Investigation of the pitch of the helix in such systems reveals a highly unusual temperature dependence in which the pitch diverges as the temperature increases and the assemblies decrease in size. Theoretical considerations both explain this effect and allow the basic chiral interactions to be explored.

9:48AM E50.00008: Inducing chirality in homeotropic nematics via confinement geometry  JAMES MCINERNEY (Presenter), Georgia Institute of Technology, PERRY W ELLIS, Harvard University, ALBERTO FERNANDEZ-NIEVES, D. ZEB ROCKLIN, ELISABETTA MATSUMOTO, Georgia Institute of Technology — The configuration of liquid crystalline phases, in particular nematics, are controlled by both the microscopic properties of their constituents and the macroscopic boundary conditions. Past work has shown that microscopically achiral chromonic liquid crystals, which have a small twisting modulus in comparison to splay and bend moduli, form chiral textures when embedded in cylindrical geometries with homeotropic boundary conditions. We show that when the cylinder is bent into a torus, these chiral configurations form at higher relative twisting moduli than it would in a straight cylinder. We use a boundary preserving Möbius transformation to shift the escaped core region toward the inner walls of the torus, yielding energetically favorable configurations. In order to match the homeotropic boundary conditions, these configurations are necessarily twisted independent of the elastic constants of the achiral mesogens. We experimentally verify the existence of such twisted textures with 5CB in toroidal droplets.

10:00AM E50.00009: Mesogen-free Liquid Crystalline Poly(ethylene oxide) with Sulfonyl Side Chains: Effects of Tacticity and Alkyl Side Chain Length  MAN HIN KWOK (Presenter), Macromolecular Science and Engineering, Case Western Reserve University, BRYAN T SEYMOUR, BIN ZHAO, Chemistry, University of Tennessee, LEI ZHU, Macromolecular Science and Engineering, Case Western Reserve University — Atactic and isotactic poly(ethylene oxide) possessing alkylsulfonfylmethyl side chains were synthesized. Because of the strong dipolar interactions among sulfonyl groups in the side chains, they have a tendency of forming self-assembled mesophases even without the presence of aromatic mesogens. These polymers were characterized by size-exclusion chromatography (SEC), differential scanning calorimetry (DSC), and X-ray diffraction (XRD) at various temperatures. These PEO-based comb-like polymers are capable of forming liquid crystals with a double layer structure, which has been determined by temperature dependent XRD. In this presentation, effects of the tacticity and alkyl chain length on the mesophase structure and dielectric properties will be discussed.

10:12AM E50.00010: Ionic Liquid Crystalline Elastomers Actuated by Low Electric Field  CHENRUN FENG (Presenter), C.P.HEMANTHA RAJAPAKSHA, Liquid Crystal Institute, Kent State University, CAMILO PIEDRAHITA, JINWEI CAO, Polymer Engineering, University of Akron, ANTAL ISTVAN JAKLI, Liquid Crystal Institute, Kent State University, THEIN KYU, Polymer Engineering, University of Akron — Over the past two decades Liquid Crystalline Elastomers (LCEs) with anisotropic properties attracted immense interest for their superior responsibility to various external stimuli. Hybrid aligned LCE films have anisotropy of thermal extension coefficient and dielectric properties in top and bottom sides, leading to large thermally and/or optically induced bend. Electric field induced bending via Maxwell stress from dielectric coupling of insulating LCEs requires electric fields close to electric breakdown, thus limiting their applications. In ionic electroactive polymers (IEAPs), ion flow causes asymmetric volume change and generates large bending even at low (~1V) voltages. In this work ionic liquids (ILs) are introduced into hybrid aligned LCE films to combine spatial anisotropic properties of hybrid alignment in LCEs with charge separation dynamics of ionic EAPs. We demonstrate that charge separation in LCE-IL system is capable for low electric field induced flexing or flexing-induced electricity effect. Additionally, ion motion induced electro-thermomechanical effects that enable spatial deformations by varying directors of LCEs are also presented.

10:24AM E50.00011: Backfolding Transitions in a Liquid Crystalline Polymer Brush*  STEVEN BLABER (Presenter), Physics and Astronomy, University of Waterloo, NASSER ABUKHDEIR, Chemical Engineering, University of Waterloo, MARK W MATSEN, Physics and Astronomy, University of Waterloo — Liquid crystalline (LC) polymer brushes offer a convenient way of modifying surface properties for LC materials in, for example, LC displays. With this motivation in mind, we begin by studying LC polymer brushes in a simple solvent using self-consistent field theory. The polymers are modeled as worm-like chains with Maier-Saupe interactions. For good solvent conditions, the isotropic interactions favor a stretched brush while the anisotropic LC interactions favor folding into a high-density nematically collapsed brush. The brush undergoes first-order transitions as the number of folds increases. The folding transitions can be qualitatively understood through a simple analytic model balancing the energetic benefit from increased LC alignment and the cost associated with the bending energy of hairpin folds.

10:36AM E50.00012: Tension-induced nematic phase separation in homopolymer melts  
WENLIN ZHANG (Presenter), RONALD LARSON, Chemical Engineering, University of Michigan — The nematic coupling parameter $\alpha$, which quantifies the interactions between backbone tangents and nematic fields, governs the nematic phase behaviors and polymer alignment in bulk and at interfaces. Together with external tension, the nematic interactions can also drive phase separation of long chains from short ones in bidisperse homopolymer melts. Combining molecular dynamics (MD) simulations and analytical theory, we extract $\alpha$ for polyethylene (PE) oligomers under applied tension, and construct a mean-field free energy to predict the phase boundary for bidisperse melts in which the longer chains are stretched by uniaxial tension. Phase separation occurs when sufficient tension is applied, consistent with a previous prediction by Olmsted and Milner. By directly observing phase separation in MD simulations, we validate the phase diagram. Using non-equilibrium MD (NEMD) simulations, we also show that extensional and shear flow may lead to nematic phase separation in molten PE oligomers, because the flow can impose a stronger tension on the longer chains than the short ones. We expect the tension-induced nematic phase separation may affect chain configurations for polydisperse polymer melts under flow, and in turn affect flow-induced crystallization.

10:48AM E50.00013: Entanglement in the isotropic-nematic crossover regime: does Edwards' primitive path picture still apply?*  
ROBERT HOY (Presenter), University of South Florida, MARTIN KRÖGER, ETH Zurich — Edwards defined entanglements in polymer melts in terms of contacts between individual chains' primitive paths (PPs). This picture breaks down in the rigid-rod-like limit: while there are no inter-PP contacts, systems remain entangled in the sense that every chain's transverse motion remains highly constrained by the other chains. How it breaks down as chains approach this limit is largely unknown. Using molecular dynamics simulations and topological analyses, we characterize how entanglement in polymer melts varies and the Edwards picture breaks down as chain stiffness and nematic order increase. We find that the diffusivity and the entanglement length $N_e$ measured by topological analyses are minimized at two different chain stiffnesses $k_1$ and $k_2$ (with $k_1 < k_2$). Both of these are below the stiffness $k_3$ at which the isotropic-nematic transition occurs. We relate these phenomena to both the gradual onset of local nematic order and the inherent limitations of Edwards’ PP picture for quantifying entanglement in semiflexible polymer melts.

8:00AM E51.00001: Polymer Physics Prize Talk: Getting the kinks out: extensional flow in polymer solutions, melts, and glasses*  
[Invited] RONALD LARSON (Presenter), Chemical Engineering, University of Michigan, SOROUSH MOGHADAM, Mechanical Engineering, University of Michigan, WEIZHONG ZOU, Chemical Engineering, University of Michigan, ROBERT HOY, Physics, University of South Florida — Using molecular dynamics and Brownian dynamics, and “kink dynamics” simulations, polymer chains under extensional flow at high stress and strains are found to unravel through folded states, wherein highly stretched strands connected by kinks, or fold points, bear most of the stress. This process occurs universally at high stresses in polymer solutions, melts, and glasses, and is responsible for the strain hardening seen in extensional flows in all these states, regardless of whether the polymer is entangled or not. We show that experimental data for stress and local orientation can be explained semi-quantitatively or even quantitatively with models that capture these dynamics.
