12:39PM S50.00006: Impact of Mixed Phases and Domain Network Tortuosity on Long-Range Charge Transport in Phase-Separated Organic Semiconductor Blends* MICHAEL HEIBER (Presenter), Center for Hierarchical Materials Design, Northwestern University, ANDREW HERZING, Materials Measurement Science Division, National Institute of Standards and Technology, LEE RICHTER, DEAN DELONGCHAMP, Materials Science and Engineering Division, National Institute of Standards and Technology — Quantitative structure-property models for how the molecular-scale and meso-scale structure in polymer blends affect long-range charge transport behavior is needed to refine design rules for a wide variety of organic electronic device applications, such as photovoltaics, field-effect transistors, thermoelectrics, and bioelectronics. In this presentation, we will demonstrate the use of kinetic Monte Carlo simulations with morphologies derived from electron tomography measurements and a simple Ising-based model to probe how the multi-length-scale structure due to disordered interfacial mixed phases and mesoscale domain network tortuosity impact long-range charge transport phenomena. We will specifically quantify how these features impact the electric field and temperature dependence of the charge carrier mobility.

Controlling the Doping Mechanism in Thin Film Transistors Through Design of Polymeric Ionic Liquid Gate Dielectrics

DAKOTA RAWLINGS (Presenter), ELAYNE THOMAS, MICHAEL L. CHABINYC, RACHEL SEGALMAN, University of California, Santa Barbara — Two disparate modes of operation can occur when gating an organic thin film transistor (OTFT) with an electrolyte. Field-effect (FE) doping occurs when the semiconductor is impermeable to ions, whereas electrochemical (EC) doping of the bulk occurs when the active layer is permeable to ions. Here, we present a method to control the mode of charge accumulation in an OTFT with a constant semiconducting layer by gating with polymeric ionic liquids (PILs) of opposite polarity. Ion infiltration into the active layer is driven by attraction between ions and electronic carriers of opposite charge. As a result, tethering either the anion or the cation to a polymer backbone in the dielectric enables a direct comparison between FE and EC doping. Two PILs of opposite polarity have been synthesized and employed as the dielectric in p-type OTFTs. Tethering either the anion or the cation is shown to dictate whether ions infiltrate the active layer. Interfacial FE doping decreases the accumulation layer thickness and increases the carrier concentration as a function of injected charge. The local carrier concentration in the accumulation layer is found to be the main factor effecting the threshold voltage and the conductivity of the devices, despite the difference in doping mechanisms.

Hysteresis and Gate Bias Stress Effects in Organic Electrochemical Transistors based on Room Temperature Ionic Liquids

VIKASH KAPHLE (Presenter), SHIYI LIU, CHANG MIN KEUM, BJORN LÜSSEM, Kent State University — Organic Electrochemical Transistors (OECTs) transduce ionic into electronic signals. The transconductance of OECTs is in the mS range and outperforms other traditional and emerging transistors.[1] Here, we show that the transconductance of OECTs is limited by a voltage dependent contact resistance at the source/drain electrodes.[2] By an optimization of the device geometry and by using a mixture of room temperature ionic liquid (C2MIM EtSo4) and PBS as an electrolyte, we reach a transconductance greater than 2 mS. For later applications of OECTs, the stability of these devices is of utmost importance. We investigate the origin of a hysteresis observed in the transfer characteristic and the origin of gate bias stress effects. We propose that these instabilities are caused by ions moving slowly inside the electrolyte and the semiconductor, leading to a different time constant and hence reversible gate stress bias effects. We discuss several approaches to minimize these instabilities.[3]

Chemical Doping Efficiency by Semiconducting Polymer Type in Electrolyte-gated Polymer Transistor

SEUNG HOON OH (Presenter), JIYOUN LEE, Pukyong National University — We report the characterization of chemical doping process with electrolyte-gated polymer transistors (EGT), where classical highly crystallized semiconducting polymer - PBTTT or amorphous donor-acceptor (D-A) type semiconducting copolymer -DPP-2T-TT was used as the active layer and an ion gel comprising a polymer network swollen with an ionic liquid was used as the electrolyte. Gate-bias dependent doping concentration that is extracted from the transfer curves reveals that the chemical doping process in disordered DPP-2T-TT copolymer film is more efficient than that of PBTTT film. These results are somewhat contrary to the general observation that neutral molecule doping such as F4-TCNQ was effectively worked in a thiophene-based highly crystalline polymer rather than a D-A type copolymer. However, optical and structural investigations using UV-vis spectroscopy and grazing incident X-ray diffraction (GIXRD) have shown that the structural factors of the polymer semiconductors have a greater influence than the chemical characteristics between the polymer semiconductors and the ionic species in electrolyte.

1:27PM S50.00010: High performance organic field-effect transistors with wire bar-coated semiconducting polymer film

DO YEON KIM (Presenter), JIYOU LEE, Pukyong National University — We fabricated high performance organic field-effect transistors (OFETs) with wire bar-coated semiconducting polymer film as an active layer. For an active layer of the OFETs, we employed cyclopentadiithiophene–benzothiadiazole (CDT–BTZ) donor-acceptor (D-A) type copolymers consisting of CDT as an electron-donating unit and BTZ as an electron-accepting unit. The OFETs with bar-coated CDT–BTZ semiconducting copolymer films shows about five times higher field-effect mobility of 0.51 cm²/Vs than 0.11 cm²/Vs of the OFETs with spin-coated CDT–BTZ film, although the charge carrier mobility of the D-A type semiconducting copolymer is less critical to the degree of alignment of the semiconducting polymer. Overall, the results demonstrate that the wire bar-coating process offers opportunities to enhance the performance of the OFETs.

1:39PM S50.00011: Polymer light emitting field effect transistors with steadily high efficiency over three orders of magnitude of current

BANG-YU HSU (Presenter), Materials Science and Engineering, National Cheng Kung University — To simultaneously achieve efficient and intensified optical output is the most challenging task for polymeric light emitting field effect transistors (PLEFETs). A p-type unipolar PLEFET with high brightness but oversaturated holes will limit recombination efficiency. Instead, an ambipolar PLEFET with high recombination current will decrease on/off ratio. An ideal solution will be the combined advantages of both LEFETs, significant on/off ratio, high current density, and efficient recombination. A bilayer PLEFET can meet the three criteria satisfactorily by applying asymmetric organic/inorganic-hybrid transparent contacts. Hole/electron injections and photon output in a p-type PLEFETs was simultaneously improved. For source-drain current over 3 orders of magnitude from sub-micro ampere to sub-mini ampere, corresponding to 26 to 3747 cd/m², external quantum efficiency (EQE) steadily sustained 0.5%. EQE of the PLEFETs in this work was enhanced remarkably, 0.5% vs. < 0.08% (conventional ones), and on/off ratio remained high at 10³–10⁵. Asymmetric organic/inorganic-hybrid transparent contacts demonstrated a promising strategy for energy-efficient PLEFETs.

1:51PM S50.00012: A Molecularly-Imprinted Electrochemical Sensor to Detect VOCs in the Breath Print of Lung Cancer Patients

SHADI EMAM (Presenter), NIAN XIANG SUN, Electrical Engineering, Northeastern University — Lung cancer is the leading cancer killer in both men and women in the United States. The cost of lung cancer was $13.4 billion in 2015 based on the National Institute of Health report. The majority of living lung cancer patients have been diagnosed within the last five years. VOCs are organic chemicals that form less than 1% of the exhaled breath. The exchange of blood and the air in the alveolar leads to transferring chemicals in the blood, which was formed during metabolism inside the body, to find a way to the exhaled breath. Thus, measurement of VOCs in the breath can provide a window into the biochemical processes of the body. In this paper, a new methodology is proposed to detect hexanal and heptane, which are two chemicals found in the breath print of lung cancer patients. A three-layer sensor was formed through deposition of a thin layer of graphene and Prussian blue onto a silicon substrate. Selective binding of the analyte was facilitated by molecular imprinting polymer. Subsequent polymerization and removal of the analyte yielded a polymer layer on top of the sensor containing molecularly imprinted cavities selective for the target molecule. The sensors were tested over 1-20 parts per billion (ppb) level of concentration while the sensor resistance has been monitored.

2:03PM S50.00013: Low-power photonic organic artificial synapse inspired by dopamine-facilitated synaptic activity

SEONGGIL HAM (Presenter), SANGHYEON CHOI, HAEIN CHO, GUNUK WANG, KU-KIST Graduate School of Converging Science & Technology, Korea university — The ability of the synaptic plasticity in an artificial synapse can offer significant improvement in low-power recognition, and learning capability in a neuromorphic system [1]. Inspired by light-assisted dopamine-facilitated, which achieves rapid learning and adaptation by lowering the threshold of the synaptic plasticity, we fabricate a organolead halide perovskite (OHP)-based photonic synapse in which the synaptic plasticity is modified by both electrical pulses and light illumination. Owing to the accelerated migration of the iodine vacancy inherently existing in the OHP film under light illumination, the OHP synaptic device exhibits light-tunable synaptic functionalities with very low programming inputs (~0.1 V). It is also demonstrated that the threshold of the long-term potentiation decreases and synaptic weight further modulates when light illuminates the device. Notably, under light exposure, the OHP synaptic device achieves rapid pattern recognition with ~81.8% accuracy with a low power consumption (4.82 nW/the initial update for potentiation), which is ~2.6×10³ times lower than when the synaptic weights are updated by only high electrical pulses. 11:15AM S51.00001: Nonlinear Elongational Rheology of Unentangled Polystyrene and Poly(p-tert-butyl styrene) Melts [Invited] HIROSHI WATANABE (Presenter), YUMI MATSUMIYA, Kyoto University, YUICHI MASUBUCHI, Nagoya University, QIAN HUANG, OLE HASSAGER, Technical University of Denmark — Nonlinear rheology under uniaxial elongation was examined for unentangled melts of polystyrene (PS27; $M = 27k$, $n_K = 30$) and poly(p-tert-butyl styrene) (PtBS53; $M = 53k$, $n_K = 35$) having nearly the same number $n_K$ of Kuhn segments per chain. For both materials, the steady state elongational viscosity $\eta_E$ exhibited hardening and then softening on an increase of the Weissenberg number $Wi \geq 0.3$ ($Wi = \tau \kappa$, with $\tau$ and $\kappa$ being the longest relaxation time and the Hencky strain rate). For these unentangled melts, the hardening was unequivocally related to the finite extensible nonlinear elasticity (FENE), and the softening, to suppression of the FENE effect due to reduction of the segmental friction $\zeta$ occurring for the highly stretched/oriented chain. Thus, the $\zeta$-reduction, speculatively discussed for entangled melts, was experimentally confirmed for unentangled melts. The softening at high $Wi$ was weaker for PtBS53 than for PS27 despite the similarity of their $n_K$ values, which suggested that the magnitude of $\zeta$-reduction depends on the chemical structure of the chain. Further details of this $\zeta$-reduction, analyzed with the aid of the FENE bead-spring model modified for the $\zeta$-reduction, are discussed in relation to the local motion of the chain necessary for adjusting $\zeta$.

11:51AM S51.00002: Salt-induced polyelectrolyte capsule formation in microfluidics* [Invited] WILLIAM SHARRATT, CARLOS LOPEZ, JOAO CABRAL (Presenter), Imperial College London — Microfluidics provides an exceptional platform for the generation of polymer solution droplets and their subsequent manipulation. We describe the formation of carboxymethyl cellulose (CMC) particles and capsules induced by salt diffusion. Generally used as a sodium salt, NaCMC is an anionic, weak, semiflexible polyelectrolyte, and one of the most widely used polyelectrolyte cellulose derivatives, with applications in the food, pharmaceutical, personal care, cosmetic, and paper industries. We employ SANS, light scattering, and rheology to probe the conformation and dynamics of aqueous NaCMC solutions across a wide range of molecular weight (Mw), degree of substitution, salt (mono, di and trivalent) and polymer concentrations. We then investigate the addition of a series of multivalent salts to induce the gelation and/or precipitation of bulk NaCMC solutions, which is spatiotemporally resolved by SANS and microscopy, establishing salt front propagation kinetics and accompanying conformational changes of the polymer. Equipped with this knowledge, we design and fabricate CMC gel capsules and particles with prescribed dimensions and external shape, microstructure and dissolution profile.

12:27PM S51.00003: Topological Effects on Movements of Charged Macromolecules in Crowds* [Invited] MURUGAPPAN MUTHUKUMAR (Presenter), University of Massachusetts Amherst — Charged macromolecules dispersed in aqueous media are ubiquitous since life began on Earth and continue to catalyze formulations of modern materials. A fundamental understanding of the rich phenomenology on movements of charged macromolecules in crowded environments continues to be elusive, due to the long-ranged nature of both the topological correlation from chain connectivity and electrostatic correlation from the charges in the system. Strong coupling among these long-ranged interactions results in a variety of rich behavior unparalleled in uncharged systems. We will present recent advances on the collective dynamics of charged macromolecules in solutions and hydrogels. In particular, the “ordinary-extraordinary” dynamics, single molecule translocation through a protein channel under coupled forces, and the newly discovered topologically frustrated non-diffusive dynamics of charged macromolecules inside charged hydrogels will be discussed.

1:03PM S51.00004: How structural modifications of pectin affect its gelling and complexation behavior [Invited]
RUTH CARDINAELS (Presenter), Eindhoven University of Technology — Pectin is a plant cell wall polysaccharide that is intrinsically present in many plant-based food products, both in the plant cell particles as well as in the serum phase. In addition, extra pectin is frequently added to food products as a gelling agent and source of dietary fibre. Pectin is a polyelectrolyte with a backbone of galacturonic acid units, organized in linear and branched domains. The detailed pectin structure can be very heterogeneous even within a single cell wall. The galacturonic acid units that originally contain methylester groups can undergo deesterification thereby leaving negatively charged acid groups. Depending on the processing steps that in general include thermal treatment as well as mechanical homogenisation, various degrees and patterns of methylesterification [1,2] as well as degrees of branching can result [3]. These structural features determine the rheological properties of pectin solutions [1] as well as their gelling propensity by viscoelastic network formation [2,3,4]. Moreover, in typical food products pectin is in contact with other polysaccharides and proteins, which can result in complex formation, aggregation or phase separation. The type of interaction, phase boundaries and resulting microstructure are strongly contingent on the structural features of pectin [5]. Here, effects of processing techniques that allow to tailor pectin’s structural features will be discussed along with the relationships between these structural features and pectin’s functional properties.

1:39PM S51.00005: Network connectivity, viscoelasticity and failure in gel networks: microscopic insights into soft complexity. [Invited] EMANUELA DEL GADO (Presenter), Georgetown University — Gel networks assembled from polymers, biopolymers, small particles or aggregates can be stretched, flow, squeezed or fractured, but controlling and being able to design such processes (think of soft inks for 3D printing technologies) requires a fundamental understanding that is still lacking. We have developed a theoretical/computational approach that addresses in particular the role of the network topology in such materials, its stress-controlled evolution over time and its implications for the mechanics. I will give an overview of the novel insight gained into the origin of the uniquely wide-ranged viscoelastic spectra and the presence of a topologically controlled softness in gel networks. I will discuss how our findings can help understand the nontrivial mechanical response of soft gels in different contexts, further develop constitutive models, and design smart materials.

Session S52 DPOLY: Block Copolymer Thin Films I: Theory and Simulation
BCEC 253B - Christopher Arges, Louisiana State University - Tag(s): Focus

11:15AM S52.00001: Self-assembly of Bottlebrush Block Polymers at Surfaces using Coarse-grained Molecular Dynamics Simulations  MICHIEL WESSELS (Presenter), ARTHI JAYARAMAN, University of Delaware — Self-assembly of block polymers on surfaces is used to engineer nanostructured materials for electronics, optics, sensing, and chemical separation applications. Past experimental, theoretical, and computational work has extensively focused on the self-assembly of block copolymers with linear architecture, and relatively fewer studies have established the polymer physics underlying self-assembly of non-linear architectures such as bottlebrushes. In this talk, I will present our coarse-grained molecular dynamics simulation study aimed at understanding structure (i.e., chain conformations, assembled morphologies) and thermodynamics (i.e., interactions between monomers vs. interactions with surface) of solutions of amphiphilic bottlebrush block polymers near surfaces. We establish the role of bottlebrush side chain length and side chain grafting density on the backbone on the behavior of amphiphilic bottlebrush block polymers near surfaces.
11:27AM S52.00002: Program the self-assembly of block copolymers for desired mesocrystals

WEI-HUA LI (Presenter), Fudan University — The packing of particles in soft matter as a fundamental problem has been paid a lot of attention. As the enthalpic and entropic contributions to the free energy is comparable and could be readily tuned, the packing of soft particles leads to rich crystalline structures (i.e. mesocrystals). To understand the packing mechanism of various soft particles into different crystalline structures and thus to modulate the packing of soft particles for desired mesocrystals is an important problem to be solved. Block copolymer provides a perfect model for solving this problem due to two main reasons. The first reason is that the self-assembly of block copolymers can be programmed by tuning the molecular architectures and modern synthesis techniques enable the precise control of the architectures. The second one is that the self-assembly of block copolymers can be accurately predicted by the well-established self-consistent field theory (SCFT). In this talk, I will talk about programming the self-assembly of block copolymers for desired mesocrystals or even mesoscale quasicrystals based on SCFT calculations.

11:39AM S52.00003: Dynamics at the Interface of Structured Block Co-Polymer Thin Films with Polar Solvents: Molecular Dynamics Simulations Insights

MANJULA SENANAYAKE (Presenter), Department of Chemistry, Clemson University, Clemson, SC, United States, 29634, DIPAK ARYAL, Department of Chemical Engineering, University of Texas at Austin, Austin, TX, United States, 78712, GARY GREST, Sandia National Laboratories, Albuquerque, NM, United States, 87123, DVORA PERAHIA, Department of Chemistry/Department of Physics, Clemson University, Clemson, SC, United States, 29634 — Structured ionic copolymers consist of multiple blocks whose dynamics facilitate their uses. Here, the dynamics at the interface of an ABCBA pentablock co-polymer with polar solvents is studied by molecular dynamics simulations. The ionic block C is a sulfonated polystyrene (sPS) with sulfonation fraction $f=0.55$, B is polyethylene-propylene (PEP), and A is poly(t-butyl styrene) (tBS). Simulations are performed using LAMMPS with the polymer and propanol modeled with OPLS-AA force field. The interface evolution with exposure time to propanol is followed and the results are compared with those for the polymer-water interface. The air interface of the neat polymer is dominated by the PEP block. With exposure to propanol, more ionic groups migrate to the interface, similar to the polymer-water interface. However, in contrast to water exposed films, the interface remains dominated by the PEP blocks. Remarkably, the interfacial width of the membrane-propanol system grows with time while the width of the membrane-water interface decreases. Further, water molecules associate predominantly with the ionic blocks and break the ionic clusters while propanol associates with both the ionic and non-ionic polymer segments.

*Supported in part by NSF DMR 1611136

11:51AM S52.00004: Microphase Separation in Dipolar Diblock Copolymer Melts

RAJEEV KUMAR (Presenter), WEI LI, BOBBY G SUMPTER, Oak Ridge National Laboratory, MURUGAPPAN MUTHUKUMAR, University of Massachusetts, Amherst, MA — Understanding microphase separation in polar-non-polar diblock copolymer melts is a topic of great interest due to its fundamental and technological importance. In this talk, we will present our work related to modeling the effects of dipolar interactions in affecting microphase separation in linear diblock copolymer melts. Results obtained for freely rotating dipoles, applicable to high temperature disordered melts, will be presented. These results will be compared with field theory-based and coarse-grained molecular dynamics simulations for lamellar morphology. Advantages and disadvantages of the field theory-based simulations will be discussed and importance of correlations in orientations of dipoles will be highlighted.

12:03PM S52.00005: DPD simulation of multilayer self-assembly of block-copolymer

HEJIN HUANG (Presenter), ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Self-assembly of block copolymers provides a powerful tool for patterning at small length scale. The chemical incompatibility of the two blocks, which are covalently linked together, leads to microphase separation upon annealing. Depending on the volume ratio of the two block, different morphologies, such as spheres, cylinders and lamellae structure can be obtained. Most researchers use self-consistent field theory (SCFT) as the simulation tool to predict self-assembled structure. Recently, a particle-based simulation method - dissipative particle dynamics (DPD) has been implemented to provide different insights into the self-assembly process of BCP. Here we use DPD to investigate the structural information propagation from layer to layer in a multilayer film. The self-assembly process of the first layer is directed by either graphoepitaxy or chemoepitaxy. After that, by depositing a second BCP layer on top, the structural information of the first layer will propagate and affect the structure of the second layer. By carefully designing the structure, we could achieve different bilayer structure such as dots-on-cylinders, parallel cylinders and nanomeshes.
12:15PM S52.00006: Is Simple Cubic Spherical Phase Possible in Block Copolymers?* YUEMING XIA (Presenter), WEI-HUA LI, Fudan University — The self-assembly of amphiphilic macromolecules into various mesocrystals has attracted abiding interest. Although many interesting mesocrystals have been achieved, the simple cubic mesocrystal is rarely reported. Here we purposely design an AB-type multiblock copolymer composed of an AB diblock copolymer with A-/B-block tethered by an extra B-/A-block at the middle point to target the simple cubic spherical phase based on the self-consistent field theory. Specifically, two sophisticated mechanisms are realized synergistically in the copolymer, i.e. packing frustration release and stretched bridge block, leading to the formation of the simple cubic mesocrystal in a significant parameter space. Moreover, more other unusual phase behaviors are predicted.

*Acknowledges the funding support by the National Natural Science Foundation of China (Grants Nos 21574026 and 21774025).

12:27PM S52.00007: Simulation studies reflecting the importance of kinetics on block copolymer self-assembly [Invited] SU-MI HUR (Presenter), Chonnam National University — The self-assembly in polymeric system is one of core principles to many of advanced nanotechnologies. Success of most of these applications utilizing the self-assembly relies on how well one can adjust, and switch the shape, size and arrangement direction of self-assembled structures. Hence, there have been active research efforts on understanding the underlying physical principles controlling the self-assembly, augmented by theoretical and numerical modeling. Complicated interactions and the wide range of length and time scales related with self-assembled structures make theoretical modeling very challenging. Moreover, many systems are in metastable states, thus kinetics, not just thermodynamics, plays a key role for the ability of a polymeric material to self-assemble into a desired state. In this work, we present our efforts on developing powerful simulation approaches capable to describe experimentally-observed microstructures, to predict new mesophases, as well as to provide the kinetic routes between various microphases in block copolymer films. Special efforts are placed on understanding the motion of defects in block copolymer thin films and their interactions, pursuing fully ordered lamellae for its successful application in nanolithography.

1:03PM S52.00008: Single chain in mean field (SCMF) simulation of flexible and semiflexible block copolymers. SOJUNG PARK (Presenter), DAESEONG YONG, JAEUP KIM, Department of Physics, UNIST — Self-consistent field theory (SCFT) has been a popular tool for the study of equilibrium properties of block copolymer nanostructures. It is a mean field theory, and thus it has limitations in that fluctuation effects are ignored. One suggestion to incorporate fluctuations into the field theoretical calculation is the single chain in mean field (SCMF) simulation which performs explicit Monte Carlo simulation of polymer chains under quasi-instantaneously updated self-consistent field. In this research, we perform SCFT calculation and SCMF simulation of block copolymers in thin film morphology. For the symmetric block copolymers, the phase transition is suppressed when confined by two neutral walls, and the surface-perpendicular lamellar phase becomes slightly preferable to the surface-parallel one. We also perform SCMF simulation of semiflexible polymer chains by adopting angle dependent potential in both bead-spring and freely-jointed chain model, and our results reveal that stiffer chains exhibit higher tendency to self-assemble into ordered structures. For the confined system, it turns out that the surface-perpendicular lamellar phase becomes more stable as the stiffness of the chain increases.

1:15PM S52.00009: Effect of free surface and substrate topography on the self-assembly of block copolymer films VIKRAM THAPAR (Presenter), Chonnam National University, JUAN DE PABLO, University of Chicago, SU-MI HUR, Chonnam National University — Theoretical and numerical studies have provided valuable insights in understanding and controlling the self-assembly of block copolymer systems, providing powerful guidelines to experimentalists. However, complicated geometric surface effects on the self-assembly are often ignored due to the limitation of previous simulation models to capture free surface effects, thus constraining systems to thin films with ad-hoc flat interfaces. In this work, we present our efforts on developing efficient simulation approaches to explore the self-assembly of complex polymeric systems with ability to develop, and interact, with non-flat interfaces. Effects of different substrate topographies and initial polymer volume shapes on the self-assembly kinetics are numerically investigated and compared with experimental data.
1:27PM S52.00010: Rational design of linear-dendritic block copolymer for overwhelming region of spherical phases** YICHENG QIANG (Presenter), WEI-HUA LI, Fudan University — Various ordered structures can be formed by the self-assembly of block copolymer, while the formation of some sophisticated phases among them is usually driven by some sophisticated mechanisms. Several mechanisms have been established to expand the spherical region, thus stabilizing some new spherical phases, e.g. Frank-Kasper phases. However, the effect of these mechanisms is still limited. In order to widen the phase regions of these desired new spherical phases drastically, we start from an intuitive hypothesis, design a kind of linear-dendritic block copolymer and investigate its self-assembly behaviors with the self-consistent field theory (SCFT). Under the optimized control parameters, the spherical phase region is expanded to be overwhelmingly large in the phase diagram and at the same time the regions of Frank-Kasper phases are largely expanded. The most important conclusion is that the discrete spherical domains can be formed by the major component with volume fraction around 0.7. These results renew our insight into the intricate mechanisms of the self-assembly of block copolymer.

**Acknowledges the funding support by the National Natural Science Foundation of China (Grants Nos 21574026 and 21774025).

1:39PM S52.00011: Stability of Dodecagonal Quasicrystalline Tiling in ABC Star Terpolymers** CHAO DUAN (Presenter), YICHENG QIANG, WEI-HUA LI, Department of Macromolecular Science, Fudan University — In this work, the thermodynamic stability of cylindrical dodecagonal quasicrystalline (DDQC) phase in ABC star-shaped triblock terpolymers for both neat and blending systems is investigated. A systematic comparison of our theoretical results to those of experiments by Matsushita’s group is performed using the self-consistent field theory (SCFT). Based on our previous work, SCFT coupled with the Stampfli self-similarity construction is adopted to accurately calculate the free energy of the periodic DDQC approximants and then a cluster model is used to predict the stability of aperiodic DDQC phase. We find that ideal tiling DDQC in these ABC star terpolymers is also metastable. Furthermore we show that the DDQC morphology observed experimentally is a kind of random tiling pattern as the mesoscopic coexistence of the (3,3,4,3,4) Archimedean tiling pattern and the 8/3 approximant. Accordingly, we conclude that the formation of random tiling DDQC structure may be possible in self-assembling block copolymer melts.

**National Natural Science Foundation of China (Grants Nos 21574026 and 21774025)

1:51PM S52.00012: Tiling Patterns Self-Assembled from Rod-Coil Copolymers with Hydrogen Bonds** PING TANG (Presenter), Macromolecular Science, Fudan University, ZHIHUI LI, College of Architecture and Environment, Sichuan University, FAQIANG LIU, HONGDONG ZHANG, YULIANG YANG, Macromolecular Science, Fudan University — Based on self-consistent field theory (SCFT), we demonstrate that X-shaped rod-coil molecules with hydrogen-bonding groups, can self-assemble into Archimedean tiling patterns. The rod blocks form the polygon edges with coil blocks filling in the inner spaces of polygons. The existence of hydrogen bonds further decreases the domain size. A new mechanism is proposed to guide the formation of Archimedean tiling patterns: the fabrication of tiling patterns is controlled by the relationship between the length to diameter ratio and volume fraction of rods in X-shaped supra-macromolecules. This study provides a concept of macromolecular tiling and suggests X-shaped rod–coil supra-macromolecules with hydrogen-bonding groups as an ideal platform for the fabrication of two-dimensional nanoscale patterns.

**National Natural Science Foundation of China (Grant Nos: 21534002, 21574027, 21774027).

2:03PM S52.00013: Self-Assembly Behaviors of B1AB2CB3 MultiBlock Copolymer** QIONG XIE (Presenter), WEI-HUA LI, Fudan University — The self-assembly behavior of linear B1AB2CB3 multiblock copolymers is investigated using the self-consistent field theory (SCFT). It has been revealed that the relative lengths between the three B-blocks are able to tune the packing crystalline lattice of binary spherical or cylindrical phases. Here we focus on the impact of the molecular architecture on more phase behaviors in a wider parameter space. Our SCFT results indicate that the relative lengths of the three B-blocks have significant influences on not only spherical/cylindrical phases but also other phases such as the alternative gyroid and lamellar phases. In particular, the stability region of the gyroid phase varies drastically and non-monotonically, which is accompanied by the drastic change of other phase regions. Furthermore, our results reveal that the change of these phase regions is resulted in by different sophisticated mechanisms associated with the relative lengths of the three B-blocks, i.e. the effect of stretched bridging B2-block, the regulation of packing frustration of the B-blocks and the solubilization of short B-blocks.

11:15AM S53.00001: Twenty Years of Network Science: From Structure to Control [Invited]  ALBERT BARABASI (Presenter), Northeastern University — Systems as diverse as the cell, the brain, the World Wide Web, or the social systems are described by highly interconnected networks with complex topology, whose structure determines their function and utility. Twenty years of research has shown that these networks are the result of self-organizing processes governed by simple but generic laws, that can be best understood using tools rooted in statistical physics. These studies have also offered evidence of a deep universality, finding that many real networks share multiple common architectural features, from the scale-free property, discovered 20 years ago today, to communities and correlations. I will discuss the order characterizing real networks and its implication, with focus on network control. Indeed, most complex systems have purpose, striving to accomplish some function, from the cell’s ability to reproduce to the brain’s ability to control our motions. For this, the underlying networks must be wired to be able to constantly control the system’s internal processes, in response to external inputs and perturbations. I will show how to adapt the tools of control theory to unveil the control principles of complex self-organized systems. Finally, I will discuss a recently developed analytical framework to study the controllability of an arbitrary complex network, and offer experimental evidence for its direct applicability to neural networks in the brain.

11:51AM S53.00002: Multilayer Networks: Structure and Dynamics [Invited]  GINESTRA BIANCONI (Presenter), School of Mathematical Sciences, Queen Mary University of London — Multilayer networks are emerging as a novel and powerful way to describe complex systems. Multilayer networks are ubiquitous and include social networks, financial markets, infrastructures, molecular networks and the brain.

Uncovering the interplay between multilayer network structure and function is a big theoretical challenge with a vast realm of applications. On the other side the urgency of understanding real-world multilayer network problems requires novel theoretical approaches. In this talk we will show how the statistical mechanics theory beyond multilayer networks reveals the information encoded in these structures and its effect on multilayer network dynamics.

12:27PM S53.00003: Temporal networks [Invited]  PETTER HOLME (Presenter), Tokyo Institute of Technology — The power of any kind of network approach lies in the ability to simplify a complex system so that one can better understand its function as a whole. Sometimes it is beneficial, however, to include more information than in a simple graph of only nodes and links. Adding information about times of interactions—modeling your system as temporal networks—can make predictions and mechanistic understanding more accurate. Just as there can be network structures affecting disease spreading, temporal structures can also govern the spreading dynamics. We will discuss recent developments in the analysis of temporal networks, including community detection, the definition of time scales, random walks and various forms of spreading processes. We argue that adding time to network representations fundamentally changes our usual network concepts—so much that it is perhaps meaningless to think of temporal networks as an extension of the network paradigm.

1:03PM S53.00004: Epidemic threshold on temporal networks [Invited]  VITTORIA COLIZZA (Presenter), INSERM — Our understanding of communicable diseases prevention and control is rooted in the theory of host population transmission dynamics. The network of host-to-host contacts along which transmission can occur drives the epidemiology of communicable diseases, determining how quickly they spread and who gets infected. A large body of epidemiological, mathematical and computational studies has provided a number of insights into the understanding of the process and the identification of efficient control strategies. The explosion of time resolved contact data has however opened the stage to new challenges. What are the structural and temporal aspects, and possibly their non-trivial interplay, that are critical for disease spread? To answer this question, I will introduce the infection propagator approach, a theoretical framework for the assessment of the degree of vulnerability of a host population to disease epidemics, once we account for the time variation of its contact pattern. By reinterpreting the tensor formalism of multilayer networks, this approach allows the analytical computation of the epidemic threshold for an arbitrary time-varying network of host contacts, i.e. the critical pathogen transmissibility above which large-scale propagation occurs. I will apply this framework to a set of empirical time-varying contact networks and show how it can be used to test different intervention strategies for infection prevention and control in realistic settings.
The dynamics of adsorbed polymer chains in polymer nanocomposite melts can be significantly perturbed from the bulk state and can dictate properties in polymer nanocomposites (PNCs). In this work, we directly observe and quantify polymer chain-scale interactions at the surface, which are significant in studying changes in miscibility of the PGNP and might be driving the morphology of the entire brush.

Let's consider the following scenarios:

1. **Effects of Matrix Chain Length on Miscibility of Nanoparticles**
   - **Presenter:** CLEMENT KOH
   - **Institution:** Columbia University, AMISH PATEL, University of Pennsylvania, SANAT KUMAR, Columbia University
   - **Description:** In this simulation, we observe brush collapse due to decreasing the graft/matrix chain ratio (N/M) for PGNPs in a homopolymer matrix of free chains. This effect is observed experimentally by decreasing the graft/matrix chain ratio. While composition profiles of the graft/matrix chains do not reveal any signs of brush collapse, brush heights calculated using a second moment of the segment density highlights a subtle indication of brush collapse. Further, by measuring free chain fluctuations and free energies via indirect umbrella sampling, we are able to suggest that the free chain length varied systematically in a series of simulations, while NP radius, grafting density, and grafted chain length were held constant.

2. **Dynamics of Adsorbed Polymer Chains in Polymer Nanocomposite Melts**
   - **Presenter:** ERIC BAILEY
   - **Institution:** RUSSELL JOHN COMPOSTO, KAREN WINEY, University of Pennsylvania
   - **Description:** The dynamics of polymer chains and chain segments near an enthalpically attractive interface can be significantly perturbed from the bulk state and can dictate properties in polymer nanocomposites. In this work, we directly observe and quantify polymer chain-scale desorption from nanoparticles in the melt using elastic recoil detection and Rutherford backscattering spectrometry on model PNCs comprised of poly(2-vinyl pyridine) and 25-nm diameter silica nanoparticles. We observe polymer desorption ~10^2 times slower than bulk chain diffusion and desorption that is slowest for longer chains and at lower temperatures. In this highly attractive system, we observe bound polymer that persists after more than 10^6 reptation times, even at T_g+100°C. By correlating the measured bound polymer to the nanoparticle concentration, we measure the adsorbed chain areal density as ~0.05 chains per nm^2 and extract a bound layer thickness that extends ~R_g from the nanoparticle surface. Two parameters that have been difficult to experimentally probe in the melt state.

3. **Rational Design of Polymer Nanocomposites to Advance Their Thermomechanical Performance via Predictive Multiscale Modeling**
   - **Presenter:** WENJIE XIA
   - **Institution:** North Dakota State University
   - **Description:** Understanding and predicting the thermomechanical responses of polymer nanocomposites are challenging as they are influenced by many factors, such as interfacial energy and filler volume fraction, giving rise to the presence of nanoscale interfaces. To better design polymer nanocomposites, we have recently established an atomistically informed coarse grained (CG) modeling approach to investigate how the nanoscale interfaces and molecular characteristics influence the mechanical and glass transition properties of polymer nanocomposites. Taking cellulose reinforced polymer nanocomposite as a relevant model system, we present a multiscale materials by design framework using CG modeling combining with advanced computational algorithms for prediction of thermomechanical properties of nanocomposites. Our established framework is validated by recent experiments and breaks new ground in predicting key structure and property relationships for optimum and tailored design of polymer nanocomposite materials.

rheological measurements exhibit 30 decades variation in aT. Further analyses suggest the local rearrangements of PNCs at different time and length scales follow identical temperature dependence with the neat polymer, although the range [1], indicating an unrealistic fast polymer dynamics at high temperatures. In this work, we decoupled the dynamic translated to evaluate the dynamics features of PNCs at different temperatures. These results clearly show the shift factors by the time-temperature superposition principles cannot be directly nanomaterials, especially at high temperatures, lead to the breakdown of the time-temperature superposition principle in transmission electron microscopy (TEM), and correlated to the long-term viscoelastic creep behavior observed by DMA. The effect of these parameters on PNC morphology is quantified by small-angle X-ray scattering (SAXS) and by hydroxyl surface groups capable of hydrogen bonding versus nanoparticle surfaces treated with a phenyl-capping agent. The interaction between nanoparticle surface and the polymer matrix is adjusted by using bare silica featuring silica nanoparticles dispersed in an amorphous polymer matrix of approximately 200,000 g/mol weight-average molecular weight. The interaction between nanoparticle surface and polymer matrix is adjusted by using bare silica featuring hydroxyl surface groups capable of hydrogen bonding versus nanoparticle surfaces treated with a phenyl-capping agent. The effect of these parameters on PNC morphology is quantified by small-angle X-ray scattering (SAXS) and by transmission electron microscopy (TEM), and correlated to the long-term viscoelastic creep behavior observed by DMA.

12:03PM S54.00005: Exchange of the Bound Polymer Layer on Silica Nanoparticles* 
SANAT KUMAR (Presenter), ANDREW JIMÉNEZ, Columbia University, JACQUES JESTIN, CEACNRS, Laboratoire Léon Brillouin — It is now commonly accepted that a bound polymer layer (BL) naturally forms when a polymer melt is mixed with nanoparticles in the limit of favorable interactions. What is unclear is the temporal persistence of this BL – its very name implies that this layer is expected to be irreversibly adsorbed. We use contrast variation methods in conjunction with small angle neutron scattering to probe this issue in the canonical case of poly(2-vinylpyridine) mixed with 14 nm diameter silica nanoparticles. We find that there is essentially no long-term reorganization of the bound layer at 150 °C, but apparently a rapid reduction of the BL thickness at 175 °C. We believe that the dramatic temperature dependence arises from the polyvalency of the binding of a P2VP chain to a NP – that is the fact that each P2VP chain is adsorbed to the NP through multiple monomers. Thus, while the adsorption-desorption process of a single segment is an activated process that occurs over a broad temperature range, the cooperative nature of requiring multiple segments to desorb converts this into a sharp process that occurs over a relatively narrow temperature range.

12:15PM S54.00006: The complexity of linear viscoelastic properties of polymer nanocomposites: polymer dynamics and nanoparticle rearrangement* 
SHIWANG CHENG (Presenter), JIE YANG, Department of Chemical Engineering and Materials Science, Michigan State University, WEI YANG, College of Polymer Science and Engineering, State Key Laboratory of Polymer Materials Engineering, Sichuan University — Polymer nanocomposites (PNCs) are widely used as structural and functional materials, whose lifetime are typically evaluated from the time-temperature superposition. Rheological measurements of PNCs usually show >30 decades variation in the horizontal shift factor, aT, over a finite temperature range [1], indicating an unrealistic fast polymer dynamics at high temperatures. In this work, we decoupled the dynamic spectra of PNCs through a combination of rheology and dielectric measurements. We found that polymer dynamics in PNCs at different time and length scales follow identical temperature dependence with the neat polymer, although the rheological measurements exhibit 30 decades variation in aT. Further analyses suggest the local rearrangements of nanoparticles, especially at high temperatures, lead to the breakdown of the time-temperature superposition principle in PNCs. These results clearly show the shift factors by the time-temperature superposition principles cannot be directly translated to evaluate the dynamics features of PNCs at different temperatures.

12:27PM S54.00007: The Effect of Nanofillers on the Viscoelastic Creep Behavior of Thermoplastics 
FRANCISCO BUITRAGO (Presenter), ANITA S YANG, University of Pennsylvania, PETER A GORDON, ExxonMobil Research and Engineering, ROBERT RIGGLEMAN, KAREN WINEY, University of Pennsylvania — The use of polymer nanocomposites (PNCs) in infrastructure applications requires a comprehensive understanding of the mechanism of nanoparticle reinforcement during viscoelastic creep. Some of the most relevant parameters that impact the mechanical reinforcement of nanoparticles to a thermoplastic matrix are the nanoparticle size and concentration, and the interaction between the nanoparticle surface and the polymer matrix. In this study, the long-term creep behavior of a model nanocomposite system is examined by applying time-temperature superposition to dynamic mechanical analysis (DMA) of PNC films at temperatures between Tg-60 °C and Tg+60 °C. The PNC system is composed of monodisperse 10-nm, 15-nm, and 28-nm silica nanoparticles dispersed in an amorphous polymer matrix of approximately 200,000 g/mol weight-average molecular weight. The interaction between nanoparticle surface and polymer matrix is adjusted by using bare silica featuring hydroxyl surface groups capable of hydrogen bonding versus nanoparticle surfaces treated with a phenyl-capping agent. The effect of these parameters on PNC morphology is quantified by small-angle X-ray scattering (SAXS) and by transmission electron microscopy (TEM), and correlated to the long-term viscoelastic creep behavior observed by DMA.
Thickness Effects on Morphology and Gas Permeability of Polystyrene-Grafted-Silica in a Polystyrene Matrix*  
SOPHIA CHAN (Presenter), CONNOR BILCHAK, MAYANK JHALARIA, ANDREW JIMENEZ, SEBASTIAN RUSSELL, Chemical Engineering, Columbia University, JULIA PRIBYL, BRIAN C BENICEWICZ, Chemistry and Biochemistry, University of South Carolina, SANAT KUMAR, Chemical Engineering, Columbia University — Polymer-grafted-nanoparticles in a polymer matrix can self-assemble into anisotropic morphologies that can be controlled by varying system parameters, such as grafting density and film thickness. The relationships between film thickness, morphology, and gas permeability of these systems, however, are not well-understood. We present the film thickness effects on gas transport properties and the surface and bulk morphologies of polystyrene-grafted-silica (PS-g-SiO₂) in a polystyrene (PS) matrix. Our thinnest films (2.5 μm) of the polymer nanocomposite exhibited a 90% reduction in CO₂ permeability relative to that of PS, while those of bulk films (100 μm) increased by 200%. Morphology characterization suggests lightly grafted PS-g-SiO₂ components are conducive to diffusing to the surface; this effect is more pronounced in thinner films, where distance to the surface is much shorter than bulk films. Nanoparticles at the surface of thinner films would then rearrange into structures that disallow gas transport. Conversely, the enhanced relative permeability in bulk films is likely due to the decreased interfacial density between the nanoparticle and the polymer chains, allowing gas molecules to more easily flow through the film.

Highly-Mobile Nanoparticles that Strongly Interact with Well-Entangled Polymer Melts Diffuse via the Vehicular Mechanism*  
KAREN WINEY (Presenter), ERIC BAILEY, University of Pennsylvania, PHILIP J GRIFFIN, University of Chicago, RUSSELL JOHN COMPOSTO, University of Pennsylvania — When particles are large relative to the entanglement mesh in well-entangled polymer melts, the Stokes-Einstein (SE) relation predicts that particle diffusion scales as M⁻³.⁴. Using Rutherford backscattering spectrometry, we measure the diffusion coefficient of very small (radius ≈ 0.9 nm) octaaminophenyl silsesquioxane nanoparticles (NPs) in well-entangled poly(2-vinylpyridine) (P2VP) melts of varying molecular weight (1 – 26 entanglements/chain). We demonstrate that these small NPs diffuse between 10–10,000X faster in P2VP melts than predicted by SE, with the diffusion coefficients scaling weakly with molecular weight M⁻⁰.⁷±⁰.¹. Furthermore, we characterize the local segmental relaxation process and chain-scale center-of-mass diffusion and find reductions relative to bulk of ~80% and ~60%, respectively, at a NP concentration of up to 25 vol%. Through the combined study of NP and polymer dynamics in this attractive nanocomposite system, we demonstrate experimentally that small and highly-mobile nanoparticles in well-entangled polymer melts diffuse via the vehicular mechanism, i.e. successive NP adsorption/desorption events that occur on Rouse length and time scales.

Using advanced field-based approaches to predict macroscale polymer nanocomposite phase behavior [invited]  
JASON KOSKI (Presenter), AMALIE FRISCHKNECHT, Sandia National Laboratories, ROBERT RIGGLEMAN, University of Pennsylvania — Predictive phase diagrams significantly improve the refinement and optimization of materials for advanced applications. Unfortunately, theoretical phase diagrams of polymer nanocomposites (PNCs) are lacking, which is a result of limitations with conventional modeling approaches such as computational expense or critical approximations. Here we describe the development of field-based approaches in modeling PNCs and demonstrate their efficacy in modeling macroscale phase behavior. The exciting advances of these field-based approaches have led to the development of phase diagrams for an array of polymer nanocomposite systems. Examples of these systems include grafted nanoparticles in a polymer melt and the assembly of mixed brush nanoparticles in solution. We find the introduction of thermal fluctuations have a significant impact on the overall phase behavior of these systems. Specifically, thermal fluctuations are necessary to properly capture depletion interactions in grafted nanoparticle systems and to describe solution-based assembly where it is understood that thermal fluctuations are significant. Excitingly, we further show the versatility of these methods to other PNC systems and provide comparisons with analogous experiments.

1:39PM S54.00011: Local structure and phase behavior of dense polymer-particle mixtures: improved theory and comparison with simulation  
YUXING ZHOU (Presenter), KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — 
The polymer reference interaction site model (PRISM) has been extensively applied to study the equilibrium behavior of polymer nanocomposites (PNC). The theory predicts three typical phases or states of aggregation: depletion clustering, steric stabilization via discrete adsorbed layers, and polymer-mediated bridging or networking, depending on polymer-particle attractive interaction, size ratio, composition, chain length and total packing fraction. While the existence of such microstructures appears to qualitatively agree with simulations and experiments, the accuracy of the predicted pair correlation functions and phase behavior has not been thoroughly examined. By performing systematic simulations, we find the PRISM pair correlation functions, selected thermodynamic properties and phase behaviors based on the commonly used Percus-Yevick and Hypernetted Chain closures sometimes incur significant errors, especially near bridging and depletion spinodal boundaries. A variety of new closure approximations are explored and we find that over a wide range of parameter space the modified Verlet approximation provides a major improvement in accuracy of structural and thermodynamic behavior for both PNCs and the corresponding atomic or colloidal mixtures.

1:51PM S54.00012: Deforming Interfacial Layers of Bare and Grafted Particle Nanocomposites in Large Amplitude Oscillatory Shear*  
SIYANG YANG (Presenter), PINAR AKCORA, Stevens Institute of Technology — 
Chemical heterogeneity around nanoparticles yields enhancement in mechanical properties in polymer nanocomposites. We have shown interfacial layers composed of two miscible polymers on well-dispersed nanoparticles control the dynamics of chains and their temperature-induced stiffening response. In this work, we examined these interfacial layers and the evolution of entanglements under large amplitude oscillatory shear to reveal the stability of mechanical and structural behavior of attractive composites. Deformation-recovery experiments have shown that particles adsorbed with low rigidity polymer (PMMA) disentangle/re-entangle and reinforcement factor increased significantly, whereas with the high rigidity polymer (P2VP) the modulus recovered to its initial value. Fourier transform rheology results indicated that strain-softening resulted from the arrangement of interfacial PMMA chains, which yielded to a higher entanglement state and stiffening. The non-linear rheology results of the PMMA-grafted particles will be discussed with the results of PMMA-, PC- and P2VP-adsorbed chains with varying rigidity. Large shear-induced entanglements can therefore be explained through the deformability of chains in interfacial layers.

2:03PM S54.00013: Dissipative Particle Dynamics (DPD) Simulations of Polymer-Filler Blends: Understanding Dispersion and Hierarchical Structure in Polymer Nanocomposites.*  
ASHISH GOGIA (Presenter), University of Dayton Research Institute, University of Dayton, OH, KABIR RISHI, ALEX MCGLASSON, MICHAEL CHAUBY, GREG BEAUCAGE, Dept. Chem. and Mat. Eng, University of Cincinnati, OH, VIKRAM K KUPPA, University of Dayton Research Institute, University of Dayton, OH — 
Nanoscale fillers are widely employed as cheap and effective additions for enhanced properties and functionality in polymeric systems. Such nanocomposites may contain fillers of varying miscibility, such as carbon black, silica, metal oxides, pigments, and/or various combinations thereof. In such systems, a complex partitioning of the components often results from the rich thermodynamics and kinetic history. Hence, the state of dispersion of the polymers and fillers is crucial to the behavior of polymer nanocomposites. In this research, we perform Dissipative Particle Dynamics (DPD) simulation of these blends, varying polymer-polymer, filler-filler and polymer-filler interaction energy, to understand the hierarchical structure and dispersion over multiple length and time-scales. The simulation results are validated against small angle x-ray scattering data to bridge a significant gap in our understanding of how complex hierarchical structure (across several decades in length) develops in these multicomponent systems. Additionally, the influence of parameters such as polymer chain stiffness and chain size on the formation of aggregates and agglomerates are explored.

11:15AM S55.00001: Distribution of label spacings for genome mapping in nanochannels* DANIEL ODMAN, University of Gothenburg, ERIK WERNER, Zenuity, KEVIN DORFMAN, University of Minnesota, CHARLES R DOERING, University of Michigan, BERNHARD MEHLIG (Presenter), University of Gothenburg — In genome mapping experiments, long DNA molecules are stretched by confining them to very narrow channels, so that the locations of sequence-specific fluorescent labels along the channel axis provide large-scale genomic information. It is difficult, however, to make the channels narrow enough so that the DNA molecule is fully stretched. In practice its conformations may form hairpins that change the spacings between internal segments of the DNA molecule, and thus the label locations along the channel axis. Here we describe a theory for the distribution of label spacings that explains the heavy tails observed in distributions of label spacings in genome mapping experiments. This talk is based on the paper Ödman, E. Werner, K. D. Dorfman, C. R. Doering & B. Mehlig, arxiv:1803.11396.

11:27AM S55.00002: Pathway-dependent nonequilibrium conformations of a polymer globule as a model for chromatin organization* SEULKI KWON (Presenter), BONG JUNE SUNG, Sogang University — The spatial organization of chromatin in nucleus resembles a fractal globule, of which structure differs from an equilibrium polymer globule. Even though there have been efforts to develop a polymer model to describe nonequilibrium structure of tightly-packed chromatin, the dependence of a transition pathway toward a globule has been often ignored. Because biological systems are often in nonequilibrium states, the transition pathway the chromatin would take before it reaches the densely-packed globule would be important. In this study, by using a simple polymer model and Langevin dynamics simulations, we investigate the conformational transition of a single polymer from swollen coil to compact globule in order to elucidate the effect of transition pathway on the final globular structure. We show that a fast collapse induces a nonequilibrium fractal-like structure, whose relaxation toward an equilibriumglobule is extremely slow. Moreover, in strong confinement, polymer conformation never relaxes into equilibrium state, thus the structure of the globule becoming dependent on the transition pathway.

11:39AM S55.00003: Organization and Dynamics of Multiple DNA Chains Confined in a Nanofluidic Compartment* ZEZHOU LIU (Presenter), XAVIER CAPALDI, LILI ZENG, YUNING ZHANG, Physics department, McGill University, THU HA DAO, Physics department, University of Camerino, WALTER REISNER, Physics department, McGill University — The dynamics of multiple chains interacting in a confined environment is a fundamental problem in polymer physics and a model system for understanding confinement in biological systems. Here we present a nanofluidic device with compartments that can be opened and closed via pneumatic actuation of a thin membrane lid. The compartments are elliptical in shape with widths and lengths varying from hundreds of nm to microns. Differentially stained chains are trapped inside the cavities and the chain interactions assessed by monitoring the chain conformation and positioning in real-time via fluorescence videomicroscopy. We observe a transition between different dynamical states as the confinement is varied from quasi-0D (cavity confinement) to quasi 1-D (nanochannel confinement).

11:51AM S55.00004: Chromatin Rheology Tells a Story: From DNA Damage Loci to Cellular Monolayers* [invited] KRIS DAHL (Presenter), Carnegie Mellon University — Over the past two decades here have been numerous intellectual intersections between polymer physics and modeling of intracellular environments including (i) soft glassy rheology as a description of the numerous relaxation states within the cell and (ii) athermal rheology from the contribution of cellular molecular motors. Within the nucleus we have also observed a powerlaw response of chromatin both by extracellular applied force and by particle tracking microrheology. Global condensation state of the chromatin greatly impacts its rheology, and both can be manipulated with epigenetic modifying drugs (trichostatin A) or growth factors. Locally, chromatin condensation can be manipulated with other methods such as tetracycline responsive elements (TRE) or is altered during transcription. We have developed methods to image changes in these regions using fluorescence lifetime imaging and particle tracking combined with multichannel registration and processing to determine the effects of DNA damage on heterochromatin and euchromatin. Measuring the impact of molecular motors within the cell show that actin-myosin forces produced in the cytoskeleton are transmitted into the nucleus where the athermal motions can be registered by nuclear particle tracking, thus allowing the dense chromatin to be used as a sensor for cellular force generation. This technique, which we refer to as SINK (Sensors from IntraNuclear Kinetics) has allowed us to determine strain variations within heterogeneous monolayers of cells. Mechanical defects in cell monolayers shows exponential propagation, which suggests that monolayers of cells may be better modeled as colloidal crystals than continuum sheets. The study of condensed chromatin inside of cells has provided interesting physical and biological insights into cells at length scales of tens of nanometers to hundreds of micrometers.

12:27PM S55.00005: Conformation and Dynamics of Nonconcatenated Ring Polymers under Planar Confinement TIANREN ZHANG (Presenter), KAREN WINEY, ROBERT RIGGLEMAN, University of Pennsylvania — Understanding the segregation of nonconcatenated ring polymers in a restricted volume is important to the biological field, because ring polymers have been proven to be a good model to study DNA organization in the cell nucleus. From our previous study, linear polymers segregate under extreme cylindrically-confined systems due to the strong correlation hole effect that is enhanced by the confining surfaces. Unlike linear polymers, the correlation hole effect of ring polymers is much stronger under confined systems since there are no chain ends. In this study, we use MD simulation to investigate the chain conformations and dynamics of ring polymers under planar confinements with different thicknesses ($H = 5, 7, 10, 14$ and $20\sigma$) that span from extreme confined case to bulk like case. Our results show that conformations of ring polymers are similar to the linear polymers under planar confines, except that ring polymers are less compressed along the direction normal to the walls. On correlation hole effect analysis, we distinguish the segregation regime from the mixing regime based on self-density calculation for ring polymers. From the diffusion and local chain relaxation dynamics, we observe that chain dynamics are primarily affected by the friction from walls.

12:39PM S55.00006: The Kinetoplast as a Model 2D Catenated Polymer ALEXANDER KLOTZ (Presenter), BEATRICE SOH, PATRICK DOYLE, MIT — Genomic length DNA molecules have served as a model system for studying the physics of single polymers, in part due to their large length scales, compatibility with fluorescence optical microscopy, excellent monodispersity, and the commercial availability of complete genomes of the lambda and T4 viruses. There has been theoretical interest in the physics of two dimensional polymers, but robust experimental systems have been lacking. Here, we extend the use of DNA as a model polymer into the second dimension by studying the physics of the kinetoplast in free solution. A kinetoplast is a complex genomic structure found in certain parasites that consists of thousands of topologically linked rings of DNA forming a two-dimensional network. Removed from the cell and viewed in fluorescence microscopy in good solvent conditions, it adopts a form akin to a jellyfish bell approximately 5 microns in diameter. We characterize the equilibrium conformation and dynamics of kinetoplasts and examine their response to flow, confinement, and varying solvent conditions. Due to the commercial availability of kinetoplasts and the possibility of controlling their size using topoisomerase reactions, this study will open the door to a new class of experiments on two-dimensional and catenated polymers.
12:51PM S55.00007: Random Walks in Disordered Environments: Membrane-Induced Confinement of DNA*

XAVIER CAPALDI (Presenter), ZEZHOU LIU, YUNING ZHANG, WALTER REISNER, McGill University — Understanding the conformation and dynamics of DNA in nanoslit structures is a topic of long-standing interest in the physics of nanoconfined polymers, yet introducing molecules into the most confined (sub 20 nm thick) structures is very challenging. Here we use a pneumatically-actuated membrane device to sandwich single DNA molecules between a flexible nitride flap and glass nanochannel floor, forcing the molecules into a degree of confinement limited only by the intrinsic roughness of the channel surfaces. In these environments the molecule undergoes a self-avoiding random walk in the disordered environment created by the surface roughness. We study single-molecule dynamics and conformation as a function of root-mean-square surface roughness and imposed confinement.

1:03PM S55.00008: Molecular Confinement on Nanostructured Polymer Surfaces

SARA HEEDY (Presenter), ALBERT YEE, Chemical Engineering, University of California, Irvine — Polymers have characteristic dimensions of assembly which depend on processing, especially in nanofabrication. These dimensions may be important in properties such as electrical or thermal conductivity. These properties will be strongly affected when fabricated polymer nanostructures have dimensions comparable to the critical length scale of physical phenomena (mean free path of electrons, mass transport, etc.). Enhanced mechanical, optical, and electrical properties of nanostructures, including nanopillar arrays less than 1 μm tall, have been well documented. We fabricated nanostructures on poly(methyl methacrylate) surfaces with nanoimprint lithography. A consequence of such a process is confinement induced reordering of polymer chains which is affected by the mold geometry, surface properties, and imprinting variables. Using thermal imprinting, and the combined topographical and nanoscale chemical mapping of photoinduced force microscopy, we found that nanopillars (100-700 nm range) confine functional groups differently depending on the feature shape, height, and periodicity. These findings suggest that surface chemistry, as well as nanoscale phenomena, can be controlled for use in adhesion and bio-electronic interfaces.

1:15PM S55.00009: Voltage-Driven Translocation through a Nanopore: How can we define a/the Capture Radius?*

GARY W. SLATER (Presenter), LE QIAO, Physics, University of Ottawa — A typical translocation event includes the following three steps: (i) the diffusion, (ii) the capture, and finally (iii) the translocation of the analyte. The capture process remains rather ill-understood because it cannot easily be visualized or inferred from the blockage current measured across the nanopore. To estimate the size of the so-called capture zone, a capture radius $R_c$ is generally defined as the radial distance from the pore where diffusion-dominated dynamics (at large distance) cross over to drift-dominated dynamics (near the pore). However, this definition is ambiguous and the models used are often over-simplified. We investigate several approaches to defining and estimating $R_c$ for the simple case of a charged particle diffusing in a liquid and attracted to the nanopore by an applied electric field. We present a theoretical analysis of the flux and Péclet number methods as well as 2D Lattice Monte Carlo (LMC) simulations with different simulation protocols and boundary conditions, including particle evaporation from the pore under a reversed field conditions. We compare our results to experimental estimates and we stress the fact that the boundary conditions and finite experimental times both matter in the interpretation of $R_c$.

*Funded by NSERC (Canada).

1:27PM S55.00010: Exploring How the Capture Process Affects the Translocation of Polymers through Nanopores*

HENDRICK W DE HAAN (Presenter), KONSTANTINOS KASTRITIS, MARTIN MAGILL, University of Ontario Institute of Technology — The translocation of polymers across membranes through nanopores has received a great deal of attention in recent years. This work is motivated by applications such as sequencing DNA and also characterizing and sorting biopolymers by size. While the great majority of this work has focused on the translocation process itself (i.e., when the polymer is in and passing through the pore), details such as the conformation of the polymer when it arrives at the pore are critical for real-world applications. In this talk I will present results from a simulation study of the capture of semiflexible polymers by nanopores and demonstrate how dynamics that yield non-equilibrium conformations affect the translocation process. The impact of these results will be demonstrated by presenting simulation and experimental results for nanofluidic devices that are designed to sort and count biopolymers. These will include having many nanopores in series connected by nano- or micro-channels and DNA passing through a nano-filtered nanopore device.

The effects of packaging on the ejection rate of a polymer from a nanopore*  CHUNG BIN PARK (Presenter), BONG JUNE SUNG, Sogang University — DNA ejection and packaging are related in terms of DNA conformation. As the DNA becomes jammed, it cannot undergo dramatic conformational change in the capsid. That is, final conformation after packaging may be correlated with the conformation right before ejected. Then, a scientific question arises; whether a packaging process affects the ejection rate or not. In this work, we find three regimes of ejection processes: (1) knot dominant, (2) non-equilibrium dominant and (3) effective-ejection regime. We perform Langevin dynamics simulations of a semi-flexible single chain with 660 monomers. We package the chain with different packaging rates into a nanopore and eject the chain subsequently. If the chain is packaged slowly enough to be knotted, its ejection process becomes slow (~35%). Also, if the chain is packaged too fast to relax its conformation, its ejection rate decreases (~20%). Then, if a packaging rate is moderate (3), where DNA can relax but cannot be knotted, DNA ejects faster than other regimes. Our results show that ejection dynamics is determined by the history of packaging and suggest that there could be most effective packaging rate for ejection process in nature.

Capture and translocation of a stiff oligomer by a nanopore*  LE QIAO (Presenter), GARY W. SLATER, Department of Physics, University of Ottawa — Both the translational diffusion coefficient \( D \) and the electrophoretic mobility \( \mu \) of an oligomer that is pulled towards a nanopore by an electric field depend on its orientation. Since a charged rod-like molecule tends to orient in the presence of an electric field gradient, \( D \) and \( \mu \) will change as the molecule approaches the nanopore, and this will impact the capture radius (a somewhat ill-defined measure of the efficiency of the nanopore to attract analytes in its vicinity). We present a study of this problem using theoretical arguments and Langevin Dynamics simulations. In particular, we define an alignment radius which we compare to the capture radius, and we examine different physical limits. The hydrodynamic interactions with the wall are also investigated by coupling the Langevin MD oligomer to a Lattice-Boltzmann fluid.

Towards Single Molecule Protein Sequencing by Nanopore Mass Spectrometry*  NICHOLAS DRACHMAN (Presenter), MATHILDE LEOPOITIEVIN, BENJAMIN WIENER, HANNAH SZAPARY, OLIVER G ISIK, DEREK STEIN, Brown University — Here we describe an approach to sequencing single protein molecules that will combine the advantages of mass spectrometry with those of nanopores. The basic idea is to cleave the individual amino acids from a protein molecule as they transit a small hole in sequence, and then identify each one by determining its mass-to-charge ratio in a mass spectrometer. We present the results of studies of the transfer of single amino acid ions from liquid into vacuum from the nanoscale orifice of a charged needle. We also summarize the development of an instrument featuring a magnetic mass filter and an array of channeltron detectors, which will be able to photo-dissociate single proteins and then measure both the mass and the time of detection of the resulting fragments.

Session S56 GSNP DPOLY: Interactions of Elastic Structures with Fluids and Granular Matter I  BCEC 255 - Douglas Holmes, Virginia Tech - Tag(s): Focus

Interactions of slender elastic structures with complex media like granular materials [Invited] EVELYNE KOLB (Presenter), NICOLAS ALGARRA, ESPCI, PMMH, ARNAUD LAZARUS, Sorbonne Université, Institut Jean Le Rond d'Alembert, DAMIEN VANDEMBROUCQ, ESPCI, PMMH — Slender elastic structures are extremely flexible and get easily unstable. As a consequence of their high geometrical aspect ratio, slender structures can be sensitive to low forces of various origins and exhibit complex mechanical behaviors due to the associated couplings with the surrounding medium, whatever it is (fluid, elastic medium, gels, frictional substrate, granular material...). The effect of flexibility has recently motivated a growing number of studies. This is in particular the case of the elasto-capillary problems (interaction between slender structures and capillary forces), and of the fluid-structure interaction, where water or air flows induce shape reconfiguration and streamlining of elastic structure, leading to drag reduction. Here we will review various cases of interaction of elastic structures with complex external medium, focusing on granular medium. Direct applications of this problem will be chosen in the bio-physics domain, like the growth of plant roots in structured soils.
11:51AM S56.00002: Elastogranular Packing of a Loop*  DAVID JAY SCHUNTER, JR. (Presenter), REGINA K. CZECH, DOUGLAS PETER HOLMES, Mechanical Engineering, Boston University — Confined thin structures are ubiquitous in nature. Spatial constraints have led to novel packing strategies at both the micro-scale, as when DNA packages inside a capsid, and the macro-scale, observable in plant root development. Previous work has focused on growing thin structures confined by rigid boundaries. Comparatively, much less is known about the behavior of slender growing structures constrained by deformable boundaries, such as granular materials. By varying the arc length of an elastic loop injected into a granular array of mono-disperse, soft, spherical grains of varying initial number density $\phi_0$, we investigate the resulting behavior of this model elastogranular system. At low $\phi_0$, the elastic loop deforms as though it were hitting a flat surface by periodically folding into the array. Above a critical packing fraction $\phi_c$, local re-orientations of grains cause the elastic loop to deform as though striking a curved surface, leading to the emergence of a distinct circular packing morphology. These results will bring new insight into the packing behavior of wires and thin sheets (where the same morphologies have been observed) and will be relevant to modeling animal burrowing & locomotive strategies, and developing smart, steerable needles.

12:03PM S56.00003: Elastic tweezers for a vibrated granular bead  PAUL RAMBACH (Presenter), University of Mons, THOMAS SALEZ, YACINE AMAROUCHENE, University of Bordeaux, PASCAL DAMMAN, University of Mons — Optical tweezers are usually used to capture colloidal particles. In this talk, we will show that this method can be transferred in the realm of vibrated granular matter. It has been shown that the velocity distribution of mechanically vibrated beads is gaussian provided that a randomization of the collisions is achieved. This can be done via a rough surface, a layer of glued beads for instance. First we checked that a bead on top of a such rough surface undergoes a Brownian motion. Then we attached the bead to a flexible string and analyzed the fluctuations of motion. It revealed the drastic influence of the string elasticity, acting as a confining potential. This being equivalent to the harmonic potential achieved with optical tweezers. This new experimental setup paves the way to study stochastic behavior of small particles that should mimic colloidal suspension in 2D.

12:15PM S56.00004: Using an Olami-Feder-Christensen model with velocity weakened friction and variable stress transfer range to model slip-stick behavior in a sheared granular fault gouge system*  RACHELE DOMINGUEZ (Presenter), Physics, Randolph - Macon College — We present a variant of the Olami-Feder-Christensen (OFC) model with variable stress transfer range and a residual stress modified according to a velocity weakened friction force. The model displays dynamical modes similar to those observed in a sheared granular fault gouge laboratory system. For long stress transfer ranges, we find dynamical phases including a steady sliding state, a stick-slip state with periodic system-wide slipping events, and an intermittent state with both steady sliding and occasional slipping. For medium stress transfer ranges, we find additionally intermediate phases with large slipping events occurring in localized patches of the system. We compare simulation results of the model to laboratory results for the sheared granular fault gauge system.

12:27PM S56.00005: Mechanical properties of jammed elastogranular columns  XIN JIANG (Presenter), MO EYDANI, KATE FLANAGAN, CASEY RICKS, DOUGLAS PETER HOLMES, Department of Mechanical Engineering, Boston University — Composite materials have unique properties due to the creative assemblies of their constituents. A mixture of grains and rods can enable the formation of stable structures via granular jamming. Understanding how these constituents govern the mechanical properties of the jammed structures is crucial for devising relevant engineering designs. Here, we examine freestanding columns composed of rocks and strings, and propose a simple physical model to explain the resulting structure's mechanical behavior. The results indicate that exterior fiber mainly contributes to stiffness, while interior fiber increases the resilience and toughness of the structures. By assembling the grains and rods in a programmable way, structures with robust mechanical properties can be formed. The results provide guidelines that allow the design of jammed elastogranular structures with desired mechanical properties.
12:39PM S56.00006: Scaling Effects in Composite Elastogranular Materials*  MO EYDANI (Presenter), XIN JIANG, CASEY RICKS, KATE FLANAGAN, DOUGLAS PETER HOLMES, Mechanical Engineering, Boston University — Composite elastogranular materials combine the characteristics of their constituents, resulting in interesting and distinct mechanical properties. In this study, the effect of scale on the mechanical properties of composite string-rock materials comprised of elastic fibers embedded in a granular rock matrix is investigated. An experimental study is carried out to explore whether the relative global size of a composite elastogranular medium affects its bulk mechanical properties. In particular, the stiffness, strength and ratcheting-like behavior of string-rock composite is investigated for a cylindrical form. The stiffness of composite string-rock columns is shown to be scale-independent while the strength and compaction are observed to be driven by the scale.

12:51PM S56.00007: Modeling the physical constraints of latch mediated, spring actuated systems*  MARK ILTON (Presenter), ANDRES COOK, NICHOLAS HELLER, Harvey Mudd College, S. N. PATEK, Duke University, ALFRED CROSBY, University of Massachusetts Amherst, SARAH BERGEBREITER, Carnegie Mellon University, EMANUEL AZIZI, University of California Irvine, GREGORY P. SUTTON, University of Bristol, SARAH LONGO, Duke University, SATHVIK DIVI, Carnegie Mellon University, CRYSTAL REYNAGA, Duke University, JEFFREY OLBERDING, University of California Irvine, RYAN ST PIERRE, Carnegie Mellon University, SUZANNE COX, Penn State University — Certain plants and animals utilize elastic structures made of biomaterials to actuate rapid movements. In some of the most extreme cases, which includes mantis shrimp and trap-jaw ants, a latching mechanism is used to control the spatio-temporal flow of energy from the organism to their environment. In this work, we model the physical constraints of latch mediated, spring actuated systems. An integrated approach rooted in physical principles that includes the loading and release of energy from these systems is presented. This approach reveals the inherent tunability of these systems, and is applicable to both biological and synthetic systems. We identify critical transitions that depend on the materials properties and geometry of the spring and latch components. The resulting kinetic energy output of these systems is ultimately limited by physical constraints placed on the organism by interaction with their environment and their control dynamics.

1:03PM S56.00008: Elastic feathers spread impact force  SUNGHWAN JUNG (Presenter), KINJAL BHAR, Biological and Environmental Engineering, Cornell University, BRIAN CHANG, Virginia Tech, LORIAN STAKER, Smithsonian Museum, EMMANUEL VIROT, Harvard University, ROMAIN PARIS, CHRISTOPHE CLANET, Mechanics, Ecole Polytechnique — Northern Gannets are seabirds that frequently employ a hunting tactic called ‘plunge-diving’ in which they dive through the water surface at high speeds to catch underwater prey; often reaching speeds of up to 24 m/s at the moment of impact. It can result in forces as high as 500 N acting on the bird’s neck during impact, yet the bird escapes uninjured, despite making 20-100 dives per foraging trip. However, little is known about how such high impact forces affect the rest of the body. The goal of this study is to investigate the role played by the feathers in spreading the hydrodynamic impact force on the skin around the impact zone. We model the feathers as elastic beams taking into account their pre-curvature and non-uniform cross-section. Results from our experiments with polycarbonate beams suggest that the interaction of feathers on the skin patch redistributes the force, thereby reducing the impact on any particular area of the skin.

1:15PM S56.00009: Entanglement of Elastic Fibers in low Reynolds Fluid Flow*  HOSSEIN SHARIFAZADEH (Presenter), YAYUN DU, Department of Mechanical and Aerospace Engineering, University of California, Los Angeles, ALI BEYZAVI, Massachusetts Institute of Technology, MOHAMAD KHALID JAWED, Department of Mechanical and Aerospace Engineering, University of California, Los Angeles — We report a discrete differential geometry based simulation for entanglement of elastic rods that couples the structural elasticity, hydrodynamic loading, and rod-rod contact. In nature, such entanglement can play a beneficial role, e.g. bundling in bacterial flagella; however, can also be a nuisance, e.g. trichobezoar (hairball) in human stomach. We consider a model system where elastic rods are injected, at a controlled velocity, one after another into a spherical tank full of viscous fluid. The simulation tool for this process is a combination of the following four components: the Discrete Elastic Rods algorithm for the elasticity of the rods, the modified mass method to impose the boundary condition, a penalty force-based collision detection and handling algorithm, and the Resistive Force Theory for hydrodynamic loading. We conduct experiments with a collaborative robot that injects the rods at a prescribed velocity and video records the process. In both experiments and simulations, we find that entanglement process is governed by the ratio of the elastic bending forces to the viscous forces. By exploring parameter space, we construct phase boundaries delineating the regions of entanglement.

Formation mechanism and morphological behavior of high aspect-ratio folds in compressed films

DEREK BREID (Presenter), Engineering Science, Saint Vincent College, SACHIN VELANKAR, Chemical Engineering, University of Pittsburgh — A thin, rigid film that is subjected to compression can exhibit a variety of buckling modes depending on the nature of the applied compression and the boundary conditions at the film surface and edges. Among the lesser-known buckling modes is the development of sharp, tall folds which are typically observed as a response to a swelling stress in a confined region of a larger film. Here, we conduct experiments to identify the essential physics underlying fold growth and the effect of constraints on the mode of buckling. We show that the folding mechanism is not limited to cases of rapid swelling, but emerges more generally in any compressed thin film which is imperfectly bound to a solid substrate. The only essential condition to achieve this mode of buckling is that the film must be able to slide along the substrate without allowing air or fluid to intrude between the film and the substrate. We demonstrate that this can occur through purely mechanical application of stress. We also show the effects of the size of the compressed region, the film thickness, and the stress application rate using swelling-based methods, and characterize our results using a model combining Flory-Rehner swelling theory with buckle initiation mechanics.

AFOSR, Award No. FA9550-10-1-0329

Rate-controlled wrinkling and folding of thin elastic films bonded to viscous substrates

SACHIN VELANKAR (Presenter), SOURAV CHATTERJEE, JUNYU YANG, University of Pittsburgh, RUI HUANG, University of Texas, XIANHENG GUAN, University of Pittsburgh, LUKA POCIVAVSEK, University of Chicago, ENRIQUE CERDA, University of Santiago — We examine the buckling of a thin elastic film floating on a viscous liquid layer which is itself supported on a prestretched rubber sheet. Releasing the prestretch in the rubber at a controlled rate induces viscous stress in the liquid, which compresses the elastic film, causing buckling. This approach allows compressive strains of several ten percent to be applied. Experiments and simulations show that two different buckle modes can appear. The first is that the elastic film develops roughly sinusoidal wrinkles. Wrinkling can be captured qualitatively by a linear stability analysis starting from a stress state that is calculated from a shear lag approach (Chatterjee, Soft Matter, 2015). The second is the appearance of tall, well-spaced folds which tend to appear at small liquid layer thickness. Folds are separated by regions where the film remains more-or-less flat. To our knowledge, the appearance of such folds in elastic films bonded to viscous supports is a new discovery. While their exact origin remains unclear, we argue that folds are energetically favorable (i.e. reduce bending energy more) as compared to wrinkles. But because folds can take a long time to develop, wrinkles may appear as a temporary intermediate state.

Session S57 GSNP DBIO: Noise-driven Dynamics in Far-from-equilibrium Systems III BCEC

Probing noisy dynamics at the nanometer scale

DAVID HAVILAND (Presenter), SHAN JOLIN, RICCARDO BORGANI, Applied Physics, KTH Royal Institute of Technology — When driven by a strong pump, a nonlinear oscillator creates correlations in the frequency domain between signal and idler pairs symmetrically placed about the pump frequency. These correlations result in two-mode squeezing and phase-insensitive amplification of the signal. Not only signals but also noise can be squeezed, leading to measurement sensitivity below the standard limits imposed by thermal or quantum fluctuations. There is currently great interest in demonstrating these effects at the quantum limit, but less attention is paid to the squeezing of thermal noise where there is great potential for practical application. We demonstrate two-mode squeezing in dynamic Atomic Force Microscopy (AFM), where the limiting noise at room temperature is the thermal Brownian motion of the cantilever. Unlike previous work on the mechanical amplification of force, we do not use an 'external' nonlinearity to realize gain. Rather the sample itself is the 'gain medium' which causes a widening of the measurement bandwidth over which dynamic AFM is limited by thermal noise.

Affirms the general principle and the possibility of a Brownian ratchet working near room temperature scale. Our work thermally the steady-state dynamics of a simple stochastic electronic system featuring two resistor-capacitor circuits coupled by a third capacitor. The resistors are subject to thermal noises at real temperatures. The voltage fluctuation across each resistor can be compared to a one-dimensional Brownian motion. However, the collective dynamical behavior, when the resistors are subject to distinct thermal baths, is identical to that of a Brownian gyrator, as first proposed by Filliger and Reimann [1]. The average gyrating dynamics is originated from the absence of detailed balance due to unequal thermal baths. We look into the details of this stochastic gyrating dynamics, its dependences on the temperature difference and coupling strength, and the mechanism of heat transfer through this simple electronic circuit. Our work affirms the general principle and the possibility of a Brownian ratchet working near room temperature scale.

*This work has been supported by Ministry of Science and Technology in Taiwan under Grants No. MOST 104-2112-M-008-003-MY3, No.105-2112-M-008-019-MY2, and No. 105-2112-M-008-023. C.-L.L. acknowledges the support from the NCTS thematic group Complex Systems.

Detecting and quantifying non-equilibrium activity is essential for studying complex living systems such as cells. We present a non-invasive approach of measuring activity in a system based on the breaking of time-reversal symmetry. We focus on "cycling frequencies" - the frequencies with which the trajectories of pairs of degrees of freedom circle around in phase space, which is related to the entropy production rate. We test our approach on simple toy-models comprised of elastic networks immersed in a viscous fluid with spatially-varying internal driving. We prove both numerically and analytically that the cycling frequencies obey a power law as a function of distance between the selected degrees of freedom. Moreover, the behavior of the cycling frequencies contains information about the dimensionality of the system and the amplitude of active noise. Finally, we aim to find a mapping between the microscopic properties of a non-equilibrium system and macroscopic observables such as the cycling frequencies by including features such as the active force moments or spatial and temporal correlations of the active noise.

11:39AM S57.00003: Electrical autonomous Brownian gyrator+ KUAN-HSUN CHIANG (Presenter), CHI-LUN LEE, PIK-YIN LAI, YUNG-FU CHEN, Department of physics, National Central University, Zhongli 32001, Taiwan — We study experimentally and theoretically the steady-state dynamics of a simple stochastic electronic system featuring two resistor-capacitor circuits coupled by a third capacitor. The resistors are subject to thermal noises at real temperatures. The voltage fluctuation across each resistor can be compared to a one-dimensional Brownian motion. However, the collective dynamical behavior, when the resistors are subject to distinct thermal baths, is identical to that of a Brownian gyrator, as first proposed by Filliger and Reimann [1]. The average gyrating dynamics is originated from the absence of detailed balance due to unequal thermal baths. We look into the details of this stochastic gyrating dynamics, its dependences on the temperature difference and coupling strength, and the mechanism of heat transfer through this simple electronic circuit. Our work affirms the general principle and the possibility of a Brownian ratchet working near room temperature scale.

11:51AM S57.00004: Experimental observation of fluctuation loops JOHN NEU (Presenter), Mathematics, University of California, Berkeley, JUAN PABLO GONZALEZ, STEPHEN TEITSWORTH, Physics, Duke University — Fluctuation loops arise in the large deviation theory of stochastic dynamical systems. Displacements from a stable critical point to a small destination box about a point many standard deviations away are rare. When they do occur, they closely follow a most probable outward path. The most probable outcome after reaching the destination box is deterministic relaxation back to the stable critical point. The union of the outward and relaxation paths constitutes a fluctuation loop. For linear stochastic dynamics, fluctuation loops can be constructed by simple averaging. Ensemble averaging over forward histories after reaching the destination box obviously recovers the relaxation segment. Less obviously, averaging over back histories prior to reaching the destination box recovers the outbound segment. The characterization of fluctuation loops by averaging means that they can be recovered from experimentally recorded time series of state variables. We demonstrate this for a simple electrical network of two capacitively coupled, noise driven RC circuits. Even when the destinations boxes are not many standard deviations away from the stable critical point, it is striking that clearly resolved fluctuation loops emerge from very noisy data.

12:03PM S57.00005: Hydrodynamic Brownian motion and nanoscale transport efficiency in liquids SEAN SEYLER (Presenter), STEVE PRESSÉ, Center for Biological Physics, Arizona State University — Recent experiments have motivated a reexamination of Brownian motion, as hydrodynamic memory and colored thermal noise arising on short spatiotemporal scales lead to substantially different dynamical behavior. We revisit the problem of particle transport in liquids at low Reynolds number, where we account for the Basset-Boussinesq force and added mass effect induced by unsteady particle motion while reincorporating thermal fluctuations so as to satisfy fluctuation-dissipation. The resulting fluctuating Basset-Boussinesq-Oseen equation is solved numerically using an efficient method based on Markovian embedding, which can simultaneously capture the algebraic decay of the memory kernel and the colored noise spectrum to an arbitrary level of precision. We apply various driving forces to ensembles of submicron spherical particles in different liquids while holding constant the amount of input work; the resulting particle displacements and velocities are analyzed in terms of the magnitude, duration, and shape of different forcing protocols. For each protocol, we compute efficiencies for particle transport—with and without hydrodynamic effects—using the mean displacement and current density as proxies for output work. Implications for subcellular biology and nanofluidics are discussed.
12:15PM S57.00006: Operator dynamics in Brownian quantum circuit*  TIANCI ZHOU (Presenter), XIAO CHEN, Kavli institute of theoretical physics — We view the operator spreading in chaotic evolution as a stochastic process of height growth. The height of an operator represents its spatial extent and a master equation governs the transition to higher operators. We derive and solve a master equation in a random N -spin model with all 2-body interactions. The mean height, being proportional to the squared commutator, will grow exponentially within log N scrambling time and saturates in a manner of logistic function. We propose that the chaos bound at finite temperature could be due to initial height biased towards the high operators, which has smaller Lyapunov exponent.

*XS and TZ are supported by a postdoctoral fellowship from the Gordon and Betty Moore Foundation, under the EPIQS initiative, Grant GBMF4304, at the Kavli Institute for Theoretical Physics. We acknowledge support from the Center for Scientific Computing from the CNSI, MRL: an NSF MRSEC (DMR-1720256).

12:27PM S57.00007: Operator dynamics in chaotic long-range interaction systems*  XIAO CHEN (Presenter), TIANCI ZHOU, University of California, Santa Barbara — We use out-of-time-order correlator (OTOC) to diagnose the propagation of chaos in one dimensional long-range power law interaction system. We consider a model called Brownian quantum circuit, which allows us to derive the master equation governing the operator dynamics and therefore transforms the evolution of OTOC to a classical stochastic dynamics problem. We find that the chaos propagation relies on the number of qubits N on each site and the power law exponent α. We use OTOC to define light cone and find that in the small N limit (N=1), there are three light cone regimes as we vary α: (1) a log light cone regime when 1<α<2, (2) a sublinear power law light cone regime when 2<α<4 and (3) a linear light cone regime when α>4. We further study the scaling behaviors of OTOC in the vicinity of light cone. Moreover, we also study the operator growth in the large N limit and find it to be remarkably different. Our result provides a unified physical picture for chaos dynamics in power law interaction system and can be generalized to higher spatial dimensions.

*We are supported by postdoctoral fellowships from the Gordon and Betty Moore Foundation, under the EPIQS initiative, Grant GBMF4304, at the Kavli Institute for Theoretical Physics.

12:39PM S57.00008: Anomalous diffusion, infinite measures, and limit distributions in a class of exactly solvable stochastic processes  GUENTER RADONS (Presenter), Institute of Physics, Chemnitz University of Technology, Germany, TAKUMA AKIMOTO, Department of Physics, Tokyo University of Science, Japan, ELI BARKAI, Department of Physics, Bar-Ilan University, Ramat Gan, Israel — We consider stochastic processes, piecewise constant in time, which can be viewed as a gapless sequences of statistically independent box functions of duration τi and height vi. Lengths and heights of the boxes are deterministically coupled, whereas the areas τivi are i.i.d. random variables. These processes are closely related to the velocity process of space-time coupled Levy walks [1,2], but can more generally be viewed as a renewal processes, where the life times τi are not simply drawn from one given distribution, but are determined via a deterministic law by the values vi of a relevant stochastic variable. Despite its simplicity, these processes can show anomalous diffusion, or, more general, anomalous behavior of its moments. The latter can be related either to invariant densities, which are non-normalizable, or, for other parameters, to certain scaling densities. We obtained exact results for these quantities because we were able to derive the exact form of the propagator analytically. In addition, we were able to derive non-trivial exact limit distributions for time-averaged quantities of interest.

12:51PM S57.00009: Optimal Finite Time Erasure: A mass transport perspective*  JAMES MELBOURNE (Presenter), SAURAV TALUKDAR, HARISH DODDI, MURTI SALAPAKA, University of Minnesota — Landauer’s principle states that the average heat dissipation in a bit erasure is atleast kBT ln 2. Recent experiments approach this bound in an asymptotic manner with respect to time. Meanwhile, in the experimentally relevant case that a single bit memory is modeled as a Brownian particle in a bistable well, developments in non-equilibrium thermodynamics and stochastic control predict larger heat dissipation for finite time erasure, dependent on the Wasserstein transportation distance between the initial and final configurations. Inspired by these considerations, we propose an experimentally feasible finite time erasure protocol which approximates a Wasserstein geodesic. Monte Carlo simulations are used to demonstrate the efficacy of the proposed erasure protocol, comparing energetics against existing erasure protocols and the theoretically optimal bounds.

*The research was supported by the National Science Foundation under the grant NSF ECCS 1809194.
1:03PM S57.00010: Exact solutions of dissipative quantum spin chains using Majorana fermions  
NAOYUKI SHIBATA (Presenter), HOSHO KATSURA, Physics, University of Tokyo — The Lindblad equation is the well-known quantum master equation which describes the evolution of open quantum systems. While Lindblad equations have been used in the past mostly to describe few-particle systems in e.g., quantum optics, recent years have witnessed a growing interest in many-body systems in the Lindblad setting. However, very few exact results are available for many-body systems. The main difficulty is that we often need to deal with effective interactions arising from dissipation [1] even when the Hamiltonian itself is reducible to that of a free-particle system. This prevents us from understanding the full dynamics of the system.

In this talk, we construct a new exactly solvable dissipative spin model which maps to an effective non-Hermitian many-body system. By Kitaev's technique [2], this model can be seen as free Majorana fermions in a static Z2 gauge field, allowing us to obtain the full dynamics of this open system sector by sector. With this method, we obtain the Liouvillian gap (the inverse of relaxation time) numerically and exactly. We also obtain a closed formula for the auto-correlation of the edge spin by relating it to the enumeration of lattice paths.

1:15PM S57.00011: Degree heterogeneity increases the probability of rare events in population networks  
MICHAEL ASSAF (Presenter), Hebrew University of Jerusalem, JASON HINDES, Plasma Physics Division, Naval Research Laboratory — There is great interest in predicting rare and extreme events in complex systems, and in particular, understanding the role of network topology in facilitating such events. In this work, we show that degree heterogeneity - the fact that the number of local connections in complex networks is broadly distributed - increases the probability of large, rare fluctuations in population networks generically.

We perform explicit calculations for two canonical examples of rare events: network extinction and switching. When the distance to bifurcation is held constant, and hence stochastic effects are fairly compared among networks, we show that the probability exponent for rare events decreases linearly with the ratio of the degree distribution's standard deviation to its mean.

1:27PM S57.00012: Using a System's Equilibrium Behavior to Reduce Its Energy Dissipation in Non-Equilibrium Processes  
SARA TAFOYA, Biophysics, University of California, Berkeley, STEVEN J. LARGE, Physics, Simon Fraser University, SHIXIN LIU, Rockefeller University, CARLOS JOSE BUSTAMANTE, Molecular & Cellular Biology, Physics, and Chemistry, University of California, Berkeley, DAVID SIVAK (Presenter), Physics, Simon Fraser University — Cells must operate far from equilibrium, utilizing and dissipating energy continuously to maintain their organization and to avoid stasis and death. However, they must also avoid unnecessary waste of energy. Recent studies have revealed that molecular machines are extremely efficient thermodynamically when compared to their macroscopic counterparts. However, the principles governing the efficient out-of-equilibrium operation of molecular machines remain a mystery. A theoretical framework has been recently formulated in which a generalized friction coefficient quantifies the energetic efficiency in non-equilibrium processes.

Moreover, it posits that to minimize energy dissipation, external control should drive the system along the reaction coordinate with a speed inversely proportional to the square root of that friction coefficient. Here, we demonstrate the utility of this theory for designing and understanding energetically efficient non-equilibrium processes through the unfolding and folding of single DNA hairpins.
11:15AM S58.00001: Phospholipid bilayer interleaflet friction from coarse-grained numerical simulations

OTHMÈNE BENAZIEB (Presenter), FABRICE THALMANN, CNRS and University of Strasbourg, France, Institut Charles Sadron — Amphiphilic lipid bilayers modify the friction properties of the surfaces on top of which they are deposited [1]. In particular, the measured sliding friction coefficient is significantly reduced compared with the one of a native surface [2]. We investigate in this work the friction properties of a numerical coarse-grained model [3] of lipid bilayer subject to longitudinal shear. Interleaflet friction coefficients are extracted from out-of-equilibrium pulling and relaxation experiments. In particular we gain access to the transient viscoelastic response of the bilayer subject to normal shear. We then show how our method can be generalized to supported lipid bilayers.

11:27AM S58.00002: Modifying lubrication in micro-patterned and polymer-grafted soft interfaces

LILIAN HSIAO (Presenter), YUNHU PENG, CHRISTOPHER SERFASS, North Carolina State University — Soft contacts are encountered in a variety of natural and technological applications. Two common strategies to modify interfacial friction include the deliberate micropatterning of surfaces and the grafting of charged polymer brushes onto the surfaces. Nevertheless, the connection between macroscopic friction and surface energies on textured substrates is not well understood. We synthesize model poly(dimethylsiloxane) (PDMS) substrates with microtextures and polyzwitterionic brushes, and use them as tribopairs to investigate the effect on elastohydrodynamic (EHL) and boundary lubrication (BL). Our results indicate that patterned surfaces exhibit micro-EHL to EHL transitions in which the critical friction coefficient and Sommerfeld numbers vary as a function of the surface geometry. The experimental data show excellent agreement with a simple scaling theory we developed from Reynold's equations for 1D lubrication flows. Furthermore, we investigate the BL changes in PDMS tribopairs in which betainized poly(2-dimethylamino ethyl methacrylate) (PDMAEMA) brushes are covalently grafted onto the surface. Our preliminary results suggest that the polymer relaxation physics may play an important role in the lubricating efficiency of the PDMAEMA brushes.

11:39AM S58.00003: Ink Transfer in Ultrathin Flexographic Printing Using Nanoporous Stamps

DHANUSHKODI MARIAPPAN (Presenter), KIM SANHA, MICHAEL S. H. BOUTILIER, Mechanical Engineering, Massachusetts Institute of Technology, JUNJIE ZHAO, Chemical Engineering, Massachusetts Institute of Technology, HANGBO ZHAO, JUSTIN BEROZ, Mechanical Engineering, Massachusetts Institute of Technology, HOSSEIN SOJOUDI, KAREN GLEASON, Chemical Engineering, Massachusetts Institute of Technology, PT BRUN, Chemical and Biological Engineering, Princeton University, JOHN HART, Mechanical Engineering, Massachusetts Institute of Technology — Printing of ultrathin layers of liquid and colloidal inks is critical to manufacturing of low-cost electronics on non-conventional substrates such as polymer films and flexible glass. A recent invention from our research group, engineered nanoporous stamps made from polymer-coated carbon nanotube (CNT) forests, are highly porous (>90%) and can retain colloidal nanoparticle inks within their volume. Using these stamps, we have achieved printing of micron-scale features with highly uniform sub-100 nm thickness. In this work, we use high-speed imaging of the contact line motion during printing on transparent substrates to observe the dynamics of liquid spreading during contact, and the evolution of a capillary liquid bridge in the stamp-substrate gap. At high approach speeds, spreading speed increases with approach speed whereas at low approach speeds, flow from the porous medium defined by the fluid and stamp properties determine the spreading speed. After bridge rupture at a critical stamp-substrate gap, liquid respreads to fill the area defined by a precursor film matching the stamp geometry with high precision, and the respreading dynamics follow Tanner's law. The transferred liquid volume decreases with retraction speed enabling speed based process control of layer thickness.
11:51AM S58.00004: Effects of Bidisperse Wettability on Interfacial Viscoelasticity of Particle Laden Interfaces
SYED EHSANUR RAHMAN, GORDON CHRISTOPHER (Presenter), Texas Tech University — Increasing use of Pickering Emulsions has led to increasing study of interfacial particles. It is known that particle contact angle determines emulsion type and modifies interfacial viscoelasticity, effecting emulsion stability and viscosity. Most studies of particle interfaces examine a mono-population of colloids. However, in applications, there can be significant distribution in contact angle. What role such distribution plays on interfacial mechanical properties is unclear.

In this work, the effects of controlled dispersity of wettability on particle laden interfaces is examined. Using hydrophobic and hydrophilic negative polystyrene and hydrophobic non-ionic polystyrene, mixed wettability systems with varying ratios of hydrophobic to hydrophilic particles are studied. An increase in interfacial elasticity is observed when the ratio of hydrophobic to hydrophilic particles reaches 1. This corresponds with an increase in local hexagonal order and decrease in area around particles. Similar but smaller magnitude changes are observed for combinations of hydrophobic particles. We believe these changes occur due partitioning of particles to either side of the interface, creating larger local density and increased resistance to deformation.

12:03PM S58.00005: Particle assembly on an evolving interface
BENJAMIN DRUECKE (Presenter), XIANG CHENG, SUNGYON LEE, University of Minnesota — The behavior of particles on fluid-fluid interfaces has a history extending back to Pickering. Much of the work on these particle rafts treats the fluid as a quasi-static interface and investigates the behavior of the particles on this passive interface. In this work, we investigate the behavior of particle rafts on dynamically evolving interfaces such that there is a strong coupling between the behavior of particles on the interface and the underlying hydrodynamics of the evolving interface. As a prototypical system, we consider a water-oil interface inside a funnel, such that the interface deforms as the water level is varied. We examine the behavior of a variety of particles on such an interface to elucidate the coupling between bulk and interfacial phenomena.

12:15PM S58.00006: A Computational Method to Study Packing on Deformable Shells
SANJAY DHARMAVARAM (Presenter), Mathematics, Bucknell University, LUIGI E PEROTTI, Mechanical and Aerospace Engineering, University of Central Florida — Many problems in softmatter and membrane biophysics, such as studying equilibrium configurations of protein clusters on cell-membranes, highly defect ridden structures of Gag polyproteins in immature HIV capsids, and the unusual fluid-like state of Archaeal viruses [1] can all be analyzed as systems of interacting particles (typically representing proteins or protein capsomers) on deformable fluid surfaces. The coupled interactions between the particles and the underlying elastic medium to which they are constrained pose significant computational challenges. Existing methods often employ expensive constraints to anchor particles to the surface or artificially restrict their movement yielding spurious equilibrium states. In this talk, we present a new approach that circumvents existing challenges to obtain reliable equilibria. We apply the method to study the generalized Thomson problem of packing interacting particles on a deformable shell. In this context, we investigate particle symmetries, surface tessellation, and surface shape as the fluid membrane is progressively covered by interacting particles.

12:27PM S58.00007: Rigid Bubbles: Novel Instabilities in Colloidal Film Rupture
PHALGUNI SHAH (Presenter), SRISHTI ARORA, MICHELLE R DRISCOLL, Northwestern University — When a soap bubble pops, a rupture opens up and grows on the timescale of milliseconds. Culick (1960) showed that this rupture grows at a constant rate. Recently, Petit et al. (2015) studied films that were rigidified due to their high surfactant concentration. They observed that these films developed crack-like instabilities during rupture, and their rupture velocity was slower than that predicted by Culick. We investigate whether soap films rigidified by adding colloidal spheres show similar instabilities. We rupture a flat film containing surfactant and colloidal spheres using a needle and record it with a high-speed camera at 75,000 frames per second. We control film rigidity by varying particle concentration and find that this dramatically alters rupture dynamics. The rupture opens at a rate that is non-constant and an order of magnitude slower than the Culick velocity. Additionally, we observe a wide variety of instabilities in these rupturing colloidal films. We systematically study film rupture dynamics as a function of colloid concentration and film thickness.
12:39PM S58.00008: Thermally assisted buckling of colloidal assemblies* SIMON STUIJ (Presenter), Institute of Physics, University of Amsterdam, JAN-MAARTEN VAN DOORN, TOM KODGER, JORIS SPRAKEL, Physical Chemistry and Soft Matter, Wageningen University, CORENTIN COULAIS, PETER SCHALL, Institute of Physics, University of Amsterdam — We investigate the effect of thermal fluctuations on the buckling instability of colloidal assemblies. Using laser tweezers to grab the ends of, and push on colloidal chains assembled with critical Casimir forces, we probe the buckling instability analogous to the Euler buckling of macroscopic beams, in the presence of thermal activation. We find that buckling fluctuations diverge upon approaching the buckling point, while their time scale diverges similar to critical slowing down. Molecular dynamic simulations allow quantitative extraction of the corresponding critical exponents, which we identify as the mean-field critical exponents. Using an analytically solvable minimal model, we elucidate the origin of these exponents. The surprisingly rich physics of this simple thermal mechanical system highlights the interplay of thermal fluctuations and elasticity in the buckling stability of micron-scale architectures such as biomaterials.

12:51PM S58.00009: Memory effects in the attachment of thin films to liquid surfaces* DEEPAK KUMAR (Presenter), THOMAS RUSSELL, BENJAMIN DAVIDOVITCH, NARAYANAN MENON, University of Massachusetts Amherst — We study the dynamics of depositing or peeling off a thin polymer film at an air-water surface. In our experiment, we control the velocity of the film withdrawal or attachment while measuring the force required to do so. The observed dynamics is hysteretic, wherein the force depends on the direction of motion even at the lowest attainable velocities, but the magnitude of the hysteresis loop appears to be independent of the velocity. When the motion of the film is halted, the relaxation to equilibrium configuration is extremely slow, and appears to be logarithmic in time. Quite remarkably, the relaxation dynamics retains the memory of velocity history. This behavior, involving hysteresis, slow relaxation and memory effects are hallmarks of glassy systems which have access to a large number of relaxation modes with a broad distribution of dynamics. The surprisingly rich physics of this simple system exhibits some of these features.

*We gratefully acknowledge support from NSF DMR 1507650.

1:03PM S58.00010: Motion of water droplets on oil infused surfaces* SOLOMON ADERA (Presenter), LILIAN MAGERMANS, School of Engineering and Applied Sciences, Harvard University, MUGHEES KHAN, Wyss Institute for Biologically Inspired Engineering, Harvard University, JOANNA AIZENBERG, School of Engineering and Applied Sciences, Harvard University — Controlling the motion of water droplets on solid surfaces has broad technological implications ranging from microfluidics to thermal management. Past approaches utilized topography and chemical composition gradients to manipulate the motion of droplets. Here we show that the motion of droplets on oil infused surfaces can be triggered via asymmetry of the wetting ridge. Our experimental results show that neighboring droplets exert force on each other through their wetting ridge. This interaction causes droplets to coalesce and self propel by releasing free surface energy. Importantly, our experiments show that the motion of water droplets on slippery oil infused surfaces is not random as has been hypothesized in past studies. Instead, the oleoplaning droplets select their path such that the force required to overcome viscous dissipation is minimum. Consequently, droplets move away from oil depleted regions where the lubrication oil thickness is small and the resistance to motion is large. This “sensing” ability of droplets to the thickness of lubrication oil enables them to maneuver by avoiding prior oil depleted paths. This study provides new mechanistic insight into the motion of water droplets on oil infused surfaces.

1:15PM S58.00011: Two-wavelength Wrinkling Patterns in Chiral Liquid Crystal Surfaces PARDIS ROFOUIE, ZIHENG WANG, ALEJANDRO REY (Presenter), McGill University — We present a model to investigate the formation of two-length scale surface patterns in biological and synthetic anisotropic soft matter through the high order interaction of anisotropic interfacial tension and capillarity at their free surfaces. Focusing on the chiral liquid crystal (CLC) material model, the generalized shape equation for anisotropic interfaces using the quartic anchoring energy is applied to understand the formation of two-length scale patterns, such as those found in floral petals. Analytical and numerical solutions are used to shed light on why and how simple anisotropic anchoring generates two-lengthscale wrinkles whose amplitudes are given in terms of anchoring coefficients. The proposed new nano-wrinkling mechanisms augment previous models dedicated to understand and mimic biological surface pattern formation. Symmetry relations and scaling laws are used to provide the explicit relations between the anchoring constants and surface profile of the two length scale wrinkles. These new findings establish a new paradigm for characterizing surface wrinkling in biological liquid crystals, and inspire the design of novel functional surface structures.
1:27PM S58.00012: Sculpting high aspect ratio particles from oil-in-water emulsions*  MATHEW GISÓ (Presenter), Physics & Astronomy, Tufts University, HAO DA ZHAO, PATRICK T SPICER, Chemical Engineering, University Of New South Wales, TIM ATHERTON, Physics & Astronomy, Tufts University — Shape is a powerful route to control the transport and rheological properties of particulate media. Here, we present a process to sculpt elongated colloidal particles from an oil-in-water emulsion. Oil droplets are crystallized by reducing the temperature. The rate of cooling determines the rate of crystallization. With the addition of surfactants, it is possible to induce dewetting of the crystals by their own liquid phase. By tuning the relative rates of dewetting and crystallization, a rich variety of crystal shapes can be grown in an easily scalable process using controlled interfacial hydrodynamics. We explain these experimental findings using a non-equilibrium Monte Carlo model that captures both the crystallization and dewetting processes. Our results reproduce the wide range of shapes seen in experiment and provide insights to control their final morphology. Prospects for expanding the space of final shapes will also be discussed.

1:39PM S58.00013: Defect screening in faceted emulsion droplets.  IRETH GARCÍA-AGUILAR (Presenter), PIEMARCO FONDA, LUCA GIOMI, Leiden University, ELI SLOUTSKIN, Bar-Ilan University — Oil emulsion droplets in water have been observed to spontaneously deform into polyhedral shapes at temperatures where the surfactant interface freezes while the bulk oil and water remain liquid. The interface monolayer crystalizes into a hexagonal lattice, which is topologically constrained to accomodate a certain number of defects, namely disclinations. Additional defects, called dislocations, are also expected to be found in crystals with large number of particles. Dislocations are not only thermally induced but, more importantly, they are known to screen the large stresses around disclinations by forming chain-like structures at their vicinity. We address the problem of faceting droplets by studying the interplay between the interface geometry and the arrangement of dislocations. We have found that the coupling between the distribution of crystal defects, surface curvature and entropy is key to understand the temperature and size-dependent behaviour of the shape transformations.

1:51PM S58.00014: Statistical Mechanics of Puckered Membranes  ABIGAIL PLUMMER (Presenter), DAVID R NELSON, Harvard University — A triangular lattice of points connected by springs that resists bending and stretching provides a discrete model of a thin elastic plate. We consider such a surface with a superlattice of ‘impurities’— sites that have longer springs connecting them to the rest of the lattice. In the continuum limit, this corresponds to a preferred metric with periodic dilations. These impurities tend to pucker either above or below the lattice. We regard this as an Ising-like degree of freedom, and characterize interactions between neighboring puckers. We find we can tune these puckered membranes from a ‘ferromagnetic’ state to an ‘antiferromagnetic’ state using elastic constants and superlattice structure, and investigate these states theoretically and numerically.

Session S59 GSOFT: Actuation in Soft Matter II BCEC 257B - Benjamin Gorissen

11:15AM S59.00001: Liquid Crystal Elastomer Micron-Rings with Pre-Designed Molecular Orientations*  HAO YU (Presenter), YUBING GUO, ZIYUAN ZHOU, MIAO JIANG, TARAS TURIV, O D LAVENTOVICH, QI-HUO WEI, Advanced Materials and Liquid Crystal Institute, Kent State University, Kent, Ohio, 44242, USA — Mechanical responses of liquid crystal elastomers (LCEs) to external stimuli are pre-programmable by predesigning molecular orientations, promising applications such as sensors and actuators and micro robotics. Recently we have developed capabilities to photopatterning arbitrary molecular orientations with high spatial resolutions and to fabricating LCEs with well-defined geometric shapes and predesigned 3D molecular orientations. In this talk, we will present studies on LCE micro-rings, especially on how their mechanical deformations and dynamics are affected by their molecular orientations and geometric shapes.

**11:27AM S59.00002: Topography from topology in liquid crystal elastomer coatings***
YOUSSEF MOSADDEGHIAN GOLESTANI (Presenter), GREGA BABAKHANOVA, MICHAEL P VARGA, HAO YU, JONATHAN SELINGER, QI-HUO WEI, O D LAVRENTOVICH, ROBIN SELINGER, Kent State University — Liquid crystal elastomer (LCE) free-standing films containing topological defects deform on heating into three-dimensional shapes [1-3]. Attaching such LCE films to a rigid substrate as a coating provides the opportunity to create temperature-responsive surface topography, a phenomenon demonstrated by Babakhanova et al [4]. Using finite element method (FEM) simulation, we model surface deformations produced by LCE coatings with defects as a function of both topological charge and orientational phase angle. We find that, on heating, a radial +1 defect produces an inward depression while a circular +1 produces an outward elevation. The -1 defect and higher order +/- integer defects produce wrinkle patterns with out-of-plane surface deformations. By contrast, +/- half-integer defects give rise to both out-of-plane and in-plane displacements. Theoretical calculations in the limit of small strain elasticity explain these results and are compared with both FEM simulation and experimental data. **11:39AM S59.00003: Multi-responsive polymeric microstructures with encoded pre-determined and self-regulated deformability***
YUXING YAO (Presenter), Department of Chemistry and Chemical Biology, Harvard University, JAMES WATERS, Chemical Engineering Department, University of Pittsburgh, ANNA SHNEIDMAN, JIAXI CUI, XIAOGUANG WANG, NIKOLAJ MANDSBERG, John A. Paulson School of Engineering and Applied Sciences, Harvard University, SHUCONG LI, Department of Chemistry and Chemical Biology, Harvard University, ANNA CHRISTINA BALAZS, Chemical Engineering Department, University of Pittsburgh, JOANNA AIZENBERG, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Dynamic functions of biological systems often rely on arrays of actively deformable microstructures undergoing a huge range of pre-determined and self-regulated reconfigurations and motions. Here, we introduce stimuli-responsive microstructures based on liquid crystalline elastomers (LCEs) that display a broad range of hierarchical, even mechanically-unfavored deformation behaviors. Using patterned magnetic fields during polymerization, we encode any desired uniform mesogen orientation into the resulting LCE microstructures, which is read-out upon heating above the nematic-isotropic transition as a prescribed deformation. By further introducing light-responsive moieties, we demonstrate multi-functionality of the LCEs with three actuation modes controlled by different external stimuli. We finally create patterned arrays of microstructures with encoded area-specific deformation modes and show their functions in responsive release of cargo, image concealment, and light-controlled reflectivity. We foresee that this platform can be widely applied in soft robotics and smart buildings.

**11:51AM S59.00004: Electromechanical actuation of dielectric liquid crystal elastomers for soft robotics***
ZOEY S. DAVIDSON (Presenter), HAMED SHAHSAVAN, YUBING GUO, LINDSEY HINES, Physical Intelligence, Max Planck Institute for Intelligent Systems, YU XIA, SHU YANG, Department of Materials Science and Engineering, University of Pennsylvania, METIN SITTI, Physical Intelligence, Max Planck Institute for Intelligent Systems — Liquid crystal elastomers, networks of anisotropic molecules, are two-way reversible shape memory polymers. They have long been considered as intelligent materials reminiscent of biological muscles with orientational order. Despite significant developments in chemistry, processing, and handling methods of liquid crystal elastomers, most demonstrated actuation mechanisms still rely on thermal or optical stimulation, which often suffers low efficiency of energy conversion into useful work. Here, we report fast and efficient electrical stimulation of liquid crystal elastomer actuators with high output work density for potential soft robotics applications. Different from conventional dielectric elastomers, which often require prestrain, the intrinsic elastic anisotropy in liquid crystal elastomers allows us to design complex patterns of locally aligned liquid crystal molecules. In turn, we demonstrate pre-programmed twisting, bending, and other actuations.

12:03PM S59.00005: Programmed anisotropic transformations of cellular structures  SHUCONG LI (Presenter), GABRIELE LIBRANDI, Harvard University — The physical properties of metamaterials are controlled by the underlying material properties (molecular scale) as well as the design of the periodic structures, including shape, geometry, size, orientation, and arrangement (unit cell scale). Harnessing instabilities in soft materials based periodic structures offers an effective strategy to achieve multifunctionalities. Here, we report the programmable anisotropic transformations of cellular structures made of liquid crystalline elastomers (LCEs) on rigid substrates. By programming the mesogen alignment of liquid crystals (LC) using magnetic fields at the molecular scale, the desired anisotropies are introduced to periodic structures with different geometric designs at the unit cell scale. We demonstrate that the coupling of the two scales of controls leads to various novel deformation modes benefiting from both the mechanical guiding and the chemical guiding, which greatly broadens the design space of metamaterials. The design principle for programmed reconfigurations with prescribed anisotropies in periodic lattices is validated by both mechanics model and finite element simulation.

12:15PM S59.00006: Bioinspired design of vascular artificial muscle+ QIGUANG HE (Presenter), SHENGQIANG CAI, Mechanical and Aerospace Engineering Department, University of California, San Diego — Recently, liquid crystal elastomers (LCEs) have drawn much attention for its wide applications as artificial muscle in soft robotics, wearable devices and biomedical engineering. One commonly-adopted way to trigger deformation of LCEs is using embedded heating elements such as resistance heating wires and photo-thermal particles. To enable the material to recover to its unactuated state, passive and external cooling is often employed to lower down the temperature, which is typically slow and environmentally sensitive. Here, inspired by biology, we design and fabricate a vascular LCE-based artificial muscle (VLAM) with internal fluidic channel in which we inject hot or cool water to heat up or cool down the material to achieve fast actuation as well as recovery. We demonstrate that the actuation stress, strain and cyclic response rate of the VLAM are comparable to mammalian skeletal muscle. Because of the internal heating and cooling mechanism, VLAM shows very robust actuating performance within wide range of environmental temperature.

12:27PM S59.00007: Colloidal Micromachines Regulated by Liquid Crystals+ WYATT SHIELDS (Presenter), Harvard University, YOUNG KI KIM, Cornell University, KOOHEE HAN, NC State University, NICHOLAS ABBOTT, Cornell University, ORLIN D VELEV, NC State University — Reconfigurable microdevices have become a subject of intense interest due to their ability to harvest energy and change shape on demand. These attributes allow them to be used as robotic structures, constituents for self-healing materials, and switchable metamaterials. Yet, many of these structures are limited in utility by lack of control over their dynamics. Accordingly, much work has been done to engineer their shape, composition, and actuation as a means to control dynamics; however, little is known about regulation of their dynamics in complex fluid milieu. Here, we show how actuation of microdevices made from the assembly of patchy magnetic microcubes, which we refer to as “microbots”, can be regulated by the anisotropic viscoelastic environment of a liquid crystal (LC). We show that the elastic energy arising from the strain of LC around microbots directly influences their folding dynamics, which can be tuned by tailoring: (i) the far-field orientation of the LC and (ii) the local ordering of the LC at the microbot surfaces. These findings represent a first step towards establishing a general set of design rules to control the dynamics of actuating devices via use of anisotropic fluids.

12:39PM S59.00008: Programming Complex and Arbitrary Shape Changes in Liquid Crystal Elastomers+ MORGAN BARNES (Presenter), RAFAEL VERDUZCO, Rice University — Liquid crystal elastomers (LCEs) are reversible shape responsive materials that are promising for many applications including biomedical devices, microfluidic pumps and soft robotics. To date, programming complex shape changes in LCEs requires locally aligning the liquid crystals throughout the material to form a predetermined director profile. Here we demonstrate a straightforward method that does not rely on foresight of the liquid crystal director to program complex reversible shape changes. Using an optimized two-step synthesis method we mechanically deform the LCEs into arbitrary shapes between the first and second cure steps. The resulting competitive double-network LCE is capable of transitioning between its initial shape and its programmed shape when heated and cooled, respectively. We demonstrate the versatility of this method in a variety of shape changes including films capable of transforming into a flower and a face.

Electrorheological model based on liquid crystals membranes with applications to outer hair cells EDMON HERRERA VALENCE (Presenter), Chemical Engineering, FESZ-UNAM, ALEJANDRO REY, Chemical Engineering, McGill University — Liquid crystal flexoelectric actuation uses an imposed electric field to create membrane bending, this phenomenon is found in Outer Hair Cells (OHC) located in the inner ear, whose role is to amplify sound through generation of mechanical power. Oscillations in the OHC membranes create periodic viscoelastic flows in the contacting fluid media. A key objective of this work on flexoelectric actuation relevant to OHC is to find the relations and impact of the electro-mechanical properties of the membrane, the rheological properties of the viscoelastic Jeffrey's media, and the frequency response of the generated mechanical power output. When the inertia is neglected, the system follows a non-monotonically behavior in the power spectrum. This behavior is associated to the solvent contributions related to the retardation-Jeffreys mechanisms.

Design of a Novel Architecture to Improve the Performance of the Dielectric Elastomer Actuators MEHDI TORBATI (Presenter), KATIA BERTOLDI, Harvard University — This work aims to develop a geometry-based strategy to exploit the capabilities of the dielectric elastomer actuators (DEAs) for applications in soft robots. Owing to their fast response, light weight and high strain energy density, DEAs offer a remarkable actuation performance. However, the high voltage required to induce the electromechanical response not only increases the manufacturing cost it may also lead to breakdown of the material. Moreover, DEAs can only generate small amount of force that limits their applications to small scale functions. Here using the nonlinear electromechanical analysis, we optimize the arrangement of the electrodes and the applied boundary conditions to reduce the voltage required to actuate the elastomer. This naturally decreases the possibility of the electromechanical instability. Also, we propose a novel architecture which creates a snap through buckling that can be utilized for variety of functions in robotic applications.
1:39PM S59.00013: Polymer nanocomposites with reversible heat stiffening properties  SHAGHAYEGH KHANI, ELVIS CUDJOE, Case Western Reserve University, STUART J ROWAN, University of Chicago, JOAO MAIA (Presenter), Case Western Reserve University — Inspired by the defense mechanism of sea cucumber, a stimuli-responsive nanocomposite was fabricated that can reversibly increase its stiffness upon exposure to warm water. Experimentally, polymers with lower critical solution temperature (LCST) were grafted on cellulose nanocrystals embedded into a viscoelastic matrix. This material shows reversible heat-stiffening behavior analogous to sea-cucumber dermis. The stiffening behavior was hypothesized to occur due to formation of a percolating network by the nanofillers above the transition temperature. Energy Conserving Dissipative Particle Dynamics (EDPD) simulations were performed to examine the hypothesis. According to experimental data and simulation results, grafted LCST polymers disrupt the interactions between the nanocrystals below the transition temperature and upon exposure to warm water collapse of the LCST chains enhances the interactions between the cellulose nanocrystals and results in the subsequent stiffening.

1:51PM S59.00014: Dynamic Microcapsules from Complex Emulsion Drops*  JOERG WERNER (Presenter), SARAF NAWAR, BRENDAN DEVENEY, DAVID A WEITZ, Harvard University — Microcapsules are widely employed to protect and release sensitive cargo at predetermined trigger-events and rates. Since common release mechanisms involve degradation or destruction of the protective shell, their functionality is one-directional with single-use applicability. We demonstrate the fabrication of microcapsules that reversibly respond to external stimuli by changing the shell membrane's property without structural degradation, enabling the repeated and dynamic change of its permeability upon changing trigger events. The encapsulating shell in our system acts as an active gate-keeper, regulating diffusion in and out of the aqueous core compartment. I will describe microfluidic fabrication methods for complex emulsion drops and the development of a number of polymer chemistries that allow for the synthesis of trigger-responsive hydrogel shells directly around water drops without the need of sacrificial templates. The trigger responsive microcapsules are distinctly different from microgels, as the properties in microcapsules are dictated only by the state of the shell membrane that can make up less than 10% of the microparticle. The shape, size, and permeability of the microcapsules are dynamically and actively tunable with external triggers.

2:03PM S59.00015: Modelling discrete differential swelling in a bi-strip rolled gel  OZ OSHRI (Presenter), SANTIDAN BISWAS, ANNA CHRISTINA BALAZS, University of Pittsburgh — We derive an analytical model that allows us to quantitatively predict the features of 2D-to-3D shape changes in polymer gels that encompass different degrees of swelling within the material and thus, can model different regions of growth within the sample. Such gels can be realized, for example, by introducing variations in the cross-link density within the network or polymerizing the chains to be relatively longer in one area of the sample than another. Focusing on a bi-strip gel that swells into a "bi-roll", we determine the radii and amplitudes within a given roll, and the length of the transition layer between the two rolls. The predictions from our model agree quantitatively with available experimental data. In addition, we carry out numerical simulations that account for the complete non-linear behavior of the gel, and show good agreement between the analytical predictions and the numerical results. Models that provide quantitative predictions on the final morphology in such heterogeneously swelling hydrogels are useful not only for understanding growth patterns in biology, but also for establishing how to accurately tailor the structure of gels to meet the requirements of various technological applications.
11:15AM S60.00001: Opportunities for Doing Science at the NIST Center for Neutron Research [Invited] JOSEPH DURA (Presenter), National Institute of Standards and Technology — The NIST Center for Neutron Research, NCNR, operates a national user facility with widespread international usage providing 29 instruments, each optimized for specific measurement capabilities in a variety of disciplines including condensed matter physics, materials science, chemistry, chemical engineering, biology, geology, and others.

Several unique features give neutrons many advantages for probing condensed matter. Unlike optical and electron probes, the scattering length is not proportional to the atomic number, thus there is often good contrast for low Z, and between neighboring elements. Many elements have large isotopic differences in scattering length (notably hydrogen/deuterium and $^7$Li/$^6$Li), enabling control of contrast. Wavelengths from 0.01nm to 10nm can be used to probe length scales from the atomic to tens of microns. Neutrons directly probe magnetic features, from anti ferromagnetic order to large scaled structures such as skyrmions. Inelastic neutron scattering in which energy is exchanged with various excitation in a material enables spectroscopy of vibrational modes without selection rules and can be combined with crystallographic direction information. Neutrons are weakly interacting, enabling penetration into numerous in-operando sample environments, studies of buried structures and in some cases simpler or unique analysis, without beam damage to samples.

The NCNR has sample environments for control of temperature, pressure, magnetic field, and humidity, etc. and many relevant sample processing and pre-characterization capabilities. Users can be trained and supported by instrument scientists. An annual summer school is run to educate graduate students and others on neutron scattering techniques.

I will present an overview of the measurement capabilities available, the types of science they enable, and the modes of accessing these capabilities.

11:51AM S60.00002: Sirius, the new Brazilian Synchrotron Light Source* [Invited] HARRY WESTFAHL (Presenter), Laboratorio Nacional de Luz Sincrotron — The use of synchrotron radiation by a great variety of fields has increased steadily worldwide. This, to a large extent, is a result of the availability of the much brighter third-generation light sources, which allowed the development of new experimental techniques. Recently, new advances in accelerator technology are opening up the possibility of even brighter sources, which are being named fourth-generation light sources. Brazil gave an important contribution to science through the development of the necessary technology and the construction of the first synchrotron in the Southern Hemisphere, the Brazilian Synchrotron Light Laboratory (LNLS), still the only one in Latin America, that operates this installation as an open facility since 1997. Its pioneering activities in synchrotron science gave rise, with time, to the Brazilian Center for Research in Energy and Materials (CNPEM), a complex of four National Laboratories – LNLS itself, the Brazilian Biosciences National Laboratory (LNBio), the Brazilian Bioethanol Science and Technology Laboratory (CTBE) and the Brazilian Nanotechnology National Laboratory (LNNano). CNPEM is a research center that benefits more than two thousand researchers yearly. Sirius, the new Brazilian synchrotron light source being constructed at CNPEM, will be one of the first fourth-generation machines in the world. It will be a 3 GeV storage ring based on a five-bend-achromat (5BA) magnetic lattice that will be able to reach 250 pm.rad emittance (bare machine). It is being planned to be a state-of-the-art light source, providing cutting edge research tools that are nonexistent today in Brazil. In this talk an overview of themain characteristics, potentialities and status of the project will be provided.

Talk presented on behalf of the Sirius team.

*Sirius is funded by the Brazilian Federal Government via a contract with the Ministry of Science, Technology, Innovation and Communications.

12:27PM S60.00003: European Spallation Source: neutron scattering and technology of the XXI century [Invited] CHRISTIANE ALBA-SIMIONESCO (Presenter), European Neutron Scattering Association — TBD
The beamtime allocation is based on proposal system. There were 54 proposals in the first round. Turkey, Pakistan, Egypt, Iran and Jordan submitted the most proposals. The list also included Italy, Cyprus, Kenya, Palestine, France, Sweden, and Colombia. Most of the proposals were submitted in life sciences, chemistry, physics and materials sciences. There were also five proposals in the archeology/cultural heritage studies, indicating strong interest in this field. Half of the proposals are allocated beamtime, already putting SESAME in oversubscription form by a factor of two.

1:39PM S60.00005: New user facilities for condensed matter and material science in China [Invited] LI LU (Presenter), Synergetic Extreme condition User Facility — TBD

Thursday, March 7, 2019 11:15 AM - 2:03 PM

Session S61 GSOFT DFD: Steerable Colloids II BCEC 258B - Stefan Egelhaaf - Tag(s): Focus

11:15AM S61.00001: Role of shape and symmetry in externally driven micromotors [Invited] ALEXANDER LESHANSKY (Presenter), Technion - Israel Institute of Technology — Motion in fluids at the micrometric scale is dominated by viscosity. One efficient propulsion method relies on a weak uniform rotating magnetic field that drives a chiral object. From bacterial flagella to artificial magnetic nanohelices, rotation of a corkscrew is considered as a universally efficient propulsion gait. Although approximate theories concerning dynamics of slender magnetic helices are available, actuation of geometrically achiral particles or random aggregates was not well understood. I will present a general theory of magnetized object of arbitrary shape in a rotating magnetic field. It appears that its propulsion velocity can be written in a compact form as Rayleigh quotient in terms of geometry-dependent chirality matrix Ch, where both the diagonal elements (owing to inherent handedness) and off-diagonal entries (that do not necessitate handedness) contribute in a similar way. The theory anticipates multiplicity of stable rotational states predicting that, e.g., two identical magnetic objects may propel with different speeds or even in opposite directions. However, for a class of simple planar objects, there is particular magnetization whereas the pair of symmetric rotational states degenerates into a unique propulsion gait closely resembling that of an ideal helix. In other words, geometrically achiral object can acquire effective chirality due to its interaction with the external magnetic field. The developed theory was further applied to optimize the geometry/magnetization and to obtain purely geometric constraint on propulsion speed of arbitrary shaped magnetic object. Finally, I will discuss general symmetries (such as parity and charge conjugation) and establish correspondence between propulsive states of geometrically achiral planar objects depending on orientation of the dipolar moment.

11:51AM S61.00002: Programmable self-assembly of magnetic handshake materials* RAN NIU (Presenter), Physics Department, Cornell University, EDWARD PAUL ESPOSITO, James Franck Institute, The University of Chicago, CHRISY DU, School of Engineering and Applied Sciences, Harvard University, WEI WANG, Mechanical Engineering, Cornell University, JAKIN NG, Physics Department, Cornell University, MICHAEL PHILLIP BRENNER, School of Engineering and Applied Sciences, Harvard University, PAUL L MCEUEN, ITAI COHEN, Physics Department, Cornell University — An outstanding intellectual problem in nanoscience is the programmable self-assembly of smart, digital, and mechanically functional structures [1]. We propose to combine magnetic patterning with the design principles of molecular biology for programmable self-assembly. To be specific, we harness magnetic forces from (i) panels with a 2 x 2 pattern of magnetic domains so they bond together using specific, intelligent, interactions, analogous to Watson-Crick base pairs in DNA, and (ii) create programmed global structures, from assembly of magnetically patterned panels as well as strands that link these encoded panels in specific sequences. As a first step towards microscopic machines, we build macroscopic prototypes for proof-of-principle demonstration of information storage capability and programmable self-assembly of magnetic handshake materials.

12:03PM S61.00003: Collapse dynamics of chains of paramagnetic particles: the role of the susceptibility.* HAMED ABDI, RASAM SOHEILIAN, RANDALL ERB, CRAIG MALONEY (Presenter), Northeastern University — We use computer simulations to study the dynamics of the collapse of chains of paramagnetic particles subject to rotating magnetic fields at various magnetic susceptibility. The system is initialized at constant magnetic field with particles forming chains along the field axis. The dynamics of the chains depends on the field rotation rate and, surprisingly, the particle susceptibility. At low susceptibility, and at sufficiently high field rotation rate, the particles undergo a period of chaotic motion and finally decay into a periodic orbit, consistent with previous simulations and experiments. Surprisingly, at high enough susceptibility we find a qualitatively different behavior. The initial chain state remains essentially intact for all time with the local moments strongly influenced by the orientation of the chain and less dependent on the applied field than in the low-susceptibility case. Our results should be important for applications of paramagnetic particles where rotating extended structures are desired such as micro mixing and should motivate new experiments on suspensions of paramagnetic particles in regimes of higher susceptibility.

12:15PM S61.00004: ABSTRACT WITHDRAWN

12:27PM S61.00005: Hurricane dynamics in a membrane NAOMI OPPENHEIMER (Presenter), MICHAEL JOHN SHELLEY, Center for Computational Biology, Flatiron Institute — We study driven microscopic rotors immersed in a membrane. We show that for small distances, interactions between rotors are identical to interactions between vortices in an ideal 2D Euler fluid, while the longer-ranged ones relate to classical models of atmospheric dynamics. Going beyond idealized interactions between rotors, we examine the more realistic setting where rotors also interact through local repulsion. We show that initially random distributions of rotors will rapidly self-organize into rotating uniform lattices or random hyperuniform structures, and exhibit activity-induced phase separation.

12:39PM S61.00006: Optically driven birefringent rotators ALVIN MODIN (Presenter), MATAN YAH BEN ZION, MELISSA FERRARI, MARK D HANNEL II, PAUL M CHAIKIN, New York University — We use circularly polarized light to induce stable rotation in hundreds of colloidal micro-particles simultaneously. The optical angular momentum transferred to the particles creates a torque causing particle rotation. In the past, optical tweezers were used to rotate individual colloids while trapping them to the narrow waist of the focused beam. We use a defocused, circularly-polarized, beam to rotate multiple particles with minimal trapping. We developed a process for synthesizing stable birefringent vaterite particles that can rotate for long periods of times and characterized their optical and physical properties. Altering the handedness and intensity of the laser source allows us to control the frequency and switch between clockwise or counterclockwise rotation. We observe and discuss the interaction between the rotating particles.
12:51PM S61.00007: Light-driven capillary assembly and motion of hydrogel nanocomposite disks at the air/water interface

HYUNKI KIM (Presenter), JI-HWAN KANG, YING ZHOU, ALEXA KUENSTLER, TODD EMRICK, RYAN HAYWARD, University of Massachusetts Amherst — Modulation of capillary forces by active changes in shape is an approach used by a number of insects to achieve propulsion at air-water interfaces. Learning from nature, we have designed light-responsive sub-millimeter hydrogel disks that exhibit: (1) attraction, leading to formation of well-defined assemblies; (2) repulsion; or (3) sustained rotation, depending on the pattern of illumination. Fabrication of light-responsive hydrogel disks containing patterned gold nanoparticles (Au NPs) was achieved by photo-chemical reduction of Au$^{3+}$ ions to metallic Au NPs within micro-patterned temperature-responsive hydrogels. Photothermal deswelling of illuminated Au NP-containing hydrogel regions induced out-of-plane buckling and deformation of the air/water interface, with a characteristic response time of seconds. This provided a versatile means to control capillary interactions in both time and space, thereby leading to a diverse range of behaviors at the air/water interface.

1:03PM S61.00008: Controlling Colloidal Assembly through Optical Binding

DUSTIN KLECKNER (Presenter), DOMINIQUE DAVENPORT, University of California, Merced — Directed assembly of colloidal particles has attracted considerable interest from both a fundamental and applied perspective. Most approaches to colloidal self-assembly use short range forces, e.g. via patchy or shaped particles. As an alternative, I will discuss the possibility of using 'optical binding' - a long range inter-particle force generated by multiple light scattering - to control the assembly of particles via a tunable external field. Although this approach has many advantages in principle; significant experimental and modelling work is required to make this a practical approach. I will discuss our efforts in both directions.

*This work was supported by a grant from the Hellman Fellows Fund.

1:15PM S61.00009: Observations of Optically Bound Colloidal Assemblies

DOMINIQUE DAVENPORT (Presenter), DUSTIN KLECKNER, University of California, Merced — In recent years there has been growing interest in assembling complex structures from colloidal suspensions for use in both fundamental and applied studies. We are exploring a relatively new and highly tunable inter-particle colloidal force known as the optical binding force. The optical binding force is mediated by light scattering between two or more particles in an intense optical field which can be externally modified. We use experimental methods to impose this optical binding force onto clusters of dielectric colloidal particles. We will discuss unique behaviors that arise from this force, including the formation of multiple extended particle chains and formation of planar arrays.

*This work was supported by the Hellman Fellows Fund.

1:27PM S61.00010: Harnessing Complex Fluid Interfaces to Control Colloidal Assembly and Deposition

XIN YONG (Presenter), MINGFEI ZHAO, WILSON LUO, Mechanical Engineering, Binghamton University — Using lattice Boltzmann-Brownian dynamics (LB-BD) simulations, we model large-scale assembly of nanoparticles on liquid-vapor interfaces with complex geometries and investigate subsequent deposition upon complete evaporation. Particles aggregate into hexagonally close-packed monolayers on flat and spherical interfaces given appropriate value of the interaction parameter that couples fluid hydrodynamics and discrete particle dynamics. Detailed force analysis reveals a long-range attraction between particles, mimicking capillary interactions due to interface disturbance. On curved fluid interfaces with complex curvature fields, the particle dynamics is governed by pair capillary interactions and curvature-induced capillary migration. We develop a minimal theoretical model to predict equilibrium particle distribution on non-evaporating curved interfaces, which agrees well with simulation observation. Finally, we demonstrate that the interplay between evaporation-induced convective flow, particle pair interaction, and curvature-particle interaction results in distinct deposition patterns, which were obtained by using curved fluid interfaces as templates.

1:39PM S61.00011: Interstitial Particle Design for Active Colloidal Microstructures*  BRYAN VANSADERS (Presenter), Materials Science and Engineering, University of Michigan, SHARON GLOTZER, Chemical Engineering, University of Michigan — Defect microstructures in colloidal crystals can be viewed as complex localized motifs, distinct from the environments present throughout the bulk of the crystalline phase. These motifs are persistent sites which interstitial particles can adsorb onto and be trapped by. The degree to which interstitial particles are bound to the vicinity of defects can be explored as a function of particle geometry. We present here a method to maximize the strength of the preferential interaction that a rod-like interstitial experiences with defect microstructures that include edge dislocations. We show that for sufficiently strongly bound interstitials, microstructural migration can be induced by applying forces to the designed particle, making it active. This approach opens up many possibilities for dynamically manipulating the microstructure of colloidal crystals, with applications in shape changing colloidal assemblies. Furthermore, the line-like nature of dislocations permits widely separated interstitials to be connected, correlating their transport properties in a manner not typically possible with local particle interactions.

1:51PM S61.00012: Maze-solving via diffusiophoresis*  TANVI GANDHI (Presenter), University of California, San Diego, SOPHIE RAMANANARIVO, LadHyX, ANTOINE AUBRET, MASSIMO VERGASSOLA, JEREMIE PALACCI, University of California, San Diego — Mazes provide a simple model for many frequently-occurring structures and phenomena (e.g. human circulatory system, traffic in a city). It is often of interest to find the most efficient path in a maze (e.g. in order to transport materials). The problem of maze-solving poses a mathematical challenge: most analytic solutions can become computationally demanding as mazes become more complex, often relying on brute-force methods that involve exploring multiple paths before arriving at the solution. In this work, we present a novel method of solving the problem by exploiting the diffusiophoretic motion of colloids in a maze. We demonstrate our method experimentally via a microfluidic maze.

11:15AM S62.00001: Local orthorhombic lattice distortions in the paramagnetic tetragonal phase of superconducting NaFe$_{1-x}$Ni$_x$As*  [Invited]  PENGCHENG DAI (Presenter), Department of Physics and Astronomy, Rice University — Understanding the interplay between nematicity, magnetism and superconductivity is pivotal for elucidating the physics of iron-based superconductors. Here we use neutron scattering to probe magnetic and nematic orders throughout the phase diagram of NaFe$_{1-x}$Ni$_x$As, finding that while both static antiferromagnetic and nematic orders compete with superconductivity, the onset temperatures for these two orders remain well separated approaching the putative quantum critical points. We uncover local orthorhombic distortions that persist well above the tetragonal-to-orthorhombic structural transition temperature $T_s$ in underdoped samples and extend well into the overdoped regime that exhibits neither magnetic nor structural phase transitions. These unexpected local orthorhombic distortions display Curie-Weiss temperature dependence and become suppressed below the superconducting transition temperature $T_c$, suggesting that they result from the large nematic susceptibility near optimal superconductivity. Our results account for observations of rotational symmetry breaking above $T_{s}$, and attest to the presence of significant nematic fluctuations near optimal superconductivity.

*The single crystal growth and neutron scattering work at Rice is supported by the U.S. DOE, BES under contract no. DE-SC0012311 (P.D.). **11:51AM S62.00002: Orbital-selective correlations and superconductivity in the nematic FeSe** [Invited] JIAN-XIN ZHU (Presenter), Los Alamos National Laboratory, HAOYU HU, Rice University, RONG YU, Renmin University of China, EMILIAN NICA, University of British Columbia, QIMIAO SI, Rice University — The interplay between electronic orders, orbital-selective electronic correlations and associated superconductivity, has played a central role in the physics of emergent phases and unconventional superconductivity. This interplay has been found to be particularly pronounced in recently discovered iron-based superconductors. Motivated by the recent low-temperature experiments on iron selenide (FeSe), we theoretically study the electronic correlation effects and emerging superconductivity in a multiorbital model for this compound. We propose that the combination of various bond nematic orders with the ferro-orbital order can give rise to a surprisingly large orbital selectivity among the Fe-3d t2g orbitals in the normal state. This enhanced orbital selectivity is also reflected in the superconducting pairing amplitudes, which gives rise to a large gap anisotropy on the Fermi surface. Our results naturally explain the seemingly unusual observation of strong orbital selectivity and related unconventional superconductivity in the nematic phase of FeSe, thereby providing new insight into the nature of both the nematic order and the iron-based superconductivity in general.

*This work has in part been supported by the National Science Foundation of China Grant numbers 11674392 and Ministry of Science and Technology of China, National Program on Key Research Project Grant number 2016YFA0300504 (R.Y.), and by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award No. DE-SC0018197, the Robert A. Welch Foundation Grant No. C-1411 and a QuantEmX grant from ICAM and the Gordon and Betty Moore Foundation through Grant No. GBMF5305 (Q.S.), and by the U.S. DOE Office of Basic Energy Sciences E3B5 (J.-X.Z.).

**12:27PM S62.00003: Orbital selective magnetism, nematicity, and fluctuations in FeSe** [Invited] RUDOLF HACKL (Presenter), ANDREAS BAUM, Walther Meissner Institute, Bavarian Academy of Sciences and Humanities, HARRISON N RUIZ, Stanford University, NENAD LAZAREVIC, Institute of Physics Belgrade, YAO WANG, Harvard University, THOMAS U BOEHM, Walther Meissner Institute, Bavarian Academy of Sciences and Humanities, THOMAS WOLF, Karlsruhe Institute of Technology, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford University — Iron pnictides and chalcogenides have rich phase diagrams displaying superconductivity, nematic and spin density wave order, fluctuations and short-range magnetism. Yet, the magnetism observed in FeSe, for instance, is not necessarily of the same type as that in the pnictides since the typical nesting conditions of the Fermi surfaces are much less robust in the chalcogenides and the question as to strong versus weak coupling magnetism arises. Raman scattering experiments afford a window into the type of ordering and allow one to distinguish between itinerant and localized magnetism. We show how the response from a weakly coupled itinerant system can be distinguished from that of a Heisenberg-type localized magnet. We present results of light scattering experiments as a function of polarization and temperature. In the pnictides the Raman spectra display all features of a spin density wave while the spectra of FeSe are similar to those of systems with localized spins such as the cuprates. Our numerical simulations using exact diagonalization of a 4x4 cluster reproduce the experiments semi-quantitatively in the limit of a nearly frustrated spin-1 Heisenberg model (localized spins), in particular the low energy peak in B1g symmetry. The results indicate that the electrons in some of the orbitals are more localized in FeSe than in the pnictides and reopen the discussion on the type of nematic fluctuations observed recently.

**1:03PM S62.00004: ARPES probe of the electronic structure in the detwinned FeSe** [Invited] DONGHUI LU (Presenter), SLAC National Accelerator Laboratory, Stanford University — TBD
Intertwined and vestigial electronic phases in hole-doped Sr$_{1-x}$Na$_x$Fe$_2$As$_2$ [Invited]  
CHRISTOPH MEINGAST (Presenter), Karlsruhe Institute of Technology — Hole-doped ReFe$_2$As$_2$ (Re = Ba, Sr, Ca) exhibit much richer phase diagrams than the corresponding electron-doped systems. In particular, the phase diagram of Na-doped BaFe$_2$As$_2$ exhibits a small pocket of a double-Q reentrant C4 magnetic phase [1], as well as another yet unidentified magnetic phase [2]. In strong analogy with the charge order observed in underdoped cuprates [3], these additional phases compete strongly with the emerging superconducting order [2,4].

Here we present a detailed phase diagram of the Na-doped SrFe$_2$As$_2$ system using thermodynamic probes (heat capacity, thermal expansion and magnetization). The double-Q C4 reentrant phase is much more stable in this system, and our data demonstrates that the phase diagram of Na-doped SrFe$_2$As$_2$ exhibits even more complexity than the K- and Na-doped BaFe$_2$As$_2$ counterparts.

Session S63 DBIO GSNP: Statistical Physics of Large Populations of Cells: from Microbes to Tissues II

11:15AM S63.00001: Modeling the Solid-Fluid Transition in Ordered Biological Tissues* [Invited]  
PREETI SAHU (Presenter), Syracuse University, JANICE KANG, Hamilton College, GONCA ERDEMCI-TANDOGAN, M. LISA MANNING, Syracuse University — Biological functionality of tissues relies on its rheology. Fluidity of a 2D non-proliferating confluent tissue is contingent on cellular rearrangements which are called T1 transitions. In a 2D vertex model for disordered tissues, the tissue fluidizes when the T1 energy barriers disappear as the target shape index approaches a critical value (~3.81) [Bi 2015]. The linear response also becomes fluidlike (i.e. the shear modulus vanishes) at this same value. However, shear modulus of ordered ground states of 2D vertex models vanishes at a lower value (3.72) [Farhadifar 2007, Staple 2010]. Therefore, an interesting open question is whether the ground states of the 2D vertex model are fluid-like or solid-like between 3.72 and 3.81. In other words, does the “equation of state” for these systems have two branches (like glassy particulate matter) or only one? Using four-cell and many-cell numerical simulations, we demonstrate that for a hexagonal ground state, T1 energy barriers vanish only at ~3.81, indicating that ordered systems have the same critical point as disordered systems. We also develop a simple geometric argument that predicts the correct scaling of energy barriers with T1 edge length in these systems.

*This work was partially supported by NSF-PHY-1607416 and NSF DMR-1757749.

11:51AM S63.00002: Cell size regulation induces sustained oscillations in the population growth rate  
FARSHID JAFARPOUR (Presenter), Physics and Astronomy, University of Pennsylvania — There are negative correlations between the generation time of a biological cell and those of its descendants. If a cell grows for a longer time than expected, its daughter cells will be larger at birth and have to compensate for their sizes by dividing slightly earlier than expected. Otherwise, the noise in the generation times would accumulate over generations in the size of the cells, leading to extremely large cells. This process is known as cell size control. In this talk, I discuss the effect of these correlations on the dynamics of population growth of microorganisms. I show that any non-zero correlation that is due to cell-size control can induce long-term oscillations in the population growth rate. The population only reaches its steady state due to the often-neglected variability in the growth rates of individual cells. The relaxation time scale of the population to its steady state is determined from the distribution of single-cell growth rates independent of the details of the division process or the cell-size regulation. I propose an experimental method to measure single-cell growth variability by observing how long it takes for the population to reach its steady state, a measurement that is significantly easier and less biased than single-cell measurements.
12:03PM S63.00003: Cell-level mechanical heterogeneity promotes rigidity in confluent tissues  XINZHI LI (Presenter), DAPENG(MAX) BI, Northeastern University — Intra-tumor heterogeneity is one of the hallmarks of cancer, which describes the phenotypic differences among cells in a tumor or cellular collective. While genetic heterogeneity has been an intense focus of study, how mechanical variations among cells influence tissue mechanics is not well understood. Here, we investigate the effect of cell-to-cell mechanical heterogeneity on the overall bulk mechanics of a confluent 2d tissue using a vertex model-based approach. We find that the rigidity of a confluent tissue depends on overall statistical properties of single-cell properties such as mean and variance, rather than the specific functional form of its distribution. A single universal parameter - the fraction of mechanically rigid cells, $f_r$, can be used to characterize the tissue mechanical state. As $f_r$ is tuned, the tissue undergoes a rigidity percolation at a critical threshold of $f_r$. Remarkably, this rigidity percolation occurs at a much lower value than what is required for rigid-cell to form a spanning cluster. A mean field model is proposed to explain the discrepancy between rigidity and contact percolations.

12:15PM S63.00004: How diverse forms of phenotypic variability affect microbial growth in changing environments*  ETHAN LEVIEN (Presenter), ARIEL AMIR, School of Engineering and Applied Sciences, Harvard University, JANE KONDEV, Department of Physics, Brandeis University — Numerous organisms utilize phenotypic variability to hedge their bets against unpredictable environmental changes. In microbiology, the most well-studied example of this is bacterial persistence — the phenomenon by which some fraction of the population grows relatively slowly in exchange for decreased susceptibility to antibiotics. Experimental evidence suggests a distribution of many phenotypes, not just two growth states, plays a role in bacterial growth, yet the quantitative consequences of more general forms of phenotypic variability are not well understood. Here we model various forms of phenotypic variability in changing environments, including deterministic variability arising from asymmetric segregation at cell division, to stochastic variability resulting from noisy gene expression. In our model, single-cell growth rates are functions of the phenotype and the environmental state. We derive conditions on these functions that guarantee phenotypic variability will be beneficial to a population.

12:27PM S63.00005: Grow or Go? Studying fitness of cell populations using a mathematical model  NOAH REUTER (Presenter), MOUMITA DAS, School of Physics and Astronomy, Rochester Institute of Technology — In nature, no organism lives in an isolated environment. Competition between different organisms is a fact of life, and we are familiar with the famous phrase “Survival of the fittest” as the principle behind natural selection. But what factors decide whether one organism is more fit than another? Similar questions can be asked about cell populations. For a long time “evolutionary fitness” was thought to be simply determined by the rate at which an organism (or cell) reproduced. Recent studies have, however, questioned this view, and have suggested fast migration and invasion as a competing mechanism to fast reproduction. It has been observed that many types of cells and organisms favor either growth and proliferation, or rapid and distant migration. This is referred to as the grow or go hypothesis. We test this hypothesis using a computer simulation of populations of two types of cells, modeled as active, interacting particles. The two cell types have different self-propulsion speeds, and different rates of proliferation and death. The simulation assumes that the faster cells divide at slower rates and have shorter life spans. We investigate the migration and phase separation in this system and look to see which population is more successful in reaching the periphery.

12:39PM S63.00006: Statistics of single cell trajectories in a bacterial swarm  N. S. KARTHIK SOMAYAJI (Presenter), HARSHITHA SHANKAR KOTIAN, AMITH Z. ABDULLA, Centre for Nanoscience and Engineering, Indian Institute of Science, Bangalore, India, SHALINI HARKAR, Robert Bosch Centre for Cyber Physical systems, Indian Institute of Science, Bangalore, India, VARSHA SINGH, Molecular Reproduction, Development and Genetics, Indian Institute of Science, Bangalore, India, MANOJ M. VARMA, Centre for Nanoscience and Engineering, Indian Institute of Science, Bangalore, India — In our work, we analyse the microscopic characteristics of the motion of individual bacterial cells in an advancing bacterial swarm consisting of over 10 million individuals. Statistical analysis of single cell trajectories in the swarm reveals a correlated random walk with a mean growth direction. The trajectory length of the random walk was found to obey a log-normal distribution. The distribution of turning angles revealed an interesting situation with a Gaussian hump centred around zero over a uniform background. The peak in the distribution of turning angles could be reasonably fitted to a truncated normal distribution. The background (angles from [-180, -100] and its mirror [100, 180]) displayed a uniform distribution. Such a distribution can be thought of as arising from a weakly biased random walk where the bias provides the global mean direction of the swarm while the overall uniform background arises from the Brownian (unbiased) portion. The bias results in finite correlation of the current direction with the previous direction resulting in the Gaussian hump centred around zero. The observed statistics of motion at the microscopic level can thus predict the mean directed swarm motion.
12:51PM S63.00007: Big data of big tissues: deep neural networks to accelerate analysis of collective cell behaviors in large populations  JULIENNE LACHANCE (Presenter), DANIEL COHEN, Princeton University — Coordinated cellular motion is crucial for proper tissue organization and function. Biophysical statistics of group behaviors can provide key insights into these behaviors, such as detecting pathological changes. Applying statistical analyses to very large tissues (>50,000 cells) offers exciting potential but requires more versatile feature extraction approaches. Convolutional neural networks are increasingly promising for tasks such as object classification and segmentation (e.g., cells, phenotypes). In this study, we apply a U-Net style architecture for label-free nuclei detection using low-magnification, transmitted light imaging. We utilize UV-excited nuclear labels to achieve automatic annotation of the data. The benefits of label-free image segmentation with transmitted light microscopy are numerous: improved accessibility by allowing for feature extraction without fluorescence imaging; eliminating the phototoxicity that results from typical UV-excited nuclear labels; and unambiguous, rapid post-processing of massive datasets. Here, we assess the accuracy of the reconstructed nuclei, and present preliminary data using this tool to explore cellular distribution and migration statistics (e.g., order, neighbor arrangements, correlations) in large, complex tissue geometries.

1:03PM S63.00008: Effects of curvature and topology on collective cell migration in dense biological tissues  MARGHERITA DE MARZIO (Presenter), Harvard Medical School, JEFFREY FREDBERG, Harvard T.H. Chan School of Public Health, DAPENG BI, Northeastern University — Confluent epithelia line every organ surface and body cavity. The epithelial tissue typically remains quiescent and non-migratory while performing its routine barrier and immune functions but becomes dynamic and migratory during morphogenesis, repair, invasion and metastasis [1]. To model these processes, recent progress has been made using agent-based simulations [2] of multicellular behavior grown in cultures on flat space [3,4]. However, native epithelia typically comprise curved surfaces, such as embryos, and respiratory bronchioles, airways, intestines and embryos. On such curved geometry out-of-plane mechanical forces can influence cytoskeletal organization, cell-cell interaction and thus could influence migration and development. Here, we develop an agent-based cellular model to simulate the collective behavior on curved surfaces, such as spheres, ellipses and tubular structures. We explore how the curvature alters the nature of unjamming and glass transitions in tissues and how topological defects introduce new motion patterns.

1:15PM S63.00009: Failure Propagation in Cooperating Multicellular Systems*  DERVIS CAN VURAL (Presenter), PINAR ZORLUTUNA, University of Notre Dame — From microbial communities to eukaryotic tissues, biological function often hinges on the exchange of diffusing cooperative factors and public goods. When stressors or statistical fluctuations compromise the population locally, this leads to an interruption of these exchanges near by and creates a cascade of failures. Here we present analytical results on how failure propagates through a multicellular system right before its catastrophic end. We find that the failure of the system progresses on two fronts; through the propagation of a wave from the surface inwards, and simultaneously, a decay of the bulk that may or may not finalize with a sudden collapse. We obtain formulas governing the population dynamics and failure propagation velocity, and fit some of these findings to experimental measurements.

1:27PM S63.00010: Power-law distributions of T-cell clone abundances in a non-neutral birth-death-immigration model  RENAUD DESSALLES (Presenter), Biomathematics, UCLA, MARIA R D’ORSOGNA, Mathematics, CalState Northridge, THOMAS CHOU, Mathematics, UCLA — T-cells can then die or proliferate to produce new T-cells carrying the same receptor. This process can be described by a stochastic multitype birth-death-immigration (BDI) process. However, predictions of a simple neutral BDI process, where cells of all receptor types have the same immigration, birth, and death rates, do not reproduce the experimentally measured power-law clone size distributions. However, it is known that T-cell proliferation depends on its specific affinity to self-ligands and T-cells of certain receptors are more likely to be produced in the thymus. Here, we study a non-neutral BDI model, in which each clone has a specific immigration rate and a specific peripheral proliferation rate arising from different ligand affinities. Realistic distributions of immigration rates are generated from measured DNA, while hypothetical distributions of proliferations rates are tested. We also include a carrying capacity through the death rate to model the competition of lymphocytes for cytokines and to ensure homeostasis of the system. The effects of sampling of T-cells from an organism are also calculated. We show that a non-neutral model with sampling can describe the experimentally observed clone size distributions provided the appropriate T-cell heterogeneity is employed.
**1:39PM S63.00011: Extreme value analysis of gut microbial alterations in colorectal cancer**  
STEPHANIE SONG (Presenter), Wellesley College, PATRICIO JERALDO, JUN CHEN, NICHOLAS CHIA, Mayo Clinic — Gut microbes play a key role in colorectal carcinogenesis, yet reaching a consensus on which microbes remains challenging in part due to reliance on mean value estimates. We present an extreme value analysis for overcoming these limitations. By characterizing a power law fit to the relative abundances of microbes, we capture the same microbial signatures as more complex meta-analyses. Importantly, we show that our method is robust to the variations inherent in microbial community profiling and point to future directions for developing sensitive, robust analytical methods.

**1:51PM S63.00012: Characterization of Swarmer Cell Differentiation in *Proteus mirabilis***  
EMRAH SIMSEK (Presenter), MINSU KIM, Emory University — Some bacteria translocate across quasi-solid surfaces via a multicellular type of motility called swarming. Swarming is performed by highly elongated and hyperflagellated differentiated swarmer cells. It is known that swarmer cell differentiation occurs upon surface contact. However, cellular and environmental factors affecting swarmer cell differentiation remain poorly understood. Here, we studied swarmer cell differentiation in *Proteus mirabilis*. We found that swarmer differentiation occurs abruptly at a critical cell density. In order to understand this tight regulation, we have analyzed the gene regulatory network controlling the expression of the master regulator *flhDC*. Interestingly, our single-cell-level experiments show that both initiation of and commitment to differentiation are stochastic. Our efforts to mechanistically bridge this single-cell-level stochasticity in differentiation and its population-level tight regulation will also be discussed.

**2:03PM S63.00013: Optimal segregation of proteins: phase transitions and symmetry breaking**  
JIE LIN, JISEON MIN (Presenter), ARIEL AMIR, Harvard University — In stressed environments, microbial cells such as bacteria or yeast utilize various mechanisms to survive. One important mechanism is the asymmetric segregation of key proteins at cell division, placing one of the two daughter cells in a more favorable condition. We provide a general framework to describe the evolutionary origin of this asymmetric segregation. We compute the population fitness as a function of the protein segregation asymmetry $a$ and show that the value of $a$ which optimizes the population growth manifests a phase transition between symmetric and asymmetric partitioning phases. Surprisingly, the nature of phase transition is different for the case of beneficial proteins as opposed to deleterious proteins: a smooth (second order) transition from purely symmetric to asymmetric segregation is found in the former, while a sharp transition occurs in the latter. Our study elucidates the optimization problem faced by evolution in the context of protein segregation and motivates further investigation of asymmetric protein segregation in biological systems.

BCEC 259B - Chen Li, Johns Hopkins University - Tag(s): Undergraduate

**11:15AM S64.00001: Importance of body and leg adjustment for traversing cluttered terrain**  
YAQING WANG (Presenter), RATAN SADANAND OTHAYOTH MULLANKANDY, CHEN LI, Johns Hopkins University — Although robots are good at avoiding obstacles, in critical applications like search and rescue in cluttered terrain like earthquake rubble, they must traverse obstacles using effective physical interaction, an ability still missing from most robots. Here, we study how the ability to adjust body parts and legs contributes to cluttered terrain traversal using animal and robophysical experiments. To traverse grass-like beams, cockroaches adjusted their head, body, abdomen, and legs in coordination. As the animal pushed against the beams, its body pitched up due to terrain interaction. In response, the animal flexed its head repeatedly to reduce body pitching and physically feel out the terrain. In addition, the animal used two hind legs differentially, extending and depressing one more than the other ($P < 0.05$, ANOVA), to roll its body to align with the gap between beams to reduce terrain resistance. Finally, the animal pushed the lower hind leg backward on the ground to propel itself forward while flexing its abdomen to break body rubbing against beams. We developed a robot with the ability to flex its head and abdomen and differentially move its legs and used it as a physical model to study the principles of using reactive motions to modulate physical interaction to traverse.
11:27AM S64.00002: JUMP: Experiment-enabled Modeling of Click Beetle Jumps for Robotic Applications  
OPHELIA BOLMIN (Presenter), LIHUA WEI, University of Illinois at Urbana-Champaign, JAKE J SOCHA, Virginia Tech, MARIANNE ALLEYNE, ALISON DUNN, AIMY A WISSA, University of Illinois at Urbana-Champaign — Click beetles use a unique jumping maneuver to self-right without using their legs. The jump is power-amplified thanks to a hinge situated in the thoracic region. The hinge is composed of a peg and a mesosternal lip, two conformal parts that allow the body to be locked in an arched position before the energy-release phase, which results in a jump. The jump of the beetles is divided into three stages: the pre-jump (latching), take-off (snapping), and airborne (jump) stages. In this paper, we present data extracted from synchrotron x-rays experiments at Argonne National Laboratory. High-speed video recordings (1,000 – 30,000 fps) show the latching phase, the contraction of soft cuticle prior to energy release, and the quick snapping maneuver. To describe the latching and snapping phases of the jump, we integrated experimental and morphological data into new analytical models. A combined mechanical/friction model predicts the initiation of slip between the peg and lip, and a dynamic force analysis model calculates the center of mass accelerations and required torques at the hinge. Understanding the enabling physics of the three jump stages creates numerous opportunities for engineering applications including self-righting robots and power-amplifying actuation systems.

11:39AM S64.00003: A Robophysical Analysis and Gait Development for the NASA Resource Prospector Rover  
SIDDHARTH SHRIVASTAVA (Presenter), ANDRAS KARSAI, YASEMIN OZKAN AYDIN, VERONICA PAEZ, Georgia Institute of Technology, WILLIAM BLUETHMANN, ROBERT O. AMBROSE, NASA Johnson Space Center, DANIEL GOLDMAN, Georgia Institute of Technology — Planetary rovers can become entrapped in soft substrates. The LCROSS lunar mission in 2009 indicated that regolith was less consolidated at the lunar poles than the equator. This led NASA JSC to develop RP-15, a 300 kg rover capable of lifting and sweeping each wheel to develop a crawling behavior. To discover techniques to improve performance, we created a scaled (2.1 kg) robophysical rover, conducting systematic experiments in our autonomous tilting, aerating, and motion capture gantry apparatus. A combination of stepping and wheel rolling produced higher drawbar-pull than wheel rotation alone in any situation (~4x increase on a 0° poppy incline). We validated our findings through experiments on RP-15 at JSC (~2x on a 0° sand incline). On steeper slopes (up to 27°, near max angle of stability), a novel gait generated forward progress via terrain remodeling via controlled avalanches. Rolling front wheels led to substrate mound formation posterior to the rover with stepping/paddling hind wheels generating forward progress; the wheel-only and walking-only gaits led to backward progress. Single paddling/rolling wheel force measurements showed a 2x increase in normal force per gait cycle over pure rolling. Our discoveries generalize to weakened (via aeration) and wet granular media.

11:51AM S64.00004: Micro and nanorobots propelled by science  
JOHANNES SACHS, PEER FISCHER (Presenter), Micro Nano Molecular Systems, Max Planck Institute for Intelligent Systems — Nature has evolved many microorganisms that operate without neurons, yet exhibit remarkably complex behaviors. These are examples of autonomous machines whose function and interaction with the environment is entirely governed by the chemistry and physics at small scales. Since consciousness plays no role, there is thus no fundamental reason why we should not also be able to build and operate analogous synthetic microrobots. One key ingredient is the ability to synthesize and engineer complex 3D parts and ways to organize or assemble these components. Another challenge is to provide energy for activation, which calls for strategies that are entirely different to the many engineering solutions that have been devised at large scales. This talk will describe our efforts in realizing such systems — some with outside control, others that are entirely autonomous — at the smallest of scales.

12:03PM S64.00005: Kirigami pop-up spikes improve soft robot anchoring and locomotion under soil  
BANGYUAN LIU (Presenter), Mechanical Engineering, Georgia Institute of Technology, YASEMIN OZKAN AYDIN, DANIEL GOLDMAN, Physics, Georgia Institute of Technology, FRANK L HAMMOND III, Mechanical Engineering, Georgia Institute of Technology — Earthworms can move beneath soil by expanding parts of their bodies radially; bristles called chetae can work as anchors during surface locomotion but their efficacy during subsurface movement is unknown. We designed a soft, worm-like robot which models the putative earthworm anchoring mechanisms by combining Kirigami skin with radially-expanding pneumatic actuators. The robot consists of three pneumatic actuator segments: head and tail segments that expand radially as anchors, and a middle segment that elongates body. The Kirigami structure pops up when an actuator is radially expanded, forming bristle-like spikes, which penetrate the soil and improve the anchoring ability of segment. Improvements in anchoring are studied by measuring the differences in segment drag forces beneath soil. The performance of robot locomotion in soil terrain with or without Kirigami skin was measured in several terrain conditions (within a wet garden soil channel, buried in wet garden soil, and buried in sand) as the robot dragged payloads behind it. The Kirigami skin-covered robot exhibits a greater maximum drag force (improved from 0.43N to 1.35N), greater forward displacement per gait cycle, and higher traction (e.g., with an 80g payload, the 1.11cm/gait cycle improved to a 2.18cm/gait cycle).
12:15PM S64.00006: The use of robophysical mantis shrimp models to study ultra-fast "impulsive" biological an
synthetic systems*  EMMA STEINHARDT (Presenter), ROB J WOOD, Harvard University — Peacock mantis shrimp are
considered the fastest strikers in the animal kingdom, achieving punches in the range of 14-23 m/s in water – fast enough
to create cavitation bubbles and break clam shells. They accomplish this with a dactyl heel striking appendage only a few
centimeters long. In order to study these remarkable capabilities, we leverage recent breakthroughs in multi-scale, multi-
material rapid fabrication to create a physical model of the mantis shrimp at scale. The rapid release of energy storage is
accomplished through a torque reversal mechanism with a spring in parallel. Our preliminary design is capable of
achieving a 15.5 m/s peak velocity, 67.4% the peak velocity of biological mantis shrimp. We're able to demonstrate the
formation of cavitation bubbles in striking, and can produce peak forces of 100 N. Our analytical dynamic model is capable
of accurately predicting the trajectory and peak velocities of our current design. We will present designs using our model
that maximize velocity. Our simulation results will be accompanied by our experimental results for various fluid loads and
design parameters. These results will then be used to inform us on how the biological system operates and how the
underlying physics contribute to its performance.

12:27PM S64.00007: Coordination of legs and body undulation during turning in quadruped locomotion  BAXI
CHONG (Presenter), YASEMIN OZKAN AYDIN, School of physics, Georgia Tech, GUILLAUME SARTORETTI, Carnegie Mellon
University, JENNIFER RIESER, School of physics, Georgia Tech, HAOSEN XING, CHAOHUI GONG, HOWIE CHOSET, Carnegie Mellon
University, DANIEL GOLDMAN, School of physics, Georgia Tech — Sprawled-postured quadrupeds like lizards and salamanders
must coordinate limb with body movements to adjust their direction of motion while walking in environments with
obstacles. However, their robotics counterpart, the quadrupedal robots, often rely on adjusting their direction of motion
by introducing a lateral asymmetry in leg motion amplitude, making the stable transition between forward and turning
gaits difficult. We hypothesize that using properly-coordinated body undulation and limb movements will enable effective
locomotion and stable transitions between gaits. Using geometric mechanics, we design gaits by prescribing a footfall
pattern and optimizing the body undulation which produces a desired motion. We predict that rotations resulting from
coordination of body undulation and limb movements can simplify gait transitions in legged robots, and we verify our
predictions by measuring displacements and rotations of a robophysical quadruped locomoting through granular media.
We find that the amplitude of body undulation controls the steering angle, and thus controls the turning radius. In
particular, we find that by increasing the body undulation amplitude from $\pi/12$ to $\pi/8$, the turning radius decreased from
10.5±0.3 body lengths (BL) to 2.9±0.1 BL.

12:39PM S64.00008: Robophysical Investigation of Root Circumnutation through Heterogeneous Environment
MASON MURRAY-COOPER (Presenter), YASEMIN OZKAN AYDIN, ENES AYDIN, Georgia Institute of Technology, NICHOLAS
NACLERIO, Mechanical Engineering, UC Santa Barbara, ERIN N MCCASKEY, JENNIFER RIESER, ELLIOT HAWKES, DANIEL
GOLDMAN, Georgia Institute of Technology — Circumnutation, a cyclic endogenous circular pattern exhibited by the tip of a
growing root, occurs in a diversity of plants, but its function is not fully understood. To investigate the hypotheses that
such motion facilitates substrate penetration and exploration, we built a planar soft robot [Hawkes et al. 2017], which
grows from the tip like a plant root and can bend in 2D space by oscillating inflation of the series pneumatic artificial
muscles (sPAMs) arranged on the two sides. Existing work observed force reduction effects from circumnutation in
homogeneous granular material [Dottore et al. 2016]. Here we demonstrated that tip oscillation aids the robot to
penetrate heterogeneous environment, e.g. hard obstacles, by growing the robotic root into a lattice of rough cylinders
(d=8cm) distributed uniformly on a board (120X120cm^2). Systematic variation of initial robot positions revealed that the
non-oscillating tip strategy led to an increased probability to become pinned to obstacles and unable to grow more than
23.8±19.7cm; the oscillating tip penetrated the lattice significantly further, 55.2±24.9cm. The results show that without
complicated control and sensing mechanism, oscillatory movement of a growing structure enables robust navigation in a
heterogeneous environment.
cycles and self-right. Allowed the system to explore more phase offsets, increasing probability and reducing time to escape from failure limit cycles. Added randomness in appendage oscillations was critical to self-righting. Periodic oscillations limited the coupled-oscillator system to visiting only a few phase offsets, causing it to often be trapped near failure limit cycles. Added randomness in appendage oscillations also increases the time to reach the peak force. This is largely due to earlier contact time which causes the sand to fluidize with impacts at the angle of repose producing 55% less force compared to impacts on a flat bed. Greater substrate incline also increases the time to reach the peak force. This is largely due to earlier contact time which causes the sand to fluidize sooner. Results from impacts with different plate angles will also be discussed.

Running up a sand dune is a challenging task due to several factors. First, sand fluidizes when an external force exceeding the material yield stress is applied. Second, at the angle of repose, the sand pile is in a metastable state, such that small perturbations will cause fluidization. Ongoing studies show that sand specialist lizards exhibit lower performance decrements than desert generalist when running up inclined sand. Preliminary evidence suggests that these differences are largely correlated with different impact angles of the feet relative to the sand, indicating that differences in foot movement can have dramatic effects on running ability. In this study, we experimentally examine the vertical impact force of a flat plate (1 in x 1 in) against a glass beads with varying plate and substrate angles. The plate impacted the substrate at 0.6 m/s with a force sensor attachment. Here, we find that impact at higher angles reduces the peak force, with impacts at the angle of repose producing 55% less force compared to impacts on a flat bed. Greater substrate incline also increases the time to reach the peak force. This is largely due to earlier contact time which causes the sand to fluidize sooner. Results from impacts with different plate angles will also be discussed.

Randomness in appendage oscillations helps a robot self-right. We tested this idea using an experimentally validated multi-body dynamics simulation of the robot. As appendage oscillation randomness (coefficient of variation) increased from 1% typical of the well-controlled robot to 20% typical of the animal, the robot self-righted more often (43% vs. 69%) and more quickly (6.8 ± 3.9 s vs. 5.2 ± 3.8 s) (P < 0.001, ANOVA). We discovered that an appropriate phase offset between the two oscillations was critical to self-righting. Periodic oscillations limited the coupled-oscillator system to visiting only a few phase offsets, causing it to often be trapped near failure limit cycles. Added randomness in appendage oscillations allowed the system to explore more phase offsets, increasing probability and reducing time to escape from failure limit cycles and self-right.
1:39PM S64.00013: The stigmatic-start: a rapid non-planar gait in snakes  NICHOLAS CHARLES (Presenter), Harvard University, RAGHUNATH CHELAKKOT, Indian Institute of Technology Bombay, BRUCE YOUNG, Kirksville College of Osteopathic Medicine, MATTIA GAZZOLA, Mechanical Science and Engineering, University of Illinois at Urbana-Champaign, L MAHADEVAN, Harvard University — Newborn and juvenile yellow anacondas exhibit a previously unreported rapid transient gait, which we term the stigmatic-start. This is characterized by the snake first bending its body and then lifting itself partly out of the plane while moving forward about the mid-section. While superficially similar to sidewinding, the stigmatic-start is qualitatively different as it is a very rapid transient gait that allows the snake to move parallel to itself. To understand our observations, we construct a mathematical model for the non-planar locomotion of snakes that shows an interesting gait transition as a function of body size; small (juvenile) snakes can move via stigmatic locomotion but large (adult) snakes cannot, just as seen. In the context of biomimetic applications, the simulations of our model also suggest an avenue for optimal control of soft active filaments.

1:51PM S64.00014: Towards Obstacle-aided Legged Locomotion in Cluttered Environments*  FEIFEI QIAN (Presenter), DIVYA RAMESH, DANIEL E KODITSCHEK, University of Pennsylvania — Modern robots are often required to perform tasks in environments filled with obstacles and disturbances. However, most legged platforms are not yet capable of coping gracefully with unanticipated repeated disturbances, and often rely on active sensing to avoid all engagements with their physical surroundings. In this study, we propose a novel framework wherein we abstract the obstacle-cluttered environment into a horizontal-plane disturbance force field, and we consider robot legs as disturbance selectors. With different gait patterns, the robot can generate different disturbance forces on its center-of-mass from the same physical environment. Our simplified model significantly reduces the complexity of representing interactions between robot and obstacle-cluttered environments, and begins to suggest an approach to using gait space affordances for purposes of generating desirable obstacle responses in multi-legged robot locomotion amidst complex environments.

2:03PM S64.00015: Mechanics of snake slithering on deformable substrates.*  PERRIN SCHIEBEL (Presenter), JENNIFER RIESER, GEORGIA INSTITUTE OF TECHNOLOGY, HENRY ASTLEY, UNIVERSITY OF AKRON, ALEX M HUBBARD, KELIMAR DIAZ CRUZ, DANIEL GOLDMAN, GEORGIA INSTITUTE OF TECHNOLOGY — Elongate, limbless animals like snakes move in both fluid and terrestrial habitats using flexural waves of the body. Little is known about their movement in materials like mud and granular matter (GM) which provide propulsion while yielding but, unlike fluids, may be permanently deformed by the interaction. We studied the ~40 cm long desert-dwelling snake *C. occipitalis* slithering on the surface of homogeneous GM. The snakes traveled 30-80 cm/s using a stereotyped shape. Surface drag measurements revealed that the ratio of thrust to drag forces, a critical component in undulatory motion, did not depend on speed or depth. We developed a surface resistive force theory (RFT) which revealed their waveform maximized center-of-mass speed given a constraint on peak muscle power. The snakes' motion was non-inertial, so we explored the performance of a robophysical model, a 10-link 70 cm long robot snake. The waveforms RFT predicted would maximize the speed of the robot instead failed to make progress, largely because the robot would re-encounter previously disturbed material. The snakes' waveform was in the regime where motion is like that in a frictional fluid; by limiting material yield the animal avoided contending with the memory-dependent effects that stymied the robot.

11:15AM S65.00001: Measuring the energetics of transcriptional regulation in living cells using allelic manifolds*

[Invited] JUSTIN KINNEY (Presenter), Cold Spring Harbor Laboratory — Gene expression in all organisms is controlled by cooperative interactions between DNA-bound transcription factors (TFs), but quantitatively measuring TF-DNA and TF-TF interactions remains difficult. Here we introduce a strategy for precisely measuring the Gibbs free energy of such interactions in living cells. This strategy centers on the measurement and modeling of “allelic manifolds”, a multidimensional generalization of the classical genetics concept of allelic series. Allelic manifolds are measured using reporter assays performed on strategically designed DNA regulatory sequences. Quantitative biophysical models are then fit to the resulting data. We used this strategy to study regulation by two *Escherichia coli* TFs, CRP and σ70 RNA polymerase. Doing so, we consistently obtained energetic measurements precise to ~ 0.1 kcal/mol (equivalently, ~0.2 k_BT). We also obtained multiple results that deviate from the prior literature. Our strategy is compatible with massively parallel reporter assays in both prokaryotes and eukaryotes, and should therefore be highly scalable and broadly applicable.

11:51AM S65.00002: The Influence of Nucleosome Energetics on Chromatin Structure Across Multiple Length-Scales*

JOSHUA MOLLER (Presenter), University of Chicago, JOSHUA LEQUIEU, Chemical Engineering, University of California Santa Barbara, JUAN DE PABLO, University of Chicago — The physics governing nucleosome interactions influence structural features of chromatin across a range of length-scales. Here, we assess the extent of these interactions through Brownian dynamics simulations using a recently-developed coarse-grained model of chromatin. Simulations are used to interpret the hierarchy of interactions in chromatin fibers by quantifying the energetics of small-fibers including di- and trinucleosomes and isolating the factors which facilitate condensed configurations. Among these factors, we consider the influences of DNA sequence, nucleosome repeat length, and inclusion of the H1 linker histone. These small-fiber results are then used to assess the structure of larger chromatin fibers, revealing that nucleosomes in larger fibers favor configurations related to those exhibited in the small-scale systems. Lastly, we show that the linker histone significantly shifts the energetic minima of smaller systems, which corresponds to similar configuration changes of the larger chromatin fiber structure.

12:03PM S65.00003: Modeling the spreading of epigenetic marks at the Oct4 promoter*

MELINDA VARGA (Presenter), WILLIAM C. AIRD, Center for Vascular Biology Research and Department of Medicine, Division of Hematology and Oncology, Beth Israel Deaconess Medical Center, Boston, MA, ERZSÉBET RAVASZ REGAN, Biochemistry and Molecular Biology Program, The College of Wooster, Wooster, OH — Epigenetic phenomena govern a wide range of processes in biological systems from cell differentiation to cancer. Genes are activated and inactivated by the presence and absence of various epigenetic marks ranging from histone methylation and acetylation to DNA methylation. Several computational models were developed to shed light on the bistability of the expressed protein, but they are mostly conceptual inventories of mechanisms required for a switch-like behavior of promoters, without an attempt to match experimental data. Here we introduce a computational model of the promoter region of the Oct4 gene, in which we incorporate the processes of histone acetylation, histone methylation and the spreading of silencing marks via the HP1 protein complex, and DNA methylation. We show that our model's dynamics align well with experimental results measured at the Oct4 promoter of mouse embryonic stem cells and can be adapted to describe the behavior of various promoters. We expect our approach to offer an important predictive tool to probe the strength of the epigenetic barrier to turn on a silenced gene and to predict the dependence of this barrier on the spatial organization of CpG sites.

The role of activity from within and outside of the cell nucleus in nuclear blebbing

KUANG LIU (Presenter), Physics Department, Syracuse University, EDWARD BANIGAN, Institute for Medical Engineering & Science, MIT, ALISON E. PATTESON, Institute for Medicine and Engineering, University of Pennsylvania, J. M. SCHWARZ, Physics Department, Syracuse University — The cell nucleus is an active environment in which molecular motors such as RNA polymerase and condensin continuously remodel chromatin. Outside the nucleus, the cytoskeleton is an active semiflexible polymer network comprised of actin, microtubules, and intermediate filaments, with motors, such as myosin and kinesin, remodeling the network. These two active environments are mechanically coupled via LINC complexes embedded in the nuclear membranes, as well as direct steric interactions at their interface. We numerically study shape fluctuations at the interface of these two active environments. We focus on the formation of nuclear blebs, which are large bulges in the nuclear envelope that frequently occur in the cells of individuals with diseases, such as muscular dystrophy or progeria. In particular, we study how bleb formation depends on the type of activity in the nucleus, be it contractile or extensile, to explain such phenomena as nuclear blebs occurring more frequently for diseased cells in stiffer or more confined microenvironments than in softer ones.

Modeling intrinsic biases in high-throughput sequencing data for chromatin accessibility

SHENGEN HU, CHONGZHI ZANG (Presenter), University of Virginia — Genome-wide profiling of chromatin accessibility with the assay for transposase-accessible chromatin using sequencing (ATAC-seq) or DNaseI hypersensitivity sequencing (DNase-seq) has been widely used for studying regulatory DNA elements and transcriptional regulation in many cellular systems. Efficient and thorough computational analysis is essential for extracting biological information from such high-throughput sequencing data. It has been reported that DNase cleavage of DNA has sequence preferences that can significantly affect the footprint patterns at transcription factor binding sites in genomic profiles. We found that enzymatic sequence biases commonly exist in both bulk and single-cell chromatin accessibility profiling data. Using a regular simplex encoding model, we developed a quantitative approach for accurate characterization and systematic correction of intrinsic sequence biases contained in ATAC-seq and DNase-seq data. This approach can be applied in bioinformatics for improved analysis of high-throughput chromatin accessibility sequencing.

Polymer models of chromosome compaction during cell division

ANTON GOLOBORODKO (Presenter), Massachusetts Institute of Technology, JOHAN H. GIBCUS, Medical School, University of Massachusetts, Worcester, KUMIKO SAMEJIMA, ITARU SAMEJIMA, University of Edinburgh, NATALIA NAUMOVA, Medical School, University of Massachusetts, Worcester, JOHANNES NUEBLER, Massachusetts Institute of Technology, MASATO KANEMAKI, National Institute of Genetics, Shizuoka, Japan, LINFENG XIE, JAMES R. PAULSON, University of Wisconsin-Oshkosh, WILLIAM C. EARNSHAW, University of Edinburgh, JOB DEKKER, Medical School, University of Massachusetts, Worcester, LEONID MIRNY, Massachusetts Institute of Technology —

During mitosis, cells compact their chromosomes into dense rod-shaped structures to ensure their reliable transmission to daughter cells. Our work explores how cells achieve this compaction. In our study, we probe the chromosome organization by microscopy and Hi-C at multiple time points during cell division. We use these data to develop polymer models of chromosomes. We show that our Hi-C data can be explained with a simple analytical model, which accounts for compaction of chromosomes into consecutive loops. We further support our conclusions with large-scale detailed polymer simulations. Finally, we show that the model of loop extrusion can also explain the observed dynamics of chromatin compaction.

As a result, we delineate a detailed pathway of mitotic chromosome folding that unifies many previous observations. In prophase, loop extrusion compacts chromosomes into arrays of consecutive loops. In prometaphase, these loops become compacted into clusters of smaller nested loops and collapsed by chromatin-to-chromatin attraction. These loops adopt a “spiral staircase” structure with a helical scaffold. The combined action of these mechanisms achieves the 10,000-fold compaction of chromatin into linearly organized dense mitotic chromosomes.
The accurate separation of chromosomes during cell division is key to survival and proper development. As the nuclear envelope breaks down, the microtubules within the spindle begin to interact with chromosomes. The disordered chromosomes, then, congress and are aligned in the mid-plane of the bipolar spindle. The underlying active forces that move the chromosomes during this process are poorly understood. We utilize the data from the first full 3D tomographic reconstructions of *C. elegans* mitotic spindle to understand how individual microtubules interact with chromosomes and propose a microscopic theory for chromosome congression. In addition to predicting the observed length distribution of microtubules in tomography, our theory correctly predicts a mechanically stable half spindle structure, as is observed in cells with monopolar spindles. Most remarkably, we find that the shapes (curvature) of microtubules based on our micromechanical theory are in good agreement with the tomography results.
1:39PM S65.00011: Optimizing chromosome disentanglement via chromatin loop organization*  
SUMITABHA BRAHMACHARI (Presenter), Center for Theoretical Biological Physics, Rice University, JOHN FREDERICK MARKO, Physics and Astronomy, and Molecular Biosciences, Northwestern University — Chromosome structure is actively regulated by a concerted action of various proteins to avail vital cellular functions, like the mitotic segregation of chromosomes. We seek to understand the microscopic scheme underlying the structure manipulation that leads to a compact disentangled mitotic state from a less compact and more entangled state in interphase, and vice-versa. We model cellular chromosomes as polymer brushes in a confined volume, and calculate the level of inter-chromosome entanglement in a fluctuating-topology ensemble for various steady-state configurations defined by structural parameters like the grafting density and side chain or loop length. We find that entanglements are minimized for certain brush configurations that depend on net chromosome length. Comparing with existing experimental observations we suggest that chromosomal loops are important for maintaining a low level of entanglement during the cell cycle. Our model provides a steady-state description of chromosomes that is consistent with experimental observations for both the interphase and mitotic stages, where the cell-cycle-specific reorganizations in the structure are accounted for by evolution of the steady state, likely driven by loop extrusion.

1:51PM S65.00012: Modulation of the DNA accessibility in the nucleosome -- insights from basic physics.*  
ALEXEY ONUFRIEV (Presenter), Virginia Tech — The nucleosome, a complex of 147 base-pairs of DNA with eight histone proteins, must protect its DNA, but, at the same time, allow on-demand access to it when needed by the cell. The exact mechanism of the control remain unclear.

A simplified electrostatic model of the nucleosome reveals that at physiological conditions the complex is extremely stable, but at the same time is close to the phase boundary separating it from the "unwrapped" states where the DNA is accessible. A small drop in the charge (e.g. through acetylation of a lysine) of the globular histone core can significantly lower nucleosome stability, and thus increase DNA accessibility. The finding suggests that charge-altering post-translational modifications in the histone core might be utilized by the cell to modulate accessibility to its DNA at the nucleosome level.

A follow-up, detailed multi-state atomistic model explores virtually all possible charge-altering post-translational modifications (PTMs) in the globular histone core. The model reveals a rich and nuanced picture: the effect of PTMs varies greatly depending on location, including counter-intuitive trends such as decrease of DNA accessibility for some lysine acetylations in the core. A connection to transcription regulation in-vivo is made.

*NSF MCB-1715207

2:03PM S65.00013: How nucleoid associated proteins stabilize supercoiled DNA  
KATELYN DAHLKE (Presenter), CHARLES E. SING, University of Illinois at Urbana-Champaign — Nucleoid associated proteins (NAPs) play an important physical role in prokaryotic cells by manipulating the shape and structure of the DNA within the nucleoid. These NAPs bend or twist DNA, and there are indications that NAPs bind preferentially to DNA that is already locally deformed. We hypothesize that these binding behaviors and local deformations strongly impact the stability and structure of DNA.

We use coarse-grained simulation of NAPs and DNA that allow us to achieve the time and length scales where DNA supercoiling occurs. Supercoils are twist-induced structures that are the result of relaxing highly-twisted DNA by inducing higher degrees of bending and writhe. This model can capture experimentally observed supercoiling behavior, and also shows that NAPs that locally bend DNA enhance DNA supercoiling. We are able to show that NAPs tend to localize along the contour of the supercoil, and this binding preference is capable of stabilizing supercoils that form within the nucleoid. By tracking different energies within the system, such as the energy due to bending, extension, or excluded volume, we gain insights into what is driving this protein-mediated supercoiling.

Session S66 DBIO: Pathogens and Parasites: Evolution and Immune Response BCEC 261 - Armita

Nourmohammad, Princeton University
11:15AM S66.00001: A statistical ensemble approach to immune discrimination* ANDREAS MAYER (Presenter), Princeton University — The immune system needs to distinguish molecular signatures of pathogens from those found in the organisms’ own proteins. A naive, but universal way to discriminate is to whitelist everything that should not elicit a reaction. Can the immune system do better? To begin to answer this question we characterize the self and pathogen proteomes as statistical ensembles. Probabilistic models reveal how both universal and phyla-specific constraints on protein evolution shape the statistics of the proteomes. The models furthermore allow us to quantify to what extent the ensembles differ systematically. We analyze whether and how these differences might be used for efficient immune defense. Finally, we compare predictions to what is known about epitopes recognized by the immune system.

*A. Mayer was supported by a Lewis-Sigler Fellowship.

11:27AM S66.00002: Force-Induced Ultrasensitivity at Cell-Cell Interfaces* BING LI, STEVEN ABEL (Presenter), Department of Chemical and Biomolecular Engineering, University of Tennessee, Knoxville — Recent experiments have revealed that B cells use mechanical forces transmitted by the actin cytoskeleton to discriminate between antigens of similar binding affinity and to internalize portions of the antigen-presenting membrane. However, there is no unifying theoretical framework to probe the role of forces in antigen discrimination at cell-cell interfaces. In this work, we develop a hybrid computational approach to account for key biophysical properties of immune cell interfaces, including stochastic receptor-ligand binding kinetics, membrane mechanics, and actin-mediated forces on the membrane. We show that the number of B cell receptors (BCRs) bound to antigens increases in an ultrasensitive manner as a function of the binding affinity, and that the stiffness of the antigen-presenting membrane influences the threshold of the response. Above the threshold, antigens are internalized through a mechanism involving BCR clustering. Taken together, our results highlight the importance of forces at B cell interfaces and suggest that affinity discrimination is enhanced by membrane deformations, intracellular forces, and the dynamic spatial organization of surface receptors.

11:39AM S66.00003: Active tuning of synaptic patterns enhances affinity discrimination MILOS KNEZEVIC, SHENSHEN WANG (Presenter), Department of Physics and Astronomy, University of California Los Angeles, Los Angeles, CA, USA — Immune cells learn about their antigenic targets using tactile sense: during recognition, a highly organized yet dynamic motif, named immunological synapse, forms between immune cells and antigen-presenting cells (APCs). Via synapses, immune cells selectively extract recognized antigen from APCs by applying mechanical pulling forces generated by the contractile cytoskeleton. Curiously, depending on its stage of development, an immune cell exhibits distinct synaptic patterns which appear to strongly impact its capacity of distinguishing antigen affinities. While complete phase separation between receptor-ligand complexes and bound adhesion molecules observed in naïve (antigen-inexperienced) cells can be captured by existing models, how and why maturing cells maintain a multifocal pattern characteristic of arrested phase separation remains an unsolved puzzle. In this talk, I introduce a statistical-mechanical model to show that normal cytoskeletal forces can tune the degree of phase separation and thereby actively control the transition between distinct patterns. What is more, we find that normal forces coupled to lateral organization of receptors provide a robust grading scheme that allows efficient and broad affinity discrimination essential for proper immune function.

11:51AM S66.00004: Electronic Monitoring of Ligands-Induced Conformational Dynamics of Single Lysozymes* JAMES FROBERG (Presenter), MYUNGKEUN OH, YONGKI CHOI, North Dakota State University — We have investigated the dynamic interactions between lysozyme and several potential inhibitors such as peptide-based inhibitors, small-molecule inhibitors, and urea. In particular, the peptide-based inhibitor showed a weak affinity to lysozyme due to the non-covalent interactions between the C-terminus and the active site of lysozyme. Compared to the peptidoglycan substrates, the peptide inhibitor induced large conformational changes of lysozyme as well as stayed longer in the active site pockets while binding. The overall effectiveness of the peptide inhibitor was 20% when tested in the presence of both peptidoglycan substrates and inhibitors. The information gained by this research fundamentally improves our knowledge of lysozyme-inhibitor interactions, potentially paving the way to more effective, mechanism-focused drugs.

**12:03PM S66.00005: Macrophage phenotype bioengineered by magnetic field interference**  
JAREK WOSIK (Presenter), Electrical and Computer Engineering Department, University of Houston, MARTHA VILLAGRAN, Dept. of Physics and Texas Center for Superconductivity, University of Houston, WEI CHEN, The Houston Methodist Research Institute, Institute for Academic Medicine, PAVITHI WEERASINGHE, JOHN H MILLER, Dept. of Physics and Texas Center for Superconductivity, University of Houston, WANDA ZAGOZDZON-WOSIK, Electrical and Computer Engineering Department, University of Houston, MALGORZATA KLOC, The Houston Methodist Research Institute, Institute for Academic Medicine — Functionally different macrophages have different shape and molecular phenotype that depend on actin cytoskeleton. In all eukaryotic cells the cell shapes and the cell functions are reciprocally related. Thus, the mechanically/magnetically, genetically or biochemically enforced change in cell shape will profoundly reverberate at cell functions. Here we report that an exposure of macrophages to a nonuniform magnetic field causes extreme elongation of macrophages and has a profound effect on their molecular components and organelles. We observed that magnetic force rearranges the macrophage actin cytoskeleton, Golgi complex and cation channel receptor TRPM2 and modifies expression of macrophage molecular markers. We also analyzed magnetic-induced forces acting on macrophages and found that location and alignment of magnetic-field-elongated macrophages correlate very well with the simulated distribution and orientation of such magnetic-force lines. Such bioengineering of the macrophages properties has a potential to be used in development of novel anti-rejection therapies in clinical organ transplantation and anti-cancer and anti-metastatic therapies.

**12:15PM S66.00006: Collapse and contingency in phage infections of migrating bacterial populations**  
Derek J Ping (Presenter), Tong Wang, David Fraebel, Sergei Maslov, University of Illinois at Urbana-Champaign, Kim Sneppen, Niels Bohr Institute, Copenhagen University, Seppe Kuehn, University of Illinois at Urbana-Champaign — Natural bacterial populations are subject to constant predation pressure by phages. Since phage are non-motile perhaps the simplest defense against phage is for bacteria to outrun their predators. In particular, chemotaxis may help the bacteria escape slowly diffusing phages. Here we study phage infection dynamics in migrating bacterial populations driven by chemotaxis. We find that expanding phage-bacteria populations support two migrating fronts, an outermost “bacterial” front driven by nutrient uptake and chemotaxis and an inner “phage” front at which bacterial population collapses due to phage infection. We show that with increasing adsorption rate and initial phage population, the rate of migration of the phage front increases, eventually overtaking the bacterial front and driving the system from a regime where bacteria outrun a phage infection to one where they must evolve phage resistance to survive. We suggest that this process requires phages to hitchhike with the migrating bacterial front by repeatedly re-infecting the fastest moving bacteria. A deterministic model recapitulates the transition. Our work opens a new, spatiotemporal, line of investigation into the eco-evolutionary struggle between bacteria and their phage predators.

**12:27PM S66.00007: Bacterial Phage Resistance Emergence in Complex Landscapes of Stress**  
Krisztina Nagy (Presenter), Institute of Biophysics, Szged, Hungary, Trung Phan, Matthew Black, Princeton University, Julia Bos, Institute Pasteur, Robert Austin, Princeton University — We have begun studies of the emergence of loss of sensitivity of E. coli to the phages T4 and T4r using a microfabricated stress landscape where phage titers are distributed across an array of localized metapopulations. Sensitivity emerges from local biofilm-like pockets of bacteria and spreads as a form of colony hopping across the landscape. Sequencing on the insensitive bacterial colonies tests for both genetic mutations and additions of viral genome fragments in the CRISPR intervening spacer regions.

*This work was supported by NSF PHY-1659940.

**12:39PM S66.00008: A physical model for the selective assembly of HIV-1.**  
Chen Lin (Presenter), Chemistry and Biochemistry, University of California, Los Angeles, Ioulia Rouzina, Molecular Biology, The Ohio State University, Paola Espinosa, Orlando Guzman, Jose-Antonio Moreno, Department of Physics, UAM (Iztapalapa), Robijn Bruinsma, Physics and Astronomy, University of California, Los Angeles — We report on finding an intramolecular bound state of the structural Gag capsid protein of HIV-1 using a combination of all-atom Molecular Dynamics (MD) simulations and statistical mechanical modeling. The presence of this bound state prevents premature capsid assembly on non-viral host RNA. It would unify numerous observations that have been made on HIV-1. We show that the presence of a GFP sequence inserted into the Gag gene interferes with the formation of the bound-state, suggesting that such constructs can not be considered as representative of the wild-type Gag. The central role of the bound-state for the kinetics suggests a variety of possible routes for interfering with HIV-1 assembly.

1:27PM S66.00012: Stabilization of fine-scale host-pathogen diversity by spatiotemporal chaos  
ATISH AGARWALA (Presenter), MICHAEL PEARCE, DANIEL S FISHER, Stanford University — DNA sequencing studies have increasingly found that within microbial species, fine-scale genetic diversity coexists. A major open question is how such diversity can develop and be maintained under pervasive selection when the subtypes all compete locally. Host-pathogen interactions are often cited as a cause of diversity. But the behavior with large numbers of closely related (but distinct) types is not understood. We analyze a generalized Lotka-Volterra model of host-pathogen interactions. The set of pathogens are all similar, as are the hosts: we thus assume no explicit specificity and approximate the variations in the host-pathogen interactions as being random. The negative effect of a pathogen on a host is correlated with the positive-effect of that host on the pathogen: thus the full matrix of interactions has antisymmetric correlations. With purely antisymmetric interactions, there is a stable chaotic phase with many types surviving but the population of each type fluctuating wildly. Deviations from this special case cause runaway extinctions. We show that the addition of spatial structure can stabilize the chaos: there are local extinctions, but repopulations from other islands prevent a substantial fraction of the types from going globally extinct.

1:03PM S66.00010: Investigation of Lymphatic Filariasis via Computational Modeling*  
KI WOLF (Presenter), J. BRANDON DIXON, ALEXANDER ALEXEEV, Mechanical Engineering, Georgia Institute of Technology — Lymphatic filariasis is a disease caused by parasitic worm such as W. bancrofti, which lives and spreads between human and mosquitoes. The condition is prevalent in tropical countries, and its complication such as lymphedema affects millions worldwide. Although the filariasis-causing parasite can be treated, limited understanding of the interaction between lymphatic valve, vessel, and the parasite slows the effort to create an effective treatment for filariasis complications. To further investigate the parasite interaction with the lymphatic system, we present a fully-coupled, three-dimensional fluid-solid computational model that incorporates the parasite movement inside the lymphatic vessel. First, the parasite movement against various flow condition inside lymphatic system is simulated to investigate the mechanism behind worm's ability to stay and navigate complex and constricting flow environment like the lymphatic system. Then, the parasite's interaction with lymphatic valves is investigated under different worm and valve parameters, which helps to understand how the worm's motion inside the lymphatic system may lead to valve damage and complications like lymphedema.

1:15PM S66.00011: A mean-field computational approach to intra-host HIV mutational dynamics  
HANRONG CHEN (Presenter), University of Pennsylvania, MEHRAN KARDAR, Physics, MIT — During HIV infection, the intra-host population is attacked by host cytotoxic T lymphocyte (CTL) responses. CTLs kill HIV-infected cells by recognizing certain HIV peptides presented on their surface. HIV strains with mutations in these regions escape CTL recognition and hence gain a relative fitness advantage. Can the dynamics of HIV mutations during intra-host infection be predicted? The intrinsic fitness landscapes of various HIV proteins, describing replicative capacity as a function of amino acid sequence, have been inferred from the global prevalence of strains infecting diverse hosts. Here, we present a new method to compute intra-host HIV mutational dynamics given an intrinsic fitness landscape and CTL responses, which we designate the evolutionary mean-field (EMF) method. EMF is a high-recombination-rate model of HIV dynamics that outputs effective fields and frequencies of mutations at each residue over time. We show via an example how intrinsic fitness costs and epistatic interactions of longer-term dynamics using the effective fitnesses yielded by EMF. Finally, we extend EMF to stochastic population dynamics and quantify stochasticity in infection outcomes.

12:51PM S66.00009: Gaussian curvature and the budding kinetics of enveloped viruses  
SANJAY DHARMAVARAM, Mathematics, Bucknell University, BAOCHEN SHE (Presenter), Physics and Astronomy, University of California, Los Angeles, GUILLERMO R LAZARO, MICHAEL F HAGAN, Chemistry, Brandeis University, ROBIJN BRUINSSMA, Physics and Astronomy, University of California, Los Angeles — Recent Brownian dynamics simulations of enveloped virus budding (Lazaro et al. 2018) have reproduced the puzzling pausing and stalling phenomena observed on in-vivo viral budding. We show that the pausing/stalling can be understood as a purely kinetic phenomenon associated with a "geometrical" energy barrier. This barrier does not show in the equilibrium thermodynamics of the system but it must be overcome by capsid proteins diffusing along the membrane prior to incorporation into the viral capsid. The barrier is generated by the conflict between the positive Gauss curvature of the capsid and the large negative Gauss curvature of the neck region. The theory is compared with the Brownian simulations of the budding of enveloped viruses.

We thank the NSF-DMR for support under Grant 1610384 (SD, BS, RB); the Brandeis Center for Bioinspired Soft Materials, an NSF MRSEC, DMR-1420382 (GRL); and the NIH, Award Number R01GM108021 from the National Institute Of General Medical Sciences (GRL and MFH). 1:39PM S66.00013: Revealing Determinants for Antibody-Antigen Coevolutionary Outcome Using a Shape-Space Model  JIMING SHENG (Presenter), SHENSHEN WANG, Physics & Astronomy, University of California, Los Angeles — B cells in the adaptive immune system produce antibody molecules that bind foreign antigens for removal. The binding affinity of antibodies for an antigen is improved \textit{in vivo} through affinity maturation (AM) – a speedy Darwinian process occurring in numerous modest-size B cell populations housed by individual germinal centers (GC). A significant challenge arises when highly mutable pathogens (notably HIV) evolve on similar timescales as do B cell populations, evading an effective immune response.

Existing theoretical studies have ignored demographic fluctuations and precluded alternative evolutionary outcomes. In this talk, I extend the classic shape-space model to describe antibody-antigen coevolution via mutation and mutual selection. Using agent-based stochastic simulations, we show that consideration of population dynamics reveals diverse evolutionary outcomes and uncovers key determinants that can potentially be manipulated, including initial antigen diversity and epitope conservation. Moreover, we find population subdivision may slow down mutational escape of antigen. Finally, we suggest a possible route to evolving cross-reactive antibodies amenable to experimental search.

1:51PM S66.00014: Ultra small carbon nanodots as fluorescence markers in primary human cells: uptake and cellular distribution*  THOMAS HEINZEL (Presenter), STEFAN FASBENDER, Department of Physics, University of Dusseldorf, Germany, RAINER HAAS, University Hospital, University of Düsseldorf, Germany — Carbon nanodots (CNDs) are promising candidates for fluorescence labeling of cellular components as well as for drug and gene delivery. Therefore, the uptake dynamics of CNDs and their cellular distribution are of vital interest. Here, we report the preparation of CNDs by a simple pyrolysis process, their structural and spectroscopic characterization, and the observation of cell-specific uptake rates by the leukocyte family as well as for hematopoietic stem cells. Large uptake rates are observed, resulting in up to approximately $10^9$ CNDs per cell after 24 hours of incubation. [1] The CNDs distribute non-uniformly across the cells. In particular, they do not enter the nucleus and have a tendency to accumulate in the Golgi apparatus in living cells. Fixation of the cells leads to a homogenization of the CND distribution across the cytoplasm. We show that this behavior suggests uptake via endocytosis, followed by intra-cellular storage inside nanoscale vesicles. Furthermore, the CNDs have only a small effect on the cell viabilities over a period of 72 hours even at very large CND concentrations.

2:03PM S66.00015: Antimicrobial activity of sulphur-doped graphene quantum dots coupled with methylene blue for photodynamic therapy applications*  ALI ER (Presenter), KHOMIDKHODZHA Kholikov, ILHOM SAIDJAFARZODA, LAUREN COOPER, ERMEK BELEKOV, Western Kentucky University, OMER SAN, Oklahoma State University — Graphene quantum dots (GQDs) have attracted much attention and are a promising material with potential applications in many fields. One application of GQDs is as a photodynamic therapy agent that generates singlet oxygen. In this work, GQDs were grown by focusing nanosecond laser pulses into benzene and then were later combined with methylene blue (MB) and used to eradicate the Gram-negative bacteria, \textit{Escherichia coli}, and Gram-positive bacteria, \textit{Micrococcus luteus}. Theoretical calculation of pressure evolution was calculated using the standard finite difference method. Detailed characterization was performed with TEM, SEM, FTIR, UV-Vis, and photoluminescence spectra. Combining MB with GQDs caused enhanced singlet oxygen generation. Our results show that the MB-GQD combination efficiently destroys bacteria. The MTT assay was used to determine if GQDs in dark conditions caused human cellular side-effects and affected cancer and noncancer cellular viability. We found that even high concentrations of GQDs do not alter viability under dark conditions. These results suggest that the MB-GQD combination is a promising form of photodynamic therapy.

T70.00001: GENERAL

T70.00002: A Neoclassical Framework That Reunifies Modern Physics
ALAN M. KADIN (Presenter), Consultant, Princeton Junction, NJ 08550 — The unity of classical physics was broken by quantum uncertainty on the micro level and curved spacetime on the cosmic level. In contrast, a novel neoclassical picture is presented*, which incorporates key aspects of quantum and relativistic physics, while maintaining deterministic local reality at all levels. This is based on the following principles:
1) Real rotating vector fields self-organize into soliton-like wave packets with quantized spin; these represent elementary particles.
2) Characteristic frequency and wavelength of these wave packets define time and space, and are modulated by gravity.
3) Wave packets maintain constant frequency for both massive and massless particles, reproducing relativistic trajectories.
4) Transitions are due to continuous interactions between wave packets that conserve total frequency, wavevector, and spin.
This approach maintains quantum discreteness without Hilbert space, and reproduces curved light without spacetime. But this also predicts sharp deviations from some simple predictions of orthodox quantum theory, such as the two-stage Stern-Gerlach experiment.

T70.00003: Mesoscopic RLC Circuit and its Associated Occupation Number and Berry Phase
ERIC GREENWOOD (Presenter), Geology and Physics, University of Southern Indiana — We consider the quantization of the time-dependent harmonic oscillator and its associated Berry phase using the invariant operator method, as well as the occupation number of the induced quasi-particle production. Furthermore, we point out that in the literature there exist different methods for determining the solution to the Milne-Pinney equation, which leads to different results. By measuring the time-dependent occupation number and associated Berry phase, one can, in principle, determine which of these methods leads to physically realized results. As a concrete example, we consider the mesoscopic RLC circuit and derive the occupation number and associated Berry phase for each of these different methods. We find that, the solution to the Ermakov equations leads to a time-dependent occupation number and associated Berry phase, while the particular solution to the Milne-Pinney equation does not.

T70.00004: Tracking UV photolysis and molecular transport induced chemical changes within tissue models treated with a cold atmospheric pressure plasma jet*
BHAGIRATH GHIMIRE (Presenter), PRADEEP LAMICHHANE, EUN HA CHOI, Electrical and Biological Physics, Kwangwoon University — Cold atmospheric plasma jets operated into ambient air provide a rich source of reactive oxygen and nitrogen species (RONS), which are known to influence biological processes important in disease. Despite plasma shown to have effects deep within tissue (e.g. destruction of subcutaneous cancer tumors), it is not understood how the plasma RONS can reach deep-seated diseased cells. In this study, we model the plasma jet delivery of RONS into a tissue target and we delineate two processes: through target delivery of RONS generated (primarily) in the plasma jet and in situ RONS generation by UV photolysis within the target. RONS are rapidly generated in the tissue target's surface by UV photolysis. Once in the target, RONS are transported to millimeter depths via a slower molecular process.

T70.00005: Convolutional Autoencoder for Denoising Images of Active Nematics
ZHENGANG ZHOU (Presenter), PENG-YU HONG, MICHAEL NORTON, SETH FRADEN, Brandeis University — The images produced in active nematics experiments are usually quite noisy. These noises (caused by the activities of materials, lighting, etc.) can significantly influence the downstream analyses and constraint our capability of understanding active nematics. Conventional denoising methods have limited power in improving the quality of those images. In this study, we developed a Deep Learning technique to tackle this problem. We designed a deep denoising model as a deep convolutional auto-encoder with skip-layers. The deep denoising model was trained using randomly chosen clean images of active nematics. We also designed a convolutional reconstruction method that uses our deep denoising model to remove noises in new active nematics images. Experimental results demonstrate the effectiveness of our approach.
T70.00006: Spectral Stability of Gravitationally Interacting Rods  CARLOS OWUSU-ANSAH (Presenter), JOHN LINDNER, College of Wooster — We investigate the spectral stability of equilibrium configurations of two line-masses (slashes or rods) interacting via gravity. The Euler-Lagrange formalism provides the equations of motion. We determine the positions, orientations and angular velocities of the slashes at their equilibrium configurations. All equilibrium solutions are checked using the equations of motion. The spectral stability of each equilibrium configuration is determined by linearizing the equations of motion about the equilibrium configurations and analyzing the path of the slashes when they are perturbed. We illustrate the parameter values that cause equilibrium configurations to be spectrally stable.

T70.00007: Sliding on a Spinning Cuboid*  KIMBERLY PATTERSON (Presenter), JOHN LINDNER, College of Wooster — Which way is downhill on a spinning asteroid? Comet nuclei and asteroids like 67P, Ryuga, and Bennu are too small to gravitationally pull themselves into spheres. As spacecraft like Rosetta, Hayabusa2, and OSIRIS-REx visit them, a better understanding of the surface motion of regolith and boulders, as well as hoppers, landers, and rovers, is needed. For a theoretical overview, previous work studied the frictionless sliding of point masses on spinning asteroids idealized as rotating spheroids. In this work, we concentrate the curvature into 12 edges and study the periodic and chaotic motion of point masses sliding frictionlessly on rotating cuboids.

*NSF DMR 1560093

T70.00008: Three Roads to Quaternion Gravity  DOUGLAS SWEETSER (Presenter), Quaternions.com of Acton, MA — Three roads merge to create a different approach to gravity. Our deepest insights into nature use symmetries because symmetries remain unchanged. Using quaternion algebra instead of tensor calculus, the conservation of space-times-time is the symmetry underlying the quaternion gravity proposal for non-inertial observers in a gravitational field. Where there is a symmetry, there need also be a transformation law to detail how change is permitted to happen. The notion of relaxed relativity holds that in a gravitational field, one observer looking at another observer measuring the speed of light will find the product of wavelength and frequency differs from the speed of light \( c \) in a precise way \( c' = c \gamma^2 \text{esc} \). Lorentz invariance remains for inertial observers, but non-inertial observers are governed by different symmetries. Gravity is different everywhere, so a field theory is also necessary using gravitational escape velocities. With some reasonable guesses constrained by observations, one can form a quaternion gravity proposal that is consistent with weak field gravity tests to first order Parameterize Post Newtonian accuracy. No gravitons are required for this technical variant of special relativity. Pre-print available on line: http://bit.ly/vp-three-roads

T70.00009: Detection of biomarkers in lipidic cubic phases  MUNIR PIRBHAI (Presenter), St. Lawrence University — Lipidic cubic phases have been shown to be versatile platforms for the detection of biomarkers, viruses, bacteria and parasites. This technique produces birefringent crystals during a positive test, which can be detected by placing the sample between crossed-polarizers and shining light through. The intensity of light emerging from the setup constitutes the output signal, and can be related to the concentration of analyte present. In this work, we investigate how the thickness of the sample affects the output signal.

T70.00010: Gravity and Waves and Dimension Reduction  THOMAS MATERDEY, University of Massachusetts Boston, ALBERT MATERDEY (Presenter), Roxbury Community College, ALEXANDER MATERDEY, Quantum FC, Inc. — Gravity can interact with a mechanical wave to convert a 3D object into a 1D string, thus reducing space-time dimensions from 4 to 2. The physics of this gravity-wave interaction could form the basis of a semi-classical approach to quantum gravity.

T70.00011: MEDICAL PHYSICS —
Hyperspectral imaging of human hands and curvature correction

LUKA ROGELJ, Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia, URBAN PAVLOVČIČ, Faculty of Mechanical Engineering University of Ljubljana, Ljubljana, Slovenia, JOŠT STERGAR, ROK DOLENEC, Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia, MATIJA JEZERŠEK, Faculty of Mechanical Engineering University of Ljubljana, Ljubljana, Slovenia, MATIJA MILANIC (Presenter), URBAN SIMONČIČ, Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, Slovenia.

Hyperspectral imaging (HSI) is a non-contact and non-invasive method that provides spectral and spatial information in a single measurement. It has been recently introduced into the medical imaging as a research tool for determination of physiological parameters distribution (e.g., hemoglobin and oxygenation maps). An imaged surface curvature significantly affects illumination distribution over the surface and thus introduces artifacts in the recorded HSI. Such artifacts markedly affect accuracy of the image analysis, therefore a curvature correction of the images should be performed. In this study, hands of human volunteers were imaged by a HSI system (400–1000 nm spectral range) and a laser triangulation profilomer (LTP) providing 3D surface of the hands. Lambert cosine law and height corrections were applied to the recorded images. The corrected images show improved illumination homogeneity, effectively eliminating the curvature artifacts.

By combining HSI and LTP, hyperspectral images can be successfully corrected for the curvature artifacts, greatly improving accuracy of the further image analysis (original image discrepancy 12 %, corrected image discrepancy 4 %).

Curvature statistics: An underused measure for epithelial to mesenchymal transition classification in pancreatic cancer

JEFFREY LA (Presenter), JONATHAN P CELLI, CHANDRA S YELLESWARAPU, University of Massachusetts Boston — Epithelial to mesenchymal transition (EMT) and mesenchymal to epithelial transition (MET) plays an essential role in the local progression and metastasis of pancreatic cancer, whereby malignant cells undergo a physical transformation associated with increased mobility and resettle in a new site. Discovering EMT and MET's underlying molecular processes have opened new therapeutic agents, however knowledge of this complex network is not complete and design consistencies in literature limit inferences and prevent meta-analysis of data. Instead of focusing on chemical pathways, we revisit ways to characterize cellular shape through cellular curvature distribution. We demonstrate this measure can improve classification models of epithelial, mesenchymal, and transitioning cells, with pancreatic cancer cells by computational analysis of optical microscopy images, which can improve risk stratification and treatment decisions.

Sub-Nano Pulsed Laser Transport through Different Skin Types for Tattoo Removal Application

SHAH FAISAL MAZHAR (Presenter), REGINALD EZE, Math, Engineering & Computer Science, LaGuardia Community College — In this study, a thin scattering tissue layer model developed using modified Monte Carlo method [1] was used as skin model to simulate African American, Asian, and Caucasian skins and different laser transport trends were found for different skin types while running picosecond pulsed laser through the skin model. The optical properties of this skin types were simulated using their optical coefficients (i.e. absorption coefficient) found from the existing literature. The study of laser transport through different skin types and finding associated trends are significant for tattoo removal application in order to optimize the wavelength and pulse width of the laser from different skin types.

Material Design for Near-Infrared Photothermal Therapy

FAITH CHEUNG (Presenter), XUAN LUO, Physics, National Graphene Research and Development Center — Photothermal therapy, as a promising and emerging method of cancer treatment, uses the emission of near-infrared light for tumor ablation. However, current photothermal agents have led to inefficient tumor ablation due to its inability to penetrate deeply into affected tissue. In our research, we perform first-principles calculations to find the optimal materials for near-infrared light emission by doping graphene. Our results show the band gaps corresponding to near-infrared light emission and we claim that oxygen doped graphene is a suitable source for near-infrared light. It is possible to improve the efficiency of photothermal therapy by using these materials, hence our results pave the way for photothermal therapy.
Recently, 3D printing has become more popular due to the availability of new materials. For example, electrically conductive graphene-PLA composites can be used as a shield for electromagnetic interference (EMI); specifically, circuit packages 3D printed using conductive composites could provide shielding. The purpose of this research is to determine how the parameters of 3D printed samples impact the shielding effectiveness. Our previous research has shown that the percentage and orientation of infill has the greatest impact on conductivity. Here, we test shielding effectiveness from 10 MHz to 3 GHz by measuring RF transmission through a sample by sandwiching it between a custom coaxial tester connected to a spectrum analyzer. The data showed that the greater the infill percentage, the less the orientation effects attenuation. For example, 100% infill samples with perpendicular and parallel orientation both attenuated by -15 dB at 1 GHz. However, at lower infill percentages, more varied infill orientations differed in RF attenuation. For example, at 25% infill, samples with perpendicular and parallel infill attenuated by -20 dB and -12 dB at 1 GHz, respectively. The most efficient sample by mass had 25% infill orientated at 4 varying angles.

References:

Limiters, with their optical properties highly dependent on the wavelength and intensity of the incoming light, are often used to protect sensitive optical components. Currently most limiters are sacrificial, destroyed after a single high intensity exposure. As an alternative, this work focuses on photonic limiters because they significantly increase the cost-efficiency by their high damage threshold and reusability. We study a photonic limiter design with phase-change material (PCM) as a key component. To incorporate PCM in the limiter design, we use ellipsometry to characterize PCM optical property at a wide range of wavelength and temperature. An example of such materials is GeSbTe (GST), an alloy consisting of germanium, antimony and tellurium. Around a critical temperature, GST transforms from amorphous to crystalline, thereby switching its optical properties. Besides GST, we also examine the optical properties of other semiconductors such as ZnO and GaAs as possible material for other limiter designs.
T70.00022: Lithium niobate optomechanical crystal*  WENTAO JIANG (Presenter), RISHI N PATEL, FELIX MAYOR, TIMOTHY MCKENNA, PATRICIO ARRANGOIZ-ARRIOLA, CHRISTOPHER SARABALIS, RAPHAËL VAN LAER, AMIR SAFAVI-NAEINI, Department of Applied Physics and Ginzton Laboratory, Stanford University — Lithium niobate (LN) has excellent piezoelectric and electro-optic properties, enabling it as the workhorse material of the essential components for classical communication. Recently LN is also considered for quantum signal transduction and modulation. High-quality LN microring resonator and LN photonic crystal have been demonstrated with quality factor as high as $10^7$ and $10^5$ respectively. Here we demonstrate 1D LN optomechanical crystals with optical quality factor as high as 300,000, 2 GHz mechanical mode with quality factor as high as 37,000 at 4 Kelvin and zero-point optomechanical coupling rate $g/2\pi \sim 120$ kHz. The optomechanical coupling is shown to be tunable down to zero by designing the orientation of the crystal. We further utilize the piezoelectric coupling to drive the mechanical mode directly and optically readout the motion. We identify both the mechanical bandgap and the mechanical modes. The optomechanical coupling and the compatibility of the LN-on-silicon material system with microwave qubits demonstrate the enormous potential of this piezo-optomechanical platform for quantum electro-optic conversion and coupling between microwave nanomechanics and superconducting qubits.

*Work supported by a Packard Fellowship, ONR MURI QOMAND, and Stanford University.

T70.00023: Influence of ZnTe nanocrystals in the laser performance parameters of Yb$^{3+}$ doped phosphate glasses*  ALYSSON MIRANDA FREITAS, RODRIGO FERREIRA FALCI, MARIA JOSE V BELL, Universidade Federal de Juiz de Fora, NOELIO OLIVEIRA DANTAS, Universidade Federal de Alagoas, VIRGILIO ANJOS (Presenter), Universidade Federal de Juiz de Fora — This work reports an optical investigation of a phosphate glass (PZABP) doped with ZnTe semiconductors nanocrystals and co-doped with Yb$_2$O$_3$. ZnTe nanocrystals growing were evidenced by optical absorption spectra and their average radius were estimated via effective mass approach. The emission cross section, absorption cross section and lifetime measurements were performed via Optical Absorption, Photoluminescence and Time-Resolved Photoluminescence techniques. Important performance parameters for solid-state lasers, like the minimum fraction of ions that must be excited ($\beta_{\text{min}}$), the pump saturation intensity ($I_{\text{sat}}$) and the minimum intensity of the pumping laser ($I_{\text{min}}$) were obtained and the product $\sigma_{\text{emi}} \times t_{\text{exp}}$ was defined as a figure of merit to analyses the efficiency of the system. The influence of the ZnTe nanocrystals in the laser performance parameters was studied. The results point the alterations caused by the presence of the nanostructures may be compensated by the intensity gain on the media active and indicates the PZABP glasses as a promising material to applications in high power lasers.

*The authors would like to thank CNPq, CAPES and FAPEMIG for their financial support.

T70.00024: Role of Ni$^{2+}$ in transparent glass-ceramics with semiconductor nanocrystals for optoelectronic applications*  RADHA MADA, SESHADRI MERUVA, MARIA JOSE V BELL, Universidade Federal de Juiz de Fora, NOELIO OLIVEIRA DANTAS, Universidade Federal de Alagoas, VIRGILIO ANJOS (Presenter), Universidade Federal de Juiz de Fora — Phosphate glass doped with 5 wt% Ni$^{2+}$ ions and glass-ceramics containing ZnTe nanocrystals with x wt% of Ni$^{2+}$ ions (x = 0.5, 1.0, 5.0 and 10.0) were prepared by fusion method. The structural analyses were performed through XRD, FTIR-ATR and Raman techniques. The XRD revealed amorphous and ZnTe crystalline phases. Several phosphate groups were observed from FTIR-ATR and Raman spectra showing that Ni$^{2+}$ ions possess octahedral symmetry. The intensity of the 1352 nm band increased with the increase of Ni$^{2+}$ ions in GC which is an indicative of the $^{6}\text{Ni}^{2+}$ coordination. The emission cross-sections ($s_{\text{emi}}$), full width at half maxima for the $^1T_2g(D) \rightarrow ^3T_2g(F)$ and $^3T_2(F) \rightarrow ^3A_2(F)$ emissions were reported. The product of $s_{\text{emi}}$ and $t_{\text{mer}}$ (figure of merit) and $s_{\text{emi}}$ ($^3T_2(F) \rightarrow ^3A_2(F)$) was higher to GC sample with 10.0 wt% of Ni$^{2+}$. Thermal diffusivity (D) and thermal conductivity (K) were obtained through thermal lens and thermal relaxation methods. D and K did not change significantly with the increase of Ni$^{2+}$ ions (0.5 – 5 %) in GCs. The 10.0 wt% Ni$^{2+}$ sample presented the lower variation of the optical path with temperature with good lasing properties suggesting it as good candidate for optoelectronic applications.

*The authors would like to thank CNPq, CAPES and FAPEMIG for their financial support.
**T70.00025: Computational electro-magnetic field modeling of TMS coils with validation in gel-based phantom brain**

JOHN R GERMICK, XIAOJING ZHONG (Presenter), YIFEI WANG, Department of Electrical and Computer Engineering, Iowa State University, AARON BOES, HIROYUKI OYA, Carver College of Medicine, University of Iowa, DAVID C JILES, Department of Electrical and Computer Engineering, Iowa State University — Transcranial magnetic stimulation (TMS) is a noninvasive brain stimulation technique for modulation of cortical neurons in the brain. One challenge with the use of TMS is that it is often difficult to determine the spatial distribution of brain regions receiving stimulation. A popular method of exploring the stimulation profile of TMS coils is through generation of virtual head models and Finite Element Simulations (FEM). However, a limitation of this approach is the models are rarely validated against actual measurements of the magnetic and electric fields. Here, we performed FEM modeling on gel-based phantom brain models with conductive properties that mimic those of the human brain. The phantom brains had implanted electrocorticography electrodes at varying depths to record the stimulation profiles recorded by the electrodes, which were then compared with FEM models of the phantom brain. Ongoing work is focused on validating FEM results relative to a novel paradigm of recording the effects of TMS in neurosurgical patients with intracranial EEG. Taken together, this work highlights the strengths and limitations of using FEM to simulate the magnetic and electric field profiles generated by TMS coils, and propose a new method of testing the performance of novel TMS coils.

**T70.00026: Investigating how coil designs and anatomical variations affect the efficacy of cerebellar TMS**

XIAOJING ZHONG (Presenter), PRIYAM RASTOGI, YIFEI WANG, Iowa State University, ERIK G LEE, Department of Psychiatry, Massachusetts General Hospital, DAVID C JILES, Iowa State University — Transcranial magnetic stimulation (TMS) is a neuromodulation technique a non-invasive treatment for various neurological disorders such as major depressive disorder. Cerebellum is a complex structure connected with almost the entire central nervous system, and TMS has promise for non-invasively probing cerebellar function. Therefore, TMS has been gaining popularity in the field of neurostimulation of cerebellum. Recent studies have reported that cerebellum plays an important role not only in motor planning and behavior but also in the cognitive domain. Nevertheless, few studies have explored how different coil designs and anatomical variations affect the effectiveness of cerebellar TMS. In this work, we investigated the effects of cerebellar TMS with different coil designs positioning on several locations. Finite element modeling was conducted with Figure-of-8 coil and DB-80 coil. Each coil was positioned in the center, 1 cm and 3 cm to the left with respect to the center of the cerebellum and all the locations were tangential to the scalp at a distance of 5 mm. Furthermore, the commercial head model MIDA and 50 MRI derived head models were used in the computer modelling to examine how anatomical variations affect the efficacy of cerebellar TMS.

**T70.00027: Magnetic properties of synthesized Fe_x(Fe_3O_4)_1-x nanoparticles with core-shell structures coated by carbon matrix**

ARAM MANUKYAN, HARUTYUN GYULASARYAN, EDUARD SHAROYAN, Laboratory of Solid State Physics, Ashtarak-2, Laboratory for Physical Research, NAS of Armenia, JENNIFER LYNN GRAY, Materials Characterization Lab, Pennsylvania State University, Materials Research Institute, OSCAR BERNAL, ARMEN KOCHARIAN (Presenter), Department of Physics, California State University Los Angeles — Here we are focused on investigation of magnetic and structural properties of synthesized nanocomposites with iron nanoparticles as effective heat mediators with high thermal energy transfer efficiency suitable for use for magnetic hyperthermia. These nanoparticles have “core-shell” structure, in which the core has a high magnetic moment (such as Fe), and the shell consists of a biocompatible material (e.g. iron oxide or carbide). Complex investigations of structural and magnetic properties of these materials are obtained using X-ray diffraction (XRD), Raman spectroscopy, magnetometry, electron paramagnetic and ferromagnetic resonances (EPR, FMR). The measured magnetization of magnetic saturation and coercivity as well as the specific absorption rate (SAR) show that these materials attractive for magnetic hyperthermia applications. Hysteresis loop of the (Fe-Fe_3C)@C nanocomposites is of special interest as it shows almost square behaviour, where M_r/M(200 Oe) = 0.75.

*This work was supported by a grant from the Russian-Armenian (Slavonic) University at the expense of the Ministry of Education and Science of the Russian Federation. The work at CSULA was supported by the National Science Foundation-Partnerships for Research and Education in Materials under Grant DMR-1523588.
T70.00028: Nucleic Acid Functionalization of Graphene and the Impact on Stem Cell Maturation  VINCENT BATTISINI OLIVIERI, Tufts University School of Medicine, LAN WEI, Molecular Cardiology Research Institute, Tufts University School of Medicine, MICHELLE CHEN (Presenter), Physics and Engineering, Point Loma Nazarene University, HOWARD H CHEN, Molecular Cardiology Research Institute, Tufts University School of Medicine — Stem cells are capable of differentiating into defined cell types, thus hold great promise for medical applications including disease modeling, drug screening, and therapeutics. When integrated with graphene, an extremely conductive and strong atomic sheet of carbon atoms, novel ways to understand and control the differentiation of stem cells may be realized. We hypothesize that nucleic-acid functionalized graphene minimally impact stem cell viability, and can further enhance stem cell differentiation. In our experiments, various nucleic acid constructs were successfully purified and characterized before functionalization onto graphene, which was synthesized on copper via chemical vapor deposition and then transferred onto glass coverslip. Stem cells, primary bone marrow mononuclear cells (BMMCs), were isolated from mice and cultured on nucleic acid functionalized graphene. Preliminary atomic force microscopy revealed prominent 3-dimensional features of greater than 30 nm in height 24 hours after stem cell attachment, suggesting the presence of viable BMMCs. Furthermore, cell topography and significant adhesion to nucleic acid-graphene substrate suggests robust cell viability. Our findings indicate potential enhancement of graphene for stem cell viability and differentiation.

T70.00029: INSTRUMENTATION AND MEASUREMENTS —

T70.00030: Determination of cantilever's spring constant by using single-optic-fiber radiation-pressure technique  HEONHWA CHOI, JAE-HYUK CHOI (Presenter), Korea Research Institute of Standards and Science — We generated sub-femtonewton radiation-pressure forces to drive a very soft silicon-nitride cantilever without highly reflective coating and determine its spring constant in the range of \(10^{-5} \text{ N/m.}\) To be applicable to cantilevers of general dimensions and reflectivity, we built an experimental setup with a single optic fiber accessing a cantilever surface and an in-situ reflectivity measurement feature. A 1320-nm laser from a superluminescent diode was used to generate oscillating forces of 0.2–1 femtonewton, and a tunable laser to measure the cantilever’s displacement and its absolute distance from the fiber. The origin of the discrepancy between the obtained and bulk values of silicon-nitride reflectivity is to be discussed.

T70.00031: Development of the Millimeter-wave Camera with High Time Resolution for Observation of the Vortex Beam  ASAKI TANABE (Presenter), Nagoya University, TOKIHKO TOKUZAWA, National Institute for Fusion Science, SOKENDAI, YUKI GOTO, Nagoya University, TORU II TSUJIMURA, SHIN KUBO, National Institute for Fusion Science — Recently, it has been shown that a charged particle with spiral motion creates a radiation field with vortex property [1]. Since an electron in the magnetic field confinement fusion plasma has a spiral motion (electron cyclotron motion), the electron cyclotron emission (ECE) should have a vortex property. In order to demonstrate the vortex property, we will investigate the ECE from the gyro phase control electron. In this research, radiation pattern measurement of less than millisecond is required, so we are developing millimeter wave camera with high temporal resolution.

The designed camera consists of an array of horn antennas followed by waveguides and microstrip lines for directing the millimeter wave power to an array of high time resolution detectors. Optimization of the coupling from the waveguide to the microstrip line and the detector is performed using the 3D finite difference time domain method (FDTD method). The details of the optimization of the camera design and resultant experimental characteristic of this camera will be discussed.

T70.00032: Extracting Ion Transport Properties from Scanning Probe Measurements on Smectite Clay Nanoparticles  AYDIN WELLS (Presenter), KELSEY YEE, N. E. ISRAELOFF, Northeastern University — Using finite element modelling, electronic simulations under an electrical load can be designed to better understand ion transport properties of smectite clay nanoparticles (NP). Smectite clay is a layered, porous material capable of changing its physical properties when hydrated upon exposure to water vapor. With a conducting atomic force microscope (AFM) tip, scans on the surface of these particles were done; data relating to particle topography and frequency-dependent electric forces was extracted from these experiments. A finite element method (FEM) model and Matlab programs were constructed to facilitate simulation of AFM system parameters, measurements, and computation. The equivalent charge method offered an advanced approach to computing NP electric properties with the irregular shaped AFM tip by modeling the force resulting from a series of test charge-image interactions. FEM simulations revealed that dielectric phase shift followed a power law with increasing voltage frequency on the AFM tip. With different conductivity anisotropy, force derivative and phase shift values were observed to have different frequency dependencies. Computational results were paired with experimental findings to extract frequency dependent NP conductivity to compare to bulk measurements.
The Casimir Effect is a physical manifestation of quantum fluctuations of the electromagnetic vacuum. When two metal plates are placed closely together, typically much less than a micron, the long wavelength modes between them are frozen out, giving rise to a net attractive force between the plates, scaling as $d^{-4}$ (or $d^{-3}$ for a spherical-planar geometry) even when they are not electrically charged. In this work we show that by modifying a post-release MEMS accelerometer, similar to the one in your phone, we can actually measure this effect in ambient conditions. This device is a step towards leveraging the Casimir Effect for cheap, sensitive, room temperature quantum metrology.

*This work is funded by the National Science Foundation grant no. 1708283, the Engineering Research Centers Program of the National Science Foundation through NSF (11) (12) 16 Cooperative Agreement under Grant EEC-0812056, Grant EEC-1647837, and Grant ECCS-1708283, and the DARPA Atoms to Product (A2P) Program/Air Force Research Laboratory (AFRL) contract no. FA8650-15-C-7545.

T70.00034: Superconducting Nanowire Single Photon Detectors for Nuclear Physics+ TOMAS POLAKOVIC (Presenter), Physics Division, Argonne National Laboratory, JOHN E. PEARSON, AXEL F HOFFMANN, Materials Science Division, Argonne National Laboratory, VOLODYMYR YEFREMENKO, CLARENCE CHANG, High Energy Physics Division, Argonne National Laboratory, WHITNEY ARMSTRONG, ZEIN-EDDINE MEZIANI, KAWTAR HAFIDI, Physics Division, Argonne National Laboratory, GORAN KARAPETROV, Department of Physics, Drexel University, VALENTYN NOVOSAD, Materials Science Division & Physics Division, Argonne National Laboratory — Superconducting nanowire single photon detectors (SNSPD) are becoming the most prominent technology in the fields of nanophotonics and quantum information sciences because of their excellent detection efficiency and timing capabilities. The possibility of high detection rates and superior timing jitter, they are also an attractive technology in the field of nuclear and particle physics as a replacement for conventional light detectors or as detectors of charged particles. These applications have unique challenges, as the detectors need to operate in strong magnetic fields and withstand radiation damage.

We present results of characterization of Niobium Nitride SNSPDs fabricated by ion beam assisted sputtering with focus on their detection capabilities in magnetic fields and effects of radiation damage on the material and detection characteristics.

*This work was supported by the U. S. Department of Energy (DOE), Office of Science, Offices of Nuclear Physics, Basic Energy Sciences, Materials Sciences and Engineering Division under Contract No. DE-AC02-06CH11357.

T70.00035: HAXPES Lab: A novel laboratory-based Hard X-ray Photoelectron Spectroscopy System ANNA REGOUTZ (Presenter), Imperial College London, MANFRED MASCHECK, TOMAS WIEL, SUSANNA ERIKSSON, CRISTOPHER LILJENBERG, Scienta Omicron, KORNELIUS TETZNER, Imperial College London, BENJAMIN WILLIAMSON, DAVID SCANLON, University College London, PAUL PALMGREN, Scienta Omicron — Hard X-ray photoelectron spectroscopy (HAXPES) uses X-rays in the 2-10 keV range to excite photoelectrons, which are used to non-destructively probe the local chemistry and electronic structure of materials. It is particularly useful as it can be applied to bulk as well as structured samples. HAXPES is a powerful technique for the study of buried layers and interfaces in multilayer thin film stacks and composite materials. Up to now HAXPES was only available at synchrotron sources, which provide the necessary intense, high energy X-rays. This work presents a new laboratory-based instrument capable of delivering monochromated hard X-rays with an energy of 9.25 keV, giving an excellent energy resolution of <0.5 eV. The instrument behaviour and capability is showcased by experimental results from reference as well as technologically relevant systems, including TiO$_2$ bulk samples and multilayer metal oxide structures used in transistors. Measurements including shallow and deep core levels, Auger lines, and valence bands will be presented, including comparison of valence data with theoretical density of states calculations.

T70.00036: Diffraction of the Millimeter Wave with Vortex Property by a Triangular Aperture YUKI GOTO (Presenter), Nagoya University, TORU II TSUJIMURA, SHIN KUBO, National Institute for Fusion Science — Recently, it has been shown that a radiation from a charged particle with spiral motion has vortex property. Various researches regarding a vortex beam has been carried out not only in the visible region but also in the various frequencies. Since an electron cyclotron motion is also spiral motion, an Electron Cyclotron Emission (ECE) should have vortex property. In order to experimentally demonstrate the vortex property of ECE, we have tried to generate the gyro-phase controlled multi-electron system, which can actively emit the ECE with vortex property. For this experiment, we developed the method to estimate the vortex property and to identify the Topological Charge (TC). This method is successfully checked by using the passively generated vortex beam from Gaussian beam in the millimeter wave region. The diffraction pattern by a triangular aperture of the passively generated vortex beam is observed. Since the diffraction pattern depends on the TC, we can identify the TC of the vortex beam. As a result, we were able to measure the characteristic diffraction patterns of millimeter wave vortex beam by a triangular aperture for the first time in the world. We will show the details of the experimental and calculation results.
T70.00037: Increasing Solution Viscosity in Dynamic Light Scattering to Lower the Detection Limit for the Determination of Nanoparticle Size* HRISTO IVANOV (Presenter), BRYAN AUGSTEIN, ANTON WIGGINS, CLAYTON PALMER, JEFFREY SIMPSON, Towson University — We report on the development of homebuilt Dynamic Light Scattering (DLS) instrumentation to measure the size of monodisperse (MD), spherical nanoparticles (NPs) of gold. HeNe and Ar-ion lasers constitute the excitation sources for the scattering experiment, while an avalanche photodiode detects the scattered light, and an autocorrelation card analyzes the resulting signal to provide a measurement of the translational diffusion coefficient, which allows for the determination of NP diameter. We characterized our instrumentation using commercially-produced gold NPs with diameters ranging from 50nm to 200nm in aqueous solution. Given the strong temperature-dependence of the solution viscosity, periodic ambient temperature measurements were used to produce dynamic values for viscosity and minimize uncertainty in the determination of NP size. Increasing the liquid viscosity slows down the Brownian motion of the NPs and affords measurement of smaller-sized particles that otherwise diffuse too fast for detection. Currently we are suspending NPs in higher viscosity solutions in an effort to lower our size detection floor from approximately 50nm to 10nm.

*The authors acknowledge support from Towson University. J.R.S. acknowledges support from NSF – CBET#1236083

T70.00038: Complex Materials Scattering (CMS) Beamline at NSLS II: Recent Developments and Progress toward Autonomous Exploration of Material Structure* MASAFUMI FUKUTO (Presenter), RUIPENG LI, National Synchrotron Light Source II, Brookhaven National Laboratory, KEVIN G. YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory — The CMS beamline at the National Synchrotron Light Source II provides small- and wide-angle x-ray scattering (SAXS/WAXS) capabilities for materials science community. Since 2017, CMS has been supporting user experiments involving a wide range of materials, from polymers, nanocomposites, liquid crystals, biomolecular materials, to self-assembled nanoparticle superlattices and lithographic nanostructures. To promote efficient exploration of material parameter spaces, CMS has implemented a variety of high-throughput and in-situ capabilities. Besides basic transmission and grazing-incidence (GI)SAXS/WAXS capabilities, CMS has demonstrated, and offers, technically demanding capabilities such as specular reflectivity, variable-angle methods (CD-SAXS/CD-GI-SAXS), and grazing-incidence scattering tomography. We will discuss these developments as well as our recent progress with implementing autonomous x-ray scattering experiments in which decision-making algorithms are integrated into a closed-loop beamline workflow pipeline.

*The CMS beamline is operated by NSLS II and CFN, which are U.S. Department of Energy (DOE) Office of Science User Facilities operated for the DOE Office of Science by Brookhaven National Laboratory under Contract No. DE-SC0012704.

T70.00039: Atomically Resolved Probe-type Scanning Tunneling Microscope for Use in Harsh Vibrational Cryogen-free Superconducting Magnet* WENJIE MENG (Presenter), JIHAO WANG, YUBIN HOU, Anhui Key Laboratory of Condensed Matter Physics at Extreme Conditions, High Magnetic Field Laboratory and Hefei Science Center, Chinese Academy of Sciences, MENGQIAO SUI, Oxford Instruments Technology (Shanghai) Co., Ltd, JUNTING WANG, Anhui Key Laboratory of Condensed Matter Physics at Extreme Conditions, High Magnetic Field Laboratory and Hefei Science Center, Chinese Academy of Sciences, GANG WU, Oxford Instruments Technology (Shanghai) Co., Ltd, JING ZHANG, Anhui Key Laboratory of Condensed Matter Physics at Extreme Conditions, High Magnetic Field Laboratory and Hefei Science Center, Chinese Academy of Sciences, JUNYUN LI, Oxford Instruments Technology (Shanghai) Co., Ltd, QINGYOU LU, Anhui Key Laboratory of Condensed Matter Physics at Extreme Conditions, High Magnetic Field Laboratory and Hefei Science Center, Chinese Academy of Sciences — We present a probe-type scanning tunneling microscope (STM) with atomic resolution that is designed to be directly inserted and work in a harsh vibrational cryogen-free superconducting magnet system. When a commercial variable temperature insert (VTI) is installed in the magnet and the STM is in turn housed in the VTI, a lowest temperature of 1.6 K can be achieved, where the STM still operates well. We have tested it in an 8 T superconducting magnet cooled with the pulse-tube cryocooler (PTC) and obtained atomically resolved graphite and NiSe2 images as well as the scanning tunneling spectrum (STS, i.e. dI/dV spectrum) data of the latter near its critical temperature, which show the formation process of the superconducting gap as a function of temperature. The drifting rates of the STM at 1.6 K in X-Y plane and Z direction are 1.15 and 1.71 pm/min respectively. This is important as a cryogen-free magnet system has long been considered too harsh for any atomic resolution measurement.

*This work was supported by the National Key R&D Program of China (Nos. 2017YFA0402903 and2016YFA0401003), National Natural Science Foundation of China (Nos. 21505139, 51627901, 11504339 and 11374278), and Chinese Academy of Sciences Scientific Research Equipment (No. YZ201628s).
**T70.00040: New Design for Inertial Piezoelectric Motors**

JING ZHANG (Presenter), Anhui Province Key Laboratory of Condensed Matter Physics at Extreme Conditions, High magnetic filed laboratory of the Chinese Academy of Sciences, LIGE LIU, University of Science and Technology of China, WENJIE MENG, JIHAO WANG, YUBIN HOU, QINGYOU LU, Anhui Province Key Laboratory of Condensed Matter Physics at Extreme Conditions, High magnetic filed laboratory of the Chinese Academy of Sciences — We have designed, implemented, and tested the performance details of a new type of piezoelectric motor called the CicadaDrive. It is a new motor design that the total friction force can be dramatically reduced or even canceled by pushing the clamping points at the ends of a piezoelectric tube in the opposite directions during piezoelectric deformation. While our new motor requires the addition of another piezoelectric tube, which leads to an increase in volume of 120% when compared with traditional inertial piezoelectric motors, we can realize far greater performance than two times, including step size, threshold voltage, stability, etc. Its highly integrated structure means that this motor is suitable for use as either a motor or a scanning unit.

*This work was supported by the National Key R&D Program of China (Nos. 2017YFA0402903 and 2016YFA0401003), the National Natural Science Foundation of China (Nos. 21505139, 11704384, 51627901), the Anhui Provincial Natural Science Foundation (No. 1608085 MB36), the Dean fund of Hefei institutes of Physical Science of CAS (No. YZjj201620), and the Chinese Academy of Sciences Scientific Research Equipment (No. YZ201628).

**T70.00041: Terahertz Interferometric Microscopy**

YESENIA A. GARCÍA, NASER QURESHI (Presenter), DAHI LUDIM HERNANDEZ-ROA, JESÚS GARDUÑO-MEJÍA, ICAT, Universidad Nacional Autónoma de México, CARLOS GERARDO TREVIÑO-PALACIOS, INAOE, Puebla, Mexico — We report on the development of a continuous wave near-field scanning microscope operating in the 500-600GHz frequency range. The use of interferometric detection allows for enhanced sensitivity and the use of low cost thermal detectors even when using a low power radiation source. We present representative images of both soft and hard matter samples.

*Work funded by CONACyT CB253754, Fronteras 344 and PAPIIT UNAM IN106316.

**T70.00042: Computing the 3D Radial Distribution Function: An Advanced Analytic Approach**

BERND KOPERA, MARKUS RETSCH (Presenter), Department of Chemistry, University of Bayreuth, 95447 Bayreuth, Germany — The radial distribution function, g(r), is ubiquitously used to analyze the internal structure of particulate systems. Applications range from molecular dynamic simulations to confocal microscopy of colloids. Measured particle coordinates are always confined in a finite sample volume. Computing g(r) is challenging once the radial distance, r, extends beyond the sample boundaries in at least one dimension. State of the art algorithms for g(r) use artificial periodic boundary conditions to circumvent this challenge. Ignoring the finite nature of the sample volume distorts g(r) significantly. Here, we present a simple, analytic algorithm for the computation of g(r) in finite samples. No additional assumptions about the sample are required. The key idea is to use an analytic solution for the intersection volume between a spherical shell and the sample volume. In addition, we discovered a natural upper bound for the radial distance that only depends on sample size and shape.

**T70.00043: In Operando micro-Raman 3D thermometry with diffraction-limit spatial resolution for GaN-based light-emitting diodes**

TAEYOUNG PARK (Presenter), YONG ZHANG, University of North Carolina at Charlotte, YONG-JING GUAN, ZHIQIANG LIU, Chinese Academy of Science, Institute of Semiconductors — Confocal micro-Raman microscopy performed in the transparent spectral region of a semiconductor can in principle be used for *operando* 3D thermometry with optical diffraction-limit spatial resolution. However, when applied to high power GaN-based light-emitting diodes (LEDs), the applicability is hindered by the often strong secondary electroluminescence (EL) in the visible spectral region that overwhelms the Raman signal. We develop a “split-time-window” scheme that can mimic the continuous wave (CW) operation but without the interference of the secondary emission, which allows us to carry out noninvasive 3D temperature profiling, thus, a comprehensive thermal analyses of the whole device, at any operation current. The technique is applied to an InGaN/GaN LED to extract its 3D temperature distribution when operated at 350 mA with µm scale resolution when using 532 nm laser. We show that although a conventional technique can yield reliable average temperature difference between the heat sink and the LED junction (a few degrees), the spatial fluctuations are much larger than the average difference. Furthermore, we show that using anti-Stokes to Stokes Raman intensity ratio as metric can yield more reliable and accurate results than using Raman frequency shift.

Chromatographic $^3$He purification system, with an acoustic purity monitor*  

WENGUANG JIANG (Presenter), YOONSEOK LEE, Physics, University of Florida, BRODIE POPOVIC, Physics, Duke University, COLIN BARQUIST, Physics, University of Florida — A system for Helium extraction and purification (SHeEP) is constructed around a chromatographic cylinder filled with activated charcoal to remove $^4$He contamination from $^3$He gas [1]. In order to monitor the composition of the mixture during the process, an acoustic cavity is designed. The acoustic cavity measures the average atomic mass of the mixture by measuring the speed of sound [2][3]. The sensitivity of the acoustic cavity is estimated to be 0.04%. It provides a cheap alternative to a mass spectrometer.

*NSF DMR-1708818

Axisymmetric Neutron Analyzers to Enable Efficient Powder Neutron Diffractometers*  

BORIS KHAYKOVICH (Presenter), IBRAHIM ALNAMI, Massachusetts Institute of Technology, ALEXANDRU STOICA, Oak Ridge National Laboratory, JAY THEODORE CREMER, Adelphi Technology, Inc. — State-of-the-art thermal neutron sources are large expensive national facilities, which serve a diverse community of scientific and industrial users. The need to improve the performance of neutron instruments stems from the fact that most neutron methods are limited by the available flux, even at high-flux facilities. Many neutron methods cannot be used effectively at small sources available at universities and industrial laboratories. Thus, the efficient use of neutron flux is important for the progress and broader use of these neutron techniques. We present a novel design of an axisymmetric analyzer for powder diffraction to enable polychromatic cold and thermal neutron diffractometers, which will have much higher throughput than existing instruments and enable diffractometers at small reactors or even laboratory neutron generators. At the large neutron sources, such analyzers would enable fast screening of multiple samples or measuring kinetic processes.

Mask aligner for ultrahigh vacuum with capacitive distance control  

PRIYAMVADA BHASKAR (Presenter), SIMON MATHIOUDAKIS, TIM OLSCHIEWSKI, FLORIAN MUCKEL, JAN RAFAEL BINDEL, MARCO PRATZER, MARCUS LIEBMANN, MARKUS MORGENSTERN, RWTH Aachen University — We present an ultrahigh vacuum mask aligner driven by three piezoelectric motors which guide and align a SiN shadow mask under capacitive control towards a conductive sample surface. The three capacitors for read out are located at the backside of the thin mask. The mask can be placed in micrometer distance from the sample surface without touching it, while deliberately keeping it parallel to the sample surface. The sample can additionally be displaced laterally with respect to the mask with a precision of few nanometers. Samples and masks can be exchanged in-situ with a wobble stick. We demonstrate an edge sharpness of the deposited structures below 100 nm, which is likely limited by the diffusion of the deposited Au on Si(111).

Characterization of LED Temperature Dependence and Power-Efficient LED Modulation Methods for Use in Fluorescence Absorption Spectroscopy  

PHILLIP KUPLIC (Presenter), LUCAS J KOERNER, Engineering, University of St. Thomas — Temperature characteristics of LEDs impact the performance of optical instruments. We have characterized these effects by powering various colors of high-powered LEDs in constant current mode and analyzing the light output with a spectrometer. Light intensity, center wavelength, and spectral full width at half maximum (FWHM) was recorded as temperature changed, allowing for a better understanding of the relationship between temperature and the characteristics of light. Results show that an increase in temperature (range of 40 °C) decreases the efficiency (average of 15%; peak of 46%), increases the FWHM (average of 6.7%), and causes the center wavelength to shift to the red. Furthermore, we present the impact of sinusoidal current modulation upon the wavelength spread of LEDs. Circuit approaches for power efficient modulation are proposed that minimize changes in LED characteristics and produce pure sine-waves. Temperature characterization measurements and modulation methods are critical for low-cost and portable medical instruments.
T70.00049: Reducing thermal conductivity through lattice softening*  RILEY HANUS (Presenter), MATTHIAS AGNE, JEFF SNYDER, Northwestern University — Two fundamentally different avenues for controlling a materials thermal conductivity are phonon scattering and lattice softening. Lattice softening recognizes that lattice defects alter the phonon dispersion relation and thus reduce the lattice thermal conductivity ($\kappa_L$) by reducing phonon frequencies and group velocities. I will discuss experimental data on several systems (Si, PbTe, and SnTe) which demonstrate that microstructural defects such as grain boundaries, dislocations, and vacancies can significantly softening a materials lattice, reducing the materials speed of sound. By analyzing the data on elasticity and thermal conductivity through transport modeling, it is shown that lattice softening is a dominate mechanism for the reduction of $\kappa_L$ in these systems. Additionally, it will be shown that lattice softening is theoretically expected to be more effective than phonon scattering effects in anharmonic materials and at high temperatures. This work demonstrates how lattice softening is emerging as an important mechanism for controlling a materials thermal conductivity, and provides new avenues to engineer a materials $\kappa_L$, beyond phonon scattering.

*GJS and RH acknowledge EFRC (S3TEC) Grant DE-SC0001299. RH acknowledges support from the Weertman Graduate Fellowship.

T70.00050: Near-field radiative heat transfer in the presence of edge states  GAO MIN TANG (Presenter), JIAN-SHENG WANG, physics, National University of Singapore — We demonstrate that dispersionless electronic edge states substantially enhance near-field radiative heat transfer. An unusual heat flux dependence on vacuum gap separation is found, where the heat transfer can reach local maxima at experimentally feasible gap separation. The underlying mechanisms for the peculiar effects are uncovered from a simple Su-Schrieffer-Heeger model, and we propose zigzag single-walled carbon nanotubes as experimental realizations. Our results offer a novel route to active radiative thermal switch, where the heat flux can be modulated through tuning the presence or absence of edge states.

T70.00051: Thermoelectric Transport at Organic-silicon interface*  NAIMING LIU, MONA ZEBARJADI (Presenter), University of Virginia — Hybrid organic-inorganic materials are among the latest class of materials proposed for thermoelectric applications. The organic-inorganic interface is critical in determining the effective transport properties of the hybrid material. We present results on the thermoelectric properties of the F4TCNQ—silicon interface. Transfer of electrons from silicon to F4TCNQ results in holes trapped within the screening length of the interface that can move parallel to the interface. We report the response of these trapped charges to applied temperature differential and compare the thermoelectric transport properties of the silicon with and without F4TCNQ. The results confirm the presence of interface charges and demonstrate enhanced interface thermoelectric power factor.

T70.00052: First principle study of lithium diffusion pathways in layered oxide Li2La(TaTi)O7  MING YU (Presenter), Physics and Astronomy, University of Louisville, SELORM JOY FANAH, Chemistry, University of Louisville, ASHFIA HUQ, Oak Ridge National Laboratory, FARSHID RAMEZANIPOUR, Chemistry, University of Louisville — Layered oxides, as the Ruddlesden-Popper family, have the potential to be a good lithium-ion conductor as solid electrolytes for lithium ion batteries. Recently, new family member, the layered Li2La(TaTi)O7 has been successfully synthesized [1] and its ionic conductivity has been examined. Our first principle calculations reveal the orientation of lithium diffusion pathways and the energy barriers in these pathways, which are directly correlated with the atomic arrangement of this material. We also found that the energy barriers will be lowered with Li deficiency, indicating that introducing lithium defects can also improve the lithium diffusion, and therefore the ionic conductivity, agreement with our experimental observations. These results have broad implications with regard to the design of a new class of Li-conducting oxides based on Ruddlesden-Popper oxides.

T70.00053: Understanding H-ion transport dynamics in superionic conductor BaH$_2$ * QIANGQIANG GU (Presenter), Peking University, FEIPENG ZHENG, Jinan University, JI FENG, Peking University — Superionic conductors have received increasingly attentions due to the potential applications to energy storage, fuel cells, solid electrolytes, etc. BaH$_2$ was experimentally reported as a superionic conductor which exhibits ionic conductivity of nearly 0.2 S/cm at 630 °C, an order of magnitude larger than that of state-of-the-art proton-conducting perovskites at this temperature [1]. However, the mechanism of H-ion conduction therein still remains investigations. In this work, we use first-principles nudged elastic band (NEB) simulations to compute the energy barriers. The quantum dynamic effects were considered by path-integral Monte Carlo (PIMC) sampling. Free energy surface was calculated using PIMC combined with umbrella sampling method. Furthermore, kinetic Monte Carlo (kMC) simulations were carried out to compute the ionic mobilities and conductivities which match well with the experimental data.

*This work was supported by National Natural Science Foundation of China (Grant No. 11725415), National Basic Research Program of China (Grant No. 2016YFA0301004), and by the Key Research Program of the Chinese Academy of Sciences (Grant No. XPDPB08-4).

T70.00054: Crystallization Dynamics of Amorphous Solid Electrolytes using Large Scale Atomistic Simulations * CHRIS ABLITT (Presenter), Department of Materials, Imperial College London, MORDECHAI C KORNBLUTH, JONATHAN P MAILOA, Research and Technology Center North America, Robert Bosch LLC, BORIS KOZINSKY, Harvard University — LiPON ceramic glass electrolytes offer the possibility to increase the energy density of batteries thanks to their resistance to dendrite formation, a problem in batteries using Li-metal anodes, yet the conductivity of oxide glasses is relatively poor. This work studies the fundamental process of amorphization, crystallization, and ion conduction within a wide composition range of lithium phosphate systems. We employ atomistic force fields developed from ab-initio dynamics trajectories and validated on lithium phosphates with comparison to ab-initio trajectories and experimental characterization. Using large-scale dynamics simulations we predict the structural relaxation and conductivity of glass electrolyte materials, reaching timescales and system sizes inaccessible to ab-initio methods. We show how the Li content determines both the ionic conductivity and the degree of corner-sharing, which in turn determines the ease of amorphization and provides insight into optimal glass processing conditions.

*This work is partially supported by the Advanced Projects Research Agency - Energy (ARPA-E), US Department of Energy, and by the Oak Ridge Leadership Computing Facility at the Oak Ridge National Laboratory, which is supported by the Office of Science of the US Department of Energy.

T70.00055: Photovoltaic and thermoelectric indirect coupling for maximum solar energy exploitation MOHAMMED HAJJI (Presenter), physics, LaMCSi, Faculty of Sciences, Mohammed V University in Rabat, Morocco — Advanced photovoltaic devices with a high performance/cost ratio is a major concern nowadays. In the resent study, we investigate the energetic efficiency of a new concept based on an indirect (instead of direct) photovoltaic and thermoelectric coupling. Using state-of-the-art thermal transfer calculations, we have shown that such an indirect coupling is an interesting alternative to maximize solar energy exploitation. In our model, a concentrator is placed between photovoltaic and thermoelectric systems without any physical contact of the three components. Our major finding showed that the indirect coupling significantly improve the overall efficiency which is very promising for future photovoltaic developments.

T70.00056: High-performance organic solar cells by adding the third component YAO WU (Presenter), THOMAS RUSSELL, Department of Polymer Science and Engineering, University of Massachusetts Amherst — Organic solar cells have attracted much attention over the past decades, which have numerous advantages, including solution-processability, low cost, light weight, and flexibility. Due to the development of non-fullerene acceptors, the efficiencies of organic solar cells were increased to 17% for a tandem junction and 14% for a single junction. To further improve the efficiency of organic solar cells, a third component can be added to the active layer making a ternary blend film. Ternary blend film contains a donor material, an acceptor material, and a third component having complimentary absorption with the donor and acceptor, increasing the light harvesting ability of the devices. Some of the third components have suitable energy levels to reduce the charge transfer barriers between the donor and acceptor. The added component can also induce the crystallization of the donors and change the morphology of the blend film. In our work, a few third components were selected to add in the active layer, which leads to an improvement of the device performance. Also, the absorption, charge transportation and the morphology of the ternary system were carefully investigated to understand how the third component influences the efficiency of organic solar cells.
levels seems to have a larger influence on the efficiency of the cell. Conduction bands would increase the open circuit voltage and possibly the efficiency of these "band-matched" solar cells. It was hypothesized that avoiding energy loss due to large differences between the CdSe and metal oxide nanoparticulate substrates. Metal oxides were chosen to closely match their conduction bands with the conduction bands of the CdSe. We found that the opposite was true and that the improved electron kinetics due to larger differences in conduction band levels seems to have a larger influence on the efficiency of the cell.

*We wish to acknowledge and thank the Neuhoff Summer Science Communities Grant for providing seed funding for this project.

**T70.00058: Light absorption induced band bending in p-type Cu$_2$(Zn,Sn)(S,Se)$_4$ thin-film photovoltaic cells: local Raman imaging and scanning probe microscopy** JURAN KIM (Presenter), Department of Physics, Ewha Womans University, KEE-JEONG YANG, DAE-HWAN KIM, JIN-KYU KANG, Convergence Research Center for Solar Energy, Daegu Gyeongbuk Institute of Science & Technology (DGIST), WILLIAM JO, Department of Physics, Ewha Womans University — Kesterite-structured Cu$_2$ZnSn(S,Se)$_4$ (CZTSSe) is one of the most promising materials for highly efficient and low-cost thin-film solar cells because of its appropriate optical and electrical properties. The best efficiency of CZTSSe solar cells is 12.6%, which was obtained using a hydrazine process, while the materials used in this study showed efficiency of 12.3%. Note that the CZTSSe thin-films were grown by sputtering and subsequent sulfur-selenium treatment. Raman spectroscopy imaging was utilized to measure local built-in voltage and its local composition. According to the surface potential results, we were able to observe upward band bending near grain boundaries, meaning intra-grains take a role as current path by collected electrons. Unlike Cu(In,Ga)Se$_2$, defects in CZTSSe thin-films have deep energy levels, which can be charge carrier recombination center and cannot be suitable for a current path. By measuring surface photo-voltage, we observed the significant changes in energy band bending under illumination, implying the existence of these interfacial states. The main contribution of the research is related to the realization of new way for carrier separation enhancing power conversion efficiency of the kesterite-based thin-film solar cells.

**T70.00059: Scalable Transparent Metal-polymer Hybrid Metamaterial for Enhanced Greenhouse Effect** TAO LI, YIN GAO, Institute of Engineering Thermophysics, Chinese Academy of Sciences, KUN ZHENG, YONGMEI MA, Institute of Chemistry, Chinese Academy of Sciences, XIULAN HUAI, Institute of Engineering Thermophysics, Chinese Academy of Sciences, DING DING (Presenter), Agency for Science, Technology and Research, HANG ZHANG, Institute of Engineering Thermophysics, Chinese Academy of Sciences — Tailoring the emissivity of optically engineered materials in both the solar and the ambient blackbody radiation wavelength has led to significant day-time radiative cooling. It is conceivable that manipulating the optical spectrums in the opposite way will lead to enhanced greenhouse effect, as demonstrated in current commercial low-emissivity (low-E) window coatings. In this work, based on Mie scattering and the principle of surface plasmon polaritons for enhanced transparency, metallic nanowire/polymer hybrid structures were designed to achieve the goal of enhancing day-time heating. This metal-polymer hybrid metamaterial can enhance solar heating in enclosed environment or reject thermal radiation for energy saving in air-conditioned environment. The resulted metamaterial can reflect the mid-infrared spectrum effectively(~80%) and be transparent(transmittance of about 85%) to sunlight spectrum at the same time. Comparing our metamaterial with commercial low-E glasses, our metamaterial is more transparent in the visible and less emissive in the infrared. In addition, this type of metamaterials is flexible and can be scalable-manufactured with lower cost than that of low-E glasses.

**T70.00060: Effects of Prolonged Heat Exposure on the Performance Characteristics of Monocrystalline Silicon Photovoltaic Cells** AMANDA PORTOFF (Presenter), ANDREW D VENZIE, JUSTIN L SMOYER, PAUL QUINN, Kutztown University of Pennsylvania — Solar energy is a rapidly growing field of study since alternative energy sources, especially those that are renewable and economically feasible, are highly sought after. Silicon photovoltaic cells are the most commonly used type of cell, yet limitations in their efficiency place a restraint on overall effectiveness. The objective of this research was to observe the effects on the performance characteristics of monocrystalline silicon photovoltaic cells after being exposed to high temperatures for fixed periods of time. In particular, we examined the open-circuit voltage, $V_{oc}$, and short-circuit current, $I_{sc}$. To observe these changes, the cells were heated at temperatures ranging from 200°C to 280°C for a duration of 20 minutes. An analysis of various IV curves was used to determine changes in performance characteristics of the cells exposed at different temperatures. Our study revealed that this heat exposure yielded a permanent alteration in the performance of the cell. Ultimately, this exposure led to an increase in the overall performance of the monocrystalline silicon photovoltaic cell. Such an increase in performance occurred with existing cells, requiring no significant changes to the manufacturing process.
Morphology Controlled Electrospun Fibers as the Catalyst Layer for Polymer Electrolyte Membrane Fuel Cells

LIKUN WANG (Presenter), Stony Brook University, GUAN HAO CHEN, St. George's School, Vancouver, Canada, DANIELLE KELLY, Friends Academy, Locust Valley, NY, ZIPEI LIU, Shenzhen Middle School, Shenzhen, China, AUDREY SHINE, Plainview Old-Bethpage JFK High School, Plainview, NY, KAO LI, MIRIAM RAFAILOVICH, Stony Brook University — The efficient operation of Polymer Electrolyte Membrane Fuel Cells (PEMFCs) largely relies on a costly and easily-degradable platinum catalyst layer. Although air spraying techniques has previously served as the main method of catalyst deposition, electrospinning deposition may provide a more promising method by granting users precise control over 3-D structures by manipulating fiber diameter, porosity, and alignment. 12wt% of poly(acrylic acid) (PAA) and Nafion (1:4 weight ratio) solution was used to obtain a semi-viscous base solution for electrospinning. Through Laser Optical Microscopy and Scanning Electron Microscopy, optimal fiber diameter of 1 μm was found when incorporated with Pt/C, allowing uniform catalyst nanoparticles attachment. The fuel cell performance tests indicate that the morphology optimized electrospun electrodes exhibited a 108% increase in max power output over air-sprayed electrodes of comparable loading. This enhancement is attributed to its unique interwoven surface morphology, which increases the specific surface area of electrode and promotes the efficiency of the reactant and proton transport to catalytic sites. Thus, electrospinning can be used as a potential strategy to improve power output of PEMFCs by altering the catalyst electrode morphology.
Battery Performance and Reaction Mechanism in Tin Sulfide as Negative Electrode: First-Principles Calculations

HIROKI KOTAKA (Presenter), Elements Strategy Initiative for Catalysts and Batteries, Kyoto University, HIROYOSHI MOMIDA, Institute of Scientific and Industrial Research, Osaka University, AYUKO KITAJOU, Organization for Research Initiatives, Yamaguchi University, SHIGETO OKADA, Institute for Materials Chemistry and Engineering, Kyushu University, TAMIO OGUCHI, Institute of Scientific and Industrial Research, Osaka University — Sodium (Na) ion batteries have been recently expected as a next-generation battery in which Li-ion batteries is replaced with Na. Tin sulfide (SnS) has been expected to have a high energy density and be a candidate for anode materials of Na-ion batteries. In this study, we investigate the battery characteristics of SnS as a negative electrode for Na-ion batteries by first-principles calculations. We calculate a phase diagram of Na-Sn-S ternary systems from energy analyses, and clarify a possible reaction route considering intermediate products in charge and discharge reactions. We theoretically estimate the voltage-capacity curves of Na/SnS half-cell systems based on the Na-SnS reaction path obtained from the ternary phase diagram, and compare with the experimental result. From the comparison between calculated and experimental results, the Na₂S reaction product can precipitate in the SnS electrodes after discharging, and it is expected that the electrode can recover to be SnS again after charging. Therefore, the conversion reactions in which Na₂S precipitates in the SnS electrodes are considered to occur reversibly.

Structural mechanisms in complex oxides enabling high-rate lithium-ion energy storage*

KENT GRIFFITH (Presenter), Northwestern University, KAMILA WIADEREK, Advanced Photon Source, Argonne National Laboratory, GIANNANTONIO CIBIN, Diamond Light Source, LAUREN MARBELLA, Department of Chemical Engineering, Columbia University, CLARE GREY, Department of Chemistry, Cambridge University — The maximum power output and minimum charging time of a lithium-ion battery depend on mixed ionic-electronic conduction. We show that complex niobium tungsten oxides with frustrated polyhedral arrangements and dense μm-scale particle morphologies can rapidly and reversibly intercalate large quantities of lithium. Analysis of high-rate and multi-electron energy storage will be discussed with insights from operando X-ray diffraction, solid-state nuclear magnetic resonance spectroscopy, and multi-edge X-ray absorption spectroscopy for the recently reported crystallographic shear structure and bronze-like oxide phases[1]. Materials and mechanisms that enable lithiation of μm particles in minutes have implications for high power applications, fast charging devices, all-solid-state batteries, and general approaches to electrode design and materials discovery.

Electrochemical kinetics of SEI growth in porous electrodes*

SUPRATIM DAS (Presenter), MICHAEL FORSUELO, MARTIN BAZANT, Chemical Engineering, Massachusetts Institute of Technology — Growth of the solid electrolyte interphase (SEI) is a major driver of capacity fade in LIBs. Despite its importance, the fundamental mechanisms remain unclear, primarily because of the complicated reaction pathways involved. SEI growth can be both electrochemical and chemical in nature, and thus, it is a strong function of the potential and degree of lithiation of the electrode. In this work, we model the early-stage and long-term growth of SEI by accurately capturing the potential dependence of its formation kinetics as well as long term rate limiting steps, and validating it against extensive experimental data. This is done using the Multiphase Porous Electrode Theory (MPET) framework on graphite (phase separating) and carbon black (non phase separating) particles. Results indicate that the peak SEI-forming currents are higher for higher driving currents. Counterintuitively, despite higher peak SEI-forming currents, the highest differential capacities or ‘extent of SEI growth’ are seen for lower driving currents, which implies that SEI formation is a stronger function of potential and cycling time, than the driving current. This work holds promise for the predictive design of procedures for manufacture and formation of LIBs.

*This project is being funded by the TRI
**T70.00068: Structure of lithium dendrite in polymer electrolytes**  
FUDONG HAN (Presenter), TIANCHENG YI, University of Maryland College Park, ROBERT GREGORY DOWNING, National Institute of Standards and Technology, ROBERT BRIBER, CHUNSHENG WANG, HOWARD WANG, University of Maryland College Park — The structure of Li dendrites grown in solid polymer electrolytes (SPE) has been studied using a symmetric sandwich cell of Li / poly(ethyleneoxide) (PEO) : lithium bis(trifluoromethane) sulfonamide (LiTFSI) / Li as a model system. In situ neutron depth profiling (NDP) during directional Li pumping and plating shows that dendrites start to grow, and eventually short-circuit the battery. Li dendrite 3D mapping reveals rather heterogeneous lateral distribution of Li over wide length scales from below a millimeter to centimeters. While the lateral mobility of Li appears to be large, most dendrites grow from the plating electrode, with the overall composition decreases linearly from the electrode interface to the bulk of the electrolyte. It is observed that dendrites also grow from the bottom electrode, where presumably only Li oxidation reaction occurs. The revelation poses new design and engineering challenges in using Li metal electrode in future batteries.

**T70.00069: Flexible Graphene-Carbon Nanotube Supercapacitors**  
KAREN PEARSON, FIT, VLADIMIR SAMUILOV (Presenter), SHI FU, Stony Brook University — A carbon fiber textile has been utilized as flexible supercapacitor electrodes with cost-effective graphene nanoplatelet composite material (GNP) as model material for coating the electrodes. GNP represent a new class of carbon nanoparticles with very high intrinsic electrical conductivity in plane and accessible surface area. Multi wall carbon nanotube (MWCNT) at the concentration 50:50 of CNT to GNP were added to take advantage of the high surface area of the composite of these two carbon nano-materials. The first experimental results without optimization showed promising supercapacitor behavior of the carbon fiber textile with bare pads, better than in [1]. GNP – MWCNT (50:50) electrode material has improved the capacitance density approximately 10 times. Our newly designed high energy supercapacitors [2] allows increasing the operational voltage window from 3V (natural restriction by the Debye length voltage drop for standard supercapacitors) to the value higher than 20V.

**T70.00070: Applying a 1D Plasma Profile Simulator to COMPASS to Model Sawtooth Instabilities**  
MARTIN LIZA (Presenter), Mechanical and Aerospace Engineering, Old Dominion University — Being able to control the plasma state and its evolution in real time is crucially important for the confinement stability. However, the complex physics that needs to be solved requires a high amount of computational power.

If experimental data is combined with a model that predicts the transport behavior of a tokamak (COMPASS), then accurate predictions can be used to develop an integrated control system that ensures the control of the plasma state and confinement stability.

An active control for the plasma instabilities will be developed using a 1D RApid Plasma Transport simulatOR (RAPTOR) code. This code solves two coupled 1D partial differential diffusion equations for the electron temperature and the poloidal magnetic flux. The RAPTOR code will be implemented in COMPASS to model and simulate sawtooth instabilities; this simulation will take into consideration Neutral Beam Injectors (NBI).

The RAPTOR code will be used as a state observer system that will predict the behavior of the plasma before it actually happens. This prediction will later be used for implementing a real time sawtooth instability control system for COMPASS and/or COMPASS-U.
T70.00071: Computational fluid dynamics modeling of a microchannel-type reactor for the coupling of OCM and reforming reactions* MYUNG-JUNE PARK (Presenter), MINJI SON, HAE LIN YANG, Ajou University, SEON-JU PARK, YUN-JO LEE, Korea Research Institute of Chemical Technology — Oxidative coupling of methane (OCM) is a reaction that converts methane to high-value added ethylene and ethane. However, strong exothermic heat of reaction leads to thermally unstable operation and lowers the selectivity of the desired species. To control the heat of OCM, we developed a microchannel-based reactor that couples OCM with the steam reforming of methane (SRM), one of strong endothermic reactions.

The computational fluid dynamics model clearly showed that temperature increase in the OCM bed was maintained below 80 °C and the reaction temperature was close to the optimal one (820 °C). However, the temperature profile in the SRM bed showed abrupt decrease due to strong endothermic characteristic. To expand the kinetically controlled region of the SRM bed, the effects of the operating conditions and structure parameters were evaluated.

In conclusion, the modeling approach in the present study could determine the optimal operation strategy, and provide important information on the design of industrial microchannel based reactors.

T70.00072: Raman Spectroscopy of Diesel and Gasoline Engine-Out Soot* ZHIPENG YE (Presenter), HAIWEN GE, RUI HE, Texas Tech University — We studied engine-out soot samples collected from a heavy-duty direct-injection diesel engine and a port-fuel injection gasoline spark-ignition engine. The two types of soot samples were characterized using Raman spectroscopy with different laser power. A Matlab program using least-square-method with trust-region-reflective algorithm was developed for curve fitting. We used a DOE (design of experiments) method to avoid local convergence. This method was used for two-band fitting and three-band fitting. The fitting results were used to determine the intensity ratio of D and G Raman bands. We find that high laser power may cause oxidation of soot samples, which gives higher D/G intensity ratio. Diesel soot has consistently higher amorphous/graphitic carbon ratio and thus higher oxidation reactivity, in comparison to gasoline soot, which is reflected by the higher D/G intensity ratio in Raman spectra measured under the same laser power.

*Supported by NSF CAREER Grant No. DMR-1760668

T70.00073: Fundamentals of the photocatalytic activity of conjugated polymers for hydrogen evolution reaction: optical and thermodynamic aspects GIANE DAMAS (Presenter), CLEBER F. MARCHIORI, C. MOYES ARAUJO, Department of Physics and Astronomy, Uppsala University — Harvesting sunlight is a convenient approach to meet the global demand of energy, a process that makes use of a suitable photo-electro-catalyst to convert solar energy into chemical fuels[1]. In this context, conjugated polymers have emerged as a subclass of materials with potential applicability as photocatalysts for hydrogen evolution reaction (HER). [2] In this work, we use density functional theory-based methods to evaluate the thermodynamic and optical properties of a set of conjugated polymers containing fluorene, cyclopenthathiophene or thiophene-based donor units and benzothiadiazole-based acceptor units. Optimizations and frequencies were held in Gaussian 09 [3] at the M06-6-31G* level of theory, whereas the excitation, solvation and electronic energies were obtained with the 6-311G** basis set. Our preliminary results show that the polymers containing benzo(triazole-thiadiazole) or benzo(triazole-selenodiazole) acceptor units present a broad absorption spectrum and a suitable reduction potential for photocatalytic HER. In particular, PFO-DSeBTrT has maximum peak at 950 nm, while showing a hydrogen binding free energy (0.02 eV) that is lower in absolute values than Pt (-0.10 eV).

T70.00074: ELDOR-detected NMR Spectroscopy at 115/230 GHz* ZAILI PENG (Presenter), SUSUMU TAKAHASHI, University of Southern California — Electron-electron double resonance (ELDOR)-detected NMR (EDNMR) spectroscopy is one type of the EPR based hyperfine spectroscopy techniques, which is used to detect hyperfine couplings between magnetic nuclei and unpaired electrons, which are too small to be resolved in the conventional EPR spectrum. Compared with other commonly used hyperfine spectroscopy, for instance, ESEEM (electron spin echo envelop modulation) and ENDOR (electron nuclear double resonance), HF EDNMR has advantages of higher sensitivity and finer spectral resolution enabling high-resolution hyperfine spectroscopy at room temperature. In this presentation, we present the principle and implementation of EDNMR in our 115/230 GHz EPR spectrometer at USC, and demonstrate the strategies to obtain high quality EDNMR spectrum by the employment of EDNMR on a standard sample. In addition, we discuss applications of HF EDNMR on the study of solid-state spin systems.

*This work was supported by the Searle Scholars Program and the National Science Foundation (DMR-1508661 and CHE-1611134).

T70.00075: TOPOLOGICAL MATERIALS —
T70.00076: Floquet generation of higher order topological phases and its quenching dynamics  TANAY NAG
(Presenter), Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, VLADIMIR JURICIC, NORDITA, Nordic Institute for Theoretical Physics, Stockholm University and KTH, Stockholm, Sweden, BITAN ROY, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — We discuss a non-equilibrium Floquet scheme to generate the higher-order topological (HOT) phases. In particular, we find that if a $d$-dimensional regular topological phase involves $m$ Hermitian matrices then a kick in the discrete symmetry breaking Wilsonian mass term, which is composed of additional $p-1$ anti-commuting matrices, can give rise to $n^{th}$ order Floquet HOT phases (with $n=1,...,p$). We demonstrate explicitly this mechanism in the cases of three-dimensional spin-1/2 Dirac semimetal, 2nd order topological insulator and nodal loop semimetal. We give analytical support for the numerical findings by using the Floquet effective Hamiltonian. Additionally, we study the relaxation dynamics of the above phases by calculating the survival probability for a topological phase followed by a sudden quench. Our results suggest that survival probability for quenching from a higher-order to a lower-order phase depends on the system size while the reverse quenching does not show any system size dependence.

T70.00077: Edge states across the topological phase transition due to approximate chiral symmetry in quantum anomalous and spin Hall systems*  DENIS CANDIDO (Presenter), Sao Carlos Institute of Physics at the University of Sao Paulo, MAXIM KHARITONOV, Institute for Theoretical Physics and Astrophysics, University of Wurzburg, CARLOS EGUES, Sao Carlos Institute of Physics at the University of Sao Paulo, EWELINA HANKIEWICZ, Institute for Theoretical Physics and Astrophysics, University of Wurzburg — In this work we demonstrate that a quantum anomalous Hall system (Chern insulator) always exhibits edge states right at the phase transition (except when the system becomes charge-conjugation symmetric), where the Hamiltonian is gapless, and in the vicinity of the topologically trivial and non-trivial gapped phases. We show that the origin of these edge states can be attributed to the approximate chiral symmetry of the Hamiltonian. Additionally, we demonstrate that while the non-trivial quantum Hall topology is responsible only for the existence of these edge states within the energy gap region, the approximate chiral symmetry is the ingredient responsible for the edge state existence in the remaining energy range in both topological and trivial phases. This behavior is described by the realistic one block of the BHZ model of a quantum spin Hall system, which was already noticed but remained unexplained.

T70.00078: Observation of multiple Dirac states in EuMg$_2$Bi$_2$*  FIROZA KABIR (Presenter), MD MOFAZZEL HOSEN, University of Central Florida, FAIROJA CHEENICODE-KABEER, ALEX APERIS, Department of Physics and Astronomy, Uppsala University, GYANENDRA DHAKAL, KLAUSS DIMITRI, CHRISTOPHER SIMS, SABIN REGMI, University of Central Florida, TOMASZ DURAKIEWICZ, Los Alamos National Laboratory, PETER OPPENEER, Department of Physics and Astronomy, Uppsala University, DARIUSZ KACZOROWSKI, Polish Academy of Science, MADHAB NEUPANE, University of Central Florida — Initiated by the discovery of topological insulators, topologically non-trivial materials especially topological semimetals and metals have emerged as a new frontier in the field of quantum materials. In this work, we perform a systematic measurement of EuMg$_2$Bi$_2$, a compound with antiferromagnetic transition temperature at 7K. By utilizing angle-resolved photoemission spectroscopy in concurrence with first principle calculation, we observe Dirac cones at the corner and the zone center of the Brillouin zone. From our experimental data odd number of Dirac states are observed per Brillouin zone. Our experimental investigation of detailed electronic structure of EuMg$_2$Bi$_2$ could potentially provide the platform to study the interplay between topology and magnetism.

T70.00079: Tunable Topological Phase Transition in 2D Heterostructures*  ANH PHAM (Presenter), PANCHAPAKESAN GANESH, Oak Ridge National Laboratory — Two dimensional (2D) materials can host a wide range of properties, such as magnetism [1], high mobility and a wide range of topological properties [2]. Recently, it has been experimentally shown that heterostructures of 2D materials can be synthesized. This leads to the exciting possibility of interfacing 2D materials in heterostructure geometries to design new and exotic quantum-materials for dissipationless quantum-transport. In this study, we theoretically demonstrate that vertical heterostructures of magnetic and topological 2D materials can give rise to quantum anomalous Hall (QAH) effect. In addition, we show that electric-fields can be used to tune the interfacial coupling to drive the system to the QAH regime. We demonstrate this concept in 2D heterostructures such as CrI$_3$/Sb/CrI$_3$, CrI$_3$/Si/CrI$_3$, and CrI$_3$/Ge/CrI$_3$.

**T70.00080: Two-Step Growth Method for High Quality (Bi0.5Sb0.5)2Te3 and Cr doped (Bi0.5Sb0.5)2Te3 on Nb surfaces for Topological Josephson Junctions**  
HE REN (Presenter), University of Waterloo, HUI ZHANG, XIAODONG MA, University of Science and Technology of China, DELER LANGENBERG, University of Waterloo — It has been theoretically predicted that Majorana bound state can appear at the interface between topological insulators and superconductors. To obtain high quality (Bi0.5Sb0.5)2Te3 films on superconducting Nb surface, a two-step growth method was developed to promote proper nucleation on Nb surfaces in the early growth stage, where Bi, Sb and Te clusters were firstly evaporated at a relatively low temperature and then annealed to form a crystallized passivation layer, and a standard (Bi0.5Sb0.5)2Te3 film was grown under the normal deposition temperature secondly. Based on the two-step method, we also grew high quality Cr doped Bi-Sb-Te films on Nb surface with a similar procedure. Reflection high-energy electron diffraction (RHEED), high resolution transmission electron microscopy (TEM), X-ray photoelectron spectroscopy (XPS) and X-ray diffraction (XRD) were used to characterize the quality of the films. Finally, a top Nb film was deposited by magnetron sputtering at the room temperature. The Hetero-Nb/epitaxial (Bi0.5Sb0.5)2Te3 (with and without Cr doped)/ Nb stacks were further fabricated into micro Josephson junctions and the results of transport measurement also demonstrate a good quality of the multi-layer stacks.

**T70.00081: Magnetic Weyl Points and Symmetry Protected Nodal Loops in 5d Cubic Double Perovskites**  
YOUNG-JOON SONG (Presenter), KWAN-WOO LEE, Department of Applied Physics, Graduated School, Korea University — 5d systems show abundant physical phenomena due to an interplay between strong spin-orbit coupling (SOC) and moderate correlation, viz. the Dirac-Mott metal-insulator transitions in Os-based oxides. In topological characters, various symmetries, SOC, and (sometimes) strength of correlation are key ingredients to generate topologically nontrivial phases. Using the *ab initio* approach, we have investigated topological characters in the Os-based cubic double perovskites of 5d1 and 5d2 which have a strong SOC, moderate correlation, and plentiful crystal symmetries. In our GGA results of both nonmagnetic(NM) and ferromagnetic(FM) cases, there are nodal lines around W and K points. Even for considering SOC, in the TRS-broken cases the nodal lines are robust on kz=0 plane, which is perpendicular to the direction of [001] SOC, whereas these disappear in the NM cases. Besides, in the TRS-broken cases, 14 pairs of Weyl points with opposite chirality on the mirror planes appear. Applying correlation as well as SOC, the nodal lines remain protected, while the WPs vanish. In this presentation, we will analyze the mechanisms of topological characters in the Os-based cubic double perovskites.

**T70.00082: Thermoelectric Imaging of Domain Boundary States in Epitaxial Graphene**  
SANGHEE CHO, Korea Research Institute of Standards and Science, YONG-HYUN KIM, Physics, KAIST, HO-KI LYEO (Presenter), Korea Research Institute of Standards and Science — We investigated electronic states associated with the boundary structure between domains of two carbon layers in epitaxial graphene. The topological structure formed between AB and BA stacking domains could be observed in microscopic thermoelectric measurements down to the atomic length scale. Measurements show that the boundary structure observed from epitaxial bilayer graphene is associated with point defects of carbon pentagon-heptagon and the structure forms a closed loop. Such structural patterns define soliton-like domain walls driven by strain in epitaxial graphene, which gives rise to prominent contrast in the thermoelectric measurement. The contrast observed over the domain walls in the measurement of thermoelectric response is the direct consequence of chiral boundary modes expected for tensile-strained boundaries, which is similar to the structures observed in exfoliated and CVD-grown bilayer graphene. These results will help to elucidate how the topological band plays in epitaxial graphene.

**T70.00083: Bulk and surface states carried supercurrent in ballistic Nb-Dirac semimetal Cd3As2 nanowire-Nb junctions**  
CAIZHEN LI (Presenter), School of Physics, Peking University, CHUAN LI, MESA+ Institute for Nanotechnology, University of Twente, LIXIAN WANG, School of Physics, Peking University — A three dimensional Dirac semimetal has bulk Dirac cones in all three momentum directions and Fermi arcs like surface states, and can be converted into a Weyl semimetal by breaking time-reversal symmetry. However, the highly conductive bulk state usually hides the electronic transport from surface state in Dirac semimetal. Here, we demonstrate the supercurrent carried by bulk and surface states in Nb-Cd3As2 nanowire-Nb short and long junctions, respectively. For the ~1μm-long junction, the Fabry-Pérot interferences-induced oscillations of the critical supercurrent are observed, suggesting the ballistic transport of the surface states carried supercurrent, where the bulk states are decoherent and the topologically protected surface states still stay coherent. Moreover, a superconducting dome is observed in the long junction, which is attributed to the enhanced dephasing from the interaction between surface and bulk states as tuning gate voltage to increase the carrier density. The superconductivity of topological semimetal nanowires is promising for brading of Majorana fermions toward topological quantum computing.

T70.00084: Gate-tuned Aharonov-Bohm interference of surface states in a quasiballistic Dirac semimetal nanowire*  
BENCHUAN LIN (Presenter), SHUO WANG, ZHI-MIN LIAO, Peking University, DAPENG YU, South University of Science and Technology of China — We report an observation of a topologically protected transport of surface carriers in a quasiballistic Cd$_3$As$_2$ nanowire. The nanowire is thin enough for the spin-textured surface carriers to form 1D subbands, demonstrating conductance oscillations with gate voltage even without magnetic field. The $\pi$-phase shift of Aharonov-Bohm oscillations can periodically appear/disappear by tuning gate voltage continuously. Such a $\pi$-phase shift stems from the magnetic field induced helical modes in the surface subbands.

*This work was supported by National Key Research and Development Program of China (Grants No. 2016YFA0300802, No. 2013CB934600, and No. 2013CB932602) and NSFC (Grants No. 11274014 and No. 11234001)

T70.00085: Fano Interference between Bulk and Surface States of a Dirac semimetal Cd$_3$As$_2$ nanowire*  
SHUO WANG (Presenter), BENCHUAN LIN, ZHI-MIN LIAO, Peking University, DAPENG YU, South University of Science and Technology of China — Dirac semimetals possess Fermi-arc surface states, which will be a set of discrete surface subbands in a nanowire due to the quantum confinement effect. Here, we report a tunable Fano effect induced by the interference between the discrete surface states and continuous bulk states of a Dirac semimetal Cd$_3$As$_2$ nanowire. The discrete surface bands lead to a zero bias peak in conductance as the Fermi level is tuned across the surface subbands. The Fano resonance results in an asymmetric line shape in the differential conductance $dI/dV$ spectrum. Furthermore, the Fano interference would introduce an additional phase into the Weyl orbits and lead to a modification of the oscillation frequency. The results are valuable for further understanding the exotic quantum transport properties of topological semimetals.

T70.00086: Observation of Dirac States in Superconducting Materials*  
KLAUSS DIMITRI (Presenter), MD MOFAZZEL HOSEN, GYANENDRA DHAKAL, University of Central Florida, HONGCHUL CHOI, Theoretical Division, Los Alamos National Laboratory, FIROZA KABIR, CHRISTOPHER SIMS, University of Central Florida, DARIUSZ KACZOROWSKI, Institute of Low Temperature and Structure Research, Polish Academy of Sciences, TOMASZ DURAKIEWICZ, National Science Foundation, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory, MADHAB NEUPANE, University of Central Florida — The massive shift in interest towards Topological Superconductors (TSC) and their potential to host Majorana fermions has been a major point that connects the rhetoric of both quantum computation and topological materials. Following this narrative, superconducting Pd-Bi binaries have large spin orbit coupling strength and can develop a TSC phase peaking the interests of both fields. Here, we report a high-resolution angle-resolved photoemission spectroscopy (ARPES) study on the normal state electronic structure of superconducting $\alpha$-PdBi2 ($T_c=1.7$ K). Our results show the presence of Dirac states at higher-binding energy with the Dirac point 1.26 eV below the chemical potential at the zone center. Furthermore, the ARPES data indicate multiple band crossings at the chemical potential, consistent with the metallic behavior of $\alpha$-PdBi2. Our experimental studies are complemented by first-principles calculations, revealing the presence of surface Rashba states in the vicinity of the chemical potential. Our study extends to other superconducting materials providing an opportunity to investigate the relationship between superconductivity and topology.

T70.00087: Dynamical correlation functions and the related novel physical effects in 3D topological semimetals*  
JIANHUI ZHOU (Presenter), Hefei Institutes of Physical Science, HAO-RAN CHANG, Sichuan Normal University, DI XIAO, Carnegie Mellon University, HONG GUO, McGill University — We present a unified derivation of the dynamical correlation functions including density-density, density-current and current-current, of 3D Weyl/Dirac semimetals by use of the Passarino-Veltman reduction scheme at T=0K. The generalized Kramers-Kronig relations with arbitrary order of subtraction are established to verify these correlation functions. Our results lead to the exact chiral magnetic conductivity and directly recover the previous ones in several limits. We also investigate the magnetic susceptibilities, the orbital magnetization, and briefly discuss the impact of electron interactions on these physical quantities within the random phase approximation. Recently, we develop a gauge invariant theory of chiral magnetic plasmons and discuss the impact of the chiral anomaly. Our work provides a starting point for the investigation of the nonlocal transport and optical properties due to the higher-order spatial dispersion in 3D Weyl/Dirac semimetals.

T70.00088: Hydrothermal Synthesis of Tellurium Nanoflakes with Post Growth Thinning*  
ANNE HERBERT (Presenter), ASU ROLLAND, GIRIRAJ JNAWALI, IRAJ ABBASIAN SHOJAEI, SAMUEL M LINSER, Department of Physics, University of Cincinnati, ANJALY NANATTUCHIRAYIL, PENG ZHANG, Department of Chemistry, University of Cincinnati, HOWARD E JACKSON, LEIGH SMITH, Department of Physics, University of Cincinnati, RUOXING WANG, School of Industrial Engineering, Purdue University, GANG QIU, School of Electrical and Computer Engineering, Purdue University, WENZHUO WU, School of Industrial Engineering, Purdue University, PEIDE (PETER) YE, School of Electrical and Computer Engineering, Purdue University — Tellurium is a hexagonal chiral crystal with covalently bonded left- or right-spiral chains of atoms along the c-axis, with much weaker van der Waals interactions between the chains. The lowest conduction bands exhibit Weyl node crossings with different chiralities at the H and H' points in the Brillouin zone. We synthesize 40 nm-thick Tellurium nanoflakes via the hydrothermal method, and confirm the quality of our samples with Raman spectroscopy. The flakes were thinned through a basic NaOH solution with acetone. Thicknesses was measured with Raman spectroscopy, via peak shift, and confirmed using atomic force microscopy.

T70.00089: Electronic structure and optical responses of chalcopyrite semiconductors ZnSnX_2 (X = P, As, Sb)  
BANASREE SADHUHKAN (Presenter), IFW Institute for Theoretical Solid State Physics, Leibniz Institute for Solid State and Materials Research — Ternary compounds having the chalcopyrite structure are of considerable interest because of their semiconducting, electrical, structural, mechanical and nonlinear optical properties. Chalcopyrite semiconductors ZnSnX_2 (X = P, As, Sb) lack an inversion symmetry. Under strong light irradiation, the noncentrosymmetric material exhibits photocurrents as nonlinear functions of the electric field of the light. The spontaneous photocurrent is due to the topological character of the constituting electronic bands; the Berry connection. The photogalvanic effect rectifies light to dc currents and often plays a crucial role in optical devices and solar cells. Under linearly polarized light, the induced photocurrent is usually called shift current originated due to the charge center shift between the valence and conduction bands in the optical excitation. We study the electronic structure, linear and nonlinear optical response, specially the shift current of chalcopyrite semiconductors ZnSnX_2 (X = P, As, Sb) using Kubo formulism via a multiband approach using first principles. We analyze the relationship between the response and the materiars properties which serves as a deep understanding of the shift current effects in noncentrosymmetric materials over linear response.
Angle-resolved photoemission spectroscopy study of the topological Kondo insulator candidates CeRhX (X=As, Sb)

SEUNGOH SEONG, Physics, The Catholic University of Korea, KYOO KIM, 2MPPHC CPM, EUNSOOK LEE, Physics, The Catholic University of Korea, CHANG-JONG KANG, TAESIK NAM, BYUNG IL MIN, physics, Pohang University of Science and Technology, TAKENOBU YOSHINO, TOSHIRO TAKABATAKE, Department of Quantum Matter, Hiroshima University, JONATHAN DENLINGER, ALS, Lawrence Berkeley National Laboratory, JEONGSOO KANG (Presenter), Physics, The Catholic University of Korea — Topological Kondo insulators (TKIs) belong to a class of symmetry-protected topological phases arising from the strong correlation. CeNiSn, CeRhSb, and CeRhAs are known as Kondo insulators with the large anisotropy [1]. Recently CeNiSn and CeRhSb are predicted to be the novel TKIs having the Möbius-twisted surface states [2]. A unique feature in these systems is the non-symmorphic glide and screw axis symmetries, which bring about the new topological surface band structures. We have investigated the electronic structure of CeRhX (X=Sb, As) employing ARPES and DFT/DMFT band calculations. The Fermi surfaces (FSs) and band structures are successfully measured for the three orthogonal crystallographic directions. For X=Sb, the metallic FSs are obtained for all three different planes. Both the FSs obtained at the Ce 4f resonance and the ARPES data are described well by the unfolded DFT FSs and the DMFT band structures, respectively. The temperature-evolution of the Ce 4f peak agrees with that of the Ce 4f Kondo resonance. The photon energy map provides evidence for the 3D character of the Fermi-edge states unlike the theoretically predicted surface states.

Discovery of topological nodal-line fermionic phase in a magnetic material GdSbTe

SABIN REGMI (Presenter), MD MOFAZZEL HOSEN, GYANENDRA DHAKAL, KLAUSS DIMITRI, University of Central Florida, PABLO MALDONADO, ALEX APERIS, Uppsala University, FIROZA KABIR, CHRISTOPHER SIMS, University of Central Florida, PETER RISEBOROUGH, Temple University, PETER OPPENEER, Uppsala University, DARIUSZ KACZOROWSKI, Polish Academy of Sciences, TOMASZ DURAKIEWICZ, National Science Foundation, MADHAB NEUPANE, University of Central Florida — Topological semimetals with accidental band touching between conduction and valence bands protected by time-reversal (TR) and inversion symmetry are at the frontier of modern condensed matter research. Mostly, the discovered topological semimetals are non-magnetic and preserve TR symmetry. Here, we report the systematic electronic structure study of the antiferromagnetic GdSbTe using angle-resolved photoemission spectroscopy (ARPES) as well as first-principles calculations. Our study reveals the presence of nodal-line semimetallic state along the Γ-M direction of the Brillouin zone (BZ). Our data also reveal a robust Dirac like state at X point of the BZ both below and above the magnetic transition temperature (T_N = 13K). With a relatively high transition temperature, GdSbTe can prove to be an archetypical platform to study the interaction between magnetism and topological states of matter.

Observation of Nodal Loops in HfP2

CHRISTOPHER SIMS (Presenter), MD MOFAZZEL HOSEN, GYANENDRA DHAKAL, Physics, University of Central Florida, Orlando, Florida 32816, USA, HUGO ARAMBERRI, Physics and Astronomy, California State University, Northridge, California 91330, USA, KLAUSS DIMITRI, FIROZA KABIR, Physics, University of Central Florida, Orlando, Florida 32816, USA, DARIUSZ KACZOROWSKI, Institute of Low Temperature and Structure Research, Polish Academy of Sciences, 50-950 Wroclaw, Poland, XIAOTING ZHOU, TAY-RONG CHANG, Physics, National Cheng Kung University, Tainan, 701, Taiwan, HSIN LIN, Physics, Academia Sinica, Taipei 11529, Taiwan, NICHOLAS KIOUSSIS, Physics and Astronomy, California State University, Northridge, California 91330, USA, MADHAB NEUPANE, Physics, University of Central Florida, Orlando, Florida 32816, USA — Topological nodal-line semimetals that arise due to band touching which are protected by crystalline symmetries are materials that are currently being pushed to further understand topology in crystals protected by different symmetries. Here we report the experimental observation of three topological nodal loops in the transition metal pnictide HfP2 using angle resolved photoemission spectroscopy. Our systematic study reveals the detailed electronic structure of HfP2 which is protected by glide symmetry. Our calculations reveal three unique nodal loops, one of which is protected by glide symmetry in the center and two non-trivial topological nodal loops in finite k-space. Our experimental data and calculations both reveal the existence of these non-trivial loops which warrants further symmetry analysis in the non-symmorphic space group.

*This work is supported by the Air Force Office of Scientific Research under Award No. FA9550-17-1-0415 and the startup fund from UCF (M.N.).
T70.00093: Temperature-dependent coherent phonon dynamics in Bi$_2$Te$_3$*  
HSUAN-YIN CHEN, Department of Photonics, National Sun Yat-sen University, JUNG-CHUN HUANG, Department of Physics, National Cheng Kung University, MENG-QING LEE, CHAO-KUEI LEE, Department of Photonics, National Sun Yat-sen University — In this work, temperature-dependent(78K~290K) coherent phonon dynamics in topological insulator Bi$_2$Te$_3$ are investigated. Four coherent phonon types(A$_{1g}^1$, A$_{1g}^2$, E$_g$, coherent acoustic phonon) with strong temperature dependency are observed in transmission pump-probe spectroscopy at low temperature(78K, 90K). These could be attributed to temperature dependent gradient force which resulting in the coherent phonons generation. Especially, lifetime of around 2.87ps for E$_g$ phonon mode is observed for the first time. The depressing signal of reflective pump probe due to the enhancing absorption of surface state for thin film topological insulator will be accordingly increasing as temperature cooling is proposed.

T70.00094: Optical nonlinearity investigation of Bi$_2$Te$_3$*  
MENG YU WU (Presenter), MENG-YUAN CHUANG, WEI-HENG SUNG, PENG LEE, JUN-PENG QIAO, CHAO-KUEI LEE, National Sun Yat-sen University — To realize 2-D material nonlinear optical applications, including wavelength generation, ultrafast optical processing, and saturable absorber for ultrafast laser, the information of optical nonlinearity property for given material is very important. In this work, ultra-low peak intensity (10$^3$ to 10$^5$ W/cm$^2$) z-scan measurement was proposed and buildup for studying the discontinuity of conventional nonlinear transmission with low and high pulse energy. The two photon absorption behavior was observed and is with tremendous large coefficient of 2.03x10$^{-2}$ cm/W for excitation power of 100uW. This can be used to interpret and resolve the discontinuity.

*The authors would like to thank financial support by the grants of Ministry of Science and Technology under project number of MOST 106-2112-M-110-006-MY3 and MOST 107-2218-E-110-016-.

T70.00095: Modulation of the universal conductance fluctuations by broken time-reversal symmetry in topological insulator  
SHUAI ZHANG, FENGQI SONG (Presenter), Nanjing University — In topological insulator BiSbTeSe$_2$ nanowire device, we extract the conductance fluctuations and study their magnetic field dependence in the gate-dependent transport of topological electrons. With the magnetic field increasing, the conductance fluctuation magnitudes are found to reduce by a ratio of $\sqrt{2}$ and form a quantized step, and this is observed both in n-type and p-type transport. This is related to the breaking of the time reversal symmetry of three-dimensional topological insulators, which reveal a crossover of the symmetry classes.

T70.00096: Magnetoresistance from Quantum Interference Effects in Topological Materials  
BO FU (Presenter), HUANWEN WANG, SHUNQING SHEN, Department of Physics, The University of HongKong — A large amount of experimental results about the longitudinal magnetoresistance (LMR) in Weyl semimetal and topological insulator systems display a nonmonotonic behavior over a wide range of magnetic field conditions. At small fields close to zero, a sharp increase of the LMR is observed. When the magnetic field exceeds some threshold value, the LMR is found to decrease as the magnetic field increases. In experiment, this crossover from positive to negative magnetoresistivity is commonly attributed to the competition between Chiral anomaly and weak antilocalization. This negative magnetoresistivity is viewed as the signature of chiral anomaly and the evidence for the existence of Weyl fermion. Using the Feynman diagram techniques, we derive the magnetoconductivity formulae from the quantum interference effects for disordered three-dimensional Dirac materials. By including all the possible contributing Cooperon modes, we can reproduce such nonmonotonict magnetoresistance behavior. We also find that by changing the chemical potential, topological trivial and non-trivial insulators exhibit distinctly different magnetoconductivity behavior. It can help us to directly distinguish the different topological phases through the bulk states transport measurement.
**T70.00097: Compressibility of the quantum spin Hall insulator HgTe**  MATTHIEU DARTIAILH (Presenter), Physics, New York University, SIMON HARTINGER, Physikalisches Institut (EP3), Universität Würzburg, ALEXANDRE GOURMELON, HUGO BARTOLOMEI, JEAN-MARC BERROIR, Laboratoire Pierre Aigrain, Ecole Normale Supérieure, CNRS, PSL Research University, Université Pierre et Marie Curie, Sorbonne Universités, Université Denis Diderot, HARTMUT BUHMANN, LAURENS W MOLENKAMP, Physikalisches Institut (EP3), Universität Würzburg, BERNARD PLAÇAIS, ERWANN BOCQUILLON, Laboratoire Pierre Aigrain, Ecole Normale Supérieure, CNRS, PSL Research University, Université Pierre et Marie Curie, Sorbonne Universités, Université Denis Diderot — Quantum spin Hall (QSH) insulators are two-dimensional electron systems which host spin-polarized edge states while the bulk remains insulating. These helical edge states provide a potential support system to encode information in 'topological quantum bits' robust to the decoherence. Despite immense theoretical and experimental efforts, the rise of these new materials has however been hampered by strong difficulties to clearly observe their predicted topological properties. These challenges motivate the investigation of the dynamics of their topological edge states using microwave techniques. Here we report on the compressibility of the QSH insulator HgTe, measured in metal-oxyde-HgTe capacitors. The quantum capacitance reflects the expected band structure of the HgTe quantum wells. A capacitance minimum associated to a resistance maximum signal the QSH regime. We analyse the dependence of this minimum as a function of the capacitor size and identify both 2D and 1D contributions, which can be used to estimate the 1D channel size. Similar measurements performed on non-topological quantum wells do not show any sizable 1D contributions in agreement with the absence of edge states.

*We acknowledge support from the ERC StG Castles (Grant 758077)

**T70.00098: Vertical Topological Josephson Junciton**  YUTONG DAI (Presenter), GUOXING MIAO, IQC, University of Waterloo — Topological Josephson junciton holds a promising platform for pursuing Majorana zero mode. Due to the proximity effect, the topological insulator layer sandwiched by two superconducting layers can be considered as topological superconductor. We explored the Andreev bound states of this heretrostructure, and observed teh 2pi periodic Andreev states, arising from the paring potential in topological superconductor. We also calculated the transport properties and compared simulation results with experimental measurements.

**T70.00099: ABSTRACT WITHDRAWN**

**T70.00102: Generalized Lieb-Schultz-Mattis theorem on bosonic symmetry protected topological phases**  SHENGHAN JIANG (Presenter), Physics, Caltech, YANG QI, Physics, Fudan University, YUAN-MING LU, Physics, OSU — We propose and proof a generalized Lieb-Schultz-Mattis (LSM) theorem for symmetry protected topological (SPT) phases on boson/spin models in any dimensions. The "conventional" LSM theorem, e.g. spin-1/2 per unit cell on square lattice, disallows symmetric short-range-entangled (SRE) phase. Here, we focus on systems with fractional spins, but have no LSM anomaly. Thus, it is possible to have symmetric SRE phases in the long wavelength. We show that, symmetric SRE phases obtained in these systems must be nontrivial SPT phases of both on-site and spatial symmetries. Depending on models, they can be either strong or higher-order SPT phases, characterized by nontrivial edge/corner states. Furthermore, given global symmetry group and fractional spins, we are able to determine all possible SPT phases by using a spectral sequence expansion of group cohomology. We also provide examples in various dimensions, and discuss possible physical realization of these SPT phases based on topological defects/quasiparticles condensation picture.

T70.00103: Charge-spin response and collective excitations in Weyl semimetals*

SAYANDIP GHOSH (Presenter), CARSTEN TIMM, Institute of Theoretical Physics, TU Dresden — We present analytical expressions for all components of the frequency- and wave-vector-dependent charge-spin linear-response tensor of Weyl fermions. The spin-momentum locking of the Weyl Hamiltonian leads to a coupling between charge and longitudinal spin fluctuations, while transverse spin fluctuations remain decoupled from the charge. Based on the response tensor, we investigate the low-energy collective excitations of interacting Weyl fermions. For a local Hubbard interaction, the charge-spin coupling leads to a dramatic change of the zero-sound dispersion: its velocity becomes independent of the interaction strength and the chemical potential and is given solely by the Fermi velocity. In the presence of long-range Coulomb interactions, the coupling transforms the plasmon modes into spin plasmons. Using a lattice model with two Weyl nodes, we show that the collective modes are strongly affected by the presence of parallel static electric and magnetic fields due to the chiral anomaly. We discuss possible experiments that could provide smoking-gun evidence of Weyl physics.

T70.00104: Non-linear optical response and HHG in 3D Dirac semimetals

JEREMY LIM (Presenter), YEE SIN ANG, LAY KEE ANG, Singapore University of Technology and Design — Attosecond-duration pulses of extreme ultraviolet to X-ray light, generated via high harmonic generation (HHG), have proven to be highly useful tools in the study of the smallest and quickest fundamental phenomena. The study of HHG in condensed matter systems has attracted much interest due to its potential to realize novel solid-state optical technologies, as well as greater brightnesses compared to gas-phase HHG. We will present results on high harmonic generation in topological materials like 3D Dirac and Weyl semimetals, which exhibit strong, non-linear response to incident fields, which result in efficient generation of odd harmonics. We consider the massless Dirac quasiparticle limit, previously used to predict the harmonic spectra of 2D graphene due to its simplicity and physical transparency, and extend it to 3D Dirac semimetals. We study its non-linear response due to incident fields, and predict its harmonic spectra. A comparison of our results with graphene as well as potential novel photonic applications will be discussed.

T70.00105: Probing Weyl nodes by inelastic neutron scattering*

MICHAEL BJERNGAARD (Presenter), Johns Hopkins University, BOGDAN GALILO, Lancaster University, ARI MARK TURNER, Technion — We present how to detect Weyl nodes in a material by inelastic neutron scattering, taking into account realistic anisotropic properties. A generic material will not have relativistic symmetry. However, under circumstances not too limiting, the dynamics of the excitations can be mapped to a relativistic symmetry. It is then possible to separate out universal properties reflecting this in the cross-section. In a fully unpolarized experiment it is possible to detect the spin-momentum locking of Weyl states, their linear dispersion, principal axis and a sum-rule independent of the material parameters. Furthermore, with polarized neutrons, it is possible to experimentally control the momentum and spin of the excited Weyl particle-hole pairs, with the consequence that the scattered neutron beam is fully polarized in a direction determined by the coupling parameters of the material. This allows one to determine cleanly the coupling parameters as well as to measure the chirality of the Weyl nodes involved in the scattering.

T70.00106: Solutions to the Chiral Fermion Problem from Topological Orders and Floquet Non-Hermition Field Integrals*

MICHAEL DEMARCO (Presenter), XIAO-GANG WEN, Physics, MIT — Defining a chiral gauge theory non-perturbatively on a lattice has posed a longstanding issue for a non-perturbative definition of the standard model. However, recent insights connecting quantum anomalies with topologically ordered states have led to a breakthrough in lattice formulations of chiral gauge theories: any anomaly-free chiral gauge theory may be formulated as the edge theory of a 2+1 slab with topogical order that is reduced to trivial order by interactions. We keep the `width' of the sla finite so that the system is truly 1+1d. We can then develop a recipe for defining chiral gauge theories that can be extended to higher dimensions. In a parallel development, our recent formulations of discrete-time field integrals allow us to formulate several chiral Floquet phases as local field integrals in discretized spacetime. Intriguingly, these field integrals have unitary correlation functions, even though their Lagrangians are non-Hermitian operators. This provides a second non-perturbative definition of a chiral field theory in 1+1d, with possible generalizations to higher dimensions.

T70.00108: Quantum criticality preempted by nematicity

SHIXIN ZHANG (Presenter), SHAO-KAI JIAN, HONG YAO, Tsinghua University — Exotic physics often emerges around quantum criticality in metallic systems. Here we explore the nature of topological phase transitions between 3D double-Weyl semimetals and insulators (through annihilating double-Weyl nodes with opposite chiralities) in the presence of Coulomb interactions. From renormalization-group (RG) analysis, we find a non-Fermi-liquid quantum critical point (QCP) between the double-Weyl semimetals and insulators when artificially neglecting short-range interactions. However, it is shown that this non-Fermi-liquid QCP is actually unstable against nematic ordering when short-range interactions are correctly included in the RG analysis. In other words, the putative QCP between the semimetals and insulators is preempted by emergence of nematic phases when Coulomb interactions are present. We further discuss possible experimental relevance of the nematicity-preempted QCP to double-Weyl candidate materials HgCr$_2$Se$_4$ and SrSi$_2$.

T70.00109: How to braid mobile with immobile non-Abelian anyons in a topological superconductor

ANTON AKHMEROV (Presenter), Kavli Institute of Nanoscience, Delft University of Technology, CARLO W J BEENAKKER, PAUL S BAIREUTHER, Lorentz institute for theoretical physics, Leiden University, INANC ADAGIDELI, Faculty of Engineering and Natural Sciences, Sabanci University, YAROSLAV HERASYMENKO, Lorentz institute for theoretical physics, Leiden University — Majorana zero-modes in a superconductor are midgap states localized in the core of a vortex or bound to the end of a nanowire. They are anyons with non-Abelian braiding statistics, but when they are immobile one cannot demonstrate this by exchanging them in real space and indirect methods are needed. As a real-space alternative, we propose to use the chiral motion along the boundary of the superconductor to braid a mobile vortex in the edge channel with an immobile vortex in the bulk. The measurement scheme is fully electrical and deterministic: edge vortices (p-phase domain walls) are created on demand by a voltage pulse at a Josephson junction and the braiding with a Majorana zero-mode in the bulk is detected by the charge produced upon their fusion at a second Josephson junction.

T70.00110: Higher-order topological superconductivity: possible realization in Fermi gases and Sr$_2$RuO$_4$

ZHIGANG WU, Shenzhen Institute for Quantum Science and Engineering and Department of Physics, Southern University of Science and Technology, ZHONGBO YAN (Presenter), School of Physics, Sun Yat-sen University, WEN HUANG, Institute for Advanced Study, Tsinghua University — We propose to realize second-order topological superconductivity in bilayer spin-polarized Fermi gas superfluids. We focus on systems with intralayer chiral $p$-wave pairing and with tunable interlayer hopping and interlayer interactions. Under appropriate circumstance, an interlayer even-parity $s$- or $d$-wave pairing may coexist with the intralayer $p$-wave. Such mixed-parity phases do not carry one-dimensional gapless Majorana modes on the boundary, but could support Majorana zero modes at the corners of the system geometry, the end points of superconducting domain walls, as well as certain bulk defects. We show how the number and location of the Majorana zero modes can be tuned by the interlayer pairing and hopping. Generalized to spinful systems, we further propose that the putative $p$-wave superconductor Sr$_2$RuO$_4$ when placed under uniaxial strains, may also realize the desired topological phase.

T70.00111: Principal component analysis of quantum Hall wave functions

HENGXI JI (Presenter), NA JIANG, XIN WAN, Zhejiang University — The fractional quantum Hall effect demonstrates the robustness of topological properties in many-body systems. The effect of mass and interaction anisotropy can be understood in terms of a geometrical description. We present a study of the evolution of quantum Hall wave functions with interaction anisotropy by a statistical learning technique known as the principal component analysis (PCA). We show that the topological and geometrical aspects of a family of wave functions can be readily separated by the PCA. We discuss how to use the PCA to extract wave function metric and to determine the stability of a fractional quantum Hall phase.
T70.00112: Anyonic statistics of quantum impurities in two dimensions  
ENDERALP YAKABOYLU (Presenter), MIKHAIL LEMESHKO, Institute of Science and Technology, Austria — We demonstrate that identical impurities immersed in a two-dimensional many-particle bath can be viewed as flux-tube-charged-particle composites described by fractional statistics. In particular, we find that the bath manifests itself as an external magnetic flux tube with respect to the impurities, and hence the time-reversal symmetry is broken for the effective Hamiltonian describing the impurities. The emerging flux tube acts as a statistical gauge field after a certain critical coupling. This critical coupling corresponds to the intersection point between the quasiparticle state and the phonon wing, where the angular momentum is transferred from the impurity to the bath. This amounts to a novel configuration with emerging anyons. The proposed setup paves the way to realizing anyons using electrons interacting with superfluid helium or lattice phonons, as well as using atomic impurities in ultracold gases [1].  

T70.00113: Composite Fermion Insulator in Opposite-Fields Quantum Hall Bilayers*  
YAHUI ZHANG (Presenter), Massachusetts Institute of Technology — We consider a quantum Hall bilayers from opposite magnetic fields close to the filling $1/2 + 1/2$. We add inter-layer repulsive interaction starting from two decoupled Composite Fermion Liquids (CFL) with opposite chiralities. In this case physical exciton is frustrated from condensation, unlike the conventional quantum Hall bilayers. We argue that more natural phases are the exciton condensates between composite fermions or between slave bosons. The resulting states are insulators with neutral Fermi surfaces coupled to an emergent $U(1)$ gauge field without Chern-Simons term. This insulating state is a generalization of the well-known CFL state. We also comment on the possibility of a topological superconductor in this system. Finally we give experimental proposals to simulate this novel system in a graphene moire system consisting of two nearly flat bands with opposite Chern numbers 1 and -1.

*The work is supported by NSF grant DMR-1608505 to Senthil Todadri.

T70.00114: Quantum Hall stripes with a reduced transport anisotropy at half-filled Landau levels in GaAs quantum wells*  
MICHAEL ZUDOV (Presenter), XIAOJUN FU, QIANHUI SHI, University of Minnesota, GEOFFREY GARDNER, JOHN WATSON, MICHAEL MANFRA, Purdue University, K. W. BALDWIN, LOREN PFEIFFER, KENNETH WEST, Princeton University — It is well known that the hard (easy) resistance due to formation of quantum Hall stripes in high Landau levels of a two-dimensional electron gas exhibits a maximum (minimum) at half-integer filling factors. Here, we report the opposite behavior, namely a local minimum (maximum) in the hard (easy) resistance at half-filling. This talk will discuss our experimental observations in several samples including the temperature dependence of the resistance anisotropy and the response to the in-plane magnetic field applied parallel or perpendicular to the native stripes.

*The work at Minnesota (Purdue) was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award No. ER 46640-SC0002567 (DE-SC0006671). The work at Princeton University was funded by the Gordon and Betty Moore Foundation through the EPIQS initiative Grant GBMF4420, and by the NSF MRSEC Grant DMR-1420541. A portion of this work was performed at the National High Magnetic Field Laboratory, which is supported by National Science Foundation Cooperative Agreement No. DMR-1644779 and the State of Florida.

T70.00115: SEMICONDUCTORS, INSULATORS, AND DIELECTRICS —

T70.00116: Diamond magnetic sensing and imaging*  
ABDELGHANI LARAOUI (Presenter), ILJA FESCENKO, Dept. of Physics and Center for High Technology Materials, University of New Mexico, Albuquerque, NM 87106, JANIS SMITS, University of Latvia, Riga, LV-1586, Latvia, Laser Center, NAZANIN MOSAVIAN, JOSHUAT DAMRON, NATE RISTOFF, Dept. of Physics and Center for High Technology Materials, University of New Mexico, Albuquerque, NM 87106, PAULI KEHAYIAS, Sandia National Laboratories, Albuquerque, NM 87185, USA, ANDREY JARMOLA, Department of Physics, University of California-Berkeley — Diamond magnetic sensing has emerged as a powerful tool to detect nanomagnetism in biological and solid-state samples, as well to measure weak signals from nuclear spins and spin textures of molecules. We report ongoing experiments that explore several applications of diamond magnetic sensing. These include: (i) microfluidic nuclear magnetic resonance spectrometer capable of sensing small quantities (< 1 pL) of analyte [1], achieving spectral resolutions capable of distinguishing proton with heteronuclear ] splitting; (ii) a wide-field magnetic microscope able to measure the stray magnetic fields produced by individual malarial hemoglobin biocrystals (size < 300 nm) [3] and magnetization relaxation of single magnetic nanoparticles (size < 25 nm) at room temperature and as a function of applied field up to 350 mT. T70.00117: Magnetic noise due to interactions between bulk impurities and electrons in nitrogen vacancy center diamonds

BRUCE BARRIOS (Presenter), SHOU LI, D H SANTAMORE, Department of Physics and Engineering Physics, Delaware State University, Dover, Delaware 19901 — Nitrogen Vacancy (NV) Centers diamond present great interest as robust atomic-scale magnetic field sensors. One of the serious problems of NV center diamond devices is electric and magnetic field noise. The noise causes ODMR line-broadening, which reduce sensitivity of the devices. In this work we theoretically study the magnetic field noise caused by the magnetic dipole-dipole interactions between the impurities of carbon-13 and nitrogen-14 and the electron in the NV center. We use the cluster correlation expansion method to calculate the magnetic field fluctuations, and then, obtain the noise spectrum. The noise is greater at lower frequencies but rapidly decrease at higher frequencies.

*NSF DMR-150641

T70.00118: Interfacial treatment of 4H SiC/SiO2 interface by shallow boron ion implantation

MD. HAIDER SHAIM, HANI ELSAYED-ALI (Presenter), Old Dominion Univ — Shallow boron ion implantation at the 4H SiC/SiO2 interface was performed using boron multicharged ions from laser plasma. A Q-switched Nd:YAG laser (wavelength 1064 nm, pulse width 7 ns, and fluence 135 J/cm2) was used to ablate a boron target generating a dense plasma source of multicharged ions. Ions up to B5+ are generated. The ions are deflected by an electrostatic field to separate them from the neutrals. SRIM simulation was used to estimate the ion penetration depth in the SiC substrate. The optical bandgap of the 4H SiC was reduced by boron ion implantation. Several MOSCAP devices were fabricated. High-low C-V measurements were used to characterize the MOSCAPs. Shallow boron implantation in the SiC/SiO2 interface reduces the flatband voltage from 4.5 V to 0.04 V.

*This material was based on the work supported by the National Science Foundation under Grant No. MRI-1228228 and a seed grant from the Virginia Microelectronics Consortium.

T70.00119: Noble gas defects in ZnO: interaction with the localized defect states

OLEKSANDR MALYI (Presenter), Centre for Materials Science and Nanotechnology, Department of Physics, University of Oslo, KOSTIANTYN SOPIHA, Department of Engineering Sciences, Uppsala University, CLAS PERSSON, Centre for Materials Science and Nanotechnology, Department of Physics, University of Oslo — Owing to fully occupied orbitals, noble gases are often considered to be chemically inert and to have limited effect on materials properties under typical synthesis conditions. However, using first-principles calculations, we show that the insertion of noble gases (i.e., He, Ne, and Ar) in ZnO results in destabilization of electron density of the material driven by minimization of the unfavorable overlap of atomic orbitals of noble gases and its surrounding atoms. Specifically, the noble gas defect (interstitial or substitutional) in ZnO pushes electron density of its surrounding atoms away from its vicinity. Simultaneously, the host material confines electron density of the inserted noble gas. Because of this, the interaction of He, Ne, or Ar with O vacancies of ZnO in different charge states (ZnO:VOq) affects the vacancy stability and electronic properties. In particular, we reveal that to minimize the unfavorable overlap of atomic orbitals of the noble gases and surrounding atoms, the noble gases can occupy the vacancy site delocalizing the otherwise localized ZnO:VOq states.

*The work is supported by RCN #251131.

T70.00120: Theoretical study on atomic and electronic structures of vacancy-defect complexes in Ga2O3

KENTA CHOKAWA (Presenter), Graduate school of engineering, Nagoya University, KENJI SHIRAISHI, Institute of materials and systems for sustainability, Nagoya University — Ga2O3 has been studied as a next generation power semiconductor material which can realize lower energy consumption power devices than those using GaN and SiC.[1] Although some theoretical studies have already clarified the atomic and electronic structures of the point defects such as vacancies,[2] there are few knowledge of the defect complexes in Ga2O3. Therefore, we perform the first principles calculations by using VASP code,[3] and examine the atomic and electronic structures of the vacancy-defect complexes in Ga2O3. We made some vacancy-defect complexes in the α-Ga2O3 and β-Ga2O3 models and determined stable defect structures. We also study the stability of defects in the Mg-doped Ga2O3 models.

T70.00121: First-principles prediction of p-type doping of β-Ga2O3 ultrawide bandgap semiconductors

BENJAMIN TATTERSFIELD (Presenter), STEVEN HARTMAN, GUANGFU LUO, JOHN CAVIN, ROHAN MISHRA, Mechanical Engineering and Materials Science, Washington University in St. Louis — β-Ga2O3 is an ultra-wide-band-gap semiconductor with a large intrinsic band gap of 4.8 eV and a high breakdown field of 8 MV/cm. These properties when combined with the availability of high-quality large-area single crystals of β-Ga2O3, make it attractive for power electronic applications than conventional wide-band-gap semiconductors such as GaN and SiC. However, the efficiency of β-Ga2O3 devices is currently limited by the lack of good p-type dopants. We present evidence based on first-principles density-functional theory calculations that β-Ga2O3 can be efficiently doped p-type by bismuth. Based on formation energies, we predict that bismuth acts as a substitutional dopant at the gallium site. At low concentrations, bismuth leads to delocalized states just above the valence band edge of β-Ga2O3. These states arise due to the antibonding interaction between the occupied 6s2 lone pair electrons of bismuth and the 2p states of oxygen. The occupancy of these delocalized defect states can be controlled by moving the Fermi level, which can lead to efficient p-type doping.

T70.00122: Development of Room Temperature Multiferroic SmFeO3 Thin Films

YUAN-CHIH WU (Presenter), YI-DE LIOU, Physics, National Cheng Chung University, CHANG-YANG KUO, ZHIWEI HU, CHUN-FU CHANG, Max-Planck-Institute for Chemical Physics of Solids, TAY-RONG CHANG, Physics, National Cheng Chung University, HENG-JUI LIU, National Chung Hsing University, YI-CHUN YANG, Physics, National Cheng Chung University — Multiferroic materials are very popular in recent decades due to its versatile functionalities for applications. A result development of new materials that possesses multiferroicity is of great importance. SmFeO3 (SFO) has been considered as new room temperature single-phase multiferroic material for few years. SFO exhibits anti-ferromagnetism and significant magnetization below $T_N \sim 670$ K. However, the existence of ferroelectricity of single crystal SFO is still under debate.

In this work, we focus on the growth of epitaxial SFO thin films on different single crystalline substrates (LaAlO3 and NdGaO3) in order to trigger the presence of room temperature ferroelectricity. Atomic force microscopy has been used to check the surface morphology to prove the layer-by-layer epitaxy growth. To certify the interfacial strain between two different oxide materials, high resolution XRD is adopted. The ferroelectricity of SFO grown on NdGaO3 substrate has been identified by the piezoresponse force microscopy (PFM). Multiple techniques have been exploited to verify the ferroelectricity in the strained SFO thin films. The existence of the ferroelectricity is further supported via density functional theory. Out results identify a new room temperature single-phase multiferroic system.

T70.00123: Epitaxial growth and multiglass order in room-temperature relaxor multiferroics*

WEICHUAN HUANG (Presenter), Department of Materials Science and Engineering, University of California at Berkeley, YEN-LIN HUANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, SUJIT DAS, Department of Materials Science and Engineering, University of California at Berkeley, YUN-LONG TANG, Materials Sciences Division, Lawrence Berkeley National Laboratory, R RAMESH, Department of Materials Science and Engineering, University of California at Berkeley — Multiferroic materials with simultaneous ferroelectricity and magnetism provide a pathway to achieving strong magnetoelectric (ME) coupling with voltage control of magnetism, leading to compact and power efficient electric-field tunable magnetic devices. In recent years, substantial progress in finding room-temperature (RT) relaxor multiferroics, a new perspective for low-power spintronics, displaying strong ME coupling coefficients has been made [1-3]. Here, we present electric and magnetic properties of single-phase $x$Pb(Fe,W)O3-(1-x)Pb(Zr,Ti)O3 (PFW-PZT) films epitaxially grown on (001) SrTiO3 and (220) GdScO3 substrates using pulsed laser deposition. It is demonstrated that the PFW-PZT films show good ferroelectric and piezoelectric properties by measuring macroscopic polarization and local piezoelectric as a function of electric-field. In addition, weak ferromagnetism via magnetic hysteresis loops was also observed at RT.

T70.00124: Characterization of $\text{Ta}_x\text{Ti}_{(1-x)}\text{O}_y$ thin film and its applications in RRAM devices. YU SHI (Presenter), RABIUL ISLAM, GUOXING MIAO, Electrical and Computer Engineering, University of Waterloo — The movement of oxygen ions plays an important role in the resistive switching behavior of $\text{TiO}_x$ based devices, therefore the designed distribution of oxygen ions may help enhance the oxygen ion's movement and improve the resistive switching performance. In this work, we dope the $\text{TiO}_x$ thin film with a graded concentration of $\text{Ta}$ in depth, to generate a spatial gradient of oxygen activation energy. Detailed characterization of the structural changes and resistive switching performance has been carried out, our result may suggest a new way to use dopants to help improve the resistive switching performance.

T70.00125: Temperature and field dependent Raman Studies on Cupric Oxide Single Crystals RAJEEV GUPTA (Presenter), BARNITA PAUL, Indian Institute of Technology Kanpur — Cupric oxide is a well known oxide material which shows two successive magnetic transitions at 230 K ($T_{N2}$) and 213 K ($T_{N1}$). Interestingly, it has been reported in recent times that a small electric polarization of $160 \mu\text{C/m}^2$ develops along the b axis between 213-230 K. The origin of the observed macroscopic polarization is attributed to the noncollinear arrangement of spins and breaking of inversion symmetry via the Dzyaloshinskii-Moriya interaction. This mechanism is rather unusual and was suggested that spin-lattice coupling plays a crucial role. In the current work, we present temperature dependent Raman measurements on single crystalline CuO in presence of a magnetic field. Room temperature Raman measurements reveal three prominent Raman modes at 302 cm$^{-1}$, 350 cm$^{-1}$ and 635 cm$^{-1}$ consistent with earlier reports. Interestingly, we find a new mode appearing at 240 cm$^{-1}$ below 175 K. This mode splits into two modes on an application of a small magnetic field. Our experiments suggests that the mode observed at 240 cm$^{-1}$ is a combination of a magnon mode and a zone folded phonon contrary to the earlier reports.

T70.00126: Point defects at ferroelectric domain walls in hexagonal YMnO$_3$* DIDRIK SMÅBRÅTEN, SANDRA SKJAERVOE, DENNIS MEIER, Department of Materials Science and Engineering, NTNU Norwegian University of Science and Technology, THOMAS TYBELL, Department of Electronic Systems, NTNU Norwegian University of Science and Technology, SVÆRRE SELBACH (Presenter), Department of Materials Science and Engineering, NTNU Norwegian University of Science and Technology — Understanding how point defects influence the domain wall (DW) mobility and properties in ferroelectrics is desirable both to control the macroscopic ferroelectric properties and to develop DW-based nanoscale electronic circuitry. Here we use DFT calculations to study the interplay between neutral ferroelectric DWs in improper ferroelectric YMnO$_3$ and lattice imperfections like aliovalent dopant cations and oxygen defects like vacancies and interstitials. We find that the DW mobility and conductivity strongly couples to the defect chemistry of the material, and our simulations are supported by experimental reports. The overall aim of this study is to obtain chemical guidelines from first principles calculations for how to control the DW mobility and conductivity through defect chemistry. YMnO$_3$ displays great chemical flexibility, where donor and acceptor doping of both cation sublattices as well as both oxygen deficiency and excess is possible, making hexagonal manganites an ideal model system for this purpose.

T70.00127: Crystal structure and dielectrical behavior of $\text{YFe}_{1-x}\text{Ti}_x\text{O}_3$* MAURY SOLORZANO (Presenter), BASIC SCIENCE, UNIVERSIDAD JUÁREZ AUTÓNOMA DE TABASCO, ALEJANDRO DURAN, Materiales Avanzados, Centro de Nanociencia y Nanotecnologia, RICHARD FALCONI, BASIC SCIENCE, UNIVERSIDAD JUÁREZ AUTÓNOMA DE TABASCO — Yttrium orthoferrite, $\text{YFeO}_3$, is a multiferroic system despite having a $\text{Pnma}/\text{Pbnm}$ centrosymmetric structure. The mechanism that gives rise to ferroelectricity is under discussion, but it is believed to be associated with the breakdown of inversion symmetry. In this work, the synthesis, structural characterization, as well as the dielectric properties of the Ti - doped $\text{YFeO}_3$ are reported. Structurally it was found that doping with Ti generates an increase in the volume of the unit cell. The relative permittivity, $\varepsilon_r$, increases with the Ti content and has a diffuse phase transition at a temperature that decreases with x. In the same way, both the dielectric loss and the activation energy decrease with Ti doping. These results are discussed considering geometrical aspects and the occupation of the d orbitals.

**T70.00128: Enhanced charge carrier lifetime in layered 2D hybrid perovskites**  
POLLY J PIERONE (Presenter),  
Department of Physics, Wesleyan University, NOOR TITAN PUTRI HARTONO, JUAN-PABLO CORREA-BAENA, TONIO BUONASSISI,  
Massachusetts Institute of Technology, MENG-JU SHER, Department of Physics, Wesleyan University — Lower dimensional layered perovskite exhibited better environmental stability than 3D organic-inorganic hybrid perovskite materials such as methylammonium lead iodide (MAPbI₃). Due to the reduced dimensionality, one drawback of these layered 2D perovskite is the reduced charge carrier mobility. Currently, using layered 2D perovskite materials, no improvement in solar cell performance has been reported. In this study, we synthesized layered 2D lead-halide perovskite samples using different ratios of t-butylammonium and methylammonium as the organic cation, creating a set of samples spanning the 3D to 2D transition. We used time resolved terahertz conductivity measurements, a non-contact conductivity probe, to study both charge carrier mobility and lifetime in these materials. We confirmed the reduced charge carrier mobility but found enhanced carrier lifetime, indicating a possibility of finding optimal composition to maximize carrier diffusion length. The increased carrier lifetime supports efficient exciton dissociation and long-lived free carriers recently reported on other 2D Ruddlesden-Popper perovskites. Lastly, we compared the device performance of the 2D perovskite solar cells with the charge carrier dynamics measured.

**T70.00129: Ultrafast Charge Transfer at CH₃NH₃PbI₃ and MoS₂ Interface**  
WISSAM SAIDI (Presenter), University of Pittsburgh, YONGLIANG SHI, JIN ZHAO, University of science and technology of China — To achieve higher power conversion efficiency of promising hybrid organic-inorganic perovskites (HOIP), interface engineering must be applied to optimize the charge carrier pathway from absorber to electron and hole transport layers. Fast charge transfer can largely avoid charge accumulation at the interface, and suppress recombination. Further, optimized band alignment between charge transfer material and adsorber would reduce the “potential loss” in the conversion efficiency of the solar cell. Herein, we employ nonadiabatic molecular dynamics (NAMD) within time dependent density functional theory to study hole transfer from CH₃NH₃PbI₃ to monolayer MoS₂. Our results show that there is an ultrafast hole transfer channel in agreement with a recent experimental study. Because of the existence of a fast charge transfer and minimal band mismatch between CH₃NH₃PbI₃ and MoS₂ at the same time, MoS₂ is a promising hole transfer material in HOIP.

**T70.00130: Epitaxial growth of MoSe₂ and MoTe₂ monolayer on GaAs by molecular beam epitaxy**  
YIPU XIA,  
Department of physics, The University of Hong Kong, HAILONG WANG, State Key Laboratory of Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, ZE MEN (Presenter), JUNQIU ZHANG, Department of physics, The University of Hong Kong, HU XU, Department of Physics, Southern University of Science and Technology, WINGKING HO, Department of physics, The University of Hong Kong, HAO TIAN, Department of Physics, Southern University of Science and Technology, JIANHUA ZHAO, State Key Laboratory of Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, MAOHAI XIE, Department of physics, The University of Hong Kong — Molybdenum diselenide (MoSe₂) and molybdenum ditelluride (MoTe₂) are promising transition metal dichalcogenides (TMDs) that have attracted great interests in recent years because of their unique electrical and optical properties. In this work, we fabricate crystallographically aligned MoSe₂ and MoTe₂ monolayers on gallium arsenide (GaAs) (111) surface by MBE as revealed by low energy electron diffraction (LEED) measurements. Unlike TMDs growth on van der Waals (vdW) substrates such as the highly oriented pyrolytic graphite (HOPG) and graphene, the interface interactions between GaAs and the epitaxial TMD films are electronically stabilized surface as suggested by X-ray photoelectron spectroscopy (XPS) and density functional theory (DFT) calculations. Ultraviolet photoelectron spectroscopy (UPS) measurements are also performed to provide additional evidence and results.

*This work is financially supported by a Collaborative Research Fund (C7036-17W) sponsored by the Research Grant Council (RGC), Hong Kong Special Administrative Region, China.
**T70.00131: Transport and photoresponse study of Bulk MoS\textsubscript{2}**

MEHDI PAKMEHR (Presenter), MOJTABA EBRABIMI, HAJAR KAZEMI, ZOHREH MOHAMMADI, Physics, Shiraz University — Molybdenum disulfide (MoS\textsubscript{2}) or Molybdenite were known as an indirect gap semiconductor with energy gap of 1.8 eV. More recently, it turns out that in 2D morphology (atomic thin film case) MoS\textsubscript{2} hosts novel physical properties including high optical absorption coefficient. To be used as a common semiconductor material within electronic and optoelectronics industry, one needs to know the types of impurity atoms within by-product powder of MoS\textsubscript{2} from copper extraction factory. We investigated structural properties of powder MoS\textsubscript{2} through PXRD, which confirm MoS\textsubscript{2} with reasonable purity. The powder used for bulk polycrystalline sample growth through common melting techniques. Transport measurements at cryogenic temperatures done to check conductivity of our bulk sample. Due to unintended dopant species, we observed conductivity dependence on temperature in range of 80-300 K. We plan to present our finding through a poster at APS march meeting 2019 being held at Boston.

*M. Pakmehr would like to Acknowledge National Elite Foundation of Iran and Shiraz University Dean Office for supporting our research work.*

**T70.00132: Thermal and Electrical Transport Properties in bulk Ge\textsubscript{2}Sb\textsubscript{2}Te\textsubscript{5}**

MING YIN (Presenter), JERESHIA BUSH, Physics/Engineering, Benedict College, LEI WANG, TIMIR DATTA, Physics & Astronomy, University of South Carolina — The remarkable ability of certain solids, the Phase Change materials (PCM), to reversibly and rapidly switch between amorphous and crystalline states with large differences in electrical, thermal and optical properties was discovered exactly half a century ago [S.R. Ovshinsky PRL, 21,1450 (1968)]. Currently ambient temperature operable PCM’s are used in electronic flash memory as well as optical data storage. Ge\textsubscript{2}Sb\textsubscript{2}Te\textsubscript{5} is such a PCM alloy; in which, we have previously reported Noritheim-Gorter like scaling between Seebeck coefficient (S) and electrical conductivity (σ). Here we report that in the room temperature regime, thermal conductivity (κ) of this material is a linear function of temperature with a slope ~ 1e-3 W/mT\textsuperscript{2}; whereas, electrical conductivity falls off with rising temperature; Remarkably, despite this deviation from Wiedemann-Franz Law, the value of Lorenz number estimated from the experimental (κ and σ) data ranges between 2-2.47 e-8 WWK\textsuperscript{-2}, not much off from the ideal kinetic theory value of 2.44e\textsuperscript{-8}. Further experimental details and results will be discussed.

*DOE DE-NA0002630*

**T70.00133: Photoexcited dynamics in tellurium probed by coherent phonons**

YU-HSIANG CHENG (Presenter), Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, SAMUEL W TEITELBAUM, FRANK GAO, KEITH ADAM NELSON, Department of Chemistry, Massachusetts Institute of Technology — We studied the photoexcited dynamics in tellurium films using ultrafast pump-probe spectroscopy. Photoexcitation with femtosecond laser pulses produces carriers that modify the interatomic potential and thus excite coherent phonons. The phonon frequency strongly depends on the carrier density and the lattice temperature. We estimated the carrier density and the corresponding electronic bond softening using the diffusion equation. We also measured the phonon dynamics at different temperatures from 80 to 500 K. Based on these measurements, the lattice temperature within 1 ns after the pump pulse can be estimated using the frequency of the coherent phonons, excited by a second pump pulse. In addition, we modified the two-temperature model to simulate the dynamics of the carrier density, carrier temperature, lattice temperature, and phonon motion at different depths.

**T70.00134: On the pitfalls of applying isotropic mobility spectrum analysis to conductors with weak anisotropy**

KENNETH S. STEPHENSON (Presenter), YAROSLAW BAZALIY, University of South Carolina — It is shown that applying isotropic quantitative mobility analysis (QMSA) to anisotropic materials can lead to drastic qualitative errors, even in the case of modest anisotropy. The procedure may provide not only wrong values for carrier mobilities and concentrations, but even a wrong number of carrier species.
T70.00135: Multiscale study on Phase Transformation of Ceramic Materials* YUHUAN FEI (Presenter), College of Engineering, Qufu Normal University — Compared with their microstructures, phase analysis of ceramic materials is rarely reported. Generally, phase analysis includes experimental phase structure determination and theoretical simulation, which are quite challengeable and require a heavy workload. Here, we proposed a series of simulation methods to analyze the phase transformation during the sintering process of Al₂O₃-ceramic materials. The structures of generated Al-Mg phases were simulated using XPFC method. The obtained potential function of Ti-C-N was applied to simulate the formation of generated Ti-C-N phases with MD methods employed. Combined with corresponding experimental results, the relationship between specific phases and mechanical properties were established.

T70.00136: In situ investigation of electric field and stress control of ferroelectric phases in PIN-PMN-PT single crystal* PETER FINKEL (Presenter), MARGO STARUCH, United States Naval Research Laboratory, MARKYS CAIN, Electrosciense, Ltd — We explored stability of relaxor ferroelectric single crystals with composition near a morphotropic phase boundary (MPB) using the three-pronged approach offered by this project of in situ, stress, temperature and E field whereby a bias of any one of these parameters can move the operating point in almost any direction. This MPB can be moved through the application of stress or electric field. In this work we demonstrate an induced rhombohedral (R) to orthorhombic (O) phase transition in [011] cut Pb(In₁/₂Nb₁/₂)O₃-Pb(Mg₁/₃Nb₂/₃)O₃-PbTiO₃(PIN-PMN-PT) single crystal relaxor ferroelectric, that can be simultaneously tuned through combination of stress and applied electric field. Direct observations of this phase transition with X-ray and Raman scattering reveal the local symmetry while sweeping through the transition with a low applied electric field when the crystal is near a critical value of stress. A coexistence of R and O phases was observed and these microscopic measurements mirror the bulk strain in the sample. Remarkably, cycling through this transition can generate reversible strain >0.35% for tens of millions of cycles with little fatigue. Details of these results and their implications will be presented.

*Office od Naval Reserach

T70.00137: Ab initio studies of electronic and vibrational properties of transition metal dichalcogenides systems under hydrostatic pressure TOMASZ WOZNIAK (Presenter), Department of Theoretical Physics, Wroclaw University of Science and Technology, JAN KOPACZEK, ROBERT OLIVA, Department of Experimental Physics, Wroclaw University of Science and Technology, PAWEL SCHAROCH, Department of Theoretical Physics, Wroclaw University of Science and Technology, JORDI IBANEZ, Instituto de Ciencias de la Tierra Jaume Almera, ROBERT KUDRAWIEC, Department of Experimental Physics, Wroclaw University of Science and Technology — We study from first principles (DFT) the electronic structure of MoTe₂ and WS₂ under hydrostatic pressure in comparison to photoreflectance spectra. The analysis based on pressure coefficients allowed for identification of several optical transitions in bulk and multilayer systems. The calculated pressure coefficients for K and H point transitions are in good agreement with the experimental values. [1]

Lattice dynamics of bulk HfS₂ and MoS₂ in comparison to high pressure Raman scattering measurements is studied. From the calculated phonon dispersions we derive linear pressure coefficients which are then compared to experimental data. DFT calculations were performed using various functionals, vdW corrections and lattice dynamics calculations methods. We find that GGA properly describes the high pressure lattice dynamics of these compounds when vdW interactions are taken into account. In contrast, we show that LDA, which is widely used to predict structural and vibrational properties at ambient conditions in 2D compounds, fails to reproduce the Raman modes evolution under compression. [2]

T70.00138: WITHDRAWN ABSTRACT
T70.00139: Modeling and Simulation of GaTlAs Quantum Well Solar Cells

Ahmed Zayan (Presenter), Thomas Vanderwende, Electrical and Computer Engineering, Tufts University — Multiple Quantum Wells (MQW) have been an ongoing topic of research and discussion for the scientific community with structures like InGaAs/GaAs and InGaP/GaAs quantum wells producing promising results that could potentially improve overall solar energy conversion. Here, we use WEIN2K, a commercial density functional theory package, to study the ternary compound Ga$_{1-x}$TlxAs and determine its electronic properties. Using these results combined with experimental confirmation we extend these properties to simulate a MQW GaAs/ Ga$_{1-x}$TlxAs solar cell. Ga$_{1-x}$TlxAs is a tunable compound, with its bandgap being strongly dependent on the concentration of Tl present. Concentrations of Tl as low as 7% can reduce the bandgap of Ga$_{1-x}$TlxAs to roughly 1.30 eV at room temperature with as little as a 1.7% increase in lattice constant. The change in bandgap, accompanied by the relatively small change in lattice constant makes Ga$_{1-x}$TlxAs a strong candidate for a MQW cell with little to no strain balancing required within the structure to minimize unwanted defects that impede charge collection within the device. Our GaAs photodiode with TlGaAs MQWs shows an expanded absorption band and improved conversion efficiency over the standard GaAs photovoltaic cell.

T70.00140: Charge carrier lifetime dependence on annealing conditions in copper oxide thin films: A transient absorption study

Lenny Shenje (Presenter), Suzanne Ullrich, University of Georgia — Ultrafast transient absorption spectroscopy has been used to study charge carrier dynamics in Copper(I) and Copper(II) oxide thin films as a function of annealing conditions. 16 samples were deposited on glass substrates and then subsequently annealed at temperatures 150 to 380 C for periods ranging from 2 to 24 hrs. Clear evidence of oxidation from the copper(I) to the copper(II) phases was observed by steady state and time-resolved spectroscopies as well as x-ray diffraction. Thin film transient absorption spectra were recorded by exciting the samples across the band gap and probing subsequent carrier dynamics with a white light continuum. The mixed Cu$_2$O/CuO thin film transient spectra were compared to those of pure Cu$_2$O and CuO to investigate the influence of annealing conditions on the films' optical properties. All samples showed multi-exponential decay kinetics with a fast component (ranging from 0.2 – 0.5 ps) and a long-lived component (>1 ns); an additional 0.8 to 3 ps intermediate time constant was observed in mixed Cu$_2$O/CuO and pure CuO films. These kinetics are attributed to carrier relaxation in the conduction band, trapping and recombination.

T70.00141: Spatially-resolved photoluminescence of Si$_2$Te$_3$ nanostructures*

Andrew Mendizabal (Presenter), Alexis Buzzell, Patrick Devlin Fitzgerald, Kateryna Kushnir, Physics Department, Worcester Polytechnic Institute, Mengjing Wang, Chemistry Department, Brown University, Teng Shi, Physics Department, Worcester Polytechnic Institute, Kristie Koski, Chemistry Department, University of California Davis, Lyubov Titova, Physics Department, Worcester Polytechnic Institute — Silicon telluride (Si$_2$Te$_3$) is a unique 2D material: it has strong optical absorption across the visible spectrum, optical emission in the red, p-type conductivity and processing compatibility with silicon and silicon oxide. It's potential application range from energy storage, thermoelectric devices and chemical sensors to light emitting diodes. It is possible to grow Si$_2$Te$_3$ nanostructures of different morphology, from nanometer-sized nanoplates to ribbons up to 10 μm long by either vapor-liquid-solid or layer-by-layer vapor solid growth[1]. Here we present spatially-resolved photoluminescence spectroscopy of 50-1000 nm-thick Si$_2$Te$_3$ nanoplates and Si$_2$Te$_3$ ribbons that are ca. 300 nm wide and 10 μm long. Correlating morphology, thickness and lateral dimension of Si$_2$Te$_3$ nanostructures to their optical emission provides important insights into their electronic and optical properties, and lays the foundation to their potential applications.

*We acknowledge the financial support of NSF DMR 1750944

T70.00142: Two-dimensional Fourier Transform Spectroscopy on Bulk GaAs in High Magnetic Fields*

Christopher E Stevens, Varun Mapara (Presenter), Jagannath Paul, Dept. of Physics, University of South Florida, Myron Kapetanakis, Dept. of Physics, University of Alabama at Birmingham, Stephen A McGill, National High Magnetic Field Laboratory, Florida State University, Ilias Perakis, Dept. of Physics, University of Alabama at Birmingham, Denis Karaiskaj, Dept. of Physics, University of South Florida — Two-dimensional Fourier transform spectroscopy was performed on Bulk GaAs in the presence of magnetic fields up to 10T. The polarization dependent exciton dynamics were studied in addition to the effects of an applied external magnetic field. The experimental results were then modeled using the optical Bloch equations.

*We acknowledge National Science Foundation for financial support.
A ferroelectric semiconductor field-effect transistor (FeS-FET) was proposed and experimentally demonstrated for the first time. In this novel FeS-FET, a 2D ferroelectric semiconductor α-In$_2$S$_3$ is used to replace conventional semiconductor as channel. α-In$_2$S$_3$ is identified due to its proper bandgap, room temperature ferroelectricity, the ability to maintain ferroelectricity down to a few atomic layers and the feasibility for large-area growth. An atomic layer deposited (ALD) Al$_2$O$_3$ passivation method was developed to protect and enhance the performance of the α-In$_2$S$_3$ FeS-FETs. The fabricated FeS-FETs exhibit high performance with a large memory window, a high on/off ratio over $10^8$, a maximum on-current of 671 μA/μm, high electron field-effect mobility with $\mu_{FE} = 312$ cm$^2$/Vs in forward sweep and $\mu_{FE} = 488$ cm$^2$/Vs in reverse sweep, and the potential to exceed the existing Fe-FETs for non-volatile memory applications.
T70.00147: Minimal double quantum dot in ZnO*  JUNYI ZHANG, Princeton University, HAO ZHENG (Presenter), School of Physics and Astronomy, Shanghai Jiao Tong University, RICHARD BERNDT, Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel — Minimal double quantum dots (DQDs) are prepared in ZnO, a wide band-gap semiconductor matrix. The DQDs are of the atomic scale that is difficult to achieve for for conventional microfabrication techniques. It is comprised of a pair of strongly coupled donor atoms that can each be doubly charged. Using scanning tunneling microscopy and spectroscopy, we mapped out the donor excitation diagram of this system which mimicks the charge stability diagram observed in transport measurements of DQDs. The charge and spin degrees of freedom of the minimal DQDs may also be used as quantum bits. The DQDs can be prepared in the quantum entangled state, e.g., in a Bell state. The results open an intriguing perspective for quantum electronics with atomic-scale structures.

T70.00148: Resistance drift of metastable amorphous and crystalline fcc GeSbTe memory devices*  HELENA SILVA (Presenter), NAFISA NOOR, SHALINI TRIPATHI, C. BARRY CARTER, University of Connecticut — Phase-change memory is an emerging technology that utilizes the electrical resistivity contrast between the amorphous and crystalline phases of chalcogenide glasses to store data. The most commonly used material for PCM has been GeSbTe (GST), which has metastable amorphous and crystalline fcc phases and a stable crystalline hcp phase [1]. One difficulty with the implementation of PCM is the upward resistance drift of the metastable amorphous and crystalline fcc phases. We are using electrical characterization together with transmission electron microscopy and finite-element electrothermal simulations [2] to study the physical mechanisms that give rise to the electrical resistance drift of GST cells.

*This work was supported by NSF under award DMR-1710468. The devices were fabricated at IBM Watson Research Center. The TEM analysis is performed at the CINT, a DOE User Facility operated by Los Alamos and Sandia National Laboratories (DE-AC52-06NA25396 and DE-NA-0003525).

T70.00149: SUPERCONDUCTIVITY —

T70.00150: Iron based superconductors on flexible coated conductor templates*  ALEENA THOMAS (Presenter), KORNELIUS NIELSCH, DR. RUBEN HÜHNE, Leibniz Institute of Solid State and Materials Research (IFW Dresden), Helmholtzstr. 20, 01069 Dresden, Germany — The discovery of high temperature superconductivity in layered iron-based material has ignited also significant scientific interest for technological applications. Iron based superconductors are particularly promising for high field applications due to its high upper critical field and low anisotropy. To realize such applications, the coated conductor technology based on textured IBAD (Ion beam assisted deposition) layers can be used. Additionally, such templates might be applied to investigate the influence of uniaxial strain on the superconducting properties. Therefore, we deposited pure as well as Te doped FeSe with a thickness of up to 200 nm on buffered IBAD substrates having a final cap layer of either CeO2 or LaMnO3. We found that FeSe1-xTex (FST) and FeSe is grown epitaxially on these buffered metal tapes under optimized conditions with a superconducting transition temperature of up to 16 K for textured FST film on CeO2 buffered metal tape. Finally, we will present first results on the influence of uniaxial strain on the superconducting transition using these templates.

*This work was supported by the German research foundation (DFG) within the research training group GRK 1621.
T70.00151: Measurements of Superconducting Anisotropy in FeSe with Resonance Frequency Technique

RONGXING CAO (Presenter), JUN DONG, College of Physics Science and Technology, Yangzhou University, D. A. CHARIEV, Institute of Experimental Mineralogy, Russian Academy of Sciences, A. N. VASILIEV, Low Temperature Physics and Superconductivity Department, Lomonosov Moscow State University, GUOQING WU, XIANGHUA ZENG, College of Physics Science and Technology, Yangzhou University — Utilizing a novel method with the resonance frequency of a LC circuit, we measured the superconducting anisotropy of single crystals of Fe-based superconductor FeSe. We found that the temperature dependence of the upper critical field $H_{c2}(T)$ of FeSe coincides with the Werthamer-Helfand-Hohenberg (WHH) model when taking the Maki parameter $\alpha$ into consideration, which suggests an important role played by spin-paramagnetic effect in suppressing the superconductivity. When temperature $T \to 0$, the values of $H_{c2,||}(0)$ and $H_{c2,\perp}(0)$ derived from the WHH fitting are close to and within the range of the Pauli limit, for field $H_0$ applied parallel to the c-axis and to the ab-plane, respectively. As compared with other typical iron-based high-Tc superconductors, lower values of $H_{c2}(0)$ and higher superconducting anisotropy were found in FeSe.

Work in Russia was supported by Act 211 of RFG (Agreements 02.A03.21.0004, 02.A03.21.0006, and 02.A03.21.0011), and Foundation for Basic Research (Grant No. 17-29-10007), and Ministry of Education and Science (Grant No. K2-2017-084).

T70.00152: Phases and Phase Transitions of an Anisotropic Ising-O(3) Model

ANZUMAAN CHAKRABORTY (Presenter), THOMAS VOJTA, Physics, Missouri University of Science and Technology — The two-dimensional anisotropic Ising-O(3) model is an effective Hamiltonian for the square-lattice J1-J2 Heisenberg model, with nearest-neighbor coupling J1 along with frustrated and dominant next-nearest-neighbor coupling J2. We employ Monte Carlo simulation of the Ising-O(3) model to determine its phase diagram as a function of the anisotropy of the O(3) spins and the temperature. For sufficiently large anisotropy, there is a direct transition from the paramagnetic high-temperature phase to the low-temperature phase that breaks both spin and nematic (Ising) symmetries. This transition splits into two separate transitions as the anisotropy is lowered, leading to the appearance of an Ising-ordered intermediate phase. We also determine the orders of the phase transitions. These results can be related to the experimental observations of the orders and sequences of magnetic and structural transitions in quasi-2D ferropnictide materials.

*This work was supported in part by the NSF under Grant numbers DMR-1506152 and DMR-1828489.

T70.00153: Magnetic properties of bulk and monolayer FeSe : A DFT+DMFT study

CHANG-YOUN MOON (Presenter), Korea Research Institute of Standards and Science — FeSe is unique among other iron-based superconductors, which shows no magnetic ordered state and becomes superconducting below 8 K in the undoped bulk system while the superconducting transition temperature soars by an order of magnitude for a monolayer FeSe on SrTiO3 substrate. Using a DFT+DMFT method, we perform a comparative study on the magnetic properties of FeSe systems and LaFeAsO, another representative iron-based superconducting material. Calculated magnetic moment in the typical stripe-type magnetic ordering pattern is finite for LaFeAsO while negligible for bulk FeSe, consistently with experiments, and is also finite for monolayer FeSe suggesting the magnetic order is restored in monolayer FeSe. We suggest a mechanism explaining why the systems with the similar magnitudes of fluctuating spin $\langle S_2^2 \rangle$ have very different magnitude of ordered moment $\langle S_z \rangle$ focusing on the different aspects of local charge fluctuation. Our work provides a comprehensive understanding of magnetism in iron-based superconducting materials, and also emphasizes on the potential importance of magnetism in the high superconducting transition temperature of monolayer FeSe on SrTiO3 substrate.
The nematicity induced $d$-symmetry charge density wave in electron-doped iron-pnictide superconductors*  
HONG-YI CHEN (Presenter), National Taiwan Normal University — The interplay among the nematicity, the stripe spin-density-wave (SDW) order and superconductivity in iron-pnictides is studied in a self-consistent Bogoliubov-de Gennes equations. Our calculations have shown that the nematic-order breaks the degeneracy of $d_{x^2-y^2}$ and $d_{yz}$ orbitals and causes the elliptic Fermi surface near the $\Gamma$ point in the normal state. In addition, the appearance of the orthorhombic magnetic fluctuations generates two uneven pairs of peaks at $(\pm\pi,0)$ and $(0,\pm\pi)$ in its Fourier transformation. All these are comparing favorably with experimental measurements. In the nematic phase, our results indicate that the charge density and its spatial image in the local density of states exhibit a $d_{x^2-y^2}$-like symmetry. Finally, the complete phase diagram is obtained and the nematic phase is found to be in a narrow region close to the SDW transition in the electron-doped iron-pnictide superconductors.

*MoST of Taiwan under Grant No. 104-2112-M-003-003-MY3 and 102-2112-M-002-003-MY3, and National Center for Theoretical Science of Taiwan.

Point Contact Spectroscopy of Iron Pnictides: Probing Superconductors to Observe the Gap Structures of (P, Co, K) Doped Iron Pnictides*  
BRETT CONTI, OBERON O WACKWITZ, KEERAN RAMANATHAN (Presenter), GABRIELLE MOSS, University of the Sciences, CHENG LIN ZHANG, YU SONG, GUOTAI TAN, PENGCHENG DAI, Rice University, ROBERTO RAMOS, University of the Sciences — We used a four-wire point contact spectroscopy system to obtain differential conductance ($dI/dV$) measurements in order to observe the energy gap structures of phosphorus, cobalt, and potassium doped iron-pnictides with varying doping levels at 2K. We were motivated to study the iron pnictides because they were only recently discovered to be superconducting (~2007) due to the presence of iron which is traditionally expected to quench all superconducting properties, and also because the iron pnictides can exhibit multi-gap structures like those of magnesium di-boride. Our goal was to obtain the differential conductance measurements for varying $x$ values of phosphorus, cobalt, and potassium, and observe the gap structures of the various families to further characterize and understand the superconducting transition of these iron pnictides. We observed both single and double gap structures for various $x$ values, with delta $1 \approx 2-5$ meV, and delta $2 \approx 7-10$ meV. We will report additional results from this ongoing work.

Growth of ultra-thin high-Tc FeSe$_{0.5}$Te$_{0.5}$ film with high Tc on piezoelectric Pb(Mg$_{1/3}$Nb$_{2/3}$)$_{0.7}$Ti$_{0.3}$O$_3$ substrates by pulsed laser deposition  
LIN ZHU (Presenter), physics, florida state university, YONGGANG ZHAO, physics, Tsinghua University — The influence of strain on the electrical transport properties of iron chalcogenide superconductors FeSe$_x$Te$_{1-x}$ may offer insight into the mechanism of superconductivity. The inverse piezoelectric effect from a piezoelectric substrate provides a method of continuous tuning of the lattice deformation on one and the same sample. Single-crystalline piezoelectric Pb(Mg$_{1/3}$Nb$_{2/3}$)$_{0.7}$Ti$_{0.3}$O$_3$ (PMN-PT) substrates have been shown to allow reversible and dynamic control of biaxial strain in epitaxially grown thin functional films. Here we present an effective method to significantly improve the epitaxy of superconducting FeSe$_1$-xTex thin films via the introduction of a semiconducting buffer layer of FeSe$_1$-xTex. The buffer layer enables subsequent growth of superconducting FeSe$_1$-xTex at reduced deposition temperatures ($275\degree$C) on PMN-PT by pulsed laser deposition. The films exhibit consistently high critical temperatures ($\geq 16$ K); the FeSe$_1$-xTex thin films show Tc as high as 15 K even when the thicknesses are less than 10 nm. This work demonstrate a versatile platform to investigate the relationship between structure and superconductivity in FeSexTe$_1$-x thin films.

Direct Visualization of the Nematic Superconductivity in Cu$_x$Bi$_2$Se$_3$  
RAN TAO (Presenter), Physics, Fudan University — Cu$_x$Bi$_2$Se$_3$ hosts both topological surface states and bulk superconductivity. It has been identified recently as a topological superconductor (TSC) with an extraordinary nematic, i. e. $C_2$-symmetric, superconducting state and odd-parity pairing. Here, using scanning tunneling microscopy (STM), we directly examine the response of the superconductivity of Cu$_x$Bi$_2$Se$_3$ to magnetic field. Under out-of-plane fields ($B_\perp$), we discover elongated magnetic vortices hosting zero-bias conductance peaks consistent with the Majorana bound states expected in a TSC. Under in-plane fields ($B_//$), the average superconducting gap exhibits two-fold symmetry with field orientation; the long $C_2$ symmetry axes are pinned to the dihedral mirror planes under $B_//=0.5$ T but rotate slightly under $B_//=1.0$ T. Moreover, a nodeless $\Delta_4^x$ gap structure is semi-quantitatively determined for the first time. Our data paint a microscopic picture of the nematic superconductivity in Cu$_x$Bi$_2$Se$_3$ and pose strong constraints on theory.
T70.00158: SUPERCONDUCTING TRANSITION TEMPERATURE OF A BORON NITRIDE LAYER WITH A HIGH TITANIUM COVERAGE.*

FERNANDO MAGANA (Presenter), GERARDO J VAZQUEZ, National Autonomous University of Mexico — We explore the possibility of inducing superconductivity in a Boron Nitride (BN) sheet, by doping its surface with Ti atoms sit on the center of the BN hexagons. Defining the coverage M as the ratio of the number of atoms of titanium to the number of hexagons of BN per cell, we take the cases of M = 1 and 1/3. We used first-principles density functional theory in the general gradient approximation. The Quantum-Espresso package [1] was used with norm conserving pseudopotentials. The structure considered was relaxed to their minimum energy configuration. Phonon frequencies were calculated using the linear-response technique on several phonons wave-vector mesh. The electron-phonon coupling parameter was calculated with several electron momentum k-mesh. The superconducting critical temperature was estimated using the Allen-Dynes formula with μ* = 0.1 - 0.15. We note that Ti is a good candidate material to show a superconductor transition for the BN-metal system.

*We thank Mitzli Super-Computing center the technical assistance.

T70.00159: Superconductivity in Niobium Nitride

TSU-LIEN HUNG (Presenter), MIN-NAN OU, FAN-YUN CHIU, TING-KUO LEE, YANG-YUAN CHEN, Institute of Physics, Academia Sinica — Niobium nitride is a well-known superconductor with many excellent physical properties, such as high hardness, high shear rigidity, high bulk modulus. It has several structure phases, including cubic, hexagonal, and tetragonal. Among these phases, the cubic phase has been extensively studied the superconductivity with a wide range of $T_c$, 9 ~ 17 K. In our work, the cubic phase specimens of NbN were been measured by X-ray diffraction, magnetic susceptibility, resistivity, and specific heat. We observed that the $T_c$ of cubic phase appeared 13.6 K from magnetic and specific heat measurements. Very recently the hexagonal phase of epsilon-NbN (ε-NbN) has been reported to have the superconducting transition temperature about 11 K [1]. A micron sized NbN crystal was obtained from commercial product, and confirmed to be epsilon phase by electron back-scattering diffraction (EBSD) technique. However, no superconductivity was found in the micron sized epsilon-NbN crystal. We inferred that the superconductivity of epsilon-NbN reported in literature may have shorter Nb-N bond length as that of the cubic NbN phase which is about 0.02 Å shorter than our epsilon-NbN crystal.

T70.00160: ABSTRACT WITHDRAWN

T70.00161: Crystalchemistry and Thermodynamics in ZnMgO$_2$, Zn$_2$MgO$_3$ and Zn$_3$MgO$_4$ compositions.

DANIEL IVÁN GUILLEN CARRILLO (Presenter), ELIZABETH CHAVIRA, RICARDO ERNESTO PANIAGUA, JOSE ANTONIO HURTADO, KARLA ERISETH MORALES, ADRIANA TEJEDA, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México, JESÚS ÁNGEL ARENAS, JORGE BARRETO, Instituto de Física, Universidad Nacional Autónoma de México, ROBERTO YSACC SATO, Instituto de Ciencias Aplicadas y Tecnología, Universidad Nacional Autónoma de México — In 2016 was reported the ZnMgO$_2$ 115 K, Zn$_2$MgO$_3$ 132 K y Zn$_3$MgO$_4$ 152 K superconductors. Our interest was study the thermodynamic behaviour, which did not reported jet. Of course, also study their crystal structure and magnetic properties. Searching in the phase diagrams thermodynamic equilibrium, we found the binary ZnO-MgO system. Then the SC compositions were in the region of the mixture of zincite-periclase solid solutions.

By simultaneous SDT (DCS-TGA) analysis it is observe the reactions and oxygen changes temperature. The solid solution mechanism was complex, occurs a cationic substitution and instantaneous accepted our lost of anions.

XRD was used to determine the reagents purity, crystal structure and reactions results. Gives the information of the formation of the mixtures of the solid solutions. CIF data helps to determined (hkl) displacement in the wurtzite crystal structure, that shows what planes happened the cation substitution. For example, (110) indicates Zn$^{2+}$ ions substitution by Mg$^{2+}$ cation. RAMAN gives only ZnO vibration, because are in a high proportion in the studied compositions. SQUID corroborate that the compositions worked were not superconductors.
SYNTHESIS OF (Bi$_{1.7}$Pb$_{0.3}$)Sr$_2$Ca$_2$Cu$_2$O$_{10}$ NANOMATERIAL SUPERCONDUCTOR. RICARDO ERNESTO PANIAGUA MARTINEZ (Presenter), ELIZABETH CHAVIRA, DANIEL IVAN GUILLEN CARRILLO, RODOLFO IVAN CRUZ HERNANDEZ, ADRIANA TEJEDA, KARLA ERISETH MORALES, Instituto de Investigaciones en Materiales, Universidad Nacional Autónoma de México., JESÚS ÁNGEL ARENAS, JORGE BARRETO, Instituto de Física, Universidad Nacional Autónoma de México. — The purpose of the study of the synthesis of the compound (Bi$_{1.7}$Pb$_{0.3}$)Sr$_2$Ca$_2$Cu$_2$O$_{10}$ is to characterize the properties of the superconductivity in the (Bi$_{1.7}$Pb$_{0.3}$)Sr$_2$Ca$_2$Cu$_2$O$_{10}$ when it is found as a nanocrystal in the stabilized 110 K superconducting compound, which will be induced in a single superconducting compound with the addition of lead that will substitute in the proportion of 15% of a bismuth, the final product will be characterized by XRD and SQUID.

To obtain the polycrystals of the material, solid state reaction was used with PbO, CuO, CaCO$_3$, SrCO$_3$, Bi$_2$O$_3$ by reagents, which were crushed by hand with an agate mortar.

To obtain nanocrystals from the sample, the wet crushing technique will be used, which consists of placing the sample with methanol and a magnetic stirring bar for a period of 68:22 hours.

The polycrystalline and nanocrystalline products were characterized with SQUID to see their hysteresis curves interpreting whether they present superconductivity or not.

Pairing in quantum-critical systems: $T_c$, $\Delta$ and their ratio* YI-MING WU (Presenter), University of Minnesota, ARTEM G ABANOV, Physics, Texas A&M U, ANDREY CHUBUKOV, University of Minnesota — We calculate the ratio of the pairing gap $\Delta$ at $T=0$ and $T_C$ for a set of quantum-critical models in which the pairing interaction is mediated by a gapless boson (the $\gamma$ model, where different $\gamma$ corresponds to different pairing models). The ratio $2\Delta/T_C$ has been recently computed numerically for $0<\gamma<2$ within Eliashberg theory and was found to increase with increasing $\gamma$ [T-H Lee et al, arXiv:1805.10280]. We argue that the origin of the increase is the divergence of this ratio at $\gamma = 3$. We obtain an approximate analytical formula for the ratio for $\gamma<3$ and show that it fits numerical data well. We also consider in detail the opposite limit of small $\gamma$. Here we obtain the explicit expressions for $T_c$ and $\Delta$, including numerical prefactors. We show that these prefactors depend on fermionic self-energy in a rather non-trivial way. The dependence is, however, the same for $T_c$ and $\Delta$, and the ratio $2\Delta/T_c$ approaches the BCS value 3.53 when $\gamma$ approaches to 0.

*We thank T-H Lee, G. Kotliar for fruitful discussions. The work by YW and AVC was supported by NSF-DMR-1523036.

Thermodynamic Properties of a nano-gram NbN crystal by 3ω Method FAN-YUN CHIU (Presenter), MIN-NAN OU, CHIA-SENG CHANG, YANG-YUAN CHEN, Institute of Physics, Academia Sinica — Niobium nitride is a well-known superconductor, which has several structure phases, including cubic, hexagonal, and tetragonal. Among them, the cubic phase has been extensively studied, and shows a superconductivity transition temperature ($T_C$) in a wide range of $T_C = 9 \sim 17$ K. In order to study the superconductivity of a single crystalline NbN, a NbN crystal with um size was selected from a commercial powder. The phase of selected crystals were confirmed by powder x-ray diffraction and electron backscatter diffraction (EBSD) analysis. In this work, crystals placed on a nanowire-device (ND) for studying its thermodynamic properties by 3ω method. The fabricated ND (30 μm × 600 nm × 100 nm) was carried out by means of thermal and sputtering deposition, and optical and e-beam lithography on a Si$_3$N$_4$/Si wafer. The chemical etching techniques followed up to realize the sagging of the ND from the membrane for thermal isolation. By 3ω technique, the temperature dependent specific heat and thermal conductivity of a NbN crystal at low temperatures were investigated. The details will be discussed in the presentation.

Structural and electronic behaviors of YBa$_2$(Fe$_{1-x}$Mn$_x$)$_3$O$_{8+\delta}$* RICHARD FALCONI (Presenter), MAURY SOLORZANO, Basic Science, Universidad Juárez Autónoma de Tabasco — In this work, the synthesis, structural, electrical and magnetic characterization of the set of polycrystalline samples: YBa$_2$(Fe$_{1-x}$Mn$_x$)$_3$O$_{8+\delta}$, with $x = 0$, 0.025, 0.05, 0.10 and 0.15 are reported. From the structural point of view, it was found that Mn doping generates a decrease in cell volume which is related to an oxidation state different from Mn$^{3+}$ as corroborated by XPS analysis. On the other hand, the magnetic behavior of the YBa$_2$Fe$_2$O$_{8+\delta}$, system presents a weak ferromagnetic transition around 16 K. Doping with Mn, results in a considerably decrease of the magnetic transition temperature. Oxygen content slightly decreases under Ti doping, but it seems not to be related to magnetic changes. Instead magnetic behavior is routed to changes in the oxidation state of Mn ion.

M.S. Acknowledges to Conacyt for a scholarship.
SOORAN KIM (Presenter), Physics Education, Kyungpook National University, XI CHEN, WILLIAM FITZHUGH, XIN LI, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Since the discovery of high-temperature superconductivity in hole-doped La$_2$CuO$_4$, the mechanism of cuprate superconductors has been one of the most important problems in condensed matter physics. In this talk, we show, using ab initio simulations, a new trend that the bonding strength between the apical cation (e.g. La, Hg, Bi Ti) and apical anion (O, Cl) is positively correlated with experimental $T_{c,max}$ across the hole-doped cuprates. The “apical structure unit” formed by the apical anion and the apical cation, the in-plane Cu and its nearest oxygen neighbors is a fundamental building block that can couple dynamically to control the superconductive properties. We present the underlying fundamental phenomena of coupled apical charge flux and the phonon/lattice dynamics of apical oxygen. Cooperative apical charge fluxes modulate the in-plane transport property by dynamically change both hopping integral and charge transfer energy. We believe our understanding here can shed light on the understanding of the complicated phenomena in cuprates, especially how the transport properties are controlled by the coupled electronic and ionic dynamic oscillations.

CHUN-CHIH HSU (Presenter), Department of Physics, National Taiwan University, Taipei, Taiwan, BO-CHAO HUANG, Institute of Atomic and Molecular Science, Academia Sinica, Taipei, Taiwan, CHIA-SENG CHANG, Institute of Physics, Academia Sinica, Taipei, Taiwan, YA-PING CHIU, Department of Physics, National Taiwan University, Taipei, Taiwan; and Institute of Physics, Academia Sinica, Taipei, Taiwan — Short-range charge density wave (CDW) order is found universally among underdoped high-$T_c$ superconductors. However, a picture on how CDW order propagates through CuO$_2$ planes remains ambiguous. In this work, we presented cross-sectional scanning tunneling microscopy and spectroscopy measurement on YBa$_2$Cu$_3$O$_6$8.81 thin film and probed both atomic and electronic structure simultaneously along the $c$-axis. Our real-space observation reveals the existence of the charge modulation on CuO$_2$ plane and CuO chain layers. The periodicity of charge modulation exhibits a wide distribution with peak value $\lambda \approx 1.3$ nm and is correlated across layers, implying a close connection of CuO$_2$ plane and CuO chain layer.

LIPSCOMBE, STEPHEN HAYDEN, H.H. Wills Physics Laboratory, University of Bristol, TITUS NEUPERT, Physics, University of Zurich, CHRISTIAN MATT, Physics Department, Harvard University, JOHAN CHANG, Physics, University of Zurich — On this poster, we present a soft x-ray angle-resolved photoemission spectroscopy study of the high-temperature superconductors La$_2$-Sr$_x$CuO$_4$ (LSCO) and La$_{1.8-x}$Eu$_{0.2}$Sr$_x$CuO$_4$. Mapping in-plane and out-of-plane components of the Fermi surface reveals a distinct $k_z$ dispersion, that was parametrizing a tight binding model [1]. In this fashion, we quantify the contribution of the van Hove singularity to specific heat found in over doped LSCO can't be assigned to the van Hove singularity and is therefore taken as evidence of quantum criticality.

T70.00169: Vortex dynamics and hysteretic flux losses due to pinning*  
DANILIO LIARTE (Presenter), DANIEL HALL, PETER N. KOUFALIS, Cornell University, AKIRA MIYAZAKI, CERN, ALEN SENANIAN, MATTHIAS ULF LIEPE, JAMES PATARASP SETHNA, Cornell University — We use a model of vortex dynamics and collective weak pinning theory to study the residual dissipation due to trapped magnetic flux in a dirty superconductor. Using simple estimates, approximate analytical calculations, and numerical simulations, we make predictions and comparisons with experiments performed in CERN and Cornell on resonant superconducting radio-frequency NbCu, doped-Nb and Nb3Sn cavities. We invoke hysteretic losses originating in a rugged pinning potential landscape to explain the linear behavior of the sensitivity of the residual resistance to trapped magnetic flux as a function of the amplitude of the radio-frequency field. Our calculations also predict and describe the crossover from hysteretic-dominated to viscous-dominated regimes of dissipation. We propose simple formulas describing power losses and crossover behavior, which can be used to guide the tuning of material parameters to optimize cavity performance.

T70.00170: Vortex dynamics in temperature gradients: Magnetic flux expulsion in type-II superconductors.*  
ALEN SENANIAN (Presenter), DANILO LIARTE, JAMES PATARASP SETHNA, Cornell University — How do vortices in type-II superconductors get expelled as they are cooled down to the Meissner state? Experiments at Fermilab and Cornell on superconducting radio-frequency cavities suggest thermal gradients are the main mechanism behind flux expulsion. Trapped flux significantly contributes to power losses in particle accelerators, thus understanding expulsion is vital to optimizing cavity performance. Here we re-derive the thermal gradient force acting on vortices and study vortex dynamics when this force is offset with pinning forces and vortex-vortex interactions. We show that a thermal gradient acting on interacting vortices is sufficient for flux expulsion in the absence of impurities. We then introduce collective weak pinning and use recent results to obtain analytic expressions for the balance of these forces for isolated vortices. We further explore flux trapping mechanisms by modeling pinning of vortices on strong, but local, pinning centers. By including vortex-vortex interactions in addition to vortex-impurity interactions, we numerically explore their implications on trapped magnetic flux. Finally, we consider the consequences of dendritic inhomogeneity in the cooling temperature-front on flux trapping.

T70.00171: Josephson Junctions Containing Antiferromagnetic FeMn and IrMn for Cryogenic Memory Application*  
ROBERT MICHAEL KLAES (Presenter), BETHANY M NIEDZIELSKI, THOMAS JOSEPH BERTUS, REZA LOLOEE, NORMAN OWEN BIRGE, Michigan State University — The study of ferromagnetic Josephson junctions for cryogenic memory applications is an area of intense research interest. The prototypical memory device takes the form of an S/F/F'/S spin valve where the two ferromagnetic layers [F, F'] have different switching fields. Switching the relative magnetizations of the two layers between parallel and antiparallel tunes the ground state phase difference across the junction to either 0 or π [1], and corresponds to a bit in a proposed memory cell [2]. It is necessary to design a device where the magnetization of the hard F' layer is robust within the switching field range of the soft F layer. A traditional method of accomplishing this in MRAM applications is to exchange-bias one of the layers by pinning its magnetization with an adjacent antiferromagnetic layer. To determine if that method can be used in cryogenic memory, we have fabricated Josephson junctions containing FeMn/NiFe and IrMn/NiFe bilayers. We present the results in this poster.

T70.00172: Terahertz Emission From Annular Microstrip Antennas

AMANDA VASQUEZ (Presenter), SHEILA BONNOUGH, RICHARD KLEMM, University of Central Florida — One of the most promising proposed sources of terahertz (THz) electromagnetic radiation is superconductor-based devices. These superconductors work by utilizing the intrinsic Josephson junctions (IJJs) present in single crystals of the superconductor Bi$_2$Sr$_2$CaCu$_2$O$_{8+δ}$ (BSCCO). To exploit the Josephson effect, a groove is inscribed in a crystal of BSCCO, producing a mesa about 1 μm thick of any shape, the geometry of which determines the emission spectrum. Alternatively, much more efficient stand alone mesa structures can be built in the desired geometry. The mesa or mesa cavity effectively functions as a microstrip antenna, which can be analyzed using standard antenna theory.

In this project, we study the one and two-dimensional wave functions of a thin annular antenna, with inner and outer radii $p_1$ and $p_2$, respectively. This involves constructing the wave functions from products of Bessel functions of the radial coordinate and trigonometric functions of the angular coordinate, finding expressions for the energy eigenvalues, and producing contour plots of the emitting wave functions. We then employ the Love equivalence principles to integrate the emission phase factor around the circumference and produce plots of the emission power patterns.

T70.00173: Characterization of cavity mode and radiation pattern in superconducting coherent terahertz emitters

KAVEH DELFANAZARI (Presenter), University of Cambridge, RICHARD KLEMM, University of Central Florida, MANABU TSUJIMOTO, University of Tsukuba, DANIEL CERKONEY, Rutgers University, TAKASHI YAMAMOTO, Delft University of Technology, TAKANARI KASHIWAGI, KAZUO KADOWAKI, University of Tsukuba — We discuss the broadly tunable terahertz (THz) radiation in solid state terahertz (THz) emitters based on high-temperature superconducting Bi$_2$Sr$_2$CaCu$_2$O$_{8+δ}$ (Bi-2212). We experimentally measure the current-voltage characteristics (IVC) of mesas of different geometries, such as triangular-, pentagonal-, hexagonal-, and elliptical- cavities, and compare the IVC of the radiating and no-radiating cavities. The THz emission spectra in radiating THz cavities was measured using the Fourier transform infrared spectrometer in order to elucidate the radiation mechanism of the emitters. Moreover, we experimentally and theoretically study the angular dependence of the emission intensity obtained in mesas’ plane at various frequencies and detection angles, by rotating the sample holder relative to the detector, to identify the excited EM cavity modes within the cavities that participate in the emitter output power enhancement.

T70.00174: Towards Measuring Vacuum Polarization of Quantum Electrodynamics with Superconducting Junctions

ALI RAD (Presenter), Physics, University of Maryland, College Park — In this proposal, we present an experimental setup based on superconducting circuits and Josephson junctions to explore the modification of Josephson coefficient in the presence of external magnetic field due to vacuum polarization of quantum electrodynamics. This robust experiment can be considered as one of the few possible chances to observe the fine quantum field theory corrections in the low energy regimes of condensed matter systems. It can also be a new check for the universality of Josephson constant which is important in metrology. We will expect the signal to noise ratio of the read-out signal to increases quadratically by running time of the experiment. This characteristic of the output signal the will guarantee the feasibility of measurements with desired precision.

T70.00175: Device for extraction of Majorana current by means of Fraunhofer diffraction in proximitized superconducting arrays*

XIANGYU SONG (Presenter), YANG BAI, JAMES ECKSTEIN, ALEXEY BEZRYADIN, Physics, University of Illinois at Urbana-Champaign — We propose a geometry in which the supercurrent carried by Majorana zero modes dominates the ordinary supercurrent. The devices is tunable through the Fraunhofer diffraction. The contribution of the Majorana current is further amplified by organizing an array of conducting channels. This system can act as a tunable source of Majorana current.

We performed transport experiment on superconductor-topological insulator-superconductor Josephson junctions array consisting of square niobium islands on a Bi$_2$Se$_3$ film.

According to a Fraunhofer diffraction model, when perpendicular magnetic field is applied such that there is exactly one flux quantum in each junction we should achieve the desired regime where Majorana current is the only supercurrent in the sample. Our results indicate that the conductance peak corresponding to ordinary supercurrent indeed disappears at such magnetic flux bias. Yet, even at this flux bias (frustration f=2) the sample resistance approaches zero rapidly with cooling. This divergence of the conductance at the flux when the ordinary superconductivity is suppressed is taken as evidence for Majorana mode supercurrent.

Geometrical inhomogeneity has been modelled and, apparently, cannot account the observed zeroing of the resistance.

T70.00176: Ferromagnetic Resonance Properties of NbCrFeCrNb multilayer stacks* MURAT CUBUKCU, London Centre for Nanotechnology, University College London, SACHIO KOMORI, Department of Materials Science and Metallurgy, University of Cambridge, ALEXANDER VANSTONE, Blackett Laboratory, Imperial College London, JULIET JOHNSON, Department of Materials Science and Metallurgy, University of Cambridge, ALEXANDER CHAN (Presenter), Blackett Laboratory, Imperial College London, KUN-ROK JEON, MARK BLAMIRE, JASON ROBINSON, Department of Materials Science and Metallurgy, University of Cambridge, LESLEY COHEN, Blackett Laboratory, Imperial College London, HIDEKAZU KUREBAYASHI, London Centre for Nanotechnology, University College London — It is by now well established that the presence of a spatially varying magnetization at a SC/FM interface can generate long range spin-polarized triplet supercurrents into the FM via the proximity effect in combination with spin mixing and spin rotation processes. Indeed junctions made up of Nb/Cr/Fe/Cr/Nb layers have been shown to carry supercurrents through significant thicknesses of Fe, showing that this combination of layers supports the generation of long range spin triplet superconductivity [1]. Quite separately, it has been recently demonstrated that spin pumping by ferromagnetic resonance (FMR) of Py when embedded in a Pt/Nb/Py/Nb/Pt stack also supports the formation of long range triplet superconductivity [2]. The characteristic signature of a spin triplet supercurrent in the latter case was an anomalous broadening of the FMR linewidth below the superconducting critical temperature \((T_C)\). In the current work we report on the FMR properties of Nb/Cr/Fe/Cr/Nb stacks, to study the behaviour of the intrinsic linewidth above and below \(T_C\) and to establish characteristics indicative of triplet superconductivity.

T70.00177: Time-dependent Ginzburg-Landau model for light-induced superconductivity in the cuprate LESCOt/8 ROSS TAGARAS, JIAN WENG, ROLAND ALLEN (Presenter), Texas A&M University — Cavalleri and coworkers have discovered evidence of light-induced superconductivity and related phenomena in several different materials [1]. Here we suggest that some features may be naturally interpreted using a time-dependent Ginzburg-Landau model. In particular, we focus on the lifetime of the transient state in \(La_{1.675}Eu_{0.2}Sr_{0.125}CuO_4\) (LESCOt/8), which is remarkably long below about 25 K, but exhibits different behavior at higher temperature. A reciprocity inherent in the free energy makes the superconducting phase just as effective in blocking the stripe phase as vice-versa, and in the simulations at low temperature (coherent 3-dimensional) superconductivity persists as a robust metastable phase for an indefinitely long period of time after the femtosecond-scale laser pulse has destroyed the (coherent 3-dimensional) stripe phase. On the other hand, as the temperature, stoichiometry, and other parameters vary, there may be no ordered phase, or either, or both coexisting, as is consistent with a large body of experimental and theoretical work.

T70.00178: High field charge order across the phase diagram of \(YBa_2Cu_3O_y\)* DAVID LEOBEUF (Presenter), FRANCIS LALIBERTÉ, MEHDI FRACHT, SIHAM BENHABIB, LNCMI, TOSHINAO LOEW, JUAN PORRAS, MATHIEU LE TACON, BERNHARD KEIMER, max planck inst., CYRIL PROUST, LNCMI, STEFFEN WIEDMANN, HFML — In hole-doped cuprates there is now compelling evidence that inside the pseudogap phase, charge order breaks translational symmetry. In \(YBa_2Cu_3O_y\) (YBCO) charge order emerges in two steps: a 2D order found at zero field and at high temperature inside the pseudogap phase, and a 3D order that is superimposed below the superconducting transition \(T_c\) when superconductivity is weakened by a magnetic field. Several issues still need to be addressed such as the effect of disorder, the relationship between those charge orders and their respective impact on the Fermi surface. Here, we report high magnetic field sound velocity measurements of the 3D charge order in underdoped YBCO in a large doping range. We found that the 3D charge order exists over the same doping range as its 2D counterpart, indicating an intimate connection between the two distinct orders. Moreover, our data suggest that 3D charge order has only a limited impact on low-lying electronic states of YBCO.

*CNRS, European Magnetic Field Laboratory (EMFL), French ANR (SUPERFIELD, contract ANR-12-BS04-0012-02) the Laboratoire d’Excellence NEXT (ANR-10-LABX-0037-NEXT), French ANR (project UNESCO COS, contract ANR-14-CE05-0007), the Laboratoire d’Excellence LANEF (ANR-10-LABX-0037-NEXT), and the Université Grenoble-Alpes (SMing-AGIR).
Pressure tuning of structure, superconductivity and novel magnetic order in the Ce-underdoped electron-doped cuprate T'-Pr$_{1.3-x}$La$_{0.7}$Ce$_x$CuO$_4$ ($x = 0.1$)

ZURAB GUGUCHIA (Presenter), Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, TADASHI ADACHI, Department of Engineering and Applied Sciences, Sophia University, ZURAB SHERMADINI, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, JOHAN CHANG, Physics Institute, University of Zürich, EMIL BOZIN, Brookhaven National Laboratory, FABIAN O VON ROHR, Department of Chemistry, University of Zürich, ANTONIO M. DOS SANTOS, JAMIE MOLAIISON, Oak Ridge National Laboratory, REINHARD BOEHLER, Carnegie Institution of Washington, YOJI KOIKE, Department of Applied Physics, Tohoku University, JEDRZEJ WIETESKA, Columbia University, BENJAMIN FRANDSEN, Brigham Young University, ELVEZIO MORENZONI, ALEX AMATO, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, SIMON J L BILLINGE, YASUTOMO J UEMURA, Columbia University, RUSTEM KHASANOV, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute — High-pressure neutron powder diffraction, muon-spin rotation and magnetization studies of the structural, magnetic and the superconducting properties of the Ce-underdoped superconducting (SC) electron-doped cuprate system T’-Pr$_{1.3-x}$La$_{0.7}$Ce$_x$CuO$_4$ with $x = 0.1$ are reported. A strong reduction of the lattice constants a and c is observed under pressure. However, no indication of any pressure induced phase transition from T’ to T structure is observed up to the maximum applied pressure of $p = 11$ GPa. Large and non-linear increase of the short-range magnetic order temperature $T_{so}$ in T’-Pr$_{1.3-x}$La$_{0.7}$Ce$_x$CuO$_4$ ($x = 0.1$) was observed under pressure. Simultaneously pressure causes a non-linear decrease of the SC transition temperature $T_c$. All these experiments establish the short-range magnetic order as an intrinsic and a new competing phase in SC T’-Pr$_{1.2}$La$_{0.7}$Ce$_0.1$CuO$_4$. The observed pressure effects may be interpreted in terms of the improved nesting conditions through the reduction of the in-plane and out-of-plane lattice constants upon hydrostatic pressure.

Vortex structures in a mesoscopic unconventional superconductors*

DAE HAN PARK, NAMMEE KIM, HEESANG KIM (Presenter), Department of Physics, Soongsil University — We investigate the vortex structures in unconventional superconductors of mesoscopic size. It is well-known that, in such small systems, the size as well as the shape have a profound influence on the formation of the vortex structure, leading to interesting phenomena such as giant vortex and anti-vortex. We present unusual vortex structures when the order parameters are unconventional and multi-dimensional. Especially, we focus on the vortex structures in mesoscopic unconventional superconductors. The results are compared with those in conventional ones. For concreteness, the order parameter which transforms according to the $E_{1g}$ representation of $D_{6h}$ is chosen. The vortex structures are obtained by minimizing the Ginzburg-Landau free energy, using the simulated annealing method.

Superconductivity in BiS$_2$-based layered compound REO$_{0.5}$F$_{0.5}$BiS$_2$ with high-entropy-alloy-type (HEA-type) blocking layers*

YOSHIKAZU MIZUGUCHI (Presenter), RYOTA SOGABE, Tokyo Metropolitan University — We have synthesized BiS$_2$-based superconductors with high-entropy-alloy-type (HEA-type) REO (RE: rare earth) blocking layers [R. Sogabe et al., APEX 2018]. In the HEA-type samples, the RE site of REO$_{0.5}$F$_{0.5}$BiS$_2$ was occupied with five RE elements with a compositional range of 5–35%. Notably, the superconducting properties were enhanced by making HEA-type REO blocking layer as compared to the BiS$_2$-based superconductors with a conventional REO blocking layer. We will discuss about the interlayer interaction in the HEA-type REO$_{0.5}$F$_{0.5}$BiS$_2$ superconductors by examining the samples having similar lattice parameters and different mixing entropy for the RE site. [R. Sogabe et al., 1808.04090]

*This study was partially supported by the Grants-in-Aid for Scientific Research (Nos. 15H05886, 16H04493, 16K17944, and 17K19058).
T70.00182: MgB₂ and NbTiN-based hyperbolic metamaterial superconductors*  
WILL KORZI (Presenter), GRACE YONG, BRYAN AUGSTEIN, Physics, Towson University, WENURA K WITHANAGE, FEI QIN, KANISHKA WIJESEKARA, NARENDR  
ACHARYA, XIAOXING XI, Physics, Temple University, ANNE-MARIE VALENTE-FELICIANO, Thomas Jefferson National Accelerator  
Facility, JOSEPH PRESTIGIACOMO, MICHAEL OSOSKY, United States Naval Research Laboratory, IGOR SMOLYANINOV, Saltena  
LLC, VERA SMOLYANINOVA, Physics, Towson University — Recent experiments have demonstrated that the metamaterial  
dielectric function engineering is capable of enhancing superconducting properties, such as tripling the critical  
temperature Tc in Al-Al₂O₃ epsilon near zero (ENZ) core-shell metamaterial superconductors. Similar effects have been  
observed in hyperbolic (superconductor/dielectric) metamaterials. In order to expand this approach to superconductors  
with higher Tc, MgB₂/MgO, MgB₂/AlN, and NbTiN/AlN multilayers were fabricated. Dielectric constants of these  
metamaterials measured via polarization reflectometry will be reported. Correlation of the results of the transport  
measurements and the hyperbolic properties of the multilayers will be discussed.  
*This work was supported by the DARPA grant W911NF1710348.

T70.00183: Non-centrosymmetric superconductivity in Re-based solid solutions*  
FABIO ABUD (Presenter), Physics, University of Sao Paulo, MILTON S TORIKACHVILI, Physics, San Diego State University, JAMES VALLES, Physics, Brown University,  
RENATO F JARDIM, Physics, University of Sao Paulo — Rhenium based superconducting compounds Re₃M (M = W, Mo, Nb, Ta)  
crystallize in the non-centrosymmetric cubic α-Mn structure and have critical temperatures Tc ranging from ~ 4 to 9 K.  
Polycrystalline samples of Re₃M and its solid solutions were synthesized through an arc-melting furnace and subsequently  
heat treated at 1700 °C. Atomic substitutions of W by Ta or Nb in Re₃W lead to single phase materials even in as-cast  
samples, a feature not observed in the parent compound. From the superconducting point of view, the low temperature  
heat capacity cp(T) data suggest conventional s-wave pairing, which is also supported by magnetization M(T), electrical  
resistivity ρ(T), and thermal conductivity κ(T) measurements. The estimated upper critical fields Hc2(0), however, are  
sizeable in comparison with the Pauli limiting field, and may be related to either a possible triplet channel or even  
disorder. Electron tunneling measurements of the superconducting density of states of Re₃M materials are also presented  
and provide further insight into the superconducting pairing mechanism. The results are discussed within the context of the  
emergence of superconductivity in non-centrosymmetric materials.  
*This work is sponsored by the Capes Foundation within the Ministry of Education, Brazil.

T70.00184: Analysis of tunneling spectroscopy measurements of Assymetrical all-MgB₂ Thin Film Josephson  
Junctions*  
JOSEPH LAMBERT, National Radio Astronomy Observatory, KEERAN RAMANATHAN (Presenter), University of the  
Sciences, MASAHITO SAKODA, MICHIO NAITO, Tokyo University of Agriculture and Technology, ROBERTO RAMOS, University of  
the Sciences — We have previously reported high-resolution tunneling spectroscopy measurements of substructure within  
the two superconducting energy gaps of Magnesium diboride (MgB₂) [1,2]. The samples used consisted of 1-gap/2-gap  
heterojunctions, where the counter-electrode is a conventional single-gap superconductor (Pb or Sn). Here, we report  
similar measurements of 2-gap/2-gap all-MgB Josephson junctions. The crystal orientations of the two MgB films are  
mostly c-axis parallel to the tunneling direction, with very small contribution from the larger σ gap. Due to differences in  
growth conditions, we find that the two MgB electrodes have different Tc’s and gap values. We represent this physical  
system using a modified tunneling model where each electrode is represented as a weighted sum of two BCS densities of  
states. We report results of this ongoing analysis that focuses on (1) a transition from SIS to NIS behavior as temperature  
increases past the lower Tc electrode, and (2) the presence of multiple quasiparticle peaks due to the sums and  
differences in pairwise combinations of disparate π and σ gap values within each electrode.  
*R.C.Ramos acknowledges support from the National Science Foundation DMR 1555775 and the Charles Kaufman  
Foundation.
T70.00185: Possible three-dimensional nematic odd-parity superconductivity in Sr₂RuO₄

WEN HUANG (Presenter), HONG YAO, Institute for Advanced Study, Tsinghua University — The superconducting pairing in Sr₂RuO₄ is widely considered to be chiral $p$-wave with $\tilde{\Delta}_k \sim (k_x + ik_y)\tilde{\hat{z}}$, which belongs to the $E_u$ representation of the crystalline $D_{4h}$ group. However, this superconducting order appears hard to reconcile with a number of key experiments. In this paper, based on symmetry analysis we discuss the possibility of odd-parity pairing with inherent three-dimensional character enforced by the inter-orbital interlayer coupling and the sizable spin-orbit coupling in the material. We focus on a yet unexplored $E_u$ pairing, which contains finite $(k_x\tilde{\hat{x}}, k_y\tilde{\hat{y}})$-component in the gap function. Under appropriate circumstances a novel time-reversal invariant nematic pairing can be realized. This nematic superconducting state could make contact with some puzzling observations on Sr₂RuO₄, such as the absence of spontaneous edge current and no evidences of split transitions under uniaxial strains.

T70.00186: Rashba and Ising superconductors

DAVID MÖCKLI (Presenter), MAXIM KHODAS, Hebrew University of Jerusalem, YOUICHI YANASE, Kyoto University, MANFRED W SIGRIST, ETH Zürich — This poster addresses the parity-mixed superconductivity in a locally noncentrosymmetric multilayer system (Rashba), and in monolayer transition metal dichalcogenides (Ising). For the Rashba system, we investigate the magnetic field dependence of an ideal superconducting vortex lattice in the parity-mixed pair-density wave phase of multilayer superconductors within a circular cell Ginzburg-Landau approach. In multilayer systems, due to local inversion symmetry breaking, a Rashba spin-orbit coupling is induced at the outer layers. On the other hand, Ising materials like monolayer NbSe₂ are nodal topological superconductors at magnetic in-plane fields exceeding the Pauli limit, with nodal points strictly on high symmetry lines in the Brillouin zone. We use a combined numerical and group-theoretical approach in real-space to characterize the unconventional superconducting state in monolayer transition metal dichalcogenides. Even with a conventional pairing interaction, the superconducting state is intrinsically parity-mixed and robust against on-site disorder. The interplay between the Zeeman magnetic field, strong spin-orbit interaction, and electronic orbital content confer the unique superconducting and topological properties.

T70.00187: Superconductivity in NbX₂

JUNYE HUANG (Presenter), DEYI FU, BARBAROS OEZYILMAZ, Centre for Advanced 2D Materials, National University of Singapore — NbX₂, X=S, Se, Te is a family of superconducting transition metal dichalcogenides. Recently, the advent of 2D materials brought new insights into the study of superconducting TMDCs, such as gate tunability and layer dependence study, revealing rich interplay of charge density waves, spin orbit coupling and superconductivity. Ising superconductivity arises in few-layer NbSe₂ due to coexistence of SOC and superconductivity, showing strongly enhanced in-plane critical field and 2nd order superconductor-insulator transition under in-plane magnetic field. In this work, we explored the cousins of NbSe₂ in the NbX₂ family: NbS₂ and NbTe₂, using transport measurements down to milliKelvin. We will show magnetoresistance measurement in normal and superconducting states, as well as angle dependence of critical field.

*NRF Investigatorship Award (NRFI001-20)
T70.00189: Magnetoelastic coupling in multiferroic CaBaCo$_4$O$_7$  BARNITA PAUL (Presenter), RAJEEV GUPTA, Indian Institute of Technology Kanpur — A large change in magnetic field induced polarization of $\Delta P \sim 8 \text{ mC/m}^2$ around $T_C$ was discovered in multiferroic CaBaCo$_4$O$_7$ suggesting a giant linear magnetoelastic effect. The crystal structure of CaBaCo$_4$O$_7$ contains alternating triangular and kagome layers along c axis with distorted corner shared CoO$_4$ tetrahedra that makes these oxides a unique class of geometrically frustrated systems. It is assumed that the large magnetoelastic coupling arises from their atypical crystal structure and the mixed valence state of Co cations. It is well known that specific spin-lattice interaction can control the direction of the electrical polarization with a magnetic field. Although strong magnetoelastic coupling is expected in these improper ferroelectrics, there are hardly any studies to investigate the same. In this work we carry out a detailed investigation on magnetoelastic coupling using temperature dependent Raman measurements. We observe anomalous deviation of phonon frequencies and line-width from anharmonicity in the magnetic ordered phase. The maximum deviation is observed across $T_C$. This study suggests a strong magnetoelastic coupling in this compound in the ferrimagnetic phase and indicates the role of lattice in the gigantic spin induced polarization along c axis.

T70.00190: Spin-orbital-lattice entangled states in cubic $d^1$ double perovskites  NAOYA IWAHARA (Presenter), VEACHESLAV VIERU, LIVIU F CHIBOTARU, KU Leuven — The magnetism of cubic 4/5$d^1$ double perovskites has been intensively investigated due to their geometrical frustration and multipolar exchange interaction, whereas many puzzling phenomena related to the lattice degrees of freedom, e.g. “violation of the JT theorem” in structural data [1] and “breaking of local point symmetry” accompanying the ferromagnetic order [2], have not been understood. In this work, the interplay of spin-orbit coupling and vibronic coupling on the heavy $d^1$ site is investigated by $ab$ initio calculations [3]. The stabilization energy of spin-orbital-lattice entangled states is found to be comparable to or larger than the exchange interactions, suggesting the presence of nonadiabatic Jahn-Teller dynamics in the systems. The entanglement of the spin and lattice degrees of freedom induces a strong magnetoelastic response. This multiferroic effect is at the origin of the recently reported breaking of local point symmetry accompanying the development of magnetic ordering in Ba$_2$NaOsO$_6$.

T70.00191: Spin Seebeck Effect in insulating SrFeO$_3$-$\delta$ films*  DESHUN HONG (Presenter), CHANGJIANG LIU, JOHN E. PEARSON, AXEL F HOFFMANN, DILLON D FONG, ANAND BHATTACHARYA, Argonne National Laboratory — SrFeO$_3$ is a metal with cubic structure and is a helicoidal antiferromagnet (AF) at low temperatures (< 134 K) [1]. Recently, an anisotropic double $q$ spin spiral and isotropic quadruple $q$ spiral hosting a three-dimensional lattice of hedgehog singularities in SrFeO$_3$ [2] was found suggesting a topologically non-trivial magnetic structure. Upon reduction, SrFeO$_3$-$\delta$ becomes insulating while retaining long wavelength incommensurate AF order. In this work we measured the spin Seebeck effect (SSE) in SrFeO$_3$-$\delta$ films synthesized by molecular beam epitaxy, and detected an SSE signal below ~120 K, near the ordering temperature of incommensurate antiferromagnetism found in SrFeO$_3$-$\delta$ bulk [3]. Control experiment were used to verify that the signal arises from a spin current originating in SrFeO$_3$-$\delta$ and to rule out magnetic proximity effect. By comparing the second derivative of the SSE signal with respect to magnetic field and comparing to a Brillouin function, we find large deviations that suggest strong spin correlations in oxygen reduced SrFeO$_3$-$\delta$ for temperatures below 120 K. Our work suggests SSE an effective way of probing magnetic correlations in non-ferromagnetic insulating films.

**T70.00192: Quantum percolation of monopoles and the response of quantum spin ice**

VADIM OGANESYAN, Physics and Astronomy, CSI and GC, CUNY, MATTHEW STERN, Physics and Astronomy, SUNY, Stony Brook, CLAUDIO CASTELNOVO (Presenter), TCM, University of Cambridge, SARANG GOPALAKRISHNAN, Physics and Astronomy, CSI and GC, CUNY — The low-temperature (magnetic) response of quantum spin ice is dominated by the coherent motion of a dilute gas of monopoles. Contrary to conventional modelling that assumes a uniform distribution of hopping amplitudes for such dynamics, recent work by Tommasello et al. has demonstrated that the distribution is in fact bimodal, and strongly correlated with the surrounding spin configuration. The larger of the two amplitudes occurs on average 2/3 of the times, and is responsible for the coherent motion of monopoles. The smaller one, on the other hand, induces dynamics that is far slower than the expected decoherence time scales in a solid state system. We exploit this structure to construct a theory of quantum monopole motion in spin ice in the limit where the slow hopping terms are set to zero. The monopole wavefunctions are fractal. The non-ergodic nature of monopole motion manifests itself in the low-frequency behaviour of spin response, and is consistent with experimental observations. We further extend our results to the case of disordered spin ice.

**T70.00193: Many-body-localization transition in the one-dimensional SYK model at finite N**

SHAOKAI JIAN, HONG YAO, Tsinghua University — We study the generalized Sachdev-Ye-Kitaev (SYK) chain consisting of N (complex or Majorana) fermions per site with random interactions and hoppings between neighboring sites. In the limit of vanishing SYK interactions, from both supersymmetric field theory analysis and numerical calculations we find that the random-hopping model exhibits Anderson localization at finite N, irrespective of the parity of N. Moreover, the localization length scales linearly with N, implying the absence of Anderson localization only at $N=\infty$. For finite SYK interactions, by performing the exact diagonalization we show that there is a dynamic phase transition from many-body localization to thermal diffusion as interaction strength exceeds a critical value $J_c$. In addition, we find that the critical interaction strength $J_c$ decreases with the increase of $N$, consistent with the analytical result of $J_c/t \sim 1/(N^{4/5}/\log N)$, derived from the weakly interacting limit.

**T70.00194: Electrically conducting rock-salt LuO epitaxial thin film**

KENICHI KAMINAGA (Presenter), WPI-AIMR, Tohoku Univ., DAICHI OKA, Graduate School of Science, Tohoku Univ., TETSUYA HASEGAWA, Graduate School of Science, University of Tokyo, TOMOTERU FUKUMURA, WPI-AIMR, Tohoku Univ. — Lutetium sesquioxide Lu$_2$O$_3$ is known as a widegap insulator with the highly stable closed shell trivalent ions. On the other hand, lutetium monoxide LuO has been recognized as gaseous phase. In this study, solid-phase rock-salt LuO was synthesized in a form of epitaxial thin film by pulsed laser deposition method for the first time [1]. LuO possesses unusual valence of Lu$^{2+}$ ($4f^{14}5d^1$). In contrast with transparent and highly insulating Lu$_2$O$_3$, LuO exhibited dark-brown color and metallic conduction with high electrical conductivity at room temperature (~60 S.cm$^{-1}$). A cusp-shaped positive magnetoresistance originating from the weak antilocalization effect suggested a significant spin-orbit coupling in LuO manifested by Lu 5$d$ electron carriers. [1] K. Kaminaga et al., ACS Omega 3, 12501-12504 (2018).

**T70.00195: Structure-property relationships in lacunar spinels from band theory**

YIQUN WANG (Presenter), JAMES M RONDINELLI, Northwestern University — The A-site deficient lacunar spinel GaM$_4$X$_8$ (M=Mo,V,Nb,Ta; X=S,Se) are ideal candidates to achieve novel electrical materials exhibiting metal-insulator transitions and may find use in resistive random-access memories (RRAM). They are experimentally narrow-bandwidth semiconductors, and undergo structural, electrical and magnetic phase transitions with external stimuli, e.g. temperature, pressure, electric pulse.

We systematically study the structure-property relationships within the lacunar spinels using ab initio density functional theory (DFT). We find that semi-local GGA functionals are able to predict insulating states with the low-symmetry rhombohedral phase without static correlation, but the high-temperature cubic phase is metallic due to orbital degeneracy. Spin-orbit coupling together with on-site Coulomb interactions are shown to reduce the local symmetry and open a small band gap within the cubic lattice. Our findings will assist understanding of the nature of these transitions and design new materials with tunable electronic states.

T70.00196: High-pressure synthesis, crystal structure, and magnetic properties of Ba$_3$CuOs$_2$O$_9$

JIE CHEN (Presenter),
National Institute for Materials Science, HAI LUKE FENG, Max Planck Institute for Chemical Physics of Solids, YOSHITAKA MATSUISHITA, ALEXEI A BELIK, YOSHIHIRO TSUJIMOTO, YOSHIO KATSUYA, MASAHIKO TANAKA, National Institute for Materials Science, MAN-RONG LI, HONGBIN LIANG, School of Chemistry, Sun Yat-sen University, LIRONG ZHENG, Institute of High Energy Physics, Chinese Academy of Sciences, KAZUNARI YAMAURA, National Institute for Materials Science — The triple perovskite Ba$_3$CuOs$_2$O$_9$ crystalizes into an orthorhombic structure (Cmcm) and shows a manifest antiferromagnetic transition at 47 K [1], while it crystalizes into a hexagonal structure (P6$_3$/mmc) when treated under a high-pressure and high-temperature condition (typically 6 GPa and 1100 °C). The change of structure gains a 1.3% increase in structural density. The hexagonal phase was quenched at ambient condition and the magnetic and electrical properties were investigated via measurements of the ac and dc magnetic susceptibilities, electrical resistivity, and specific heat capacity. The data indicated that the magnetic transition temperature increased to 290 K by the structure change. We discuss details of the magnetic and electrical properties of the newly synthesized hexagonal Ba$_3$CuOs$_2$O$_9$.

T70.00197: Strong Pseudospin-Lattice Coupling in Sr$_3$Ir$_2$O$_7$: Coherent Phonon Anomaly and Negative Thermal Expansion*

LILI HU, MENG YANG, YANLING WU, QIONG WU, HUI ZHAO, FEI SUN, WEI WANG, Chinese Academy of Sciences, RUI HE, Texas Tech University, SHAOLONG HE, Chinese Academy of Sciences, HONG ZHANG, Sichuan University, RONGJIN HUANG, LAIFENG LI, YOU GUO SHI, JIMIN ZHAO (Presenter), Chinese Academy of Sciences — The similarities with cuprates make iridates interesting materials to investigate superconductivity. Equivalently attractive is their puzzling intrinsic complex interactions. Here, we report an ultrafast optical spectroscopy investigation of the coherent phonon in Sr$_3$Ir$_2$O$_7$, a bilayer Ruddlesden-Popper perovskite iridate. An anomaly in the $A_{1g}$ optical phonon ($\nu = 4.4$ THz) is unambiguously observed below the Néel temperature ($T_N$), which we attribute to pseudospin-lattice coupling (PLC). Significantly, we find that PLC is the dominating interaction at low temperature, and we directly measure its coefficient to be $\lambda = 150 \pm 10$ cm$^{-1}$, which is two orders of magnitude higher than that in manganites (< 2.4 cm$^{-1}$) and comparable to that in CuO (50 cm$^{-1}$, the strongest PLC or spin-lattice coupling known so far). Moreover, we find the strong PLC induces an anisotropic negative thermal expansion. Our finding identifies essential role of PLC in iridates at low temperature and uncovers a possible novel similarity with cuprates.

T70.00198: Electronic Transport in Thin Crystals of Ruthenium Chloride*

NAOMY MARRUFO (Presenter), AMIRARI DIEGO, JOSUE RODRIGUEZ, Physics & Astronomy, California State University, Long Beach, GILBERT LOPEZ, Physics, University of California, Berkeley, NICHOLAS BREZNAY, Physics, Harvey Mudd College, ROBERT KEALHOFER, Physics, University of California, Berkeley, FRANCISCO RAMIREZ, SAMANTHA CROUCH, Physics & Astronomy, California State University, Long Beach, JAMES G. ANALYTIS, Physics, University of California, Berkeley, CLAUDIA OJEDA-ARISTIZABAL, Physics & Astronomy, California State University, Long Beach — Ruthenium chloride (RuCl$_3$) has gathered significant interest in the recent years, as it is a layered material that presents key features such as a honeycomb geometry and bond-directional interactions, making it a promising candidate for the experimental realizations of the Kitaev-Heisenberg model. Exciting ground states have been predicted for this system, such as quantum spin liquids, consistent with recent inelastic neutron scattering experiments as well as long ranged magnetic ordered states. Here we present preliminary electronic transport experiments on exfoliated thin crystals of RuCl$_3$ and the effects of ionic liquid gating.

T70.00199: Doping driven spin-flop transition in mixed 3d-5d compounds*  WEIGUO YIN (Presenter), WENHU XU, ROBERT KONIK, Brookhaven National Laboratory — The in-plane magnetization of the layered iridate Sr$_2$IrO$_4$ turns to out-of-plane upon partial substitution of ruthenium or manganese atoms for iridium. Based on first-principles electronic structure analysis, we present an effective low-energy Hamiltonian to model this doping effect. We found that the spin-flop transition originates from the M-Ir bond direction changes from the local easy axis to the hard axis as M changes from Ir to Ru or Mn.

T70.00200: Semi-classical Theory of Large N Tensor Model Chaos  JAEWON KIM (Presenter), EHUD ALTMAN, THOMAS SCAFFIDI, University of California, Berkeley — Lately, the Sachdev-Ye-Kitaev (SYK) model has become increasingly important due to its chaotic dynamics and its approximate conformal symmetry. The model's conformal symmetry suggests the existence of a holographic dual, rendering the model important in the study of quantum gravity. Tensor models have been found to be similar to the SYK model, in that they exhibit the dominance of melonic diagrams. In this paper, we study the chaotic dynamics of the Tensor Models semi-classically, by finding the spectrum of the Lyapunov exponent. We introduce a classical version of the Tensor model for which chaos can be understood as arising from nonlinear dynamics of the equation of motion.

T70.00201: 2D fermi gases under the microscope  AIRLIA SHAFER-MOAG (Presenter), CEDRIC WILSON, BISWAROOP MUKHERJEE, PARTH PATEL, ZHENJIE YAN, RICHARD J FLETCHER, MARTIN ZWIERLEIN, MIT — Confining a quantum fluid in two dimensions (2D) profoundly changes its behavior and leads to a host of new phenomena, for example the possibility of topological superfluid transitions and quantum Hall states. Here we report our progress towards creating a uniform 2D fermionic gas of 6Li confined in a highly flexible optical potential. The homogenous density enables the study of physics typically difficult to access in harmonically trapped samples, such as critical phenomena, correlation functions, superfluid properties and the spectroscopic response. Incorporating a dual-objective high-resolution imaging system allows us to both manipulate and image the gas with sub-micron resolution, permitting the projection of tailored potentials and in situ imaging of topological defects.

T70.00202: Machine learning of quantum phase transitions  XIAOYU DONG (Presenter), California State University, Northridge, USA, XUEFENG ZHANG, Chongqing University, Chongqing, People's Republic of China, FRANK POLLMANN, Technische Universität München, Garching, Germany — Machine learning algorithms provide a new perspective on the study of physical phenomena. In this paper, we explore the nature of quantum phase transitions using multi-color convolutional neural-network (CNN) in combination with quantum Monte Carlo simulations. We propose a method that compresses (d + 1)-dimensional space-time configurations to a manageable size and then use them as the input for a CNN. We test our approach on two models and show that both continuous and discontinuous quantum phase transitions can be well detected and characterized. Moreover we show that intermediate phases, which were not trained, can also be identified using our approach.

T70.00203: Unbinding slave spins in the Anderson impurity model*  DANIELE GUERCi (Presenter), International School for Advanced Studies, ADRIANO AMARICCI, Democritos National Simulation Center, Istituto Officina dei Materiali del CNR and International School for Advanced Studies, MICHELE FABRIZIO, International School for Advanced Studies — We show that a generic single-orbital Anderson impurity model, lacking, for instance, any kind of particle-hole symmetry, can be exactly mapped without any constraint onto a resonant level model coupled to two Ising variables, which reduce to one if the hybridization is particle-hole symmetric [1]. The mapping can be straightforwardly extended to a multiorbital impurity model where the isolated impurity Hamiltonian does not include Coulomb exchange terms. We also demonstrate how single-particle Green's functions of the physical fermions can be calculated without constraints, which would, for instance, allow exploiting DMFT to study in the slave-spin representation Hubbard-like models in lattices with infinite coordination. The generality of the mapping allows to study a wide range of problems varying from the Mott-transition in infinite-dimensionality to transport in quantum dots.

T70.00204: ABSTRACT WITHDRAWN —
T70.00205: Local electrodynamics of disordered conductor model systems measured with scanning microwave impedance microscopy

HOLGER THIERSCHMANN (Presenter), Quantum Nanoscience, Delft University of Technology, HALE CETINAY, Faculty of Electrical Engineering, Mathematics and Computer Science, Delft University of Technology, MATVEY FINKEL, MARC P. WESTIG, ALLARD J. KATAN, Quantum Nanoscience, Delft University of Technology, PIET VAN MIEGHEM, Faculty of Electrical Engineering, Mathematics and Computer Science, Delft University of Technology, TEUN M Klapwijk, Quantum Nanoscience, Delft University of Technology — We have measured the local impedance of disordered conductor model systems at GHz frequencies in order to study the electrodynamic response of systems around the metal-insulator phase transition for non-trivial patterns of conductive and insulating regions at small scales. We realize the disordered conductors through nano patterning of metallic thin films into networks which exhibit a phase transition from the conducting to the insulating state through bond percolation. The electrodynamic response is measured with a scanning microwave impedance microscope at room temperature. When the networks are patterned out of aluminum with highly conductive bonds, we observe a correlation of the local signal and the size of the respective cluster, at different degrees of percolation. When the bonds are made more resistive through using NbTiN, the signal varies within a cluster, depending sensitively on the local network topology. Our results are well reproduced within a network model of resistors and capacitors that takes into account the specific network topologies as well as the electric and dielectric environment.

T70.00206: Mesoscopically confined 2D holes with strong correlation

CHIEH-WEN LIU (Presenter), Case Western Reserve University, LOREN PFIEFFER, KENNETH WEST, Princeton University, XUAN GAO, Case Western Reserve University — We present a transport study on the mesoscopic confinement effects on a strongly interacting two-dimensional holes (2DH) in a GaAs quantum well with low density (~2×10¹⁰/cm²) and high mobility. By applying a voltage to a split-gate, the 2DH underneath the gate is depleted, leaving a narrow (~2 μm wide) channel conducting. The channel formation is reflected in the evolution of the temperature (T)-dependent resistance at various gate voltages \( V_g \) as well as the \( V_g \) dependent resistance. Interestingly, when the mesoscopic channel starts to form, a strong magneto-resistance peak with an insulating-like \( T \) dependence was observed before the \( ν = 1 \) quantum Hall (QH) state. When the channel is further depleted, the magnetic field induces a rapidly increasing magneto-resistance and a ‘metal-to-insulator’ transition appears at a moderate magnetic field (~ 0.2 T) where the sample resistivity \( ρ_{xx} < h/e^2 \) along with the destruction of the \( ν = 1 \) QH state. Our results suggest that mesoscopically constricted dilute 2D systems can be a rich playground for exploring interaction effects and phase transitions in 2D.

T70.00207: Optical control of magnetism in NiFe/VO₂ heterostructures

GUODONG WEI, XIAOYANG LIN (Presenter), Beihang University, STEPHANE MANGIN, University of Lorraine, WEISHENG ZHAO, Beihang University — Optical methods for magnetism manipulation have been considered as a promising strategy for ultralow-power spintronics. Strategies based on all optical switching (AOS), hot electrons and photosensitive-material-based devices have already generated exciting new prospects both for fundamental physics and technological applications. However, a widely applicable method to combine optical operation with magnetic modulation is still highly desired. Here, the strongly correlated electron material VO₂ is introduced to realize phase-transition based optical control of the magnetism in NiFe. [1] The heterostructure features appreciable modulations both in electrical and magnetic properties. Utilizing this optically controlled magnetism modulation feature, programmable Boolean logic gates (AND, OR, NAND, NOR, XOR, NXOR and NOT) for high-speed and low-power data processing are demonstrated based on this engineered heterostructure. As a demonstration of phase-transition spintronics, this work may pave the way for next-generation electronics in the post-Moore era.

*This work was supported by the NSFC (Nos. 51602013 and 11804016), the International Collaboration 111 Project (No. B16001), and the Beijing Advanced Innovation Center for Big Data and Brain Computing (BDBC).
demonstrate the ability to tune the insulating behavior of TiSe$_2$ with different synthesis parameters. We confirm the metallicity in single crystalline TiSe$_2$ grown by the transition forms, but there has been little reported on the low temperature resistivity, where there is large discrepancy been paid to the anomalous feature in temperature dependent resistivity near 150 K where a charge-density-wave interaction is not the sole driving force of these transitions and that lattice degrees of freedom play an important role. Our analysis indicates that the electron–electron interaction is not the sole driving force of these transitions and that lattice degrees of freedom play an important role.

**T70.00212: Exploring “hidden order” (HO) through Re and Rh co-substitution in URu$_2$Si$_2$**

KALYAN SASMAL (Presenter), University of California, San Diego, SHENG RAN, University of Maryland, College Park, TREVOR KEIBER, BOB WANG, ROBERT A ROBINSON, M BRIAN MAPLE, University of California, San Diego — The identity of the mysterious “hidden-order” (HO) phase in the correlated $f$-electron superconductor (SC) URu$_2$Si$_2$ has eluded researchers for more than three decades. Substitution of transition metals into URu$_2$Si$_2$ at the Ru sites reveals how factors such as lattice parameters, charge carrier concentration, disorder and $d$-$f$ electron hybridization influence the HO phase and SC. We discuss the effects of the co-substitution of equal amounts of Re and Rh, which are isoelectronic on average, into URu$_2$Si$_2$ to form URu$_2$$_{2-x}$Re$_x$Rh$_x$Si$_2$, pseudo ternary alloys based on the physical properties including structure and lattice parameters, electrical resistivity, magnetic susceptibility, and specific heat. The features in the physical properties that characterize the energy gap associated with the HO phase (e.g., exponential $T$-dependence of the specific heat) are suppressed rapidly with Re and Rh co-substitution level so that by $x = 0.11$, the HO phase transition is no longer discernible. The HO phase transition temperature ($T_{HO}$) and the gap decrease monotonically with Re-Rh concentration $x$.

**T70.00213: A Dirac Fermion Hierarchy of Composite Fermi Liquids**

JIE WANG (Presenter), Princeton University — Composite Fermi liquids (CFLs) are compressible states that can occur for 2D interacting fermions confined in the lowest Landau level at certain Landau level fillings. They have been understood as Fermi seas formed by composite fermions which are bound states of electromagnetic fluxes and physical fermions due to the celebrated work by Halperin, Lee and Read [Phys. Rev. B 47, 7312 (1993)]. At half filling, an explicitly particle hole symmetric theory based on Dirac fermions [Phys. Rev. X 5, 031027 (2015)] was proposed by Son as an alternative low energy description. In this work, we propose an effective theory, which generalizes Son’s Dirac fermion theory, by internal gauge flux attachment, from half filling to all fillings that CFLs for fermions can occur. We also numerically investigated the Berry curvature of CFL model wave functions at fillings not being one half, and observed that it is uniformly distributed on the Fermi sea except at the center where an additional $\pi$ phase was found. The numerical results support the idea of internal gauge flux attachment.

**T70.00214: First-principles study of charge and magnetic ordering in monolayer NbSe$_2$**

ZHIMOU ZHOU (Presenter), Peking University, FEIPENG ZHENG, Jinan University, XIAOQIANG LIU, JI FENG, Peking University — Monolayer NbSe$_2$ has recently been shown to be a two-dimensional superconductor, with a competing charge-density wave (CDW) order. This work investigates the electronic structure of monolayer NbSe$_2$ based on first-principles calculations, focusing on charge and magnetic orders. It is found that decreased screening in the monolayer NbSe$_2$ with a perfect lattice exhibits magnetic instability, which is removed by the formation of CDW. Two energetically competitive but distinct $3 \times 3$ CDW structures are revealed computationally, which have a significant impact on the Fermi surface. The relations of the potential CDW phases with experimental structure and the coexisting superconductivity are discussed.

**T70.00215: Fermionic retro reflection, hole jets, and magnetic steering in 2D electron systems**

LEV KENDRICK (Presenter), Physics, Massachusetts Institute of Technology, PATRICK J. LEDWITH, Massachusetts Institute of Technology, ANDREY SHYTOV, Physics, Massachusetts Institute of Technology, LEONID LEVITOV, Massachusetts Institute of Technology — The combination of fermion exclusion and momentum conservation leads to unusual dynamics in two-dimensional Fermi liquids. We show that the response of a 2D Fermi liquid to an injected beam of current includes hole jets centered at the backscattering direction. We propose a magnetotransport measurement to probe the angular structure of the hole jets.
T70.00216: SmB\textsubscript{6} in-gap states encoded inside the hybridization*  EDWIN RAMOS, JERESON SILVA VALENCIA, ROBERTO FRANCO, Physics Department, National Colombian University, MARCOS FIGUEIRA (Presenter), Physics Department, Federal Fluminense University — In this article we investigate the effects of short-range anti-ferromagnetic correlations on the gap opening of topological Kondo insulators. We add a Heisenberg term to the periodic Anderson model at the limit of strong correlations. This new model [1] is adequate for studying the topological Kondo insulator SmB\textsubscript{6}.

We solve the problem on a two dimensional square lattice considering the $\Gamma_8$ symmetry group representation that already encoded the spin-orbit coupling of the $J=5/2$ multiplet structure of the Samarium ions orbitals. We investigate the role of the hybridization on the generation of in-gap states inside the topological gap. We also discuss the effects of those in-gap states over the band structure, the density of states, the differential conductance and the optical conductivity, comparing them with recent Arpes experimental results [2,3,4].

T70.00217: Quantum effects in the system of Boltzmann hard spheres*  SERGEI STISHOV (Presenter), Institute for High Pressure Physics, Moscow, Troitsk, Russia — The quantum contribution to the energy of the Boltzmann gas of solid spheres turns out to be practically constant to the highest temperatures, when the De Broglie thermal wavelength is only a small fraction of the diameter of the solid sphere. Accordingly, the heat capacity of the system is not much different from the classical value of $3/2 \ k$ everywhere except for the region of the lowest temperatures, where the dependence of the heat capacity of the system on temperature has a Debye appearance, but with a very low "Debye" temperature of the order of several degrees.

The quantum crystal-liquid equilibrium line of the "Boltzmann" system of hard spheres coincides with the classical one except for the region of very low temperatures. In the system under consideration, high-temperature quantum effects appear in a kind of "naked" form, while in the case of more realistic systems or models they can be masked by the complex behavior of the other components of the total energy.

T70.00218: Spontaneous symmetry breaking from anyon condensation*  MARCEL BISCHOFF, Mathematics, Ohio University, COREY JONES, Mathematics, Ohio State University, YUAN-MING LU (Presenter), Physics, Ohio State University, DAVE PENNEYS, Mathematics, Ohio State University — As a cornerstone for condensed matter physics, Landau theory of symmetry breaking dictates that the symmetry group G of a physical system can spontaneously breaks down to any subgroup H, characterized by a local order parameter valued in the quotient group G/H. However this paradigm breaks down when topological orders and anyons come into play. What is the relation between symmetry groups G and H of two symmetry enriched topological orders (SETOs), if they are connected to each other through a continuous quantum phase transition (QPT)? To address this issue, we develop a mathematical framework within the category theory of topological orders, which determines the compatibility of symmetry groups G and H for two SETOs connected by a QPT driven by anyon condensation. We identify two symmetry obstructions for such anyon-condensation transitions. which are demonstrated by many examples.

Identification of low-lying energy states in quantum critical Ce(Fe$_{0.76}$Ru$_{0.24}$)$_2$Ge$_2$

THOMAS HEITMANN (Presenter), WOUTER MONTFROOIJ, University of Missouri, YIMING QIU, SHANNON M WATSON, ROSS WEBB ERWIN, WANGCHUN CHEN, National Institute of Standards and Technology, YANG ZHAO, University of Maryland - College Park — The compound Ce(Fe$_{0.76}$Ru$_{0.24}$)$_2$Ge$_2$ has long been known to be a quantum critical point system. One of the features discovered in this material is hyperscaling of the dynamic response of the system. Chemical doping is used to prepare the system at the quantum critical point, which results in a distribution of local Kondo temperatures and consequently the formation of magnetic clusters. We present direct evidence for the spin-flipping of these magnetic clusters, which provides the low energy states required to explain the hyperscaling at the quantum critical point. The superspin flipping was first identified using spin-polarized neutron spectroscopy on the BT7 triple-axis spectrometer at the NIST Center for Neutron Research, then—once the magnetic signal was separated from that of the lattice—tracked using unpolarized neutron spectroscopy on the TRIAX thermal neutron triple-axis spectrometer at the University of Missouri Research Reactor.

Braiding of worldlines in Monte Carlo configurations as nonlocal probe for quantum phase transitions

LIANA SHPANI (Presenter), Clark University, WEI WANG, Max Planck Institute for the Physics of Complex Systems, FABIO LINGUA, BARBARA CAPOGROSSO-SANSONE, Clark University — We propose to use the braiding of particles’ trajectories in path-integral Monte Carlo configurations, to characterize entanglement “patterns” in strongly-correlated hardcore lattice bosons. By extracting certain statistical properties of worldline configurations, we are able to detect the SF-insulator transition and SF-Z2 topological insulator transition.

Ultrafast transient interference in pump-probe spectroscopy of band and Mott insulators

KAZUYA SHINJO (Presenter), TAKAMI TOHYAMA, Tokyo University of Science Katsushika Campus — Ultrafast pump-probe spectroscopy with high temporal and spectral resolutions provides new insight into ultrafast nonequilibrium phenomena. We propose that transient interference between pump and probe pulses is realized in pump-probe spectroscopy of band and Mott insulators, which can be observed only after recent developments of ultrafast spectroscopic techniques [1]. A continuum structure in the excitation spectrum of band insulators is found to act as a medium for storing the spectral information of the pump pulse, and the spectrum detected by the probe pulse is interfered with by the medium, generating the transient interference in the energy domain. We also demonstrate the transient interference in the presence of electron correlations in a one-dimensional half-filled Hubbard model. Furthermore, bosons coupled to electrons additively contribute to the interference. Our finding will provide an interpretation of probe-energy-dependent oscillations recently observed in the pump-probe spectrum for a two-dimensional Mott insulator [2].

Dynamical t/U Expansion Theory of a Doped Hubbard Model

WENXIN DING (Presenter), School of Physics and Materials Science, Anhui University, RONG YU, Physics Department, Renmin University — In this work, we construct a new U(1) slave representation for the single band Hubbard model in the large-U limit. By employing a dynamic Green’s function method for the slave spins, we formulate a dynamic t/U expansion for the Hubbard model which reduces the model to a t-J-type low energy effective theory for the spinons and an XXZ-type effective theory for the slave spins. This new approach recovers our previous slave rotor results for the Mott insulating state at half-filling, and is more amenable to describe the strong correlation effects in the finite doping regime. By solving the slave spin theory at the mean field level for finite doping, we find that the superexchange interaction strength J, as well as the effective spinon hopping amplitude, develops doping dependence. More interestingly, pairing-type interaction in the dynamic Green’s function shows up, which solely stems from quantum fluctuations of the doping driven Mott-insulator-to-metal transition.

Energy-Momentum Photoluminescence Spectroscopy of Quantum Emitters in Hexagonal-Boron Nitride

YANG WANG (Presenter), JUAN LIZARAZO FERRO, RASHID ZIA, Brown University — Defects in hexagonal-boron nitride(h-BN) have recently been characterized and identified as light emitters that are ideal for quantum information applications. These photostable emitters have narrow and tunable emission spectra, operate at room temperature, and exhibit high quantum efficiency. However, the electronic structure of these quantum emitters are still under intense debate. In this presentation, we use angle- and polarization-resolved photoluminescence spectra to study the origin of light emission from a range of point emitters in h-BN.
T70.00225: Visualization of domain and interfacial structures of Monolayer semiconductors by Nonlinear Optical Microscopy*  
CHUN AN CHEN (Presenter), YING-YU LAI, National Tsing-Hua University, National Tsing Hua University, PO-YEN LIN, Academia Sinica, Taiwan, XIN-QUAN ZHANG, MENG-HSI CHUANG, YI-HSIEN LEE, National Tsing-Hua University, National Tsing Hua University — Domain and interfacial structures of the monolayer transition metal dichalcogenides (TMD) are significant to diverse physics and performances. Unique carrier transportation and bandgap tunability could be engineered with inter-grain twisting, which provide an extra degree of freedom for device designing. Here, the correlation between GBs and inter-grain twisting in monolayer WS2 is studied using nonlinear microscopy. With the change of inter-grain twisting, domain and interfacial structures of the monolayer is monitored and studied.

T70.00226: Energy transfer in van der Waal stacked MoS2 – Graphene Quantum Dots with Ab-initio validation  
RAJARSHI ROY (Presenter), Plasma Technologies, CEITEC MU — Graphene based van der Waals (vdW) heterostructures can facilitate enticing charge transfer dynamics in between the layers with emission of excitonic quasi-particles. In this work, an attempt has been made to probe such van der Waal (vdW) heterostructures between few layer MoS2 sheet embedded quantum dot (QD) and amine-functionalized graphene quantum dot (GQD) to explore the energy transfer mechanism. Our findings reveal interesting non-radiative Forster type energy transfer with quenching of functional GQD PL after GQD/MoS2 hetero interface formation and validates the existing charge transfer shown that is analogous between a 0D and 2D system. This non-radiative type energy transfer characteristics from GQD into MoS2 layer through vdW interaction has been confirmed by with a combination of photoluminescence and time decay analyses with ab-initio calculation affirms the same observation with shifting of Fermi level in density of states towards conduction band in van der Waals distance separation limit. This result encourage exploration of optical properties in other QD/2D based heterostructures for understanding the charge transfer mechanism and luminescence quenching for future optoelectronic device and optical sensing applications.

T70.00227: When graphene meets electrolyte: how does graphene sense proton (H+)?  
XIAOYU JIA (Presenter), ZHAOYANG LIU, ZONGPING CHEN, AKIMITSU NARITA, MÜLLEN KLAUS, Max Planck Institute for Polymer Research, KLAAS-JAN TIELROOIJ, ICFO - The Institute of Photonic Sciences, MISCHA BONN, I. HAI WANG, Max Planck Institute for Polymer Research — Graphene has been extensively used as electrodes in electrochemical applications [1,2,3]. Despite its relevance for these various applications of graphene, the effect of electrolyte solutions on the electronic properties, specifically conductivity, of graphene remains poorly understood. In the few available studies using graphene field effect transistors (FETs) for ionic sensing, conflicting results have been reported [4,5]. One major challenge is to separate contributions to the overall FET conductance from bulk electrolyte conductivity and from graphene itself, as the FET contacts are typically also exposed to the electrolyte. Here we introduce THz spectroscopy as a contact-free, all optical means to track the intrinsic carrier conductivity of silica-graphene in contact with protons (H+) in water. Our report provides new insight on the graphene's proton sensing mechanism, and highlights the importance and impact of proton transfer though graphene and interfacial charge screening on the graphene conductivity enhancement.

T70.00228: Thermal conductivity of TMPS₃ (TM=Fe, Ni, and Mn): role of a boundary scattering  
HWIIN JU (Presenter), YOUNGGWAN CHOI, DOGYEOM JEONG, Department of Physics and Photon Science, Gwangju Institute of Science and Technology, Gwangju, South Korea, SUNGMIN LEE, JE-GUEN PARK, 2 Center for Correlated Electron Systems, institute for Basic Science; and 3 Department of Physics and Astronomy, Seoul National University, Seoul, South Korea, JONGSEOK LEE, Department of Physics and Photon Science, Gwangju Institute of Science and Technology, Gwangju, South Korea — Among various van der Waals (vdW) materials, a TMPS₃ (TM=Fe, Ni, Mn) group undergoes an antiferromagnetic transition at about 100 K, and hence can be an important magnetic layer in realizing multi-functional heterostructure. Although a thermal conduction through vdW materials is a fundamental issue in optimizing device performances, thermal properties of TMPS₃ has rarely been studied. In this work, we measured the thermal conductivity of TMPS₃ materials with a time-domain thermoreflectance method. We found that the cross-plane thermal conductivity of TMPS₃ is relatively low compared to other vdW materials, such as graphite and transition-metal dichalcogenides. By comparing the temperature–dependent thermal conductivities of these materials, we demonstrated that effective boundaries caused by a stacking fault of vdW layers act as a main scattering channel in the heat conduction in these materials.

T70.00229: Transition metal dichalcogenide phase-change materials for infrared photonics  
AKSHAY SINGH (Presenter), YIFEI LI, JIAN ZHOU, Massachusetts Institute of Technology, HESHAN YU, ICHIRO TAKEUCHI, University of Maryland, JU LI, RAFAEL JARAMILLO, Massachusetts Institute of Technology — Transition metal dichalcogenides (TMD) exist in 2H (usually semiconducting) and 1T’ (semi-metallic) polymorphs. Switching between these polymorphs offers a new paradigm for controlling light. However, energy required for phase-change (PC) in pure phases is large. Alloying 2H and 1T’ materials, for example MoS₂ and TiS₂, could offer low-energy PC. This low energy transformation would especially be useful for infrared (IR) integrated photonics.

We present a combined experimental and theoretical study of IR properties of MoS₂, TiS₂ and alloys thereof. Our density functional theory (DFT) calculations predict a large refractive index contrast in the 1-1.5 μm spectral range, between 2H and 1T’ phases, for optimized alloys. We experimentally test our DFT predictions using spectroscopic ellipsometry and Fourier-transform IR spectroscopy (FTIR). We measure the complex dielectric constants of bulk crystals, and of synthesized (many-layer) thin films. We characterize the quality of our samples – including wafer-scale combinatorial composition spreads - using Raman and X-ray diffraction mapping. Our work lays the foundation for thin-film TMD PC active IR materials that can be switched optically, electrically, or mechanically.

T70.00230: Large area synthesis of GaSe and GaS monolayers by Chemical Vapor Deposition*  
ALGENE FYER, TARIQ AFANEH, HUMBERTO RODRIGUEZ GUTIERREZ (Presenter), Department of Physics, University of South Florida — Two-dimensional crystals of group-III metal monochalcogenides [i.e. MX where M=In, Ga] and X=S, Se,Te] have gained attention in the last years as alternative 2D semiconductors. They present high carrier mobility, thickness dependent electronic properties, as well as good photoresponse and on/off ratio. To date, most of the fundamental studies in these materials have been performed on mechanically exfoliated samples and few groups have reported chemical vapor deposition (CVD) synthesis of these materials. The implementation of practical electronic applications will rely on developing approaches to deposit high quality films over large areas. The CVD approaches reported to date usually involve low pressure environment and MX powders with the right stoichiometry (pre-synthesized in vacuum sealed ampules) used as evaporation sources, as well as. Here we report large area deposition of GaSe and GaS monolayers, using atmospheric pressure CVD and commercially available precursors. We systematically studied the influence of the growth parameters on the quality of the as grown materials. The samples were characterized using micro-Raman spectroscopy, scanning electron microscopy and atomic force microscopy.

*This work was supported by startup funds from the University of South Florida.

T70.00231: A Novel Method for Thermal Conductivity Measurements in Atomically Thin Materials*  
TALIP KASIRGA (Presenter), ONUR ÇAKIROĞLU, HAMID REZA RASOULI, Bilkent University — Study of thermal properties of materials are crucial for applications and fundamental science. There are many techniques available in the literature to measure thermal conductivity. Measuring the thermal conductivity of atomically thin materials however, is a major challenge. The most common method is to measure the temperature calibrated shift of a well-defined Raman peak with increasing laser power over a suspended sample. Thea fit to the measured data with a temperature profile yields the thermal conductivity. Applicability of this method is limited to materials with relatively low thermal conductivity and well established Raman peaks. In this presentation, I will talk about the method we developed for measuring the thermal resistivity of atomically thin materials relies on a laser beam and two terminal resistivity measurement. The technique can be applied to any conductive material.

T70.00232: Origin of anisotropic negative Poisson's ratio in graphene  ZHENZHEN QIN (Presenter), Zhengzhou University, GUANGZHAO QIN, RWTH Aachen University, MING HU, University of South Carolina — Negative Poisson's ratio (NPR) in auxetic materials is of great interest due to the typically enhanced toughness, shear resistance, and sound and vibration absorption, which enables plenty of novel applications such as aerospace and defense. Insight into the mechanism underlying NPR is significant to the design of auxetic nanomaterials and nanostructures, and a thorough and fundamental understanding is lacking. In this paper, we report anisotropic differential NPR in graphene for uniaxial strains applied along both zigzag and armchair directions based on first-principles calculations. The mechanism underlying the emergence of NPR in graphene (evolution of bond length and bond angle) is found to be different from the conclusions from previous classical molecular dynamics simulations with empirical potential. We propose that the decentralized electron localization function (ELF) driven by strain leads to ELF coupling between different types of bonds, which results in the counter-intuitive anomalous increase of the bond angle and thus the emergence of NPR in graphene. Moreover, the NPR phenomenon can be anticipated to emerge in other nanomaterials or nanostructures with a similar honeycomb structure as that of graphene, where the ELF coupling would also be possible.

T70.00233: Magnetic doping of 2D semiconductor crystals* NALAKA KAPURUGE (Presenter), VIJAYSANKAR KALAPPATTIL, FLORENCE A NUGERA, MANH-HUONG PHAN, HUMBERTO RODRIGUEZ GUTIERREZ, Department of Physics, University of South Florida — Recently reported ferromagnetism in two dimensional crystals have gain increasing interest due to its potential for developing a new generation of 2D spintronic devices. Doping transition metal dichalcogenides with magnetic atoms such as Cr, Mn and Fe, is another approach worth exploring. High doping levels can lead to 2D diluted magnetic semiconductors with crystalline structure compatible with the TMDs that can be connected laterally to create in-plane lateral heterostructures with potential for spin valves or spin-FETs applications. In this work, we report on the Mn magnetic doping of Transition metal dichalcogenides (e.g MoSe2) using a chemical vapor deposition approach. The optical properties of the as grown films were studied by micro-Raman and PL spectroscopy. Morphology and thickness of the samples were characterized via SEM and AFM, respectively. The samples display room-temperature magnetism and a clear temperature dependent ferromagnetic characteristic.

*This work was partially supported by startup funds from the University of South Florida and by the National Science Foundation Grant DMR-1557434

T70.00234: Electronic and Structural Properties of Defects in Few Layer Molybdenum Disulfide Films* MARCUS FORST (Presenter), DAN TRAINER, Department of Physics, Temple University, MARIAN PRECNER, TOMAS POLAKOVIC, Department of Physics, Drexel University, QIAO QIAO, YIMEI ZHU, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, XIAOXING XI, Department of Physics, Temple University, GORAN TRIPUN KARAPETROV, Department of Physics, Drexel University, MARIA IAVARONE, Department of Physics, Temple University — Molybdenum disulfide (MoS2) has emerged as an attractive candidate for next-generation 2D electronic devices yet the exact role of defects on its electronic properties is still not well understood. In this study we employ scanning tunneling microscopy and spectroscopy, transmission electron microscopy and kelvin probe force microscopy to obtain quantitative measurements of the local density of states, work function and nature and mobility of these defects. The defects investigated include individual point defects such as sulfur and molybdenum vacancies and extended defects like grain boundaries and film edges.

*This work was supported as part of the Center for Complex Materials from First Principles, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Grant No. DE-SC0012575. The electron microscopy facilities at BNL were supported by the Materials Science and Engineering Divisions, Office of Basic Energy Sciences of the U.S. Department of Energy under Contract # DE-SC0012704.
T70.00235: Inversion-domain-free growth of epitaxial MoS$_2$ on hBN assisted by substrate defects: towards full orientation control*  
YUANXI WANG (Presenter), FU ZHANG, NASIM ALEM, VINCENT HENRY CRESPI, Pennsylvania State University — Progress in growing exceptionally high-quality single crystals has long been impeded in polar 2D materials by the ubiquitous presence of inversion domain boundaries caused by what are often near-degenerate 0° and 180° orientations with respect to their substrate. For transition metal dichalcogenides (TMD), it has not yet proven possible to lift this degeneracy, even when grown on lattice-matched polar substrates. We perform a systematic structural search for a TMD/hBN heterostack system using density functional theory and hybrid functional calculations to identify a new mechanism to lift this near-degeneracy: the energetic distinction between eclipsed and staggered configurations during nucleation at a point defect in the substrate. Orientation control is then verified in experiments that achieve ~90% consistency in the orientation of as-grown MoS$_2$ flakes on hBN, as confirmed by aberration-corrected scanning/transmission electron microscopy. [arXiv:1801.00487]

*We acknowledge support from NSF under EFRI 2-DARE Grant 1433378 and DMR-1420620. The computational work is supported by the 2-Dimensional Crystal Consortium Materials Innovation Platform under NSF DMR-1539916, and by XSEDE under TG-DMR170050 for allocation on the LSU superMIC cluster.

T70.00236: Gunther Martin, Maxwell Rabe, Dr. Alem Teklu: Investigation of the mechanical properties of MOS2 and ReSe2 using an AFM.  
GUNTHER MARTIN (Presenter), College of Charleston — We measured the mechanical properties of MOS2 and ReSe2 using an AFM. MOS2 and ReSe2 are promising materials for their flexibility combined with their optical and electronic properties. Values relevant to their commercial use were obtained for Young's Modulus, stiffness, and hardness.

T70.00237: Electronic properties, dynamical stability and mechanical properties of zeolite-templated carbon Schwarzites*  
ROSS SIEGEL, KORY BEACH, ZACHARY WARD, MICHAEL C LUCKING, HUMBERTO TERRONES (Presenter), Rensselaer Polytechnic Institute — Periodic crystalline carbon structures, with negative Gaussian curvature, have been recently obtained theoretically by the simulated impregnation of microporous zeolite templates in an attempt to address the nature of porous carbon materials obtained by this method in the lab. While encouraging, more work needs to be done to make the connection between the structures obtained by theory and those which have been synthesized. Here, we report the results of first principles and classical molecular dynamics simulations on the electronic and mechanical properties of the theoretically proposed structures that are identified as Schwarzites and potentially synthesizable. Through a comparison of electron and phonon density of states, we confirm that these structures are dynamically stable, graphitic in nature and can be regarded as semimetals. Their mechanical properties including the bulk moduli and the universal anisotropy indices are calculated. Our results serve to guide and supplement experimental work on zeolite-templated carbon Schwarzites.

*We are grateful to the National Science Foundation (EFRI-1433311).

T70.00238: Characterization of 2D Hybrid Systems: Graphene and Beyond*  
SAJEDEH POURIANEJAD (Presenter), JSNN, UNC Greensboro, FREDERICK ARYEETEY, JSNN, North Carolina A&T State University, ADEYINKA ADESINA, JSNN, UNC Greensboro, SHYAM ARAVAMUDHAN, JSNN, North Carolina A&T State University, TETYANA IGNATOVA, JSNN, UNC Greensboro — High-quality junction between semiconductor and metallic contact with no energy barrier is crucial for high-performance device, which is hard to achieve for 2D MoS$_2$ because of its large bandgap. The heterostructure of single-layers MoS$_2$/graphene has been demonstrated. However, a critical challenge has emerged: to develop reliable methods to transfer this graphene from its growth substrate to the application substrate without damaging the fragile patchwork or leaving undesired residues on the graphene surface. To ascertain the MoS$_2$ and graphene layer number and their defects, Confocal Raman spectroscopy and photoluminescence measurements were conducted before and after transfer. To identify the thin film thickness atomic force microscopy (AFM) was performed. Scanning electron microscopy was used to investigate the surface morphologies of MoS$_2$ and Graphene. To confirm the low surface defect results, X-ray Photoelectron Spectroscopy (XPS) was also carried out. We speculate that the tunable Fermi level in graphene allows excellent work-function to be well-matched with MoS$_2$, resulting in low contact resistance.

*Funding Acknowledgement: Samples for this paper were provided by The Pennsylvania State University 2DCC-MIP supported by NSF cooperative agreement DMR-1539916
T70.00239: Healing a Topological Scar*  
BENJAMIN KATZ (Presenter), VINCENT HENRY CRESPI, Pennsylvania State University  
— A novel defect type in two-dimensional systems is presented, which changes the local coordination number of an atom in an otherwise regular structure. While point-like by itself, such a ‘coordination defect’ has an unusually large number of involved atoms and a potentially dramatic influence on the growth of the system following its formation, due to its introduction of a mismatch between bond network topology and physical ring size. The potential growth pathways after the occurrence of such a defect in graphene are followed using molecular dynamics and first-principles calculations; the inherent conflict between the topological requirements and the actual chemical/physical structure that occurs as the system heals the defect can result in varied morphologies, including a runaway feedback that spawns one or more semi-infinite grain boundaries. Energy comparisons from first principles are used to evaluate the likelihood of this result under various conditions. The appearance of this defect type is predicted to have similar ramifications across a broad array of two-dimensional systems, potentially providing a new method of controlling grain boundary behavior and location.

*Research performed under a training fellowship for CoMET, an NRT at Penn State funded by NSF.

T70.00240: Gate-defined Quantum Confinement in few-layer Black Phosphorus Transistor  
JIAWEI YANG, RUOYU CHEN (Presenter), SHI CHE, Ohio State University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, SEONGPHILL MOON, DMITRY SMIRNOV, Natl High Magnetic Field Lab, CHUN NING LAU, Ohio State University — Black phosphorus is a novel two-dimensional(2D) semiconductor which has attracted considerable research interest due to its tunable band gap and high electron mobility. Here we demonstrate quantum confinement defined by split gate in devices based on few-layer black phosphorus. The tunability of split gate can be illustrated by the fact that a device can be tuned off by split gate alone. In quantum Hall regime, gate-controlled pinching off of quantum Hall states(with filling factor ν = -1, -2, -3, -4) indicates the realization of strong confinement and the potential of manipulation of edge states. The work opens the door for using black phosphorus as platform for electronic and optoelectronic applications.

T70.00241: Polarized Raman spectroscopy in monolayer ReSe2*  
GEOVANI CARVALHO DE RESENDE, Universidade Federal de Minas Gerais, BRUNO R CARVALHO (Presenter), Departamento de Física Teórica e Experimental, Universidade Federal do Rio Grande do Norte, MARCOS PIMENTA, Universidade Federal de Minas Gerais — Raman spectroscopy is a powerful tool to study two-dimensional compounds and has been widely used to obtain important information of their electronic and vibrational structures. In the case of graphene and MoS2-type compounds, the Raman spectrum is isotropic when the light polarization lies in the layer plane. However, for low-symmetry materials such as black phosphorus and triclinic transition metal dichalcogenides, the spectra are polarized dependent and polarized Raman spectroscopy should be used. By changing the angle between the light polarization and the crystallographic axes, the elements of the Raman tensors for the different phonon modes can be determined. Previous studies in black phosphorus showed that Raman tensor elements are complex numbers, but the physical origin of the phase differences are not yet well understood. In this work, polarized Raman spectroscopy is used to investigate the anisotropic behavior in monolayer ReSe2. The angular dependence of the polarized Raman spectra using different polarization configurations is obtained for the 18 Raman active modes as well as the Raman tensor elements for each mode. It was also observed that the principal axes of those Raman tensors are not along the crystallographic axes.

*CNpq, CAPES, FAPEMIG and INCT-Nanocarbono

T70.00242: Magnetoplasmons and magnetoexcitons in doped double-layered α-T₃ lattice in a strong magnetic field  
GODFREY GUMBS (Presenter), DIPENDRA DAHAL, Physics and Astronomy, Hunter College/CUNY, ANDRII IUROV, Center for High Technology, University of New Mexico, DANHONG HUANG, Advanced E/O Space Sensors Group, Air Force Research Laboratory — We investigate the conditions for the occurrence of Bose-Einstein condensation and superfluidity of indirect magnetoexcitons for a pair of quasi-two-dimensional spatially separated α-T₃ layers. The energy dispersion of collective excitations, the spectrum of sound velocity, and the effective magnetic mass of magnetoexcitons are obtained in the integer quantum-Hall regime for strong magnetic fields. The superfluid density and the temperature of the Kosterlitz-Thouless phase transition are probed as functions of the excitonic density, magnetic field and the interlayer separation.
T70.00243: Exciton luminescence efficiency and dynamics in flux-growth MoSe2 monolayers  HONGHUA FANG, BO HAN, CEDRIC ROBERT, DELPHINE LAGARDE, XAVIER MARIE, BERNHARD URBASZEK (Presenter), CNRS/INSA, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS Tsukuba, SEFAATTIN TONGAY, ASU — Monolayers of transition metal dichalcogenide like MoS2 are promising materials for optoelectronics applications due to their exceptionally strong light-matter interaction governed by very robust excitons (Coulomb bounded electron hole pairs). Nevertheless, practical usage has been hindered by their relatively low quantum efficiency (0.1-1%) due to the presence of non-radiative recombination channels (defects, exciton-exciton annihilation, relaxation to dark states ...). In this work, we compare the optical properties of monolayers of MoSe2 exfoliated from different bulk crystals: commercially available crystals from 2D Semiconductors and bulk crystals synthetized with the low temperature flux-growth technique. We perform temperature dependent photoluminescence (PL) and time resolved PL measurements and observe strong differences between the materials in terms of doping level, the PL intensity evolution with temperature and the exciton dynamics at both cryogenic and room temperature. These results are interpreted evoking the lower defect density measured in our flux-growth samples.

T70.00244: Diverse Strain Dependent Thermal Transport in 2D Materials  GUANGZHAO QIN, MING HU (Presenter), Department of Mechanical Engineering, University of South Carolina — Manipulation of thermal transport is in increasing demand as heat transfer plays a critical role in a wide range of practical applications. While 3D bulk materials usually exhibit decreased lattice thermal conductivity upon mechanical stretching and enhanced thermal transport by compression, the thermal response of 2D materials to mechanical strain is not that simple. Perfectly planar atomically-thin materials such as graphene have reduced thermal transport ability when stretched. In contrast, some 2D materials with intrinsic buckled structure will possess enhanced thermal conductivity upon tension. However, many exceptions exist in other 2D materials. The thermal conductivity of 2D planar group III-nitrides (h-BN, h-AlN, h-GaN) is tremendously enhanced by stretching. By deeply analyzing the orbital projected electronic structure, we establish a microscopic picture of the lone-pair electrons driving strong phonon anharmonicity in group III-nitrides. However, the lone-pair electrons do not necessarily lead to enhanced thermal conductivity in strained penta-like 2D materials. Our findings offer perspectives of modulating thermal transport properties of broad 2D materials for applications such as thermoelectrics, thermal circuits, and nanoelectronics.

T70.00245: Band Gaps and Optical Spectra of Fluorinated and Hydrogenated Graphenes*  FRANTISEK KARLICKY (Presenter), Department of Physics, University of Ostrava — Two-dimensional (2D) materials derived from graphene by attachment of hydrogen and halogens have attracted considerable interest over the past few years because of their potential applications (e.g., in electronic devices or sensing)[1]. Here, we consider the effect of electron-electron and electron-hole correlation on the electronic/optical properties of materials under study. Large difference between the experimental optical gap and the electronic band gap from many-body GW theory for fluorographene CF, fluorographite, and graphane CH is explained by unusual large binding energies of excitons obtained by solution of Bethe-Salpeter equation (BSE)[2,3]. Fluorographane C2FH is found as material with the widest electronic gap (~10 eV) and a largest binding energy of exciton (~3 eV) in the class of currently known 2D materials [4]. Finally, we show the importance of careful computational setup for reliable usage of many-body methods.

**T70.00246: Impact of structure on exciton physics in organic-inorganic 2D perovskites**  
JEAN-CHRISTOPHE BLANCON (Presenter), Rice University, JACKY EVEN, INSA Rennes, ANDREAS STIER, Technical University of Munich, CLAUDINE KATAN, Universite de Rennes, JARED CROCHET, Los Alamos National Laboratory, ADITYA D. MOHITE, Rice University  
Organic-inorganic (hybrid) 2D perovskites is a new class of 2D layer materials that feature unique structural characteristics related to their hybrid nature, which includes soft and dynamic lattice structure and organic-inorganic interfaces. There is still little knowledge of the interplay between, on the one hand, their photo-excited states and electronic properties and, on the other hand, their structural characteristics. Here, using optical spectroscopy and 60-Tesla magneto-absorption, we report the dependence of the formation, dynamics, and recombination of exciton states on the structural and compositional details of hybrid 2D perovskites [Nature Communications 9, 2254, 2018 & Science 355, 1288, 2017]. Our work reveals the changes in the exciton properties due to the tuning of the thickness of the 2D perovskites and the size of the organic molecules in the lattice. The exciton characteristics are explained by an advanced model which includes quantum and dielectric confinement. Moreover, we demonstrate the existence of unique electronic states located at the edges of the 2D perovskite layers, which result from local distortions of the lattice at the edges. Finally, we will provide insight into the hetero-coupling between 2D perovskites and transition metal dichalcogenides.

**T70.00247: Refractory metals as alternate contact metals for 2D/3D Heterostructures**  
MAHESH NEUPANE (Presenter), DMITRY A RUZMETOV, ROBERT A BURKE, MATTHEW L CHIN, MIKE D VALENTIN, A. GLEN BIRDWELL, TERRANCE O'REGAN, TONY IVANOV, US Army Rsch Lab - Adelphi  
Vertical three-terminal complex devices based on 2D/3D heterostructures require metal contacts that can withstand high temperature and harsh chemical environment brought about by the 2D/3D material synthesis that follows the metal contact fabrication [1, 2, 3]. Refractory metals, such as Mo, W and Cr, are candidates for this purpose and have been used by our team for the fabrication of contacts to the Base (MoS₂) in a vertical GaN/MoS₂/GaN heterojunction bipolar transistor. Since refractory metals exhibit endurance toward high temperature, abrasion and degradation, they are expected to form sharp, high-quality interface with 2D materials. Motivated by this, we have performed first principle simulation study of refractory metals/2D/3D systems and analyzed structural and electronic properties, such as binding energies, Schottky barrier heights (SBH), and mid-gap charge densities, and investigated the feasibility of using refractory metals as contact metals in 2D/3D systems. Furthermore, we have made an attempt to establish a correlation between the metal type and degree of Fermi level pinning using theoretical as well as in-house experimental data. 1. ACS Nano 10, 3580, 2016, 2. App. Phys. Lett 111, 051602, 2017, 3, 2D Materials 5, 045016, 2018

**T70.00248: Electric-field tunable fine-structure splitting in monolayer semiconductors**  
CHITRALEEMA CHAKRABORTY (Presenter), Electrical Engineering and Computer Science, MIT, NICHOLAS R JUNGWIRTH, GREGORY FUCHS, School of Applied and Engineering Physics, Cornell University, NICK VAMIVAKAS, The Institute of Optics, University of Rochester  
Semiconducting quantum dots (QDs) are among the most promising source of on-demand, indistinguishable single and entangled photon source which are the basic ingredients for quantum communications and computing applications. The most common approach to generate entangled photon pairs in QDs is to utilize the bieexciton to exciton radiative cascade. Recently, single confined exciton and bieexciton emission have been demonstrated at locally strained sites in semiconducting two-dimensional (2D) materials. The 2D host makes them ideal for integrated quantum photonics studies. However, a sizable fine-structure splitting (FSS) (~800 μeV) due to anisotropic electron-hole exchange interaction in these quantum-confined excitons and bieexcitons poses a limit to the indistinguishability of the generated photon pairs. We demonstrate a suppression of the FSS by leveraging on van der Waals heterostructure and fabricate a voltage tunable device to minimize the effect of exchange interaction.

T70.00249: Spin transistors built on 2D van der Waals heterostructures  SHENGWEI JIANG, LIZHONG LI, ZEFANG WANG (Presenter), JIE SHAN, KIN FAI MAK, Cornell University — A transistor based on spin rather than charge (spin transistor) was first proposed by Datta and Das in 1990. Such a spin-based device promises non-volatile data storage and a faster and more energy-efficient performance than present transistors. Many approaches have been pursued to realize spin transistors, but they remain a formidable challenge. Recent discovery of two-dimensional magnetic insulators such as CrI$_3$ with electrically switchable magnetic order and effective spin filtering effect inspires a new operational principle for spin transistors. Here we demonstrate spin field-effect transistors based on dual-gated graphene/CrI$_3$/graphene tunnel junctions. These devices show an ambipolar behavior and tunnel conductance that is dependent on the magnetic order in the CrI$_3$ tunnel barrier. The gate voltage switches the tunnel barrier between an interlayer antiferromagnetic and ferromagnetic state under a constant magnetic bias near the spin-flip transition, thus effectively altering the device between a low and a high conductance state with a large hysteresis. Based on the electrically controlled spin-flip transition in the magnetic tunnel barrier, these new spin transistors achieve spin injection, control and detection in a single device with a conductance ratio approaching 400%.

T70.00250: High Photo-response in Conformally Grown Monolayer MoS$_2$ on Rugged Substrate* YONG SOO KIM (Presenter), TRI NGUYEN, TAM CHINH LE, FARMAN ULLAH, Department of Physics and Energy Harvest Storage Research Center, University of Ulsan, KYO-IN KOO, Department of Biomedical Engineering, University of Ulsan, ZEESHAN TAHIR, Department of Physics and Energy Harvest Storage Research Center, University of Ulsan, EUNAH KIM, DONGWOOK KIM, Department of Physics, Ewha Womans University, JOON JANG, Department of Physics, Sogang University — Conformal growth of atomic-thick semiconductor layers on patterned substrates can boost up the performance of electronic and optoelectronic devices remarkably. However, conformal growth is a very challenging technological task, since the control of the growth processes requires utmost precision. Herein, we report on conformal growth and characterization of monolayer MoS$_2$ on planar, micro-rugged, and nano-rugged SiO$_2$/Si substrates via metal-organic chemical vapor deposition. The continuous and conformal nature of monolayer MoS$_2$ on the rugged surface was verified by high-resolution transmission electron microscopy. Strain effects were examined by photoluminescence (PL) and Raman spectroscopy. Interestingly, the photo-responsivity (~254.5 mA/W) of as-grown MoS$_2$ on the nano-rugged substrate was 59 times larger than that of the planar sample (4.3 mA/W) under a small applied bias of 0.1 V. Such enhancement in the photo-responsivity arises from a large active area for light-matter interaction and local strain for PL quenching, where the latter effect is the key factor and unique in the conformally grown monolayer on the nano-rugged surface.

*This research was supported by the NRF of Korea (2009-0093818; 2014R1A4A1071686; 2017R1E1A1A01075350).

T70.00251: Monolithic image sensor and optoelectronics of monolayer.* CHEN PO-HAN (Presenter), CHANG-NING LIAO, MENG-HSI CHUANG, KUAN-CHANG CHIU, MENG-CHYI WU, CHIH-CHAO YANG, YI-HSIEN LEE, National Tsing Hua University — Development of advanced optoelectronic devices for ultrahigh speed, low power consumption, and low cost image sensors are emergent applications of Internet of Things (IoT). To achieve ultrasensitive image sensors, high responsivity, fast response speed, and low power consumption are required. Monolayer transition metal dichalcogenides (TMD) crystals are potential candidates for high performance optoelectronic devices with high responsivity and low power consumption. Here, persistent photoconductivity (PPC) of the monolayer TMD are studied and improved. Monolithic image sensor and optoelectronic transport properties of the MoS$_2$ are demonstrated.

T70.00252: Study of graphene/hBN heterostructures using Raman Spectroscopy* JESSICA SANTOS LEMOS (Presenter), LEANDRO MALARD MOREIRA, DANIEL CUNHA ELIAS, Universidade Federal de Minas Gerais — In this work, heterostructures of graphene and hexagonal boron nitride (hBN) were built using the pick-up method and dry-transferred to an insulator substrate (glass). Then, electric contacts were made in order to control the charge carrier concentration applying a voltage between graphene and the golden contact deposited on hBN. In this way, it was possible to access charge concentrations higher than $10^{13}$ cm$^{-2}$. Aligned sample was desired in order to obtain a Moiré patterning such that the cloning of the Dirac cones would occur for small energy values, being accessible by voltage application. In order to check the formation of the cloning of the Dirac cones due to the Moiré patterning, Raman spectroscopy was used. It was observed a frequency reduction and width increase in the G band for three distinct values of the voltage applied in the sample. The electron-phonon coupling effect was investigated to explain such experimental observations between the different Dirac points and the G band phonons.

Electrical properties of graphene field-effect transistors functionalized with aryldiazonium salts

Among functionalization strategies, aryldiazonium salts are often chosen to form stable covalent adducts. Here we analyze the effect of this chemistry on the electrical properties of graphene field-effect transistors (G-FETs). First, we conducted an extensive review of published experiments and developed a theoretical framework to compare data obtained under different conditions (channel size, reagent concentration, incubation time). From the aggregated dataset, we found that the electronegativity of the para group seems to have little impact on the electrical response, which contrasts with conclusions found in the literature. We also found that the type of graphene (exfoliated, CVD, RGO) seems to have a much more dominant impact, which could explain strong differences between previous studies. Finally, we argue that device-to-device variations are significant, and we propose an experimental design based on multiple GFET arrays and statistical analysis to unambiguously characterize the effect of aryldiazonium functionalization on graphene transport properties.

T70.00257: Graphene-based catalytic mats for Belousov Zhabotinsky reaction* D JAYA PRASANNA KUMAR (Presenter), SACHIN VERMA, KABEER JASUJA, PRATYUSH DAYAL, Department of Chemical Engineering, Indian Institute of Technology Gandhinagar — Use of hybrid materials that have morphological features at various length scales has opened up new avenues to design multi-functional materials. Here, we synthesize graphene-based catalytic mats and harness their unique properties to tune the kinetics of self-oscillating BZ reactions. In particular, we create catalytic mats containing 0D-2D heterostructures by decorating Ce, Ru, Ag, and Au nanoparticles (NPs) onto the graphene sheet and subsequently, use these nanocomposites to catalyze the BZ reaction. The NPs attached on the graphene function as spacers by increasing the interlayer distance to several nanometers and thus, prevent the stacking of individual graphene sheets. Moreover, the presence of NPs on highly conductive graphene sheets provides enhanced access to active catalytic sites and reveals a multi-fold increase in the number of chemical oscillations frequency in BZ reactions. We also validate the kinetic model of the BZ reaction with our experimental results and identify key parameters to model the reaction kinetics for our BZ system. We expect that our findings will offer a novel approach to design synthetic smart materials with tunable dynamic behavior.

*DST-SERB: EMR/2016/007778

T70.00258: Nanoelectromechanical resonators from thin superconducting crystals of BSCCO SUDHIR SAHU (Presenter), Department of Physics, Indian Institute of Science Bangalore, JAY KUMAR VAIDYA, DIGAMBAR JANGADE, ARUMUGAM THAMIZHAVEL, MANDAR DESHMUKH, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, VIBHOR SINGH, Department of Physics, Indian Institute of Science Bangalore — High transition-temperature superconductors host a rich variety of quantum phases. Cavity optomechanics techniques could be helpful in a sensitive detection of long-wavelength phonon modes carrying imprints of the electronic phases. Here we present mechanical resonators fabricated with thin exfoliated crystals of BSCCO at low temperatures. For mechanical readout, we couple their motion to a coplanar waveguide microwave cavity fabricated with a superconducting alloy of molybdenum-rhenium. We perform spectroscopic and time-domain measurements to understand dissipation in these systems. Our results suggest that the performance of these devices is limited by the contact resistance arising from the insulating outer layer, and interlayer friction.

T70.00259: Superconductivity from Valley Fluctuations and Approximate SO(4) Symmetry in a Weak Coupling Theory of Twisted Bilayer Graphene YIZHUANG YOU (Presenter), ASHVIN VISHWANATH, Department of Physics, Harvard University — We develop a weak coupling approach to superconductivity in twisted bilayer graphene, starting from the Fermi liquid regime. A key observation is that near half filling, the fermiology consists of well nested Fermi pockets derived from opposite valleys, leading to enhanced valley fluctuation, which in turn can mediate superconductivity. This scenario is studied within the random phase approximation. We find that inter-valley electron pairing with either chiral (d+id mixed with p-ip) or helical form factor is the dominant instability. An approximate SO(4) spin-valley symmetry implies a near degeneracy of spin-singlet and triplet pairing. On increasing interactions, commensurate inter-valley coherence wave (IVCW) order can arise, with simultaneous condensation at the three "M" points in the Brillouin Zone, and a 2 × 2 pattern in real space. In simple treatments though, this leads to a full gap at fillings ±(1/2 + 1/8), slightly away from half-filling. The selection of spin-singlet or spin triplet orders, both for the IVCW and the superconductor, arise from SO(4) symmetry breaking terms. Mott insulators derived from phase fluctuating superconductors are also discussed, which exhibit both symmetry protected and intrinsic topological orders.

T70.00260: Realizing Td phase at room temperature in ultrathin MoTe2* GAIHUA YE (Presenter), ZHIPENG YE, RUI HE, Texas Tech University, LOGAN WINFORD, University of Northern Iowa, SHAZHOU ZHONG, HYUN HO KIM, ADAM TSEN, University of Waterloo, Canada — MoTe2 emerges as a new type of transition metal dichalcogenide (TMD) whose different polymorphs show very different properties. In bulk MoTe, both hexagonal 2H phase (semiconducting) and monoclinic 1T' phase (semimetallic) can be formed at room temperature depending on the growth conditions. When temperature is lowered to 250K, the 1T' phase transforms into an orthorhombic Td phase in which the MoTe2 crystal is a type-II Weyl semimetal with novel quantum phenomena. We exfoliated 1T'-MoTe2 flakes on SiO2 substrates and protected them with boron nitride from oxidation. Electrical transport measurements show that the ultrathin flakes do not show a phase transition below 250K. Raman studies reveal that the MoTe2 ultrathin flakes exhibit a Td phase even at room temperature, making it a potential host material for realizing type-II Weyl semimetal at room temperature.

Electronic properties of bare and functionalized 1- and 2-Dimensional Tellurene structures

Daniel Wines (Presenter), Fatih Ersan, Jaron Kropp, Gracie M Chaney, Can Ataca, University of Maryland, Baltimore County — Recently, 1D and 2D Tellurene structures have been experimentally synthesized. These structures possess high mobility and air stability which make them ideal candidates for applications in electronics, optoelectronics and energy devices. We performed density functional theory and molecular dynamics simulations to investigate the stability and electronic structure of 1D α, β and Γ Tellurene chains, 2D α and β Tellurene sheets, and hydrogen, oxygen, and fluorine functionalized counterparts, including spin-orbit coupling effects. Our calculations show that bare α and β Tellurene sheets are stable and have direct band gaps of 0.56 eV and 1.02 eV respectively. When hydrogenated, α-Tellurene displays metallic properties while the direct band gap of β-Tellurene increases to 1.72 eV. Our calculations also show that α and β Tellurene chains are unstable while Γ Tellurene chains are stable. Our molecular dynamics calculations indicate that Γ Tellurene chains gain kinetic energy and rotate around the chain growth direction. This rotation provides stability to the Γ Tellurene chains. Our results indicate that functionalized-Tellurene chains and monolayers are not only suitable for future optoelectronic devices, but they can be used as metallic contacts in nanoscale junctions.
T70.00265: Interaction of the system titanium-borophene with lead substrate with water molecule. **GREGORIO RUÍZ-CHAVARRIA** (Presenter), Universidad Autonoma Chapingo — In this work I made an computational study of the interaction of the system titanium-borophene with lead substrate with water. I first established the stability of the borophene system with lead substrate, then added titanium, studying the stability of this system, which was stable. Finally, an water molecule is added, studying the evolution of the interaction between this molecule and the system titanium-borophene with lead substrate. To do this work, I use Density Functional Theory, Born-Oppenheimer Approximation, atomic pseudopotentials and molecular dynamics. The results obtained are compared with experimental results, as well as with similar calculations.

T70.00266: Critical electronic and many-body properties of $\alpha$-T$_3$ nanoribbons **PAULA FEKETE** (Presenter), United States Military Academy, ANDRII IUROV, Center for High Technology Materials, University of New Mexico, Albuquerque, NM, GODFREY GUMBS, Hunter College, City University of New York, New York, NY, DANHONG HUANG, Kirtland Airforce Base, Air Force Research Laboratory, Albuquerque, NM — Quasi-one-dimensional nanoribbons of finite width could be produced from the recently proposed $\alpha$-T$_3$ materials with variable hub-rim coupling parameter similarly to nanoribbons fabricated from graphene. We investigate their critical electronic and collective properties, such as plasmons, based on the tight-binding model for the low-lying energy bands and spin-1 Dirac-Weyl equation with the proper boundary conditions. Our results strongly depend on the type of boundary which our nanoribbon has. We believe that the novel electronic properties we obtained will significantly benefit the field of currently existing carbon-based nanoelectronics and nanodevices.

T70.00267: A First-Principles Investigation of Spintronic Capabilities of Nitrophosphorene Doped With 3d Transition Metals **LAWRENCE SHI** (Presenter), XUAN LUO, National Graphene Research and Development Center — There has been search for materials with spintronics properties as they have potential advantages in data transfer and storage over their conventional electronics counterparts. Notably, phosphorene is at the center of such material search with its widely tunable band gap and high carrier mobility. Nitrophosphorene (PN), a newly discovered material in 2017, is considered to be a superior semiconductor to Black Phosphorene (BP) because of its larger band gap. However, unlike BP, whose spintronic properties have been well studied, little is known about the spintronic properties of PN. We present strong evidence that PN is potentially an even better material for spintronics than BP. Specifically, we used first-principles calculations to investigate the spintronic properties of 3d transition metal-doped PN. Sc, Cr, and Co doping result in a DMS. V, Mn, and Fe doping result in a half metal, and Ti and Ni doping result in a semiconductor with no magnetization. We also compared the spintronic properties of interstitial Mn-doped PN and interstitial Mn-doped BP. Although both of them are half-metals, Mn-doped PN has a higher magnetization and band gap. Our discovery in PN spintronics contributes to the recent advances in the fundamental studies and search for spintronics materials.

T70.00268: Predicting Synthesizable Functional Edge Reconstructions in 2D Monolayers* **GUOXIANG HU** (Presenter), XIAHAN SANG, RAYMOND UNOCIC, PANCHAPAKESAN GANESH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — Two-dimensional (2D) transition metal dichalcogenides (TMDCs) have attracted tremendous interest due to their exceptional electronic and optical properties. More interestingly, it has been found that edges of 2D TMDCs are responsible for their promising catalytic activity, while the basal plane is chemically inert. In addition to the conventional armchair and zigzag edges, more complex edge reconstructions have recently been realized by various experiments. Therefore, it is highly desirable to computationally predict the family of stable edges so as to screen their functional properties. Here we report development of such a computational approach and demonstrate it on the 2D TMDC family of systems such as MoS2 & MoSe2. Starting from configuration ensemble generations, we screen for stable edges using cheaper force-fields or surrogate (Neural-Network-based) models, which are then further refined using DFT-level of theory. We predict many stable edges that are superior for hydrogen evolution reaction (HER). Our study thus provides a comprehensive yet tractable computational approach for predicting synthesizable functional edges in 2D monolayers.

JARVIS (Joint Automated Repository for Various Integrated Simulations) is a unique integrated framework to accelerate material design using classical force-fields (FF), density functional theory (DFT) and machine learning (ML). The JARVIS-DFT hosts data for more than 30000 materials. We discovered more than 1500 2D materials using lattice parameter criteria and exfoliation energy calculations. We charted improved lattice parameters, formation energies and elastic tensors using van der Waals functional for more than 12000 materials and established relation between exfoliation energies and elastic constants. To alleviate bandgap underestimation in conventional DFT and improve frequency dependent dielectric function predictions, we evaluated meta-GGA based approaches for more than 10000 materials. We use spectroscopic limited maximum efficiency approach to identify potential photovoltaic materials. Using spin-orbit spillage criteria, we discovered more than 1500 potential topological materials including topological insulators, Weyl and Dirac semimetals, and topological crystalline insulators. The database is publicly available at https://jarvis.nist.gov/.

While theoretical modeling of the atomic scale structure of non-crystalline solids has become well developed, deriving functional properties from these models still faces challenges. In order to address this deficit, we analytically demonstrate a decomposition of the non-equilibrium glassy macrostate into a statistical ensemble of crystalline microstates with an effective temperature. Crystalline microstates are calculated as local potential energy minima using density functional theory. With the radial distribution function and powder diffraction intensity as signatures of short- and long-range order respectively, we show that the glassy states of both silicon and silica can be reproduced with remarkable fidelity using crystalline microstates with unit cells on the order of just a few dozen atoms. Our approach offers a complementary view to the conventional supercell-based continuous random network model, which typically singles out a single representative microstate for the purposes of modeling. By contrast, our model presents the glassy state as an effective liquid, which visits crystalline potential energy minima ergodically, opening the door to new predictive methods for property calculations based on ensemble averaging and to the rational design of glassy solids.

MSCD Framework A Novel Computational Design Software for High-Temperature Superconductors

We present recent results on stable and reliable synthesis of boron nitride nanotubes (BNNTs) in volume by an anodic arc discharge at near atmospheric pressure of nitrogen. This arc was operated with the boron-rich anode and the cathode made from a refractory metal which has a melting temperature above the melting point of boron. Ex-situ characterization of synthesized BNNTs with electron microscopy and Raman spectroscopy revealed that independent of the cathode material, the tubes are primarily single and double walled. Ex-situ analysis results also show evidence of root-growth of BNNTs produced in the arc discharge. In order to understand nanostructure formation we needed to determine the plasma and gas composition conditions in the nucleation and growth region. We determined plasma parameters in the growth region using plasma diagnostics and thermodynamic modelling. Previous atomistic simulations helped to analyse crucial processes in nanomaterial synthesis. References are available at nano.pppl.gov

T70.00273: Towards Understanding of Arc-Based Synthesis of Carbon Nanotubes*  
YEVENY RAITSES, SHURIK YATOM, ALEXANDER KRABRYI, VLAD VEKSELMAN, IGOR KAGANOVICH (Presenter), Princeton Plasma Phys Lab — This work reports on studies of arc-based synthesis of carbon nanomaterials. Applying a set of the in-situ diagnostics of plasma and nanoparticles, our synthesis experiments revealed that the carbon arc forms a highly inhomogeneous plasma consisting of distinguishable regions with different dominant species, including ions, atoms, molecules and clusters, and nanoparticles. Measurements revealed clouds of nanoparticles in the arc periphery bordering the region with a high density of diatomic carbon molecules. Two-dimensional CFD simulations of the arc combined with thermodynamic modeling show that this is due to the interplay of the condensation of carbon molecular species and the convection flow pattern. The formation of nanoparticles is strongly affected by unstable arc behavior.
References are available at nano.pppl.gov

T70.00274: Multilayer graphene shows intrinsic resistance peaks in the carrier density dependence: experiments in tetra- and hexlayer graphene  
RYUTA YAGI (Presenter), TAIKI HIRAHARA, RYOYA EBISUOKA, TAKUSHI OKA, SHINGO TAJIMA, AdSM, Hiroshima Univ., KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science (NIMS) — Since the advent of graphene, a variety of studies have been done to elucidate its fundamental physics, or to explore its practical applications. Gate-tunable resistance is one of the most important properties of graphene and has been studied in 1-3 layer graphene in a number of efforts to control the band gap to obtain a large on-off ratio. On the other hand, the transport property of multilayer graphene with more than three layers is less well understood. Here we show a new aspect of multilayer graphene. We found that four-layer shows intrinsic peak structures in the gate voltage dependence of its resistance at zero magnetic field. Measurement of quantum oscillations in magnetic field confirmed that the peaks originate from the specific band structure of graphene and appear at the carrier density for the bottoms of conduction bands and valence bands. Similar but different peak structures were observed in six-layer graphene. The intrinsic peak structures should generally be observed in AB-stacked multilayer graphene. The present results would be significant for understanding the physics of graphene and making graphene FET devices. (Sci. Rep. 8, 13992 (2018). DOI: 10.1038/s41598-018-32214-7)

T70.00275: Controlling graphene structures and electronic properties by Ion beam irradiation*  
KOSUKE NAKAMURA (Presenter), KAZUYUKI TAKAI, TOMOAKI NISHIMURA, HIROKI YOSHIMOTO, Hosei University — Irradiation of ion into graphene is interesting in view of defect-introduction and chemical modification. In this study, we attempted 200 keV Au or I ion injection to graphene. Irradiation to bare graphene will cause damage, so a sacrificial layer protecting graphene was designed and fabricated on the surface. NaCl thin-film was applied for sacrificial layer, where it has been confirmed NaCl hardly affects structural and electronic properties of graphene after removal process. Raman spectroscopy of Au or I ion irradiated graphene by using NaCl thin-film as a sacrificial layer, shows peculiar G band intensity of graphene near 1580 cm-1, indicating honeycomb structure of graphene was preserved after irradiation. Also defects that cause significant intervalley scattering (D band : 1340 cm-1) and intravalley scattering (D’ band : 1620 cm-1) appeared after irradiation. Field effect transistor (FET) of graphene was fabricated after irradiation, and the mobility of irradiated graphene was measured by applying gate voltage sweep range. The mobility of Au and I irradiated graphene decreased down to 0.114 cm2 / Vs and 0.034 cm2 / Vs respectively, being responsible for extremely less conductivity.

*This work was supported by JSPS KAKENHI Grant No. 16K05758 and 26107532
Defects introduction is one of the important strategy to tune graphene properties. Especially, it is known that an ion beam irradiation can introduce atomic vacancies in graphene. Although, the number of defects is usually focused, the chemical structure of defects has been not well considered. Actually, for hydrogenated atomic vacancies, the theoretical calculation shows a low energy barrier and little adsorption heat for the additional adsorption of hydrogen molecules, suggesting an efficient hydrogen storage and release in this system. In this study, hydrogenated / oxygen-terminated atomic vacancies are introduced into epitaxial graphene and the amount of hydrogen and carrier scattering related to vacancies are evaluated. Hydrogenated and oxygen-terminated atomic vacancies were introduced into epitaxial graphene by ion beam sputtering, followed by exposing to H2 gas and air, respectively. After introducing hydrogenated vacancies, the increment of hydrogen is comparable to the upper limit for the number of vacancies. The smaller Raman D-band for hydrogenated vacancies than that for oxygen terminated vacancies suggests the inter valley scattering depends on the chemical structure of defects in graphene.

*This work was supported by JSPS KAKENHI Grant No. 16K05758 and 26107532.

Free radical ions generated at the surface can cleave a cross-linked polymer mesh that holds together colloidal assemblies or can polymerize acrylic acid monomer at the particle surface (viz. bond breaking or bond formation). Proximity of polymeric amine groups allows photo-induced electron transfer from excited dye molecules, to form free radical ions. Formation of free radical ions is not a function of the size of the colloid, neither is it restricted to a specific fluorophore. Fluorophores with redox potentials that allow photo-induced electron transfer with amine groups show formation of free radical ions.

*SERB, DST-India.

How atoms acquire three-dimensional bulk character is one of the fundamental questions in materials science. Before addressing this question, how atomic layers become a bulk crystal might give a hint to the answer. While atomically thin films have been studied in a limited range of materials, a recent discovery showing how to mechanically exfoliate bulk crystals has opened up the field to study the atomic layers of various materials. Here, we show systematic variation in the band structure of high mobility graphene with one to seven layers by measuring the quantum oscillation of magnetoresistance. The Landau fan diagram showed distinct structures that reflected differences in the band structure, as if they were finger prints of multilayer graphene. In particular, an even-odd layer number effect was clearly observed, with the number of bands increasing by one for every two layers and a Dirac cone observed only for an odd number of layers. The electronic structure is significantly influenced by the potential energy arising from carrier screening associated with a gate electric field. (Sci. Rep. 8, 13018 (2018). DOI:10.1038/s41598-018-31291-y)
**T70.00279: Magnetic Proximity Effect in Graphene/BiFeO$_3$ Hybrid System**

HUA-DING SONG (Presenter), ZHI-MIN LIAO, Department of Physics, Peking University, DAPENG YU, Department of Physics, Southern University of Science and Technology — Graphene, a very intriguing 2D massless fermionic system with high carrier mobility, is promising for spintronics. However, the spin splitting is always weak in pristine graphene. Here, we report the transport properties of graphene coupled to an antiferromagnetic insulator BiFeO$_3$. It is found that the magnetic proximity effect results in a strong Zeeman splitting in graphene with the obvious spin splitting in Landau levels. $\nu=0$ quantum Hall state of the coupled system undergoes quantum phase transitions as a result of the combined effect of exchange field and external field. The direction of the external magnetic field also shows its capability to adjust the proximity effect at the interface, by tuning the interfacial magnetization. We also achieve the electrical control of the magnetic proximity effect via strong magneto-electric coupling in BiFeO$_3$ nanoplates. Our findings in graphene/BiFeO$_3$ heterostructure are therefore promising for future spintronics.

**T70.00280: Thermal Conductivity of Pure and Doped Graphene**

GIRIJA DUBEY (Presenter), Department of Earth & Physical Sciences and Department of Physics & Engineering Physics, York College of CUNY and Fordham University, New York, NY, USA, SARITA MANN, Department of Physics, Punjab University, Chandigarh, India, VASSILIOS FESSATIDIS, Department of Physics and Engineering Physics, Fordham University, Bronx, New York, USA, HITESH SHARMA, Department of Physics, Punjab Technical University, Kapurthala, India, GODFREY GUMBS, Department of Physics & Astronomy, Hunter College of CUNY, New York, NY, USA, VIJAY JINDAL, Department of Physics, Punjab University, Chandigarh, India — In this work we have studied the thermal conductivity of both pure graphene and boron-doped graphene structure. The calculations have been performed using ab-initio density functional perturbation theory, implemented in VASP software, to study structural properties and calculated the interatomic forces/force constants of pristine/doped graphene. Thermal conductivities are calculated by solving linearized Boltzmann transport equations (LBTE) using single mode relaxation time approximation (RTA). The phonon density of states and thermal conductivity were calculated using phonopy and phono3py. A graphene sheet of 32 atoms was considered for calculating second order force constants while an 8 atom sheet was used to calculate third order force constants. A smaller sheet was used for third order force constant calculation as it requires high computation. Doping concentrations of 12.5% and 25% B dopants were used in this work since higher concentration of dopants lead to unstable structures.

Using this approach, we have obtained thermal expansion results for pure graphene which match well earlier calculations using similar approach. The results have suggested that the thermal properties could be highly tuneable and have interesting application prospects.

**T70.00281: Infrared Spectroscopy of Dual-Gated Bilayer Graphene**

JORDAN RUSSELL, JORDAN PACK (Presenter), YASHIKA KAPOOR, Washington University in St. Louis, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ERIK HENRIKSEN, Washington University in St. Louis — We have performed infrared transmission spectroscopy measurements on dual-gated encapsulated bilayer graphene. In these measurements, we have observed intra- and inter-band resonances of bilayer graphene which we study as a function of magnetic field, filling factor, and displacement field. We will share comparisons between measurements of devices with metal and graphite gates. Methods of distinguishing sample resonances from resonances observed in the silicon and graphite gates will also be discussed.
**T70.00282: Energy Relaxation of Hot Dirac Carriers in CVD Graphene-based Heterostructures**

JINGGAO SUI (Presenter), Department of Physics, University of Cambridge, JACK ALEXANDER-WEBBER, YE FAN, Department of Engineering, University of Cambridge, HIROMU GAMOU, Department of Materials Science, University of Tokyo, S HOFMANN, Department of Engineering, University of Cambridge, MALCOLM CONNOLLY, CHARLES G SMITH, Department of Physics, University of Cambridge — The two dimensional character of graphene makes it a promising material to be used in the post-silicon electronics era. Despite the exceptional electronic properties, the lack of a bandgap in monolayer graphene limits its potential applications. The creation of heterostructures based on graphene and other two-dimensional crystals can help overcome some limitations. We present a fabrication process and magnetotransport measurements to study the hot carrier dynamics in scalable bilayer CVD graphene and graphene-on-WSe2 heterostructures. Energy relaxation of hot Dirac fermions in these systems is experimentally investigated by Shubnikov–de Haas oscillations and weak localization\(^1\). Energy loss rates in graphene-based heterostructures have been found to follow the predicted Bloch–Grüneisen power-law behaviour. The electron-phonon relaxation time has also been observed to be carrier density dependent. Hot carrier dynamics in graphene has considerable importance in determining the performance of high frequency and high power electronics, high-speed sensors and quantum Hall metrology for accurate measurements\(^2\).

**T70.00283: Electronic transport in graphene decorated with Bi2Te3 nanoparticles**

JOSHUA COHEN (Presenter), JAMIE ELIAS, Department of Physics, Washington University in St. Louis, 1 Brookings Dr, St. Louis, MO 63130, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, 1-2-1 Sengen, Tsukuba, Ibaraki 305-0044, Japan, FUDONG WANG, WILLIAM BUHRO, Department of Chemistry, Washington University in St. Louis, 1 Brookings Dr, St. Louis, MO 63130, ARASHDEEP S THIND, ROHAN MISHRA, Department of Mechanical Engineering and Materials Science, Washington University in St. Louis, 1 Brookings Dr, St. Louis, MO 63130, ERIK HENRIKSEN, Department of Physics, Washington University in St. Louis, 1 Brookings Dr, St. Louis, MO 63130 — We investigate the electronic transport in monolayer graphene Hall bars in which the graphene surface is carefully cleaned and then decorated with a dilute coating of Bi2Te3 nanoparticles. The devices include both monolayer-on-silicon oxide and monolayer-on-boron nitride variants. The Bi2Te3 nanoparticles are high quality with few defects, and mono-disperse with a diameter of approximately 15 nm. Initial measurements were made on graphene with a low coverage of \(~1\) nanoparticle per \(10^4\) nm\(^2\), and indicate transport not dissimilar from standard for graphene. Upon annealing the sample in Ar to promote removal of the nanoparticle polymer coating, a small leftward shift indicating electron doping was observed. Results in devices with higher nanoparticle densities will be presented.

**T70.00284: STATISTICAL THERMODYNAMICS OF DICE LATTICE CARRIERS**

NORMAN J.M. HORING (Presenter), Physics, Stevens Inst. of Tech., Hoboken, NJ, USA, M LAWRENCE GLASSER, Physics, Clarkson University, Potsdam, NY, USA, JAY D MANCINI, Physical Sciences, Kingsborough Community College, Brooklyn, NY, USA — We have developed the retarded and thermodynamic Greene’s functions for Dice Lattice carriers and employed them in the determination of the Dice Lattice statistical thermodynamic functions, including the Helmholtz Free Energy, grand partition function, ordinary partition function, and entropy. These evaluations are carried out for arbitrary temperature and chemical potential, including the degenerate and nondegenerate statistical regimes.
T70.00285: Are freestanding Xene monolayers excitonic insulators in their ground state?* MATTIAV BRUNETTI (Presenter), CUNY Graduate Center, OLEG BERMAN, ROMAN KEZERASHVILI, Physics, CUNY - City Tech — We present evidence that monolayers of Xenes (silicene, germanene and stanene) suspended in vacuum behave as excitonic insulators in their ground state, by drawing upon well-established ab initio and theoretical models of the electronic structure of these materials. By solving the Schrödinger equation for electrons and holes interacting via the Rytova-Keldysh potential, it is shown that the direct exciton binding energy exceeds the band gap when the external electric field is small or zero [1]. We propose a phase transition in freestanding monolayer Xenes from the semiconducting phase to the excitonic insulating (EI) phase can be induced by reducing an external electric field below some critical value which is unique to each material. Our calculations show the coexistence of the semiconducting phase of A excitons with the EI phase of B excitons for a particular range of electric field. Enhanced dielectric screening in supported or encapsulated monolayer Xenes precludes the existence of the EI phase in those scenarios.

T70.00286: Mechanical and electronic properties of 2D green phosphorene, a first-principles study GUANG YANG, Arizona State University, TIANXING MA, Beijing Normal University, XIHONG PENG (Presenter), Arizona State University — Recently, a phosphorus isomer named green phosphorus was theoretically predicted with a similar interlayer interaction compared to that of black phosphorus, thus indicating that individual layers can be mechanically exfoliated to form two-dimensional (2D) layers known as green phosphorene. The 2D structure shows high stability and was predicted to have a direct band gap up to 2.4 eV. First-principles density functional theory calculations were used to investigate the mechanical properties and strain effect on electronic band structure of the 2D green phosphorene along two perpendicular in-plane directions. Remarkably, it was found that the material can sustain a tensile strain in the armchair direction up to a threshold of 35% which is larger than that of black phosphorene, suggesting that green phosphorene has more puckered structure. The results also showed that the Young's modulus and Poisson's ratio in the zigzag direction are four times larger than those in the armchair direction, which confirms the anisotropy of the material. Furthermore, uniaxial strain can trigger the direct-indirect bandgap transition in the material, and the critical strains for the bandgap transition are revealed.

T70.00287: Van-der-Waals-gap tunneling spectroscopy for low dimensional materials* DONG HWAN CHOI (Presenter), JU-JIN KIM, Physics, Chonbuk National University, MYUNG-HO BAE, Korea Research Institute of Standards and Science, KYUNG-AH MIN, SUK-LYUN HONG, Physics, Sejong University — Field-effect transistors based on low-dimensional materials such as carbon nanotubes (CNTs), graphene, and transition metal dichalcogenides have been developed in order to provide enhanced electronic performance, with significant efforts to overcome the van der Waals (vdW) gap between the metal and inert material components. We report a new method that offers a high resolution tunneling spectroscopy by adopting tunnel barrier as the vdW interface indium (In) metal and low-dimensional nano-structures without an artificial insulating tunnel barrier. We show that multiple differential conductance peaks for varying bias voltages correspond to the van Hove singularities existing in the electronic density of states of CNTs. For the multi-layer MoS2 FET, conductance shoulders were observed at the source-drain voltage ($V_{sd}$) of $-0.9$ V and were attributed to a semiconducting gap. For the 1T-TaS2 case, Mott-gap induced conductance peaks at $V_{sd} \sim 0.2$ V were observed at $T = 4$ K, which coexist with the commensurate charge-density-wave phase.

T70.00288: Temperature-dependent optical and transport conductivities in doped silicene* ANDRII IUROV (Presenter), University of New Mexico, GODFREY GUMBS, Hunter college, DANHONG HUANG, Air Force Research Labs. — We examined the thermal transport properties of silicene, germanene and other buckled honeycomb lattices with finite electron doping. Both Boltzmann and optical conductivities are computed based on the finite-temperature polarization function, Such thermally convoluted polarizability is calculated using temperature-dependent chemical potentials. We have analyzed the frequency dependence of both real and imaginary parts of the optical conductivity. Specific features of the obtained spectral dependence can be used for analyzing plasmon damping in silicene and ultrafast light modulations. We also calculated transport conductivities for various doping concentrations and band gaps using the second-order Born approximation and derived several important analytical expressions for the inverse relaxation times.

T70.00290: Low-energy bandstructure, electronic states and Berry phases in α-T₃ materials under external irradiation

* LIUBOV ZHEMCHUZHNA (Presenter), Hunter college, ANDRII IUROV, University of New Mexico, GODFREY GUMBS, Hunter college, DANHONG HUANG, Air Force Research Labs. — Electron dressed states, or interacting Floquet states, have been derived analytically for α-T₃ materials. These arise from the off-resonant coupling of Dirac pseudospin-1 electrons to the external irradiation. Results will be presented over the allowable range of values of the interaction parameter $\alpha_0 < \alpha < 1$ and for all possible types of incoming light polarizations. For elliptical and circular polarizations, an energy band gap could be opened, there is no longer symmetry between the valence and conduction bands, and the obtained low-energy bandstructure directly depends on the valley index $\tau$. In contrast, applying linearly polarized light could induce $\alpha$-dependent anisotropy of the dispersions, but there is no change to the flat band. We have obtained and examined the corresponding wave functions, their structure and Berry phases.

T70.00290: Exploration of exciton behavior in atomically thin WS₂ layers by ionic gating

XIN HE (Presenter), ZEHUI ZHANG, CHENHUI ZHANG, Physical Science and Engineering Division (PSE), King Abdullah University of Science and Technology (KAUST), YANG YANG, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, MING HU, Institute of Mineral Engineering, Division of Materials Science and Engineering, Faculty of Georesources and Materials Engineering, RWTH Aachen University, WEIKUN GE, School of Physics, Peking University, XIXIANG ZHANG, Physical Science and Engineering Division (PSE), King Abdullah University of Science and Technology (KAUST) — The photoluminescence spectra of mono- and bilayer WS₂, gated by the ionic liquid, were systematically studied at 77 K. Interesting phenomena, such as a redshift of the exciton peaks and a change in the spectral weight of the exciton, trion, and biexciton peaks, were observed at intermediate doping levels. By increasing the doping level, all the exciton, trion, and biexciton peaks vanished, which is attributed to the phase-space filling effect and the Coulomb screening effect. The variation in the band structure, which was induced by the quantum-confined Stark effect in both the mono- and bilayer WS₂, was also studied using first-principle calculations.

T70.00291: The control of the double-slit silicene interferometer by the spin-Hall effect

BARTLOMIEJ RZESZOTARSKI (Presenter), BARTLOMIEJ SZAFRAN, Faculty of Physics and Applied Computer Science, AGH University of Science and Technology — Silicene [1] is a novel 2D-material similar to the graphene with buckled structure that provides spin-orbit coupling (SOC) which is a source of topological physics. In silicene zigzag nanoribbons for low Fermi energy the quantum spin Hall effect [2] occurs and the charge currents for both spin orientation flow along opposite edges of the ribbon. Here, we present an idea for the double-slit-interference device with one input lead that splits to double channels (Y-shape) based on the atomistic tight-binding approach [3]. The double channel is connected to an unconfined silicene half-plane with a third lead used as a detector. The double-slit interference can be detected with the external magnetic field that triggers the Aharonov-Bohm conductance oscillations only when the electron wave functions passes through both the arms of the split input channel. The Aharonov-Bohm oscillations are attenuated when the system is driven in the quantum spin Hall regime, when the wave functions passing through both the channels have opposite spins.

T70.00292: Polarization charge coupling effect in 2D van der Waals-ferroelectric heterostructure

HYE-JIN JIN (Presenter), JAYEONG KIM, YEJIN KIM, SEOKHYUN YOON, Department of Physics, Ewha Womans University, YANGJIN LEE, KWANPYO KIM, Yonsei University, WILLIAM JO, Department of Physics, Ewha Womans University. — In two-dimensional (2D) layered semiconducting materials, charge distribution is controlled by ferroelectric polarization and inequivalent charge distribution is obtained vertically. Ferroelectric polarization induced accumulation or depletion in 2D semiconductors resulting in polarization charge coupling effect. In this study, 2D semiconductors ($n$-type MoS₂ and $p$-type WSe₂) and ferroelectric PbTiO₃ (PTO) thin films were integrated vertically. We used conductive atomic force microscopy to study vertical transport and light illumination effect is also studied. Enhanced resistive switching effect was obtained and polarization was exploited to control resistive switching characteristics. In addition, charge separation is effectively obtained due to built-in interfacial electrical field at interface between 2D semiconductor and PTO thin films. In particular, photovoltaic response is obtained in the heterostructure and polarization can behave as a physically-doped electrode. Polarization gives stable and additional separation of electron-hole pairs in 2D semiconductors and increase of photoresponse is obtained. Therefore, we can expect application for a photo-memristor and suggest new memory and photovoltaic devices by integrating 2D semiconductors and ferroelectrics.
T70.00293: Tunnelling spectroscopy of localized states in WS₂ based van der Waals heterostructures*  
NIKS  
PAPADOPOULOS (Presenter), PASCAL GEHRING, Kavli Institute of Nanoscience, Delft University of Technology, Lorentzweg 1, Delft 2628 CJ, The Netherlands, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan, HERRE S.J. VAN DER ZANT, GARY STEELE, Kavli Institute of Nanoscience, Delft University of Technology, Lorentzweg 1, Delft 2628 CJ, The Netherlands — Defects in semiconductors and dielectrics can provide rich physics with technological potential such as quantum photon emission, spin control and they might be potential platforms for realizing quantum entanglement. In transition metal dichalcogenides, defects have been found to play important role as they affect the doping and the spin-valley relaxation dynamics. Herein we study localized states in WS₂ by means of tunnelling spectroscopy using van der Waals heterostructures of h-BN/graphene/WS₂/metal. The monolayer graphene electrodes provide for weak screening of electric-fields, which allows us to tune the chemical potential of WS₂ with the back-gate. The obtained conductance maps as a function of bias and gate voltage reveal single-electron transistor behaviour (Coulomb blockade) with a rich set of transport features like excited states and negative differential resistance regimes. Moreover, by applying a perpendicular magnetic field, we study the spin ground- and excited states of single defects.  
*This work is part of the Organisation for Scientific Research (NWO) and the Ministry of Education, Culture, and Science (OCW). Growth of hexagonal boron nitride crystals was supported by the Elemental Strategy Initiative conducted by the MEXT, Japan and the CREST (JPMJCR15F3), JST.

T70.00294: Spin Polarized Excitonic Superfluids in Topological Insulators*  
HENRY TRAVAGLINI (Presenter), University of California, Davis —  
Topological insulators (TIs) are a remarkable class of materials due to their linear dispersion relation and exotic spin textures at the surface, and have recently been proposed as a candidate system for achieving a condensate state of excitonic particles. We use scanning photocurrent microscopy to study Sb doped Bi₂Se₃ at varying temperature, wavelength, polarization, and incident angle. This suite of measurements confirm that electrons and holes form bound states at low temperature, and demonstrate ballistic transport at temperatures up to 40 K, as evidenced by millimeter exciton transport lengths. Furthermore, photocurrent magnitude is drastically different depending on which side of the channel the photoexcitation occurs, which we attribute to spontaneous magnetization of the exciton condensates and spin momentum locking. We also explore spin polarization at the TI surface from the dependence of photocurrent distributions on the polarization of the photoexcitation at oblique-incidence-angle.  
*This work was supported by National Science Foundation Grant DMR-1838532.

T70.00295: Finite-Size Effect in the Photonic Topological System  
YUHAO KANG (Presenter), Physics, The Graduate Center of the City University of New York, AZRIEL Z GENACK, Physics, Queens College of the City University of New York — Measurements of the transmission matrix of a topological system supporting edge state between metacrystal emulating quantum valley-Hall and spin-Hall effects show the disruption of ballistic propagation. We observe a decrease of transmission and an increasing of the dwell time for the edge mode in a finite topological system. The non-linear spatial decrease of the logarithm of the intensity along the edge highlights the differences between transport statistics of an edge state and normal 1D channel.

T70.00296: Effect of band-offsets on the valley polarization properties of WSe₂ lateral homojunctions  
ANIL RAJAPITAMAHUNI (Presenter), NEREA ONTOSO, LUIS HUESO, FELIX CASANOVA FERNANDEZ, JOSE IGNACIO PASCUAL, REYES CALVO, CiC nanoGUNE — We have studied the effect of band-offsets on the valley polarization of lateral homojunctions composed of 1L/n-layer WSe₂ flakes. WSe₂ flakes are transferred onto SiO₂/Si substrates using elastic film assisted micromechanical exfoliation. Optical microscopy combined with Raman spectroscopy is used to identify and determine the layer number of 1L/n-layer WSe₂ structures. We worked with naturally occurring 1L/n-layer lateral homojunctions to eliminate the band-offsets resulting from twist angles and stacking order. Spatially-resolved photoluminescence (PL) spectroscopy measurements are performed using a scanning confocal microscope at low temperatures down to 4.2 K and in magnetic fields up to 5T. The intensity and energy position of the different excitation peaks in the PL spectra are mapped to determine the effects of inhomogeneities and band-offsets on the valley polarization properties of the lateral homojunctions. We intend to study the valley Zeeman effect in the lateral homojunctions via polarization-resolved PL spectroscopy. Our work will facilitate in understanding the effects of band alignment on the valley polarization phenomena in TMD homo/heterostructures for valleytronic applications.
T70.00297: Valleytronics in two-dimensional merging Dirac cone system: Universal reversible Boolean gate* YEE SIN ANG (Presenter), LAY KEE ANG, SHENGYUAN YANG, Science and Math, Singapore University of Technology and Design — Due to the logical irreversibility, the energy efficiency of Boolean logic gates is fundamentally capped by the Landauer’s waste heat energy generation limit of $k_B T \log_2 p$ per bit of irreversible operation. Here we show that valley degree of freedom in two-dimensional (2D) material can be harnessed to reassert the logical reversibility of classical two-input Boolean logics. The valley index manifests macroscopically in the electrical current as three distinct polarization states: two opposite valley polarizations plus a null state. These triplet of valley polarization states can be used to encode additional information, thus removing all ambiguity and recovering logical reversibility in Boolean logic gates. We use 2D merging Dirac cone system, which occurs in few-layer black phosphorus, strained graphene, and 2D topological Dirac semimetal, as a toy model to demonstrate three fundamental valleytronic building blocks: valley filter, valve, and logic gates. We show that the all-important universal reversible gate, such as the NAND gate, can be realized using this valleytronic approach. Our findings provide a new valleytronic route towards ultimately energy-efficient classical reversible computing.

T70.00298: SUPERLATTICES, NANOSTRUCTURES, AND OTHER ARTIFICIALLY STRUCTURED MATERIALS —

T70.00299: Solvent and Concentration Effects Governing the Hierarchical Organization of Asphaltenes: A Small-Angle X-Ray Scattering Study HASAN RAHMAN (Presenter), Physics, New Mexico State University, JOSE L BANUELOS, Physics, The University of Texas at El Paso — Asphaltenes are a group of planar molecules found in crude oil and are prone to aggregation which causes blockage of pipes along the oil production stream. The solution-state nanostructure of various asphaltene solutions was studied using small-angle x-ray scattering (SAXS) (over a Q-range of 0.008 - 0.4 Å⁻¹) in order to understand solvent and concentration effects on asphaltene hierarchical organization. The fractal aggregate structure of asphaltene was characterized as a function of concentration in toluene (1-50 mg/ml), tetrahydrofuran (1-500 mg/ml), and benzene (1-100 mg/ml). In toluene, the varying cutoff length, primary radius parameters, and the growing mass fractal dimension, all suggest that at a certain chain length, asphaltene nano-aggregates (NA) begin to collapse onto themselves to form a larger and denser aggregate. The experimental data has also been fit with several models including the Unified Power Law and the Ellipsoidal/Spherical Hayter Mean Spherical Approximation models to compare their characteristic parameters such as the ‘Guinier Radius’ and ‘Porod Slope’ to develop a consistent view of the hierarchical structure of asphaltene which will aid as a valuable input to develop strategies to mitigate the effects of asphaltene aggregation.

T70.00300: A generalised shapelet-based method for analysis of nanostructured surface imaging NASSER ABUKHDEIR (Presenter), THOMAS AKDENIZ, Chemical Engineering, University of Waterloo — The determination of quantitative structure-property relations is a vital but challenging task for nanostructured materials research due to the presence of large-scale spatially varying patterns resulting from nanoscale processes such as self-assembly and nano-lithography. Focusing on nanostructured surfaces, recent advances have been made in automated quantification methods for translational order using shapelet functions, originally developed for analysis of images of galaxies, as a reduced-basis for surface pattern structure.

In this work, a method combining shapelet functions and a machine learning clustering method is developed and applied to a representative set of images of self-assembled surfaces from experimental characterization techniques including SEM, AFM, and TEM. The method is shown to be computationally efficient and able to quantify salient pattern features including deformation, defects, and grain boundaries from a broad range of patterns typical of self-assembly processes.

T70.00301: Second Harmonic Generation On Hydrothermal Grown Zno Nanowires And Colloidal Nanostructures Films DOMINIC TRAN (Presenter), CHRISTOPHER VALDES, MOSTAFA SADOQI, St. John's University, IWAN KITYK, Electrical Engineering Department, Czestochowa University Technology, GEN LONG, St. John's University — We report a non-linear optical study on ZnO nanowires grown on FTO substrate and spin-cast colloidal nanostructures (PbS and PbS-Au) based films for the first time. Zinc oxide (ZnO) nanowire was grown by hydrothermal method on pre-cleaned, seeded FTO substrates, placed facedown in the aqueous solution of zinc nitrate hydrate and HMTA (Hexamethylenetetramine) for a few hours. The diameters diameters, lengths and density of ZnO nanowires could be controlled by varying seedling concentration, growth temperature and growth time. Non-linear optical measurement was done using a systems of mirrors M1, M2, M3 stable for the power densities up to 1.5 GW/cm², the laser fundamental beam of Nd:YAG laser was frequency doubled by a-BiB₃O₆ second harmonic crystals. Second harmonic generation was observed on the ZnO-nanowire-grown substrates. It was also noted the SHG pattern showed same pattern as the ZnO nanowire growth pattern. The general origin of the observed effect is caused by local acentricity of the titled compounds. Further studies will be done on nanostructures based devices. Similar studies were also done on spin-cast films made of colloidal nanostructures such as PbS and PbS-Au nanoparticles. SHG was also observed in such films.
T70.00302: Ion-implanted silver nanoparticles for metal-enhanced fluorescence SHAHID IQBAL (Presenter), MOHAMMAD HATSHAN, PRASHANTA NIRAULA, ABUBKAR ARZAQ, HASNA ABDULLAH, RAMAKRISHNA GUDA, ASGHAR KAYANI, Western Michigan University — Metal Enhanced Fluorescence (MEF) has promising applications in the field of optical displays, bio-sensing and photodynamic therapy. In this work, we exploit the plasmons of embedded silver nanoparticles (Ag-NPs) fabricated by ion implantation to enhance the fluorescence of Coumarin 515 dye (C515) via MEF. Ion implantation of 70 keV Ag ions in quartz matrix at different fluences was carried out to synthesize Ag-NPs inside quartz matrix. The formation of Ag-NPs is characterized by the optical absorption measurements. Rutherford Backscattering Spectrometry (RBS) measurement was used to obtain the depth profile and concentration of silver within the substrate. From the RBS results, it was determined that front edge of the layer containing Ag was formed at an average depth of 16 nm below the surface, which closely agreed with Stopping and Range of Ions in Matter (SRIM) calculations. The MEF of drop casted C515 dye was studied using steady-state emission and excitation spectra measurements. Photoluminescence (PL) enhancement factor ranging from 1.2 to 2.1 with a maximum enhancement for the largest fluence was obtained. The observed MEF was ascribed to a combination of plasmon enhancement with larger nanoparticles due to increase in fluence and to increase plasmonic hot spots.

T70.00303: Reflection from bare and gold coated InP nanowire arrays* CHIAWEI TU (Presenter), Department of Physics, University of Cincinnati, Cincinnati, OH 45221, U.S.A., QIAN GAO, HOE TAN, CHENNUPATI JAGADISH, Department of Electronic Materials Engineering, Research School of Physics and Engineering, Australian National University, Canberra ACT 0200, Australia, MASOUD KAVEH-BAGHBADORANI, Department of Physics and Astronomy, James Madison University, Harrisonburg, Virginia 22807, U.S.A., HEIDRUN SCHMITZER, Department of Physics, Xavier University, Cincinnati, OH 45207, U.S.A., MARTIN FRAENZL, Department of Physics, University of Leipzig, 04103 Leipzig, Germany, HANS-PETER WAGNER, Department of Physics, University of Cincinnati, Cincinnati, OH 45221, U.S.A. — We investigated the spectral and angle resolved reflectance from bare and gold coated (plasmonic) InP nanowire (NW) arrays which were grown by selective area epitaxy. The NWs in the arrays have diameters of 180 nm, heights of ~2 and ~1 micrometers and a pitch of 666 and 500 nm (named areas NWA-1 and NWA-2), respectively. In NWA-2 the NWs additionally possess a 10 nm thick surrounding Al2O3 layer to reduce surface state and metal induced band-bending. A nominally 10 nm thick gold layer was deposited around the NWs in both arrays to study the influence of plasmonic effects. The NW arrays were illuminated with a cw laser at 880 nm for the angle resolved reflectance measurements and with an incandescent light sourced ranged from 500 nm to 1000 nm spectrally resolved experiments. The incident light beams were polarized in p- and s-orientation. The measured spectral and angle resolved reflectance of both uncoated arrays is in very good agreement with finite-difference-time-domain (FDTD) simulations. The MEF of drop casted C515 dye was studied using steady-state emission and excitation spectra measurements. Photoluminescence (PL) enhancement factor ranging from 1.2 to 2.1 with a maximum enhancement for the largest fluence was obtained. The observed MEF was ascribed to a combination of plasmon enhancement with larger nanoparticles due to increase in fluence and to increase plasmonic hot spots.

*T70.00304: Compact localized states in open scattering media FABRIZIO SGRIGNUOLI (Presenter), Boston University, MALTE RÖNTGEN, CHRISTIAN MORFONIOS, PETER SCHMELCHER, Zentrum für optische Quantentechnologien, Universität Hamburg, LUCA DAL NEGRO, Boston University — In this work, we study the compact localized scattering resonances of periodic and aperiodic chains of dipolar nanoparticles by combining the powerful Equitable Partition Theorem (EPT) of graph theory with the spectral dyadic Green's matrix formalism for the engineering of embedded quasi-modes in non-Hermitian open scattering systems in three spatial dimensions. We provide analytical and numerical design of the spectral properties of compact localized states in electromagnetically coupled chains and establish a connection with the distinctive behavior of Bound States in the Continuum. Our results extend the concept of compact localization to the scattering resonances of complex open systems with aperiodic order beyond tight-binding models, and are relevant for the efficient design of novel photonic and metamaterials architectures with enhanced light-matter interactions.

T70.00305: Simulations of Nanostructure Plasmonic Resonators PARVEEN KUMAR (Presenter), University of California, Merced, 95353, USA — Semiconductor nanostructures with and without plasmon enhancement are studied and explored extensively for nanodevice applications ranging from bio/chemical sensors to medical monitors and photovoltaics. Plasmonic resonances strongly depends on the size, shape, spacing and interaction of metal nanoparticles with semiconductor nanostructure. A lot of resources as well as efforts are required to realize plasmonic resonator devices and optimization with different shapes and sizes. In contrast, device modeling and simulations offer a much economical substitute to tackle such challenges. To solve this problem in most economical and reliable mode, is to use Maxwell equation solver which helps in simulating the nanoparticles as surface plasmon resonator on the top of semiconductor nanostructures. The sharp features as well as the nanoparticle asymmetry is usually used for reported the enhancement of the electric field. To enhance the absorption rate as well as the photocurrent signal, I report the simulation the electrical field profile for spherical, cylindrical, and bipyramidal nanoparticles (of different materials) and model the interaction of these nanoparticles with semiconductor nanostructures.
T70.00306: Novel Two-Dimensional Tellurium Allotropes from the First-principles Predication*  CHUNYAO NIU, CHUNXIANG ZHAO, XIAOLIN CAI, CHAOSHENG LIAN, ZHILI ZHU, YU JIA (Presenter), School of Physics and Engineering, Zhengzhou University — Very recently, the successful predication and synthesis of α-, β-, and γ- tellurene have extended the two-dimensional (2D) materials family to group-VI elements and provided new candidates for next-generation electronic and optoelectronic applications. Based on our previous work, we have further predicted 33 newly 2D tellurium allotropes with mono- and multi-layers of tellurium atoms using the particle-swarm crystal structure searches methods and the first-principles calculations. The stability of these 2D structures is well verified by the total energy calculations, as well as phononspectrum calculations. Four kinds of new allotropes are found energetically more stable than the β-Te phase which already has been synthesized experimentally. Among these structures, we found three of them exhibit topological properties and two with superconductor properties. The present findings enlarge the family of tellurene and will stimulate future experimental studies to synthesize novel group-VI 2D materials.

T70.00307: Light stops at exceptional points†  TAMAR GOLDZAK (Presenter), Massachusetts Institute of Technology, ALEXEI A MAILYBAEV, Instituto Nacional de Matemática Pura e Aplicada-IMPA, NIMROD MOISEYEV, Technion - Israel Institute of Technology — Light travels in vacuum with a constant speed of 300,000,000m/sec, almost twenty years ago the light was slowed down to less than 10⁻⁷ of its vacuum speed in a cloud of ultracold atoms of sodium. Upon a sudden turn-off of the coupling laser, a slow light pulse can be imprinted on cold atoms such that it can be read out and converted into photon again. Alternatively, the light can be stopped at the band edge in photonic-crystal waveguides. Here we extend the phenomenon of stopped light to the new field of parity-time (PT) symmetric systems.

We show that zero group speed in PT symmetric optical waveguides can be achieved if the system is prepared at an exceptional point, where two optical modes coalesce. This effect can be tuned for optical pulses in a wide range of frequencies and bandwidths, as we demonstrate in a system of two coupled waveguides with gain and loss. We also investigate how the structure of multiple coupled wave guides affect the dispersion relation of the two coalesced modes.

T70.00308: Quantum to Classical Transitions in Multilayer Plasmonic Metamaterials*  EVAN SIMMONS (Presenter), University of Massachusetts Lowell, KUN LI, ANDREW BRIGGS, SETH BANK, DANIEL WASSERMAN, Electrical and Computer Engineering, University of Texas at Austin, VIKTOR PODOLSKIY, University of Massachusetts Lowell, EVGENII NARIMANOV, Electrical and Computer Engineering, Purdue University — Electromagnetic response of noble metals, transparent conducting oxides, and highly doped semiconductors are all dominated by the dynamics of their free electron plasma. AlInAs/InGaAs heterostructures have emerged as a reliable platform that provides epsilon-near-zero, plasmonic, and hyperbolic responses in the important mid-infrared frequency range. The electromagnetic properties of semiconductor multilayers can be related to the properties of individual layers via effective medium theory (EMT). It is typically assumed that the validity of EMT improves as the layers in metamaterials become thinner. However, quantum-confinement is expected to affect the dynamics of the free charges in ultra-thin layers. In this work, we analyze, experimentally, analytically, and numerically, the optical response of semiconductor designer metal multilayers that undergo transition from bulk to quantum-confined regime. We demonstrate that this transition can be used as a doping-independent control mechanism to engineer the optical response of designer metals and the optical topology of the resulting multilayer metamaterials.

*This research is sponsored by NSF-DMREF program
T70.00309: Interlayer excitons at the tunable Moire line defect*  JIANJU TANG (Presenter), HONGYI YU, WANG YAO, The University of Hong Kong — Van der Waals stacking of two monolayers semiconducting transition metal dichalcogenides is a powerful approach to create semiconductor heterojunctions for engineering functional devices. The inevitable mismatch in lattice constants and crystallographic axes leads to the formation of Moire pattern, giving new possibilities to tailor the material properties. Interlayer excitons in such Moire pattern experience an effective superlattice potential and have a nanoscale patterned light-coupling properties. The low energy physics of those excitons can be described by a tight binding model with giant spin-orbit coupling. Here, we investigate interlayer excitons in such Moire pattern with a line defect due to the twin domain boundary in one of the layers, which can localize one-dimensional excitonic modes of topological origin. We show that the defect configuration in the Moire superlattice can be tuned by the interlayer translation, twisting angle and reflects the atomic configuration of the domain boundary. The effects of the Moire line defect configuration on the exciton modes are systematically investigated. We also find the defect exciton mode has distinct light-coupling properties on the two sides of the twin domain boundary.

T70.00310: Photoluminescence studies of lysozyme mediated zinc oxide (ZnO) nanoparticles  NIKESH MAHARJAN (Presenter), MIM L NAKARMII, Department of Physics, Brooklyn College and The Graduate Center of the CUNY, Brooklyn, NY 11210, USA, DEEPENDRA DAS MULMI, Department of Physics, Nanomaterials Research Laboratory, Faculty of Science, Nepal Academy of Science and Technology, Khumaltar, Lalitpur, GPO Box 3323, Nepal, NARESH M SHAKYA, Department of Applied Physics, New York University, NYU - Tandon School of Engineering, Brooklyn, NY 11201 — Ultraviolet Photoluminescence spectroscopy was employed to study optical properties of lysozyme mediated zinc oxide (ZnO) nanoparticles. The Zinc oxide nanoparticles using lysozyme (L: ZnO) were prepared through a facile synthesis. The samples were annealed at 550 °C for 2 hours. Third harmonic laser (260 nm) generated from the Ti: sapphire laser was used for optical excitation in the experiments. Photoluminescence spectrum measured at low temperature has emission peaks around 3.3 eV and a broad emission around 2.45 eV. We performed temperature and excitation power dependent photoluminescence measurements to identify the origin of the emission peaks in the spectra. We will present our findings on the optical properties of lysozyme mediated zinc oxide nanoparticles and discuss the effect of lysozyme in the optical properties of ZnO nanoparticles.

T70.00311: Phonon induced resistance oscillations (PIRO) caused by THz laser  BEATE HORN-COSFELD (Presenter), MIHAII CERCHEZ, THOMAS HEINZEL, Condensed Matter Physics, Heinrich-Heine University Düsseldorf — PIRO terms the magneto-resistance (MR) oscillation originating from the resonant interaction of 2D electrons with thermal acoustic phonons [1], observed only in very high mobility samples (>10⁷ cm²V⁻¹s⁻¹) [2]. This manifests itself as a 1/B periodic oscillation of the MR of GaAs/AlGaAs heterostructure, in a temperature range of 4-10 K and high filling factors (magnetic fields below 500 mT).

In this work we use THz excitation of the acoustic phonon branch of GaAs by means of a 1.8 THz pulsed quantum cascade laser, so the acoustic phonons are excited by the THz radiation rather than thermally. Electrons resonantly absorb the acoustic phonons accompanied by a 2 kF momentum transfer, causing indirect transitions between Landau levels.

The thermally induced PIRO's are not observable in our samples, probably due to the electron mobility being about a factor of two lower than those given in [2].

T70.00312: Tunability of thermal conductivity in low-dimensionality chalcogenide and perovskite heterostructures*  MACK ADRIAN DELA CRUZ (Presenter), NICK BOECKER, GARY PENNINGTON, Towson University — Recent work in lead chalcogenide alloys of PbSe, PbS, and PbTe has shown interesting electronic properties. Perovskites, such as SrTiO₃, have been the focus of much research in the past few years. The thermal properties of such materials are of interest for thermoelectric applications. We further consider low-dimensionality heterostructures, which generally have lower thermal conductivities compared to bulk. We use a computationally efficient shell model to find the phonon dispersion of bulk, and approximate the heterostructure phonon dispersions. Phonon Transport is modeled with a Monte Carlo formulation of the Boltzmann transport equation using an interfering particle method with phonon-phonon scattering, boundary scattering, defect scattering, interface scattering, and quantum confinement. We will report on the tunability of thermal conductivity by manipulating low-dimensionality heterostructures of these lead chalcogenide alloys and perovskites.

T70.00314: Phonon backaction in diatomic molecular junctions: Negative differential conductance, quantum interference and super-Poissonian noise  TAE-HO PARK (Presenter), HAN-YONG CHOI, Sungkyunkwan University — We present a study of the non-equilibrium electron transport through diatomic molecular junctions employing the full counting statistics (FCS) in combination with the self-consistent Born approximation (SCBA). Here, we consider two different types of electron-phonon coupling in a molecule. One is the coupling of the molecular vibration to the electrons in each orbital (intra-orbital coupling) and the other is to the transferring electrons (inter-orbital coupling). We show that the super-Poissonian noise is enhanced by increasing the electron-phonon coupling in the presence of the phonon backaction. In the weak coupling regime for the inter-orbital coupling, the negative differential conductance (NDC) can take place in the resonant tunneling regime. It turns out that the current fluctuation suppresses NDC, but induces the quantum interference in molecular conductance.

T70.00315: Molecular Architecture’s Impact on Directional Charge and Energy Transfer within Organic Assemblies*  SARAH MARQUES (Presenter), MICHAEL D BARNES, Chemistry, University of Massachusetts Amherst — The goal of my work is to understand the connection between molecular architecture and directional charge and energy transfer within organic assemblies. Organic optoelectronic devices are based on a materials ability to directionally transfer charge and energy after excitation. Our group has found that extended crystals of 7,8,15,16-tetrazaterrylene (TAT) can produce charge separated states when directionally excited, but the mechanism be it intrinsic or extrinsic in which charge separation occurs is still unknown. To disentangle these mechanisms, we have isolated different stages of TAT crystal growth and probed their molecular orientation (order) using defocused imaging and polarization anisotropy, as well as, their interchromophore interactions and exciton recombination kinetics using photoluminescence spectroscopy and time resolved measurements. We found that even though the spectral signatures of extended crystals (microns) and small clusters (<250 nm) are incredibly different, TAT intrinsically forms ordered assemblies that have a 1D coupling mechanism. These results support an optoelectronic device design based on a monomolecular design platform that intrinsically generates directional charge transport.

T70.00316: Phonon-Plasmon Scattering and Localization in Graphene Structures  BRAHMANANDAM JAVVAJI, DEBIPROSAD ROY MAHAPATRA (Presenter), Indian Institute of Science — In this paper we discuss about a self-consistent model of phonon-plasmon coupled dynamics and investigate the nature of the coupling in the graphene nanostructures. Effect of length-scale in three types of structures namely graphene nano-ribbon, graphene on silicon and graphene defects are investigated. Nonlinear conversion arising from aperiodic localization of phonon modes in the nanoribbon are observed. We show how the chirality plays a role on this relationship. Effect of silicon substrate atoms on the dynamics are analyzed. We then review the present understanding and new ways to design thermal energy transport in graphene based optoelectronic devices. Another aspect of phonon generation is plasmonic extinction due to RF, field emission or lasing with application in filters or sensors. In context of these ideas, we show how the structure of defects in graphene alters the plasmonic extinction. The charge localization around the defects are studied in details and the stability limits of the defects in terms of size and shape are analyzed. To this end, new results showing signature of these instabilities in the optical spectra and phonon spectra will be discussed.
T70.00317: Nanoscopic Hyperlensing from Natural and Monoisotopic Hexagonal Boron Nitride Crystals*

SWATHI IYER (Presenter), ALEXANDER GILES, United States Naval Research Laboratory, SAI SUNKU, Department of Physics, Columbia University, New York 10027, THOMAS FOLLAND, Mechanical Engineering Department, Vanderbilt University, Nashville, TN, USA, NICHOLAS SHARAC, United States Naval Research Laboratory, SONG LIU, JAMES H. EDGAR, Tim Taylor Department of Chemical Engineering, Kansas State University, Manhattan, Kansas 66506, USA, DIMITRI BASOV, Department of Physics, Columbia University, New York 10027, JOSHUA D CALDWELL, Mechanical Engineering Department, Vanderbilt University, Nashville, TN, USA — Hyperbolic media, where the permittivity is opposite in sign along orthogonal axes, support highly directional propagation of volume-confined, hyperbolic polaritons (HPs) for use in super-resolution imaging via the hyperlens concept. Hexagonal boron nitride (hBN), a natural hyperbolic material, supports deeply subdiffractional, low-loss HPs in both planar slabs and nanoscale resonators within the mid- to long wavelength IR. These losses could be reduced even further by using monoisotopic (i.e. material with just a single boron isotope) hBN. Here we exploit these ultralow losses and natural hyperbolic response to realize unprecedented spatial resolution in hyperlensing with long-wavelength IR light. We provide a direct comparison of the imaging power of hyperlens designs using flat slabs of naturally abundant and monoisotopic hBN via scattering-type near field optical microscopy (s-SNOM). Our experimental (s-SNOM) and simulated results show the ability to resolve features as small as 50 nm with 6-7.1 µm free-space wavelength light, providing at least l/125 spatial resolution. We complement this with electromagnetic field simulations of the hyperlens response to demonstrate and quantify the improvements from the monoisotopic over the naturally abundant materials.

T70.00318: Thermal transport in holey silicon membranes investigated with optically-induced transient thermal gratings*

RYAN DUNCAN (Presenter), GIUSEPPE ROMANO, Massachusetts Institute of Technology, MARIANNA SLEDZINSKA, Catalan Institute of Nanoscience and Nanotechnology, ALEXEI MAZNEV, Massachusetts Institute of Technology, JEAN-PHILIPPE PERAUD, Lawrence Berkeley National Laboratory, OLLE HELLMAN, Linköping University, CLIVIA SOTOMAYOR TORRES, Catalan Institute of Nanoscience and Nanotechnology, KEITH ADAM NELSON, Massachusetts Institute of Technology — In semiconductor nanostructures with feature sizes on the order of 100 nm, thermal transport is expected to be well-described by the phonon Boltzmann transport equation (BTE) with diffuse boundary scattering. However, over the past several years there have been reports of anomalously low effective thermal conductivity values in one- and two-dimensional semiconductor nanostructures. In this study, we investigate thermal transport in nanostructured holey silicon membranes using the non-contact optical transient thermal grating (TTG) technique. We compare the experimental results with two ab-initio BTE numerical techniques. We obtain excellent agreement between theory and experiment, indicating that semiclassical Boltzmann transport theory for phonons is adequate for describing thermal transport in semiconductor nanostructures with feature sizes on the order of 100 nm.

T70.00319: OpenBTE: A Multiscale Solver for the Phonon Boltzmann Transport Equation

GIUSEPPE ROMANO (Presenter), Department of Mechanical Engineering, Massachusetts Institute of Technology — We present OpenBTE, an open-source tool to compute heat transport in nanostructured materials with arbitrary shape and dimensionality. The code solves the space-dependent Boltzmann transport equation taking into account the material's Brillouin's zone and diffuse boundaries. For phonon mean-free-paths (MFP) that are much smaller than the characteristic length of the material, we employ a heat diffusion solver so that we lift most of the computational load with negligible loss in the accuracy [1,2]. After an introduction to OpenBTE's main features, we will show the software architecture, including parallelization and interfaces to popular first-principles phonon solver. Then, we illustrate key examples and comparison with experiments. A brief tutorial will conclude the talk.

T70.00320: Symmetry selective oxygen orbital polarization in spinel Al$_2$O$_3$ films* RUYI ZHANG (Presenter), YANG SONG, YANWEI CAO, Key Laboratory of Magnetic Materials and Devices, Ningbo Institute of Industrial Technology, Chinese Academy of Sciences. — Orbital polarization is common for the 3$d$ orbitals of cations as a result of strain, symmetry breaking, or charge transfer, but very rare for 2$p$ orbitals of simple anions. Here, we report a symmetry-selective measurement of orbital polarization for O 2$p$ orbitals in γ-Al$_2$O$_3$/SrTiO$_3$ thin films via linearly polarized X-ray absorption spectroscopy (XAS) at the O K-edge. The O 2$p$ orbitals with octahedral coordination exhibit a large subband splitting exceeding ~ 0.35 eV, while those with tetrahedral coordination show a very weak orbital polarization. These results pave a new way to engineer band structure and quantum states of functional oxide materials via local symmetry effects on anion orbitals.

*National Natural Science Foundation of China (No:11874058)

T70.00321: d-orbital symmetry of BaTiO$_3$ thin film* YANG SONG (Presenter), RUYI ZHANG, YANWEI CAO, Key Laboratory of Magnetic Materials and Devices, Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences — A high-quality BaTiO$_3$ thin film was grown on a DyScO$_3$ single crystal substrate using pulsed laser deposition. Soft X-ray absorption spectroscopy was performed at the Ti $L_{2,3}$ edges of the film to characterize the d-orbital symmetry. Novel split Ti d-orbital $e_g$ and degenerate $t_{2g}$ subbands of the BTO film have been observed. The energy of $d_{x^2-y^2}$ orbital is lower than the $d_{3z^2-r^2}$ orbital by about 100 meV, the opposite of what would normally be expected for Jahn-Teller octahedral distortion. This is likely a result of the displaced Ti cation. This novel d-orbital symmetry is very likely to be found in other perovskite-based ferroelectric materials.

*National Natural Science Foundation of China (No:11874058)

T70.00322: Synapse-like modulation of photoconductance at the LaAlO$_3$/SrTiO$_3$ interface. YU CHEN, BLAI CASALS, FLORENCIO SANCHEZ, GERVASI HERRANZ (Presenter), Institute for Materials Science of Barcelona ICMAB-CSIC — We analyze the properties of LaAlO$_3$/SrTiO$_3$ interfaces in relation to its persistent photoconductance (PPC). In this phenomenon the conductance is increased after excitation with visible or ultraviolet light, so that the initial value prior to the photoexcitation is recovered only after prolonged periods of time. Among applications, an interesting prospect for PPC is to exploit its modulation capability to emulate the plasticity of biological synapses using optical stimuli. This requires knowing the dynamical PPC response and its magnitude with respect to illumination conditions so that the potential for neuromorphic vision can be evaluated. Our experiments show that the LaAlO$_3$/SrTiO$_3$ interface is sensitive to 100-millisecond-scale timing of pairs of light stimuli, causing long-term changes of photoconductance. We show that the PPC changes plastically in response to optical stimuli of varying strength and duration, demonstrating that fine-tuning of the photoconductive signal is feasible over a diversity of cumulated timespans. Based on these remarkable observations, we propose that complex information can be extracted from patterns imprinted as spatiotemporal modulations of PPC.

T70.00323: Modulation doping in SrSnO$_3$/BaSnO$_3$ heterostructures* ABHINAV PRAKASH (Presenter), Chemical Engineering and Materials Science, University of Minnesota - Twin Cities, NICHOLAS F QUACKENBUSH, Materials Measurement Science Division, National Institute of Standards and Technology, HWANHUI YUN, JACOB T HELD, TIANQI WANG, K. ANDRE MKHOYAN, BHARAT JALAN, Chemical Engineering and Materials Science, University of Minnesota - Twin Cities — Through a combination of MBE growth, hard X-ray photoelectron spectroscopy (HAXPES), magnetoresistance measurements and transport modeling, we report on the realization of two-dimensional electron gas (2DEG) at SrSnO$_3$/BaSnO$_3$ (SSO/BSO) heterointerfaces. The HAXPES revealed the valence band offset between SSO and BSO to be 0.7 eV resulting in a favorable conduction band offset for modulation doping of BSO using SSO as a spacer layer. Two-channel conduction suggested by the non-linear transverse hall resistance as a function of magnetic field revealed the transfer of electrons from La-doped SSO to BSO. The sheet carrier density on the BSO side was measured to be 5×10$^{12}$ cm$^{-2}$ consistent with the value obtained using a self-consistent solution to one-dimensional Poisson and Schrödinger equations. The role of band offset, interface roughness and threading dislocations in BSO will be discussed with the goal to obtain high mobility oxide heterostructures.

*Work supported by NSF DMR and AFOSR YIP
**T70.00324: Magnetic Structure in Entropy Stabilized Single Crystal Spinel Ferrite Films**

YOGESH SHARMA (Presenter), ALESSANDRO MAZZA, ELIZABETH SKOROPATA, LIAM COLLINS, ZHENG GAI, THOMAS WARD, Oak Ridge National Laboratory —

“Entropy-stabilized oxides” possess large configurational entropy driven by the multi-cation disorder which dominates over the enthalpy of formation. The random distribution of constituent elements into the cation sublattice(s) enhances the configurational entropy. These oxide systems possess new possibilities for generating complex electronic and magnetic states due to the near degeneracies of cation spin-charge-orbital order parameters. Here, we grow single-crystal epitaxial thin films of extremely configurationally disordered spinel ferrites. We find that high entropy spinel oxide (HESO) films of (Mg₀.₂Ni₀.₂Fe₀.₂Co₀.₂Cu₀.₂)Fe₂O₄ grown on various substrates—MgAl₂O₄ (MAO), MgO, and SrTiO₃ (STO)—demonstrate an interesting array of magnetic properties in terms of long-range stripe domains, strain-controlled magnetic anisotropy, unusual element-specific magnetization, and magnetic phase transition well above room temperature. The extreme number of cations and configurational degeneracy is expected to open many new avenues for fundamental physics and applied works.

*This work was supported by the DOE Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division and the Office of Science Early Career Research Program.

**T70.00325: Theoretical study of piezotronic metal–insulator–semiconductor tunnel devices**

XIAOLONG FENG (Presenter), Singapore University of Technology and Design — Piezotronics has been an emerging concept coupling piezoelectric and semiconducting properties with potential applications in sensors, flexible electronics and nanoelectromechanical systems. Piezoelectric field is created under an applied strain, which controls the carrier generation, transport, separation or recombination processes at the interface or junction of the semiconductor devices. Based on the piezotronic theory, we present a 1D model for the metal–insulator–semiconductor (MIS) tunnel diode based on the piezoelectric semiconductor. Analytical solutions of piezoelectric modulated tunneling are described to reveal the piezotronic effect on the MIS tunnel junction. A numerical simulation of the carrier transport properties is provided for demonstrating the piezotronic effect on MIS tunnel devices.

**T70.00326: Rare-earth metal organic frameworks for quantum information applications**

DONNY PEARSON (Presenter), Physics, University of Maryland, College Park, ELIZABETH GOLDSCHMIDT, Army Research Lab, HAQUAN FAN, Physics, University of Maryland, College Park — Rare-earth atoms in solids are excellent candidates for atomic ensemble-based quantum memory due to their long-lived optical and spin lifetimes, high density of emitters, and suitability for photonic integration. In rare-earth doped systems, a major problem implementing long-lived, efficient quantum memory is the inhomogeneous broadening of the energy levels due to the site-to-site variations, which in doped materials is primarily caused by the dopant itself. Crystals that are stoichiometric in the rare-earth atom, i.e. the rare-earth species is part of the chemical formula of the crystal rather than a substitutional dopant for some element, have demonstrated the potential for smaller inhomogeneous line widths due to the lack of doping induced disorder. We investigate the potential of metal organic frameworks to host rare-earth atoms with narrow optical inhomogeneous linewidth as a platform for quantum memory and other related applications. We will present progress towards growing macroscopic single crystals and initial optical measurements of these high-density, rare-earth ensembles.

**T70.00327: Spectroscopy of Erbium-167 doped yttrium orthosilicate for quantum photonic technologies**

MI LEI (Presenter), IOANA CRAICIU, JAKE ROCHMAN, JONATHAN KINDEM, JOHN BARTHOLOMEW, ANDREI FARAON, Caltech — Rare-earth ions in crystals are one of the most promising candidates for quantum memories due to their long optical and spin coherence times. They have been used to realize solid-state quantum memories in bulk crystals and in nanophotonics devices. Erbium is of particular interest because it has an optical transition in the telecom band, which allows integration with silicon photonics and telecommunication compatibility. Recently, erbium-167 doped yttrium orthosilicate has been shown to have good properties for quantum memories. With a nuclear spin of 7/2, erbium-167 has 16 hyperfine levels in the optical ground state manifold, which can be used as shelving levels for spectral holeburning, and to store coherence in the nuclear spin.

We study erbium-167 doped yttrium orthosilicate at dilution refrigerator temperatures and in a magnetic field. We obtain long hyperfine lifetimes approaching 30 minutes, observe good spectral hole burning and characterize the optical coherence properties. These properties point to a very promising material for optical quantum memories.

*We would like to acknowledge funding support from the Air Force Office of Scientific Research.*
Materials that couple electric and magnetic ordering create interesting possibilities for the next generation of data storage technologies. However, there are few of these multiferroic materials that exist at room temperature, and even fewer with strong, coupled polarization and magnetization. One promising avenue to develop these materials is through oxide molecular beam epitaxy, which can generate new combinations of properties through heterostructures and interface phases. Here, we combine the ferroelectric LuFeO$_3$ with the ferrimagnetic CoFe$_2$O$_4$ into a superlattice to develop a material with spontaneous polarization and magnetization above room temperature. To study how these materials are layered at the atomic scale, we use scanning transmission electron microscopy (STEM) combined with x-ray energy dispersive spectroscopy (EDS) and electron energy-loss spectroscopy (EELS). We map the elemental profiles through the film and across the bottom electrode to determine the relation between interdiffusion and growth conditions, which provides critical feedback for further growths.

*Thanks to the NSF for funding under DMR-1539918 as part of the Materials Innovation Platform program.

**T70.00329: Epitaxial Growth of Phosphorus Nanostripe Arrays on Cu(110)**

SHUO SUN (Presenter), JIALIN ZHANG, National University of Singapore, SONGTAO ZHAO, University of Science and Technology of China — Black phosphorus has attracted significant attention as a new emerging two-dimensional (2D) material in recent years. New 2D phosphorus allotropes with various structures have also been predicted by theoretical calculations. It has been theoretically predicted that substrate plays a critical role in stabilizing phosphorus nanoflakes on surface. Here, we report a molecular-beam-epitaxial growth of phosphorus nanostripe arrays on Cu(110) by using black phosphorous as precursor, through the combination of in-situ low temperature scanning tunneling microscopy (STM), low energy electron diffraction, X-ray photoelectron spectroscopy (XPS) and density functional theory (DFT) calculations. Atomically resolved STM image and the corresponding DFT simulations reveal that phosphorus atoms are adsorbed on top of the valley copper atoms and arranged periodically to form nanostripe arrays. XPS and Bader charge analysis confirm a significant charge transfer from the Cu(110) substrate to P atoms on top.

**T70.00330: Nitrogen-Vacancy (NV) centers in Nano diamonds: Toward optimization and photo stability**

RAVI KUMAR (Presenter), Advanced Carbon Products and Metrology, CSIR-National physical Laboratory, New Delhi, DILIP KUMAR SINGH, Physics, BIT Mesra, SANJAY R. DHAKATE, Advanced Carbon Products and Metrology, CSIR-National physical Laboratory, New Delhi — Nitrogen-Vacancy (NV) centers in Nano diamonds (NDs) are one of the most promising room temperature atom like system for an array of present and future technological applications. These include bio imaging, nano metrology and quantum information processing (QIP). All of these applications depend upon the optimized concentration of NV centers (NV- ) in NDs and their photo stability over continuous excitation. Both of these factors i.e. optimization of concentration of NV centers and their stable photo-physical behavior are major hurdles for different applications. In the present work, we have optimized the fabrication condition for the efficient creation of NV centers. Interestingly, we have successfully created the uniform concentration of NV centers in NDs by dispersed low energy ion irradiation . While investigating the effect of surface functionalization, it was revealed that different degree of surface oxidation of NDs leads to different photo-stability of NV centers. With the optimized concentration of NV centers, we have observed the single photon emission at room temperature and optical bio imaging. Our findings provide new insight to achieve the optimized as well as photo-stable concentration of NV centers and prepare the platform for wide range of applications of NDs.

**T70.00331: Tin catalyzed-silicon nanowires prepared by solid-liquid-solid mechanism**

KAIGUI ZHU (Presenter), KHAMIS MASOUD, Beihang University — The fabrication of silicon nanowires (SiNWs) catalyzed by low melting metal through solid-liquid-solid (SLS) mechanism makes it very useful in electronic device applications. However, little research has been done in combining SLS mechanism with Sn catalyst deposited as continuous film by magnetron sputtering system to grow SiNWs. The growth of Sn catalyzed-SiNWs through SLS mechanism by thermal annealing technique on a Si <100> substrate was investigated, and initially Sn catalyst was deposited as a continuous film by magnetron sputtering system. Randomly and voluminous SiNWs are observed on the Si substrate after 1000 0C annealing process with a feature that looks like a tree having many numbers of long branches of SiNWs. These confirm the growth of Sn catalyzed-SiNWs through SLS mechanism, with Sn catalyst initially being deposited as a continuous film.
T70.00332: Modeling the Growth of Salt Nano-Wires* CHARLES AY (Presenter), GARY PENNINGTON, Towson University — The purpose of our research has been to successfully model the growth of NaCl nano-wires from a supra-molecular gel. The interest in these wires is the ease of growth and the potential application of integrating them into electrical circuitry. Our model is based off of diffusion driven crystal formation through evaporation. We used two different crystallization constants to represent the overall mass-transfer rate of the process. The first crystallization constant is a reaction constant; this is present during the initial formation of the seed crystals directly below the gels surface. The second constant is the diffusion crystallization constant. The first constant is taken to be at its maximum before it deforms the gel. This is calculated from the salt mass ratio the gel in which the gel is deformed in the initial growth phase. While the second constant is derived from the supporting material. The main two parameters that we are observing are the height of the wires and width of the wires, where we see experimentally a maximum width of 5.64 Angstroms, which is the reported width of a single NaCl crystal lattice.

*The authors acknowledge support from the NSF Grant DMR 1709781 and PAGS Department of Towson University specifically Dr. Pennington and Dr. Kolegani.

T70.00333: Synthesis and characterization of Co-based magnetic nanowires POK LAM TSE (Presenter), University of Southern California — Pure Co, pure Cu and Co/Cu two-segment nanowires with high pore filling rate and uniform sizes were successfully synthesized through the direct electrochemical deposition in Anodic Aluminum Oxide (AAO) membrane. By applying different deposition currents in a single mix bath, nanowires with different materials and different crystal structure were fabricated. The length of the nanowires is several micron and diameter is between 80-100 nm. The pure Co nanowires and the Co segment in the Co/Cu nanowires show hexagonal close packed (hcp) crystal structure. The pure Cu nanowires and the Cu segments in Co/Cu nanowires show face centered cubic (fcc) structure. Magnetic force microscopy (MFM) analysis illustrates the quasi-periodic magnetization modulation along the pure Co wires and the Co segment in Co/Cu two-segment nanowires. A pair of Co/Cu two-segment nanowires partially in contact showed magnetization interactions at the Co segments. The magnetization modulation is explained by the competition between shape anisotropy and magnetocrystalline anisotropy.

T70.00334: Interaction Effects in Open Nanoelectromechanical Systems* BILAL TANATAR (Presenter), Department of Physics, Bilkent University, VALERIU MOLDOVEANU, RADU DRAGOMIR, STEFAN STANCIU, National Institute of Materials Physics — We discuss the transient and steady-state transport properties of nanoelectromechanical systems (NEMS) in the quantum regime. The system consists of quantum wire electrostatically coupled to a nearby nanoresonator (NR). The intertwined dynamics of the open NEMS is described within a generalized master equation which is exact with respect to the electron-vibron coupling. The eigenfunctions of the nanoelectromechanical system are found using configuration-interaction methods. We introduce an improved description of the electron-vibron coupling by taking into account the sample specific single-particle functions. We analyze how the electron-vibron coupling and the Coulomb interaction affect the energy spectrum of the NEMS. This fact causes the removal or the onset of the Coulomb blockade as the distance between the NR and the mesoscopic system is changed. The time-dependent filling of the vibronic states is analyzed as a function of bias.

T70.00335: Topological Insulator Sb$_2$Te$_3$ and Phase Change Material GeTe Nanowires Synthesis and their Electrical Properties Measurements  
POK LAM TSE (Presenter), Materials Science, University of Southern California — Sub-100nm topological insulating(TI) Sb$_2$Te$_3$ nanowires(NWs) and phase change material GeTe nanowires were fabricated by Catalytic Chemical Vaporized Deposition(CVD). The Vapor-Liquid-Solid(VLS) growth mechanism in the fabrication process effectively decreased the growth temperature to around 400°C from around 600-800°C. The stoichiometry ratios of Sb$_2$Te$_3$ NWs(2:3) and GeTe NWs(1:1) had been measured by energy-dispersive X-ray Spectroscopy(EDX) analysis along the NW samples. For the electron spin transports in TI, Magnetic Tunnel Junction contacts at 4K showed a sharp conductance change of non-local magnetoresistance at ±0.5kG, indicates the spin momentum locking effect of topological insulator. P-type conduction property of Sb$_2$Te$_3$ nanowire$^1$ was measured by the field effect transistor(FET) measurement at 68K with back gate voltage up to 100V across 300nm SiO$_2$ dielectric layer. Phase change property of GeTe nanowire was tested for crystalline and amorphous transition by applying 3V to 5V voltage few hundred ns width voltage pulses, the crystalline form had a resistance at about few kilo-ohm and the amorphous form was at about 30k ohm to 1M ohm range. Preliminary results showed 10 to 20 cycles of switching with no degradation.

T70.00336: The observability of Quantum Pinch Effect in the magnetized semiconducting Quantum Wires  
MANVIR KUSHWAHA (Presenter), Rice University — We investigate a two-component, cylindrical, quasi-one-dimensional quantum plasma subjected to a \( \Omega \)-radial confining harmonic potential and an applied magnetic field in the symmetric gauge. It is demonstrated that such a system as can be realized in semiconducting quantum wires offers an excellent medium for observing the quantum pinch effect at low temperatures. An exact analytical solution of the problem allows us to make significant observations: surprisingly, in contrast to the classical pinch effect, the particle density as well as the current density display a \( \Omega \)-determinable maximum before attaining a minimum at the surface of the quantum wire. The effect will persist as long as the equilibrium pair density is sustained. Therefore, the technological promise that emerges is the route to the precise electronic devices that will control the particle beams at the nanoscale.

T70.00337: Collective excitations in quantum wires made up of vertically stacked quantum dots  
MANVIR KUSHWAHA (Presenter), Rice University — We report on the theoretical investigation of the elementary electronic excitations in a quantum wires made up of vertically stacked self-assembled InAs/GaAs quantum dots. The length scales (of a few nanometers) involved in the experimental setups prompt us to consider an infinitely periodic system of two-dimensionally confined (InAs) quantum dot layers separated by GaAs spacers. Since the wells and barriers are formed from two different materials, we employ the Bastard's boundary conditions in order to determine the eigenfunctions along the z direction. We compute and discuss the behavior of the single-particle and collective excitations and finally size up the importance of studying the inverse dielectric function in relation with the quantum transport phenomena. It is remarkable to notice how the variation in the barrier- and well-widths can allow us to tailor the excitation spectrum in the desired energy range. Given the advantage of the vertically stacked quantum dots over the planar ones and the foreseen applications in the single-electron devices and in the quantum computation, it is quite interesting and important to explore the electronic, optical, and transport phenomena in such systems.

T70.00338: Single-Molecule Super-Resolution Fluorescence Lifetime Microscopy  
ZACHARY HALLENBECK (Presenter), NATHAN KIMMITT, ESTHER A WERTZ, Rensselaer Polytechnic Institute — The environment of an emitter has a remarkable impact on its emission properties, and on its lifetime in particular. Emitters coupled with plasmonic nanoparticles show enhanced emission rates, dependent on their proximity and orientation with respect to the nanoparticles, and on the overlap in wavelength between emission and plasmon resonance. We propose a method that combines fluorescence lifetime imaging microscopy with single-molecule super-resolution microscopy to study these properties with spatial resolution below the diffraction limit and picosecond time domain resolution. In order to study single molecule emission in these environments, a nanoscale emitter must be immobilized long enough to confocally scan over its diffraction limited emission. This challenge will be overcome using fast scanning speeds and careful dye deposition. Combining single-molecule super-resolution microscopy with fluorescence lifetime imaging techniques allows for a new level of precision and isolation that avoids the loss of information associated with ensemble averaging. Our study will provide new insight into the physics of plasmonic environments which will be essential to the development of plasmonic technology in growing fields like biomedicine, nanoscale imaging, and quantum information.
All-inorganic halide perovskites at an ambient atmosphere. We reported the conversion from three-dimensional CsPbBr3 nanocrystals has until now, been too complex. Our newly developed saponification approach was employed to synthesize applications in optoelectronic devices because of their excellent photophysical properties, however, the synthesis of those nanocrystals has until now, been too complex. Our newly developed saponification approach was employed to synthesize all-inorganic halide perovskites at an ambient atmosphere. We reported the conversion from three-dimensional CsPbBr3 to lead depleted zero-dimensional Cs4PbBr6 nanocrystals by altering the amount of Cs-oleate precursor at a low-temperature synthesis so that the transformation remarkably changes the properties of the nanocrystals. The XRD spectra, TEM images, absorption and photoluminescence spectra have been taken for the systematic study of properties of CsPbBr3 and Cs4PbBr6 nanocrystals. The CsPbBr3 emitting a strong blue emission (460 nm) and is shifted to the green region (528 nm) for Cs4PbBr6, which demonstrates the intrinsic luminescence nature of the Cs4PbBr6 nanocrystals. In addition, the lead depleted Cs4PbBr6 structure is of great interest that minimizes the chemical instability, and particularly, toxicity issues. These exciting properties offer them an advantage to be used in optoelectronic devices.

**T70.00340: Hydrostatic pressure effect on the intraband absorption coefficient in a core-shell spherical GaAs/AlxGa1-xAs quantum dot**

K. A. RODRÍGUEZ-MAGDALENO (Presenter), JUAN CARLOS MARTINEZ OROZCO, Unidad Académica de Física, Universidad Autónoma de Zacatecas — In this work we present the intraband absorption coefficient calculation in a core-shell spherical GaAs/AlxGa1-xAs quantum dot. The quantum dot is composed of GaAs and surrounded by three shells of AlGaAs and GaAs, respectively. The electronic structure is calculated within the effective mass approximation and considered the hydrostatic pressure effect using a numerically stable transfer matrix method. The intraband absorption coefficient is computed by means of the Fermi’s Golden rules under the dipolar matrix approximation. We reported the absorption coefficient between the 1s and 1p states as a function of the internal and external radius size, Aluminium concentration and the hydrostatic pressure. The results show that the absorption coefficient undergoes a change in the magnitude as well as in the resonance peak location. These results can be used to improve the absorption tuning and could be useful for enhance the solar devices.

*K. A. Rodriguez-Magdaleno acknowledge to CONACyT México for is postdoctoral position at the Universidad Autónoma de Zacatecas.

**T70.00341: Color Tunable All-Inorganic Mixed Halide Perovskites for Optoelectronic Applications**

SAROJ THAPA (Presenter), GOPI ADHIKARI, HONGYANG ZHU, PEIFEN ZHU, University of Tulsa — All-inorganic lead halide perovskites have attracted tremendous attention in recent years due to their superior optical properties such as tunable bandgap, narrow line-width emission, and high photoluminescence quantum yield (PLQY). Herein, CsPb(Br1-xIx)3 [0 x<1] perovskite nanocrystals with tunable emission (464-667 nm) and narrow line-width emission (23-47 nm) were synthesized at an ambient atmosphere employing a newly developed saponification technique in our laboratory. The inert gas-glovebox free protocol adopted in this technique offers a simplicity in the preparation of high-quality perovskite nanocrystals. The application of these nanocrystals in white light-emitting diodes (LEDs) leads to tunable correlated color temperature (CCT) with a high color rendering index (CRI).

*The University of Tulsa faculty start-up fund, The University of Tulsa Faculty Development Summer Fellowship, and The Student Research Grant, Office of Research and Sponsored Programs, The University of Tulsa

**T70.00342: Auto-Desiccating Synthesis of Lead Halide Perovskite Nanocrystals via a Saponification Process**

PRESTON VARGAS (Presenter), GOPI ADHIKARI, HONGYANG ZHU, PEIFEN ZHU, University of Tulsa — In this work, a new process is developed to synthesize lead halide perovskite nanocrystals with the goal of reducing the manufacture cost. By using a saponification reaction to create the cesium precursor solution, synthesis can be achieved at room temperature and without the use of a vacuum oven. Blue-green tunable emission is obtained by varying the synthesis temperature. The crystal phase of the nanocrystals exhibit an increasingly directionally aligned orthorhombic phase with increasing temperature. Also, the saponification process uses low-cost compounds to produce the cesium precursor. Furthermore, the moisture instability of halide perovskite nanocrystals is well managed by this process because the highly hygroscopic by-products in this process auto-desiccate the reactants. Therefore, the nanocrystals can be efficaciously synthesized in an air atmosphere without interference from local humidity. This provides an accessible and low-cost pathway for synthesizing this material outside of controlled laboratory conditions.

Nonlinear optical properties of double asymmetric Al_xGa_{1-x}N/GaN quantum wells considering strain effects

FLAVIO MANUEL NAVA MALDONADO (Presenter), JOSE GUADALUPE ROJAS BRISEÑO, Universidad Autónoma de Física, Universidad Autónoma de Zacatecas, MIGUEL EDUARDO MORA RAMOS, Centro de investigación en Ciencias, Universidad Autónoma de Morelos, JUAN CARLOS MARTINEZ OROZCO, Universidad Autónoma de Física, Universidad Autónoma de Zacatecas — A theoretical study has been carried out to investigate the optical absorption coefficient and the relative change in the refraction index in asymmetric double zinc-blende Al_xGa_{1-x}N/GaN quantum wells. Highlighting the effect of lattice strain on these properties.

The electronic energy structure is determined in the scheme of the effective mass and parabolic band approximations while the strain effects are incorporated with the use of the model solid theory. Optical coefficients are calculated through the expressions obtained within the compact matrix density formulation. In general we conclude that the strain effects are of paramount importance for the cubic phase of the considered heterostructure, because this contribution considerably affect the band offset of the system and, despite the ground, and the first excited, state are not modified significantly, the studied optical properties becomes slightly affected, particularly for narrow well widths.

Principal transport properties of α-T3 model in the presence of external irradiation.

DIPENDRA DAHAL (Presenter), CUNY Graduate Center, GODFREY GUMBS, Physics and Astronomy, Hunter college, CUNY, ANDRII IUROV, DANHONG HUANG, Physics, University of New Mexico — Using a simplified s-wave approximation approach for the conventional Boltzmann conductivity equation, we have obtained the transport properties of pseudospin-1 electrons in the α-T3 lattice irradiated by external light with linear or circular polarization. Basic transport properties of such dressed states significantly depend on their low-energy band structure and the corresponding wave functions. These electronic states are mainly determined by the polarization of the incident dressing field. For instance, circularly-polarized radiation leads to opening an energy gap, which could substantially suppress the conductivity. Electron transport also shows dependence on the coupling strength parameter α of an α-T3 lattice, which has also been thoroughly investigated.

Effective Plasma Frequency in Graphene-Based Photonic Crystals

IVAN FUENTECILLA-CARCAMO (Presenter), FELIPE RAMOS-MENDIETA, Universidad de Sonora, MARTHA PALOMINO-OVANDO, ALEJANDRO HERNÁNDEZ-López, Facultad de Ciencias Físico-Matemáticas, Benemérita Universidad Autónoma de Puebla — Photonic crystals, based on graphene-dielectric multilayers, have been shown to exhibit tunable Bragg gap opening due to Fermi level tunability at each graphene layer. At low Frequencies (THz regime), a metallic-like gap is also observed with a doping dependent cutoff frequency which marks the beginning of the first transmission region. In this work, we numerically analyze this cutoff frequency as a function of Fermi level, interlayer distance and immersing dielectric constant for an equally doped graphene stack immersed in homogeneous dielectric. We give an analytical approach to deduce a Drude-like effective index for a graphene-dielectric unit cell which in turn, allows to obtain an analytical formula for this cutoff frequency. We determine parameter ranges where our analytical model fits better with the data obtained by numerical computation.

Transverse Electric Mode Excitation in Graphene-Based Multilayers Through Attenuated Total Reflection Technique

FELIPE RAMOS-MENDIETA, IVAN FUENTECILLA-CARCAMO (Presenter), Universidad de Sonora, MARTHA PALOMINO-OVANDO, ALEJANDRO HERNÁNDEZ-López, Facultad de Ciencias Físico-Matemáticas, Benemérita Universidad Autónoma de Puebla — Graphene monolayer can support transverse electric plasmonic modes where in-plane current oscillations are present and parallel to electric field vector. These modes, as recently shown, can be excited by Attenuated Total Reflection (ATR) Technique where mode coupling is obtained above a cutoff distance between prism and graphene. In this work, we extend this analysis by considering a graphene (equally doped)/dielectric stack immersed in homogeneous dielectric. We show that Surface Plasmonic (SP) modes are excited through this technique showing smaller cutoff distances than those reported for monolayer graphene. We found that cutoff distance, \( d_c \), decreases as the number of stacked layers grows following the rule \( d_c = \alpha / (2n) \), where \( \alpha \) is the decaying length and \( n \) is the number of graphene layers. We prove surface plasmon excitation, corresponding to minima in the ATR, by numerical calculation of dispersion relations of SPs for two, three and four graphene layers in the stacking.

IFC aknowledge financial support from CONACyT M'èxico.
In this study, we examine the interaction of Dirac fermions and bosons, we investigated the electronic and magnetic properties of rare-earth-metal intercalated in bilayer graphene. Using density functional theory, we determined the electronic structure, density of states, magnetic moment, and total energy for lanthanum (La), gadolinium (Gd), holmium (Ho), and erbium (Er) in a honeycomb configuration. An analysis of the total energy and magnetic structure, shows that the Gd and Ho substitutions obtain a FM ground state, while the La and Er substitutions have an AFM ground state, which means that Gd and Ho layered sandwiches may have possible Dirac boson interactions. The electronic structure provides information on Dirac fermionic interactions. We find that the presence of rare-earth materials shifts the Dirac cone in the electronic structure into the valence band, and while Lanthanum does not provide any f-orbital interactions, Gd, Ho, and Er have strong f-orbital characteristics. However, this seems to be at the expense of the Dirac fermionic cone.

**T70.00348: Ordered Particle Arrays via a Langmuir Transfer Process: Large Area Access to Any Two-Dimensional Bravais Lattice**

MIRIAM MAUER, CHRISTIAN STELLING, BERND KOPERA, FABIAN NUTZ, Department of Chemistry, University of Bayreuth, 95447 Bayreuth, Germany, MATTHIAS KARG, Physical Chemistry I, Heinrich-Heine-University, 40204 Düsseldorf, Germany, MARKUS RETSCH (Presenter), Department of Chemistry, University of Bayreuth, 95447 Bayreuth, Germany, STEPHAN FÖRSTER, JCSN-1/ICS-1, Forschungszentrum Jülich, 52425 Jülich, Germany — The preparation of particle arrays on solid substrates is an essential step for the fabrication of functional surfaces and thin-film devices with applications in lithography, optics, photonics, high-density data storage and as adhesive/non-adhesive surfaces. Colloidal self-assembly represents an attractive and scalable route towards hexagonally close-packed particle arrays. To significantly broaden the structural variability, the fabrication of non-close-packed and also non-hexagonal particle arrays are required. Here, we demonstrate how to fabricate non-close-packed particle arrays with symmetries of all possible Bravais lattices in a simple solution-based process. Our process starts with readily self-assembled, hexagonally close-packed monolayers, which are immobilized on an air/water interface. Upon transfer onto the target substrate, stretching along a specific crystallographic direction occurs. This yields non-close-packed structures with non-hexagonal symmetry. We demonstrate how to control the stretching factor by interfacial modification of the target substrate to access all possible Bravais lattices.

**T70.00349: High energy particles detection through high mobility GaAs/Al0.3Ga0.7As QW Hall bar sensor**

MEHDI PAKMEHR (Presenter), MUHAMMAD ASTERAKI, Physics, Shiraz University — GaAs as a well-known semiconductor has been used widely for detection and different types of sensor fabrication for diverse purposes within last decades. We used high carrier density GaAs/Al0.3Ga0.7As QW with relatively high mobility with an ultimate goal of being used to fabricate high energy particles detector. The carrier density of our samples are relatively high \( n_c = 6.24 \times 10^{11} \text{ cm}^{-2} \) with hall mobility of \( 1.5 \times 10^5 \text{ cm}^2\text{V}^{-1}\text{s}^{-1} \). The large Hall bars samples were fabricated form modulation doped MBE grown wafer used for our experimentations. The sample sits at the bottom of probe stick within VTI at Liquid nitrogen temperature (T=77 K) while chopped high energy particle beams (positrons) from Na22 source hit it. Through common lock-in technique we detected signal due to interaction of beam particles with 2DEGs confined within QW of our samples. We plan to present our findings through a poster at March 2019 APS meeting being held at Boston

*M. Pakmehr would like to acknowledge Shiraz University office of Dean for supporting our research work.

**T70.00350: SURFACES, INTERFACES, AND THIN FILMS**

**T70.00351: The coordination of Metal-Salen to diatomic molecules**

DAN LIU (Presenter), Peking University — Salen is a Schiff base complex which is condensed from salicylaldehyde and ethylenediamine. The chemical, electronic and magnetic properties of metal-salen could be altered by adjusting the central metals. These metal-salen register wide applications in materials science, heterogeneous catalysis, geology, biology and so on due to the diversity of their properties. Thanks to the invention of scanning tunneling microscopy (STM) in 1980s, people are able to observe the single atoms and molecules. Up to date, the morphological and electronic properties of metal-salen have been systematically studied in surface science. However, their catalytic performances have not been fully explored. Therefore, this proposal focuses on the coordination of several metal-salen complexes to diatomic molecules (such as CO) as well as analyses of its morphological and electronic properties with STM and surface science techniques. Specifically, Metal-Salen as a surface model catalyst will be extensively explored to uncover its catalytic properties towards small molecules.
In this work, we investigate the icing and deicing characteristics of a sessile droplet on an Al-based superhydrophobic surface and aim to understand the surface and interface phenomena occurred during icing and deicing. During icing, ice front always propagates from the bottom of the droplet, finally forming a singular tip at the droplet top, while the nucleation position is various under different conditions. When the surround air is very humid, the nucleation tends to appear at the solid-liquid interface of the droplet; otherwise, the nucleation appears at the liquid-air interface of the droplet. During deicing, melting also first occurs at the bottom of the freezing droplet, but the ice-water interface is more flexible compared with that during icing with obvious swaying and rotating behavior of the unmelted ice cover. The possible Marangoni effect occurred during deicing may be the reason for these behavior.

T70.00353: Ionic effectiveness in the self-assembly and crystallization of polymer grafted Au nanoparticles at the gas-liquid interface* WENJIE WANG, Ames Laboratory, Iowa State University, WEI BU, NSF's ChemMatCARS, University of Chicago, DAVID VAKNIN (Presenter), Ames Laboratory, Iowa State University — Salts in solutions promote aqueous surface self-assembly of gold nanoparticles (AuNPs) that are grafted with non-ionic and water soluble polymers such as poly(ethylene glycol) (PEG) or poly(N-isopropylacrylamide) (PNIPAM). Using AuNPs functionalized with PEG (PEG-AuNPs) as a model system, previous studies have demonstrated that ions can be ranked in their effectiveness to promote the two-dimensional superlattice formation of PEG-AuNPs. Similar ranking for the aqueous biphasic system (ABS) of PEG in salt solutions. However, we show that ionic species that do not readily induce ABS at ambient temperatures can lead to surface crystallization of PEG-AuNPs. Synchrotron x-ray reflectivity and grazing incidence small angle x-ray scattering methods are used to determine the structures of the surface assembly for various ionic species. Here, we report on grazing incidence x-ray fluorescence spectroscopic measurements that in conjunction with Compton and Thomson scattering reveal ion-specific distributions at the surface and in the bulk in the presence of PEG-AuNPs suspensions and compare them to salt solutions without NPs. We find that the ion distributions of CsCl and NaI correlate with the quality of surface PEG-AUNPs crystallization.

T70.00354: First-Principles Prediction of Temperature Dependence of Surface Wettability and Interfacial Tension in Multiphase Systems QIAOYU GE, JIN-YOU LU, AIKIFA RAZA, TIEJUN ZHANG (Presenter), Mechanical Engineering Department, Masdar Institute, Khalifa University — Temperature dependences of solid surface wettability and liquid-liquid interfacial tension play important roles in many applications involving interfaces or thin films working at elevated temperature, such as subsurface energy production and organic solar cell fabrication. In this work, a first-principles approach based on ab initio molecular dynamics is proposed to reveal the insightful effect of temperature on solid surface wettability and liquid-liquid interfacial tension. Temperature-dependent adhesion and cohesion energies are calculated from ab initio molecular dynamics and used to evaluate the temperature dependency of interfacial properties. A system of calcite-water-decane is simulated to predict the contact angle of water on calcite surface in presence of decane, as well as water-decane interfacial tension at different temperatures. The predicted reduction rates of contact angle and interfacial tension with temperature agree well with our experimental validation. The first-principles nature of this method makes the prediction accurate and intrinsic, meanwhile it provides physical insight into experimental multiphase behaviors and prediction of new wetting phenomena.
**T70.00355: Resistive switching in La$_{0.3}$Ca$_{0.7}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-\delta}$ devices**

JOHN BETANCOURT (Presenter), Physics, Center of excellence on novel materials, JOHN E ORDONEZ, MARIA GOMEZ, CARLOS WILLIAM SANCHEZ, WILSON LOPERA, KATHERINE GROSS, Physics, Thin Films group, JUAN RAMIREZ, Physics, Universidad de los Andes — We have deposited La$_{0.3}$Ca$_{0.7}$MnO$_3$ (LCMO) /YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO) on SrTiO$_3$ (STO) (100) oriented substrate by sputtering technique at pure oxygen atmosphere at high pressure (4 mbar) to study the resistive switching response. We grew systematically the insulator LCMO film with different thicknesses ($t_{LCMO} = 60, 30$ and $15$ nm) on YBCO layer ($t_{YBCO} = 60$ nm), which acts as bottom electrode. For the electric characterization, we deposited Ag circles on top of the heterostructures as top electrode. From XRD we found that the LCMO and YBCO layers grew textured aligned with substrate. The electrical properties with temperature measurements indicated the LCMO insulator behavior and the YBCO conduction at room temperature. I versus V curves at room temperature showed hysteric behavior and the presence of two resistive states, whose electrical transport mechanism could be associated with space charge limited conduction (SCLC). The performed resistance switching with applied voltage tests indicate a dependence of the high resistance state (HRS)/ low resistance state (LRS) ratio with LCMO thicknesses.

**T70.00356: Realizing Narrow Band Thermal Emitters in the Mid-Infrared by Utilizing Polaritonic Metasurfaces.**

DIEGO GARCIA (Presenter), Department of Physics and Astronomy, University of Texas at Rio Grande Valley — The purpose of this study is to show evidence that surface phonon polaritonic(SPhP) metasurfaces can produce a well-defined thermal emission signal in the optical phonon band of Silicon Carbide to realize narrow band emitters in the mid-IR wavelengths. Preliminary data and results have demonstrated strong localized SPhP resonances of these devices, so there is a high possibility that a well-defined emission signal will be obtained if we apply Kirchhoff’s Law of Heat Radiation. To observe the thermal radiation from the polaritonic metasurface patterns, an optical setup was built in which the beam path of the visible light and thermal radiation would be equivalent. This was done primarily for the precise alignment of the metasurface and to maximize the collection of thermal radiation. The device was heated conventionally and data analysis was attained using a FTIR Spectrometer. Initial results showed an emission spectrum with broad resonances from 820 cm$^{-1}$ to 960 cm$^{-1}$ and it was determined the resonances were from multiple patterns on the metasurface. Currently, we have improved the setup to collect emissions from single patterns.

*Research was supported by the NSF-REU program at the University of Texas Rio Grande Valley, and the University of Texas system STARs award.

**T70.00357: Set of Techniques for High-Q Noble Metals Deposition: from Continuous Ultrathin to Single-crystalline Films**

ALEKSANDR BABURIN (Presenter), AIDAR R. GABIDULLIN, DMITRIY O. MOSKALEV, EVGENIY LOTKOV, MICHAEL ANDRONIC, ANTON I. IVANOV, REC FMN, Bauman Moscow State Technical University, ILYA A. RYZHIKOV, ITAE RAS, ILYA A. RODIONOV, REC FMN, Bauman Moscow State Technical University — Losses are the most serious challenges, which impede high-Q plasmonic devices rapid development. There are numerous types of plasmonic devices with conflicting requirements for the films. One can conclude that most devices require continuous silver and gold films with ultra-low losses, extremely low roughness, single-crystalline structure and maximum possible surface plasmon polarization wave (SPP) propagation length on various substrates including amorphous.

We present a full row of techniques as contribution to material platform. Among them single-crystalline ultra low loss (SCULL) sub-50 nm single-crystalline silver films, which provide SPP propagation length 200 μm (at wavelength 780 nm) [1] and allow ultra-bright single photon sources fabrication [2]. For amorphous substrates, we proposed polycrystalline big grain film deposition with high aspect ratios between grain size and film thickness that ensured high-Q light source fabrication [3]. Finally, for ultrathin films, less than 15 nm thick, we developed technologies to reduce percolation threshold of gold and silver without using wetting layers.

Resistive switch on Iron oxides thin films* RAFAEL SILVA GONÇALVES, ROMUALDO SANTOS SILVA JUNIOR, PETRUCIO BARROZO DA SILVA (Presenter), Physics Department, Federal University of Sergipe — The resistive switch properties on binary oxides has largely studied due to the non-volatile properties and its potential to be used to develop data storage devices. The resistive switch has been attributed to the percolation of a conductor pathway across the insulator matrix. However, the properties of the growth of the conductor pathways and the speed of the switch between the different resistive states on iron oxide has not yet been reported. In this work, we describe the mechanism of the resistive switch on the thin films of iron oxide growth by sputtering. The dynamics of growth of the conductor pathways in iron oxide and the speed of switch also will be reported.

*Thanks to Brazilian fund agencies CNPq and CAPES.

Nanoscale Imaging Studies of Cobaltite Thin Films Using X-Ray Nanodiffraction* GEOFFERY IAN RIPPY (Presenter), LACEY L TRINH, ALEXANDER MICHAEL KANE, ALEKSEY IONIN, MICHAEL STEVEN LEE, RAJESH V CHOPDEKAR, University of California, Davis, DUSTIN GILBERT, ALEXANDER GRUTTER, National Institute of Standards and Technology, PEYTON MURRAY, University of California, Davis, MARTIN HOLT, ZHONGHOU CAI, Argonne National Laboratory, KAI LIU, YAYOI TAKAMURA, ROOPALI KUKREJA, University of California, Davis — The perovskite (ABO3) and closely related brownmillerite (ABO2.5) phase of cobaltites possess a wide range of functional properties, which makes them promising candidates for solid oxide fuel cells, ionically-gated devices, and magneto-ionic devices. However, the role played by nanoscale morphology, i.e. phase separation and defects in these oxide thin films and heterostructures, remains unknown. This poster presents nanoscale imaging studies of emergent structural phases and their morphology in cobaltite heterostructures using x-ray nano-diffraction. Gd/La0.67Sr0.33CoO3 heterostructures were ionically and stoichiometrically controlled via the thickness of the Gd oxygen-gettering layers. Our measurements, using the hard x-ray nanoprobe at the Advanced Photon Source, show lateral and transverse nanoscale separation of the perovskite and brownmillerite phases. These nanoscale heterogeneities were characterized and strain mapped in real space with a spatial resolution of 25 nm. Our studies provide insights into the nanoscale morphology which can be utilized to tune the macroscopic functional properties of cobaltite heterostructures.

Steering on the high-temperature oxidation of Ru(0001) HAORAN CHEN (Presenter), Peking University — Ruthenium oxide is the active phase and plays a significant role in many catalytic reactions. By virtue of ultrahigh vacuum low temperature scanning tunneling microscopy, it has been observed that Ru(0001) could be oxidized to several novel kinds of ruthenium oxide films at different temperatures. High-resolution STM images showed that these films resulted from the novel structures formed at surface. Interestingly, these oxidation structures were inter-changeable upon reduction in hydrogen at different temperatures. After series of studies, the structural evolutions of Ru(0001) surface caused by high-temperature oxidation and reduction were revealed.

Chemical Reactivity at the Co/CuO interface* ANIL CHOURASIA (Presenter), Texas A&M University - Commerce — The chemical reactivity at the Co/CuO interface has been investigated using the technique of x-ray photoelectron spectroscopy. Thin films of hafnium have been deposited on CuO substrates at room temperature by the e-beam method. The Oxford Applied Research EGN4 was used for this purpose. The spectral data in the hafnium 4f core level and copper 2p core level were investigated by XPS. The copper oxide was observed to get reduced to elemental copper while cobalt was observed to get oxidized to CoO. The thickness of the cobalt overlayer resulting in no chemical reactivity has been determined. The investigation was also performed at substrate temperatures of 100, 200, 300, 400, 500, and 600°C. The diffusion of copper through the overlayer was observed. The interface consists of a mixture of elemental cobalt, CoO and elemental copper. The amount of these materials is governed by the processing conditions. The results of the investigation will be presented.

*Texas A&M University-Commerce
**T70.00362: Modeling of molecular stripe formation on insulating surfaces**  
CHRISTOPH SCHIEL (Presenter), University of Osnabrück, MAXIMILIAN VOGLTAND, ANGELIKA KÜHNLE, University of Bielefeld, PHILIPP MAASS, University of Osnabrück — We discuss theoretical approaches to model molecular stripe formation on dielectric surfaces as observed for 3-hydroxybenzoic acid (3-HBA) and 3-aminobenzoic acid (3-ABA) on calcite (104). For the self-assembly of the 3-HBA and 3-ABA molecules it is argued that adsorption-induced dipolar interactions cause an ordering towards a regular spacing between the molecular stripes. Measured stripe distance distributions show a good agreement with analytical results for a simplified one-dimensional model [1]. In this model scaling relations for the distance distribution are predicted that can be tested experimentally. In a refined approach, we further study the stripe formation on a two-dimensional lattice by an anisotropic Ising model with dipole-dipole interactions. For this model, stripe length and distance distributions as well as spatial correlation properties are determined by Monte Carlo simulations and compared with experimental data.

**T70.00363: The Effect of Au Nanoparticles on the Photovoltaic Conversion Efficiency in CdTe/CdS Thin Films**

YUNIS YILMAZ (Presenter), OLIVIA RODGERS, ANTHONY J VISCOVICH, RALPH NUNEZ, MEHMET ALPER SAHINER, Seton Hall University — In our previous studies, we've worked on the effects silver nanoparticles have on the efficiency of CdS/CdTe thin film solar cells. In short, the addition of the nanoparticles in the np affects junction light scattering in a way that have a positive effect on efficiency of photovoltaic conversion. Currently, we’re testing gold nanoparticles on the same solar cells and plan on comparing the effects of different deposition times, particle sizes, and how they compare to the efficiencies of that of silver. The deposition method used to create these thin film solar cells is Pulsed Laser Deposition (PLD). The laser shoots at the target material we want to deposit (CdS/Au/CdTe) turning it into a plume of plasma that deposits onto a slide of ITO (indium tin oxide) coated glass. Varying how long the laser shoots at the gold changes the amount of gold deposited. The more gold in the np junction, the more light scattering happens, increasing the efficiency of the solar cell. However, the efficiency cuts off with enough gold added. The Au embedded CdS/CdTe thin film solar cells were characterized by XRD, AFM, SEM/EDX and the photovoltaic conversion efficiency were determined by Ketihley Sourcemeter setup.

**T70.00364: Electrical and Physical Properties of Pulsed Laser Deposited Thin Films of YSZ**

MATTHEW MELFI (Presenter), WILLIAM E COCKERELL, ERICA WILEY, KELLEN MURPHY, MEHMET ALPER SAHINER, Seton Hall University — Solid Oxide Fuel Cells, SOFC’s, are devices that convert chemical energy from fuel into electricity from a series of electrochemical reactions. These fuels can be H₂, CO, O₂, etc. with a high efficiency of conversion. Comparing SOFC’s to coal power plants, the SOFC’s produce a higher electrical conversion efficiency. However, SOFC’s high temperatures create a lower ionic conductivity of the electrolytes. When decreasing the temperature, the ohmic resistance is increased hurting the performance. The method we are trying to take is decrease the ohmic resistance as a thin-film. An Yttria Stabilized Zirconia, YSZ, layer is produced from the fine dimple grain structure allowing high flow of oxygen ion mobility. The goal of our research is to optimize Pulsed Laser Deposition and determine the synthesis conditions which lead to minimum ohmic resistance in these films. We will also use different substrates and monitor the effect of the choice of the substrate on the YSZ thin-film properties. These thin-films will be characterized through electrical measurements such as 4 pt. probe resistivity measurements, Hall Effect, and structural and compositional characterization such as AFM, SEM, and EDX.

T70.00365: Structural stability and electronic levels of carbon-associated defects in SiO₂: First-principles study*  
YU-ICHIRO MATSUSHITA (Presenter), Tokyo Institute of Technology, ATSUSHI OSHIYAMA, Nagoya University — Silicon Carbide (SiC) attracts much attention as the power semiconductor materials due to its superior material properties such as wide-band gap and high breakdown electric field [1]. In spite of the great materials properties, SiC has a big issue to be solved. That is the low electron mobility of SiC-MOS(Metal-oxide semiconductor) devices caused by the high density of interface traps (Dit). In particular, carbon-associated defects staying around the SiC/SiO₂ interface are the strong candidate for the Dit. In this study, we have clarified the structural stability and electronic levels of C-associated defects near the SiC/SiO₂ interface on the basis of the density-functional theory (DFT). Consequently, we have found that near the SiC/SiO₂ interfaces the carbon clustering is likely and some particular carbon defects cause defect levels near the conduction-band edge of SiC rendering them a strong candidate of the mobility killer.

T70.00366: Surface Morphology Studies of Strained and Oxygen Deficient Epitaxial Thin films of Strontium Titanate and Calcium Manganese Oxide*  
ANTON WIGGINS (Presenter), AZRIEL WEINREB, FRANCIS WALZ, JOSEPH CARTELLI, DAVID HOUSTON, BRIDGET M LAWSON, JESSICA L SIZEMORE, RAJESWARI M KOLAGANI, GARY PENNINGTON, DAVID SCHAEFER, Towson University — Calcium Manganese Oxide (CMO) and Strontium Titanate (STO) are technologically important materials for applications. Our recent work on epitaxial thin films of CMO have shown that films with a tensile lattice mismatch strain exhibit structural and electrical properties that indicate oxygen deficiency. Our Atomic Force Microscopy studies of CMO thin films reveal time dependent surface morphological changes accompanying oxygenation and de-oxygenation of the CMO films. AFM images indicate possible ordering of oxygen vacancies on the surface. Currently we are extending these studies to epitaxial thin films of STO to investigate strain-oxygen stoichiometry coupling. We will report the results of our systematic studies of the evolution of surface morphology with changes in the strain state and oxygen stoichiometry

*We acknowledge support from the NSF grant DMR 1709781 and support from the Fisher General Endowment Grant from the Jess and Mildred Fischer College of Science and Mathematics at Towson University.

T70.00367: Structural characterization of BaSnO₃ thin films via x-ray scattering  
CLAUDIA LAU (Presenter), Yale Univ, YOUJUNG KIM, KOOKRIN CHAR, Seoul National University, CHARLES H AHN, FREDERICK J WALKER, Yale Univ — The alkaline earth stannate BaSnO₃ is a semiconductor with high carrier mobility at room-temperature when doped with La³⁺. BaSnO₃ can be easily integrated with other perovskites for use in oxide electronic devices such as field effect transistors and sensors. We study the crystalline structure of BaSnO₃ thin films grown on SrTiO₃ substrates by pulsed laser deposition and molecular beam epitaxy via a variety of x-ray scattering techniques. With high intensity synchrotron scattering, we measure crystal truncation rods. Analysis of these rods yields information on structural distortions at the thin film surface and interface. We also measure rocking curves of BaSnO₃ fundamental Bragg peaks for H+K+L=even and odd, where the intensity of the odd peaks are particularly sensitive to minute structural changes in the BaSnO₃ film. These measurements have high accuracy, with a coefficient of variation within 5 percent for symmetrically identical peaks in the four quadrants of reciprocal space. We fit the integrated intensity of these fundamental even and odd peaks to a kinematic model of x-ray diffraction and determine parameters, including the Debye-Waller factor and the stoichiometry.

T70.00368: Computational study of the adsorption of bi-metallic clusters*  
NUSAIBA ZAMAN (Presenter), KARIMA LASRI, ABDELKADER KARA, University of Central Florida — It was shown that small silver clusters can control the rate of LiO₂ formation in Li-O₂ batteries. The gap near the fermi energy was shown to control the oxygen reduction, an important reaction for LiO₂ formation. Controlling the gap would ultimately control the rate of LiO₂ formation. One can vary the size of the cluster to control the gap, however, this “knob” provides limited variance. Alloynig, in combination with size variation offer a much wider control of the LiO₂ formation. Here, we investigate the effect of Pd₃M₂ (where M varies from Ag, Au, Co, Cu, Mn, Ni, Pt, and Ru) clusters on the rate of O₂ reduction at the hydroxylated alumina surface. Using DFT, we calculated the binding energies of these clusters on the alumina substrate which ranges from depending upon the composition of the alloy-cluster, its orientation and the adsorption site. We also find that Pd atom binds strongly with the substrate oxygen atom with a short bond-length of about 2.2 Å. We explore how the gap between the HOMO of the cluster and the Fermi energy of the system varies as a function of elemental composition. These preliminary results will open the door for more systematic studies of alloy clusters of different size and stoichiometry.

*Argonne National Laboratory.
T70.00369: Development of Disordered and Ordered Nanoscale Terraced Topographies on Si Under Oblique Incidence Xe⁺ Ion Bombardment*  
EMMETT RANDEL (Presenter), CARMEN SUSANA MENONI, RICHARD M BRADLEY, Colorado State Univ — We explored disordered and ordered nanoscale terraced topographies that develop when a solid surface is bombarded by an ion beam at oblique incidence. It is shown that a flat Si surface when bombarded with 1500 eV Xe⁺ ions at 75° off normal incidence develops a disordered terraced topography. Using a Si surface pre-patterned with 500 nm pitch lines, it is demonstrated that ordered terraced topographies with sub-nanometer roughness on the facets develop under the above conditions. Ordered terraced substrates can be used in the fabrication of EUV multilayer blazed gratings. This work was performed in tandem with theory in an effort to refine models.

*NSF DMR Grant No. 1508745

T70.00370: Graphene-oxide monolayers at the air-water interface  
BRENT LA MURO (Presenter), MICAH VANDERSTEEN, Augsburg University, Minneapolis MN, ISSAM ISMAIL, Khalifa University of Science and Technology, BENJAMIN STOTTRUP, Physics, Augsburg University, Minneapolis MN — Graphene-oxide is a novel material with tremendous applications to coatings and electronics. We utilize investigations of self-assembled GO monolayers at the air-water interface as the basis for experimental investigations in an undergraduate laboratory experience partnered with Augsburg University’s sophomore level Modern Physics course. A Langmuir trough with dual tensiometers oriented parallel and perpendicular to the barrier compression is used to measure the anisotropic forces during the compression and expansion of the monolayer. Investigations of size distribution and pH modulation of the aqueous subphase are presented here. Scanning electron microscopy of Langmuir-Blodgett deposited GO films provides a complementary look at GO morphology. Finally, we present the feasibility of GO studies at liquid-liquid interfaces.

T70.00371: Equating Cu(111) Stepped Surface and Nanoparticle Oxidation Energetics: A Multiscale Computational Study*  
MATTHEW CURNAN, JUDITH YANG, WISSAM SAIDI (Presenter), University of Pittsburgh — Understanding how to inhibit oxide formation on Cu interfaces is critical to corrosion prevention and catalyst deactivation. Oxide growth on metal surfaces is supplied by diffusing O atoms, such that anisotropy in O diffusion rates along different surface structures proportionally affects their observed growth. Structural defects, such as Cu(111) surface steps and similarly faceted nanoparticles (NPs), selectively oxidize with respect to adjacent flat surfaces and differently oriented defects. Previous research suggests that differences in defect atomic coordination, attributed to dangling surface Cu bonds, yield this selective oxidation. In this study, we confirm that these oxidation preferences are conserved over morphologically distinct, equivalently oriented, Cu(111) stepped surfaces and NPs with shared edge orientations. O diffusion energetics are calculated via density functional theory, cross-validated via reactive force field molecular mechanics, and reconciled with molecular dynamics simulations. Equating surface step and NP oxidation energetics furthers the understanding of how defect structure impacts selective oxidation.

*This work is supported by NSF DMR-1410055.

T70.00372: Unconventional properties of superconductivity in SrTiO₃/LaAlO₃/SrTiO₃  
YONGSU KWAK, JONGHYUN SONG (Presenter), Chungnam National University, JINHEE KIM, Korean Research Institute for Stand Science — The 2-Dimensional Electron Gases (2-DEGs) observed at the LaAlO₃/SrTiO₃ (LAO/STO) hetero-interface exhibits superconductivity, which has phase diagram as function of carrier density like high-temperature superconductor. However, the superconducting energy gap in LAO/STO has conventional superconductivity because the temperature dependence of superconducting energy gap follows Bardeen-Cooper-Schrieffer (BCS) theory. Here we report unconventional properties of superconductivity in STO/LAO/STO. We have fabricated vertical Josephson junction to measure the superconducting energy gap. We found that the superconducting energy gap estimated from the Andreev reflection of the Josephson junction did not follow BCS theory from the gap ratio, Δ/k_BTc = 1.31. Additionally, we found evidence of unconventional superconductivity from the magnetic field dependence of superconducting critical current. It has opposite hysteresis, when it was compared with the hysteresis of magnetoresistance in STO/LAO/STO.
T70.00373: Ethylene Epoxidation on Ag(100), Ag(110), and Ag(111) - A First-principles and Kinetic Monte Carlo Study
MATEJ HUS, Department of Catalysis and Chemical Reaction Engineering, National Institute of Chemistry, ANDERS HELLMAN (Presenter), Chalmers University of Technology — Ethylene epoxidation is commercially one of the most important selective oxidation reactions. Silver-based catalysts are the most common catalyst formulation in industry, albeit with significant doping. In this work, we present results from first-principles and kinetic Monte Carlo (kMC) modeling of the reaction on three pristine silver surfaces Ag(100), Ag(110), Ag(111), and on the missing-row reconstructed Ag(110). To better understand the kinetics on different surfaces and veraciously describe the surface coverages, we explicitly take into account the lateral interactions between the adsorbates and their effect on the activation barriers. Comparing with experimental data shows a good agreement with the modeling data especially for Ag(111) and somewhat worse for Ag(100). We show that Ag(100) offers better activity and activity than Ag(111). Differences in the active intermediates surface coverage were also studied. Furthermore, we studied the influence of alkali metals on selectivity. Our calculations show that the combination of electronegative Cl and electropositive Cs offers an optimal compromise between activity and selectivity.

T70.00374: Upgrading scanning tunneling microscopy with a radio-frequency modulation system for the detection of ferromagnetic resonance
HUNG-HSIANG YANG (Presenter), KANTA ASAKAWA, FUMIKAZU OGURO, YUDAI SATO, Institute for Solid State Physics, University of Tokyo, SUSUMU TAKAHASHI, Department of Chemistry, University of Southern California, YUKIO HASEGAWA, Institute for Solid State Physics, University of Tokyo — Scanning tunneling microscope (STM) usually provides us with only static information of material surfaces. Recently, however, dynamics of a single electron spin can be successfully detected by using STM through the resonance under the irradiation of radio-frequency wave [1]. We are developing radio-frequency STM (RF-STM), intending to detect ferromagnetic resonance of nanosize ferromagnetic island structures and to generate spin waves around them. One of the key issues for the development is to generate constant-amplitude radio frequency sweeps at the tunneling junction [2]. Because of magnetostriction-induced drift, sweeping magnetic fields is not preferable. In the presentation, we will discuss the progress of the development and its performance.

T70.00375: Carrier Dynamics and Ultrafast Zero-Bias Photocurrents in SnS2 Single Crystals*
ERIN MORISSETTE (Presenter), KATERYNA KUSHNIR, ALEXIS BUZZEL, CURTIS DOIRON, RONALD GRIMM, LYUBOV TITOVA, Worcester Polytechnic Institute — Moderate band gaps, high carrier mobility, and environmental stability make layered transition metal dichalcogenides attractive for optoelectronic and solar energy conversion applications. Of these materials, SnS2 demonstrates promise as a photocatalyst for visible light water splitting and in field-effect devices, with reported on-off current ratios >10^6 and carrier mobilities up to 230 cm^2 V–1 s–1 [1,2]. Further progress in application of this emergent material requires the understanding of the dynamics of photoinjected carriers and optical excitations.

We present the synthesis of single-crystal SnS2 and its subsequent characterization by terahertz (THz) spectroscopy of carrier dynamics with sub-picosecond time resolution. Emission spectroscopy of photoinduced ultrafast currents probe the presence of shift currents, or zero-bias photocurrents, that appear to be a function of crystal orientation. The observation herein of zero-bias photocurrents indicates the viability of SnS2 nanosheets for third generation shift current photovoltaics.

T70.00376: Molybdenum Nitride Thin-Film Development and Screening* MUHAMMAD SAJID (Presenter), ASIM KHANIYA, WILLIAM KADEN, ABDELKADER KARA, University of Central Florida — Hydrodenitrogenation (HDN), the process of through which nitrogen groups are removed from organic molecules present in petroleum and coal feedstocks, is a preliminary step in petroleum refinement. With shifts towards renewable biomass feedstocks, which may be harvested free of sulfur impurities, HDN optimization could become an increasingly relevant industrial challenge. HDN proceeds with greater activity and long chain selectivity on molybdenum nitride powders than conventional Co-Mo hydrotreatment catalysts. δ-MoN is suggested to be the most active phase, but more thorough experimental as well as computational studies are needed to better understand the correlation of activity and atomic structure of catalysts.

Using Density Functional Theory (DFT) and Ultra-High Vacuum surface science techniques, we are actively screening/developing different phase-pure MoN thin-films as model catalysts to isolate and explore reaction pathways associated with hydrodenitrogenation of simple nitrogen-containing aromatic molecules. This will aid us towards reaching to the subtle connection between properties at the atomic level with desired catalytic properties.

T70.00377: Fluctuation Dynamics of Ferroelectric Nano-domains in BaTiO3 Thin Films JIANHENG LI (Presenter), RAHUL JANGID, GEOFFERY IAN RIPPY, CHRISTOPHER KOHNE, Materials Science and Engineering, University of California, Davis, ARNOUD EVERHARDT, Materials Science and Engineering, University of California, Berkeley, BEATRIZ NOHEDA, Zernike Institute for Advanced Materials, University of Groningen, ANDREI FLEURASU, National Synchrotron Light Source II, SYLVIA MATZEN, CNRS, University of Paris - Sud 11, ROOPALI KUKREJA, Materials Science and Engineering, University of California, Davis — Ferroelectric materials possess a thermodynamically stable polarization which can be controlled using temperature, voltage, and recently with optical pulses, enabling numerous device applications including non-volatile memories, actuators, and sensors. Ferroelectric domain structure plays an important role in manipulating polarization switching behavior and depends upon factors including strain, temperature and interfacial properties. In this study, we focused on understanding domain dynamics and fluctuations in BaTiO3 (BTO) thin films, which show ordered 90° alternating in-plane and out-of-plane domain from 50 °C to 130 °C (Curie Temperature). We utilized X-ray photon correlation spectroscopy (XPCS) to probe domain fluctuations by accessing satellite peaks formed by ordered stripe domain in Bragg geometry. Our measurements show a two-step behavior, where from 50 °C to 90 °C, a slowing down of fluctuation timescales was observed due to stabilization of a/c domains. Above 90 °C, an increase in fluctuation timescales was observed as the material undergoes ferroelectric to paraelectric transition. This research demonstrates the characteristic behavior and timescales of nano-domain fluctuations in BTO thin films which have not been previously studied.

T70.00378: Intermetallic formation at deeply supercooled Ni/Al multilayer interfaces: a molecular dynamics study* PENG YI (Presenter), MICHAEL FALK, TIMOTHY P. WEIHS, Johns Hopkins University — Reactions at interfaces between solids are critical processing steps for applications including microelectronics, coatings on turbine blades, and reactive materials. It is established experimentally that the first phase to form through an interfacial reaction need not be the most stable phase. Understanding the thermodynamics and kinetics of the solid-state reaction at interface is crucial for device engineering.

We study the formation of the intermetallic NiAl in the Ni/Al multilayer system, focusing on how composition gradients at the interfaces impact intermetallic formation. High composition gradients (10^9-10^10 m^-1) were generated to mimics Ni/Al interface. Simulation temperatures below 800K were chosen so that both Ni and Al remain crystalline. We observed melting/amorphization at the interface region due to intermixing and stress. The intermetallic phase then forms at the interface from the melted/amorphous region through heterogeneous nucleation. Kinetics of the transformation follows the Johnson-Mehl-Avrami model. The NiAl formation is growth-controlled and the growth rate is found to increase with decreasing composition gradient. Our finding supports a growth-competition mechanism of phase selection for interfacial reactions.

*National Science Foundation (DMR-1308966)
T70.00379: Evident effects of Hofstadter-type energy spectra of modulated bilayer graphene  
DANHONG HUANG (Presenter), Air Force Research Lab - Kirtland, ANDRII IUROV, Center for High Technology Materials, University of New Mexico, GODFREY GUMBS, LIUBOV ZHEMCHUZHNA, Hunter College of the City University of New York, Department of Physics and Astronomy — When a uniform perpendicular magnetic field is applied to a graphene layer, a two-dimensional periodic scatter array only mixes the Landau levels from the same valley to form split electron-hole Hofstadter-type energy spectra. However, in the case of bilayer graphene, this periodic array is able to mix different sets of Landau levels originating from the two separate valleys. Such a valley mixing effect has been carefully investigated in this work using a projected model Hamiltonian which includes an interlayer effective mass, interlayer coupling and different on-site energies. The computed Hofstadter-type energy spectra and associated density-of-states are employed for further calculations of the ballistic conductance of electrons in bilayer graphene.

T70.00380: Valley splitting in a van der Waals heterostructure WSe2/CrI3: A first-principles study*  
ZHIIYA ZHANG (Presenter), National & Local Joint Engineering Laboratory for Optical Conversion Materials and Technology, Lanzhou University, XIAOJUAN NI, HUAQING HUANG, LIN HU, FENG LIU, Department of Materials Science and Engineering, University of Utah — Atomically thin transition metal dichalcogenides (TMDs) have been considered as a wonderland for the research of valleytronics. Lifting the ±K valley degeneracy in TMDs has become an important research topic in the field of valleytronics. It is crucial to achieve large valley polarization for the development of valleytronics devices. In this work, we investigate the effects underpinning the ±K valley splitting in a van der Waals heterostructure WSe2/CrI3 based on first-principles calculations. We demonstrate that the stacking configuration affects the valley splitting dramatically and the influencing factors are discussed in details. The findings would further our basic understanding of the substrate effect on the valley degeneracy lifting in TMDs-based heterostructures beyond the WSe2/CrI3 and provide a useful guide to the valleytronic control in realistic applications.

*We acknowledge financial support from the China NSFC (No. 11874189) and U.S. DOE-BES (No. E-FG02-04ER46148). We also acknowledge DOE-NERSC and CHPC at the University of Utah for providing the computing resources.

T70.00381: Ion gating of the charge density wave order in two-dimensional NbSe2  
DIFEI ZHANG (Presenter), Physics, Nanjing University — Recent experimental advances in atomically thin transition metal dichalcogenide (TMD) metals have unveiled a range of interesting phenomena including the coexistence of charge-density-wave (CDW) order and superconductivity down to the monolayer limit. The atomic thickness of two-dimensional (2D) TMD metals also opens up the possibility for control of these electronic phase transitions by electrostatic gating. Here, with the ionic liquid gate we tune the carrier density in 2D NbSe2 with the expectation to bring up a CDW phase, which is detailedly characterized with the Raman spectroscopy. We also investigate the variation of CDW order with the change in carrier density and complement phase diagram of 2D NbSe2, including CDW order and superconducting phase.

T70.00382: A first principle investigation on the surface properties of β-Ga2O3 with a focus on the stability mechanism and electronic characteristics: GGA and hybrid DFT studies*  
SAJIB BARMAN (Presenter), MUHAMMAD NURUL HUDA, University of Texas at Arlington — β - Ga2O3 a transparent wide band gap semiconductor which has gained wide attention due to its suitability to a wide range of applications. Even though this is not a van der Waals material, it has shown that this material can be mechanically cleaved and exfoliated easily along favorable surfaces to make ultra-thin layers and used in device fabrications. One of the interesting properties of this material is that thin layers preserve the pristine bulk-like electronic properties, which makes it even more promising for applications in power devices. However, detail mechanism for such ultra-thin exfoliation is not known. Hence, a systematic study on the surface properties is essential. In this presentation, we have employed both GGA and HSE employed DFT to investigate surface properties. We are going to present our calculated surface stability, electronic band structures and electrons effective mass as a function of layer thickness for both (100)A and (100)B surfaces of this material. The understanding based on this study will provide a better control to fabricate thin film 2D devices.

*All the computational work was done at TACC in Austin, TX.
**T70.00383: Cross-plane thermal transport in SrRuO₃ thin films investigated by time-domain thermoreflectance technique**  
DOGYEOM JEONG (Presenter), YOUNGWAN CHO, HWIIN JU, Department of Physics and Photon Science, Gwangju Institute of Science and Technology, Korea, SUNGMIN WOO, WOO SEOK CHOI, Department of Physics, Sungkyunkwan University, Korea, JONGSEOK LEE, Department of Physics and Photon Science, Gwangju Institute of Science and Technology, Korea — A SrRuO₃ thin film has been widely used as a metal electrode in electronic devices based on transition metal oxides, and hence it is important to understand thermal transport properties through the SrRuO₃ thin film to minimize a thermal degradation problem during the device operation. Using the time-domain thermoreflectance measurement technique, we investigate the cross-plane thermal conductivity of the SrRuO₃ thin films with a thickness variation from 1 um to 8 nm. We find that the thermal conductivity becomes reduced from 5.0 W/m-K for the 1 um thick film to 0.94 W/m-K for the 8 nm thick film, and attribute such a large reduction of the thermal conductivity to the boundary scattering of thermal carriers, i.e., electron and phonon. In addition, we find a signature of the ballistic phonon transport at low temperature particularly when the film thickness becomes much smaller than the phonon mean free path.

**T70.00384: Nonlinear optical responses of Rashba spin-split GeTe thin films**  
SOON-HEE PARK (Presenter), JEONG GI CHO, CHANG JAE ROH, Gwangju Institute of Science and Technology, SEONG WON CHO, SUYOUN LEE, KIST, JONGSEOK LEE, Gwangju Institute of Science and Technology — Ferroelectric alpha-phase germanium telluride (α-GeTe) has been known to have a giant Rashba spin split band, and hence can be a promising material for the spintronic application. We prepare α-GeTe thin films on a Si substrate with a thickness variation from 2 to 100 nm, and investigate their structural and electrodynamic properties by using second harmonic generation (SHG) and terahertz emission spectroscopy. From the azimuth-dependent anisotropy observed in the SHG responses, we find that all the films have a non-centrosymmetric crystal structure identified as a 3m point group. From the THz emission results, we demonstrate that a fairly strong built-in field exists at the film interface with the Si substrate. In particular, we observe a non-negligible helicity-dependence in the THz emission which can be a possible signature of a spin-polarized photocurrent arising from the spin-split Rashba bands.

**T70.00385: METALS AND METALLIC ALLOYS**

**T70.00386: Imaging magnetic and non-magnetic metal nanostructures using a field emission SEM.**  
STEPHEN BLAMA (Presenter), Dept. of Physics Astronomy and Geosciences, Towson University, MARY SAJINI DEVADAS, Dept. of Chemistry, Towson University — An electron microscope can be used to image materials of nanoscale dimensions allowing for examination of size and shape characteristics, and chemical composition. We use an FEI Apreo scanning electron microscope to image magnetic (using electromagnetic mode) and nonmagnetic nanostructures (using electrostatic mode) of various metals (Au and Ag) and metal alloys (Fe/Co, Fe/Au) using different sample preparation methods, and varying system parameters for optimal image quality and resolution. Samples are prepared with spin coating followed by plasma cleaning, with controlled plasma composition. System parameters of spot size and accelerating voltage for different built-in detectors (ETD, EBSD, in-column BSD detectors, and STEM) are studied. Methods for obtaining optimal EDX maps are also investigated, as EDX is prone to sample charging and image drift due to extended exposure of the sample to the electron beam. Details of the imaging parameters and sample preparation for these nanostructures will be presented.

*We acknowledge funding from NSF MRI 1626326, Fisher Endowment Grant, Fisher Chair Grant and FDRC, GSA Research and travel grants and FCSM travel award from Towson University.

**T70.00387: Dynamic behavior of carbon in steel by using soft X-ray absorption spectroscopy and spectrum simulation**  
KAKERU NINOMIYA (Presenter), KAZUTAKA KAMITANI, Kyushu University, YUSUKE TAMENORI, KAZUKI TSURUTA, Japan Synchrotron Radiation Research Institute, TOSHIHIRO OKAJIMA, DAIKUKE YOSHIMURA, Kyushu Synchrotron Light Research Center, HIDEAKI SAWADA, KEISUKE KINOSHITA, Nippon Steel & Sumitomo Metal Corporation, MAIKO NISHIBORI, Kyushu University — The ferritic steel with supersaturated solid solution carbon remarkable increase in hardness by heat treatment (so-called aging) at low temperature. This has been considered to cause by the formation of the carbon cluster in ferritic steel.¹ In this study, we aimed to understand the low temperature aging behavior of low-carbon steel focusing on carbon atoms, and the chemical state and local structural changes of carbon in low-carbon steel with aging were observed by soft X-ray absorption spectroscopy. Furthermore, we tried to clarify the structure of carbon cluster from the observed absorption spectrum by first principles calculation and spectrum simulation. As a result, we succeeded in clarifying the relationship between microscopic chemical state and macroscopic hardness change. Furthermore, it was found that the chemical state of carbon related to form carbon clusters changes dynamically in the early stage of heat treatment. The results of the spectral analyses suggested that solid solution carbon was interacted with the vacancies in bcc lattice. Therefore, it is suggested that vacancies may play an important role in the formation of carbon clusters.

ASH (Presenter), Biology, Misericordia University, GOPAL VERMA, JEAN-PIERRE DELVILLE, LOMA, University of Bordeaux — Current compaction. Understanding this pathway has implications in biomaterial, epigenetic, and fertility research.

by protamine, we expect a change in the standard deviation of the DNA tether's movement due to further DNA microscopy, we track the motion of the bead and measure the length of the tether over time. When histones are replaced attached to a 1 μm “polystyrene bead on one end and is attached to a glass coverslip on the other. Using video study this phenomenon, we utilize a Tether Particle Motion (TPM) assay. In the TPM assay, a single DNA molecule is specifically, we are interested in reconstructing the direct histone-protamine replacement pathway that occurs in fish. To protected. In this study we aim to understand the mechanics of DNA condensation in the nucleus of sperm cells. More structure that is packed inside the nucleus. However, during human spermatogenesis approximately 85-90% of the histones in the DNA are replaced by an arginine rich protein called protamine. This allows for more efficient packaging of the DNA in the sperm cell. As a result, the sperm cell's movement is more hydrodynamic and the genetic material is protected. In this study we aim to understand the mechanics of DNA condensation in the nucleus of sperm cells. More specifically, we are interested in reconstructing the direct histone-protamine replacement pathway that occurs in fish. To study this phenomenon, we utilize a Tether Particle Motion (TPM) assay. In the TPM assay, a single DNA molecule is attached to a 1 μm “polystyrene bead on one end and is attached to a glass coverslip on the other. Using video microscopy, we track the motion of the bead and measure the length of the tether over time. When histones are replaced by protamine, we expect a change in the standard deviation of the DNA tether's movement due to further DNA compaction. Understanding this pathway has implications in biomaterial, epigenetic, and fertility research.

T70.00391: Creating a viscoelastic spectrum of aqueous polyacrylamide gel at varying concentrations* MICHELLE ASH (Presenter), Biology, Misericordia University, GOPAL VERMA, JEAN-PIERRE DELVILLE, LOMA, University of Bordeaux — Current methods to obtain microrheological measurements inside liquid materials hold the problem of contaminating samples with an internalized foreign particle, especially problematic for intracellular microrheological measurements. Optical interferometry solves this problem by allowing for pico- and nanoscale rheological measurements without coming into contact with the interior system of a sample. Aqueous polyacrylamide (PAAm), a non-Newtonian gel can be used as a model of a cell, mirroring the experimental setup needed to study cellular systems. With a simple setup, a high-power green pump laser is incident on a PAAm droplet, inducing droplet height deformation via radiation pressure, then detected by interferometry using a low-power red probe laser. Firing a pump laser pulse deforms the gel droplet height between maxima and minima, from which the viscosity is calculated. Comparison of our experimental viscoelastic data of PAAm at a single pulse and varying frequencies to literature values confirms an accurate viscoelastic spectrum of PAAm. Based on our measurements and the noninvasiveness of this technique, mechanical perturbation of a gel surface demonstrates possibility of replication for cellular measurements.

*National Science Foundation Grant PHY-1359195
Lehigh University
We propose a disordered ladder spin model which can be designed in a scalable cold atom setup at the hard-core boson limit to dynamically detect out-of-time order correlators (OTOC) and hence information scrambling. Our protocol utilizes the Hamiltonian sign reversal for the evolution backward in time by applying single spin gates successively. We study different limits of disordered Ladder-XY model with focusing on its OTOC behavior and level statistics. We show that in its chaotic limit, disordered ladder-XY model decays exponentially in early-time with power-law tails before its scrambling time and it demonstrates a range of lightcones due to local spin-spin interactions. Based on our results, one can observe how the ladder systems could be useful to understand and experiment information scrambling in the transition from well-studied 1D models to unexplored 2D models.

Session V01 DCMP: Frontiers of Topological Materials: Mostly Theory

2:30PM V01.00001: Magnetic quadrupole moment in higher order topological semimetals* JACOPO GLIOZZI (Presenter), College of William & Mary, MAO LIN, TAYLOR HUGHES, University of Illinois Urbana-Champaign — One characteristic feature of conventional two dimensional Dirac semimetals is the bulk orbital magnetic dipole moment (MDM), which is proportional to the energy separation of the bulk nodes, and manifests as boundary circulating currents. In this presentation, we instead consider the magnetic quadrupole moment (MQM) in the three dimensional higher order topological semimetals (HOTS). In contrast to all semimetals considered previously, the bulk energy bands of a HOTS could be gapped, and its surfaces form one (or half of a) two dimensional Dirac semimetal with surface Dirac nodes. By adding perturbations, an energy difference can be created between pairs of surface nodes. We show analytically and numerically that the nodal energy difference generates a bulk MQM and is associated with circulating hinge currents. We discuss possible experiments in solid state systems as well as in metamaterials to verify our predictions.

2:42PM V01.00002: 't Hooft anomalies in symmetry-enriched U(1) gauge theories* SHANGQIANG NING (Presenter), Institute for Advanced Study, Tsinghua University, LIUJUN ZOU, Department of Physics, Harvard University, MENG CHENG, Department of Physics, Yale University — The 3+1D U(1) gauge theory is the effective field theory of a three-dimensional U(1) quantum spin liquid, which is an exotic gapless phase with emergent gapless photon and also gapped fractionalized electric charges and magnetic monopoles. In the presence of global symmetries, these fractionalized excitations can transform in different fractionalization patterns, which can be captured by projective representations of the symmetry group. Symmetry properties of these gapped excitations determine the universal properties of a symmetric U(1) quantum spin liquid, as well as the nature of its proximate phases. However, certain patterns of symmetry fractionalization cannot be realized in strictly 3+1D . Instead, they can only be realized on the boundary of 4+1D symmetry-protected topological phases. This type of symmetry fractionalization patterns are referred to as possessing 't Hooft anomalies. We obtain the classification of the patterns of symmetry fractionalization in symmetry-enriched U(1) gauge theories, and, in particular, an explicit formula to determine the relevant 't Hooft anomalies in terms of the fractionalization patterns.

2:54PM V01.00003: Type-II Fracton Models with Gapped Boundaries DANIEL BULMASH (Presenter), University of Maryland, College Park, ARPIT DUA, Yale University, THOMAS IADECOLA, University of Maryland, College Park, DOMINIC WILLIAMSON, Yale University — Type-II fracton systems are exotic models whose pointlike excitations are strictly immobile at zero temperature and have locally indistinguishable degenerate ground states, and unusual error correction properties. We study gapped boundaries of such models, including Haah's code. After enumerating the set of possible gapped boundaries, we study the ground state degeneracy and logical operators in the presence of these boundaries. Although these properties are complicated on the torus, they simplify dramatically for certain open boundary conditions. We discuss the interpretation of the degeneracy in terms of surface line defects, i.e. the domain walls between distinct gapped boundaries.
3:06PM V01.00004: Variational Monte Carlo study on a magnetization process of the Kitaev honeycomb model under a magnetic field  KOTA IDO (Presenter), TAKAHIRO MISAWA, ISSP, University of Tokyo — Recently, the Kitaev model under a magnetic field has been intensively studied, because the magnetization processes offer useful information for characterizing the nature of the quantum spin liquid. It was reported that an intermediate state appears in the antiferromagnetic coupling Kitaev model (AF KM) under a magnetic field by several numerical methods such as Majorana mean field, exact diagonalization, and DMRG. However, these methods are not appropriate for highly accurate analyses of physical properties in the 2D system with large system sizes. To identify whether the intermediate state exists as the ground state of the AF KM under a magnetic field in the bulk limit, it should be necessary to use an accurate numerical method which is applicable to the large 2D system.
In this talk, we will report the magnetization process of the AF KM obtained by using the variational Monte Carlo (VMC) method. The trial wave function we used is the BCS wave function with the Jastrow correlation factor, which can exactly represent the ground state of the pure Kitaev model fermionized by the Jordan-Wigner transformation. We will also explain the details of VMC and its accuracy.

3:18PM V01.00005: Model of spin liquids with and without time-reversal symmetry  JYONG-HAO CHEN (Presenter), CHRISTOPHER M MUDRY, Condensed Matter Theory Group, Paul Scherrer Institute, CLAUDIO CHAMON, Boston University, ALEXEI TSVELIK, Brookhaven National Laboratory — We study a model in (2+1)-dimensional spacetime that is realized by an array of chains, each of which realizes relativistic Majorana fields in (1+1)-dimensional spacetime, coupled via current-current interactions. The model is shown to have a lattice realization in an array of two-leg quantum spin-1/2 ladders. We study the model both in the presence and absence of time-reversal symmetry, within a mean-field approximation. We find regimes in coupling space where Abelian and non-Abelian spin liquid phases are stable. In the case when the Hamiltonian is time-reversal symmetric, we find regimes where gapped Abelian and non-Abelian chiral phases appear as a result of spontaneous breaking of time-reversal symmetry. These gapped phases are separated by a discontinuous phase transition. More interestingly, we find a regime where a non-chiral gapless non-Abelian spin liquid is stable. The excitations in this regime are described by relativistic Majorana fields in (2+1)-dimensional spacetime, much as those appearing in the Kitaev honeycomb model, but here emerging in a model of coupled spin ladders that does not break SU(2) spin-rotation symmetry.

3:30PM V01.00006: Monolayer Mg2C: Negative Poisson's ratio and unconventional two-dimensional emergent fermions  SHAN-SHAN WANG (Presenter), SHENGYUAN YANG, Singapore University of Technology and Design — We analyze the phonon spectrum, reveal the Raman-active modes, and show that it has small in-plane stiffness constants. Particularly, the Mg2C monolayer shows an intrinsic negative Poisson's ratio $\sim -0.023$ along zigzag. The material is metallic at its equilibrium state. A moderate biaxial strain can induce a metal-semimetal-semiconductor phase transition, during which several types of 2D unconventional fermions emerge, including Dirac fermions, the 2D double Weyl fermions in the semimetal phase, and the 2D pseudospin-1 fermions around which three bands cross at a single point on the Fermi level. In addition, uniaxial strains along the high-symmetry directions break the threefold rotational symmetry and reduce the number of Dirac points. Interestingly, it also generates 2D type-II Dirac points. We construct effective models to characterize the properties of these fermions. Our result reveals Mg2C monolayer as an intriguing platform for the study of 2D unconventional fermions, and also suggests its great potential for nanoscale device applications.

3:42PM V01.00007: Unconventional Pairing Induced Anomalous Transverse Shift in Andreev Reflection  ZHI-MING YU (Presenter), YING LIU, Singapore University of Technology and Design, YUGUI YAO, Beijing Institute of Technology, SHENGYUAN YANG, Singapore University of Technology and Design — Superconductors with unconventional pairings have been a fascinating subject of research, for which a central issue is to explore effects that can be used to characterize the pairing. The process of Andreev reflection—the reflection of an electron as a hole at a normal-metal-superconductor interface—offers a basic mechanism to probe the pairing. Here we predict that in Andreev reflection from unconventional superconductors, the reflected hole acquires an anomalous spatial shift normal to the plane of incidence, arising from the unconventional pairing. The transverse shift is sensitive to the superconducting gap structure, exhibiting characteristic features for each pairing type, and can be detected as voltage signals. Our work not only unveils a fundamentally new effect with a novel underlying mechanism, but also suggests a possible new technique capable of probing the structure of unconventional pairings.
3:54PM V01.00008: Goos-Hänchen-like shifts at a metal/superconductor interface  YING LIU (Presenter), ZHI-MING YU, Engineering Product Development, Singapore University of Technology and Design, HUA JIANG, Soochow University, SHENGYUAN YANG, Engineering Product Development, Singapore University of Technology and Design — At a normal-metal/superconductor interface, an incident electron from the normal-metal (N) side can be normally reflected as an electron or Andreev reflected as a hole. We show that pronounced lateral shifts along the interface between the incident and the reflected quasiparticles can happen in both reflection processes, which are analogous to the Goos-Hänchen effect in optics. Two concrete model systems are considered. For the simplest model in which the N side is of the two-dimensional electron gas, we find that while the shift in Andreev reflection stays positive, the shift in normal reflection can be made either positive or negative, depending on the excitation energy. For the second model with the N side taken by graphene, the shift in Andreev reflection can also be made negative, and the shifts have rich behavior due to the additional sublattice pseudospin degree of freedom. We show that the shift strongly modifies the dispersion for the confined waveguide modes in an SNS structure. We also suggest a possible experimental setup for detecting the shift.

4:06PM V01.00009: Dynamical Localization and Delocalization in Floquet Systems*  TILEN CADEZ (Presenter), RUBEM MONDAINI, Beijing Computational Science Research Center, PEDRO D. SACRAMENTO, CeFEMA, Instituto Superior Técnico, Universidade de Lisboa, Portugal — We study the localization aspects of a kicked noninteracting one-dimensional quantum system of spinless fermions and a topological superconductor subject to either time-periodic or aperiodic pulses. The universality class of the transition from delocalized to localized regimes is studied in the case of time-periodic and spatially quasi-periodic kicks. In the case of aperiodic kicks, delocalization ultimately sets in and a diffusive spreading of an initial wave packet is obtained even for small time-aperiodicity of the driving. In the case of Floquet topological superconductors, one finds both Majorana and fermionic localized edge modes in the topological regime. In the intermediate driving period regime, one can identify a region in the phase diagram with a mobility edge between critical and localized states. Finally, we analyze the robustness of the Majorana modes to deviations on the driving period, finding they are stable in a small set of the parameters.

4:18PM V01.00010: Prethermalization and topological transport in slowly driven Floquet systems*  NETANEL LINDNER (Presenter), TOBIAS GULDEN, Physics, Technion - Israel Institute of Technology, EREZ BERG, Physics, Weizmann Institute of Science, MARK RUDNER, Physics, University of Copenhagen — Topological phenomena in periodically driven quantum many body systems are difficult to obtain due to the generic tendency of such systems to heat up and tend towards an infinite temperature-like state. We investigate a mechanism to transiently stabilize topological phenomena over a long-time window for systems driven at low frequencies. We derive an analytical bound for the rate of change in the number of particles populating the Floquet bands of the system. The bound is exponentially small in the ratio between the instantaneous bandgap and the maximum between the driving frequency, interaction strength, and the bandwidth. Within the resulting prethermal time window, a quasi-steady state is stabilized, characterized by maximum entropy density subject to the constraint of fixed number of particles in each band. This mechanism provides a route for obtaining long-lived prethermal states with anomalous topological properties, unattainable in equilibrium, such as universal chiral currents in one dimension and magnetoelectric transport in three dimensions.

4:30PM V01.00011: Bulk-edge correspondence of periodically driven 2D systems with time-reversal symmetry*  XU LIU (Presenter), FENNER HARPER, RAHUL ROY, Physics & Astronomy, University of California, Los Angeles — We propose an edge invariant for two-dimensional Floquet systems with time-reversal symmetry. This edge index is physically motivated and locally computable. In addition, we generalize an existing construction of a bulk invariant to systems with disorder. Finally, we derive a bulk-edge correspondence which relates the nontrivial bulk behavior with the edge modes present on a boundary at the end of the evolution. Our results provide the first bulk-boundary correspondence for Floquet systems in this symmetry class.

*Bhaumik Institute, NSF
4:42PM V01.00012: FLOQUET ENGINEERING OF EXCHANGE INTERACTIONS IN 2D MAGNETIC MATERIALS*  SWATI CHAUDHARY (Presenter), GIL REFAEL, DAVID HSIEH, California Institute of Technology — Periodic drive can be used to modify the spin exchange interactions in some magnetic materials. These effects arise mainly due to photon-assisted hopping and can be understood within the framework of periodically driven Fermi-Hubbard model. In real materials, these interactions are usually mediated by the non-magnetic ions, and many different channels are available for the exchange process. We take into account the presence of these ligand ions, and investigate the effects of the periodic drive on magnetic coupling strengths between different neighboring spins in transition metal trichalcogenides for a variety of exchange pathways available in these materials. Additionally, the strength of these interactions depends on the orbitals involved in the superexchange process. We also provide a novel method to control the exchange interactions by manipulating the properties of these orbitals with a periodic drive. In this case, the magnetic coupling strength is altered due to the AC stark shift of the states available for virtual excitations. We discuss two different orbital floquet engineering schemes involving the orbitals of ligand ions and the magnetic ions.

4:54PM V01.00013: Light driven magnetic and topological phase transitions in magnetic topological insulator thin films  XIAOYU LIU (Presenter), Institute for advanced study, Tsinghua University, PEIZHE TANG, HANNES HUEBENER, Max Planck Institute for the Structure and Dynamics of Matter and Center for Free-Electron Laser Science, DUAN WENHUI, Institute for advanced study, Tsinghua University, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter and Center for Free-Electron Laser Science — The external manipulation of the magnetism in topological materials would be important both for fundamental interests and practical applications. Herein, we predict that topological and magnetic properties in magnetically doped topological insulator thin films can be well tuned by the laser field. With increasing the strength of the circularly polarized laser (CPL), we can observe a topological phase transition in such system. Remarkably, the CPL could even induce the magnetic phase transition driving thin films from ferromagnetism to paramagnetism. Its critical behavior strongly depends on the quantum quenching, indicating that different Curie temperatures can be observed in different time scales and experimental setups. Furthermore, we propose an all-optical transistor device in which the on-off signal from polar Kerr-rotation angle can be controlled by the applying laser field. Our discoveries not only deepen our understanding of the relationship between topology and magnetism in the magnetic topological insulator in the non-equilibrium regime, but also extend optoelectronic device applications in topological materials.

5:06PM V01.00014: Stability of Periodically Driven Topological Phases against Disorder*  RAMIS MOVASSAGH (Presenter), IBM Thomas J. Watson Research Center, OLES SHTANKO, Physics, Massachusetts Institute of Technology — Time-dependent periodic fields are used to create exotic topological phases of matter with potential applications ranging from quantum transport to quantum computing. These nonequilibrium states, at high driving frequencies, exhibit the quintessential robustness against local disorder similar to equilibrium topological phases. However, proving the existence of such topological phases in a general setting is an open problem. We propose a universal effective theory that leverages on modern free probability theory and ideas in random matrices to analytically predict the existence of the topological phase for finite driving frequencies and across a range of disorder. We find that, depending on the strength of disorder, such systems may be topological or trivial and that there is a transition between the two. In particular, the theory predicts the critical point for the transition between the two phases and provides the critical exponents. We compare with exact diagonalizations for driven-disordered 1D Kitaev chain and 2D Bernevig-Hughes-Zhang models and find excellent agreement. This Letter may guide the experimental efforts for exploring topological phases.

5:18PM V01.00015: Surface Acoustic Wave Study in Microwave-Induced Non-Equilibrium Electron System  JIANLI WANG, International Center for Quantum Materials, Peking University, CHI ZHANG (Presenter), SKLSM, Institute of semiconductors, Chinese Academy of Science, LOREN PFIEFFER, KENNETH WEST, K. W. BALDWIN, Electrical Engineering, Princeton University — Microwave-induced resistance oscillations (MIRO) and zero-resistance states (ZRS) occur under microwave irradiation in the ultrahigh mobility two-dimensional electron gas (2DEG) in GaAs/AlGaAs quantum wells (QW). We employed the surface acoustic wave (SAW) to study the structure of MIRO and ZRS. We observe that the velocity shift ($\Delta v/v$) shows minima at the peak resistance regime ($j = \omega/\omega_C \sim 1, 2, 3, \text{etc}$). And in the ZRS regime, an increase of the velocity shift appears at $j = 5/4$. The results conform to the theoretical and experimental studies of current domains at ZRS under high power microwave.

Thursday, March 7, 2019 2:30 PM - 5:18 PM
2:30PM V02.00001: Pressure Induced Fermi Surface in Sb$_2$Se$_3$ *

UMA GARG (Presenter), NATHANIEL SMITH, WILLIAM CHRISTOPHER REXHAUSEN, Department of Physics, University of Wisconsin Milwaukee, Wisconsin 53211, AUDREY GROCKOWIAK, ALEXEY SUSLOV, STANLEY W TOZER, National High Magnetic Field Laboratory, Tallahassee, Florida 32310, PRASENJIT GUPTASARMA, Department of Physics, University of Wisconsin Milwaukee, Wisconsin 53211 — Studies of a new class of Topological Insulators, believed to be a new quantum phase of matter with a 2-dimensional Fermi surface, have led to a search for other insulators or semi-metals in which topologically non-trivial properties can be tuned using a chemical, structural, or external thermodynamic parameter. Here, we report studies of Shubnikov-de Haas oscillations as a function of pressure and magnetic field orientation on single crystals of antimony selenide (Sb$_2$Se$_3$). Sb$_2$Se$_3$ is a band insulator with a 1 eV bandgap under ambient conditions; it is metallic above 3 GPa, and superconducting above 10 GPa. Our Sb$_2$Se$_3$ single crystals are orthorhombic, unlike rhombohedral Bi$_2$Se$_3$ and Sb$_2$Te$_3$. Following up on our previous collaborative studies of Raman spectroscopy and first-principles DFT, which revealed an electronic topological transition (ETT) with pressure, we performed non-contact conductivity measurements using a tunnel diode oscillator (TDO) circuit under high pressure in a diamond anvil cell. A Fermi Surface (FS) is found to appear at 6.4 GPa. We also find evidence for a Berry phase ($\beta$) of value $\pi$ independent of magnetic field orientation, indicating possible non-trivial topologies.

2:42PM V02.00002: Electronic Transport Properties of few-layer PdTe$_2$

GUIXIN CAO (Presenter), RUOYU CHEN, DONGYING WANG, MARC BOCKRATH, CHUN NING LAU, Ohio State University — The interplay of superconductivity and topological states in layered transition-metal dichalcogenide materials have attracted much attention due to their possible promise to realize topological superconductors. PdTe$_2$ is one of such compounds that exhibit coexistence between two-dimensional superconductivity and topological states. We report experimental investigations on the electrical transport and magnetic properties of mechanically exfoliated single crystal PdTe$_2$ bulk and few layers. Latest data as function of layer thickness, temperature and magnetic field will be reported.

2:54PM V02.00003: Observation of Quantum Oscillations in PdTe$_2$ Single Crystals

RAMAKANTA CHAPAI (Presenter), Louisiana State University, DAVID E GRAF, National High Magnetic Field Lab, Tallahassee, FL, JOHN DITUSA, RONGYING JIN, Louisiana State University — Transition-metal dichalcogenide PdTe$_2$ exhibits superconductivity and topologically non-trivial surface states. Here, we present a detailed study of the de-Haas van Alphen (dHvA) oscillations in single crystalline PdTe$_2$. In analyzing the magnetic field dependence of the magnetization and magnetic torque, we identify two frequencies from the oscillations: $F_\alpha = 8$ T and $F_\beta = 117$ T. Using the Lifshitz-Kosevich equation to fit experimental data, the effective masses are obtained with $m^*_\alpha = 0.059m_0$ and $m^*_\beta = 0.067m_0$ ($m_0$ is the free electron mass). Further analysis of the dHvA oscillations reveals that the $\alpha$ band possesses a non-trivial Berry phase (~ 0.94$\pi$) while the $\beta$ band consists of a smaller Berry phase (~ 0.32$\pi$). This indicates that the $\alpha$ band is likely responsible for the topological properties.

3:06PM V02.00004: Surface Repair and Passivation of InAs Quantum Wells with ALD*

SEBASTIAN PAUKA (Presenter), JAMES WITT, School of Physics, Univ of Sydney, CIOFFI NICOLE MURPHY, Microsoft Station Q Sydney, GEOFFREY C. GARDNER, SERGEI GRONIN, TIAN WANG, CANDICE THOMAS, MICHAEL MANFRA, Microsoft Station Q Purdue, DAVID REILLY, MAJA C CASSIDY, Microsoft Station Q Sydney — The two-dimensional electron gas formed in InAs quantum wells and proximitized with epitaxially grown Aluminium has attracted interest as a possible host for Majorana zero modes. This is due to the strong spin-orbit coupling and large Landé g-factor in this material. However, the need to induce superconductivity in the quantum well requires it to be grown close to the surface (~12nm), making the 2DEG highly sensitive to any processing. In particular, the aluminium etch, typically a Transene-based wet etch, has limited measured mobility in InAs quantum wells.

In this work, we report on the use of Al$_2$O$_3$ grown by ALD, with in-situ surface pre-treatment via TMA pulses or an Ar/H plasma, to repair and passivate the surface after processing, and demonstrate the reduction of charged surface states. We show that by this method, we are able to enhance the measured carrier mobility of these devices up to ~45000 cm$^2$/V s. Finally, the spin orbit length is extracted as a function of density, controlled using a global top-gate, to determine spin-scattering mechanisms. Our results provide a path towards high quality, shallow 2DEG-based Majorana devices.

*This work was supported by funding from Microsoft Station Q.
3:18PM V02.00005: Core-Shell Nanowires of 3D Topological Insulators  KEVIN GEISHENDORF (Presenter), Leibniz IFW and TU Dresden, TOMMI PAAVO TYNELL, Leibniz IFW, KORNELIUS NIERSCH, Leibniz IFW and TU Dresden, ANDY THOMAS, Leibniz IFW — Topological insulators (TI) are promising candidates for next generation electronic/spintronic devices. The gapless surface states (SS) in TI exhibit a very high mobility and strongly suppressed backscattering due to spin-momentum locking. However, to exploit those advantageous one has to decrease the finite bulk conductance present in most TI systems.

One approach to achieve this reduction is to utilize band bending which occurs at the interface between two materials with different Fermi levels. The band bending leads to a charge depletion/ or accumulation near the interface. It therefore provides a tool to shift the fermi energy closer to the Dirac point.

In this work, we have grown core-shell NW using Vapor-Liquid-Solid (VLS) growth and Atomic Layer Deposition (ALD). As core material Bi2Se3 and as shell materials Al2O2 and Sb2Te3 were employed. The uniformity, crystallinity and composition of those core-shell NW was investigated using transmission electron microscopy, nanodiffraction and EDX. Furthermore, devices for transport experiments were built using optical lithography and lift-off techniques. With those devices magneto transport measurements have been performed revealing quantum interference effects such as weak-antilocalization and universal conductance fluctuations.

3:30PM V02.00006: Measurement of g-factor in InAs and InAs0.5Sb0.5 Surface Quantum Wells* MEHDI HATEFIPOUR (Presenter), JOSEPH YUAN, WILLIAM ANDREW MAYER, KAUSHINI WICKRAMASINGHE, Physics, New York University, WENDY L. SARNEY, STEFAN P. SVENSSON, US Army Research Laboratory, JAVAD SHABANI, Physics, New York University — The rising interest into topological superconductors has led to the exploration of hybrid superconductor-semiconductor structures. In these structures two dimensional electron gases are confined near surface and can make epitaxial contact to superconducting thin films. Large Zeeman splitting and spin orbit coupling are necessary ingredients to look for when choosing the semiconductor. Here we present findings of our experiments on two prime candidates with strong spin orbit interaction and high g-factor: InAs and InAs0.5Sb0.5. We measure weak anti-localization signal and integer quantum hall energy gaps as a function of carrier density in near surface quantum wells of both materials. We use fitting of weak anti-localization to determine strength of spin orbit interaction and the energy gaps of odd Integer quantum Hall states (v=3 and v=5) to extract g-factors.

*We acknowledge support for this research from NSF and Darpa TEE.

3:42PM V02.00007: Current-induced nuclear spin polarization effects in Bi(111) film flakes with strong spin-orbit interaction* ZIJIAN JIANG (Presenter), VICTORIA SOGHOMONIAN, JEAN HEREMANS, Physics Department, VIRGINIA POLYTECHNIC INSTITUTE — The influence on quantum transport of nuclear spin polarization, induced by hyperfine interactions and the Edelstein effect, was investigated in individual micrometer-size 40 nm thick Bi(111) film flakes. The flakes were obtained by exfoliation and PDMS stamping from epitaxial Bi(111)-on-mica films. The growth method will be discussed. AFM and SEM micrographs of the Bi(111) film clearly show micrometer-size triangular structured islands with 0.4 nm step height (Bi(111) bilayer height). At low temperatures a high current density is applied to generate nonequilibrium carrier spin polarization by the Edelstein effect, which then induces nuclear polarization by hyperfine interactions and dynamic nuclear polarization. The low-temperature quantum transport measurements are carried out both before and after the current application. The quantum phase coherence time and the spin-orbit scattering time are obtained by fitting of weak-antilocalization magnetotransport data. In our Bi(111), the phase coherence time and the spin-orbit scattering time show a dependence on the nuclear spin polarization obtained by hyperfine interactions with the spin-polarized carriers, in turn obtained by the Edelstein effect.

Topological Hall Effect in Dual-gated Magnetic Topological Insulator Heterostructures

XIAO (Presenter), DI XIAO, JUE JIANG, MORTEZA KAYYALHA, JAE HO SHIN, FEI WANG, LING ZHANG, JIANXIAO ZHANG, CHAOXING LIU, MOSES H W CHAN, CUI-ZU CHANG, NITIN SAMARTH

Physics, Penn State University

Magnetic chiral spin textures in real space serve as excellent model systems for fundamental studies of Berry curvature physics. The interaction of itinerant charge carriers with chiral spin textures induces an excess Hall voltage known as a ‘topological Hall (TH) effect,’ providing an indirect signature of non-trivial spin textures in transport measurements. Here, we report the observation of a possible TH effect in a heterostructure that sandwiches a topological insulator (TI) layer in between two magnetic TI layers. By varying the chemical potential using top and bottom gates, we map out the behavior of the TH effect and show that it is greatly enhanced when the chemical potential difference between the two surfaces is increased. This observation suggests that the excess Hall voltage is a result of a finite Dzyaloshinskii-Moriya interaction induced by the magnetization asymmetry in two magnetic layers. Apart from providing new insights into the TH effect, our study paves a new route for demonstrating proof-of-concept topological spintronic devices that rely on the interplay between momentum- and real-space spin textures.

Surface State Transport in 3D Topological Insulators

NADYA MASON (Presenter), University of Illinois at Urbana-Champaign

In this talk, I will discuss transport measurements of the topological surface state of the 3D TI Bi2Se3. By carefully configuring devices and controlling doping levels, we are able to demonstrate the unique properties of surface transport. In particular, we show that the supercurrent flows primarily through surface states in TI-superconductor junctions, that there is ballistic surface transport in nanowires exhibiting Aharonov-Bohm effects, and that finite momentum shifts of Cooper pairs is evident in superconducting junctions studied via Fraunhofer spectroscopy.

Accessing the intrinsic spin transport in a topological insulator with a four-probe scanning tunneling microscope

WONHEE KO (Presenter), GIANG NGUYEN, HOIL KIM, JUN SUNG KIM, AN-PING LI, XIAOGUANG ZHANG

Center for Nanophase Materials Sciences, Oak Ridge National Laboratory

The electrical transport through topologically protected surface states in topological insulators is expected to exhibit superior mobility from prohibited backscattering and spin-polarized current from spin-momentum locking. However, access to the intrinsic transport properties of surface states remains an experimental challenge, due to the extrinsic effects such as device geometry and environmental contaminations. Here, we directly access the intrinsic surface conductance of topological insulators by using a four-probe scanning tunneling microscope to tune the crossover of bulk-to-surface conductance. By controlling the probe-spacing and temperature, we realize 100% surface conductance on the bulk single crystal of Bi2Te2Se. It allows us to measure more than an order of magnitude higher surface carrier mobility than the bulk, and a spin polarization approaching theoretically predicted value. A scattering-free spin transport is revealed at micrometer scale through topological surface states. In this manner, we achieve a direct and quantitative measurement of the intrinsic spin-polarized transport associated with topological surface states.

This work is supported by 2DCC-MIP (DMR-1539916), DOE (DE-SC0019064 and DE-SC0019331), ONR (N00014-15-1-2370), and the Alfred P. Sloan Research Fellowship.

This research was performed at the Center for Nanophase Materials Sciences which is a DOE Office of Science User Facility.
4:54PM V02.00011: Acoustic Polaron on the Surface of Topological Insulators  JIANTAO KONG (Presenter), ALEXANDER SHVONSKI, KRZYSZTOF KEMPA, Boston College — We report a plasmon-polaron mode of a 2D electron gas occupying the surface states of a 3D topological crystal. This new, low-frequency, acoustic plasmon mode splits-off from the conventional spin-plasmon mode [1], as a result of the strong interactions between surface electrons and bulk phonons. We show that, like in the case of the conventional spin-plasmon, the scattering of this mode is strongly suppressed in some regions of the phase space. This signature of the topological protection leads to an Umklapp-free mode dispersion at the Brillouin zone boundary. Such a plasmon-polaron mode has indeed been recently observed in the topological metal Be 2 Se 3 [2].

5:06PM V02.00012: Energy Dependence of the Photogalvanic Effect in a Bi$_2$Se$_3$ Nanoflake Device* SEYYEDESADAF POURNIA (Presenter), GIRIRAJ JNAWALI, HOWARD E JACKSON, LEIGH SMITH, Department of Physics, University of Cincinnati, RYAN NEED, STEPHEN WILSON, Materials Department, University of California, Santa Barbara — Bi$_2$Se$_3$ is a prototypical topological insulator exhibiting gapped bulk states with topologically protected conducting surface states. Here we study the linear photogalvanic effect (LPGE) in a Bi$_2$Se$_3$ nanoflake device as a function of energy from 0.3 to 1.8 eV. At 800 nm (1.5 eV) with the laser polarized parallel to the current, we measure a positive or negative response when the laser excitation is close to one of the contacts. Fixing the laser at the peak response, we measuring the energy dependence of the LPGE as we scan from 0.3 eV to 1.8 eV. Peaks are seen at 0.35 eV, and other higher lying optical transitions. We modulate the 800 nm excitation laser between left and right circularly polarized light observing, when current flows, positive and negative peaks at the edge of the nanosheet in line scans, consistent with a spin-Hall effect.

Session V03 DCMP GMAG: Topological Spin Liquids BCEC 107B - Etienne Lefrancois, Universite de Sherbrooke

2:30PM V03.00001: Solvable 3D classical statistical models and a spin-fermion mapping ZHIYUAN WANG (Presenter), KADEN R A HAZZARD, Rice University — In this talk, I will describe an exactly solvable classical statistical model on a 3D lattice. The model has two classical topological phases (one of which has been introduced previously [1]), and a finite-temperature phase transition between them. In contrast to prior 3D solvable statistical models [2], our system is much simpler, yet does not trivially reduce to a 2D model, and thus displays genuinely 3D correlations. Excitingly, this provides the first exactly solvable model in which to explore genuinely 3D critical phenomena; a caveat, however, is that the model Hamiltonian has imaginary terms. The construction and solution of this model are the first application of a new method that we introduce, developing ideas of [3], to map between a locally interacting fermionic Hamiltonian and a locally interacting spin Hamiltonian, in arbitrary dimension, in a simple way based on the use of algebraic isomorphisms. We expect that the spin-fermion mapping can be used not only for exact solutions, but for other applications such as numerical algorithms or perturbative calculations.

Higher Order Bosonic Topological Phases in Spin Models

OLEG DUBINKIN (Presenter), TAYLOR HUGHES, Department of Physics and Institute for Condensed Matter Theory, University of Illinois at Urbana-Champaign — Motivated by the recent discovery of the higher order topological phases in the fermionic systems we propose a natural extension of these phases to bosonic systems. We discuss two bosonic models for a second-order topological phase protected by a global $Z_2 \times Z_2$ symmetry. One model is built from layers of an exactly solvable cluster model for a one-dimensional $Z_2 \times Z_2$ topological phase. The other is built from more conventional spin-couplings (XY or Heisenberg) and repeats the structure of the quadrupole model. These models host gapped, but topologically protected, edges, as well as protected corner modes that fall into a projective representation of the symmetry. Using Jordan-Wigner transformations we show that our models are both related to a bilayer of free Majorana fermions that form a fermionic second-order topological phase. In fact, the XY model was shown to be in exact correspondence with the fermionic Quadrupole model. We also discuss possible extension to 3D bosonic models for 2nd and 3rd order topological phases.

The Cyclotron resonance as a smoking gun for U(1) spin liquids with gapless fermions

PENG RAO (Presenter), INTI SODEMANN, Max Planck Institute for the Physics of Complex Systems — Certain U(1) spin liquids with gapless neutral fermions are expected to have the mind-boggling property that their optical conductivity vanishes as a power law of frequency. Thus, they are insulators to DC electric fields but without a "hard" optical gap, allowing them to absorb light at low frequencies. Additionally, they can also develop Landau levels in a magnetic field. In this work, we show that they can also have cyclotron resonance peaks in their optical spectrum analogous to metals, even though they are charge insulators. Interestingly, we have found that in contrast to metals, the principal Kohn harmonic of the cyclotron resonance is missing. The cyclotron resonance could therefore serve as a beautiful smoking gun test for the existence of these states which have been proposed in 2D organic materials and SmB$_6$.

A Microscopic Definition of the F-symbol

KYLE KAWAGOE (Presenter), MICHAEL LEVIN, University of Chicago — The theory of anyons is a powerful tool for studying interacting topological phases of matter in two spatial dimensions. In this approach, topological phases are characterized by the properties of their anyonic excitations --- in particular, the statistical phases associated with braiding or fusing anyons. Some of these statistical phases, however, are missing a precise definition that would allow for their computation from a microscopic Hamiltonian. In this talk, we will address this issue by giving a microscopic definition of the “F-symbol” --- one of the most poorly understood pieces of data that characterize anyons. We will show that our definition is consistent with known values of the F-symbol and can easily be applied to new systems as well.

*We thank the NSF for their support of this work under grant NSF DMR-1254741.

Symmetric gauge theories and Lieb-Schultz-Mattis-type constraints

XU YANG (Presenter), YING RAN, Boston College — It is known that certain symmetric gauge theories can only exist on the surface of a higher dimensional symmetry protected topological (SPT) state, in which case the symmetric gauge theory is anomalous. The anomaly class of such a gauge theory is represented by the bulk SPT index. Given an anomaly class, what kind of the symmetric gauge theories are allowed? Based on physical arguments and tensor-network constructions, we point out a sharp mathematical relationship between the symmetry properties of Abelian gauge theories and the anomaly class: the cup product. When the physical system hosts Lieb-Schultz-Mattis-type constraints, which is a specific type of anomaly class, our result sharply determines the physically allowed symmetric gauge theories via the preimage of the cup product. As applications, we algebraically compute the physically allowed skyrmion quantum numbers in various Neel states in 2+1D, and gauge charge/monopole projective representations in U(1) quantum spin liquids in 3+1D. We also compute the allowed Z2 gauge theories in several 2+1D quantum spin systems.

*XY and YR acknowledge support from the National Science Foundation under Grant No. DMR-1712128.
3:30PM V03.00006: A model of symmetry enriched topological phases and its symmetry breaking gapped boundaries* BOWEN SHI (Presenter), YUANMING LU, Ohio State University — We present a model of symmetry enriched topological phases (SET) based on the toric code model, with symmetry group being the tensor product of translation and a $Z_2$ onsite unitary symmetry. The symmetry does not permute anyon types and the model is in a nontrivial symmetry fractionalization class. We also discuss a gapped boundary with spontaneous symmetry breaking (SSB). This boundary condenses an anyon in the usual way, and the excitations at the boundary are domain walls. A domain containing an even number of effective spins could be created locally and a domain with an odd number of effective spins carry m charge. On a cylinder with an odd circumference, the $Z_2$ symmetry permutes the minimal entangled states (MESs). A boundary with odd circumference could absorb an m by flipping all its effective spins. This leads to a correlation of symmetry breaking sectors at the boundary to the bulk MES sectors.

*This work is supported by the National Science Foundation under Grant No. NSF DMR-1653769.

3:42PM V03.00007: Gapped Boundaries of (3+1)-Dimensional Gapped Quantum Liquids FAROOGH MOOSAVIAN, HEIDAR MORADI, Perimeter Institute, APOORV TIWARI (Presenter), Department of Physics, University of Zurich — We study gapped boundaries of $3+1$ gapped quantum liquids with topological order. From a field-theory perspective, we derive a generalization of the concept of Lagrangian subgroups to $3+1d$ and discuss properties of condensed and confined operators. More generally, we show that for a general $3+1d$ topological order defined by a 2-group $G$, the gapped boundaries are labeled by $(\mathbf{H}, \psi)$ such that $\mathbf{H}$ is a 2-subgroup of $G$ and $\psi$ is a cohomological twist. We interpret both these pieces of data physically. We study string and particle like excitations for gapped boundary theories and differentiate between anomalous and non-anomalous boundaries. Finally we study domain walls between two different boundaries.

3:54PM V03.00008: Thermal Transport Study of the Dimerized Quantum Magnet Strontium Copper Borate* COLIN TINSMAN (Presenter), ZIJI XIANG, LU CHEN, DMITRI MIHALIOV, Physics, University of Michigan, SARA HARAVIFARD, Physics, Duke University, LU LI, Physics, University of Michigan — Strontium Copper Borate (SrCu$_2$(BO$_3$)$_2$, or SCBO) has a unique crystal structure in which pairs of copper atoms with spin-1/2 states hybridize to form spin-1 dimers, making it a realization of the Shastry Sutherland model. This compound has a singlet ground state at each dimer separated by an energy gap from a triplet excited state. It is predicted that this system should contain topologically-protected edge states consisting of itinerant triplets known as triplons, making SCBO a bosonic topological insulator. Since these triplons do not carry charge, thermal measurements are required to observe them. We report on the field-dependent thermal conductivity of this material as well as our progress in observing triplon states using the thermal Hall effect.

4:06PM V03.00009: Entanglement Spectra of Stabilizer Codes: A Window into Fracton Order and Sub-System Symmetry Protected Topological States* ALBERT SCHMITZ (Presenter), SHENG-JIE HUANG, University of Colorado, Boulder, ABHINAV PREM, Princeton University — We discuss the entanglement spectrum (ES) for stabilizer Hamiltonians with arbitrary weak local perturbations to contrast the entanglement features of gapped topological phases. In particular, we compare fracton order to both conventional topological order and sub-system symmetry-protected topological (SSPT) order. Our results show that non-local surface stabilizers (NLSS)—a set of symmetries of the Hamiltonian formed along the boundary of the entanglement cut—protect the universal non-local features of the ES. In conventional topological and fracton orders, some NLSS retain a form of topological invariance, whereas subsystem symmetric systems—fracton and SSPT phases—show a non-trivial geometric dependence corresponding to the sub-system symmetries. This demonstrates the interplay of geometry and topology in fracton phases as encoded in the ground states of the phase. We further show a version of the edge-entanglement correspondence in three dimensions.

*The authors acknowledge support from the Air Force Office of Scientific Research under award number FA9550-17-1-0183, the U.S. Department of Energy, Office of Science, Basic Energy Sciences (BES) under Award number DE-SC0014415 and the Princeton Center for Theoretical Science at Princeton University.
α-RuCl₃ and other materials with Kitaev spin interactions are thought to be proximate to spin liquid phases although they exhibit magnetic order under normal conditions. An important question is thus what features in the spectral function seen in neutron and THz spectroscopy can be understood as precursors of the nearby spin liquid. We address this question by using a simplified model: a strongly-anisotropic Kitaev honeycomb model supplemented by Ising interactions. In certain limits this model is exactly solvable and shows a topological transition with reduced dimensionality. Using numerical simulations and perturbation theory we extend our conclusions to the more generic situation.

Classification of Symmetry Enriched Topological Phases Under Spatial Groups Interchanging Anyons* TIANFU FU (Presenter), ANDRIY NEVIDOMSKYY, Department of Physics and Astronomy, Rice University, FIONA BURNELL, Department of Physics, University of Minnesota Twin Cities — Symmetry classification of 2d topologically ordered phases, such as topological spin liquids, has received much attention in the past. Previous works have focused on the trivial group action, where symmetries (spatial or internal) do not exchange the anyons. In this work, we extend classification to cases where the group action is nontrivial so that a subset of symmetry elements exchanges the anyon types. We formulate a general framework, based on the theory of group extensions, and apply it to the Z₂ topological phases considering the 17 2d space groups under all possible nontrivial group actions. We demonstrate that the symmetry localization is no longer possible, meaning that two-particle symmetry operations cannot be written as a direct product of the one-particle actions. Moreover, because the anyons are exchanged by the symmetry group, it is no longer possible to discuss symmetry fractionalization that would assign a symmetry class for each anyon independently, and instead projective representations of different anyon types become intertwined. We show that the symmetry classification can nevertheless be formulated in a mathematical rigorous way, and prove its application to the Wen plaquette model on a square lattice as a special case.

Foliated Quantum Field Theory of Fracton Order and String-Membrane-Net Condensation* KEVIN SLAGLE (Presenter), Physics, Caltech, DAVID AASEN, University of California, Santa Barbara, DOMINIC WILLIAMSON, Yale University — Foliated fracton order is a new kind of phase of matter which is similar to topological order, but where a layered structure, referred to as a foliation, plays an essential role (in addition to topology) and determines the mobility restrictions of the topological excitations characteristic of fracton phases. I will introduce a new kind of field theory to describe these phases: a foliated field theory. I will also introduce a new string-membrane-net condensation picture of these phases, which is analogous to the string-net condensation picture of topological order.

Thermal Hall effect in the quantum spin liquid candidate α-RuCl₃ ETIENNE LEFRANCOIS (Presenter), GAEL GRISSONNANCHE, University of Sherbrooke (Canada), PAULA J KELLEY, University of Tennessee (Knoxville, USA), CHRISTIAN BALZ, JIAQIANG YAN, Oak Ridge National Laboratory (USA), DAVID GEORGE MANDRUS, University of Tennessee (Knoxville, USA), STEPHEN NAGLER, Oak Ridge National Laboratory (USA), LOUIS TAILLEFER, University of Sherbrooke (Canada) — Kasahara et al. have reported the observation of a quantized thermal Hall conductivity κₓᵧ in the Kitaev spin-liquid candidate α-RuCl₃ at low temperature, when antiferromagnetic order is suppressed with an in-plane magnetic field [1]. The reported magnitude of κₓᵧ / T is consistent with the quantized value expected from topologically protected chiral edge currents of charge-neutral Majorana fermions [2]. If confirmed, this is major advance in the physics of quantum spin liquids. Given that the magnitude of both κₓᵧ and the longitudinal thermal conductivity κₓₓ varies greatly from sample to sample [3,4], we report further measurements of heat transport in α-RuCl₃, with the aim of shedding light on the factors responsible for this considerable variability.

5:06PM V03.00014: Electrical probes of the non-Abelian spin liquid phase in α-RuCl₃*  DAVID AASEN (Presenter), Kavli Institute for Theoretical Physics, University of California, Santa Barbara, ROGER MONG, Physics, University of Pittsburgh, BENJAMIN MATTHEW HUNT, Physics, Carnegie Mellon University, DAVID GEORGE MANDRUS, Department of Materials Science and Engineering, University of Tennessee, JASON ALICEA, Physics, California Institute of Technology — Recent thermal-transport experiments indicate that the Kitaev material α-RuCl₃ realizes a non-Abelian spin liquid with Ising topological order over a range of magnetic fields. We propose a series of measurements for electrically detecting the hallmark chiral Majorana edge states and bulk anyons in the spin-liquid phase — despite the fact that α-RuCl₃ is a good Mott insulator. In particular, we introduce circuits that exploit interfaces between electronic systems and α-RuCl₃ to convert physical fermions into emergent fermions, thus enabling analogues of transport probes of non-Abelian-anyon physics in topological superconductors. We further propose detection of individual bulk neutral fermions via a spin counterpart of charge sensing. Our results illuminate a partial pathway towards using Kitaev materials for topological quantum computation.

5:18PM V03.00015: Thermal Hall effect in square-lattice spin liquids*  RHINE SAMAJDAR (Presenter), Department of Physics, Harvard University, SHUBHAYU CHATTERJEE, Department of Physics, University of California, Berkeley, MATHIAS SCHEURER, SUBIR SACHDEV, Department of Physics, Harvard University — The extension of the notion of a topology-driven Hall effect to charge-neutral excitations has been an exciting theoretical development. Motivated by recent experimental observations in high-Tc cuprate superconductors in a magnetic field, we study the thermal Hall conductivity in materials with topological order, focusing on the contribution from the deconfined neutral gapped spinons in the insulating state. More specifically, we examine different Schwinger-boson mean-field ansätze for the Heisenberg antiferromagnet on the square lattice, allowing for both Dzyaloshinskii-Moriya interactions and additional terms that break time-reversal and reflection symmetries but preserve their product. We show that the bosonic bands acquire nontrivial Chern numbers and evaluate the thermal Hall coefficient. On top of a significantly enhanced conductivity, which should yield a sizable experimental signal, we also observe an anomalous contribution.

Session V04 DMP DCOMP: Dielectric & Ferroic Oxides -- Structure, Phase Stability, and Competition II  BCEC 107C - Cyrus Dreyer, Stony Brook University - Tag(s): Focus

2:30PM V04.00001: Nature of the Phase Transitions Leading to Hybrid Improper Ferroelectricity in Ca₃X₂O₇*  SIZHAN LIU, HAN ZHANG, New Jersey Institute of Technology, SANJIT GHOSE, Brookhaven National Laboratory, MALI BALASUBRAMANIAN, Argonne National Laboratory, ZHENXIAN LIU, Brookhaven National Laboratory, SUYIN GRASS WANG, YUSHENG CHEN, Argonne National Laboratory, BIN GAO, JAEWOOK KIM, SANG-WOOK CHEONG, Rutgers University, ELIZABETH NOWADNICK, TREvor TYSOn (Presenter), New Jersey Institute of Technology — Detailed structural and optical measurements reveal that the tilt and rotation distortion relative to the high symmetry phase driving ferroelectricity in the system Ca₃X₂O₇ (X=Mn and Ti) condense at different temperatures. The condensation of the rotation and tilt distortions at distinctly different temperatures is unexpected. Experimental results, combined with DFT simulation of the atomic force constants, suggest that this loss of a polar state is driven by the relative strength of the A-O bonds to the X-O bonds. Raman measurements under isotropic pressure are used to assess the stability of the tilt and rotational distortions.

*This work is supported by NSF Grant No. DMR-1809931.
Lattice dynamics of hybrid improper ferroelectric (Ca,Sr)3Ti2O7*
DIPANSHU BANSAL (Presenter), Mechanical Engineering, Indian Institute of Technology Bombay, JENNIFER L NIEDZIELA, Oak Ridge National Laboratory, XING HE, TYSON LANIGAN-ATKINS, Mechanical Engineering and Materials Science, Duke University, AYMAN SAID, AHMET ALATAS, Argonne National Laboratory, DOUGLAS L ABERNATHY, Oak Ridge National Laboratory, YANG REN, Argonne National Laboratory, BIN GAO, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics & Astronomy, Rutgers University, OLIVIER DELAIRE, Mechanical Engineering and Materials Science, Duke University — In hybrid improper ferroelectric (Ca,Sr)3Ti2O7, the anharmonic coupling between a stable zone-center polar phonon mode and two unstable zone-boundary non-polar modes, and quasi-2D behavior of c-polarized acoustic modes are theoretically proposed but remain to be experimentally validated. We have performed comprehensive T-dependent single-crystal diffraction, calorimetry, and phonon measurements in (Ca,Sr)3Ti2O7 for x = 0, 0.6, and 0.9, including the behavior across the ferroelectric transition Tc. We also performed first-principles phonon simulations. Our results revealed a strong broadening but little shifting of mean phonon energy on heating across Tc. Among two unstable modes, rotational mode remains robust, but the tilt mode shows substantial softening on heating, consistent with previous studies. However, contrary to previous simulations, our momentum and energy resolved inelastic x-ray scattering measurements did not show a quadratic dispersion of acoustic modes, theoretically associated with a quasi-2D character. Our detailed lattice dynamics study enables to benchmark simulations of anharmonic phonons and associated thermodynamic properties such as thermal expansion and thermal conductivity.

Effect of cation ordering and pressure on n=2 Ruddlesden-Popper oxides from first principles
SRIRAM POYYAPAKKAM RAMKUMAR (Presenter), ELIZABETH NOWADNICK, Physics, New Jersey Institute of Technology — Octahedral tilts and rotations are ubiquitous in perovskite oxides and couple strongly to the electronic and magnetic properties. Furthermore, the interplay of octahedral rotations and layering can enable novel functionalities. For example, it has recently been shown that in n=2 Ruddlesden-Popper A3B2O7 layered perovskites, two octahedral rotations of different symmetries can induce a polarization via a trilinear coupling mechanism, known as hybrid improper ferroelectricity. While there has been extensive work on engineering octahedral rotation amplitudes and patterns in ABO3 perovskites, this has been much less studied in the Ruddlesden-Popper phases. By performing first-principles density functional theory calculations for a range of A3B2O7 materials, we explore two different approaches for engineering octahedral rotations in these systems. First, we consider the impact of A-site cation ordering (e.g. A2A′B2O7) on the energetics of a range of structural phases. Second, we elucidate the effect of hydrostatic pressure on octahedral rotation amplitudes and in turn on the energetics of the phases. We hence provide possible mechanisms to control the stability between polar and non-polar phases as well as tune structural distortions necessary for hybrid improper ferroelectricity.

First principles study of structure and electronic properties of a stannate Hybrid Improper Ferroelectric*
SHUTONG LI (Presenter), TURAN BIROL, Department of Chemical Engineering and Material science, University of Minnesota — Hybrid improper ferroelectricity provides a means to design lead-free ferroelectrics. Sr3Sn2O7, which is recently shown to be ferroelectric, can bring together the low electronic effective mass observed in stannates with the robust, switchable polarization of hybrid improper ferroelectricity. In this talk, we are going to present a systematically investigation on structure and electronic properties of Sr3Sn2O7 under biaxial strain. We find that the biaxial strain has significant effect on ground state structure, polarization switching, as well as the electronic structure.

*This work was supported primarily by the National Science Foundation through the University of Minnesota MRSEC under Award Number DMR-1420013.

Ultra-Small SrTiO3 Nanoparticles: Understanding the Polar Phases and Possible Ferroelectricity*
SIZHAN LIU, New Jersey Institute of Technology, NATHANIEL HURLEY, Stony Brook University, VITALI PRAKAPENKA, ERAN GREENBERG, Argonne National Laboratory, ZHENXIAN LIU, MILINDA ABEKYKOON (Presenter), Brookhaven National Laboratory, STANISLAUS S WONG, Stony Brook University, TREVOR TYSON, New Jersey Institute of Technology — Previous work revealed that 10 nm SrTiO3 (STO) nanoparticles host a polar and possibly ferroelectric phase stable under high pressure and over a broad range of temperatures. In this work, a full range of free standing nanoparticle samples between 2 and 60 nm have been studied and compared to bulk STO. Detailed structural and optical measurements are used to explore the evolution of the structure and corresponding phonon modes for varying temperatures and pressures. To understand the nature of the polar state and the existence of ferroelectricity, nonlinear optical measurements were conducted.

*This work is supported by NSF Grant No. DMR-1809931.
3:30PM V04.00006: Pressure Induced Unusual Multiferroicity in Perovskite PbCoO₃  
FENG LOU (Presenter), fudan university — We develop a global structure search approach to predict the ground state of magnetic materials based on the genetic algorithm. With this new approach, we predict that the unusual phase transitions can happen in the recently synthesized perovskite oxide PbCoO₃ [J. Am. Chem. Soc. 139, 4574 (2017)] under the different hydrostatic pressure. At low pressure, the PbCoO₃ phases are polar and weakly ferromagnetic, indicating that these phases are multiferroic. When the pressure is increased to 13 GPa, a polar-to-nonpolar transition takes place, which is associated with the charge order transition. The simultaneous A-site and B-site charge ordering pattern in the nonpolar phase is in agreement with the experimental result.

3:42PM V04.00007: In-situ lego-like construction of Ruddelsden-Popper surfaces using octahedra building blocks.* 
PRAHALD SIWAKOTI (Presenter), MOHAMMAD SAGHAYEZHIAN, ZHEN WANG, Department of Physics and Astronomy, Baton Rouge, Louisiana 70803, US, Louisiana State University, YIMEI ZHU, Department of Energy Science and Technology, Upton, New York 11973, USA, Brookhaven National Laboratory, ROSALBA FITTIPALDI, ANTONIO VECCHIONE, CNR-SPIN Unità di Salerno and Dipartimento di Fisica “E.R. Caianiello”, I-84084 Fisciano, Salerno, Italy, Università di Salerno, JIANDI ZHANG, Department of Physics and Astronomy, Baton Rouge, Louisiana 70803, US, Louisiana State University — The surface of Ruddelsden-Popper (RP) ruthenates provides a rich playground to study the emergent phenomena originating from the coupling of lattice, charge and spin, mediated through RuO₆ octahedron network. Because of the octahedra rotation, Sr₂RuO₄ surface shows a (√2 ×√2)R45° reconstruction. In addition to enhanced bulk-like octahedral rotation, Sr₃Ru₂O₇ surface displays octahedral tilt as well. In this work, using ultra-high-vacuum cleaved surface of Sr₂RuO₄ as a platform, we have sequentially grown different number of SrRuO₃ unit cells (u.c.) thin films, to mimic progression of “surface layer/s” of Sr₂RuO₄ to those of higher RP ruthenates (i.e. one u.c. is equivalent to Sr₃Ru₂O₇, two u.c. for Sr₄Ru₃O₁₀ surface and so on). Combining low energy electron diffraction with transmission electron microscopy, we systematically study the evolution of the lattice structure and discuss their properties.

*Supported by U.S.NSF under Grant No. DMR1608865.

3:54PM V04.00008: Computational discovery of Bi-based perovskite oxide polymorphs* 
OSWALDO DIEGUEZ (Presenter), AKANSHA SINGH, VIVEKA NAND SINGH, Tel Aviv University, ENRIC CANADELL, ICMAB-CSIC, JORGE INIGUEZ, LIST — In this paper we present our recent study[1] of the energy surface of BiScO₃, BiCrO₃, BiMnO₃, BiFeO₃, and BiCoO₃. In normal conditions, the bulk crystals of these materials show three very different variations of the perovskite structure: an antipolar phase, a rhombohedral phase with a large polarization along the space diagonal of the pseudocubic unit cell, and a supertetragonal phase with even larger polarization. With the aim of understanding the causes for this variety, we have used a genetic algorithm to search for minima in the energy surface of these materials. Our results show that the number of these minima is very large when compared to that of typical ferroelectric perovskites like BaTiO₃ and PbTiO₃, and that a fine energy balance between them results in the large structural differences seen. As byproducts of our search we have identified charge-ordering structures with low energy in BiMnO₃, and several phases with energies that are similar to that of the ground state of BiCrO₃. We have also found that a inverse supertetragonal phase exists in bulk, likely to be favored in films epitaxially grown at large values of tensile misfit strain.

*This work is supported by the Army Research Office through Grant No. W911NF-15-1-0017.
Correlation between Rietveld refinement yielded spontaneous polarization and experimentally obtained polarization data for Bi$_2$Mo$_{1-x}$W$_x$O$_6$ nanomaterials

*ANURAG PRITAM (Presenter), VAIBHAV SRIVASTAVA, Shiv Nadar University — Single phase perovskite Bismuth Molybadate, Bi$_2$Mo$_{1-x}$W$_x$O$_6$ [x=0.00, 0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.08 and 0.10] compositions were prepared using microwave sintering in air for 5 hours. The prepared compacted ceramics were characterized by X-ray diffraction (XRD) at room temperature and obtained XRD data was fitted for Rietveld refinement. The analysis of results confirmed the formation of the orthorhombic crystal structure with the space group of pca21. The atomic displacements for various sites a, b, c yielded close spontaneous polarization and indicated about schematic tilting of octahedrons atmospheric carbon adsorption as contamination on nano open surfaces. Reduced direction cosines indicated about increased strength of MoO$_6$ octahedrons against IR absorptions as shown by FTIR analysis, due to large oxygen bond strength of tungsten W than molybdenum Mo in BMO materials. Contaminated carbon groups were confirmed via additionally appearing FTIR peaks

Thursday, March 7, 2019 2:30 PM - 5:30 PM

Session V05 DMP: Topological Superconductivity: General I

2:30PM V05.00001: Gauge-Invariant Variables Reveal the Quantum Geometry of Fractional Quantum Hall States

RUDRO BISWAS (Presenter), YINGKANG CHEN, Purdue University — We introduce the framework of gauge invariant variables to describe fractional quantum Hall (FQH) states, and prove that the wavefunction can always be represented by a unique holomorphic multi-variable complex function. We use this representation to combine the quantum geometry of charged particles in a magnetic field with the theory of coherent states and provide an analytical route, hitherto elusive, for deriving the properties of fractional quantum Hall phases from experimentally relevant microscopic Hamiltonians.

2:42PM V05.00002: Connecting the responses of quantum Hall states to gravitational and electric fields

YINGKANG CHEN (Presenter), GUODONG JIANG, RUDRO BISWAS, Physics and Astronomy, Purdue University — We introduce the framework of gauge invariant variables to describe quantum Hall states. This representation exploits novel aspects of the quantum geometry of charged particles in a magnetic field. We use this representation to reveal the geometric response of cyclotron orbits to non-uniform electric fields. We visualize the known connection between the gravitational response of quantum Hall states and their current response to nonuniform electric fields. We also conjecture that gravitational response is connected to the charge response of quantum Hall states to non-uniform electric fields.

2:54PM V05.00003: Dephasing dynamics of noisy Majorana-based qubits: Topological versus Andreev

RYAN MISHMASH, UC Berkeley, BELA BAUER, Microsoft Station Q, FELIX VON OPPEN, Freie University, JASON ALICEA (Presenter), Caltech — Topological quantum computation schemes encode quantum information nonlocally through non-Abelian anyons separated by macroscopic distances $L$, typically spanning the length of the constituent qubit device. This nonlocality renders topological qubits exponentially immune to dephasing from all sources of classical noise with operator support local on the scale of $L$. We explore detailed theoretical and numerical analyses of a time-domain Ramsey-type protocol for noisy Majorana-based qubits which is designed to validate this coveted topological protection in near-term nanowire devices. By assessing dependence on wire length $L$, our proposed protocol can sharply distinguish a bona fide Majorana qubit from one constructed from Andreev bound states, which can otherwise closely mimic the true Majorana scenario in local probes; for a fixed wire length, the protocol can also inform which scenario is likely realized. This proposed experiment requires no pulsing and only (relatively slow) measurement of two nearby Majorana modes for both initialization and readout---achievable, for example, by tunnel coupling to a nearby quantum dot---and thus serves as an enticing pre-braiding experiment aimed at quantifying the utility of Majorana-based qubits.

3:06PM V05.00004: Vortices in a Monopole Superconducting Weyl Semimetal

CANON SUN (Presenter), SHU-PING LEE, YI LI, Johns Hopkins University — A monopole superconductor is a novel topological phase of matter with topologically protected gap nodes as a result of Cooper pairs acquiring a non-zero Berry phase. We study the vortex structure of a Weyl semimetal with broken time-reversal symmetry in the monopole superconducting phase. Within each single isolated vortex, there exists a zero-energy Majorana bound state. The spin up and down components of the Majorana zero mode exhibit a non-trivial winding as a consequence of spin-orbit coupling.

3:18PM V05.00005: Phases and phase transitions in Kitaev ladders: symmetries and finite size scaling  KE WANG (Presenter), TIGRAN SEDRAKYAN, Physics, Umass Amherst — We discuss phases and phase transitions in Kitaev ladders with and without interactions. In the noninteracting system, the phase diagram of a two-leg Kitaev ladder with time-reversal (TR) symmetry contains three distinct phases possessing 0, 2, and 4 Majorana edge modes and one tricritical line separating these phases. We discuss the finite-size corrections to energy along the tricritical line and finite-size scaling away from it which exhibits a non-trivial universal shape. Upon breaking the protecting TR symmetry, we find that the phase described by four Majorana edge modes in TR protected state crosses over to a trivial phase with no edge modes via symmetry broken path G in parameter space. The energy gap remains finite along G indicating that Z-classification (class BDI) reduces to Z_2 (class D) classification upon breaking of TR. Remarkably, the finite size scaling function in the vicinity of a critical line separating trivial phase from the nontrivial one in TR broken phase, exhibits a new nontrivial behavior. We also show that there is a phase transition of Ising universality in an interacting Kitaev chain and discuss its implications in ladder models.

3:30PM V05.00006: Spin-Orbit Coupling Effects on the Current-Phase Relation of a DC SQUID*  ALEX MATOS ABIAGUE (Presenter), NARAYAN MOHANTA, Department of Physics and Astronomy, Wayne State University, WILLIAM ANDREW MAYER, SICHAO YU, KAUSHINI WICKRAMASINGHE, JOSEPH YUAN, JAVAD SHABANI, Department of Physics, New York University, IGOR ZUTIC, Department of Physics, State University of New York at Buffalo — We consider a dc superconducting quantum interference device (SQUID) composed of two Josephson junctions (JJs) in a loop threaded by a magnetic flux. The JJs are built on a heterostructure where a semiconducting two-dimensional electron gas (2DEG) is partially covered by a conventional superconductor. Due to proximity effect, superconductivity is induced in the covered 2DEG, while the uncovered region remains in the normal state. Top gates allow for tuning both the carrier density and Rashba spin-orbit coupling (RSOC) strength in the normal region of each JJ, individually. We theoretically investigate the effects of self-inductance, charge density, and RSOC as well as their distinctive signatures on the current-phase relation (CPR) of the device. The sizable effects of RSOC tuning on the CPR make the considered SQUID a promising device not only for the detection of RSOC fields in proximitized materials but also for studying tunable topological transitions and the potential formation of Majorana bound states upon the application of a Zeeman field. The theoretical results are in good agreement with recent experimental measurements of the CPR in SQUIDs composed of InAs/Al JJs.

3:42PM V05.00007: Spontaneous Edge Current in Higher Chirality Superconductors*  XIN WANG (Presenter), ZHIQIANG WANG, CATHERINE KALLIN, McMaster University — The effects of finite temperature, Meissner screening and surface roughness on the spontaneous edge current for higher chirality quasi-two dimensional superconductors are studied in the continuum limit using the quasiclassical Eilenberger equations. We find that the total spontaneous current is non-zero at finite temperature T and maximized near $T=T_c/2$, where $T_c$ is the transition temperature, although it vanishes at $T=0$. In the presence of surface roughness, we observe a surface current inversion in the chiral d-wave case that can be understood in terms of a disorder induced s-wave pairing component in the rough surface regime. This conclusion is supported by a Ginzburg-Landau analysis. However, this current inversion is non-universal beyond the continuum limit as demonstrated by self-consistent lattice Bogoliubov-de Gennes calculations.

3:54PM V05.00008: Unconventional Josephson Effect in a topological Kondo insulator  XUECHENG YE, Physics, Missouri University of Science and Technology, JACOB COOK, Physics, University of Missouri, ERIK HUEMILLER, Physics, University of Illinois at Urbana-Champaign, AARON D FINCK, IBM Thomas J. Watson Research Center, POUYAN GHAEMI MOHAMMADI, Physics, The City College of New York, CUNY, THOMAS VOJTA, Physics, Missouri University of Science and Technology, SHANTA SAHA, JOHNPIERRE PAGLIONE, Physics, University of Maryland, CIHAN KURTER (Presenter), IBM Thomas J. Watson Research Center — Proximity-induced superconductivity in three dimensional (3D) topological insulators forms a new quantum phase of matter and harbors exotic quasiparticles such as Majorana bound states. One of the biggest drawbacks of the commonly studied 3D topological insulators is having conducting bulk that obscures the role of surface states. Introducing superconductivity in topological Kondo insulators such as SmB$_6$ is particularly promising due to their robust insulating bulk at low temperatures. In this work, we develop an unconventional Josephson junction by coupling superconducting Nb leads to the surface states of a SmB$_6$ crystal. We observe a distinct critical current at low temperatures that exhibits a Fraunhofer diffraction pattern with the application of an out-of-plane magnetic field. The appearance of Shaprio steps under microwave irradiation gives further evidence of a Josephson Effect. The Fraunhofer patterns show an anomalous hysteresis with magnetic field sweep direction suggesting coexistence of ferromagnetism with superconductivity in the topological surface states of SmB$_6$. The experimental work will advance the current understanding of topologically nontrivial superconductors and emergent states associated with such unconventional superconducting phases.
4:06PM V05.00009: Simulating the spectral response of a Majorana-transmon device  ANNA KESELMAN (Presenter), BERNARD VAN HECK, BELA BAUER, Microsoft — We perform a numerical study of a toy-model for the Majorana-transmon device, obtaining its spectral response across the topological phase transition. To this end, we employ the DMRG and TEBD techniques. We model the superconducting wires on either end of the Josephson junction as spinful fermions hopping on a 1D lattice with Rashba spin-orbit coupling in a Zeeman field perpendicular to the spin-orbit direction. As the Zeeman field is increased and the superconducting wires are driven across the topological phase transition, we observe the splitting of the plasma mode due to the zero-energy Majorana modes forming at the ends of the wires. Interestingly, the spectral function is largely unaffected by the gap closing in the bulk of the superconducting wires. When the length of the junction is finite, additional Andreev bound states can form. We show that the appearance of these states gives rise to additional spectral lines, obscuring the signatures of the topological phase.

4:18PM V05.00010: Prediction of Hall effects from geometrical properties of the Fermi surface  ELENA DERUNOVA (Presenter), MAZHAR ALI, Max Planck Institute for Microstructure Physics, YAN SUN, Max Planck Institute for Chemical Physics of Solids, STUART S PARKIN, Max Planck Institute for Microstructure Physics — Recently, the intrinsic Hall effects (e.g. spin, anomalous, and planar Hall effects) have been investigated as topological properties stemming from a material's electronic band structure. In our work we show the connection of these properties to the local geometry of the Fermi surface. Specifically we introduce the concept of geodesic flow of the Fermi surface and using this concept we link the Berry curvature term in the semiclassical equation of motion of Bloch electrons with the evolution of the Riemannian metric in the tangent bundle of the Fermi surface. As an example, we consider the comparison of Kubo formalism for the spin Hall effect with the geometrical analysis of the Fermi surface for Pt and Beta-W. Such geometrisation of topological properties can be applied to an algorithmic material search in crystallographic databases, paving the way for high throughput analysis of materials and topologically driven properties.

4:30PM V05.00011: Parafermions in the Fractional Quantum Hall Spin Transitions*  JINGCHENG LIANG (Presenter), GEORGE E SIMION, LEONID ROKHINSON, YULI LYANDA-GELLER, Purdue University — Parafermion zero modes are promising for universal topological quantum computation because of their richer non-Abelian braiding properties. However, physical systems that are predicted to host these exotic excitations are rare and difficult to realize in experiments. In this work, we show that parafermion zero modes can emerge in the spin transitions in the fractional quantum Hall regime. Exact diagonalization of the Hamiltonian in a disk and torus geometries demonstrates formation of counter-propagating edge states with different spin polarizations at a boundary between polarized and unpolarized ν=2/3 phases. By analytical and numerical methods we find conditions for parafermion zero modes to emerge when these edge states are coupled to an s-wave superconductor. The phase diagram shows that the parafermionic phase, which is represented by the six-fold ground state degeneracy, is separated from gapped phases by a topological phase transition. Parafermion modes in fractional quantum Hall systems coupled to s-wave superconductors are experimentally feasible.

4:42PM V05.00012: Blurring the boundaries between topological and non-topological phenomena in dots*  DENIS CANDIDO (Presenter), Sao Carlos Institute of Physics at the University of Sao Paulo, MICHAEL FLATTÉ, Department of Physics and Astronomy and Optical Science and Technology Center, University of Iowa, CARLOS EGUES, Sao Carlos Institute of Physics at the University of Sao Paulo — In this work we investigate the electronic and transport properties of topological and non-topological InAs0.85Bi0.15 quantum dots (QDs) described by a Bernevig-Hughes-Zhang (BHZ) model with cylindrical confinement, i.e., "BHZ dots". We analytically show that (it non-topological) dots have discrete helical edge states, i.e., Kramers pairs with spin-angular-momentum locking similar to topological dots. These unusual and unexpectedly non-topological edge states are geometrically protected due to confinement in a wide range of parameters and are not guaranteed to exist by the bulk-edge correspondence. In addition, for a conduction window with four edge states, we find that the two-terminal conductance G vs. the QD radius R and the gate Vg controlling its levels shows a double peak at 2e^2/h for both topological and trivial BHZ QDs. Our results blur the boundaries between topological and non-topological phenomena for conductance measurements in small systems such as QDs thus showing an equivalence between the BHZ QDs in different topological phases.

Topological Superconductivity in a Phase-Controlled Josephson Junction

HECHEN REN (Presenter), FALKO PIENTKA, SEAN J HART, ANDREW T PIERCE, MICHAEL KOSOWSKY, Harvard University, LUKAS LUNCZER, RAIMUND SCHLERETH, BENEDIKT SCHARF, EWELINA HANKIEWICZ, LAURENS W MOLENKAMP, Wuerzburg University, BERTRAND I. HALPERIN, AMIR YACOBY, Harvard University — While signatures of Majorana bound states have been observed in one-dimensional systems, there is an ongoing effort to find alternative platforms that do not require fine-tuning and can be easily scalable. Using a Josephson junction made of HgTe quantum well coupled to thin-film aluminum, we can tune between a trivial and a topological superconducting state by controlling the phase difference $\phi$ and an applied in-plane magnetic field, as we measure the tunneling conductance at the edge of the junction. At low magnetic fields, we observe a minimum in the tunneling spectra near zero bias, consistent with a trivial superconductor. As the field increases, the tunneling conductance develops a zero-bias peak which persists over a range of $\phi$ that expands systematically with increasing magnetic fields. Consistent with theoretical predictions for this system, our observation establishes this system as a promising platform for realizing topological superconductivity and for creating and manipulating Majorana modes in two-dimensional systems.

Proximity-Induced Superconductivity in a Topological Crystalline Insulator

BRYAN RACHMILOWITZ (Presenter), HE ZHAO, Boston College, JOHN SCHNEELOCH, RUIDAN ZHONG, GENDA GU, Brookhaven National Lab, ILIJA ZELJKOVIC, Boston College — Inducing superconductivity at the surface of topological crystalline insulators (TCIs) can give rise to new topologically protected phases. These phases are theorized to be different than the ones observed at the surface of superconducting $\mathbb{Z}_2$ topological insulators. Here we report molecular beam epitaxy synthesis of a heterostructure involving a prototypical TCI SnTe and a high temperature superconductor Fe(Fe,Se). Using low-temperature scanning tunneling microscopy and spectroscopy, we provide a strong evidence for proximity-induced superconductivity at the surface of a few bi-layer thick SnTe films. Our work provides a platform for investigating the emergent phenomena in superconducting TCIs.

Spectroscopic visualization of aluminum islands in the Coulomb blockade regime deposited on InAs nanowires

HAIM BEIDENKOPF (Presenter), JONATHAN REINER, ABHAY K NAYAK, AMIT TULCHINSKY, YUVAL OREG, HADAS SHTRIKMAN, NURIT AVRAHAM, Weizmann Institute of Science — Hybrid InAs/Al nanowires are studied as a platform for topological superconductivity. Here we visualize spectroscopically the Coulomb blockade regime of aluminum islands deposited in situ on InAs nanowires. We find no changes in the chemical potential before and after aluminum deposition signifying absence of charge doping and of local band bending at the immediate vicinity of the islands. On the aluminum islands we find Coulomb blockade features typical to double barrier tunneling junction. From these we characterize the resistive and capacitive properties of the nanowire-aluminum interface. We identify a finite barrier for tunneling of electrons across that interface. Our observations strongly reflect on the ability to induce robust topological superconductivity by deposition of aluminum on InAs nanowires.

*We acknowledge funding by the ERC (Project TOPONW).

Session V06 DCMP: Correlations in Helium and Hydrogen

BCEC 109A - Paul Sokol, Indiana University

Bloomington
2:30PM V06.00001: Neutron Scattering Studies of superfluid helium confined in preplated nanoporous materials.*

PAUL SOKOL (Presenter), GARFIELD WARREN, Indiana University Bloomington, TIMOTHY PRISK, NCNR, NIST, NATHAN NICHOLS, ADRIAN DEL MAESTRO, Physics, University of Vermont — One dimensional systems have been of long standing interest due to a profound difference from their 2 and 3 dimensional counterparts whose properties can be described in terms of quasi-particles. This quasi-particle picture breaks down completely in one dimension where the fundamental excitations are collective and described by the universal Tomonaga-Luttinger liquid (TLL) theory. Superfluid helium confined in one-dimensional templated materials, such as MCM-41, provide an attractive model system for studying the properties of a TLL. Unfortunately, the pore size attainable in these materials is too large to reach the one-dimensional limit. Preplating these porous materials with an adsorbate offers a route to smaller pore sizes where one-dimensional confinement can occur. We will present the results of neutron scattering studies of the excitations of superfluid helium confined in MCM-41 preplated with a monolayer of Argon. The observed scattering departs dramatically from the bulk superfluid and may be consistent with a TLL.

2:42PM V06.00002: The Damping of a Micro-electromechanical Resonator in the Presence of Quantum Turbulence in He II*

COLIN BARQUIST (Presenter), WENGUANG JIANG, KEEGAN GUNTHER, YOONSEOK LEE, University of Florida, HO BUN CHAN, Physics, Hong Kong University of Science and Technology — A micro-electromechanical plate resonator was immersed in ⁴He down to 13 mK at saturated vapor pressure. The resonator consists of a 125x125x2 μm³ plate suspended 2 μm above a substrate. Due to its small mass and large surface area it is sensitive to vortices in the fluid and vortices pinned to the surface of the device. The device is studied in the presence of fully developed quantum turbulence generated by a quartz tuning fork and in the presence of remnant vortices pinned to the device. Specifically, the velocity dependent damping of the device in these conditions is measured and reported.

2:54PM V06.00003: The Use of ³He in Obtaining Ultra-Low Temperatures at the NHMFL High B/T Facility*

ANDREW WOODS (Presenter), CHAO HUAN, NAOTO MASUHARA, JIAN-SHENG XIA, NEIL SULLIVAN, Department of Physics and NHMFL, University of Florida — The High B/T Facility at the National High Magnetic Field Laboratory (NHMFL) provides access to unique ultra-low temperature, high magnetic field and ultra-quiet environments. The facility operates nuclear demagnetization refrigerators capable of reaching 0.5 mK at 16 T and 0.1 mK at 8 T. This enables user experiments in diverse fields including ultrasound studies, FQHE studies in tilted fields, high sensitivity NMR, high sensitivity dielectric measurements, sub-mK susceptibility measurements, novel states (Bose glass, Wigner crystals) and studies of superfluid ³He. These experiments require that the ³He, the electrical leads and samples be efficiently cooled to ultra-low temperatures. In this talk I will discuss the use of liquid ³He in cooling at the High B/T Facility, experimental platforms developed to make best use of this method, recent experimental results obtained, and potential future developments.

3:06PM V06.00004: Mass Flux Measurements in Solid 4He.*

VALENTYN RUBANSKYI, ROBERT HALLOCK (Presenter), University of Massachusetts Amherst — We previously explored the characteristics of mass flux through solid 4He that takes place from one superfluid-filled reservoir to the other through a solid-filled experimental cell off the melting curve (1). We measured flow characteristics that appear to match expectations for one-dimensional Luttinger-Liquid conductivity (2) and we documented the effects that various concentrations of 3He impurity have on the temperature dependence of the flow (3). Our most recent experiments show that reducing the interface between superfluid helium in the Vycor rods and solid helium reduces the flux and that significantly blocking the cross section of the channel filled with solid 4He further suppress the flux. These results further support the possibility that the observed mass flux is due to the superfluid cores of edge dislocations.

*Support: NSF DMR 1205217 and 1602616.
3:18PM V06.00005: Dynamics of 1D $^3$He adsorbed in $^4$He plated MCM-41: NMR Studies*  
JOHNNY ADAMS (Presenter), MARC L. LEWKOWITZ, CHAO HUAN, NAO TO MASUHARA, NEIL S. SULLIVAN, Department of Physics and NHMFL, University of Florida — We report the results of NMR studies of the dynamics of $^3$He confined to 1D in the interior of the hexagonal nanochannels of MCM-41. The walls of the MCM-41 were coated with a monolayer of $^4$He and $^3$He was added afterwards to form a 1D $^3$He line density of 0.1 Å$^{-1}$. The nuclear spin-lattice relaxation times were measured for temperatures 0.050 $<$ $T$ $<$ 3.0 K. A distinct peak is observed at 95 mK which is interpreted as the expected maximum of the “spin-drag” relaxation time predicted by theory for $T$ = 2$T_F$ where $T_F$ is the Fermi degeneracy temperature.

*The measurements were carried out at the High B/T facility of the National High Magnetic Field Laboratory which is supported by the NSF through DMR-1644779 and the State of Florida.

3:30PM V06.00006: Measuring Corrections to the Amplitude Mode Masses in Superfluid $^3$He*  
MAN NGUYEN (Presenter), ANDREW ZIMMERMANN, WILLIAM HALPERIN, Northwestern University — Superfluid $^3$He has a rich spectrum of collective modes with both massive (gapped) and massless (gapless) excitations. The masses of these modes can be precisely measured with acoustic spectroscopy and fit to theoretical models to extract interaction strengths of the underlying superfluid. Prior comparisons between theory and experiment accounted for Fermi-liquid effects, $f$-wave interactions, and the strong-coupling energy gap. However, strong-coupling corrections to the mode mass itself were not included. In this work, we employ a simple procedure to incorporate these corrections$^{[1]}$ to the mode which improve the determination of the $f$-wave pairing strength, $(1/x_3)$. Results from several independent experiments are brought into better agreement with the improved theoretical model.

*This work is supported by the National Science Foundation, DMR 1602542

3:42PM V06.00007: The Polar Phase of Superfluid $^3$He in the Limit of Small Anisotropy*  
ANDREW ZIMMERMANN (Presenter), MAN NGUYEN, WILLIAM HALPERIN, Northwestern University — The polar phase of superfluid $^3$He is characterized by a single orbital component of the p-wave order parameter, and is favored by the breaking of the orbital rotational symmetry. This can be achieved by introducing anisotropic impurities into pure superfluid. Prior comparisons between theory and experiment accounted for Fermi-liquid effects, $f$-wave interactions, and the strong-coupling energy gap. However, strong-coupling corrections to the mode mass itself were not included. In this work, we employ a simple procedure to incorporate these corrections$^{[1]}$ to the mode which improve the determination of the $f$-wave pairing strength, $(1/x_3)$. Results from several independent experiments are brought into better agreement with the improved theoretical model.

*This work is supported by the National Science Foundation, DMR-1602542.

3:54PM V06.00008: Simplified calculations of the frequencies of Higgs modes in superfluid $^3$He-B using N-point Padé approximants  
JOHN PALIOTTA (Presenter), JOSEPH W SERENE, Georgetown University — Previous calculations of the frequencies of the Higgs modes in superfluid $^3$He-B have been done on the real-frequency axis, most recently using the Keldysh formalism. Recently Sauls and Mizushima$^{[1]}$ showed how the unperturbed weak-coupling mode frequencies can be found by solving the imaginary-frequency version of the kinetic equation, followed by standard analytic continuation to real frequencies and evaluation of remaining integrals there. We show that perturbed frequencies due to magnetic fields or strong-coupling effects can be calculated on the imaginary axis and the final results can then be obtained, to high accuracy, by N-point Padé approximants, which greatly simplifies these calculations. $^{[1]}$J.A. Sauls and Takeshi Mizushima, On the Nambu fermion-boson relations for superfluid 3He, Phys. Rev. B 95, 094515 (2017)
4:06PM V06.00009: Quantum Monte Carlo simulation of superfluid helium confined inside pre-plated nanoporous materials*  
NATHAN NICHOLS (Presenter), ADRIAN DEL MAESTRO, University of Vermont, TIMOTHY PRISK, NCNR, NIST, GARFIELD WARREN, PAUL SOKOL, Indiana University Bloomington — In one spatial dimension, enhanced thermal and quantum fluctuations should preclude the existence of any long range ordered superfluid phase of matter. Mesoporous ordered silica-based structures such as the molecular sieve MCM-41 offer an experimental route towards the observation of this effect through the physical confinement of superfluid helium inside quasi-one-dimensional channels. However, the angstrom-scale coherence length of the wavefunction away from the bulk superfluid transition temperature requires novel nano-engineering approaches to reach the one-dimensional limit. In this talk we will describe ab initio quantum Monte Carlo simulations of superfluid helium confined inside MCM-41 that has been pre-plated with adsorbates to reduce the diameter of the confining media. We will describe how the choice of adsorbate (e.g. argon, neon, krypton) can be modified to obtain different types of helium structures inside the pores. Phase and density correlations may be further tuned via the external pressure of helium with the goal of realizing an emergent one-dimensional quantum liquid.

*This work was supported by the NSF through grants DMR-1809027 and DMR-1808440. Simulations performed on the Vermont Advanced Computing Core were partially supported by NSF grant OAC-1827314.

4:18PM V06.00010: Anomalous attenuation of piezoacoustic surface waves by liquid helium thin films*  
KOSTYANTYN NASYEDKIN (Presenter), HEEJUN BYEON, JUSTIN LANE, LIANGJI ZHANG, NIYAZ BEYSENGULOV, REZA LOLOEE, JOHANNES POLLANEN, Michigan State Univ — We report on the experimental observation of an anomalously high attenuation of high frequency surface acoustic waves (SAW) by thin films of liquid 4He [1]. The piezoelectric SAW propagate along the surface of a lithium niobate substrate, which is covered by liquid helium films of varying thicknesses. When the thickness of the helium layer is much larger than the wavelength of the SAW on the substrate the SAW attenuation is dominated by emitting compressional waves into the bulk liquid, in good agreement with theory and previous measurements. However, for sufficiently thin helium films, we find that the SAW attenuation significantly exceeds that measured with the substrate submerged in bulk liquid. Possible mechanisms for this enhanced attenuation are discussed.

*This work was supported by the NSF (Grant no. DMR-1708331).

4:30PM V06.00011: Elastic Anomaly of Helium, Hydrogen and Neon Films on Disordered Substrate  
TAKAHIKO MAKIUCHI (Presenter), KATSUYUKI YAMASHITA, MICHIHIRO TAGAI, YUSUKE NAGO, KEIYA SHIRAHAMA, Keio University — We report systematic elasticity measurements of helium (4He and 3He), hydrogen (H2, HD, D2) and neon films physisorbed on a porous glass substrate. The elastic constant and dissipation as a function of temperature were measured by means of torsional oscillator technique with changing the film coverage. We have found that films of all species (4He, 3He, H2, HD, D2, Ne) showed an increase of the elastic constant accompanied by a dissipation peak at low temperatures, which we call the elastic anomaly. This suggests that any atomic and molecular films adsorbed on disordered substrates exhibit a crossover from a soft state at high temperature to a stiff state at low temperature. Only 4He and 3He films exhibit insulator-(super)fluid quantum phase transitions at critical coverages corresponding to about 2 atomic layers. Helium films below those critical coverages are in a gapped and compressible ground state. Hydrogen films show multiple dissipation peaks depending on the film coverage. The elastic anomaly of neon has single dissipation peak, and the peak temperature did not decrease below 5 K which signifies quantum phase transition does not occur in neon films.

4:42PM V06.00012: Transition in Wave Behavior on a Superfluid Vortex at Large Excitation Amplitude*  
RENA ZIEVE (Presenter), JOSEPHINE SPIEGELBERG, ANDREW DIGGS, University of California, Davis — We study a single quantized vortex stretched between a wire and the wall of a cylindrical container. The wire serves both as a probe and as a means of exciting the system. Vibrating the wire creates oscillations along the vortex. One consequence of these oscillations is that the spot where the vortex joins the wire moves. This in turn changes the normal modes of the wire's vibration, which lets us detect the vortex location. We find a qualitative change in behavior at sufficiently large excitation. Below the crossover, clear vortex waves are induced, with amplitude near the expected threshold for instability. As the excitation increases, the signal becomes much less regular. Higher-frequency oscillations appear, as well as a slow feature that may indicate recurrence. The vortex appears to undergo significant length changes during the process.

*This work was supported in part by NSF through the award PHY-1560482.
The condensed phases of molecular hydrogen are systems of fundamental importance in quantum many-body physics. Zero-point motion makes a large contribution to the kinetic energy and mean-squared displacement $<u^2>$ of hydrogen molecules in the liquid and solid phases. At present, there is a significant disagreement between theory and experiment about the relative importance of thermal and quantum effects near the liquid-solid phase transition of parahydrogen. Path Integral Monte Carlo calculations predict that $<u^2>$ increases as the melting temperature is approached from below, implying a combination of thermal and quantum effects [Phys. Rev. B 95, 104518 (2017)]. However, an inelastic neutron scattering study of the rotational transitions in solid parahydrogen suggests that $<u^2>$ is independent of temperature, and is thus determined by quantum-mechanical zero-point motion alone [Phys. Rev B 86, 144524 (2012)]. In this presentation, we report new inelastic neutron scattering measurements of $<u^2>$ obtained using the ARCS spectrometer at Oak Ridge National Laboratory and the DCS spectrometer at the NIST Center for Neutron Research.

The effect of confinement on the thermodynamic properties and phase transitions of liquids and solids in confinement has been of long-standing interest and recent interest has focused on the effects of dimensionality. Hydrogen has been of interest due to the importance of quantum effects, in particular zero-point motion, and has been studied extensively in a variety of porous media. Templated porous materials, such as MCM-41, provide an attractive model system for studying the effects of confinement due to their highly uniform one-dimensional pores with variable pore size. Unfortunately, the minimum pore diameter is typically limited to a few nanometers which limits our ability to approach the one-dimensional limit. We will present measurements of adsorption isotherms and heat capacity of hydrogen confined in MCM-41. We will present the results for both bare MCM-41 and samples that have been preplated with noble gases to reduce the effective pore diameter.

*This work was supported by the NSF through grants DMR-1809027.

Supersolids are theoretically predicted quantum states that break the continuous rotational and translational symmetries of liquids while preserving superfluid transport properties. Over the last decade, much progress has been made in understanding and characterizing supersolid phases through numerical simulations for specific interaction potentials. The formulation of an analytically tractable framework for generic interactions still poses theoretical challenges. By going beyond the usually considered quadratic truncations, we derive a systematic higher-order generalization of the Gross-Pitaevskii mean-field model in conceptual similarity with the Swift-Hohenberg theory of pattern formation. We demonstrate the tractability of this broadly applicable approach by determining the ground state phase diagram and the dispersion relations for the supersolid lattice vibrations in terms of the potential parameters. Our analytical predictions agree well with numerical results from direct hydrodynamic simulations and earlier quantum Monte-Carlo studies. The underlying framework is universal and can be extended to anisotropic pair potentials with complex Fourier-space structure.
2:30PM V07.00001: Tricritical Points in the Underscreened Anderson Lattice Model*  PETER RISEBOROUGH (Presenter), Temple University, ANA LAUSMANN, Fisica, USFM Santa Maria, ELEONIR CALEGARI, Fisica, USFM Santa Maria, SERGIO G MAGALHAES, Fisica, UFRG, Porto Alegro — We report calculations on the Underscreened Anderson Lattice Model that has been proposed to describe the Hidden Ordered phase of URu2Si2. Since the proposed Hidden Ordered Phase is associated with a spin-orbital density wave, in which the spins condense in a spontaneously chosen plane, the magnetic properties become anisotropic in the low temperature phase. The anisotropy is similar to that found by magnetic torque measurements. We examine the field-temperature phase diagram. At zero field, the transition to the Hidden Ordered phase is second order. The application of a magnetic field has the effect of reducing the transition temperature towards zero. However, at a critical value of the applied field, the transition becomes first-order in agreement with high field measurements. We present an analysis of the tricritical point, which shows that the upper critical dimension of the model is reduced to d=3. Therefore, the transition may be reasonably described by a Gaussian approximation.

2:42PM V07.00002: Schwinger boson approach to the Kondo lattice model  JIANGFAN WANG (Presenter), YUNG-YEH CHANG, Department of Electrophysics, National Chiao Tung University, CHUNG-YU MOU, Department of physics, National Tsing-Hua University, STEFAN B. KIRCHNER, Department of Physics, Zhejiang University, SILKE BUEHLER-PASCHEN, Institute of Solid State Physics, Vienna University of Technology, CHUNG-HOU CHUNG, Department of Electrophysics, National Chiao Tung University — The microscopic mechanism of the heavy-fermion systems close to anti-ferromagnetic quantum critical point constitutes an outstanding open problem in correlated electron systems. To address this issue, we employ a distinct route from the dynamical mean-field theory by solving the 2D Kondo-Heisenberg model via a dynamical large-N multichannel Schwinger boson approach. We identify the quantum critical point separating the anti-ferromagnetic long-ranged ordered and the heavy Kondo-screened Fermi-liquid phases. Various thermodynamical observables near criticality show non-Fermi liquid behaviors and agree qualitatively well with the experiments seen in CeCu_{6-x}Au_x and YbRh_2Si_2.

2:54PM V07.00003: The splitting of electrons on the Kondo lattice  EOIN QUINN (Presenter), LPTMS, Université Paris-Sud, ONUR ERTEN, Arizona State University — We demonstrate that strong correlations in Kondo lattice models can be organised around a splitting of the electronic degree of freedom. This provides a fresh perspective on the behaviour of local moment systems, in which the formation of a heavy fermion band and violation of the Luttinger sum rule are naturally accounted for.

3:06PM V07.00004: The 4f electron character on core-level spectroscopies of AuCu_3-type Ce intermetallics  NORIMASA SASABE (Presenter), Japan Synchrotron Radiation Research Institute — The 3d transition metal compounds and 4f rare earth compounds show attractive phenomena, such as superconductivity and Kondo effect, due to strong electron correlations among localized 3d and 4f electrons. Especially, the 4f electron state of Ce intermetallics causes the various phenomena of Ce intermetallics, Kondo effects and magnetic ordering, for example. X-ray core-level spectroscopy is an efficient technique to investigate the electronic states of strongly correlated systems. Recent years, experimental techniques have been rapidly developing and, especially, the progress in experimental resolution has enabled us to observe fine spectral features, which were not formerly observed. These advantages will enable us to observe spectral fine features related with the 4f electron state related to Kondo and/or magnetic ordering of the Ce intermetallics. In this study, we discuss 4f electron character of AuCu_3-type Ce intermetallics by means of X-ray spectra, especially paying attention on the polarization dependence and the incident photon energy. In order to simulate the electronic state of AuCu_3-type Ce intermetallics, we use an impurity Anderson model including realistic valence structure.

3:18PM V07.00005: Synchrotron-Mossbauer study of the pressure-driven magnetic evolution in EuGa_4  ANJANA KRISHNADAS (Presenter), Okinawa Institute of Science and Technology, STEPHEN ARMSTRONG, Caltech, WENLI BI, JIYONG ZHAO, ESEN ALP, APS, Argonne National Lab, RIKI KOBAYASHI, MASATO HEDO, TAKAO NAKAMA, YOSHICHIKA ONUKI, University of The Ryukyus, THOMAS F ROSENBAUM, Caltech, YEJUN FENG, Okinawa Institute of Science and Technology — Rare-earth Eu compounds represent an intriguing class of magnetic materials that provide a competing playground of Kondo physics, RKKY exchange interactions, and valence evolution. Here, we explore the evolution of antiferromagnetism under pressure via synchrotron-based Mossbauer spectroscopy. Contrary to previous electrical transport results, our observation provides direct evidence of a magnetic ground state at high pressure, continuous through a first order phase transition at 5 GPa and persisting to at least 13.6 GPa. We discuss this result in the framework of a potential interaction between evolution of the valence condition and an increase in the ordering temperature.
3:30PM V07.00006: Order fractionalization and the two channel Kondo lattice  
ARI WUGALTER (Presenter), YASHAR KOMIJANI, PIERS COLEMAN, Physics and Astronomy, Rutgers, The State University of New Jersey — The symmetric two-channel Kondo lattice, involving two separate conduction electron seas, interacting with a lattice of local moments, provides an idealized model for the novel cubic heavy electron superconductors, PrX$_2$Al$_2$O$_{10}$, (X=Ti, Va) and UBe$_{13}$. There are many indications that two-channel Kondo lattice is unstable to the development of broken channel symmetry, in which the Kondo effect develops selectively in one channel giving rise to a \( \text{\textbackslash channel magnetization} \) We study this novel phase using the large N expansion. One of the remarkable features of the resulting mean-field theory, is the emergence of a two-component spinor describing the channel magnetization, suggesting the possibility of order fractionalization. Using the large N expansion, we show that the long-wavelength physics of the two-channel Kondo lattice is described by the principle chiral model, in which the skyrmion density of the channel magnetization couples to the difference of the electromagnetic and internal gauge fields. We will discuss the implications of these results for the order fractionalization conjecture and possible observable consequences.

3:42PM V07.00007: Impact of Rashba spin-orbit coupling on f-electron materials  
YOSHIHIRO MICHISHITA (Presenter), ROBERT PETERS, Kyoto University — We study the interplay between Rashba spin-orbit coupling (RSOC) and the Kondo screening in noncentrosymmetric f-electron materials. We show that the Kondo interaction of the f-electrons becomes anisotropic at high temperatures due to the RSOC in these materials leading to a suppression of the Kondo temperature. However, an isotropic Kondo effect is restored at low temperature which leads to a complete Kondo screening. We furthermore demonstrate that the Kondo effect has influence on the Rashba splitting in the band structure, which becomes temperature dependent. We show that although f electrons are localized at temperatures above the Kondo temperature, already at these temperatures a helical spin polarization emerges. With decreasing temperature, the Kondo screening occurs, which leads to drastic changes in the band structure. Remarkably, these changes in the band structure depend on the helical spin polarization. For strong RSOC, we observe that one of the helical bands becomes gapped at low temperature and a helical half-metal is formed.

3:54PM V07.00008: Charge and heat transport in a charge 2 channel Kondo device  
LARS FRITZ (Presenter), GERWIN VAN DALUM, Physics, Utrecht University, ANDREW K MITCHELL, School of Physics, University College Dublin — Recently, the charge two channel effect was realized in an experimental setup for the first time. Remarkably, the scaling curve of the critical conductance was measured over many decades and was in excellent agreement with theoretical calculations. In this talk we focus on the heat transport in the setup. We theoretically show a violation of the Wiedemann-Franz law and point out an interesting connecting to the central charge of one dimensional Majorana fermions.

4:06PM V07.00009: Coupled charge-Kondo quantum dot devices  
ANDREW K MITCHELL (Presenter), School of Physics, University College Dublin — Exquisite experimental control over exotic states of quantum matter has recently been demonstrated in charge-Kondo quantum dot devices [1,2]. These systems constitute a new paradigm for circuit realizations of fundamental models of quantum criticality, with essentially perfect agreement between experiment and theory for fractionalized two-channel and three-channel Kondo physics [2,3].

Here we study theoretically a device comprising two charge-Kondo quantum dots, coupled together by a quantum point contact. This system is the first step towards constructing more elaborate nanodevices using charge-Kondo building blocks, which could eventually lead to quantum simulations of exotic lattice models.

Depending on dot occupation, different variants on the classic two-impurity Kondo model can be realized, and clear signatures of quantum criticality show up in measurable conductance as a function of tunable parameters.

*AKM acknowledges funding from the Irish Research Council through the Laureate Award "Quantum-boosted functionality in single-molecule transistors" (IRCLA/2017/169).
Using this model, we investigated the effect of interaction and the applied magnetic field near the half-filled region. We consider a Two-Impurity Anderson model. In the non-interacting limit (U=0), the AB orbital is decoupled from the site at the center of the wire and to its nearest neighbors. Taking advantage of the dot symmetry, we work with the bonding and anti-bonding (AB) levels resulting from the symmetric and antisymmetric combinations of the dot levels. We consider a Two-Impurity Anderson model. In the non-interacting limit (U=0), the AB orbital is decoupled from the conduction band and is hence a BIC. For U≠0, our Numerical Renormalization-Group results show that the interaction couples the bonding and anti-bonding orbitals and hence broadens the latter. The RKKY interaction between the magnetic moments of the two dots can either be ferro- or antiferromagnetic, to form a singlet or a triplet, which affects the formation of the Kondo cloud. In the strongly particle-hole asymmetric coupling limit, the AB orbital is reduced to a singly occupied level that is decoupled from the continuum, i.e., a Spin-BIC.

4:42PM V07.00012: Correlation effects in the emergence of Bound Spin State in the Continuum* LUIZ H. GUESSI (Presenter), LUIZ OLIVEIRA, Sao Carlos Institute of Physics, University of Sao Paulo — Bound States in the Continuum (BICs) are states with localized wave-function even though lying in the continuum. Here, we explore theoretically the emergence of a Spin-BIC in a system comprising two identical quantum dots side-coupled to a quantum wire. The dots are symmetrically coupled to the site at the center of the wire and to its nearest neighbors. Taking advantage of the dot symmetry, we work with the bonding and anti-bonding (AB) levels resulting from the symmetric and antisymmetric combinations of the dot levels. We consider a Two-Impurity Anderson model. In the non-interacting limit (U=0), the AB orbital is decoupled from the conduction band and is hence a BIC. For U≠0, our Numerical Renormalization-Group results show that the interaction couples the bonding and anti-bonding orbitals and hence broadens the latter. The RKKY interaction between the magnetic moments of the two dots can either be ferro- or antiferromagnetic, to form a singlet or a triplet, which affects the formation of the Kondo cloud. In the strongly particle-hole asymmetric coupling limit, the AB orbital is reduced to a singly occupied level that is decoupled from the continuum, i.e., a Spin-BIC.

4:54PM V07.00013: Maximally Localized Wannier Orbitals and the Anderson Impurity Model for Twisted Bilayer Graphene* XI CHEN (Presenter), Center for Computational Quantum Physics, Flatiron Institute, EMANUEL C GULL, Physics, University of Michigan, ANDREW MILLIS, Center for Computational Quantum Physics, Flatiron Institute — We developed an effective Anderson impurity model to describe the low energy electronic properties of the twisted bilayer graphene. By using the method of selectively localizing Wannier orbitals, we construct a model that captures the key energetic and symmetry features of the original low energy bands and is possible for further calculation with non-perturbative methods. Using this model, we investigated the effect of interaction and the applied magnetic field near the half-filled region.

*This project is funded by Simons Foundation.
5:06PM V07.00014: Impact of Quenched Disorders on The Holstein Model*

BO XIAO (Presenter), University of California, Davis, NATANAELE DE CARVALHO COSTA, Instituto de Física, Universidade Federal do Rio de Janeiro, EHSAN KHATAMI, Department of Physics and Astronomy, San Jose State University, GEORGE BATROUNI, Institut de Physique de Nice, Universite de Nice-Sophia Antipolis, RICHARD THEODORE SCALETTAR, University of California, Davis — Over the last few decades, there has been considerable interest in the effects of disorder on the competition between superconductivity and charge order wave (CDW) in underdoped cuprates. Similar questions arise in the study of the interplay of polaron formation and ordering with Anderson localization in disordered electron-phonon systems such as superconducting peroskites, and colossal magnetoresistance manganites. Many interesting phenomena are observed including non-Fermi liquid behavior and metal-insulator transitions (MIT) due to the opening of a CDW gap or due to Anderson localization. The combination of electron-phonon coupling and randomness leads to rich phase regimes as the phonon frequency $\omega$, electron-phonon coupling $\lambda$ and disorder strength $\Delta$ vary. Here we present results from the DQMC method for the two-dimensional disordered Holstein model. We focus on the dependence of sizes of domain walls as well as the correlation length of density fluctuations. We also show the results for the temperature dependence of the conductance and compare to existing dynamical mean field theory results.

5:18PM V07.00015: Universal entanglement of typical states in constrained systems*

SIDDHARDH MORAMPUDI, ANUSHYA CHANDRAN, CHRISTOPHER LAUMANN (Presenter), Boston University — We develop a formalism to exactly evaluate the bipartite entanglement of random states in large Hilbert spaces with local and global constraints. We solve the simplest class of constraints which includes the much studied Rydberg-blockaded/Fibonacci chain. The resulting entanglement spectra may be classified into `phases' depending on their singularities. Our results predict the entanglement of infinite temperature eigenstates in thermalizing constrained systems and provide a baseline for numerical studies.

2:30PM V08.00001: Towards the Kitaev model with quantum dot chains in semiconductor nanowires

HAO WU (Presenter), PO ZHANG, JUN CHEN, University of Pittsburgh, SASA GAZIBEGOVIC, ROY OP HET VELD, GHADA BADAWY, ERIK P. A. M. BAKKERS, Eindhoven University of Technology, SERGEY M FROLOV, University of Pittsburgh — We experimentally explore whether chains of quantum dots in semiconductor nanowires can be used to emulate important one-dimensional Hamiltonians such as Kitaev model that describes a topological p-wave superconductor. In our devices, quantum dots are electrostatically confined in an InSb nanowire by an array of closely spaced narrow gates. Quantum dots are coupled to NbTiN superconducting leads. We study transport properties and magneto-spectroscopy of Andreev bound states in these quantum dots with magnetic fields parallel to the nanowire axis. Up to three quantum dots and three superconducting contacts are defined in a single nanowire. We compare results from quantum dot chain experiments to those of experiments on closely related Majorana nanowires.

2:42PM V08.00002: Analytical Noise Spectra Calculations for High-Temperature Superconducting Nanowires*

COREY OSTROVE (Presenter), LINDA E REICHL, University of Texas at Austin — In this talk we present analytical results for the noise spectrum of a superconducting heterostructure formed by a high temperature superconductor (HTS) nanowire. The scattering matrix is calculated from first principles using the Bogoliubov-de Gennes equations with appropriate boundary conditions and without the Andreev approximation. The current-current correlation function is calculated directly using the scattering coefficients and from this the noise spectrum (and in particular the shot noise contribution) is generated. The effects of the anisotropy of the order parameter in the scattering properties of the structures are investigated. We also consider some of the consequences of the quasi-1d geometry in terms of the restrictions on allowed propagation modes through the nanowire. Recent advances in materials synthesis have brought the production of high quality HTS nanowires closer widespread use in the design and construction of superconducting devices, which makes theoretical characterization of these structures of particular importance.

2:54PM V08.00003: Competition between the Yu-Shiba-Rusinov and Kondo screening in double quantum dot based Cooper pair splitters*  
IRENEUSZ WEYMANN (Presenter), KACPER WRZESNIEWSKI, Faculty of Physics, Adam Mickiewicz University, Umultowska 85, 61-614 Poznan, Poland — The Andreev transport properties of double quantum dot based Cooper pair splitters with one superconducting and two normal leads are studied theoretically in the Kondo regime. The influence of the Yu-Shiba-Rusinov screening resulting from superconducting pairing correlations on the local density of states, Andreev transmission coefficient, and Cooper pair splitting efficiency is thoroughly analyzed. It is shown that finite superconducting pairing potential quickly suppresses the SU(2) Kondo effect, which can however reemerge for relatively large values of coupling to superconductor. In the SU(4) Kondo regime, a crossover from the SU(4) to the SU(2) Kondo state is found as the coupling to superconductor is enhanced.

3:06PM V08.00004: Andreev Blockade in a Double Quantum Dot with a Superconducting Lead*  
DAVID PEKKER (Presenter), SERGEY M FROLOV, Department of Physics and Astronomy, University of Pittsburgh — A normal metal source reservoir can load two electrons onto a double quantum dot in the spin-triplet configuration. We show that if the drain lead of the dot is a spin-singlet superconductor, these electrons cannot form a Cooper pair and are blockaded on the double dot. We call this phenomenon Andreev blockade because it arises due to suppressed Andreev reflections. We identify transport characteristics unique to Andreev blockade. Most significantly, it occurs for any occupation of the dot adjacent to the superconductor, in contrast with the well-studied Pauli blockade which requires odd occupations. Andreev blockade is lifted if quasiparticles are allowed to enter the superconducting lead, but it should be observable in the hard gap superconductor-semiconductor devices. Andreev blockade should be considered in the design of topological quantum circuits, hybrid quantum bits and quantum emulators.

3:18PM V08.00005: Transport in superconductor/ferromagnet multilayers with Néel-type domain walls*  
XAVIER PALERMO, ANKE SANDER (Presenter), SOPHIE D'AMBROSIO, SALVATORE MESORACA, K BOUZEHOUANE, SOPHIE COLLIN, NICOLAS REYREN, VINCENT CROS, JAVIER VILLEGAS, Unité Mixte de Physique, CNRS, Thales, Université Paris-Sud, Université Paris-Saclay, Palaiseau, France — We experimentally investigate the coupling between magnetization reversal and magneto-transport in the metallic superconductor/ferromagnet multilayers. The ferromagnet consists itself of a multilayer in which the materials' stack (Co, Pt, Ir and Ru) is engineered in order to tailor i) the magnetic domains morphology and ii) their size. These variables have a striking effect on the magneto-transport properties below the superconducting critical temperature. In particular, in the presence of magnetic domains the mixed-state resistance is radically diminished to an extent that depends on the domains structure morphology. Contrarily, when the ferromagnet is saturated, an excess resistance is observed. Furthermore, and interestingly, those changes in the longitudinal resistance are accompanied by an anomalous transverse resistance which strongly depends on the applied magnetic field direction and magnetic history. We will discuss the mechanisms contributing to that behavior, which include Pearl vortex pinning and generation, as well as inhomogeneous superconductivity induced by the magnetic template.

3:30PM V08.00006: Anisotropic purity of entangled photons from Cooper pairs in heterostructures*  
HAE-YOUNG KEE (Presenter), JACOB S. GORDON, University of Toronto — It has been theoretically proposed that a forward-biased p-n junction with a superconducting layer (P-N-S) would produce pure, polarization-entangled photons due to inherent spin-singlet pairing of electrons. However, any heterostructure interface generically induces Rashba spin-orbit coupling, which in turn generates a mixed singlet-triplet superconducting order parameter. Here we study the effect of triplet pairing on the purity of photons produced through Cooper pair recombination. A unique directional dependence of the state purity is found: in a triplet superconductor with fixed d-vector, pure, entangled photons are produced when the photon polarization axis is parallel to d, with diminished purity for other directions. Induced triplet pairing in a singlet superconductor is shown to degrade the state purity, while induced singlet pairing in a triplet superconductor is shown to enhance the production of entangled pairs. These considerations may aid the design of functional devices to produce entangled photons.

3:42PM V08.00007: Subgap states and Dynes parameter in hard-gap tunnel junctions* CHRISTIAN SCHELLER (Presenter), Department of Physics, Univ of Basel, MARIO PALMA, Department of Physics, University of Wisconsin-Madison, LUCAS CASPARIS, Niels Bohr Institute, Univ of Copenhagen, TARAS PATLATIUK, Department of Physics, Univ of Basel, LUCA CHIROLLI, IMDEA-Nanoscience, ANNA V FESHCHENKO, Department of Applied Physics, Aalto University, DARIO MARADAN, Physikalisch-Technische Bundesanstalt (PTB), MATTHIAS MESCHKE, JUKKA P PEKOLA, Department of Applied Physics, Aalto University, DOMINIK ZUMBUHL, Department of Physics, Univ of Basel — Normal metal – insulator - superconductor (NIS) tunnel junctions are the basic building blocks for Josephson junctions, superconducting qubits and many other applications. Ideally, the single particle current is zero within the superconducting gap; while photon assisted tunneling (PAT) can lead to sub-gap currents (Dynes parameter). Here, we examine hard gap NIS tunnel junctions in a well filtered and shielded environment where PAT is negligible. We observe discrete, sharp current steps in the sub-gap regime which can be used as a primary thermometer, in excellent agreement with regular NIS thermometry [1], but cooling as low as 4 mK on a nuclear refrigerator [2]. In an in-plane magnetic field, the steps exhibit Zeeman splitting with g = 2 and display diamagnetic shifts. We model the steps as geometric resonances within the weakly disordered normal metal giving enhanced Andreev reflection due to multiple reflections. The model shows that disorder is a possible microscopic origin for Dynes-type linear leakage current.

3:54PM V08.00008: Induced superconducting gap vs. barrier thickness in hybrid Al/Al0.15In0.85As/InAs heterostructures SAEED FALLahi (Presenter), Department of Physics and Astronomy, Purdue University, West Lafayette, Indiana 47907 USA, RAY KALLAHER, SERGEI GRONIN, Microsoft Quantum at Station Q Purdue, Purdue University, West Lafayette, Indiana 47907, USA, CANDICE THOMAS, TIAN WANG, Department of Physics and Astronomy, Purdue University, West Lafayette, Indiana 47907 USA, GEOFFREY C. GARDNER, Microsoft Quantum at Station Q Purdue, Purdue University, West Lafayette, Indiana 47907, USA, GEOR W. WINKLER, Station Q, Microsoft Research, Santa Barbara, California 93106-6105, USA, JAN GUKELBERGER, JOHN GAMBLE, Quantum Architecture and Computation Group, Microsoft Research, Redmond, Washington 98052, USA, ANDREY ANTIPOV, ROMAN LUTCHYN, Station Q, Microsoft Research, Santa Barbara, California 93106-6105, USA, ANTONIO FONIERI, ALEXANDER WHITICAR, ASBJORN C. C. DRACHMANN, Eoin C O'FARRELL, FABRIZIO NICHELE, CHARLES M MARCUS, Center for Quantum Devices and Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, Universitetsparken 5, 2100 Copenhagen, Denmark, MICHAEL MANFRA, Department of Physics and Astronomy, Purdue University, West Lafayette, Indiana 47907 USA — The two dimensional electron gas (2DEG) in InAs proximitized by aluminum (Al) is a promising platform for scaling topological qubits based on Majorana zero modes. The 2DEG lies in an InAs quantum well and is separated from the epitaxial Al layer by a barrier of Al0.15In0.85As with thickness d. Due to hybridization between the wave functions of 2DEG and superconductor, the strength of induced gap in the 2DEG will largely depend on the barrier thickness. We present a systematic study of the strength of the induced gap in hybrid Al/Al0.15In0.85As/InAs superconductor/semiconductor heterostructures as a function of barrier thickness. We estimate the induced gap by analyzing multiple Andreev reflections in SNS junctions and differential conductance measurement in S-QPC-N junctions in the tunneling regime. We compare our results with self-consistent calculations of induced gap for our particular geometry.

4:06PM V08.00009: Interaction of Skyrmions and Pearl Vortices in Superconductor-Chiral Ferromagnet Heterostructures* SAMME DAHIR, ANATOLY F. VOLKOV, ILYA EREMIN (Presenter), Ruhr University Bochum — We investigate a hybrid heterostructure with magnetic skyrmions (Sk) inside a chiral ferromagnet interfaced by a thin superconducting lm via an insulating barrier. The barrier prevents the electronic transport between the superconductor and the chiral magnet, such that the coupling can only occur through the magnetic elds generated by these materials. We nd that Pearl vortices (PV) are generated spontaneously in the superconductor within the skyrmion radius, while anti-Pearl vortices (PV) compensating the magnetic moment of the Pearl vortices are generated outside of the Sk radius, forming an energetically stable topological hybrid structure. Finally, we analyze the interplay of skyrmion and vortex lattices and their mutual feedback on each other. In particular, we argue that the size of the skyrmions will be greatly a ected by the presence of the vortices o ering another prospect of manipulating the skyrmionic size by the proximity to a superconductor.

*The authors acknowledge support from the DFG Priority Program SPP2137, Skyrmionics, under Grant No. ER 463/10.
4:18PM V08.00010: Tunneling Anomalous Hall Effect (TAHE) in Ferromagnet/Superconductor Junctions* ANDREAS COSTA (Presenter), University of Regensburg, ALEX MATOS ABIAGUE, Wayne State University Detroit, JAROSLAV FABIAN, University of Regensburg — The competition of two antagonistic interactions, spin-singlet superconducting pairing and ferromagnetic exchange, in one heterojunction leads to extraordinary phenomena. Owing to the additionally broken inversion symmetry, not only the interplay of superconductivity and ferromagnetism, but also the induced strong interfacial spin-orbit fields (SOFs) offer interesting subjects for experimental and theoretical investigations; several studies unraveled an intriguing impact of interfacial SOFs on transport already in normal-conducting systems, e.g., TAMR1 and TAHE2 effects. Our theoretical work focuses on ferromagnet/superconductor junctions, demonstrating the existence of a superconducting TAHE effect. While the effect's fundamental characteristics are comparable to what has been found in the normal-conducting analog2, our numerical simulations predict a much larger tunability of the TAHE conductance in the superconducting scenario, mostly due to the presence of Andreev reflection. Together with a simultaneously generated transverse supercurrent response in the superconductor, these findings might offer an interesting future perspective for experimentalists.

4:30PM V08.00011: Optimizing spin-triplet supercurrent through a ferromagnetic Josephson junction* VICTOR AGUILAR (Presenter), JOSEPH A GLICK, REZA LOLOEE, WILLIAM P PRATT, NORMAN OWEN BIRGE, Michigan State University — Ferromagnetic Josephson junctions show promise for application to energy efficient cryogenic memory [1]. Both spin-singlet and spin-triplet supercurrents are being studied by our group for this purpose. Engineering adjacent F layers in a three-layer system to have perpendicular magnetizations allows singlet pairs to convert to spin-aligned triplet pairs. Recent work in our group exploited a synthetic antiferromagnet (SAF) with perpendicular magnetic anisotropy (PMA) for the middle F layer [2]. These junctions exhibit phase control [2], but have a low critical current when compared to singlet junctions. To make the triplet junction a viable option for memory we show that removing the SAF while maintaining the PMA increases the critical current. To estimate the fraction of the supercurrent carried by spin-triplet pairs in our junctions, we also fabricate comparison junctions with the order of the F layers shuffled to suppress generation of spin-triplet pairs.

4:42PM V08.00012: Geometry and pairing-symmetry effects in superconductor/half-metallic ferromagnet vertical junctions* SALVATORE MESORACA (Presenter), SOPHIE D'AMBROSIO, XAVIER PALERMO, Unité Mixte de Physique, CNRS/Thales, Université Paris Sud, Université Paris-Saclay, Palaiseau, France, DAVID SÁNCHEZ-MANZANO, FABIAN CUELLAR, GFMC, Dpto. Física de Materiales, Universidad Complutense de Madrid, Spain, SOPHIE COLLIN, ANKE SANDER, Unité Mixte de Physique, CNRS/Thales, Université Paris Sud, Université Paris-Saclay, Palaiseau, France, JACOBO SANTAMARIA, GFMC, Dpto. Física de Materiales, Universidad Complutense de Madrid, Spain, JAVIER VILLEGAS, Unité Mixte de Physique, CNRS/Thales, Université Paris Sud, Université Paris-Saclay, Palaiseau, France — The interactions between superconductors (S) and ferromagnets (F) are widely studied nowadays due to the possibility of obtaining equal-spin triplet pairing, which is immune to the exchange field and therefore can propagate over long distances into the F. This effect has fundamental interest as well as a potential for spintronic applications. In this context, we study vertical S/F/S junctions made of a half-metallic F (La_{0.7}Sr_{0.3}MnO_{3} or La_{0.7}Ca_{0.3}MnO_{3}) with either a d-wave S (YBa_{2}Cu_{3}O_{7}) or a s-wave one (Mo_{80}Si_{20}), aiming to understand to role of the pairing symmetry on the proximity effect and, particularly, on the generation of equal-spin triplet correlations. We will compare low-temperature magneto-transport measurements made in vertical micro-junctions having different geometries, namely three-probe vs. a novel four-probe junction scheme, which is designed to separate conductance features linked to the top electrode's contact resistance from effects due to transport across the entire S/F/S junction.

*Work supported by the ERC grant N. 647100 “SUSPINTRONICS“ and French ANR grant ANR-15-CE24-0008-01 “SUPERTRONICS“.
4:54PM V08.00013: Transport in ferromagnetic/superconducting heterostructures* EVAN MOEN (Presenter), ORIOL TVALLS, University of Minnesota — We consider the transport theory in nano-scale ferromagnetic/superconducting heterostructures with multiple ferromagnetic layers. We do so using fully self consistent, numerical methods in the clean limit. Many properties unique to these systems arise due to the proximity effects between ferromagnets and superconductors. We determine the conductance in each spin channel and analyze its dependence on the magnetic misalignment angle between the ferromagnets, as well as on other physical parameters pertinent to multi-layered systems. We quantitatively describe some of these properties and we discuss our results in connection to proposed experiments.

*This work was supported in part by DOE Grant No. DE-SC0014467

5:06PM V08.00014: Thermoelectric effects in superconductor-ferromagnetic hybrids* KIRSTEN BLAGG (Presenter), ZACHARY PARROTT, Colorado Sch of Mines, MICHAEL P LILLY, Sandia National Labs, MEENAKSHI SINGH, Colorado Sch of Mines — The conflicting spin order in superconductor-ferromagnetic systems has lead to a host of fascinating phenomena. However, most experimental studies have focused on electrical and spin transport measurements. While there have been numerous theoretical predictions of exciting thermal phenomena, thermal properties of these systems remains largely unexplored. In particular, thermoelectric effects which are usually negligible in superconductors have been predicted to increase dramatically in superconductor hybrid structures when in the presence of a spin splitting exchange field. This presentation will focus of the experimental design and measurement of the Seebeck coefficient in superconductor-ferromagnetic hybrids.

*This work is supported by NSF DMR 1807583, user proposal 2018AC0054 at the Center for Integrated Nanotechnologies at Sandia National Laboratories, and startup funds from the Colorado School of Mines.

5:18PM V08.00015: High-critical-field superconducting heterostructures using anodic oxidation ASBJØRN DRACHMANN (Presenter), HENRI J SUOMINEN, Center for Quantum Devices, University of Copenhagen, ALEX R HAMILTON, School of Physics, University of New South Wales, SERGEI GRONIN, TIAN WANG, GEOFFREY GARDNER, CANDICE THOMAS, Department of Physics and Astronomy, Purdue University, ALEXANDER WHITICAR, ANTONIO FORNIERI, Center for Quantum Devices, University of Copenhagen, MICHAEL MANFRA, Department of Physics and Astronomy, Purdue University, CHARLES M MARCUS, FABRIZIO NICHELE, Center for Quantum Devices, University of Copenhagen — In-situ growth of Al on top of shallow InAs 2DEG heterostructures gives close to perfect proximity effect [1-2]. The transparent super/semi interface combined with customizable 2DEG lithography hold promise to many interesting applications, e.g. topological quantum computation [3-4].

When the aluminum is chemically etched the underlying InAs is degraded by surface impurities. [2] Instead of etching the aluminum, here we show that controllably oxidizing the Al through anodic oxidation (AO) gives up to a factor 2 increase in InAs mobility and Quantum Hall effect emerges before 3 Tesla.

We will also show how AO can be used to controllably thin down Al, thus increasing its superconducting properties [2,5-6], obtaining an in-plane critical field > 6 T and a perpendicular critical field > 3T on a mesoscopic structure.

Besides enhancing superconducting properties of established devices, this technique paves the way to new research topics, e.g. Quantum Hall edge states proximitized by the surface Al with close to unity transparency.

Session V09 DCMP: Nanowires and One-Dimensional Structures: Optical and Electronic Properties BCEC 151A - Patrick Vora, George Mason Univ - Tag(s): Focus
The ultraviolet region indicates: a) that the B1l mode is related to a resonance effect, i.e. Fröhlich interaction plays a role in infra-red spectroscopies. However, the B1l mode appears with a small linewidth in the Raman scattering spectra on high and b) the mechanism allowing the appearance of the B1l does not allow the observation of the B1h. After performing

2:30PM V09.00001: Turning light-guiding nanowires into a fluorescence-based biosensing assay* MOHAMMED ALMOKHTAR, Department of Physics, Assiut University, Egypt, WILFREDO IBARRA-HERNANDEZ, Faculty of Engineering, BUAP, Mexico, MAURICIO MORAIS.DE LIMA JR., Molecular Science Institute, University of Valencia, Spain, CANTARERO (Presenter), SIMON FRASER UNIVERSITY, DAMIANO VERARDO, Division of Solid State Physics, Lund University, MARTIN J. ZUCKERMANN, NANCY FORDE, Simon Fraser University, HEINER LINKE, Division of Solid State Physics, Lund University — In some designs, semiconductor nanowires act as nanoscale optical fibres. Their quasi-1D structure can allow for the coupling of photons, which are then guided along the central axis of the nanowire structure to be emitted through its tip. In this talk, I will discuss our collaborative effort to passivate the surface of nanowires with cleavage-activated fluorogenic peptides, thereby turning a lattice of GaP nanowires into a high-throughput biosensing assay. I will present our results showing that we are able to detect the presence and activity of enzymes free in solution. This detection happens via the increase in light intensity at the nanowire tips as the surface-tethered substrates are cleaved and become fluorescent. The generality of this finding is further improved with use of our newly developed triblock-copolymer surface chemistry, which enables both specific modification of nanowire surfaces and the blocking of undesired nonspecific adhesion (e.g. of quantum dots from solution).

2:42PM V09.00002: Size dependent surface band bending in GaN nanowires* SANTANU PARIDA (Presenter), KISHORE K. MADAPU, SANDIP DHARA, Indira Gandhi Centre for Atomic Research — Group III-nitride nanowires (NWs) are recently emerged as a potential candidate for the single nanostructure high-performance optoelectronic devices because of the unidirectional conduction of charge carriers and absence of extended defects. However, surface states play important role in nanostructure-based device performance. The role of surface states and Fermi-level pinning is still unclear for III-nitride semiconductors. Therefore, the present study intends to investigate the effect of surface states on the band bending of the unintentionally doped n-GaN NW using Kelvin probe force microscopy (KPFM) with high spatial resolution. The KPFM measurements were carried out at high vacuum (~10^-7 mbar) to avoid the effect of surface adsorbents. Single-pass imaging was adopted for the simultaneous measurement of topography, and the contact potential difference (CPD). Several measurements were carried out for the NWs with different diameter and the corresponding surface band bending were calculated. The surface band bending value was found to depend on the diameter of the NWs. Diameter dependent surface band banding of the NWs is attributed to the variation in the density of surface states in the NWs.

2:54PM V09.00003: Electronic homogeneity of III-Nitride nanowire Light Emitting Diodes (LEDs) grown on amorphous and nanocrystalline metals CAMELIA SELCU (Presenter), BRELon J MAY, ROBERTO CORREA MYERS, Ohio State University — Conductive atomic force microscopy (c-AFM) is a powerful technique to probe electrical inhomogeneities at nanometer scale in as-grown nanowire ensembles without introducing uncertainty due to additional device processing steps. Using c-AFM, we investigated the nanoscale current uniformity of III-Nitride nanowire LEDs grown on Pt thin films and amorphous metal foil. In this talk, I will discuss the variation of the current distributions in GaN nanowire LEDs grown on p-Si and Pt thin films. By taking IVs on individual nanowires, we found that there is a reduction in the threshold voltage for the GaN nanowire LEDs grown on Pt films compared to those grown on p-Si.

3:06PM V09.00004: Crop up of the B_{11} mode in high quality GaN nanowires due to isotopic disorder* ANDRES CANTARERO (Presenter), CARLOS RODRIGUEZ-FERNANDEz, Molecular Science Institute, University of Valencia, Spain, MOHAMMED ALMOKHTAR, Department of Physics, Assiut University, Egypt, WILFREDO IBARRA-HERNANDEz, Facultad de Ingeniería, BUAP, Mexico, MAURICIO MORAIS.DE LIMA JR., Molecular Science Institute, University of Valencia, Spain, ALDO ROMERO, Applied Physics Department, West Virginia University, USA, HAJIME ASAHI, Institute of Scientific and Industrial Research, Osaka University, Japan — The B_{11} and B_{1h} vibrational modes of GaN are silent, i.e. they cannot appear neither in Raman nor in infra-red spectroscopies. However, the B_{11} mode appears with a small linewidth in the Raman scattering spectra on high quality ultra-narrow GaN nanowires, while the B_{1h} mode does not. The simultaneous appearance of the A_{11}(LO) and B_{11} in the ultraviolet region indicates: a) that the B_{11} mode is related to a resonance effect, i.e. Fröhlich interaction plays a role and b) the mechanism allowing the appearance of the B_{11} does not allow the observation of the B_{1h}. After performing density functional theory calculations and discarding several options we have concluded that the only difference between both modes is the isotopic composition [1]. While Ga, which contributes to the B_{11} mode, has mainly two isotopes, $^{69}$Ga and $^{71}$Ga, N, the main contributor to the high frequency mode, has basically one isotope, i.e. it is isotopically ordered. Harnessing the magneto-optics of quantum wires for designing the optical amplifiers

MANVIR KUSHWAHA (Presenter), Rice University — Quantum wires occupy a unique status among the semiconducting nanostructures with reduced dimensionality. No other system seems to have engaged researchers with as many appealing features to pursue. This letter aims at a core issue related with the magnetoplasmon excitations in the quantum wires characterized by the confining harmonic potential and subjected to a longitudinal electric field and a perpendicular magnetic field in the symmetric gauge. Despite the substantive complexity, we obtain the exact analytical expressions for the eigenfunction and eigenenergy, using the scheme of ladder operators, which fundamentally characterize the quantal system. Crucial to this inquiry is an intersubband collective excitation that evolves into a magnetoroton -- above a threshold value of magnetic field -- which observes a negative group velocity between maxon and roton. The evidence of negative group velocity implies anomalous dispersion in a gain medium with the population inversion that forms the basis for the lasing action of lasers. Thus, the technological pathway that unfolds is the route to devices exploiting the magnetoroton features for designing the novel optical amplifiers and hence paving the way to a new generation of lasers.

ABSTRACT WITHDRAWN

Magneto-Chiral Anisotropy in Carbon Nanotubes

NEDA LOTFIZADEH (Presenter), Department of Physics and Astronomy, University of Utah, MITCHELL J. SENGER, DANIEL MCCULLEY, ETHAN D. MINOT, Department of Physics, Oregon State University, VIKRAM V. DESHPANDE, Department of Physics and Astronomy, University of Utah — Chiral conductors exist in two forms which are mirror images of each other and have different handedness. The nonlinear term in powers of voltage is an odd function of magnetic field and its coefficient in chiral conductors depends on the handedness and electron-electron interactions. Due to the importance of electron-electron interactions in carbon nanotubes and their large magneto-chiral anisotropy, they are one of the best candidates to study nonlinear magneto-transport in chiral conductors. In this work we use ultra clean suspended carbon nanotubes to investigate electrical magneto-chiral anisotropy in these materials, which can be used as a probe to deduce the electron-electron interaction strength and handedness of the tubes. Using photocurrent spectroscopy, we identify our nanotubes’ structure to compare the transport data with the existing theories.

Ultrafast Stimulated Raman Scattering in Carbon Nanotubes

STEVEN DRAPCHO (Presenter), CHAW KEONG YONG, University of California, Berkeley, AVISHEK SAHA, STEPHEN K. DOORN, Los Alamos National Lab, FENG WANG, University of California, Berkeley — We perform ultrafast transient absorption spectroscopy on (6,5) carbon nanotubes in aqueous solution, using a near-IR pump and supercontinuum near-IR probe. We observe stimulated Raman scattering between the pump and probe light involving the nanotube G phonon mode, and examine the dependence of this Raman feature on the pump and probe wavelengths and pump fluence. We find that the stimulated Raman process is enhanced when the probe energy is near the nanotube exciton resonance, allowing us to investigate exciton-phonon coupling in the nanotubes.

Modification of Second Harmonic Generation Signals From Multiferroic Nanofibers Under Changing Magnetic Field

SABA ARASH (Presenter), BRYAN CHAVEZ, Department of Physics and Astronomy, University of South Carolina, MATTHEW BAUER, JENNIFER ANDREW, Department of Materials Science & Engineering, University of Florida, THOMAS M CRAWFORD, YANWEN WU, Department of Physics and Astronomy, University of South Carolina — Multiferroic materials have recently attracted widespread attention as a novel class of materials due to their diverse multifunctional properties and applications. In particular, multi-phase structures are easier to synthesis and more common at room temperature in comparison to the single-phase materials. The hybrid structures investigated in this study are Janus nanofibers consisting of two hemi-cylinders of ferroelectric barium titanate (BTO) and ferrimagnetic cobalt ferrite (CFO). The mechanism involved in the magnetoelastic (ME) coupling between the two phases for this particular system is strain. In this study, we used the optical second harmonic generation (SHG) technique to monitor changes in the ferroelectricity of the BTO half while modifying the magnetization of the CFO half. The optical investigation was performed on an ensemble of pre-aligned nanofibers. In addition, the polarizations of the SHG signal were analyzed at different magnetic field orientations. We observed a clear signature of the SHG polarization rotation as the magnetic field direction was changed. This result suggests the existence of a measurable ME coupling between the two phases of this hybrid structure at room temperature which is essential for realizing devices with multiferroic applications.
4:18PM V09.00010: Intrinsic quality of InSb NWs grown in template pores  
ABHAY SINGH (Presenter), USHA PHILIPOSE, University of North Texas — InSb NWs were grown in two different types of templates: nanoporous anodic aluminum oxide (AAO) and polycarbonate. In this talk, the difference in the structural quality of the as-grown NWs in both cases will be presented. NWs grown in commercially available AAO templates were found to have rough surfaces attributed to non-uniform pores in the membrane. On the other hand, InSb NWs grown in the polycarbonate track-etched membranes showed very uniformly, smooth surfaces. Both types of NWs were characterized by Raman spectroscopy, which showed different Raman spectrum. The strong defect related peak in the polycarbonate-grown InSb NWs attest to the fact that they are possibly amorphous. Temperature-dependent measurements on these NWs also show very different behavior. The NWs grown in the polycarbonate membrane show Mott Variable Range Hopping in the low-temperature regime and Arrhenius (thermally activated) transport in the high-temperature regime. This is contrary to the AAO template grown InSb NWs which shows thermally activated conduction mechanism in both low and high-temperature regime.

4:30PM V09.00011: Investigating surface migration energy barriers of self-assembly ZnO nanorods by multi-optical methods  
FENG-MING CHANG (Presenter), ZONG-ZHE WU, JING-HENG HUANG, WEI-TING CHEN, SANJAYA BRAHMA, KUANG YAO LO, National Cheng Kung University — Post-annealing treatment plays an important role for self-assembly (SA) metal oxide by providing thermal energy for oxygen atoms to overcome the migration energy barrier. With theoretical methods, it's hard to calculate the height of migration energy barrier from the surface to bulk which depends on depth. Due to the high surface-to-volume ratio of SA ZnO nanorods (ZNRs), the optical properties and structural evolution on the surface obtained by ultraviolet/X-ray photoemission spectroscopy (UPS/XPS) and photoluminescence (PL) could be well investigated and reveal mutual agreement in all results in PL, XPS and UPS. In this work, we first demonstrated structural variation on the surface of SA-ZNRs by scanning over a range of annealing temperatures and durations by rapid thermal annealing (RTA) system and then characterized the multi-optical properties by integrating the results of PL, XPS and UPS. Finally, the model of migration energy barriers reveals the well ZNRs formed at 570°C and the further oxidation process with formation of hydroperoxide on the Zn-rich surface of ZNRs at 640°C.

4:42PM V09.00012: Maximizing Photonic Response with Simple Resonating Structures in Various Geometries*  
CONSTANTINOS VALAGIANNOPOULOS (Presenter), ARSEN SHEVERDIN, ADILKHAN SARSEN, AIVAR ABRASHULY, Nazarbayev University — Resonances are all over us in multiple forms concerning the collaboration of two (or more) parts in order to maximize an output. In Photonics, the effect is interpreted as an optimally balanced regime between electric and magnetic response in domains with different optical axes or opposite-sign permittivities. In this talk, we examine simple structures of different geometries serving various purposes from large wave polarization conversion to efficient absorbance and maximal scattering.

Firstly, we consider a planar structure consisting of two slabs positioned back-to-back with different thicknesses but the same binary multilayered texture. By rotating in-plane the two slabs, we aim at tilting the linearly polarized incident field by 90 degrees; it is a particularly challenging task when working with such simple configurations.

Secondly, an isolated core-shell nanowire, where the resonance occurs between the metallic cylinder and the semi-conducting coat, is regarded. The potential of these realistic designs to operate as switches, sensors or as components in filtering and tagging optical systems, is also identified by evaluating the corresponding frequency responses.

4:54PM V09.00013: Dark vertical conduction of cavity-embedded semiconductor heterostructures*  
CASSIA NAUDET-BAULIEU (Presenter), NICOLA BARTOLO, GIULIANO ORSO, CRISTIANO CIUTI, Laboratoire MPQ, Université Paris Diderot - Paris 7 — We present a linear-response theory for the electronic transport along the growth direction of an arbitrary semiconductor heterostructure coupled to a photonic resonator in its vacuum state (no real photons are injected or created). To ensure a coupling between intersubband and photonic excitations, the cavity field is assumed to be polarized along the growth direction. We point out how the light-matter and electron-electron interactions hybridize the (confined) many-body ground state with the continuum, showing how this can affect the conduction properties in the growth direction. Our findings are relevant, for instance, in the development of cavity-embedded quantum-well infrared photodetectors (QWIP).

*We thank the Doctoral School EDPIF for the PhD scholarship of C. N-B.
Arrays of gratings can be multiplexed to create multi-view backlights, where each super-pixel is composed of several angularly directive beams. However, real applications of this technology are hampered by a limited field of view. In particular, diffractive optics are incapable of efficiently radiating light perpendicular to the plane of the array. This causes a hole in the center of the field of view because the refracted beam intensity from a diffraction grating coupler at wavelengths near cut-off. The grating is unable to produce a beam at the broadside, due to a standing wave formed in the plane of the array.

To overcome this limitation, we have developed metasurface-based pixel. The design consists of an array of high-index dielectric pillars, which exhibit simultaneous electric and magnetic resonances. The resulting metasurface supports leaky waves above the light line, which efficiently radiate into the broadside at telecom and visible frequencies. The Dirac-cone metasurface can produce beams over a continuous range of angles around the broadside due to its linear dispersion at the center of the Brillouin zone. By carefully tuning the interference of multiple bound modes, we can independently control the radiative efficiency, beam width, and beam angle.
**3:06PM V10.00002: DFT+eDMFT study of lattice dynamics in FeSe**

GHANASHYAM KHANAL (Presenter), KRISTJAN HAULE, Physics and Astronomy, Rutgers University — Effect of electron-electron interactions in the high-temperature superconductivity has been one of the challenging issues in condensed matter physics. We study the lattice dynamics of one of the iron-based high-temperature superconductors FeSe using ab-initio Density Functional Theory (DFT)+ embedded Dynamical Mean-Field Theory (eDMFT) functional approach. We found that the electron-electron interaction plays an important role in determining the phonon frequencies of different vibrational modes in this material. The phonon frequencies are in a very good agreement with the experimentally reported values in particular when compared to previously reported DFT results. The agreement extends also in the phonon band structure along with the phonon density of states.

*We acknowledge the support of NSF DMR-1709229.

**3:18PM V10.00003: Quantum Phase Transitions in a Multi-Orbital Hubbard Model for Iron Pnictides**

WENJUN HU (Presenter), Rice University, LUCA FAUSTO TOCCHIO, Institute for condensed matter physics and complex systems, HSIN-HUA LAI, Rice University, RONG YU, Renmin University of China, FEDERICO BECCA, International School for Advanced Studies, QIMIAO SI, Rice University — Quantum criticality in iron pnictides was proposed within an effective field theory that contains both antiferromagnetic and nematic order parameters [1,2]. Its proposed realization in P-doped BaFe2As2 has received extensive experimental evidence [3,4]. Here we study this problem within a multi-orbital Hubbard model containing both the Hubbard and Hund's interactions. We analyze the effect of electron correlations in a non-perturbative way, through a variational Monte Carlo method that is based on a Jastrow-Slater wave function. We study the evolution of the electronic orders as the interaction strength is varied, report evidence for concurrent antiferromagnetic and nematic quantum critical points, and discuss the implications for superconducting pairing.

*This work is supported by the DOE Award # DE-SC0018197 and Welch Foundation.

**3:30PM V10.00004: Quantum dynamical screening of the local magnetic moments in the different families of Fe-based superconductors**

CLEMENS WATZENBÖCK, Institute of Solid State Physics, TU Wien, MARTIN EDELMANN, University of Würzburg, DANIEL SPRINGER, Institute of Solid State Physics, TU Wien, ANDREAS HAUSOEL, GIORGIO SANGIOVANNI, University of Würzburg, ALESSANDRO TOSCHI (Presenter), Institute of Solid State Physics, TU Wien — The formation of localized magnetic moments and their dynamical screening represents one of the crucial ingredients of the physics of correlated metals. Their theoretical treatment is, in fact, crucial to correctly predict the spectroscopic observations in several important classes of correlated materials [1,2]. In this talk, we investigate [3] the local spin dynamics in different families of Fe-based superconductors by means of realistic dynamical mean-field theory calculations: We compute the dynamic magnetic correlations on the Fe sites both in real frequency and in real time domain. The former allows for a direct comparison with inelastic neutron spectroscopy, explaining the trends observed in the experiments on the different families of Fe-based superconductors. The latter allows to identify the characteristic time scales of the spin dynamics in these materials, which is useful for the interpretation of the discrepancies between different experimental probes, and, in perspective, for the analysis of future non-equilibrium experiments.

3:42PM V10.00005: Symmetry analysis of magnetoelastic couplings in the Fe-based superconductors* WILLIAM MEIER (Presenter), ANDREAS KREYSSIG, PAUL CANFIELD, Ames Laboratory and Dept. of Physics, Iowa State University — Antiferromagnetism (AFM) is a reoccurring theme in the Fe-based superconductors. The stripe-type AFM on the Fe lattice in these compounds is accompanied by a sympathetic orthorhombic distortion of the tetragonal structure. This is not the only kind of magnetoelastic coupling possible between magnetic and structural degrees of freedom. Based on a symmetry analysis of the crystal structures we obtain the symmetry-allowed coupling terms in the Landau free energy. We propose that many of the compounds in this family (including FeSe, BaFe₂As₂ and CaKFe₄As₄) will develop a periodic structural modification when a magnetic field is applied to the AFM ordered phase. This should produce additional Bragg peaks which could provide a sensitive indicator of the AFM order under extreme conditions, such as in high pressure cells.

*We thank M. H. Christensen, R. M. Fernandes, S. L. Bud'ko, R. Flint, and P. P. Orth for their insightful discussions. This work is supported by the Gordon and Betty Moore Foundation’s EPiQS Initiative through Grant GBMF4411 and the US DOE, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

3:54PM V10.00006: Simple transport models for the temperature-dependent linear magnetoresistance of pnictide and cuprate superconductors* JOHN SINGLETON (Presenter), National High Magnetic Field Laboratory, Los Alamos National Laboratory — Taken in conjunction with the temperature (T) dependence of the zero-field resistivity, simple transport models invoking e.g., realistic variations in charge-carrier density are shown to be sufficient to explain the linear magnetoresistance and field-temperature resistance scaling recently observed in high-temperature pnictide and cuprate superconductors. Hence, though the T-linear zero-field resistance is a definite signature of the "strange metal" state of high-temperature superconductors, their linear magnetoresistance and its scaling need not be; instead they may merely be signatures of disorder. Straightforward experimental tests of these assertions are proposed.

*Supported by the US DoE BES FWP Science in 100 T, and carried out at NHMFL, which is funded by NSF Cooperative Agreement DMR-1157490, the State of Florida and U.S. DoE.

4:06PM V10.00007: Pairing symmetry and topological surface state in iron-chalcogenide superconductors LUN HU (Presenter), CONGJUN WU, Department of Physics, University of California, San Diego — The gap function symmetries remain an important question in the study of iron-based superconductors. Motivated by the recent ARPES experiments, we investigate the gap function symmetries by examining the behavior of the surface Dirac cone of the iron-chalcogenide superconductors.

Whether the surface Dirac cone can be gapped when entering the superconducting state provides a constraint on the pairing symmetries, based on which possible time-reversal symmetry breaking gap functions are analyzed. This study provides a helpful connection between the gap function symmetries and surface state topology.

4:18PM V10.00008: Theory for quasiparticle interference in the presence of spin-orbit coupling in strongly electron-doped iron-based superconductors JAKOB BÖKER (Presenter), Ruhr University Bochum, PAVEL VOLKOV, Ruhr-University Bochum and Rutgers University, PETER HIRSCHFELD, Department of Physics, University of Florida in Gainesville, ILYA EREMIN, Ruhr University Bochum — Motivated by recent experimental reports on sizable spin-orbit coupling (SOC) and a sign-changing order-parameter in the Li₁₋ₓFeₓ(OHFe)₁₋₂ZnₓSe superconductor with only electron Fermi surface present, we study the possible Cooper-pairing symmetries and their quasiparticle interference (QPI) signatures. We find that each of the resulting states - s-wave, d-wave and helical p-wave - can have a fully gapped density of states (DOS) consistent with ARPES experiments and, due to spin-orbit coupling, are a mixture of spin singlet and triplet components leading to intra- and inter-band features in the QPI signal. Analyzing predicted QPI patterns we find that only the s- and d-wave pairing states with a dominant even parity triplet component can fit the experimental data with the two dominant peak positions in the DOS roughly correspond to the gap sizes at each pocket. Moreover we show that pairing states with dominant triplet component can be further verified using spin-resolved STM.
4:30PM V10.00009: Broken time-reversal symmetry in s+is and s+id states of multi-band superconductors: vortices, skyrmions, domain walls and spontaneous magnetic fields.*  
EGOR BABAEV (Presenter), KTH the Royal Institute of Technology, JULIEN GARAUD, CNRS Tours, MIHAIL SILAEV, Jyvaskyla University, ALBERTO CORTICELLY, KTH the Royal Institute of Technology — The recent experiments on Iron-based superconductors reported two interesting situations: the formation of s-wave superconducting state in Ba1−xKxFe2As2 that breaks time-reversal symmetry (BTRS) (i.e. the so-called s+is state) and disorder-driven crossover from s− to s++ state. Both of these situations should be accompanied by unconventional physics that will be discussed in this talk. I will discuss the origin of the spontaneous magnetic fields in the s+is state [1], unconventional topological excitations arising due to BTRS such as domains walls and Skyrmions [2], the breakdown of type-I/type-II dichotomy due to a divergent coherence lengths at the s− to s+is transition causing the magnetic field penetration length to be intermediate length scale: ξ1<λ< ξ2 [3,4] resulting in vortex clustering, and a rather generic coexistence of the s− and s++ states near the s− to s++ crossover [5].

*Supported by the Swedish Research Council and the Goran Gustafsson Foundation

4:42PM V10.00010: Interplay of structural properties and van der Waals forces in presence of magnet disorder in FeSe and FeTe by density-functional theory calculations  
FELIX LOCHNER (Presenter), Max Planck Institute for Iron Research GmbH, ILYA EREMIN, Theoretische Physik III, Ruhr-University Bochum, TILMANN HICKEL, JÖRG NEUGEBAUER, Max Planck Institute for Iron Research GmbH — We investigate the structural origin of the iron-based superconductors FeSe and FeTe in the presence of several magnetic orders, where we focus on the competition between stripe-type anti ferromagnetism (AFM) and paramagnetic disorder (PM). Here, the PM state is implemented by using the spin-space average approach [1] in combination with constrained magnetic moments for our density-functional calculations (DFT). To predict the correct ground state in respect to the lattice parameters, we use the similarity of the AFM and PM state to transfer the correlations for specific structural properties of the AFM picture to those correlation for the PM approach.

Moreover, we found that the specific energy-volume behavior of FeSe, which looks like an “L”, leads to a weak inter-layer interaction. Therefore, we include several approaches of van der Waals (vdW) interactions to these systems to correct the Se-Se interactions and Te-Te interactions respectively. Our results show, that the additional vdW forces are as necessary to reduce the lattice mismatch between experimental and predicted values as magnetic order is [4].

4:54PM V10.00011: Anomalous Non-Superconducting Time-Reversal-Symmetry Breaking State in Multicomponent Superconductors*  
DANIEL WESTON (Presenter), EGOR BABAEV, KTH Royal Institute of Technology — Multicomponent superconductors can break time-reversal symmetry, either due to phase frustration in Josephson-coupled superconductors with at least three components, or due to higher-order Josephson coupling in superconductors with at least two components. Beyond mean-field theory, such systems may have an anomalous phase in which time-reversal symmetry is broken despite superconducting order being absent. Models of the aforementioned type have been argued to describe the multiband superconductor Ba1−xKxFe2As2. We report properties of the fluctuation-induced precursory normal state that breaks time-reversal symmetry.

*The work was supported by the Swedish Research Council Grant No. 642-2013-7837 and by the Göran Gustafsson Foundation for Research in Natural Sciences and Medicine.

Thursday, March 7, 2019 2:30 PM - 5:30 PM

2:30PM V11.00001: Peculiar spectra of dark and bright excitons in alloyed nanowire quantum dots*  
MICHAL ZIELINSKI (Presenter), Institute of Physics, Nicolaus Copernicus University, Torun, Poland — Excitons in alloyed nanowire quantum dots have unique spectra as shown here using atomistic calculations. The bright exciton splitting is triggered solely by alloying and despite cylindrical quantum dot shape reaches over 15 μeV, contrary to previous theoretical predictions, however, in line with experimental data. This splitting can however be tuned by electric field to go below 1~μeV threshold. The dark exciton optical activity is also strongly affected by alloying reaching notable 1/3500 fraction of the bright exciton and having large out-of-plane polarized component.

*Support from the Polish National Science Centre based on decision No. 2015/18/E/ST3/00583 is kindly acknowledged.

2:42PM V11.00002: Precision Displacement Measurement Using a Shearing Interferometer*  
RAJU KC (Presenter), CAINAN NICHOLS, JAXON LEE, EDWARD B FLAGG, West Virginia University — The emission spectra from semiconductor quantum dots consists of closely spaced spectral peaks, which cannot be resolved by a conventional grating spectrometer. An alternative solution is to use a scanning Fabry-Perot interferometer (FPI), which functions as a narrow bandwidth tunable filter, to enhance the resolution. This technique demands very precise control of the distance between the two FPI mirrors with a resolution of 1 nm. Direct optical feedback would be ideal, but would require an expensive frequency-tunable laser. We demonstrate an economic way to achieve the required precision by mechanically connecting the FPI cavity to a shearing interferometer where fluctuations in the mirror separation can be measured using the interference pattern formed by a relatively inexpensive single-frequency laser. We are able to stabilize the RMS displacement fluctuation between the two mirrors in the shearing interferometer to 0.11 nm. This precision was sufficient to keep the FPI stable for ~40 minutes.

2:54PM V11.00003: Spin-selective AC Stark shifts in a charged quantum dot*  
TRISTAN WILKINSON (Presenter), DILLION COTTRILL, JOSHUA CRAMLET, COLE MAURER, COLLIN FLOOD, Department of Physics and Astronomy, West Virginia University, Morgantown, West Virginia 26506, USA, ALLAN S BRACKER, Naval Research Laboratory, Washington, DC 20375, USA, EDWARD B FLAGG, Department of Physics and Astronomy, West Virginia University, Morgantown, West Virginia 26506, USA — The energy levels of an optically active quantum system can be shifted via the AC Stark effect by applying a strong, far-detuned laser. We achieve an AC Stark shift of up to 20 GHz in a single negatively charged InGaAs quantum dot. In addition to the AC Stark shift we observe a small Overhauser shift of <1 GHz which we attribute to dynamic nuclear polarization via electron spin pumping induced by the high power, although far-detuned AC Stark laser. Both shifts are polarization selective, meaning polarization control of the applied laser provides control over the energy level structure of the system. Applying a circularly polarized laser therefore allows for a spin-selective modification to the energies, shifting one spin manifold and not the other. The reconfiguration of the energy levels is reversible and can be applied or removed rapidly on the timescale of a few nanoseconds. In principal this ability to rapidly and coherently reconfigure the energy structure and polarization selection rules may enable single-shot fluorescence readout in a small transverse magnetic field.

Superconducting transport in InAs nanowire double quantum dots

DANIEL BOUMAN (Presenter), RUBEN VAN GULIK, DOMINIQUE LAROCHE, QuTech, Delft University of Technology, JESPER NYGÅRD, PETER KROGSTJUP, Niels Bohr Institute, ATTILA GERESDI, QuTech, Delft University of Technology — Quantum dot arrays in narrow-gap semiconductors coupled to superconducting reservoirs can serve as a platform for studying the interaction between solitary spins and the Cooper pair condensate, which can give rise to topologically protected Majorana modes.

We define double quantum dots (DQDs) in InAs nanowires with epitaxial aluminum shell. We demonstrate that we can reach both the strongly and weakly coupled regimes owing to the five wrap-around electrostatic gates on the nanowire. We characterize the Josephson coupling via the DQD as a function of the charge occupation of the islands, and find abrupt changes which are possible experimental signatures of the change in the ground state spin configuration of the device. Finite voltage bias spectroscopy reveals Yu-Shiba-Rusinov states below the superconducting gap exhibiting the weakly and strongly coupled behavior at different gate configurations.

Charging of a Single InAs QD with Electrically-Injected Holes using a Lateral Electric Field*

XIANGYU MA (Presenter), YUEJING WANG, JOSHUA ZIDE, MATTHEW F DOTY, University of Delaware — InAs/GaAs quantum dot (QD) and quantum dot molecules (QDM) are self-assembled semiconductor nanostructures that can trap a single electron or hole in a 3-D potential-well. Grown by molecular beam epitaxy (MBE), they have excellent optical qualities that can be used in applications of quantum information processing and quantum computing. The property of a single QD can be tuned by external electric field, giving it great potential for scalable quantum photonic applications. Deterministically charging a QD with a single electron or hole has been demonstrated by embedding the QD in a diode structure and applying growth direction electric fields. Here, we report a new charging mechanism of a single QD using lateral electric field with a 3-electrode device. We designed a 3-electrode device that embeds a single QD in an unintentionally doped GaAs matrix. We fabricate the device with E-beam lithography and characterize a single QD’s photoluminescence under different bias configurations. We observe charging of a single hole through the lateral electric field, supported by device simulation using COMSOL. We will discuss the potential applications of a 2-D electric field on a single QD using a 3-electrode device.

Quantum mechanics on a torus: Energy levels, Zeeman splitting and transport properties*

DEBANIK DAS (Presenter), SATHWIK BHARADWAJ, SIDDHANT PANDEY, Department of Physics, Worcester Polytechnic Institute, Worcester, MA 01609, L RAMDAS RAM-MOHAN, Department of Electrical and computer engineering, Worcester Polytechnic Institute, Worcester, MA 01609 — Carrier confinement and transport in novel geometries have generated immense theoretical and experimental interest in recent years. Here we investigate the properties of an electron constrained to move on the surface of a torus. We derive the Schrodinger-Riccati equation on a torus using differential geometry. We construct the corresponding action and obtain the eigensolutions through a generalized varational approach. We show that the dual circular symmetries related to the minor and major radii give rise to at most a 4-fold degeneracy. We obtain the level splitting pattern in the presence of a perpendicular magnetic field. We investigate the transport properties for an electron on a torus with two contacts attached. The torus being a multiply connected topology shows the Ahronov-Bohm effect in presence of a magnetic vector potential and manifests the interference occurring due to electron waves travelling through two different paths. Semiconductor quantum dots and carbon nanotori, for certain chirality, have bandgaps at K-points in the Brillouin zone. Hence they obey nonrelativistic equations, making our study relevant for experimentally amenable outcomes.

*We thank the Center of Computational NanoScience (CCNS) at WPI for the computational resources used for these calculations.
3:42PM V11.00007: Spectroscopy of Quantum-Dot Orbitals with In-Plane Magnetic Fields* LEON CAMENZIND (Presenter), LIUQI YU, University of Basel, PETER STANO, Center for Emergent Matter Science, RIKEN, JERAMY D. ZIMMERMAN, ARTHUR C GOSSARD, Materials Department, UC Santa Barbara, DANIEL LOSS, DOMINIK ZUMBUHL, University of Basel — While spins in quantum dots have received a lot of attention for the development as a qubit, the orbitals which are hosting the qubit have largely been ignored. However, important processes such as electric-dipole spin resonance and spin relaxation depend sensitively on the dot shape due to the anisotropic nature of the spin-orbit interaction. Here, we present a method which allows quantifying the in-plane orientation angle and the strength of the hard confinement perpendicular to the 2D gas in which the gate-defined single-electron GaAs dot is formed. Using a piezo electric rotator, we control the direction of the magnetic field in the 2D plane and measure the in-plane orbital energies using pulse gate spectroscopy. Based on a model of the orbitals, we extract the orientation angle of the dot in the 2D plane, quantify the strong confinement and characterize deviations from a harmonic oscillator potential. Our measurements demonstrate a versatile tool for quantum dots with one dominant axis of strong confinement.

3:54PM V11.00008: Toward exploring multichannel charge Kondo effects for investigating quantum criticality CONNIE HSUEH (Presenter), Department of Applied Physics, Stanford University, ASBJORN C. C. DRACHMANN, Center for Quantum Devices and Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, CANDICE THOMAS, Department of Physics and Astronomy and Station Q Purdue, Purdue University, GEOFFREY C. GARDNER, Microsoft Quantum at Station Q Purdue, Purdue University, TIAN WANG, Department of Physics and Astronomy and Station Q Purdue, Purdue University, SERGEI GRONIN, Microsoft Quantum at Station Q Purdue, Purdue University, CHARLES M MARCUS, Center for Quantum Devices and Station Q Copenhagen, Niels Bohr Institute, University of Copenhagen, DAVID GOLDHABER-GORDON, Department of Physics, Stanford University — Recent proposals[1,2] have demonstrated a non-Fermi liquid fixed point in superconducting and topological superconducting islands, analogous to the charge Kondo effect in normal metallic islands. The topological Kondo effect is predicted to be robust against channel detuning and to have a heightened crossover temperature when tuned to charge degeneracy, making this an especially attractive regime for investigating quantum criticality and for demonstrating nonlocal quantum phenomena through Majorana modes. I will talk about our efforts in experimentally realizing new multichannel charge Kondo devices on InAs 2DEG platforms.

4:06PM V11.00009: Transient dynamics of a quantum-dot: From Kondo regime to mixed valence and to empty orbital regimes* YONGXI CHENG (Presenter), ZHEN-HUA LI, Simulation of Physical Systems, Beijing Computational Science Research Center, JIAN-HUA WEI, Department of Physics, renmin university of China, YI-HANG NIE, Institute of Theoretical Physics, Shanxi university, YIJING YAN, Hefei National Laboratory for Physical Sciences at the Microscale, University of Science and Technology of China — Based on the hierarchical equations of motion approach, we study the time-dependent transport properties of a strongly correlated quantum dot system in the Kondo regime (KR), mixed valence regime (MVR), and empty orbital regime (EOR). We find that the transient current in KR shows the strongest nonlinear response and the most distinct oscillation behaviors. Both behaviors become weaker in MVR and diminish in EOR. To understand the physical insight, we examine also the corresponding dot occupancies and the spectral functions, with their dependence on the Coulomb interaction, temperature, and applied step bias voltage. The above nonlinear and oscillation behaviors could be understood as the interplay between dynamical Kondo resonance and single electron resonant tunneling.

*This work was supported by the NSF of China (Grant Nos. 11747098, 11504017, 11774418, 11374363, and 21633006) and the Research Funds of Renmin University of China (Grant No. 11XNJ026).
4:18PM V11.00010: Fano and Fano-Kondo resonance in double quantum dot in parallel  YUJIE ZHANG (Presenter), MIKIO ETO, Faculty of Science and Technology, Keio University — It has been a controversial issue whether the Fano resonance is observed or not in the transport through a mesoscopic ring with an embedded quantum dot, so-called Aharonov-Bohm interferometer. To address this issue, we theoretically examine the nonequilibrium transport through a double quantum dot (DQD) in parallel: resonant tunneling at the Coulomb peak or Kondo effect in the Coulomb valley in quantum dot 1, with a broad linewidth in quantum dot 2. Our model is more tractable than a model for the AB interferometer [1]. We stress the importance of multiple channels in external leads to simulate the experimental systems, which was often neglected in previous studies. In the case of single channel in the leads, we find an asymmetric Fano resonance or Fano-Kondo resonance as a function of energy level in quantum dot 1. With an increase in the number of channels, these approach the symmetric Breit-Wigner resonance or Kondo plateau. This is because the coherence between the quantum dots is weakened, which can be characterized by the off-diagonal element normalized by the diagonal elements in a two-by-two matrix of the linewidth function.

4:30PM V11.00011: Single-Electron Charging Effects in Sketched LaAlO3/SrTiO3 Single-Electron Transistors* PHILIP SHENK (Presenter), Department of Physics, University of Pittsburgh, JOHN MAIER, Department of Physics, University of Notre Dame, JULIANA SEBOLT, Department of Physics, Allegheny College, JUNGWOO LEE, HYUNGWOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, JIANAN LI, PATRICK IRVIN, JEREMY LEVY, Department of Physics, University of Pittsburgh — Mesoscopic devices like the single-electron transistor (SET) exhibit quantum behavior by forcing electrical current through a point-like constriction with quantized energy levels. Such devices typically require extreme nanofabrication techniques. Complex-oxide heterostructures such as the LaAlO3/SrTiO3 system support conductive interfaces that can be controlled using a reversible conductive-AFM lithography technique. These interfaces have richer properties than III-V or silicon-based systems, and support intrinsic magnetic, superconducting and structural phases. Here we describe renewed efforts to explore the properties of “sketched” SETs at the LaAlO3/SrTiO3 interface, focusing on the temperature and magnetic-field dependence of transport. We observe non-equilibrium conductances that cleanly resolve addition energies in nanoscale quantum dots, and track interactions between electronic states vs. experimental parameters such as gate voltage, temperature and magnetic field. These results yield new insights into intrinsic interactions between electrons confined within the quantum dot.

4:42PM V11.00012: Ultra-stable atomically precise single electron transistors in Silicon RANJIT KASHID (Presenter), ANDREW MURPHY, JONATHAN WYRICK, PRADEEP NAMBOODIRI, XIQIAO WANG, SCOTT SCHMUCKER, RICHARD M. SILVER, NEIL ZIMMERMAN, Atom Scale Device Group, Nanoscale Device Characterization Division, National Institute of Standards and Technology — Single electron transistor devices (SETs) in solid-state quantum computing architecture serve as sensitive electrometers for realizing spin selective initialization & single shot readout during spin manipulation, & demand very stable operation. In this context, we demonstrate fully functional, ultra-stable atomically precise SETs fabricated using scanning tunneling microscope (STM) lithography on the Si (100) 2x1: H surface. Low-temperature transport measurement of SETs reveal highly stable Coulomb blockade oscillations. To better understand low-frequency time instabilities we have measured charge offset drift over a period of 4.5 days. SETs fabricated using STM lithography exhibit low charge offset drift magnitude (less than 0.02 e over 4 days, at both base temperature & 6 K) as compared to conventional metal & Silicon based SETs. The low charge offset drift magnitude likely results from the lack of a nearby interface & suggests low defect density in the STM fabrication process & low temperature epitaxial overgrowth. However, at elevated temperatures above 3 K a glassy relaxation is observed in response to gate voltage changes with a settling time that is strongly temperature- dependent.
4:54PM V11.00013: Tunnel Junction Design and Characterization in Si:P Single Electron Transistors  JONATHAN WYRICK (Presenter), XIQIAO WANG, RANJIT KASHID, PRADEEP NAMBOODIRI, SCOTT W SCHMUCKER, RICHARD M. SILVER, National Institute of Standards and Technology — Atomically precise Si:P quantum devices are a promising architecture for scalable solid-state quantum computing. Quantification and control of the tunnel coupling between device components at the atomic scale is essential to successful donor-based quantum information processing (e.g. gate-tunable exchange coupling, electron spin readout, and ultrasensitive charge sensing all require precise control over tunnel coupling). We report on reproducibility of tunnel coupling as measured in atomically precise single electron transistors (SETs). We systematically vary gap separations on the nanometer scale, observing orders of magnitude changes in resistance. Combining low-temperature transport measurements with the orthodox theory of Coulomb blockade, we have extracted tunnel resistances in SETs and analyze to what degree resistances depend on applied voltages. We analyze the relationship between the tunnel conductance and physical barrier parameters and will discuss the limits of lithographically defining an atomically abrupt Si:P tunnel junction. We find the behavior of the tunnel junctions in these devices to be of exceptional quality and will discuss potential reasons for these improvements compared to previous devices fabricated in a similar manner.

5:06PM V11.00014: Fabrication and Measurement of Atomically Precise Single Electron Islands*  DANIEL WARD (Presenter), DEANNA CAMPBELL, MICHAEL MARSHALL, TZU-MING LU, LISA A TRACY, LEON MAURER, ANDREW BACZEWSKI, SHASHANK MISRA, Sandia National Laboratories — Phosphorous donor devices fabricated in silicon with a scanning tunneling microscope (STM) are used as a discovery platform for everything ranging from quantum physics to ultra-efficient tunnel field effect transistors because the underlying hydrogen lithography step can be performed with atomic precision. Many of these devices designs rely on electrostatic gating to tune electrical tunneling through the device. It is expected that out-of-plane gates will be more efficient at gating than in-plane gates. We present on fabrication techniques for adding top gates to devices and the resulting low-temperature measurements on tunnel junctions and single electron islands.

5:18PM V11.00015: The role of confinement and interaction in the emergence of aromatic features in nanoscale synthetic molecules*  ANTHONY RUTH (Presenter), DAVID B GREEN, KENJIRO KIMURA GOMES, BOLDIZSAR JANKO, University of Notre Dame — It has recently been demonstrated that the electronic structure of polyaromatic hydrocarbons can be qualitatively reproduced by quantum corrals made via atomic manipulation. This presents a quandary since the electronic structure of these molecules has been ascribed to a resonating valence bond like state requiring strong confinement to molecular orbitals and significant electron-electron interactions. However, quantum corrals fundamentally exhibit single-electron physics as evidenced by a short lifetime for an electron in a corral, resulting in the absence of Coulomb effects between electrons. We examine this problem from the experimental data obtained via scanning tunneling spectroscopy and topography, tight-binding modeling of hopping and interaction Hamiltonians, as well as density functional theory calculations to determine what aspects of the fully-interacting picture can be produced by the single-electron approach.

Session V12 DCMP: Optical and Electronic Properties of Graphene Nanoribbons and Nanowires  BCEC 153A - Vikram V. Deshpande - Tag(s): Focus
Flexible electronics has directed development and research of unique instrumentation and measurement to achieve conformable sensors for a wide range of applications. Conventional high-performance electronic materials such as silicon are not flexible, whereas flexible materials such as conducting polymers, are often characterized by poor electric properties. Thus, high mobility materials in a flexible configuration are desirable, and carbon nanotubes (CNTs) are promising due to their excellent electric properties and flexibility. Here, we present an all-solid state flexible and stretchable pressure sensor composed of vertically aligned CNTs (VACNTs) partially embedded in polydimethylsiloxane (PDMS). VACNTs are grown via chemical vapor deposition (CVD) and transferred onto PDMS as a stretchable electrode. Two electrodes are placed face-to-face and increased pressure is directly proportional to a detectable change in resistance, enabled by increased contact between opposing electrodes. The resistance is maintained at stretching up to 180%, with a rapid response time during loading and unloading. As a proof-of-concept, the sensor is successfully tested for medical and e-skin applications by measuring biological signals of a person.

We report the reflection contrast spectra of atomic-precise armchair graphene nanoribbons (GNRs) on insulating substrates. As-grown GNRs are transferred from gold to an insulating substrate by the “bubbling” method. Polarization control of light is employed to directly probe the one-dimensional (1D) optical resonances of armchair GNRs with different ribbon widths by the reflection contrast spectroscopy. We observed well-defined 1D optical resonances which are identified as optically-bright inter-band transitions in GNR samples. Our experimental interpretations are further supported by theoretical calculations within the GW framework, which reveals a strong exciton effect with exceptionally large exciton binding energies.

Graphene nanoribbons (GNRs) exhibit an electronic bandgap due to the lateral confinement of charge carriers and edge effects. They can be fabricated by bottom-up on-surface synthesis from molecular precursors resulting in atomically precise structures [1]. This approach promises tunable optical and electronic properties [2]. We use Raman spectroscopy to characterize different types of GNRs and investigate their interaction with growth and devices substrates. In particular, we investigate new geometry-dependent signatures beyond the radial breathing like mode (RBLM) and how they are correlated with charge transport properties.

*JO and MC acknowledge funding by the Swiss Nanoscience Institute.

It is known that 7-armchair graphene nanoribbon (AGNR) holds topological end states at its zigzag ends. A superlattice with such end states is predicted to give rise to in-gap bands whose energies differ from the bulk states’ significantly, which will form a well-isolated subspace. Utilizing these characters of the topological states, we develop a novel AGNR superlattice that possesses two zigzag edges per unit cell. We further show using first principle calculations that, by modifying the geometry of such GNRs, it is possible to get metallic GNRs with tunable bandwidth. Explicitly, the occurrence of five-membered rings would change the bandwidth drastically. After including substrate effects, we reach good agreement with experimental results. In addition, we predict that one of the structures would have ferrimagnetic orders based on Lieb’s theorem and confirmed by density functional theory (DFT) calculation.

*This work is supported by the NSF, DOE, and Office of Naval Research under MURI program, and computational resources from NERSC and XSEDE.
3:18PM V12.00005: Quantum Resonant Tunneling in In-Plate Graphene Nanoribbon/h-BN Heterojunctions
MITSUYOSHI TOMIYA (Presenter), SHOICHI SAKAMOTO, Faculty of Science and Technology, Seikei University — The first principle calculations of the electrical properties of in-plate hetero-junctions of armchair graphene nanoribbon/hexagonal boron nitride(AGNR/h-BN)s are presented. They are carried out using SIESTA package, which consists of numerical codes of the density functional theory(DFT) and the non-equilibrium Green’s function(NEGF). The center part is made of two in-plate hetero-junctions of two transverse h-BN arrays embedded into the conductive (3n-1)-family of AGNR((3n-1)-AGNR) and remains two-dimensional. Adopting (3n-1)-AGNR to the both side lead parts, which must be metallic. Two transverse arrays of h-BN, which is wide-gap semi-conductor, act as a double barrier system. The quantum resonant tunneling through the double barrier system is found in the transmission function(TFs) clearly and I-V characteristics of 8, 11, 14-AGNR/h-BN. The TF has sharp peaks in a neighborhood of the Fermi energy due to the tunneling and the I-V characteristics becomes step-wise. The one-dimensional(1D) Dirac equation model is proposed to study double barrier system. Though the 1D Dirac model is very simple, it reproduces most of the peaks of the TF nearby the Fermi energy. The in-plate hetero-junctions of zigzag graphene nanoribbon/h-BN are also discussed.

3:30PM V12.00006: Resonance Raman Spectroscopy of 7-Atom Wide Armchair Graphene Nanoribbons*
VIVIANE VALQUÍRIA DO NASCIMENTO (Presenter), ELIEL GOMES DA SILVA NETO, Departamento de Física -ICEx, Universidade Federal de Minas Gerais, JUAN P LLINAS, Department of Electrical Engineering and Computer Sciences, University of California, CRISTIANO FANTINI, Departamento de Física -ICEx, Universidade Federal de Minas Gerais, GABRIELA BORIN BARIN, Empa, AKIMITSU NARITA, MÜLLEN KLAUS, Max Planck Institute for Polymer Research, ROMAN FASEL, Empa, JEFFREY BOKOR, University of California — Graphene Nanoribbons (GNRs) exhibit interesting electronic and optical properties strongly dependent on their width and edge. The bottom-up approach to fabricate graphene nanoribbons leads to a precise width and extremely high edge quality, and, as a consequence of this uniformity, the quantum confinement plays a significant role in its electronic and optical properties. This work reports the optical response of armchair graphene nanoribbons of width N=7 atom (7AGNR) on Si/SiO2 substrate using Raman spectroscopy. The 7AGNR presents a rich Raman spectrum, with more than 20 peaks, in good agreement with the theoretical predictions. At room temperature, the nanoribbons degrade in a few seconds under laser exposition as shown by time series Raman experiments. Under nitrogen atmosphere and low temperature, the degradation process is shown to be much slower, allowing us to perform resonance Raman spectroscopy of the 7AGNR in a wide range of excitation energies. The results show a strong dependence of the Raman spectrum with the excitation energy, with a resonance peak around 2.3 eV in agreement with reflectance experiments.

*We thank the financial support given by CAPES, Fapemig, CNPq and INCT/Nanomaterials de Carbono.

DEBORAH PREZZI (Presenter), CLAUDIA CARDOSO, ANDREA FERRETTI, Nanoscience Institute of the National Research Council (CNR-NANO) — Graphene nanoribbons (GNRs) have attracted increasing attention in the last decade as a viable route for graphene-based opto-electronic applications, especially in view of the successful production of ultranarrow and atomically precise structures by means of bottom-up techniques. While GNR absorption properties have been addressed in depth [1, 2], emission properties are still largely unexplored. We here report on the optical response of finite-length GNRs as resulting from state-of-the-art ab initio calculations beyond mean field [3, 4]. Our results indicates that bulk-like excitations coexist with below-bandgap states localized at the GNR extremities, which are almost independent on the length. By investigating both the presence of defects and the coupling with a gold tip, our simulations allow us to identify unpredicted optical transitions in GNRs and to elucidate the origin of below-bandgap STM-induced light emission recently observed in suspended GNRs [3], providing a promising route for the realization of bright, robust, and controllable graphene-based light-emitting devices.

3:54PM V12.00008: Evolution of bandgap with size in armchair and zigzag graphene quantum dots* LUDMILA SZULAKOWSKA (Presenter), YASSER SALEEM, LOUIS NAJERA BALDO, ALAIN DELGADO GRAN, PAWEL HAWRYLAK, University of Ottawa — We present here the evolution of the bandgap energy with size in armchair and zigzag graphene quantum dots (GQDs). The results of the tight binding model are analyzed by dividing zigzag graphene quantum dots into concentric rings. For each ring, the solutions are obtained analytically and then the effect of inter-ring tunneling on the energy gap is determined. The growth of zigzag terminated GQD into armchair GQD is shown to be associated with the addition of a one-dimensional Lieb lattice of carbon atoms with a shell of energy levels in the middle of the energy gap of the inner zigzag GQD. This causes a difference in the nature of the wave functions between zigzag and armchair GQD which manifests itself in the oscillation of the energy gap with increasing size. The evolution of the bandgap with the number of carbon atoms is compared with the notion of confined Dirac Fermions and tested against ab-initio calculations of Kohn-Sham and TD-DFT energy gaps.

*PH, YS, AD and LS acknowledge support from NSERC and uOttawa University Research Chair;

4:06PM V12.00009: Photoluminescence Quantum Efficiency of III−V Nanowires on Silicon Substrates YUI CLIFFORD (Presenter), JIARONG CUI, HO VINH, YIFEI WANG, VINH Q NGUYEN, Department of Physics & Center for Soft Matter and Biological Physics, Virginia Tech — The III−V nanowires monolithically grown on silicon substrates provide promising technologies for integrating advanced photonic technologies on a silicon microelectronics. We report the photoluminescence quantum efficiency of nanowires as well as the thermal quenching mechanism in nanowires prepared by vapor−liquid−solid method. High-resolution spectroscopy, quantum yield and temperature dependence measurements of photoluminescence intensity from nanowires were performed. The data provides a picture of the quantum efficiency, thermal quenching processes and activation energy levels of nanowires. The results provide an important step in the realization of III−V quantum information and photonic devices on silicon platform.

4:18PM V12.00010: Gate-tunable Aharonov-Bohm interference in Bi2O2Se nanowires JIANGHUA YING (Presenter), HUAIXIN YANG, FANMING QU, LI LU, Institute of Physics, Chinese Academy of Sciences — Semiconducting Bi2O2Se shows excellent air stability and high carrier mobility. High-quality single-crystalline Bi2O2Se nanowires were synthesized by means of gold-catalyzed vapor-liquid-solid growth. We fabricated nanowire-based devices and performed electron transport measurements down to low temperatures. Oscillations in magnetoresistance under the magnetic field oriented parallel to its axis with a period of the magnetic flux quantum were observed. The quantum oscillations which demonstrate the existence of coherent transport through closed-loop quantum states encircling the wire axis also show a tunable phase shift by the gate voltage. The results indicate clear gate-tuned Aharonov-Bohm interference of surface states in a semiconductor nanowire.

4:30PM V12.00011: Structural and optical properties of Si2Te3nanowires* JIYANG CHEN (Presenter), JINGBIAO CUI, XIAO SHEN, THANG HOANG, University of Memphis, KEYUE WU, College of Electrical and Photoelectronic Engineering, West Anhui University — Si2Te3 has recently attracted attention as a new class of layered 2D materials, which promise useful applications in thermal electrics and chemical sensing. Here, we report a study of the structural and optical properties of Si2Te3nanowires (NW) at various conditions. Single-crystalline Si2Te3NWs were synthesized by using gold nanoparticles as catalysts through the vapor-liquid-solid (VLS) mechanism. It was observed that these NWs prefer to grow along the [0001] direction, which is perpendicular to the 2D layers. Spectral and temporal characteristics of photoexcited carriers in these Si2Te3 NWs were investigated at various temperatures and excitation powers. Photoluminescence spectrum of Si2Te3 NWs was dominated by defect and surface states related emissions at both low and room temperatures. Consequently, the decay time of photoexcited carries strongly depends on the measurements at different temperatures and excitation powers. Our results quantitatively elucidate decay mechanisms that are important towards understanding and controlling of the electronic states in Si2Te3nanostructures for optoelectronic applications.

4:42PM V12.00012: Electrically Driven Structural Phase Transition in Single Ag₂Te Nanowire Devices* KASUN PREMASIRI, Case Western Reserve University, WEI ZHENG (Presenter), YUE WU, Iowa State University, XUAN GAO, Case Western Reserve University — Exploring new phase-change materials are instrumental in the progression of electronic memory devices. Ag₂Te with its reversible structural phase transition, and in the form of nanowires becomes an apt candidate to potentially use in nanoscale memory devices. Here we report a study on the temperature- or electrically-driven phase change properties of crystalline Ag₂Te nanowires. We first demonstrate that this structural phase change can be achieved via heating up the nanowires, which results in a sharp drop in conductance. Then we show that a DC voltage (< 1V) induced Joule heating can be used to reach the phase transition, even without any external heating. This work shows the potential of using Ag₂Te nanowires as a phase-change material in low voltage and low power nanoscale devices.

4:54PM V12.00013: Theoretical Study on VO₂ Nanowire Structures for Energy Applications* PRABAL BHUYAN, Department of Physics, Gujarati University, Ahmedabad, India, SANJEEV K. GUPTA (Presenter), Department of Physics, St Xavier’s College, Ahmedabad, India, YOGESH SONVANE, Department of Applied Physics, SV National Institute of Technology, Surat, India, P. N. GAJJAR, Department of Physics, Gujarati University, Ahmedabad, India — Recent studies on electronic, magnetic and optical properties of VO₂ (vanadium dioxide) material motivates to explore one-dimensional VO₂ nanowire. We have studied the structural and electronic, optical properties of monoclinic and rutile phase of VO₂ nanowire by performing first-principles calculations. The monoclinic phase showed semiconducting behaviour with a band gap of 1.17eV, while its bulk form showed a band gap of 0.7eV. The rutile phase behaves like as spin gapless semiconducting material. The rutile phase of VO₂ NW could find its applications in spintronic devices. We have also investigated the effect of SO₂, CO₂ and N₂ gas dopant on the monoclinic structure of VO₂ nanowire. The optical properties, density of states (DOS) have been investigated to understand the effect of dopant. It is clear from our results that the VO₂ monoclinic NW could likely to open up its application as an optical gas sensor.

*We would like to thank Science and Engineering Research Board (SERB), India for the financial support (Grant no.: YSS/2015/001269).

5:06PM V12.00014: Nano-wire to Film Transitions During Pulsed-Laser Deposition: the Role of Plasma Plume Expansion* DAVIDE DEL GAUDIO (Presenter), Materials Science and Engineering, University of Michigan, CARL T BOONE, SELFIA, KAITLYN SALLANS, Materials Science and Engineering, University of Michigan, ERICA MASON, University of Texas, ANDREW WILLIAMSON, SNEHA YARLAGADDA, JOHN HERON, Materials Science and Engineering, University of Michigan, ILAN SHALISH, Electrical and Computer Engineering, Ben Gurion University, RACHEL GOLDMAN, Materials Science and Engineering, University of Michigan — Due to their high conductivity, optical transparency, and high surface/volume ratio, indium-tin oxide (ITO) nanowires (NWs) are promising for flexible transparent electronics and gas sensors. During pulsed laser deposition (PLD) of ITO, NWs vs. films are typically selected via inert vs. reactive atmospheres. In other studies, both NWs and films are observed during PLD in inert atmospheres. Here, we consider the influence of the plasma plume expansion on NW vs film formation. For low pressure N₂, we hypothesize that oxygen is strongly scattered, leaving a metal-rich plume, resulting in metal droplet formation, followed by vapor-liquid-solid growth of NW. As the N₂ pressure is increased, the plasma plume and its metal rich core are compressed, resulting in a transition to films growth. This approach is likely applicable to a wide variety of metal-oxide NW core-shell structure for nanoscale devices.

*We gratefully acknowledge the support of NSF grant # ECCS-1610362 and BSF grant #2015700.

Toward Quantum Optoelectronics and Optomechanics in Flatland

HONGKUN PARK (Presenter), Dept. of Chemistry and Chemical Biology and Dept. of Physics, Harvard University — Transition metal dichalcogenide monolayers and multilayers are atomically thin semiconductors that support tightly bound intra- and inter-layer excitons. In this presentation, I will describe our recent efforts to realize solid-state quantum optoelectronic devices using these atomically thin materials. In particular, I will describe how we prepare high-quality van der Waals heterostructures that feature spatially homogeneous, nearly lifetime-broadened excitons. I will then discuss the spectroscopy of intra- and inter-layer excitons in these structures and how we use them to realize atomically thin, electrically tunable mirrors. I will also describe a new approach for dynamically manipulating the exciton dynamics in these structures via electromechanical control over the suspended structures. I will end the presentation by discussing the ongoing efforts in my group to realize new quantum optical/optoelectronic/optomechanical effects in these structures.

THz Electrical Response of Graphene Antennas

DAVID CAREY (Presenter), MOJTABA DASHTI, University of Surrey — Studies of high frequency electrical properties offer an important route in exploring the underexplored unique characteristics of graphene. Here the GHz to THz response of graphene is investigated as a proof of principle concept for use as an ultrawide band patch antenna as part of a graphene based near-field communication system. We show that it is possible to produce a graphene multimode variable surface impedance microstrip antenna with several hundred GHz bandwidth via careful selection of the antenna geometry and substrate, and via engineering the relative contributions of the intra- and interband transitions. For an operating frequency of 2 THz an optimized return loss of -26 dB, bandwidth of 504 GHz and an antenna efficiency of -3.4 dB are calculated. Arising from the circular nature of the antenna structure higher order modes are possible and at 3.5 THz the antenna efficiency improves to -0.36 dB however this is accompanied by a reduction in the bandwidth to 200 GHz. Calculations of the real and imaginary parts of the dielectric constant between 1 and 10 THz have been performed which may be important for metamaterial applications.

Attosecond Dynamics and Electronic Rehybridization in MoS2

OLIVER MONTI (Presenter), CALLEY EADS, SARA ZACHRITZ, BRENT MAUGHAN, University of Arizona, DENNIS NORDLUND, SLAC, Stanford — Two-dimensional transition metal dichalcogenides exhibit highly unusual and layer-dependent electronic structure, caused by quantum confinement effects. The results of these changes have been widely documented in their valley-dependent optical properties. The impact of electron-electron interactions on the carrier dynamics is however at present less clear. Here we report on the attosecond dynamics in MoS2 as a function of carrier density in the conduction band. We show that increased electron density in the conduction band leads to orbital rehybridization, which is the source of the observed layer decoupling. These effects are also clearly observed in the electronic structure in the conduction band region. Our results uncover the many-body effects that govern the electronic properties of MoS2 and likely other 2D materials.

Quantum optics with atomically thin materials

NICK VAMIVAKAS (Presenter), University of Rochester — Two-dimensional, atomically-thin, materials have received enormous interest as a result of their unique mechanical, electrical and optical properties. Although these materials have been investigated for applications in optoelectronics, not much work has focused on these systems as a platform for quantum photonics and quantum optics. In this talk I will describe some approaches that leverage atomically thin semiconductors, and other two-dimensional materials, assembled in layered van der Waals heterostructures for applications in these areas. In the first part of the talk I will describe the unique photophysical properties of quantum emitters hosted by single layer two-dimensional materials. I will describe our recent efforts to controllably charge the quantum emitters and realize a localized spin-valley-photon interface. I will also present results on valley-polaritons that are a manifestation of many body physics arising when coupling an atomically thin semiconductor to a planar optical cavity.

AFOSR FA9550-16-1-0020, NSF CAREER DMR 1553788, NSF EFRI EFMA-1542707, and the Cornell Center for Materials Research with funding from the NSF MRSEC program (DMR-1719875)
4:06PM V13.00005: Tunable nonlinearity in a Graphene-Silicon Nitride hybrid resonator  RAJAN SINGH (Presenter), ARNAB SARKAR, CHITRES GURIA, Department of Physics, Indian Institute of Technology Kanpur, India, RYAN J NICHOLL, Department of Physics and Astronomy, Vanderbilt University, United States, SAGAR CHAKRABORTY, Department of Physics, Indian Institute of Technology Kanpur, India, KIRILL BOLOTIN, Department of Physics, Freie Universität Berlin, Germany, SAIKAT GHOSH, Department of Physics, Indian Institute of Technology Kanpur, India — Silicon Nitride (SiNx) resonators with high Q have garnered attention due to their strong promise of operation in the quantum regime at room temperature. Simultaneously, graphene resonators with high Young's modulus leading to large and tunable mechanical nonlinearity, have opened up possibilities of mixing and manipulating frequency modes. Here we propose a hybrid system that integrates high Q of SiNx resonator with nonlinearity of graphene resonator. When both resonator modes are tuned on resonance, the motional backaction of graphene induces nonlinear response in SiNx. The hybrid mode, when driven parametrically at twice the resonant frequency, demonstrates parametric amplification and cascaded four wave mixing. Generated peaks and their dispersion reveal the rich interplay between nonlinear damping and cubic nonlinearity. Observations match well with numerical simulations. Furthermore, in direct analogy with optomechanics, the graphene acts as an auxiliary cavity leading to induced nonlinearity on SiNx at resonance. These results indicate that such a hybrid mechanical system can be an efficient, alternate platform for coherent control of modes, in the growing field of opto and electromechanics.

4:18PM V13.00006: Ambient effects on hysteresis and photogating in MoS2 photodetectors* PEIZE HAN (Presenter), ELI ADLER, YIJING LIU, LUKE ST. MARIE, A EL FATIMY, PAOLA BARBARA, Georgetown University — Transition metal dichalcogenides (TMDs) are ideal candidates to create ultra-thin optoelectronics that can be flexible and semitransparent. Photodetectors based on TMDs have demonstrated remarkable performance, with high responsivity and high detectivity [1], however these devices are hindered by a slow response time caused by charge trapping. Gas adsorbents which create charge traps, are a main contribution to hysteresis and photogating [2,3]. Here we study the effect of ambient conditions on the performance of MoS2 photodetectors through vacuum pumping and illumination.

4:30PM V13.00007: Temperature Dependence of the Photoconduction in the Few-Layered ReSe2 Field-Effect Transistor* PRASANNA DNYANESHWAR PATIL (Presenter), MILINDA WASALA, RANA ALKHALDI, LINCOLN WEBER, Department of Physics, Southern Illinois University Carbondale, IL-62901, USA., KIRAN KUMAR KOVI, BHASWAR CHAKRABARTI, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL-60439, USA., DANIEL A RHODES, National High Magnetic Field Laboratory, Tallahassee, FL-32310, USA., DANIEL ROSENMANN, RALU DIVAN, ANIRUDHA SUMANT, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, IL-60439, USA., LUIS BALICAS, National High Magnetic Field Laboratory, Tallahassee, FL-32310, USA., NIHAR R PRADHAN, Department of Chemistry, Physics and Atmospheric Science, Jackson State University, Jackson, MS-39217, USA., SAIKAT TALAPATRA, Department of Physics, Southern Illinois University Carbondale, IL-62901, USA. — We will present the photo response of the few-layered ReSe2 field-effect transistor fabricated using mechanically exfoliated crystals grown using the chemical vapor transport method. The temperature dependence of the photoconductivity was measured as a function of temperature from 20 K to 300 K using a continuous laser source (λ = 640 nm; E = 1.94eV), over a broad range of illuminating laser power, P_{eff} (0.2 nW < P_{eff} < 84 nW). We measured the power dependence of the steady state photocurrent (I_{ph}) on P_{eff} (I_{ph} ~ (P_{eff})^{\gamma}, where 0.3 < \gamma < 0.8). The highest responsivity (R) and external quantum efficiency (EQE) obtained from the few-layered ReSe2 phototransistors at P_{eff} = 0.2 nW were ~ 2150 A/W and 10^5 %, respectively. These findings and the temperature dependence of the photoconductivity as a function of gate voltage will be presented.

*This work was performed, in part, at the Center for Nanoscale Materials, a U.S. Department of Energy Office of Science User Facility, and supported by the U.S. Department of Energy, Office of Science, under Contract No. DE-AC02-06CH11357. This work was also supported by NSF-PREM through NSF-DMR # 1826886 and partially supported by the U.S. Army Research Office MURI grant # W911NF-11-1-0362.
4:42PM V13.00008: Temperature dependent electrical and photoconductive properties of few-layer Indium Selenide (InSe) FETs* MILINDA WASALA (Presenter), PRASANNA DNYANESHWAR PATIL, SUJOY GHOSH, RANA ALKHALDI, LINCOLN WEBER, Department of Physics, Southern Illinois University Carbondale, Carbondale, IL, USA, SIDONG LEI, Department of Materials Science and Nano Engineering, Rice University, Houston, TX, USA, HANSIKA SIRIKUMARA, THUSHARI JAYASEKERA, Department of Physics, Southern Illinois University Carbondale, Carbondale, IL, USA, ROBERT VAJTAI, PULICKEL M AJAYAN, Department of Materials Science and Nano Engineering, Rice University, Houston, TX, USA, SAIKAT TALAPATRA, Department of Physics, Southern Illinois University Carbondale, Carbondale, IL, USA — Here we report on the temperature dependent electrical and photoconductive properties of n-type few-layer InSe Field Effect Transistors (FETs), micromechanically exfoliated from bulk crystal grown using chemical vapor transport method. The temperature dependent electrical conduction in these InSe FETs shows two distinct conduction mechanisms. At high temperatures electrical conduction is governed by thermally activated behavior, while at low temperatures electrical conduction follows Mott’s 2D variable range hopping mechanism. Further, photoconductivity measurements show that these InSe FETs display room temperature photo-responsivities of ~0.05 AW⁻¹ when illuminated with a laser of wavelength λ = 658 nm and a power of ~23 nW. The photo-responsivities of these FETs showed several orders of magnitude improvement (up to ~ 15 AW⁻¹) upon application of a gate voltage (VG = 60 V). These key findings and temperature dependent photoconductivity study will be presented and discussed.

*This work was supported by the U.S. Army Research Office MURI grant # W911NF-11-1-0362.

4:54PM V13.00009: Electric field effect studies of atomically thin crystals of ferroelectric In2Se3 JUSTIN RODRIGUEZ (Presenter), YIXUAN CHEN, SENG HUAT LEE, KAZUNORI FUJISAWA, TIANYI ZHANG, MAURICIO TERRONES, WILLIAM MURRAY, ZHIWEN LIU, YING LIU, Pennsylvania State University — Ultrathin films of ferroelectric materials are important for applications, including non-volatile memories, electromechanical actuators, and sensors. For a ferroelectric film of transition metal oxide to possess electrically switchable polarization, a minimal film thickness is required. In2Se3 is a layered III–VI compound with the unit cell consisting of a quintuple layer (QL) of In and Se ions in a triangular lattice featuring covalent bonding within the unit cell but van der Waals bonding between neighboring unit cells. It was predicted recently that In2Se3 is ferroelectric down to single unit-cell thickness, possessing both in- and out-of-plane polarizations in the a- and b-phases of In2Se3 polymorphism, respectively. We have carried out electric field effect studies of atomically thin crystals of a-In2Se3 down to liquid helium temperatures. These 2D crystals were prepared by mechanical exfoliation and characterized by Raman spectroscopy, photoluminescence, and second harmonic generation measurements. We found that the crystals are easily gated to possess a finite electrical conductivity characterized by thermally activated behavior. Source-drain current vs. gate voltage measurements revealed a hysteresis loop in the transfer characteristic, typical for ferroelectric devices.

5:06PM V13.00010: Crossover between Photochemical and Photothermal Oxidations of Atomically Thin CrPS4 SU HYEON KIM (Presenter), SUNMIN RYU, Pohang University of Science and Technology — Two-dimensional (2D) semiconductors represented by transition metal dichalcogenides have optical bandgaps that can be tuned via thickness, strain, dielectric screening and intercalation, and thus stand promising candidates for optoelectronic devices. Despite the potential, however, many including phosphorene and CrI3 lack photostability even in the ambient air. Here, we studied photoreaction mechanisms of 2D chromium thiophosphate (CrPS4), an antiferromagnetic semiconductor, using Raman spectroscopy and atomic force microscopy (AFM). Few-layer CrPS4 underwent photodegradation which accelerated with increasing partial pressure of O2. Topographic analysis by AFM showed that 2D CrPS4 is photo-oxidized at a laser power density two orders of magnitude lower than that required for MoS2 obeying a photothermal mechanism. Based on various control experiments over photon energy, power density and humidity, we propose that the low-power photoreaction of CrPS4 is a one-photon photochemical oxidation mediated by CrPS4-sensitized generation of singlet O2 and is switched over to a photothermal oxidation in a high-power regime. Additionally, the efficacy of thin Al2O3 films will be discussed as protecting layers of 2D CrPS4.
Spectroscopic Characterization of Interlayer Contaminants within van der Waals Heterostructures

JEFFREY SCHWARTZ (Presenter), Institute for Research in Electronics and Applied Physics, University of Maryland, College Park, MD 20742, United States, HSUN-JEN CHUANG, MATTHEW R. ROSENBERGER, BEREND T. JONKER, Naval Research Laboratory, Washington, D.C. 20375, United States, ANDREA CENTRONE, Physical Measurement Laboratory, National Institute of Standards and Technology, Gaithersburg, MD 20899, United States — Van der Waals heterostructures (vdWHs) leverage the characteristics of disparate 2D material building blocks to create a myriad of structures with unique and desirable properties. A common fabrication strategy relies on polymeric stamps to assemble layers of 2D materials into vertical stacks. However, the properties of structures produced in this way frequently are degraded by contaminants, typically of unknown composition, trapped between the constituent layers. This contamination impedes the study and application of intrinsic heterostructures requiring pristine interfaces. Here, we use a photothermal induced resonance technique to obtain nanoscale infrared spectra and maps of the contamination with ~20 nm spatial resolution. Heterostructures comprised of WS₂, WSe₂, and hBN layers were found to contain significant amounts of polydimethylsiloxane and polycarbonate, corresponding to the stamp materials used in their construction. Additionally, we validate spectroscopically a previously reported “nano-squeegee” technique as an effective means of locally removing contaminants. These insights into the chemical makeup and sources corrupting vdWHs provide guidance for devising mitigation strategies and enhance capabilities for producing materials with precisely engineered properties.

Session V14 DMP: 2D Materials (Metals, Superconductors, and Correlated Materials) -- Heterostructures and Twisted Graphene

BCEC 153C - Young Jun Chang, University of Seoul - Tag(s): Focus

2:30PM V14.00001: Coulomb drag between graphene and LaAlO$_3$/SrTiO$_3$ heterostructures* QING GUO (Presenter), JIANAN LI, JEN-FENG HSU, Department of Physics and Astronomy, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin–Madison, PATRICK IRVIN, Department of Physics and Astronomy, University of Pittsburgh, BRIAN R D’URSO, Department of Physics, University of Montana, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh — Vertical stacking of heterostructures that combine layered materials offer new ways of combining interesting properties of dissimilar electronic materials. Over the past few years we have been integrating graphene with complex-oxide heterostructures, specifically, the LaAlO$_3$/SrTiO$_3$ system. Furthermore, conducting nanostructures can be written under graphene, producing interesting interactions between the two systems. Here we report Coulomb drag measurements between single-layer graphene and a conductive LaAlO$_3$/SrTiO$_3$ interface. The observed Coulomb drag resistance is non-monotonic and increases for temperatures below 20 K. The temperature dependence is also non-monotonic, showing a notable departure from quadratic scaling, as expected from Fermi-liquid theory. Coulomb drag experiments between the graphene and LaAlO$_3$/SrTiO$_3$ layers show strong coupling in both the normal and superconducting state of the LaAlO$_3$/SrTiO$_3$.

*This research was supported by N00014-16-1-3152 (JL, BD), and N00014-15-1-2847 (JL). The work at University of Wisconsin-Madison was supported by the National Science Foundation under DMREF Grant No. DMR-1629270, AFOSR FA9550-15-1-0334 and AOARD FA2386-15-1-4046.

2:42PM V14.00002: Polarity of Coulomb drag signal in carbon nanotube-graphene heterostructures LAUREL ANDERSON (Presenter), AUSTIN K CHENG, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, PHILIP KIM, Harvard University — Coulomb drag is an inter-conductor interaction in which current in one conductor induces a current in a proximate conducting object. This electron-electron coupling can transfer momentum or energy between isolated conductors, creating inter-conductor electronic responses without particle exchange. Coulomb drag has been extensively studied as a probe of interactions in low-dimensional systems. We report measurements of 1D-2D drag resistance between a carbon nanotube and graphene separated by a thin boron nitride insulating layer. The carrier densities of the nanotube and graphene can be separately tuned to access different regimes of drag response. The polarity of the observed drag signal is inconsistent with inter-conductor momentum transfer, suggesting it is a possible signature of energy drag or hydrodynamic electron transport in graphene.

3:18PM V14.00005: Electron pairing by remote-phonon scattering in oxide-supported graphene junction, akin to light bending at interfaces between mismatched media.

Our results provide evidence of coherent refraction of electrons passing through graphene that can be controlled on an atomic level, and is thus an ideal candidate for investigating light-like behavior of molecules arranged on a copper surface so as to confine the electrons to a honeycomb lattice, is an artificial form of molecules analogous to the focusing of light by optical instruments. Molecular graphene, consisting of carbon monoxide, suggests the possibility of constructing devices, such as Veselago lenses, that can focus electron wavefunctions in a manner analogous to the focusing of light by optical instruments. Molecular graphene, consisting of carbon monoxide molecules arranged on a copper surface so as to confine the electrons to a honeycomb lattice, is an artificial form of graphene that can be controlled on an atomic level, and is thus an ideal candidate for investigating light-like behavior of Dirac fermions. We report experiments that probe the behavior of electrons incident upon a graphene junction through quasiparticle interference measurements of a molecular graphene system in a low-temperature, ultra-high vacuum Dirac fermions. We report experiments that probe the behavior of electrons incident upon a graphene junction through quasiparticle interference measurements of a molecular graphene system in a low-temperature, ultra-high vacuum scanning tunneling microscope. Our results provide evidence of coherent refraction of electrons passing through the junction, akin to light bending at interfaces between mismatched media.

MORGEN BRUBAKER (Presenter), Physics, Stanford University, YI-TING CHEN, Applied Physics, Stanford University, ALISON DAY, Stanford University, HARI MANOHARAN, Physics, Stanford University — One of the many interesting features of graphene is the light-like behavior of its electrons near the Dirac points, characterized by a massless dispersion relation. This behavior suggests the possibility of constructing devices, such as Veselago lenses, that can focus electron wavefunctions in a manner analogous to the focusing of light by optical instruments. Molecular graphene, consisting of carbon monoxide molecules arranged on a copper surface so as to confine the electrons to a honeycomb lattice, is an artificial form of graphene that can be controlled on an atomic level, and is thus an ideal candidate for investigating light-like behavior of Dirac fermions. We report experiments that probe the behavior of electrons incident upon a graphene junction through quasiparticle interference measurements of a molecular graphene system in a low-temperature, ultra-high vacuum scanning tunneling microscope. Our results provide evidence of coherent refraction of electrons passing through the junction, akin to light bending at interfaces between mismatched media.

MORGAN BRUBAKER (Presenter), Physics, Stanford University, YI-TING CHEN, Applied Physics, Stanford University, ALISON DAY, Stanford University, HARI MANOHARAN, Physics, Stanford University — One of the many interesting features of graphene is the light-like behavior of its electrons near the Dirac points, characterized by a massless dispersion relation. HARALD TOPOLOG AND JENS NORDMANN, Physics, University of Basel — Edge states have recently attracted a lot of attention due to their appearance at surfaces of topological materials and quantum Hall systems. Here we study quantum Hall edge states formed in a GaAs 2D electron gas using a tunnel-coupled quantum wire [1]. We use momentum-conserving tunneling spectroscopy to distinguish spatially overlapping states with different momenta. The tunneling conductance is proportional to the overlap between the edge state and the wire mode wave functions. Because of the varying shape of wire wave functions, their overlaps with edge states will also vary, resulting in a distinct sequence of tunneling conductance intensity patterns for different wire modes. We use self-consistent calculations to obtain the electrostatic potential at zero magnetic field and employ a Schrödinger solver to get the wave functions of the Landau level edge states and wire modes at a finite field. Conductance maps obtained using simulated wave functions agree very well with the measured data, thus confirming the calculated wave functions.

HIROYUKI TAKENAKA (Presenter), Department of Physics, University of Texas at Austin, MASSIMO V FISCHETTI, Department of Materials Science and Engineering, University of Texas at Dallas, ALEXANDER DEMKOV, Department of Physics, University of Texas at Austin — Using first principles calculations (density functional theory) we find that placing graphene on an (111)-oriented perovskite SrTiO₃ (STO) surface provides a convenient doping mechanism. Moreover, further theoretical analysis suggests that coupling of electrons in graphene to interfacial hybrid plasmon/optical modes via remote-phonon scattering may result in an effective attractive electron-electron interaction that, in turn, could lead to electron pairing and superconductivity. Specifically, we consider the graphene sheet supported by the STO and also gated. Using the full RPA dynamic polarizability of the whole system (including the hybrid mode arising from the coupling of the graphene plasmons to the optical phonons of the STO substrate and gate insulator), we estimate the superconductive transition temperature in both the weak- and the (Eliashberg) strong-coupling limits and also by solving the gap equation.

HIROYUKI TAKENAKA (Presenter), SHANE SANDHOEFNER, ALEXEY E KOVALEV, EVGENY Y TSYMBAL, University of Nebraska - Lincoln — The appearance of topological states in antiferromagnetic (AFM) materials has recently aroused considerable attention, resulting in the emergent field of topological AFM spintronics. Here, we theoretically explore the effect of voltage-controlled AFM order in chromia (Cr₂O₃) on the emerging topological states in graphene coupled across the Cr₂O₃/graphene interface. Chromia is a magnetoelectric AFM insulator exhibiting surface magnetization, intrinsically coupled to the Néel vector, which can be switched by an electric field. We find that the proximity effect leads to the broken time-reversal symmetry and the Rashba spin-orbit coupling in graphene, producing the topologically nontrivial band gaps. The resulting topological states and the quantum anomalous Hall effect in graphene are switchable by voltage with the Néel vector in chromia. Interestingly, the band gaps near the K and K' points in graphene are different due to the staggered coupling on the two sublattices, resulting in the non-vanishing valley current and the valley-polarized anomalous Hall state. The switchable Néel vectorpotentially produces a topological phase transition in graphene.
Fractional Chern insulators in graphene heterostructures

ERIC SPANTON (Presenter), ALEXANDER ZIBROV, HAOXIN ZHOU, JOSHUA ISLAND, XIAOMENG CUI, FANGYUAN YANG, University of California, Santa Barbara, TAKASHI TANIGUCHI, KENJI WATANABE, Advanced Materials Laboratory, National Institute for Materials Science, MICHAEL ZALETEL, University of California-Santa Barbara, ANDREA YOUNG, University of California, Santa Barbara — Graphene is a highly tunable platform for studying the effects of electron-electron interactions in two dimensions. Encapsulation with a 2D dielectric (hexagonal boron nitride, hBN), and more recently the use of single-crystal graphite top and bottom gates have decreased the electronic disorder to a level suitable for the study of fragile and exotic strongly correlated states. Additionally, control of twist angle between closely-matched crystal lattices allows for unique control of electronic properties, leading to the “Hofstadter butterfly” and more recently unconventional superconductivity. I will describe the first experimental observation of a class of states in nearly aligned hBN/graphene heterostructures called fractional Chern insulators, a close relative of the fractional quantum Hall effect. In graphene, fractional Chern insulators arise in the presence of electron-electron interactions, high magnetic fields, and a long wavelength ‘moiré’ superlattice formed by close alignment between hBN and graphene lattices. Twist angle between graphene and hBN, electron density and perpendicular electric field tune the underlying single-particle bands to realize different types of fractional Chern insulators. The realization of fractional Chern insulators opens the door for the study of novel topological phase transitions and exotic defect states.

Normal state transport in superconducting twisted bilayer graphene

HRYHORIY POLSHYN (Presenter), YUXUAN ZHANG, University of California, Santa Barbara, MATTHEW YANKOWITZ, SHAOWEN CHEN, Department of Physics, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, DAVID E GRAF, National High Magnetic Field Laboratory, CORY R DEAN, Department of Physics, Columbia University, ANDREA YOUNG, University of California, Santa Barbara — Twisted bilayer graphene (tBLG) near the flat band condition is a versatile new platform for the study of correlated physics in 2D. Resistive states have been observed at several commensurate fillings of the flat miniband, along with superconducting states near half filling. To better understand the electronic structure of this system, we study electronic transport of graphite gated superconducting tBLG devices in the normal regime. At high magnetic fields, we observe full lifting of the spin and valley degeneracy. The transitions in the splitting of this four-fold degeneracy as a function of carrier density indicate Landau level (LL) crossings, which tilted field measurements show occur between LLs with different valley polarization. Similar LL structure measured in two devices, one with twist angle θ=1.08° at ambient pressure and one at θ=1.27° and 1.33GPa, suggests that the dimensionless combination of twist angle and interlayer coupling controls the relevant details of the band structure. In addition, we find that the temperature dependence of the resistance at B=0 shows linear growth at several hundred Ohm/K in a broad range of temperatures. We discuss the implications for modeling the scattering processes in this system.

Fabrication and measurement procedures for magic angle graphene devices

ORIOL RUBIES-BIGORDÀ (Presenter), YUAN CAO, DANIEL RODAN LEGRAIN, VALLA FATEMI, Massachusetts Institute of Technology, SHIANG FANG, Physics, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, EFTHIMIOS KAXIRAS, Physics, Harvard University, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — Understanding the behavior of strongly correlated materials, such as unconventional superconductors, has been a challenge for decades. Graphene has turned out to be a new platform to study these phenomena. In particular, we have observed unconventional superconductivity and correlated insulating states by stacking two graphene layers and twisting them at a small angle, of about 1.1°. In this talk, we will focus on the fabrication procedures leading to reproducibly achieving high quality and low disorder ‘magic angle’ twisted bilayer graphene devices, with maximum critical temperatures over 2K and critical fields over 100mT. Such achievements with graphene further contribute to an emerging field, commonly referred to as ‘twistronics’, where other 2d –materials can be twisted to give rise to new correlated systems.

This work has been primarily supported by the National Science Foundation (DMR-1809802) and the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF4541 for device fabrication, transport measurements, and data analysis. ORB acknowledges support from Fundació Privada Cellex.
Systematic analysis of superconductivity in magic-angle twister bilayer graphene nanodevices

DANIEL RODAN LEGRAIN (Presenter), YUAN CAO, ORIOL RUBIES-BIGORDA, VALLA FATEMI, Department of Physics, Massachusetts Institute of Technology, SHIANG FANG, Department of Physics, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, EFTHIMIOS KAXIRAS, Department of Physics, Harvard University, PABLO JARILLO-HERRERO, Department of Physics, Massachusetts Institute of Technology — Superconductivity and correlated insulating states have recently been observed in ‘magic-angle’ twisted bilayer graphene heterostructures at twist angles close to 1.1 degrees, featuring nearly-flat bands owing to strong interlayer coupling. We here perform a systematic study of superconductivity and correlated phenomena in more than 10 different superconducting devices with angles comprised between 0.99 degrees and 1.19 degrees. Angle dependence of critical temperature and field, together with the interplay between superconductivity and insulating states, are examined. Higher quality devices allow us to extend the analysis to superconductivity when doping the twisted bilayer system with electrons. This 2D superconductor, based on graphene moiré superlattices, offers a uniquely tunable, clean and relatively simple platform for the investigation of strongly correlated physics.

*This work has been primarily supported by the National Science Foundation (DMR-1809802) and the Gordon and Betty Moore Foundation's EPIQS Initiative through Grant GBMF4541 for device fabrication, transport measurements, and data analysis. Transport Properties of a Few-layer Rhombohedral-stacked Graphene

YANMENG SHI (Presenter), YAPING YANG, SERVET CANOZDEMIR, SEOK-KYUN SON, SHUIGANG XU, JUN YIN, SERGEY SLIZOVSKIY, ARTEM MISHCHENKO, School of Physics and Astronomy, University of Manchester — Recently, two-dimensional systems that host flat bands have been extensively investigated experimentally and theoretically, due to the intriguing correlation effects as a result of large density of states. In a few-layer rhombohedral-stacked graphene, the dispersionless flat band localised at the outer surfaces is a promising candidate to realise such strong correlation physics. In this talk, I will present our preliminary data on the electrical transport in a few-layer rhombohedral-stacked graphene. We found that a gap is opened at the surfaces when a displacement field exceeds a threshold value. In a magnetic field we found robust quantum oscillations suggesting the high electronic quality of the observed flat-band surface states.

Quantum Hall effect in a monolayer graphene magnetized by an antiferromagnet

YINGYING WU (Presenter), GEN YIN, LEI PAN, University of California, Los Angeles, ALEXANDER GRUTTER, NIST, KANG L. WANG, University of California, Los Angeles — We experimentally demonstrate the quantum Hall effect in a monolayer graphene magnetized by an underlying layer of an antiferromagnet. When interfacing with the AFM, the π bond formed by the p orbitals of carbon is found to sufficiently overlap with the Cr atoms in the AFM layer, and therefore experiences a sizeable Hund's-rule exchange energy. Through field-cooling, the change in the antiferromagnetic order modifies the spin splitting, and thereby shifts quantum Hall plateau, as well as the SdH oscillation. This transport behavior is then used to quantitatively estimate the spin split energy (about several hundreds of meV).

Anomalous drag in double bilayer graphene quantum-Hall superfluids

ALLAN MACDONALD (Presenter), MING XIE, Department of Physics, University of Texas at Austin — Semiconductor double-layers in the quantum Hall regime tend to have superfluid exciton condensate ground states when the total filling factor is an odd integer, provided that the Landau orbitals at the Fermi level in the two layers have the same orbital character. Since the $N = 0$ Landau level of bilayer graphene contains states with both $n = 0$ and $n = 1$ orbital character, the physics of double bilayers falls outside previously studied cases. We show that the superfluid phase stiffness vanishes in double bilayer graphene when $n = 0$ and $n = 1$ orbitals states are degenerate in one of the layers, even though the gap for charged excitations remain large, and speculate that this property is behind the recent discovery of strong anomalous drag near a $n = 0/1$ degeneracy point.

2:30PM V15.00001: Kinetic Pathways Towards Mass Production of Single Crystalline Stanene on Topological Insulator Substrates

LIYING ZHANG (Presenter), School of Physics and Engineering, Zhengzhou University; International Center for Quantum Design of Functional Materials (ICQD), Hefei National Laboratory for Physical Science at the Microscale, WEI QIN, LEIQIANG LI, International Center for Quantum Design of Functional Materials (ICQD), Hefei National Laboratory for Physical Sciences at the Microscale, and Synergetic Innovation Center of, SHUNFANG LI, School of Physics and Engineering, Zhengzhou University, PING CUI, International Center for Quantum Design of Functional Materials (ICQD), Hefei National Laboratory for Physical Sciences at the Microscale, and Synergetic Innovation Center of, YU JIA, School of Physics and Engineering, Zhengzhou University, ZHENYU ZHANG, International Center for Quantum Design of Functional Materials (ICQD), Hefei National Laboratory for Physical Sciences at the Microscale, and Synergetic Innovation Center of — As a highly appealing new member of the two-dimensional materials family, stanene was first epitaxially grown on three dimensional topological insulator of Bi₂Te₃; yet to date, a standing challenge is to drastically improve the overall quality of such stanene overlayers for various potential applications. Here we use first-principles approaches to explore the atomistic growth mechanisms of stanene on different Bi₂Te₃(111)-based substrates. We fist show that, when grown on the experimentally studied Te-terminated Bi₂Te₃, stanene would follow an unusual partial-layer-by-partial-layer growth mode, characterized by short-range repulsive pairwise interactions of the Sn adatoms; the resultant stanene overlayer is destined to contain undesirable grain boundaries. More importantly, we find that stanene growth on Bi₂Te₃(111) pre-covered with a Bi bilayer will follow a highly desirable nucleation-and-growth behavior, strongly favoring single crystalline stanene. Interestingly, the latter system also provides new opportunities for potential realization of topological superconductivity in 2D heterostructures. The novel kinetic pathways revealed here will be instrumental in achieving mass production of high-quality stanene with emergent physical properties of technological significance.

2:42PM V15.00002: First principles studies of 2D transition metal dichalcogenides on 3D magnetic oxides

ELIZABETH PETERSON (Presenter), Physics, University of California, Berkeley, JEFFREY B NEATON, Lawrence Berkeley National Laboratory — Monolayer transition metal dichalcogenides are desirable for new high-speed, low-power and miniaturized valley optoelectronics. One way to create valley polarization is via magnetic proximity coupling, facilitated by interfacing single-layer TMDs and magnetic substrates; this approach has recently been shown to generate significantly larger valley splitting than applied magnetic fields. However, the reported valley splitting is still relatively small and the details of the interface between TMDs and magnetic substrates are poorly understood. Using first principles and model calculations, we explore the structure of the TMD-oxide interface, and predict the magnitude of the valley splitting generated by proximity to magnetic substrates. We examine the most critical attributes of this interface and develop general design principles that connect the structure of TMD-oxide interfaces to functionality relevant for valleytronics.

2:54PM V15.00003: Tunable band alignment in 2D ferroelectric In₂Se₃ based van der Waals heterostructures

ZHE WANG (Presenter), WENGUANG ZHU, University of Science and Technology of China — Van der Waals heterostructures with the advantages of atomically sharp interfaces, digitally controlled layered components, and no lattice parameter constraint, have been attracted substantial research interests in recent years due to their great potentials in electronic and optoelectronic applications and such properties critically depend on the band alignment between the constituent layers. Here we, based on first-principles calculations, demonstrate that by taking advantage of a recently discovered 2D ferroelectric material In₂Se₃ its van der Waals heterostructures with other known 2D materials have the ability to tune their band alignment between different types of semiconductor junctions or the Schottky barrier height by switching the orientation of the electric polarization of the ferroelectric In₂Se₃ layer with an external electric field. This work provides a generic guideline for the application of the 2D ferroelectric In₂Se₃ in tuning the electronic properties of van der Waals heterostructures.
The two-dimensional ferroelectric material GaTeCl monolayer*  
SHI-HAO ZHANG (Presenter), BANG-GUI LIU, Institute of Physics, Chinese Academy of Sciences — Searching for new ferroelectric atomic-thick materials is an important issue in the condensed matter physics. Through first-principles investigation we proposed a new two-dimensional ferroelectric material GaTeCl monolayer which can be exfoliated from pre-existing GaTeCl bulk. The calculated in-plane ferroelectric polarization reaches 578 pC/m. The energy barriers per formula unit of the ferroelastic 90-degrees rotational and ferroelectric reversal transitions are 476 meV and 754 meV respectively. A tensile stress of 4.7 N/m perpendicular to the polarization can drive the polarization to rotate by 90 degrees. The second harmonic generation susceptibility calculations reveal that the GaTeCl monolayer has giant optical second harmonic generation with the intensity being strongly anisotropic. These ensure the great potential of GaTeCl monolayer in high-performance multifunctional applications.

Injection current in single-layer group IV-monochalcogenides*  
SUMAN PANDAY (Presenter), BENJAMIN M. FREGOSO, Physics, Kent State University — Single-layer group-IV monochalcogenides GeS, GeSe, SnS, SnSe are two-dimensional ferroelectrics predicted to exhibit giant second harmonic generation and photovoltaic shift current. Using density functional theory methods, we show that these materials also exhibit giant injection current (circular photogalvanic effect). The magnitude can reach values up to $10^{11}$ A/V²S in the visible spectrum which is two orders of magnitude larger than that of prototypical nonlinear semiconductor CdS. We discuss the correlations between injection current, density of states and electric polarization using analytical and numerical methods. The injection current varies nonmonotonically with polarization reaching a maximum at an optimal polarization but is not correlated with the density of states. Our results establish GeS, GeSe, SnS, SnSe as versatile nonlinear materials suitable for optoelectronic applications.

ABSTRACT WITHDRAWN

Tuning band structures and electronic properties of few-layer InSe by uniaxial strain  
CHAOYU SONG (Presenter), FENG-REN FAN, NINGNING XUAN, SHENYANG HUANG, GUOWEI ZHANG, CHONG WANG, ZHENGZONG SUN, HUA WU, HUGEN YAN, Fudan University — Atomically thin InSe joins the family of 2-dimensional materials recently with the advantage of high carrier mobility and layer-dependent bandgap. In this work, we engineer the band structures of few-layer InSe by uniaxial tensile strain. Prominent redshifts (90-100 meV per 1% strain) of photoluminescence peaks were observed in 4- to 8-layer samples. Density functional calculations well reproduce the observed strain effect and reveal that the shift rate decreases with increasing layer number for few-layer InSe, which can be understood based on the strain-induced change of the inter-layer interactions. In addition, resonant Raman spectroscopy was employed to study the vibrational properties of few-layer InSe. Sizable strain-induced redshifts of first order phonon modes and resonance effect were observed.

Ab initio Carrier Mobility of Two-Dimensional Indium Selenide*  
WENBIN LI (Presenter), SAMUEL PONE, FELICIANO GIUSTINO, Department of Materials, University of Oxford — Owing to its exceptionally high electron mobility, indium selenide (InSe) is emerging as one of the most promising layered semiconductors for two-dimensional electronics and optoelectronics. However, the intrinsic carrier mobility of InSe in the monolayer limit and the corresponding carrier scattering mechanisms remain unknown. By performing ab initio calculations of the intrinsic carrier mobility of InSe in the Boltzmann transport formalism, we find that the electron carriers in InSe are predominantly scattered by the coupling to longitudinal-optical phonons, namely the Fröhlich interaction. We also find that the carrier mobility of InSe exhibits strong layer dependence. At 300 K, the electron mobilities of InSe are found to be 120, 220, and 1060 cm²V⁻¹s⁻¹ for monolayer, bilayer and bulk, respectively, in good agreement with transport measurements.

4:06PM V15.00009: First-principles studies on electronic band structure of PdSe₂ with GW approximation

HANYU KIM (Presenter), HYOUNG JOON CHOI, Department of Physics, Center for Computational Studies of Advanced Electronic Material Properties, Yonsei University, Seoul 03722, Korea (the Republic of). — We studied the electronic band structure of PdSe₂ using the density functional theory (DFT) and the GW method. It is known that PdSe₂, a material with stacks of pentagonal layer structure, has a semiconducting band structure experimentally. However, DFT calculations show that bulk PdSe₂ has a semi-metallic band structure because of DFT underestimation of the band gap of the material. To obtain the band gap of PdSe₂ correctly, we calculated the quasiparticle band structure of bulk PdSe₂ using the one-shot GW method and obtained a band gap which is consistent with experimental results. Then we calculated the electronic structure of two-dimensional PdSe₂ to investigate the layer-number dependence on the energy gap. We discuss band-to-band transition energies and other physical properties obtained from band structures of PdSe₂.

4:18PM V15.00010: Scalably-nanomanufactured atomically-thin piezoelectric semiconductor for ubiquitous electronics and smart sensors

[Invited] WENZHUO WU (Presenter), Purdue University — The reliable production of atomically-thin crystals is essential for exploring new science and implementing novel technologies in the 2D limit. In this talk, I will discuss our recent discovery of a new 2-D piezoelectric semiconductor, tellurene, synthesized by a substrate-free solution process. The tellurene crystals exhibit process-tunable thicknesses from a monolayer to tens of nanometers, and lateral sizes ~ 100 mm. Our prototypical tellurene transistor device, which is air-stable, shows an excellent all-around figure of merits compared to existing 2D materials. We further carry out the first experimental exploration of piezotronic effect in tellurene and systematically investigate the piezotronic transport properties. The fundamental understanding of piezotronic coupling in tellurene is expected to provide insights for the development of 2-D material piezotronics and electronics, leading to the realization of “smarter” electronics for a multitude of emerging technologies, e.g., wearable electronics, soft robotics, medical prosthetics, and human-machine interface.

4:54PM V15.00011: ABSTRACT WITHDRAWN

5:06PM V15.00012: Study of dipolar excitons in TiS₃ double layer

ROMAN KEZERASHVILI (Presenter), Physics Department, New York City College of Technology, City University of New York — The most studied layered semiconductors to date are the transition metal dichalcogenides and nowadays there is a flurry of effort to study the transition metal trichalcogenides (TMTC) with MX₃ composition (M is a metal X is a chalcogen) that have highly anisotropic crystal structure. We present the results of study of the formation of dipolar excitons in a TMTC double layer in the framework of a Wannier-Mott model for the indirect excitons that takes into account the anisotropic effective masses. The energy spectrum and wave functions for a single dipolar exciton are obtained and binding energies are calculated within the harmonic oscillator approximation for the Rutova-Keldysh and Coulomb potentials. In the framework of the Bogoliubov approximation spectrum of collective excitations for the dilute weakly interacting Bose gas of dipolar excitons si studied and the mean field critical temperature for the superfluidity is obtained. It is demonstrated that as a result of the strong in-plane anisotropy, superfluidity is vastly differ in different crystalline directions. The calculations are performed for a direct band gap semiconductor TiS₃ that is a prototypical representative of TMTC materials.

5:18PM V15.00013: Van der Waals charge-transfer interfaces* YUTA KASHIWABARA (Presenter), MASAKI NAKANO, YUJI NAKAGAWA, YUE WANG, HIDEKI MATSUOKA, YOSHIHIRO IWASA, Department of Applied Physics, The University of Tokyo — The creation of functional interfaces between different materials has often led to a discovery of a unique electronic property and functionality that is missing in the constituent materials, providing an invaluable material platform in modern science and technology. 2D materials are suitable compounds for construction of such an interface due to existence of the van der Waals gap that enables creation of an atomically-abrupt interface, and in fact various types of heterostructures named ‘van der Waals heterostructures’ have been more and more developed for the last few years. However, those researches have mainly focused on electrical transport across the interface, while lateral transport properties along the interface have been less studied so far. In this presentation, we will demonstrate emergence of electrical conduction at the interface between insulating 2D materials fabricated by molecular-beam epitaxy with our growth recipe [1]. [1] M. Nakano, et. al., Nano Lett. 17, 5595 (2017).

Thursday, March 7, 2019 2:30 PM - 5:30 PM

Session V16 DCOMP: Quantum Manybody Systems: Theory and Computation II

2:30PM V16.00001: Off-Diagonal Expansion Quantum Monte Carlo* ITAY HEN (Presenter), TAMEEM ALBASH, LALIT GUPTA, University of Southern California — I will discuss a novel, parameter-free Trotter error-free, quantum Monte Carlo technique designed to tackle a very broad range of physical models within a single unifying framework. The method builds on a series expansion of the canonical partition function around its classical component. The expansion further allows for a group-theoretical abstraction of the QMC algorithm. Some results showcasing the capabilities of the algorithm will be presented.

*The computing resources were provided by the USC Center for High Performance Computing and Communications. The research is based upon work supported by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), via the U.S. Army Research Office contract W911NF-17-C-0050.

2:42PM V16.00002: Finite-temperature Auxiliary-Field Quantum Monte Carlo: Recent Developments and Applications* YUAN-YAO HE (Presenter), CCQ, Flatiron Institute, Simons Foundation, MINGPU QIN, Department of Physics, College of William and Mary, HAO SHI, CCQ, Flatiron Institute, Simons Foundation, ZHONG-YI LU, Department of Physics, Renmin University of China, SHIWEI ZHANG, CCQ, Flatiron Institute, Simons Foundation — We present a highly accurate auxiliary-field quantum Monte Carlo (AFQMC) method to study finite-temperature properties of correlated fermion systems. This approach eliminates the minus sign problem by introducing constraints in auxiliary-field space. Building on earlier ideas [1] and incorporating the latest developments in zero-temperature methods, we introduce a self-consistent formalism [2] to improve the constraint in the finite-temperature framework. This with several other algorithmic advances leads to a more accurate, more efficient, and numerically more stable approach for finite-temperature calculations. We carry out systematic benchmark study in the 2D Hubbard model. Temperatures as low as T=1/80 (in units of hopping) are reached. The finite-temperature method is exact at high temperatures, and approaches the result of the zero-temperature constrained-path AFQMC as temperature is lowered. The benchmark shows that systematically accurate results are obtained for thermodynamic properties. The properties of the 2D doped Hubbard model as functions of temperature will be presented and discussed.

*We acknowledge the support from NSF and Simons Foundation.
ANISH BHARDWAJ (Presenter), Florida State University Tallahassee FL USA; National High Magnetic Field Laboratory, EFSTRATIOS MANOUSAKIS, University of Athens, Panepistimiopolis, Zografos, Athens, Greece; Florida State University, Tallahassee, FL, USA; National High Magnetic Field Laboratory — A diagrammatic expansion for the pair distribution can be derived by starting from the many-body path-integral and using the idea of cluster expansion. The expansion is written as a sum of nodal and non-nodal diagrams. The sum of all the nodal diagrams can be expressed in terms of the non-nodal diagrams using the hypernetted equation technique. The sum of the non-nodal diagrams, which are irreducible diagrams in momentum space, are written as a perturbation expansion in powers of the particle density. Our approach is analogous to the well-known many-body perturbation expansion of the n-body Green's function. The approach was tested on a system of distinguishable particles and our results agree very well with those obtained from the path-integral Monte Carlo.

ZHENGQIAN CHENG (Presenter), CHRIS MARIANETTI, Columbia University — We formulate a general method for constructing a variational expression of the total energy based on two projective ansatz from the weak and strong coupling limits. These two ansatz are then combined according to individual and mutual interactions of low and high energy degrees of freedom. We apply our approach to the single band Hubbar model, where the theory yields the double occupancy and the nonlocal single-particle density matrix. We compare to exact results for $d=1$ and $d=\infty$. For $d=1$, the insulating state is properly obtained at infinitesimal $u$; in addition to an accurate prediction of the ground state energy over a broad range of $t/U$. In infinite dimensions, we properly find a finite-U metal-insulator transition with reasonable quantitative accuracy across all parameter space. Our approach has a negligible computational cost as compared to dynamical mean field theory and could be highly applicable in the context of total energies for strongly correlated materials and molecules.

Johan Nilsson (Presenter), Uppsala University — We discuss some new methods for truncating and closing the equations of motion for composite operators. Our formalism automatically generates a physical theory in the sense of having positive spectral weights. Another important advantage of our methods is that (for judiciously chosen set of operators) all averages necessary to close the formalism can be calculated self-consistently from within the theory itself. We discuss how the method can be applied to the Hubbard model in both fermionic and bosonic sectors.

Fernando Reboredo (Presenter), Oak Ridge National Laboratory — An approach to evaluate a family of semi-local observables from the fixed-node ground state will be discussed. The celebrated importance-sampling diffusion Monte Carlo (DMC) method by Ceperley and Alder is a real space approach. Therefore, beyond the calculation of the total energy of the fixed-node ground state, DMC facilitates the evaluation of observables that are local in real space such as the density, albeit pure estimators or extrapolations are required. The evaluation of semi-local observables is expected to be more involved. It can be shown, however, that the DMC algorithm carries additional information of the fixed-node solution. DMC results for semi-local operators will be compared with exact results, in the hydrogen atom and the harmonic oscillator. The perspectives, computational cost, and potentials problems of this approach when applied to realistic many-body systems will be discussed.

*Supported by the Materials Science and Engineering Division, Basic Energy Sciences, Office of Science, Department of Energy.

ABDULGANI ANNABERDIYEV (Presenter), CODY MELTON, MICHAEL BENNETT, GUANGMING WANG, LUBOS MITAS, North Carolina State University — We present high accuracy total energies of pseudo-atoms, i.e., atoms with effective core potentials (ECP). The pseudo-atoms considered are the 1st, 2nd and 3rd-row elements with correlation consistent effective core potentials (ccECP) we constructed. For each element, we perform configuration interaction, coupled-cluster, and quantum Monte Carlo calculations with systematically eliminated/improved errors. We carry out FCI/CCSDT(Q) calculations with aug-cc-pVnZ (n=3-6) basis set extrapolated to complete basis set limit to obtain highly accurate energies. For these methods, the achieved accuracy in the 1st row is typically 0.1-0.3 mHa, the 2nd row is 0.1-0.2 mHa, and 5-10 mHa in the 3rd row. Wherever possible, we included the kinetic energies obtained from FCI calculations to estimate the smoothness/curvature of the particle density. These accurate total energies will serve as a benchmark for independent calculations as well as the assessment of systematic and methodological errors.
3:54PM V16.00008: Compton Profile of Solid and Liquid Lithium from Quantum Monte Carlo* YUBO YANG (Presenter), University of Illinois at Urbana-Champaign, MARKUS HOLZMANN, Physics, Laboratoire de Physique et Modélisation des Milieux Condensés, DAVID M CEPERLEY, University of Illinois at Urbana-Champaign — Compton scattering cross section is directly related to the electronic momentum distribution and provides an important check of many-body theory. We computed the Compton profile of solid and liquid lithium using quantum Monte Carlo (QMC) and compared with recent experiments obtaining excellent agreement. Importantly, we find it necessary to explicitly include the core electrons for quantitative accuracy. To account for lattice effects, we sampled finite-temperature configurations using molecular dynamics (MD), then performed pseudopotential diffusion Monte Carlo (DMC) simulations on each configuration. We used Slater-Jastrow wavefunction and twist-averaged boundary condition. QMC pseudopotential correction was derived from an all-electron DMC simulation of the perfect crystal. Our calculations provide the first all-electron QMC benchmark for the Compton profile of lithium under both liquid and solid conditions.

*This work made use of the Blue Waters sustained-petascale computing project and the Illinois Campus Cluster, supported by the National Science Foundation (awards OCI-0725070 and ACI-1238993), the state of Illinois, the University of Illinois at Urbana-Champaign and its National Center for Supercomputing Applications.

Yubo Yang and David Ceperley were funded by DOE 0002911.

4:06PM V16.00009: Prediction of the singlet-triplet excitation energy for the spinel, MgTi2O4 via downfolding approach combined with first-principles Quantum Monte Carlo* BRIAN BUSEMEYER (Presenter), GREG MACDOUGALL, LUCAS WAGNER, University of Illinois at Urbana-Champaign — The spinel, MgTi2O4 undergoes a transition into a dimerized state at low temperatures that is expected to be a spin singlet. However, no signature of a singlet-triplet transition as been discovered, in part due to the difficulty of predicting the energy of the transition from theory. Using high-accuracy first-principles quantum Monte Carlo combined with a novel model-fitting approach, we predict the singlet-triplet gap to be 350(50) meV, a higher energy than previous experimental observations have considered. Confirmation of our prediction would suggest that our approach should enable calculation of other excitation energies on the basis of first-principles quantum Monte Carlo combined with effective model calculations.

*This research is part of the Blue Waters sustained-petascale computing project, which is supported by the National Science Foundation (awards OCI-0725070 and ACI-1238993) and the state of Illinois. Blue Waters is a joint effort of the University of Illinois at Urbana-Champaign and its National Center for Supercomputing Applications.

4:18PM V16.00010: An Efficient Calculation of the Total Energy Variation in DFT+DMFT Implemented using Orthogonal Basis sets BENNY WAH (Presenter), HYOWON PARK, University of Illinois at Chicago — Calculations of the total energy variation in density functional theory plus dynamical mean field theory (DFT+DMFT) with respect to the structural change are important for atomic force and stress computations for strongly correlated materials. In this talk, we will show that the energy variation of DFT+DMFT implemented using orthogonal basis sets such as Wannier functions can be computed efficiently using analytic formula since the potential energy variation can be exactly cancelled out and the DMFT self-energy itself or its variation does not need to be explicitly accounted. We will use DMFT with the Continuous-Time Quantum Monte Carlo (CTQMC) impurity solver to compute its total energy variation of the two-dimensional one-band Hubbard model with respect to changes of hopping parameters and compare to the results of its analytic energy derivative formula to verify their quantitative agreement. We will also compare the potential energy contributions sampled directly from CTQMC and computed using the Migdal-Galitzki formula. The application of our formula to the calculations of forces and stress in DFT+DMFT will be also discussed.

4:30PM V16.00011: Systematic corrections to the Thomas-Fermi approximation without a gradient expansion JUN HAO HUE (Presenter), THANH TRI CHAU, MARTIN-ISBJÖRN TRAPPE, BERGE ENGLERT, National University of Singapore — We improve on the Thomas–Fermi approximation for the single particle density of fermions by introducing inhomogeneity corrections. Rather than invoking a gradient expansion, we relate the density to the unitary evolution operator for the given effective potential energy and approximate this operator by a Suzuki–Trotter factorization. This yields a hierarchy of approximations, one for each approximate factorization. For the purpose of a first benchmarking, we examine the approximate densities for a few cases with known exact densities and observe a very satisfactory, and encouraging, performance. As a bonus, we also obtain a simple fourth-order leapfrog algorithm for the symplectic integration of classical equations of motion.
4:42PM V16.00012: Approximate States of the Hubbard Model from Heisenberg’s Equation* ROGER HAYDOCK (Presenter), University of Oregon — Operators which add electrons with definite energies to states of interacting electrons are solutions of the time-independent Heisenberg equation. Expanding the operators in the number of electron-hole pairs generated to screen each added electron provides systematic approximations for the energies of these operators. This is illustrated for the simplest Hubbard model on a cubic lattice by relations between the energies and electron densities of ground states.

*Snyder Gift to University of Oregon

4:54PM V16.00013: Bond energies of molecules using strictly-correlated-electron (SCE) limit of Density-Functional-Theory* KSHITEEJ DESHMUKH (Presenter), KAUSHIK DAYAL, Civil and Environmental Engineering, Carnegie Mellon University — Standard Kohn-Sham DFT starts from a mean-field approximation: the kinetic energy is modeled exactly, while the electron-electron interactions are modeled through a split into a mean-field term, and corrections from the exchange-correlation term. The SCE limit starts from the opposite limit: the electron-electron interactions are assumed to dominate over the kinetic energy, and hence it is a semi-classical limit. It is hence well suited to study strongly-correlated situations, e.g. bond breaking. While the SCE limit includes many-body interactions, it can be identified as a problem from Optimal Transport theory with Coulomb cost function. Hence it can be solved by a nested optimization in its dual (Kantorovich) formulation. We incorporate the Kantorovich solution within the KS-DFT framework and solve using Finite Element Method.

*AFSOR MURI

5:06PM V16.00014: Correlated states in magnetic quantum dots with multiple occupancy TIAGO DE CAMPOS (Presenter), University at Buffalo, The State University of New York, JAMES PIENTKA, Physics, ST. BONAVENTURE UNIVERSITY, ALEX MATOS ABIAIGUE, Department of Physics and Astronomy, Wayne State University, JONG E HAN, IGOR ZUTIC, University at Buffalo, The State University of New York — The motivation to magnetically dope semiconductor quantum dots comes from the possibility for an enhanced control of magnetic ordering as compared to their bulklike counterparts. Unlike in the bulk structures, adding a single carrier in a magnetic QD can have important ramifications. An extra carrier can both strongly change the total carrier spin and the temperature of the onset of magnetization[1]. While QDs have been recognized for correlation effects, inherent in the analog of Wigner crystals referred to as Wigner molecules (WMs), the modification of underlying correlated states with magnetic doping is largely unexplored[2]. By focusing on Mn-doped II-VI QDs[3] we show correlated states, which can be viewed as a generalization of WMs, can be studied using exact diagonalization and conditional probability density. We explain how the formation of a shell structure in these Mn-doped QDs and magnetic frustrations are altered by the changes in strength of the Coulomb interaction.

5:18PM V16.00015: Resilience of the Mixed State Wigner Function ALBERT MATERDEY, Roxbury Community College, THOMAS MATERDEY (Presenter), University of Massachusetts Boston, ALEXANDER MATERDEY, Quantum FC, Inc. — Solution of the quantum Vlasov equation shows the phase space dynamics of a mixed-state Wigner function is more resilient against changes in external electric and magnetic fields than a pure-state Wigner function. A particle in a mixed-state is harder to follow and localize, but the freedom to access a range of pure states increases its inertia against changes in external conditions. This could explain the electron’s stability in the Shrodinger’s atomic orbital model and perhaps provides a way to preserve the information of a qubit sufficiently long for quantum computing.

Thursday, March 7, 2019 2:30 PM - 5:18 PM

Session V17 DCOMP: Matter in Extreme Environments: Warm Dense Matter BCEC 156A - Paul Loubeyre, CEA de Bruyeres-le-Chatel - Tag(s): Focus
**2:30PM V17.00001: Modeling Materials at Extreme Conditions for High Energy-Density Science** [Invited]  STEPHANIE HANSEN (Presenter), TAI SUKE NAGAYAMA, ANDREW BACZEWSKI, ATILLA CANGI, THOMAS GOMEZ, Sandia National Laboratories — Modern High Energy-Density experimental facilities study inertial confinement fusion, laboratory astrophysics, and extreme states of matter by compressing energy in space and time to produce hot, dense, and strongly coupled plasmas. In such extreme environments, changes in electronic and ionic structure impact the material equation-of-state, transport properties, and observable signatures that inform both hydrodynamic simulations and interpretations of experimental data. This talk will survey experimental programs in HED science and describe an ongoing effort to develop a highly constrained, fully self-consistent atomic-scale model of material at extreme conditions. Generating equations of state, transport properties (thermal and electrical conductivities, opacities, stopping powers) and diagnostic signatures (X-ray Thomson scattering, spectroscopic line shifts and broadening) from a single, consistent core model helps to constrain simulations and improve the reliability of data interpretation from complex experiments.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia, LLC., a wholly owned subsidiary of Honeywell International, Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA-0003525. This work was supported by the U.S. Department of Energy, Office of Science Early Career Research Program, Office of Fusion Energy Sciences under FWP-14-017426.

**3:06PM V17.00002: A Stochastic approach to thermal DFT**  YAEL CYTTER (Presenter), Department of Chemistry, Fritz Haber Center for Molecular Dynamics, Hebrew University of Jerusalem, Israel, DANIEL NEUHAUSER, Department of Chemistry and Biochemistry, University of California Los Angeles, USA, ERAN RABANI, Department of Chemistry, University of California Berkeley and Lawrence Berkeley National Laboratory, USA, ROI BAER, Department of Chemistry, Fritz Haber Center for Molecular Dynamics, Hebrew University of Jerusalem, Israel — Despite progress in observational astronomy, some elements such as the internal composition of planets are still not well-understood. A root cause is our limited understanding of matter under extreme conditions (MEC) - pressures in the GPa-TPa range and temperatures (T) up to 10^5 K. Due to the difficulty in preparing MECs, the experimental input is limited, and ab initio calculations are sometimes the only source of information. The Kohn-Sham density functional theory (KS-DFT) seems as a reliable and useful tool for obtaining information on MEC. Calculations in finite temperatures, however, are expensive due to the large number of fractionally occupied KS orbitals involved. A stochastic method developed recently[1],[2], appears to be a fitting approach to this problem. By performing a stochastic trace, the KS Hamiltonian is directly obtained from the density, resulting in a scaling of O(T^{-1}). I will introduce the convergence and errors involved in calculations of the canonical free energy. In addition, a stochastic approach to calculate the Kubo-Greenwood conductivity will be presented.

**3:18PM V17.00003: A new capability for large-scale linear scaling Kohn Sham DFT calculations for materials at high temperatures.**  SEBASTIEN HAMEL (Presenter), Physics and Life Sciences, Lawrence Livermore Natl Lab, MANDY BETHKENHAGEN, Physics, University of Rostock, JOHN PASK, BABAK SADIGH, Physics and Life Sciences, Lawrence Livermore Natl Lab, PHANISH SURYANARAYANA, School of Civil and Environmental Engineering, Georgia Tech — We developed a new capability for the accurate and efficient quantum simulation of material properties across an extreme range of densities, pressures and temperatures. This code, SQDFT, enables the use of full Kohn-Sham quantum molecular dynamics from the condensed matter regime, through the warm dense matter regime and into the plasma regime, well beyond the previous state-of-the-art which was restricted to temperatures below approximately 100 000 Kelvins. We demonstrate this new capability by calculating the Hugoniot curve of different materials up to millions of degrees Kelvin and Gigabar of pressure and investigating the structural and transport properties of the materials under these extreme conditions. We also present a performance study of our SQDFT code on various supercomputing platforms. SQDFT scales linearly with system size which allows us to run full Kohn-Sham QMD simulations with several thousand of atoms.

SCAN-L extended to an exchange-correlation free-energy density functional for extreme conditions

Daniel Mejia-Rodriguez (Presenter), Sam B Trickey, University of Florida — The predictive potential of density functional theory (DFT) for simulation of systems under extreme conditions of temperature and pressure depends crucially on having an exchange-correlation (XC) free-energy functional that is accurate for such state conditions. Distinct from zero-temperature XC functionals, the XC free-energy functional must have an explicit temperature dependence. Recently, that has been achieved for the local density approximation ["KSDT", Phys. Rev. Lett. 112, 076403 (2014)] and generalized-gradient approximation ["KDT16", Phys. Rev. Lett. 120, 076401 (2018)].

By use of the systematic construction scheme of the KDT16 GGA, we extend the recent SCAN-L ground-state orbital-free meta-GGA XC functional [Phys. Rev. A 96, 052512 (2017), Phys. Rev. B 98, 115161 (2018)] to a semilocal XC free-energy functional. This completes the ladder of computationally efficient orbital-free free-energy XC functionals. The accuracy of the new SCAN-LF in the warm dense matter regime is assessed and compared to KSDT and KDT16.

Fast First-Principles Predictions for Warm Dense Matter with Orbital-free Free Energy Density Functional Theory

Kai Luo (Presenter), University of Florida, Valentin Karasiev, Laboratory for Laser Energetics, Sam B Trickey, University of Florida — Warm dense matter encompasses the phase-space region between ordinary condensed matter and plasmas. That poses inconvenient challenges for theory. Conventional Kohn-Sham density functional theory (KS-DFT) is computationally demanding due to a large number of thermally occupied bands involved at high temperature. Meanwhile, path-integral Monte Carlo (PIMC) has intrinsic difficulties for the low-temperature scenario. In contrast, orbital-free free energy density functional theory (OF-FEDFT) is a consistent approach spanning the whole T range. The key to OF-FEDFT usage is good approximate functionals. Here we extend the recent LKT ground-state generalized gradient approximation (GGA) non-interacting kinetic energy density functional (KEDF) (Phys. Rev. B 98, 041111(R) (2018)) to a semi-local free energy functional. In tests on hydrogen at elevated T, it outperforms the previously best single-point free energy functional, VT84F (Phys. Rev. B 88, 161108(R) (2013)) for the equation of state (EOS). For deuterium, it is roughly comparable to KS-DFT and PIMC in accuracy.

Approach to Orbital-Free DFT with Englert-Schwinger model

Jouko Lehtomäki (Presenter), Olga Lopez-Acevedo, Department of Applied Physics, Aalto University — Orbital-free density functional theory (OFDFT) is a variant of DFT which tries to circumvent construction of Kohn-Sham orbitals in order to efficiently scale to larger system sizes. Most of the research on OFDFT is on improving the accuracy of the non-interacting kinetic energy density functional (KEDF) as a direct functional of density, which requires use of pseudopotentials. Instead of density functionals, we focus on potential functional formalism. This formalism allows us to sidestep use of pseudopotentials and directly use atomic orbitals alongside orbital-free functionals. We assess the self-consistent performance of potential functionals by Englert and Schwinger[1].

Specifically we compare the Englert-Schwinger model to Kohn-Sham and Thomas-Fermi-Dirac-Weizsäcker models self-consistently on small systems, especially atoms showing that the potential functionals by Englert and Schwinger are a viable alternative to the non-interacting kinetic energy density functionals. We also present the augmentation of this model with Kohn-Sham orbitals, which allow us to explore OFDFT solution without the use of pseudopotentials.

WILLIAM NELLIS (Presenter), Harvard University — An equation of state at extreme conditions in Warm Dense Matter (WDM) is needed for exoplanets and Inertial Confinement Fusion. Development of theory for WDM is problematical because of the need for experimental data for verification. At shock pressures 0.5 - 20 TPa (200 Mbar) measured Hugoniot data of fluid metals [1] are essentially co-linear in U_S (U_P), where U_S and U_P are shock and particle velocity, respectively, essentially independent of material. Calculated shock temperatures of those data range from a few thousand K up to a million K. Those shock-compressed fluids are WDM with Minimum Metallic Conductivity (MMC) [2]. The linear fit to 40 measured data points is known as the Universal Hugoniot of Fluid Metals (UHFM), which is possible verification data for WDM theory. TFD is Thomas Fermi theory for ionized atoms, Fermi-Dirac statistics for electrons, and electron correlation [3]. A possible theory for why co-linear fit is universal might be a common electron correlation function in TF theory that yields the UHFM for Al, Cu, Fe, Mo, Kr, Gd_3Ga_5O_12, etc.

THOMAS SCHENKEL (Presenter), SVEN STEINKE, QING JI, JIANHUI BIN, STEPAN BULANOV, JAEHONG PARK, WIM PIETER LEEMANS, Lawrence Berkeley National Laboratory — We use the BELLA petawatt laser [1] to accelerate ions to multi-MeV energies at a repetition rate of up to 1 Hz [2]. Ion acceleration is now routinely conducted at BELLA in parallel to laser-plasma acceleration of electrons. For laser intensities in the 10^19 W/cm^2 regime, we find ion intensities up to 10^12 ions/shot with low divergence. When transported to a second target, ion pulses can drive the formation and annealing dynamics of defects and they can uniformly heat materials to temperatures of 1-10 eV, well into the warm dense matter regime [3]. Ion intensities can be tuned for materials processing at selected temperatures to form desired defect structures or to drive desired phase-transitions. We present results from ion acceleration and target heating campaigns, including color center synthesis for spin qubits in diamond.

ANDREW KRYGIER (Presenter), Lawrence Livermore Natl Lab, USA, MARION HARMAND, IMPMC, Université Pierre et Marie Curie, France, BRUNO ALBERTAZZI, LULI, Ecole Polytechnique, France, EMMA MCBRIDE, SLAC National Accelerator Laboratory, USA, KAREN APPEL, European XFEL, Germany, KOHEI MIYANISHI, NORIMASA OZAKI, Institute for Laser Engineering, Osaka University, Japan, GUILLAUME FIQUET, IMPMC, Université Pierre et Marie Curie, France — Earth's core is composed of Fe mixed with small amounts of light elements like Si, O, and C. Determining the properties of high-pressure liquids, the melting curve, and solid phase relations of Fe and derivative alloys is important for understanding the cores of Earth and terrestrial exoplanets. High pressure and temperature conditions can be achieved with high power lasers, but the states are highly transient, and the inherently high strain rate introduces physics not expected to occur in planetary interiors. The recent advance of facilities with high-power lasers coupled to XFELs enables characterization of shocked states with the powerful suite of X-ray techniques used by the static community. Here we present results from recent ultrafast X-ray diffraction measurements of shocked Fe alloys at the coupled XFEL-optical laser facilities using the EHS end station at the SACL laboratory (Japan) and the LCLS end station MEC at SLAC National Accelerator Laboratory (USA).

4:42PM V17.00010: Thermal conductivity and equation-of-state measurements in warm dense matter* [Invited]
YUAN PING (Presenter), Lawrence Livermore Natl Lab — Thermal conductivity is one of the most fundamental physical properties of matter. It determines the heat transport rate and has an enormous impact on a variety of mechanical, electrical, chemical, and nuclear systems. Thermal conduction is important in high energy density (HED) matter such as laboratory fusion plasmas, planetary cores, compact stars, and other celestial objects. Examples are in the ablation and instability growth in inertial confinement fusion (ICF) capsules, in energy loss from ICF hot spot, and in the evolution of Earth's core-mantle boundary. Despite the importance of thermal conductivity in HED systems, experimental measurements under relevant conditions are scarce and challenging. We have developed a method of differential heating for thermal conductivity measurements. In this talk, experimental designs will be described for two different platforms: proton heating and x-ray laser heating. Data from various facilities on amorphous carbon, aluminum and iron will be presented and comparison with models will be discussed.

*This work was performed under DOE contract DE-AC52-07NA27344 with support from OFES Early Career program and LLNL LDRD program.

Session V18 DCOMP: Electronic Structure Methods II BCEC 156B - Rajendra Zope

2:30PM V18.00001: Bringing Electronic Structure Codes into the Modern Software Ecosystem
RAN ADLER (Presenter), Rutgers University, New Brunswick, ANDREY KUTEPOV, Brookhaven National Laboratory, GABRIEL KOTLIAR, Rutgers University, New Brunswick — We propose a novel framework (“Portobello”) for assimilating Electronic Structure codes into the modern software ecosystem and facilitating an efficient software development process. First we discuss some of the pitfalls of Fortran / Python - centric paradigms, which often lead to flawed design and unwieldy code. We identify a culprit to be the lack of high-level abstraction, which prevents reuse of components, obscures developers' intent, and hinders collaboration. Our new object-oriented framework facilitates all steps of the software developments life-cycle, and is applicable to Fortran-based systems, as well as ones written in C/C++.

Next, we demonstrate how the framework provides a concrete way to address important questions in the physics of Correlated Electronic Structure, as well as implement and test new ideas. Following this approach, we combine A. Kutepov's Fortran-based FlapwMBPT (Full potential LAPW Many-Body Perturbation Theory) with a C++ implementation of CTQMC and Materials Project Pymatgen (crystal and symmetry code) to create a Pythonic charge-self-consistent toy DFT+DMFT program. We demonstrate the calculation of correlated electronic structure, as well as calculation of transport properties, and discuss how the program can be used and extended.

2:42PM V18.00002: ComDMFT: a Massively Parallel Computer Package for the Electronic Structure of Correlated-Electron Systems*
SANGKOOK CHOI (Presenter), PATRICK SEMON, BYUNGKYUN KANG, ANDREY KUTEPOV, GABRIEL KOTLIAR, Brookhaven National Laboratory — ComDMFT is a massively parallel computational package to study the electronic structure of correlated-electron systems (CES). Our approach is a parameter-free method based on ab initio linearized quasiparticle self-consistent GW (LQSGW) and dynamical mean field theory (DMFT). The non-local part of the electronic self-energy is treated within ab initio LQSGW and the local strong correlation is treated within DMFT. In addition to ab initio LQSGW+DMFT, charge self-consistent LDA+DMFT methodology is also implemented, enabling multiple methods in one open-source platform for the electronic structure of CES. This package can be extended for future developments to implement other methodologies to treat CES

*This work was supported by the U.S Department of Energy, Office of Science, Basic Energy Sciences as a part of the Computational Materials Science Program
3:30PM V18.00003: Hubbard interactions from density-functional perturbation theory  IURI TIMROV (Presenter),
MATTEO COCCOCCIONI, NICOLA MARZARI, EPFL STI IMX THEOS, Ecole polytechnique federale de Lausanne — DFT+U+V is a novel
and powerful tool to model systems containing partially-filled manifolds of localized states. However, there is a history of
treating Hubbard parameters semi-empirically, which is unsatisfactory. Conceptual methods to determine e.g. Hubbard U
from first principles have nevertheless been introduced long ago, based either on the constrained random-phase
approximation or on linear response theory. Still, these approaches are often overlooked due to their cost or complexity.
Here, we introduce a computationally inexpensive and straightforward approach [1] to determine on-site U and inter-site
V Hubbard parameters, bypassing the need to use supercells. By recasting linear-response susceptibilities in the language of
density-functional perturbation theory we substitute monochromatic perturbations to supercells, and allow for a fully
determined automation of Hubbard parameters in primitive cell calculations. Such developments provide the
community with a robust and reliable tool to calculate consistent values of U and V for any system at hand, while opening
the way for deployment in high-throughput studies. The approach is showcased with applications to the vibrational
spectra of selected transition-metal compounds.

3:06PM V18.00004: RESPACK software to derive ab initio effective low-energy Hamiltonians and its extension to
treat materials with strong spin-orbit interaction.* MAXIME CHARLEBOIS (Presenter), YUSUKE NOMURA, Department of
Applied Physics, University of Tokyo, YOSHIHIDE YOSHIMOTO, Department of Computer Science, University of Tokyo, TERUMASA
TADANO, Materials Science, National Institute for Materials Science (NIMS), MASATOSHI IMADA, Department of Applied Physics,
University of Tokyo, KAZUMA NAKAMURA, Quantum Physics Section, Department of Basic Sciences, Kyushu Institute of Technology —
RESPACK [1] is an open source library that allows to calculate electron correlation effects and to derive effective low-
energy Hamiltonians starting from the density functional theory (DFT). The downfolding to low-energy Hamiltonians is
achieved by combining maximally localized Wannier functions [2] and full (or constrained) random phase approximation. It
can be interfaced with both Quantum ESPRESSO [3] and xTAPP [4]. Here, we present an extension of RESPACK to treat
materials with strong spin orbit effects and application to various test materials.

3:18PM V18.00005: Full-potential relativistic four-component Dirac–Kohn–Sham method for periodic systems using
Gaussian-type functions* MARIUS KADEK (Presenter), MICHAL REPISKY, KENNETH RUUD, Hylleas Centre for Quantum
Molecular Sciences, University of Tromso — I will present a new full-potential all-electron Kohn–Sham theory for obtaining
fully-relativistic band structures of spin–orbit-coupled solids. Our method is based on the four-component Dirac–Coulomb
Hamiltonian, and all operators are represented compactly in real space using Gaussian-type orbitals (GTOs). The local
nature of GTOs allows for explicit handling of one-, two-, and three-dimensional periodic systems avoiding the need to
introduce vacuum layers. In combination with a variational treatment of spin–orbit coupling, this makes the method
suitable for studying two- and three-dimensional topological insulators as well as spin–orbit-induced splittings of bands.
The GTO-based methodology makes no assumptions about the electronic density in the vicinity of nuclei, and can be used to
calculate core-related properties, such as nuclear magnetic resonance parameters. Large-scale relativistic calculations
of solids containing thousands of heavy atoms in the simulation supercell are possible due to the use of quaternian
algebra for the time-reversal-adapted basis and employment of fast-multipole methods.[1]

3:30PM V18.00006: Density-functional theory for noncollinear magnetism: exact and approximate results on small
Hubbard chains* EDWARD PLUHAR (Presenter), CARSTEN ULLRICH, University of Missouri — We apply a class of orbital-
dependent exchange-correlation functionals (exact exchange and Singwi-Tosi-Land-Sjoelander exchange-correlation) to
two-electron systems on small Hubbard chains in the presence of noncollinear magnetic fields. We compare these
approximations with benchmark results obtained from exact diagonalization and inversion of the Kohn-Sham equation via
a conjugate-gradient optimization. In general, good agreement is found for total energies, densities and magnetizations
over a range of interaction strengths. Exchange-correlation torques, on the other hand, are more subtle and can be
difficult to approximate, especially for strong correlations.

*This work was supported by Research Corporation and by DOE Grant No. DE-SC0019109
3:42PM V18.00007: Metals: Automatic k-point generation for a 60% speed-up of total energy calculations*  
GUS HART (Presenter), WILEY S MORGAN, JEREMY JORGENSEN, RODNEY W. FORCADE, Brigham Young University — A generalized regular k-point grid generation method (more general than the traditional Monkhorst-Pack method) leads to a 60% speed-up for total energy calculations of metallic systems. Generalized regular grids can be generated using the JHU k-point server: http://muellergroup.jhu.edu/K-Points.html. We have developed a new algorithm that can generate these same grids on the fly so that a web request is not necessary. The algorithm relies on group theoretical ideas that connect the concepts of lattices and integer matrices to yield extremely fast grid generation, enabling scans over thousands of candidate grids and select one with the highest efficiency (best k-point symmetry reduction).

*Supported by the Office of Naval Research (MURI N00014-13-1-0635).

3:54PM V18.00008: Get 10 materials for the price of 1: computationally efficient DFT*  
JEREMY JORGENSEN (Presenter), THOMAS W. SEDERBERG, GUS HART, Brigham Young University — We have developed a numerical algorithm that will allow us to run density functional theory (DFT) computations ten times faster. Our improvements in efficiency result from accelerating the convergence rate of the band energy calculation by employing local polynomial interpolation and adaptive mesh refinement. Tests of the algorithm on 2D toy pseudopotentials show an order of magnitude improvement over the rectangular method, the method currently implemented in DFT programs. Our tests demonstrate two counterintuitive results: 1) accurately approximating the Fermi surface is critical to accurately calculate the band energy, and 2) band crossings are inconsequential. Implementing our algorithm in DFT programs will accelerate both the growth of theoretical materials databases and the discovery of materials.

*Authors acknowledge funding from ONR (MURI N00014-13-1-0635).

4:06PM V18.00009: Band Unfolding Made Simple*  
SARA GARCÍA MAYO (Presenter), JOSE M. SOLER, Departamento de Física de la Materia Condensada, Univ. Autónoma de Madrid — We present a simple point of view on band unfolding of the energy bands obtained from supercell calculations that relies on the relationship existing between the local density of states in reciprocal space (qLDOS) and the fully unfolded band structure of a system. This new concept provides an intuitive and valid approach not only for periodic, but also for non-translationally symmetric systems, as well as a way to recover the conventional band structure by doing a refolding back into the primitive Brillouin zone of the pristine crystal. We implemented this algorithm in the Siesta package and tested some of its potential applications on silicon-based systems, such as defective crystals, surfaces and amorphous structures.

*Funded by Spain’s MINECO grant FIS2015-64886-C5-5-P

JASON MUNRO (Presenter), VINCENT LIU, VENKATRAMAN GOPALAN, ISMAILA DABO, Pennsylvania State University — The nudged elastic band (NEB) method is an effective approach for calculating minimum energy pathways of kinetic processes. However, the final paths obtained by the algorithm rely heavily on the initially chosen path. This often necessitates running multiple calculations with different initial conditions in order to obtain reliable results. Recently, this problem has been reformulated using the language of distortion symmetry, which consists of combining static spatial symmetries with a new operation called distortion reversal, and has the property of only being conserved or raised by the NEB optimization [1]. Using this knowledge, symmetry-adapted perturbations to an initial path can be generated and used to systematically lower its symmetry. By doing so, the exploration of other low-energy pathways that may exist is enabled. The group and representation theory details behind this new approach are presented and implemented in standalone software (DiSPy). The algorithm is then demonstrated by applying it to the calculation of ferroelectric switching pathways in LiNbO3. Previously reported pathways are recovered, with new paths that involve a higher degree of atomic coordination also being discovered.

**4:30PM V18.00011: Evaluation of self-energy matrix for electrode based on real-space pseudopotential method**  
SHIGERU IWASE (Presenter), TOMOYA ONO, Department of Physics, University of Tsukuba  
— Evaluation of self-energy matrix for electrode is one of the bottleneck parts of the first-principles transport calculation. Over the past years, several methods have been developed to reduce the computational cost, however calculation is still slow especially when the real-space pseudopotential method is employed because the Hamiltonian matrix of the unit cell becomes very large. We present a method to evaluate the self-energy matrix especially for real-space pseudopotential method. The method combines the partitioning technique [1] with singular value decomposition, which transforms the Hamiltonian matrix of a unit cell into the maximally contracted form. Because of the simplicity of the method, typical methods such as quick decimation method [2] and semi-analytical method [3] can be used for the contracted Hamiltonian without large modification. We applied this method for several examples and validated the accuracy and efficiency of the method.

**4:42PM V18.00012: On the δ-function broadening in Kubo-Greenwood equation**  
PAVLO BULANCHUK (Presenter), Physics, Pennsylvania State University  
— We propose a solution to a long-standing issue in the calculation of Kubo-Greenwood DC conductivity in finite-sized quantum systems. The Kubo-Greenwood equation contains a sum of delta-functions, which are usually broadened. The estimate of the DC conductivity depends significantly on the type of broadening applied, making the estimate ambiguous. We eliminate the ambiguity by mapping the broadening onto a specific way of introduction of the electric field and making a correction based on Drude equation. We also consider the influence of delta-function broadening on conductivity averaged over disorder. We demonstrate the influence can be reduced to a convolution of the average conductivity with the broadening function over the frequency. Even though in finite systems the average conductivity is an oscillatory function of frequency, if convolved with a slowly varying function, it behaves similarly to a Lorentzian. We propose a procedure of extracting the parameters of the Lorentzian by extrapolation similarly to a single system.

**4:54PM V18.00013: Minimizing Reflections in Electronic Structure Calculations**  
GREGORY BENESH (Presenter), Department of Physics, Baylor University, ROGER HAYDOCK, Department of Physics, University of Oregon  
— In electronic structure calculations, large aggregates of atoms are usually approximated by model systems containing far fewer atoms—introducing artificial boundaries that do not occur in the original system. These boundaries ordinarily produce reflected waves that interfere with outgoing solutions of the Schrödinger equation. Depending on the degree of interference, computational results from model calculations may differ widely from the characteristics of the real physical system. Examples of computational studies exhibiting this interference effects abound in many areas of physics. One approach to eliminating the reflection problem is to choose Schrödinger solutions that minimally reflect at the artificial boundary of the model system. These so-called Maximum Breaking of Time-Reversal Symmetry (MBTS) solutions come in pairs that maximally carry current in opposite directions. In effect, by using MBTS solutions, the boundary becomes transparent or nearly-transparent to traveling waves. The MBTS formalism and results for several model systems will be presented.

**5:06PM V18.00014: Long-wavelength density-functional perturbation theory**  
MASSIMILIANO STENGEL (Presenter), ICMAB-CSIC and ICREA  
— Density-functional perturbation theory (DFPT) is nowadays the method of choice for the accurate computation of linear and non-linear response properties of materials from first principles. A notable advantage of DFPT over alternative approaches is the possibility of treating incommensurate lattice distortions with an arbitrary wavevector, \( \mathbf{q} \), at comparable computational cost as the lattice-periodic case. In this talk, I will show that \( \mathbf{q} \) can be formally treated as a perturbation parameter, and used in conjunction with established results of perturbation theory (e.g. the \( 2n + 1 \) theorem) to perform a long-wave expansion of an arbitrary response function in powers of the wavevector components. This provides a powerful, general framework to accessing the physical response to the spatial gradient of an arbitrary external field (electric, magnetic, strain or atomic displacement), with a computational cost that is comparable to that of a standard linear-response calculation. As applications of the method, I will discuss the flexoelectric tensor (the polarization response to a gradient of the strain field) and on the "dynamical quadrupoles" (a higher-order multipolar generalization of the Born effective charge tensor).
5:18PM V18.00015: Tight Binding Molecular Dynamics Study of the Cu-Ag Binary Noble Metal System SWABIR SILAYI (Presenter), DIMITRIOS A PAPACONSTANTOPoulos, George Mason University, MICHAEL MEHL, US Naval Academy — The Naval Research Laboratory tight-binding (NRL-TB) method has been quite successful in accurately describing the electronic and mechanical properties of many systems from semiconductors and simple metals to transition and noble metals. We used the NRL-TB method with parameters determined from a fit to reproduce the electronic structure and total energy versus volume values of first-principles Augmented Plane Wave (APW) calculations to study the Cu-Ag noble metal binary system. The parameters were fit to the structures B1(NaCl), B2(CsCl), L12 (Cu3Au), and C1 (Fluorite) and the NRL-TB method reproduced the APW ordering of these structures and the ground-state structure of the system to be the CsCl. Other structural properties such as bulk moduli and electronic densities of states and energy bands were reproduced as well. We also performed molecular dynamics simulations to determine the energies for vacancy formation, temperature dependence of the coefficient of thermal expansion and the mean squared displacement. The TB parameters are demonstrated to be robust for calculating additional static and dynamical properties which had not been fitted.

Thursday, March 7, 2019 2:30 PM - 5:18 PM

Session V19 DMP: Computational Materials Design and Discovery -- High Throughput Computing and Data Mining BCEC 156C - Geoffroy Hautier, Université catholique de Louvain - Tag(s): Focus

2:30PM V19.00001: Polymer Genome: An Informatics Platform for Rational Polymer Dielectrics Design and Beyond [Invited] RAMAMURTHY RAMPRASAD (Presenter), Georgia Institute of Technology — The Materials Genome Initiative (MGI) has heralded a sea change in the philosophy of materials design. Here, we highlight the importance of computational data generation and screening, targeted synthesis and characterization, polymer fingerprinting, machine-learning prediction models, and the creation of an online Polymer Informatics platform (https://www.polymergenome.org) to guide ongoing and future polymer discovery and design. We lay special emphasis on the fingerprinting of polymers in terms of their genome or constituent atomic and molecular fragments, an idea that pays homage to the pioneers of the human genome project who identified the basic building blocks of the human DNA. By scoping the polymer genome, we present an essential roadmap for the design of polymer dielectrics, and provide future perspectives and directions for expansions to other polymer subclasses and properties.

3:06PM V19.00002: High-throughput computational design of electrode-electrolyte interface for solid-state Li-ion batteries* CHUHONG WANG (Presenter), TIM MUELLER, Materials Science and Engineering, Johns Hopkins University — All-solid-state lithium-ion batteries have attracted significant interest for their enhanced safety compared with conventional batteries employing an organic liquid electrolyte. However the interfacial reaction between electrodes and electrolyte can hinder the transport of charge carriers, thus degrading the battery performance. In this work, we present a systematic high-throughput screening method to identify coatings to maintain interface stability during battery operation. Promising coating materials are rapidly selected from computational databases containing a vast collection of inorganic materials. Material candidates found in this work consist of known electrode coatings as well as a list of promising compounds for further testing. We demonstrate that our approach is an efficient way to predict and evaluate functional coatings for a high performance solid state battery design.

*Toyota Motor Corporation

3:18PM V19.00003: New Olivine-Based Cathode Materials HONG FANG (Presenter), PURUSOTTAM JENA, Physics, Virginia Commonwealth University — Olivine-type lithium transition metal orthosilicates, considered as promising cathode materials for the next-generation lithium-ion batteries, have attracted considerable interest in recent year. This is due to their low cost, good safety, and high theoretical capacity. However, great challenges still remain regarding their relatively low practical capacity, phase instability during charge/discharge, and low electronic conductivity. Here, combining data mining with state-of-the-art first-principles calculations, we present a comprehensive study of new olivine-based materials that can meet the above challenges and serve as ideal candidates for cathode materials of next-generation batteries.
3:30PM V19.00004: High-throughput workflow for discovery of multiferroic materials based on ab initio calculations

STEPHANIE MACK (Presenter), University of California, Berkeley, SINEAD MAGELLA GRIFFIN, TESS SMIDT, JEFFREY B NEATON, Lawrence Berkeley National Laboratory — Expanding the catalogue of multiferroics has thus far mostly relied on finely tuning complex perovskite oxides through strain engineering and chemical substitution. While this has been a successful strategy yielding over a dozen new bulk oxide multiferroics, few new classes of multiferroics have been discovered as typical strategies rely on knowledge of structural motifs of known multiferroics. Prior work [1] has developed a high-throughput workflow to screen the Materials Project database for ferroelectrics based on space group symmetry requirements and ab initio calculations. We extend this strategy and develop a workflow to search for candidate polar insulating materials with magnetic order and switchable polarization. Analysis of the trends identified through the search will be discussed.

*Funding provided by DOE, and computational resources provided by NERSC

3:42PM V19.00005: High-throughput analysis of large heterogeneous and dynamic data spaces with signac

CARL SIMON ADORF (Presenter), VYAS RAMASUBRAMANI, BRADLEY DICE, SHARON GLOTZER, University of Michigan — High-throughput generation and analysis of vast data sets offers enormous opportunities for accelerated scientific discovery, but also requires prudent strategies for the management of computational resources and data spaces. This is especially critical when researchers work with heterogeneous and possibly highly dynamic data. The signac framework enables researchers to maintain well-formed and reusable data spaces from early exploration all the way to production runs on supercomputing scales. This is achieved through a transparent data and workflow model as well as a simple and unobtrusive programmatic interface that scales well between preliminary prototyping and concluding stages of a particular computational investigation. Here, we demonstrate the framework's efficacy and versatility by showcasing examples of how signac is applied across various research projects and disciplines.

*Development and deployment supported by UM and MICCoM, as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Subcontract No. 6F-30844. Project conceptualization and early implementation supported by the National Science Foundation, Award # DMR 1409620.

3:54PM V19.00006: High-throughput First-principles Screening of the Layered Magnetic Double-Perovskites Cs₄MSb₂X₁₂

TAO ZHANG (Presenter), DAN HAN, DEYAN SUN, SHIYOU CHEN, East China Normal University — Compared to the three-dimensional halide perovskites, the layered perovskites can exhibit better air-stability and more flexible optoelectronic properties. Among them, Cs₄CuSb₂Cl₁₂ attracted our attention due to its supreme properties such as suitable bandgap, high conductivity, high photo- and thermal-stability in photovoltaic devices. We investigated a series of <111> layered double-perovskites which can be derived from Cs₄CuSb₂Cl₁₂ through the elemental substitution. High-throughput first-principles calculations identified three stable layered double-perovskites Cs₄MnSb₂Cl₁₂, Cs₄CuSb₂Cl₁₂ and Cs₄ScSb₂Br₁₂. The ground state structure of Cs₄MnSb₂Cl₁₂ has the R-3m symmetry and exhibits antiferromagnetic(AFM) ordering, while the Cs₄CuSb₂Cl₁₂ and Cs₄ScSb₂Br₁₂ favor the C2/m symmetry and show AFM ordering. Our calculated results are consistent with the experimental observations, i.e., the ground state structures of Cs₄MnSb₂Cl₁₂ and Cs₄CuSb₂Cl₁₂ have R-3m and C2/m symmetry and they both exhibit AFM behavior, showing that our high-throughput calculation is valid for searching the thermodynamically stable <111> layered magnetic double-perovskites. A new layered double-perovskite Cs₄ScSb₂Br₁₂ is predicted for the first time and it may be synthesized experimentally in the future.
High-throughput Computational Search for Ternary Oxypnictide Mixed Anion Materials

JIAHONG SHEN (Presenter), VINAY I HEGDE, JIANGANG HE, CHRISTOPHER WOLVERTON, Materials Science and Engineering, Northwestern University — Mixed anion, or heteroanionic materials (HetMs), have seen a recent resurgence in interest owing to their intriguing properties for a wide range of applications, including photocatalysts, thermoelectrics and transparent conductors. Though HetMs present more degrees of freedom for materials design, only a relatively small amount of HetMs have been reported comparing to single anion materials. By means of high-throughput density functional theory (HT-DFT) computations, combined with the Open Quantum Materials Database (OQMD), new HetMs and their thermodynamic stabilities can be predicted across a wide range of compound chemistries. In this work, HetMs MOX (M is periodic table elements; X=N, P, As) are studied and several promising stable HetMs are found. Both experimentally observed and hypothetical new compounds (in total 438 compounds) are calculated, and analyzed for thermodynamic ground state stability. Phase diagrams with respect to anion chemical potentials are constructed for these potential candidates to provide constraints on the gas-phase temperature and pressure conditions under which these compounds are stable, guiding future experimental synthetic efforts.

Computational Exploration of Stable Heteroanionic Compounds ABOX (A and B are metal; X=S, Se, and Te)

JIANGANG HE (Presenter), VINAY I HEGDE, Northwestern University, ZHENPENG YAO, Department of Chemistry and Chemical Biology, Harvard University, S. SHAHAB NAGHAVI, Department of Physical and Computational Chemistry, Shahid Beheshti University, KYLE BUSHICK, CHRISTOPHER WOLVERTON, Northwestern University — Compared with single anion compounds, such as oxides, chalcogenides, and fluorides, compounds with multiple anions (heteroanionic or mixed-anion) are less explored[1]. Many of the known heteroanionic compounds have been found to have compelling properties and promising applications. High-throughput ab initio screening is an efficient approach for new materials discovery and can significantly accelerate the experimental synthesis by pointing out promising candidates. In this talk, we will demonstrate the use of high-throughput ab initio calculations combined with the Open Quantum Material Database (OQMD) of formation energies to discovery hundreds new synthesizable ABXO (X=S, Se, and Te) compounds. Crystal structures, dynamical stabilities, and promising applications of these oxysulfides compounds for thermoelectric, transparent conductors, and ionic conductors have been explored within first principles framework as well.

AFLOW-XTAL-MATCH: Automated method for quantifying the structural similarity of materials and identifying unique crystal prototypes

DAVID HICKS (Presenter), CORMAC TOHER, DENISE FORD, CARLO DE SANTO, OHAD LEVY, Duke University, MICHAEL MEHL, United States Naval Academy, STEFANO CURTAROLO, Duke University — The rapid development of computational materials-property databases has generated an abundance of compounds exhibiting various geometries. As materials are continuously added, distinguishing unique structures from duplicates is a growing challenge. We introduce a crystal comparison module – AFLOW-XTAL-MATCH – that quantifies the similarity between structures, independent of the unit cell representation. Employing the misfit criteria from Burzlaff [1], the routine identifies structurally unique or duplicate crystals. To accommodate automatic workflows, the program's infrastructure can analyze numerous structures simultaneously, performing all necessary comparisons. The tool is integrated into the AFLOW framework [2], with functionality to compare compounds to entries in the AFLOWLIB repository and the library of AFLOW prototypes [3]. The algorithm i) elucidates materials with similar properties, ii) determines distinct crystal prototypes, and iii) guides the discovery of unexplored materials.

Herein, a new module is presented for autonomous thermodynamic stability analysis implemented within the open-source AFLOW framework. Powered by the AFLUX Search-API, AFLOW-CHULL leverages data of more than 1.8 million compounds and can be employed locally from any UNIX-like computer. The module integrates a range of functionality: the identification of stable phases and equivalent structures, phase coexistence, measures for robust stability, and determination of decomposition reactions. As a proof of concept, thermodynamic characterizations have been performed for more than 1300 binary and ternary systems, enabling the identification of several candidate phases for synthesis - including 17 promising C15b-type structures and 2 half-Heuslers. An interactive, online web application has been developed showcasing the results of the analysis and is located at aflow.org/aflow-chull.

4:54PM V19.00011: Novel functionalities in chemically-modified quasi-2D clay minerals.* PRIYA GOPAL (Presenter), MARTA GUSMAO, ILARIA SILOI, Department of Physics, University of North Texas, Denton, TX, STEFANO CURTAROLO, Materials Science and Engineering, Center for Materials Genomics, Duke University, Durham, NC, MARCO FORNARI, Department of Physics and Science of Advanced Materials, Central Michigan University, Mt. Pleasant, MI, MARCO BUONGIORNO NARDELLI, Department of Physics, University of North Texas, Denton, TX — Clays are among the most common, cheap, non-toxic and abundant materials found in nature with an inherent \textit{quasi-2D} crystal structure that can be chemically modified to obtain novel functionalities. In this work, we used our High-Throughput infrastructure, \textit{(AFLOW + PAOFLOW),} to compute the electronic structure and related properties for minerals in the clay family: lizardite \textit{(Mg$_3$(Si$_2$O$_5$(OH)$_4$)}, talc \textit{(Mg$_3$(Si$_2$O$_5$)$_2$(OH)$_2$)}, kaolinite \textit{(Al$_2$(Si$_2$O$_5$)(OH)$_4$)} and pyrophyllite \textit{(Al$_2$(Si$_2$O$_5$)$_2$(OH)$_2$)}. We studied the effect of chemical substitutions on the mechanical, optical, electronic and magnetic properties in these four prototypes. We found that Ni-substituted kaolinite \textit{(Ni$_3$(Si$_2$O$_5$)(OH)$_4$)} is structurally stable and is a promising candidate for spintronic applications.

*We acknowledges collaboration within the AFLOW Consortium (www.aflow.org) under the sponsorship of DOD-ONR (Grants N000141310635 and N000141512266).

5:06PM V19.00012: A Map of the Inorganic Ternary Metal Nitrides* WENHAO SUN (Presenter), Materials Sciences Division, Lawrence Berkeley National Laboratory, CHRISTOPHER BARTEL, University of Colorado, ELISABETTA ARCA, SAGE BAUERS, BETHANY E MATTHEWS, National Renewable Energy Laboratory, BERNARDO ORVANANOS, Massachusetts Institute of Technology, BOR-RONG CHEN, MICHAEL F TONEY, LAURA SCHELHAS, SLAC National Accelerator Laboratory, BILL TUMAS, National Renewable Energy Laboratory, JANET TATE, Oregon State University, ANDRIY ZAKUTAYEV, National Renewable Energy Laboratory, AARON M HOLDER, University of Colorado, GERBRAND CEDER, Materials Sciences Division, Lawrence Berkeley National Laboratory — Exploratory synthesis in novel chemical spaces is the essence of solid-state chemistry. However, uncharted chemical spaces can be difficult to navigate, especially when materials synthesis is challenging. Nitrides represent one such space, where synthesis challenges have limited the exploration of this important class of functional materials. Here, we employ a suite of computational materials discovery and informatics tools to construct a large stability map of the inorganic ternary metal nitrides. Our map highlights hundreds of promising new ternary nitride spaces for experimental investigation, from which we experimentally realized 7 new Zn- and Mg-based ternary nitrides. The map further visualizes broad overarching relationships between nitride chemistry and thermochemical stability. To rationalize these stability trends from their underlying chemical origins, we extract the mixed metallicity, ionicity, and covalency from the DFT-computed electron density—revealing the fascinating and complex interplay between chemistry, composition, and solid-state bonding in governing the stability of ternary nitride materials.

First-principles evidence of strong radiative recombination in hybrid perovskites

XIE ZHANG (Presenter), JIMMY SHEN, WENNIE WANG, CHRIS VAN DE WALLE, University of California, Santa Barbara — Understanding the origin of the high solar conversion efficiency of hybrid perovskites is one key research focus in the field. A number of research groups attributed the high efficiency to low radiative recombination due to strong Rashba spin-orbit coupling. In this work, we perform first-principles calculations to explicitly compute the radiative recombination coefficient in the prototypical hybrid perovskite, CH$_3$NH$_3$PbI$_3$. We demonstrate that the radiative recombination in hybrid perovskites is actually strong, and that spin-orbit coupling has only a minor impact on radiative recombination. The computed radiative recombination coefficient is around $10^{-10}$ cm$^3$s$^{-1}$, which is as high as in typical direct-gap semiconductors. However, our first-principles calculations of nonradiative rates show that strong Auger recombination may suppress efficiency. Fortunately, our insights into the origins of the strong Auger recombination indicates potential avenues for engineering the Auger coefficient.

Nonlinear optical properties of organic-inorganic hybrid perovskite

WENSHEN SONG (Presenter), Physics, Washington University in St. Louis, SU HUANG, Electrical & Systems Engineering, Washington University in St. Louis, GUANG-YU GUO, Physics, National Taiwan University, LAN YANG, Electrical & Systems Engineering, Washington University in St. Louis, LI YANG, Physics, Washington University in St. Louis — Nonlinear optical properties of materials play important roles in lasers, frequency conversion, electro-optic modulators, etc. Here we explore the nonlinear optical properties of hybrid CH$_3$NH$_3$MX$_3$ perovskites (M= Ge, Sn, Pb; X=Cl, Br, I), which are widely studied in photovoltaic areas. Using first-principles approaches, different phases of hybrid perovskites have been studied, and we find considerably large second harmonic generation (SHG) in some of them. Interestingly, large non-diagonal SHG tensors appear in certain structures, which are fairly useful for real-world applications, such as tuning the directions of lasers. All calculations are implemented in our self-developed package aiming for large-scale parallel calculations of nonlinear optical properties.

Second Order Nonlinear Optical Study on The Polar Order in MAPbI$_3$

XIANGPENG LUO (Presenter), WENCAN JIN, Department of Physics, University of Michigan, SUNEEL JOGLEKAR, LINGJIE JAY GUO, Department of Electrical Engineering and Computer Science, University of Michigan, LIUYAN ZHAO, Department of Physics, University of Michigan — Hybrid organic-inorganic methylammonium (MA) lead-halide perovskite MAPbI$_3$ has shown record-breaking photovoltaic conversion efficiency and demonstrated great potential in solar cell applications. Its unusual long carrier lifetime has drawn much research interest, yet its origin remains a debated subject. Whether or not the tetragonal phase of this material is polar is key to resolve the ongoing debates. In this talk, we present clarifying evidence to show the absence of spatial inversion symmetry in single-crystalline MAPbI$_3$ bulk over a wide temperature range starting from 300 K down to 80K, using rotational anisotropy (RA) second harmonic generation (SHG) spectroscopy. We will further discuss the tetragonal to orthorhombic structural phase transition, by analyzing the temperature-dependence of SHG susceptibility tensors. Finally, we will discuss how this non-centrosymmetric phase response to ultrafast optical excitations, from the time-resolved RA SHG measurement results.

Ultrafast Amplified Spontaneous Emission Dynamics in Hybrid Perovskites

KENAN GUNDOGDU (Presenter), North Carolina State University — Methylammonium lead iodide (MAPI) has received significant interest due to high performance of this material in photovoltaic applications. MAPI is also now known to be an efficient light emitter, due in part to its high mobility and long carrier diffusion lengths, which make it a good solar cell. Specifically at reduced temperatures, the light emission process is quite interesting. Specifically at low temperatures due to coexistence of multiple crystal phases, energy and charge transfer dynamics play a significant role in light emission process. At room temperature the crystal structure is tetragonal, whereas at low temperatures material goes through a phase change to orthorhombic crystal structure. However even below the phase transition temperatures, the thin films exhibit tetragonal domain inclusions. Since the tetragonal phase has lower bandgap, most excitations diffuse to these low energy sites and recombine. In this work we studied exciton and charge relaxation dynamics that lead to amplified spontaneous emission (ASE) in MAPI. Our results indicate that reveal the duration of the ASE process and the dynamics that limits ASE in MAPI thin films.

3:18PM V20.00005: Waterproof perovskite-hexagonal boron nitride hybrid nanolasers with low lasing thresholds and high operating temperature  HAORAN YU (Presenter), YU YE, LUN DAI, School of physics, Peking University — Solid-state perovskites have recently emerged as promising coherent light sources. Realization of an electrical perovskite-based laser diode still remains challenging due to the heat management and intrinsic instability of the perovskites. Here, we demonstrate waterproof perovskite-hexagonal boron nitride (hBN) hybrid nanolasers with low lasing thresholds and high operating temperature. After capping with the hBN flake which possesses superb and anisotropic thermal conductivity, heat dissipation of the hybrid nanolaser is accelerated, resulting in the significant reduction of lasing thresholds, and clear lasing behavior under a temperature as high as 75.6 °C. Moreover, hBN with high environmental stability can effectively protect the perovskite from the polar solvents. The hBN encapsulated CsPbI₃ nanolasers can incessantly lase in water for an hour, and the lasing behavior can be retained even after 24-hour immersion in water. The reduction of lasing threshold, improved heat removal, and higher temperature tolerance of the hybrid nanolaser marks a major step towards CW-pumped perovskite laser at room temperature, while also allowing perovskites to be integrated into high power density optoelectronic devices and future electrically driven lasers.

3:30PM V20.00006: Shifting the Thermodynamics of Polymorph Transitions in Metal-Halide Perovskites  XIAOQING KONG, Chemical Engineering and Materials Science, Stevens Institute of Technology, KAMRAN SHAYAN, STEFAN STRAUF, Physics, Stevens Institute of Technology, STEPHANIE LEE (Presenter), Chemical Engineering and Materials Science, Stevens Institute of Technology — We demonstrate nanoconfinement as a strategy to stabilize high-temperature cubic phases of metal-halide perovskites and prevent humidity-induced degradation. A combination of temperature-dependent x-ray diffraction and photoluminescence experiments were employed to track polymorph transitions in the range of 4 – 373 K. For methylammonium lead triiodide (MAPbI₃) confined within the nanopores of anodized aluminum oxide templates, the tetragonal-to-cubic phase transition shifted from T = 300 K to T = 170 K. These crystals were stable for a period of at least two years of storage in air, compared to unconfined crystals that degrade into perovskite precursors within two weeks of air exposure. For nanoconfined cesium lead triiodide (CsPbI₃), the tetragonal-to-cubic phase transition, which typically occurs at 583 K, was absent to temperatures as low as 4 K. We hypothesize that nanoconfinement introduces lattice strain into the crystals, shifting the relative free energies of the respective polymorphs and increasing energy barrier to polymorph transitions. In both systems, the cubic phase represents the smallest band gap polymorph, with important implications for solar cell device operation and efficiency.

3:42PM V20.00007: Anisotropic heat conduction in the metal-organic framework perovskites*  DHARMENDRA SHUKLA (Presenter), NARAYAN PRASAI, Physics, University of Miami, THOMAS M. CARLINO, MERCEDES M. A. MAZZA, AMY M. SCOTT, Chemistry, University of Miami, JOSHUA COHN, Physics, University of Miami — We report thermal conductivity (κ) measurements on single crystals of the metal-organic framework perovskite compounds [C(NH₂)₃]X(HCOO)₃ (X=Cu, Zn) in the temperature range 5K ≤ T ≤ 300K. The directionality of N-H---O bonds and their stretching due to the Jahn-Teller distortion in the Cu compound are identified as mechanisms underlying differences in κ(T) behavior for the two compounds and its anisotropy. For heat flow along a direction preferentially transverse to the N-H---O bonds, κ = 0.6 W/mK near 300 K, approaching the theoretical minimum value. A possible magnetic contribution to the heat flow in the Cu compound will also be discussed.

*This material is based upon work supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Material Sciences and Engineering, under grant No. DE-SC0008607, and by the Univ. Miami CAS Convergence grant.

3:54PM V20.00008: Halide perovskite thin films for thermoelectrics*  TIANJUN LIU (Presenter), OLIVER FENWICK, School of Engineering and Materials Science, Queen Mary, University of London — Halide perovskites have emerged as promising candidates for photovoltaics and light-emitting diodes. Recently, promising thermoelectric performance has been reported for single nanocrystals of a halide perovskite, but there is not yet a good understanding of how thermoelectric performance can be optimised in these materials, especially in thin films where a diverse range of structures and morphologies are accessible. In this presentation I will report a record thermoelectric figure of merit (ZT) for halide perovskites, using the example of CsSnI₃ thin films. This result is in part due to the ultralow thermal conductivity of our films (0.38 W/mK at room temperature), as well as high electrical conductivity enabled by self-doping of the films through controlled Sn oxidation. I will also discuss the potential role of mixed-halide films in developing these materials further. Finally I will demonstrate how thin film morphology and composition can be used to further reduce the thermal conductivity in vapour- and solution-deposited CH₃NH₃PbI₃.

4:06PM V20.00009: Origin of Pressure-Induced Phase Transition and Metallization in Hybrid Halide Perovskites
JUNG-HOON LEE (Presenter), JEFFREY B NEATON, University of California, Berkeley — Hybrid halide perovskites are promising optoelectronic materials due to their favorable electronic properties and low cost. Here we investigate the effects of high pressure on the structural and electronic properties of (MA)PbI3 (MA = CH3NH3+) using first-principles density functional theory (DFT) calculations. Our calculations predict that with increasing external pressure, the cubic high-pressure Im-3m phase becomes more energetically favorable for the MA cations than the orthorhombic low-pressure Fmmm phase, leading to a predicted phase transition at 0.22 GPa, in good agreement with the experiment (~0.3 GPa). With increasing pressure we also find severe octahedral tilting occurs at 6 GPa, introducing I 5p – I 5p* antibonding and Pb 6p – Pb 6p bonding character into the valence band maximum (VBM) and the conduction band minimum (CBM) states, respectively. This leads to a different trend in the VBM and CBM energies under compression compared to their behavior below 6 GPa. Our DFT calculations show that this trend eventually leads to metallization at significantly higher pressures.

4:18PM V20.00010: Pb-free halide double perovskites: Computational materials design and surface properties*
GEORGE VOLONAKIS (Presenter), FELICIANO GIUSTINO, Department of Materials, University of Oxford — Halide double perovskites have been investigated extensively as lead-free alternatives to lead halide perovskites. Since our theoretical predictions, four crystals have successfully been synthesized: Cs2BiAgCl6, Cs2BiAgBr6, Cs2SbAgCl6, and Cs2InAgCl6. These compounds exhibit low carrier effective masses, and Cs2BiAgBr6 has a band gap of 1.9 eV, well within the visible range. Hence, these are candidates for opto-electronic applications such as photovoltaics, sensors, and photo-catalysts. In this talk, we will briefly present the computational design principles that lead to the synthesis of these compounds. In addition, we will focus on the structural and electronic properties of the four synthesised compounds and their surfaces. We will show that based on first-principles calculations, double perovskites Cs2BiAgCl6 and Cs2BiAgBr6 might be promising compounds for photo-catalytic water splitting. For all compounds it is shown that their energy levels, hence their photocatalytic properties, strongly depend on the surface termination. Our computational findings expand the range of potential applications of Pb-free double perovskites.

*Graphene Flagship (Horizon 2020 Grant No. 785219-GrapheneCore2), Leverhulme Trust (Grant RL-2012-001), UK EPSRC (grant No. EP/M020517/1),

4:30PM V20.00011: Structural relationships and relative stability of different ABX3 phases of inorganic halide perovskites with B=Ge*
SANTOSH KUMAR RADHA (Presenter), WALTER RL LAMBRECHT, Case Western Reserve University — Pb-free halide perovskites have recently attracted interest. In Phys.Rev.Mat.2,063605(2018) we proposed the use of Si & Ge as B sites cation and found that these perovskites undergo an off-centering of the group-IV atom leading to a rhombohedrally distorted perovskite with band structure similar to those of the cubic ones. However, for some of these materials, like RbGeX3, a monoclinic structure has been found experimentally.

In this work, we show that the monoclinic structure and the rhombohedral ferroelectric structure are closely related. In fact, if one considers these structures as GeX3 tetrahedrons rather than corner sharing octahedrons, we find that the monoclinic and rhombohedral structure to have parallel and oppositely oriented tetrahedral units. Thus the monoclinic structure can be understood as an anti-ferroelectric arrangement of the GeX3 dipoles. They have a completely different band topology with a wide band gap compared to that of the cubic ones yet are energetically close to each other. We understand this energy difference using a spin-1/2 hamiltonian for dipole interactions, favouring the antiferroelectric alignment of the GeX3 dipoles, and additional Ge-X bonding due to parallel tetrahedron orientation causing the ferroelectric alignment.

*Supported by DOE-BES

4:42PM V20.00012: Effect of water on structural, optical and hot carrier cooling properties of MASnI3 perovskite
MOHAMED EL-AMINE MADJET (Presenter), ALI KACHMAR, GILIBJON BERDIYOROV, Qatar Environment and Energy Research Institute, Hamad Bin Khalifa University, Doha, Qatar — Understanding the stability, carrier transport and relaxation of Sn based perovskites CH3NH3SnI3 are of high interest to develop lead free perovskite solar cells. In this study, we performed first principles and non-adiabatic molecular dynamics simulations to address the electronic, optical, and hot carrier relaxation dynamics of the pristine CH3NH3SnI3 and its monohydrated phase CH3NH3SnI3.H2O. Our results show that the water molecule interacts strongly with the organic cation by forming hydrogen bonding, while having also an interaction with the iodide ions. Our study also indicates that the water molecule has in general a negative impact on the optical properties of perovskite materials. In fact, the water molecule reduces the absorption of the system mostly in the visible range of the solar spectrum, and it leads to a faster hot-carrier cooling and to an increase in the polarization of the material.
Investigation of charge dynamics and photoinduced charge transfer in metal halide perovskite/carbon nanotube composites by vibrational spectroscopy*

KATALIN KAMARAS (Presenter), LEILA BADEEB, MEHMET DERYA ÖZEREN, ARON PEKKER, Wigner Research Centre for Physics, SEHAM KAMAL ABDEL-AAL, AHMED SABRY ABDEL-RAHMAN, Physics Department, Cairo University, PAVAO ANDRICEVIC, LASZLO FORRO, ENDRE HORVATH, Laboratory of Physics of Complex Matter, Ecole Polytechnique Federale de Lausanne — Composites formed from metal halide perovskites and semiconducting carbon nanotubes show a fast photoinduced charge diffusion and a slow structural rearrangement due to ionic movement. To understand this latter, phonon-related mechanism, we performed a study of vibrational spectra on various perovskites and composites, changing the central ion of (Pb, Sn, Co and Cu) and the halide (I, Br and Cl). We measured the temperature dependence, followed the phase transitions, and investigated the photoinduced changes by both infrared and Raman spectroscopy. As the structural rearrangement is accompanied by Fermi level alignment and thus modifies the optical gap, our results are useful for fine-tuning the optical properties in solar cell applications of perovskites and perovskite/carbon nanostructure composites.

Control of Emission and Energy Transfer with Metamaterials, Plasmonic Structures and Cavities*

SAMANTHA KOUTSARES, Norfolk State University, SRUJANA PRAYAKARAO, University of Kansas, DEVON COURTWRIGHT, SANGEETA ROUT, Norfolk State University, MONIKA BIENER, ZHEN QI, Lawrence Livermore National Laboratory, CARL E BONNER, MIKHAIL NOGINOV (Presenter), Norfolk State University — Metamaterials, plasmonic structures and cavities have been shown to enable and control scores of spontaneous emission, stimulated emission, and energy transfer phenomena. The recent findings of our group in this research area will be discussed at the conference.

Acknowledgments: NSF HBCU-RISE grant # 1646789, NSF EiR grant # 1830886, AFOSR grant # FA9550-18-0417, DoD grant # W911NF1810472.

Mechanisms of GaN quantum dot formation during nitridation of Ga droplets*

HONGLING LU (Presenter), CALEB REESE, SUNYEOL JEON, Materials Science and Engineering, university of Michigan, YAMING FAN, EMILY RIZZI, YUQUN ZHUO, Tsinghua University, LIANG QI, RACHEL GOLDMAN, Materials Science and Engineering, university of Michigan — GaN-based quantum dots (QDs) have been proposed for a variety of optoelectronic devices. Typically, QD formation is driven by a Stranski-Krastanov growth mode transition. Alternatively, the nucleation and conversion of metal droplets to QDs via nitridation, known as droplet epitaxy (DE), has emerged as a promising approach to achieve strain-free QDs. To date, GaN DE has been described as a liquid-phase epitaxy-like and/or a surface-diffusion driven process. Here, we investigate the formation mechanisms for DE GaN QDs using a combined computational-experimental approach. Our first-principles calculations of activation barriers suggest that N is immobile while Ga has a relatively high surface diffusivity, independent of the starting surface structure and chemistry. We consider the temperature and substrate dependence of the size distributions of droplets and QDs, and report on two competing mechanisms mediated by Ga surface diffusion, Ga droplet coarsening with QD formation via impinging N atoms and Ga droplet out-diffusion with QD nucleation at absorbed N surface sites. We also discuss the relative roles of nucleation and coarsening dominant growth, as well as the phase selection, on various substrates.

**3:30PM V21.00004: Harnessing Evanescent Waves by Metasurfaces: An All-Optical Analogue of On-Chip Control of Smith-Purcell Emission**

LIN LI, Department of Mechanical and Industrial Engineering, Northeastern University, KAN YAO, Department of Electrical and Computer Engineering, Northeastern University, ZUOJIA WANG, School of Information Science and Engineering, Shandong University, YONGMIN LIU (Presenter), Department of Mechanical and Industrial Engineering, Northeastern University —

The exponentially decaying nature of evanescent waves renders it difficult to capture, extract and engineer the wealth of energy and information that they can carry. Utilizing the out-of-plane electric dipoles and in-plane magnetic dipoles produced by a C-aperture metasurface, in this work we show that we can mold evanescent waves on demand. Specifically, we demonstrate an all-optical analogue of manipulating Smith-Purcell emission, in which the evanescent waves are produced by attenuated total reflection rather than moving electrons, and subsequently tailored by the designer metasurfaces. The phase, beam profile and polarization state of the Smith-Purcell emission can be controlled via the orientation of C-aperture nanostructures. Our work opens a new avenue for metasurfaces to work in the critical near-field region to efficiently harness evanescent waves, and promises many potential applications, including on-chip free-electron light sources, tabletop particle detectors and near-field energy harvesting.

**3:42PM V21.00005: Radiative spontaneous decay enhancement near an ultrathin plasmonic film**

HAMEZ MOUSAVI (Presenter), IGOR BONDAREV, Math and Physics, North Carolina Central University, USA — We develop a quantum electrodynamics theory for the spontaneous decay process of a point dipole emitter near a thin metallic film. It was previously shown that the strong vertical electron confinement causes the film plasma frequency to become spatially dispersive[1], resulting in a (confinement induced) nonlocal dielectric response of the film[2]. Using this fact we calculate the electromagnetic Green's function and the emitter-to-surface distance dependence for the dipole spontaneous decay rate near the metallic film of finite thickness. We show that the confinement induced dielectric response nonlocality of the ultrathin films can result in a two-order-of-magnitude radiative decay rate enhancement relative to vacuum. The effect can be qualitatively understood in terms of the interacting image dipoles and can be controlled by varying the material composition, the thickness and the surroundings of the film. The inelastic electron scattering diminishes the effect. These are the universal peculiarities of the light-matter interactions in close proximity to ultrathin plasmonic nanostructures. --

4:06PM V21.00007: Yagi-Uda nanolithographic antennas on a Si photodiode for infrared detection*  WILLIAM RIEGER (Presenter), JEAN HEREMANS, Physics, Virginia Tech, HANG RUAN, YUHONG KANG, RICHARD CLAUS, NanoSonic Inc., TIGRAN ASRYAN, Physics, Virginia Tech — Nanoscale Yagi-Uda antennas were fabricated on a metal-semiconductor-metal rectifying photodetector to enhance detector efficiency. A new approach for characterizing the nanolithographic optical antennas was based on a direct electrical measurement obviating the need for an ITO coating or back contact. The measurements demonstrate control of directivity and wavelength selectivity in an array of 400 nanoantennas. With incident light nearly aligned to the center lobe of the Yagi-Udas, resonances in measured photocurrent were observed at 1110 nm and 1690 nm. These correspond to scaled effective wavelengths of 388 nm and 776 nm, respectively, in agreement with plasmonic theory. Estimated quantum efficiencies are 5.1% and 3.1% at 1110 nm and 1690 nm, respectively, representing a fourfold increase over a device lacking the antenna array. The spatial dependence of the contribution of individual antennas in the array has been investigated to determine the process whereby resonant plasmons contribute to the photocurrent. Associated finite element modeling results will be discussed, aimed at predicting resonances in plasmonic structures with similar geometries.

*U.S. Navy N68335-13-C-0184, NASA NNX17CC63P

4:18PM V21.00008: Theoretical Investigation of Plasmonic Properties of Quantum-Sized Silver Nanoparticles  MASOUD SHABANINEZHAD NAVROOD (Presenter), Physics, Western Michigan University, RAMAKRISHNA GUDA, Chemistry, Western Michigan University — Metallic nanoparticles (NPs) can strongly absorb the incident light and produce enhanced localized electric field when the frequency of the incident light is in phase with coherent oscillation of conduction electrons in them. This characteristic feature of metallic NPs can be tuned by changing parameters such as size, shape, polarization direction of incident light and refractive index of medium. Although plasmonic properties of larger size nanoparticles are extensively investigated, little has been done on smaller sized particles in the size range of 3 to 10 nm. By reducing the size, band structure of the metallic particles discretizes, leading channeling plasmon properties of the NPs from classical to quantum regime. In this work, plasmonic properties of the spherical silver (Ag) NPs in the size range of 3 to 20 nm has been investigated using both quantum and classical model. We performed theoretical calculations using normal Mie theory, and studied size and surrounding medium effects on the absorption efficiency, LSPR energy peak shift and field enhancement of the samples. The results indicate that the quantum model is able to predict blue shift of LSPR peak with decreasing size of the samples from 10 to 3 nm while the classical model fails to observe this effect.

4:30PM V21.00009: Networks of helical, braided quantum wells  ALEXANDRA COURTIS (Presenter), University of California, Berkeley — Architectures with complex and reconfigurable topologies present in a series of naturally occurring systems that have precise nanoscale organization and that execute efficient, rapid, and scalable information transfer. Artificial nanosystems explicitly engineered to probe and mimic these networks hold promise for fundamental studies on energy transfer alongside for the design of new architectures to store and convert information. Here, topological networks comprised of atomically precise, colloidal quantum wells are presented. The experiment highlights structural properties and establishes design strategies for preparing controlled hierarchies of low-dimensional, quantum confined materials distinguished by a high degree of organizational complexity. The discussion addresses the findings in the context of understanding and controlling some properties of atomically precise nanosystems in the limit of jammed, frustrated environments.

4:42PM V21.00010: Metasurfaces to control the quantum dynamics of color centers in hexagonal boron nitride  PANKAJ JHA (Presenter), GHZALEH KAFAEI SHIRMANESH, HAMIDREZA AKBARI, ARUN NAGPAL, BENJAMIN VEST, CORA WENT, WEI-HSIANG LIN, RUZAN SOKHOYAN, HARRY ATWATER, California Institute of Technology — Photonic metasurfaces have revolutionized optical designs by enabling the realization of virtually flat optics via the replacement of bulky optical components with ultrathin planar elements, which possess ease-of-fabrication advantages. However, majority of the application-oriented research in this field has been limited to classical regime and it remains an open question if these metasurfaces can be used for single-photon applications. Here, we perform theoretical and experimental studies to quantify the role of metasurface induced tailored environment to control the quantum dynamics of color centers in hexagonal boron nitride. These color centers in semiconductors have garnered great interest because they can serve as single-photon sources, which are the building blocks for photonic quantum technologies. We investigate the fundamental properties of color centers in hexagonal boron nitride, such as saturation count, life-time etc. and investigate how these characteristics can be manipulated with metasurfaces.
**4:54 PM V21.00011: Effects of Nanostructured Plasmonic Environment on Electrochromic Polymer Switching**

MOHAMMAD SHAHABUDDIN (Presenter), CARL E BONNER, NATALIA NOGINOVA, Center for Materials Research, Norfolk State University — Strong modification of local environment associated with plasmonic nanostructures provides possibilities to control various processes, including charge transfer processes and chemical reactions. In this work, we explore the opportunities to enhance electrochromic polymer performance using plasmonic metasurfaces, and study the origin of this enhancement. Electrochromic polyaniline (PANI) films deposited onto gold metasurfaces demonstrate non-monotonous coloration behavior at low voltages, step-like color-change and much faster saturation in color with the increase in voltage in comparison with polyaniline films deposited on flat gold. The additional small voltage peak in the cyclic voltammogram in nanomesh/PANI cell and the asymmetric and nonlinear I-V characteristics of the sandwich nanomesh/PANI/flat gold structure indicate a possible formation of Schottky-like interface between polyaniline and nanostructured gold, whereas the Ohmic contact is observed for the flat gold-PANI system. The results are discussed in terms of the modified work-function of nanostructured gold, interface charging and threshold-like charge transport. Possibility to engineer optical and charge transport properties of electrochromic materials via nanostructured interfaces can bring niche applications.

**5:06 PM V21.00012: FRET Enhancement using Surface Plasmon Modes on Gold Nanogratings**

JENNIFER STEELE (Presenter), CHAE RAMNARACE, Physics and Astronomy, Trinity University, WILLIAM R FARNER, Astrophysics, Drexel University — The plasmonic properties of structured metal surfaces can be engineered to enhance the output of nearby quantum emitters through the manipulation of the local density of optical states (LDOS). Although metal enhanced fluorescence (MEF) has been well understood for decades, the influence of plasmonic modes in Förster resonance energy transfer (FRET) is still a debated issue. Gold nanogratings provide a unique plasmonic substrate to study the effects of altering the LDOS on FRET efficiencies. Gratings support narrow plasmon resonances at a range of wavelengths, allowing for the comparison of FRET efficiencies by increasing the LDOS at donor and acceptor emission wavelengths on a single substrate. In this work, the increase in efficiency was found to be greatest when the surface plasmon modes overlapped the acceptor emission spectrum. Furthering the understanding of the application of MEF to FRET will aid developing methods for the enhancement of FRET, expanding its use in biological systems, photosynthesis, and photovoltaic devices.

**2:30PM V22.00001: Materials selection rules for optimum power factor in 2-dimensional thermoelectrics**

ADITHYA KOMMINI (Presenter), ZLATAN AKSAMIJA, Electrical and Computer Engineering, University of Massachusetts, Amherst — Thermoelectrics (TE) can improve the efficiency of power sources to meet ever-growing energy demand by converting waste heat into electricity. With the advent of new 2D materials and the knowledge of their material properties, the ability of these materials for future TE use need to be studied. Studies have predicted the stability of around 2000 van der Waals materials that can be exfoliated into 2D atomic films. Here, the distinct features of 2D materials like effective mass, density of states, and electron-phonon scattering deformation potentials are used to formulate simple material selection rules that can optimize TE power factor. These parameters are widely available in material databases or computationally inexpensive to calculate. Our simulations show that when inelastic scattering with optical phonons is dominant in a material, the TE power factor is highest with phonon energy of 5 kT. Further enhancement is possible with larger height in the step-like 2D density of states, lower effective mass, and higher degeneracy for the conduction band valley that participate in the transport. Employing these material selection rules help in identifying future thermoelectric materials that can have applications in thermal harvesting, thermal sensors, and electronic cooling.
2:42PM V22.00002: Theory of generation and conversion of phonon angular momentum*  MASATO HAMADA
(Presenter), SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology — Mechanical rotations in solids can be converted to magnetization and spin current via the spin-rotation coupling. Recently, in general solids, the phonon angular momentum has been formulated as the microscopic local rotation in the lattice. However, it usually cancels between phonon modes. In this talk, we propose the two ways of generation of phonon angular momentum in non-magnetic and magnetic insulators. In nonmagnetic insulators without inversion symmetry, a heat current induces the phonon angular momentum, in analogy with the Edelstein effect [1]. In magnetic insulators preserving the product of the inversion and time-reversal symmetries, the electric field can induce the phonon angular momentum, in analogy with the magnetoelectric effect. We also discuss microscopic mechanisms how the microscopic local rotations of atoms, i.e. the phonon angular momentum, is converted into electronic spins.

2:54PM V22.00003: Impact of Quartic Anharmonicity on Lattice Thermal Transport in SnSe  YI XIA (Presenter),
CHRISTOPHER WOLVERTON, Materials Science and Engineering, Northwestern University — Layered SnSe has demonstrated exceptional thermoelectric properties with record high energy conversion efficiency, majorly owning to the ultralow lattice thermal conductivity. However, a fundamental understanding of the lattice dynamics and thermal transport properties is still lacking, particularly for the high temperature phase. The theoretical challenge originates from the second-order phase transition from low-temperature Pnma to high-temperature Cmcm phases between 700-800~K, wherein the Cmcm-SnSe displays lattice instability and imaginary phonon frequencies. To overcome this limitation, we go beyond harmonic approximation by further incorporating anharmonic phonon renormalization due to quartic anharmonicity. Moreover, both three- and four-phonon scatterings are accounted for in solving Phonon Boltzmann transport equation. We apply this strategy to perform a comparative study of lattice dynamics and thermal transport properties of SnSe at 300~K (Pnma) and 800~K (Cmcm). We reveal in detail the impacts of quartic anharmonicity on lattice stability, phonon quasiparticle energies and lattice thermal conductivities of both Pnma- and Cmcm-SnSe. Our theoretical calculations are in good agreement with experimental measurements performed on SnSe single crystals.

3:06PM V22.00004: Optoacoustic spectrum of GaP: experiment and theory  ANDREY BAYDIN (Presenter), RUSTAM GATAMOV, HALINA KRZYZANOWSKA, Vanderbilt University, CHRISTOPHER J STANTON, University of Florida, NORMAN H TOLK, Vanderbilt University — GaP is an important indirect band gap material with variety of applications in optics ranging from LEDs to possible applications in GaP/Si based solar cells. We investigated the spectral dependence of the opto-acoustic response of GaP using time-domain Brillouin scattering. We found that the amplitude of the Brillouin oscillations varies significantly near the direct transition at Γ point. The developed theoretical model quantitatively explains the experimental data and shows that one can use coherent phonon spectroscopy to provide detailed information about electronic structure and optical transitions in indirect band gap materials. The results for GaP are also compared to GaAs and Si.

3:18PM V22.00005: Electronic properties of IV-VI semiconductors obtained with G0W0 including off-diagonal corrections*  PABLO AGUADO-PUENTE (Presenter), PIOTR CHUDZINSKI, TCHAVDAR TODOROV, JORGE KOHANOFF, School of Maths and Physics, Queen's University Belfast, STEPHEN B FAHY, Department of Physics, University College Cork, MYRTA GRÜNING, School of Maths and Physics, Queen's University Belfast — The computation of electronic properties of IV-VI semiconductors constitutes a challenge for traditional density functional theory (DFT) methods. The underestimation of the bang gap by DFT can lead, in these materials, to a spurious band gap inversion that hinders the characterization of their electronic properties, and therefore the modeling of their thermoelectric performance. In addition, the G0W0 approach often used to correct the DFT band structure also fails because of its perturbative nature, making necessary to improve the starting wavefunctions (e.g. using hybrid DFT) or to use more sophisticated approaches such as quasiparticle self-consistent GW. Here instead we use traditional DFT+G0W0 with corrections from the relevant off-diagonal elements of the self-energy in order to obtain the band structure of some of these materials, e.g. PbTe. This method, which does not require adjustable parameters, is utilized to extract from first principles band structure characteristics necessary for the calculation of transport coefficients. Band gaps, effective masses and deformation potentials are obtained in good agreement and at a fraction of the computational cost of more sophisticated methods.

*Funding from SFI-DfE NI, grant 15/IA/3160. Computational resources provided by ARCHER.
3:30PM V22.00006: Temperature dependent electronic transport in concentrated solid solutions of the 3d-transition metals Ni, Fe, Co and Cr from first principles.* GERMAN SAMOLOYUK (Presenter), SAI MU, ANDREW MAY, Oak Ridge National Laboratory, SEBSTIAN WIMMER, SERGIY MANKOVSKY, HUBERT EBERT, Department Chemie/Physikalische Chemie, Ludwig-Maximilians-Universitat Munchen, BRIAN CRAIG SALES, GEORGE MALCOLM STOCKS, Oak Ridge National Laboratory — An approach to the calculation of transport coefficients is applied to the calculation of transport properties of fcc alloys of Ni, Fe, Co, Cr. The coherent potential approximation used to treat chemical disorder, temperature induced magnetic moment fluctuations and lattice vibrations via the alloy analogy. For the nonmagnetic alloys, Ni20Cr, and NiCoCr the combined effects of chemical disorder and lattice vibrations result in a monotonic increase in the resistivity as a function of temperature from an already large residual resistivity. For magnetic NiCo, NiFe, NiFeCo, additional electron scattering from magnetic fluctuations results in a rapid increase of the resistivity with temperature. The electronic part of the thermal conductivity in Ni20Cr, and NiCoCr, monotonically increases with temperature. In the magnetic alloys, electron scattering from magnetic fluctuations leads to an initial rapid decrease in thermal conductivity until this is overcome by an increasing number of carriers.

*This work was supported as part of the Energy Dissipation to Defect Evolution, an EFRC funded by the US DOE, Office of Science, BES under Contract DE-AC05-00OR22725; Office of Science, BES, Materials Sciences and Engineering Division; Deutsche Forschungsgemeinschaft Priority Program SPP 1538.

3:42PM V22.00007: Bonding Hierarchy Induced High Thermoelectric Performance in Layered Zintl Compound BaAu2P4 KOUISKHI PAL (Presenter), JIANGANG HE, CHRISTOPHER WOLVERTON, Northwestern University — The search for new thermoelectric materials has gained rapid progress in recent years as thermoelectric technology offers the potential for environmentally friendly and sustainable energy conversion methods from waste heat to electricity. Using first-principles calculations based on density functional theory we show that bonding hierarchy gives rise to high thermoelectric performance in BaAu2P4, a layered Zintl compound with a small band gap. BaAu2P4 exhibits crystallographic heterogeneity in which rigid [Au2P4]2− units are separated by layers of Ba2+ cations, which are bonded relatively weakly to the lattice through electrostatic interactions. While the covalently bonded chains of phosphorus atoms facilitate large electrical conductivity, the presence of multiple bands near the Fermi level gives rise to an enhanced Seebeck coefficient. On the other hand, the loosely bound Ba along with the heavy Au atoms strongly scatter the heat carrying acoustic phonons, inducing a very low lattice thermal conductivity along the stacking direction. As a consequence of this coexisting rigid and fluctuating sublattices, BaAu2P4 exhibits a large power factor and low lattice thermal conductivity, which results in a high thermoelectric figure of merit (zT).

3:54PM V22.00008: Emergent localized states in twofold PT-symmetric ladder lattice.* JUNG-WAN RYU (Presenter), SANG-JUN CHOI, SUNGJONG WOO, ARA GO, Institute for Basic Science, NOJOON MYOUNG, Chosun University, HEE CHUL PARK, Institute for Basic Science — We have investigated the localized states at the interface of intertwined PT-symmetric systems which are robust against external pumping and damping. The intertwinement induces an additional PT-symmetry and interface exceptional points (EP) emerge and play the role of new critical points of non-Hermitian phenomena with bulk exceptional point. There are two distinct regimes possessing solidly localized states even though balanced gain and loss is increased. We obtain analytic expressions for the localization length and exceptional points in terms of tight-binding formalism. This theory is demonstrated by numerical calculation of eigenenergies and wave functions on quasi 1D ladder lattice and 2D bi-layered square lattice.

*This work was supported by Project Code (IBS-R024-D1).

4:06PM V22.00009: Local thermal current from cold to hot in a classical harmonic system with multi-path geometry PALAK DUGAR (Presenter), CHIH-CHUN CHIEN, University of California, Merced — The second law of thermodynamics forbids an overall flow of heat from a cold object to a hot one. However, it does not rule out a local heat flow from cold to hot in a multi-path geometry. We show an atypical, local steady-state thermal current from cold to hot emerge in a classical harmonic system of Hookean springs and masses driven by two Langevin Reservoirs at different temperatures. The simulations were performed by the standard molecular dynamics, and physical quantities such as the thermal current were averaged over random realizations in the steady-state regime. Our results show that the atypical thermal current depends explicitly on the system-reservoir coupling, in addition to the spring constants and masses. Including non-linear on-site potentials which models the system-substrate coupling further tunes the regime where the atypical local thermal current can survive. Our theoretical framework is universal and applies to classical systems following Newtonian dynamics. If we consider possible realizations using nano-mechanical systems, the device with a tunable local thermal current may function as a thermal switch or memory element.
4:18PM V22.00010: Activated lone-pair electrons lead to low lattice thermal conductivity: a case study of boron arsenide

GUANGZHAO QIN (Presenter), MING HU, University of South Carolina — Due to the ability of firsthand solid-state conversion to electrical power from thermal energy, thermoelectrics have attracted a lot of attention for the valuable applications in reusing waste resources and thus may make crucial contributions to the crisis of environment and severe energy problems. Reducing the thermal conductivity is an efficient way to boost the thermoelectric performance. In this talk, I would like to introduce an effective way to realize low thermal conductivity by introducing lone-pair electrons or making the lone-pair electrons stereochemically active through bond nanodesigning. With proper bond nanodesigning, the intrinsic thermal conductivity of BAs is largely lowered, which thus would benefit its applications in thermoelectrics with further nanostructuring. Fundamental insight is gained for the underlying mechanism of the reduction of thermal conductivity. Similar approach can also extended to other semiconductor systems, such as silicon and gallium nitride. The approach for realizing low thermal conductivity and the underlying mechanism uncovered in this talk would largely benefit the design of thermoelectric devices with improved performance, especially in future researches involving novel materials for energy applications.

4:30PM V22.00011: Anderson localization of surface plasmon polaritons in engineered disorder*

RUWEN PENG (Presenter), WEN-BO SHI, R. H. FAN, Nanjing University, XIAN-RONG HUANG, Argonne National Laboratory, MU WANG, Nanjing University — In this work, we experimentally demonstrate Anderson localization of surface plasmon polaritons (SPPs) at visible regime in metallic nanogratings with short-range correlated disorder. By increasing the degree of disorder, the confinement of SPPs is significantly enhanced, and the effective SPP propagation length dramatically shrinks. Strong localization of SPPs eventually emerges at visible regime, which is verified by the exponentially decayed fields and the vanishing autocorrelation function of the SPPs. Physically, the short-range correlated disorder induces strong interference among multiple scattered SPPs and provides an adequate fluctuation to effective permittivity, which leads to the localization effect. Our study demonstrates a unique opportunity for disorder engineering to manipulate light on nanoscale and may achieve various applications in random nanolasing, solar energy, and strong light-matter interactions.

4:42PM V22.00012: Bipolaron insulators and polaron liquids in high-temperature superconductors Ba$_{1-x}$K$_x$BiO$_3$

SHAOZHI LI (Presenter), Department of Physics and Astronomy, University of Michigan, STEVEN JOHNSTON, Department of Physics and Astronomy, Univ of Tennessee, Knoxville — The Su-Schrieffer-Heeger (SSH) type electron-phonon (e-ph) coupling, arising from the modulation of the atomic overlap integrals, has been proposed as a driving mechanism formation of an insulating state in the high-temperature superconducting bismuthates Ba$_{1-x}$K$_x$BiO$_3$. However, this e-ph interaction has not been well studied in dimensions greater than one due to a lack of suitable numerical techniques. In this talk, we present a determinant quantum Monte Carlo (DQMC) method for simulating the SSH-type e-ph interaction in a three-orbital model defined on a two-dimensional Lieb lattice. At half-filling, we observe a bipolaron insulating phase characterized by a long-range dimerized distortion, where the ligand oxygens collapse and expand about alternating Bi atoms creating a bond-disproportionated state. This state is robust against moderate hole doping but is eventually suppressed at large hole concentrations, leading to a metallic polaron-liquid-like state with fluctuating patches of local dimerized distortions. Our result suggests that the polarons are highly disordered in the metallic state and freeze into a periodic array across the metal-to-insulator transition. Moreover, our results have broad implications for many perovskite materials, where the bond phonons are essential.
4:54PM V22.00013: Lattice dynamics and superionic transition in ceria from first principles* SERGEI SIMAK
(Presenter), Linkoping University — We show how lattice dynamics in high-temperature ceria, CeO₂, can be studied beyond the quasiharmonic approximation [1]. The results indicate that the previously proposed precursor for the transition to the superionic phase is an artifact of the failure of the quasiharmonic approximation. We further directly observe the superionic transition at high temperatures [2] in our ab initio molecular dynamics simulations and find that it is initiated by the formation of oxygen Frenkel pairs. The Frenkel pairs are shown to form in a collective process involving simultaneous motion of two oxygen ions.

*The support from Swedish Research Council (VR) (Project No. 2014-4750) and the Swedish Government Strategic Research Area in Materials Science on Functional Materials at Linkoping University (Faculty Grant SFO-Mat-LiU No. 2009 00971) are acknowledged. The computations were performed on resources provided by the Swedish National Infrastructure for Computing (SNIC) at the PDC Centre for High Performance Computing (PDC-HPC), the National Supercomputer Center (NSC).

5:06PM V22.00014: Kinetic Theory of Rectified Motion in a Smarticle Gas* ZACHARY JACKSON (Presenter), WILLIAM C SAVOIE, SHENGKAI LI, KURT A WIESENFELD, DANIEL GOLDMAN, Georgia Institute of Technology — Smarticles are battery powered, self-deforming, three link robots that undergo a repeated prescribed gait. When a small number are confined inside an untethered ring the system undergoes undirected (isotropic) diffusion. Upon deactivation of one of the smarticles, the system displays directed diffusion, with speed and direction which depend on the mass of the confining ring. We present a collisional model that accurately predicts the directed motion.

5:18PM V22.00015: Phase Stability of Dynamically Disordered Solids from First Principles JOHAN KLARBRING (Presenter), SERGUEI I SIMAK, Linkoping University — The study of phase stability in solid materials containing dynamic disorder, eg. solids with rotating molecular units, or superionic conductors, is a challenging problem in theoretical materials science. This is mainly due to the failure of the standard picture of atoms vibrating around fixed equilibrium positions, which makes theoretical phonon schemes inapplicable. Superionic conductors are dynamically disordered solid materials with exceptionally high rates of ionic conductivity, which makes them very promising solid electrolytes for fuel cells and solid-state batteries.

Here, we present a method to study the phase stability of dynamically disordered materials [1]. The method is based on a stress-strain thermodynamic integration on a deformation path that connects the dynamically disordered phase to a stable variant. We apply the method to study the phase stability of superionic Bi₂O₃. The phase transformation from the low temperature ground state α-phase to the heavily disordered superionic δ-phase is well reproduced, with the critical temperature and the (very large) transition enthalpy closely matching the experimental values.

Session V23 GIMS: Low Temperature Instrumentation BCEC 158
2:30PM V23.00001: Compact Telescoping Sample Manipulator for Ultra-High Vacuum*  
ROBERT TURNER (Presenter), CHRISTIAN MATT, JENNIFER HOFFMAN, MOHAMMAD H HAMIDIAN, Department of Physics, Harvard University — Scanning tunneling microscopes (STMs) are used to resolve the morphology and electronic structure of a material surface with atomic resolution. Key factors to achieve state of the art STM measurements are stability (i.e. decoupling from external noise sources), low temperatures (<10K) and ultra-high vacuum (UHV) conditions, which usually require a long sample transfer mechanism. However, such a long manipulator is a pendulum that acts as an antenna for acoustic and vibrational noise in the lab and couples the noise into the STM. Here we show the design, construction, and performance of a compact telescoping manipulator attached to an STM system. Our compact manipulator reduces noise coupling both by decreasing the oscillation amplitude and by increasing the resonant frequency and shifting it away from typical ambient noise frequencies (typically 10s of Hz) and resonances of the vibration isolation systems (typically 1 - 3 Hz). In addition, our telescoping arm would be a useful tool for any UHV precision measurement system in a confined space.

*MHH was funded by the Gordon and Betty Moore Foundation's EPiQS Initiative through Grant GBMF4536. CEM is supported by the Swiss National Science Foundation under fellowship P2EZP2_175155

2:42PM V23.00002: Design and development of a low temperature, inductance based 3.5 MHz ac susceptometer.*  
SEAN GIBLIN (Presenter), EDWARD RIORDAN, School of Physics and Astronomy, Cardiff University, FREDRIK AHRENTORP, RISE, GEORGINA M KLEMENCIC, DANIEL MARGINEDA, School of Physics and Astronomy, Cardiff University, CHRISTIAN JONASSON, CHRISTER JOHANSSON, JAKOB BLOMGREN, RISE — We discuss the development of an induction based, low temperature high frequency ac susceptometer capable of measuring at frequencies up to 3.5 MHz and at temperatures between 2 K and 300 K, in applied magnetic dc fields of up to 9 T. Careful balancing of the detection coils and calibration have allowed a sample magnetic moment resolution of 5x10^{-10} Am^2 at 1 MHz. We will discuss the design and characterization of the susceptometer, and explain the calibration process and the applicability of the system to existing cryostat designs. We also include some example measurements on the spin ice materials, iron oxide based nanoparticles and superconductors to describe functionality to illustrate functionality.

*EPSRC, grant number EP/L019760/1.

2:54PM V23.00003: A Modular Design for Ultra-High Vacuum Millikelvin STM Systems*  
KEVIN P NUCKOLLS (Presenter), DILLON WONG, MYUNGCHUL OH, SANGJUN JEON, ALI YAZDANI, Princeton University — We describe the unique modular design of an ultra-high vacuum (UHV) STM system, capable of reaching dilution-refrigerator temperatures (10 mK) and equipped with a vector magnetic field. The goals of our design are to separate the UHV needs of STM instrumentation from the typical non-UHV construction of a dilution fridge system, and to make the STM head module interchangeable. To accomplish this, a custom-built dilution refrigerator surrounds a cooled UHV tube chamber, which houses our STM, with specially designed electrical connections at low temperatures to connect to an interchangeable STM head module. For diagnostic purposes, the microscope can also be used at room temperature in the UHV preparation chambers that are integrated with the low-temperature UHV tube system. The microscope exchange can be done at any time without compromising cryogenics or vacuum. The system works with a 240L liquid He cryostat, with a vector magnet (9T-1T-1T), that has a 10-day hold time. Our current microscope head design features multiple contacts to perform STM on gated structures and simultaneous low-temperature transport measurements on devices. Microscope designs, instrument construction, and preliminary data will be discussed.

*We acknowledge funding from the Moore Foundation for this project.
3:06PM V23.00004: Scanning probe microscopy at ultra-high magnetic fields* LISA ROSSI, High Field Magnet Laboratory (HFML-EMFL), Radboud University, JAN W. GERRITSEN, Institute for Molecules and Materials, Radboud University, LIJNIS NELEMANS, ALEXANDER A. KHAJETTOORIANS, BENJAMIN BRYANT (Presenter), High Field Magnet Laboratory (HFML-EMFL), Radboud University — Up to now, low temperature scanning probe microscopy (SPM) has been limited to a magnetic field strength of around 20 T, as most designs have been based on superconductor magnets. For some experimental applications – for example fractal spectra in graphene superlattices, the room temperature quantum Hall effect and some metamagnetic transitions – higher fields are required. Static fields of more than 30 T can be generated in dedicated high-field facilities by water-cooled, resistive Bitter magnets or hybrid resistive-superconducting magnets. However, implementing SPM in a Bitter magnet is a major challenge, due to the high level of vibrational noise produced by the turbulent cooling water, in addition to the space constraints resulting from the small magnet bore.

We present a novel cryogenic scanning tunnelling microscope (STM) designed to operate inside a 38 T water-cooled Bitter magnet. The performance of the STM is demonstrated through Landau level tunnelling spectroscopy of graphite, at 4.2 K in magnetic fields up to 34 T. Additionally we show the design of a highly compact atomic force microscope (AFM) for operation at cryogenic temperatures in an extremely high magnetic field. We show preliminary imaging data on the frustrated spinel CdCr2O4 at up to 30 T.

*HFML-RU/FOM

3:18PM V23.00005: Achieving µeV resolution in scanning tunneling spectroscopy at mK temperatures in Al-Al SIS junctions JOHANNES SCHWENK (Presenter), SUNGMIN KIM, National Institute of Standards and Technology, JULIAN BERWANGER, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, WILLIAM G CULLEN, STEVEN R BLANKENSHIP, National Institute of Standards and Technology, YOUNG KUK, Center for Quantum Nanoscience, Ewha Womans University, Seoul, Korea, FRANZ J GIESSIBL, Institut für Experimentelle und Angewandte Physik, Universität Regensburg, JOSEPH A STROSCIO, National Institute of Standards and Technology — Improved energy resolution in spectroscopic measurements is one of the main motivations for conducting Scanning Probe Microscopy (SPM) experiments at temperatures of tens of mK using a dilution refrigerator (DR). However, SPM instruments at these temperatures have not always achieved an energy resolution consistent with the DR temperature due to electrical noise coupling into the tunnel junction. Here, we present Scanning tunneling spectroscopy measurements of an Al-Al Josephson junction using an Al thin film grown in situ, together with an Al probe tip. The improved performance is achieved by optimizing our SPM operating in ultra-high vacuum (UHV) inside a DR with a base temperature of 10mK and magnetic field up to 15T [1]. Home built Radio Frequency (RF) powder filters located at the mixing chamber shield the tunnel junction from room temperature RF noise. Further RF filtering at the UHV chamber room temperature feedthroughs, together with attention to grounding, lead to an order of magnitude improved resolution over previous measurements. We demonstrate an energy resolution in the low ueV range and discuss the trials and tribulations to achieve this resolution and the causes of the residual intrinsic energy broadening that is observed.

3:30PM V23.00006: Josephson-junction-based bolometer* ROOPE KOKKONIEMI (Presenter), JOONAS GOVENIUS, VISA I VESTERINEN, QCD Labs, Aalto University, RUSSELL LAKE, Boulder, NIST, ANDRAS GUNYHO, KUAN YEN TAN, QCD Labs, Aalto University, SLAWOMIR SIMBIEROWICZ, LEIF GRÖNBERG, JANNE LEHTINEN, MIKA PRUNNILA, JUHA HASSEL, OLLI SAIRA, QTF Centre of Excellence, VTT Technical Research Centre of Finland, IIRO SALLINEN, DIBYENDU HAZRA, QCD Labs, Aalto University, ANTTI LAITINEN, PERTTI JUHANI HAKONEN, NANO, Aalto University, MIKKO MÖTTÖNEN, QCD Labs, Aalto University — We recently introduced a calorimeter capable of detecting packets containing 200 8.4-GHz photons, or 1.1 zJ of energy. Now we report a record low noise equivalent power (NEP) of 50 zW/rtHz, which is reduced to 20 zW/rtHz by introducing a Josephson parametric amplifier to the readout circuitry. The lower NEP value suggests energy resolution of $h \times 480$ GHz. Sensitivity of the detector can be further increased by decreasing the heat capacity of the absorbing element. To this end, we have experimentally studied graphene as an absorber, which is promising material due to its two-dimensional structure. Our preliminary results suggest energy resolution of $h \times 60$ GHz, bringin resolution of thermal detectors close to the qubit-based detectors while maintaining superior detection bandwidth.

3:42PM V23.00007: Temperature sensing via photoluminescence lifetimes of Rhodamine B*  JOHN COLTON, Brigham Young University, KATE WATSON (Presenter), Arkansas State University — Non-invasive temperature probes have use in many settings where conventional thermometers may not be suitable or as efficient. An optical temperature probe is a material whose optical properties, such as photoluminescence (PL) or PL lifetime, are known as a function of temperature. We present results of PL lifetime studies of the organic dye Rhodamine B, which is a good candidate for use in temperature probes due to its large PL emission. We have measured PL lifetimes using time correlated single photon counting (TCSPC). The lifetimes were measured from temperatures of 15 K to 330 K. The lifetimes appear to be non-monotonic: they increase with temperature to a point, then decrease again. It is uncertain what is causing this unexpected trend, and we are in the process of verifying these lifetime measurements as well as studying other possible luminescent materials such as semiconductor quantum dots for application as temperature probes.

*Research was performed at BYU as part of the NSF REU program, grant no. 1757998.

3:54PM V23.00008: Single cell temperature measurement with a thin-film thermocouple array  FAN YANG (Presenter), SHENG-YONG XU, Key Laboratory for the Physics & Chemistry of Nanodevices, and Department of Electronics, Peking University — Single cell temperature measurement is an important fundamental issue. A full picture of the temperature distribution and thermal response of a single cell under different conditions is very helpful for answering fundamental biology questions in cell thermogenesis and thermal regulation. However, a reliable method for precise cellular temperature measurement remains a technical challenge.

In this work, we developed high-performance Pd/Cr micron thin-film thermocouple (TFTC) arrays and double-stabilized system with a stability of ±5 mK for single cell temperature measurement. We have obtained frequent temperature increments of 10-60 mK and a maximum up to 200-300 mK for cultured HepG2 cells1. Recently, we have reduced the stripe width of TFTC down to 170 nm, and fabricated 10×10 TFTC arrays on 100×100 µm² Si₃N₄ suspended platforms. We aim to realize the real-time 2D mapping of local temperature distribution for a single live cell with our nano-sized TFTC arrays and double-stabilized measurement system. The measurement results may shed some light on further investigation in determining the absolute temperature distribution of individual cultured live cells, both outside and inside of the cells, in a more precise way.

4:06PM V23.00009: Development of a New Dark Matter Detector that Uses Liquid He and Field Ionization*  DAVID OSTERMAN (Presenter), HUMPHREY J MARIS, GEORGE M SEIDEL, DEREK STEIN, Physics, Brown University — We discuss a new method of dark matter detection[1] that involves He atoms evaporated from a cold surface and their detection using field ionization. When a dark matter particle collides with a liquid He atom it produces phonons and rotons. When these excitations make it to the surface of the liquid He they evaporate a He atom, which can then be detected by ionization in a strong electric field. The >1 meV binding energy of a He atom to the surface opens the door for the detection of dark matter particles with a mass as low as 1 MeV/c². We will discuss the design of the proposed detector as well as the results of preliminary experiments on field ionization. We will also discuss the future of such experiments

Session V24 DAMOP: General Atomic, Molecular, and Optical Physics II: Photonics and New Platforms for Topological States  BCEC 159 - Stojan Rebic, American Physical Society APS
Aharonov-Bohm cages in photonic lattices  
SEBABRATA MUKHERJEE, Heriot-Watt University, MARCO FEDELE DI LIBERTO (Presenter), Université Libre de Bruxelles, PATRIK ÖHBERG, ROBERT R. THOMSON, Heriot-Watt University, NATHAN GOLDMAN, Université Libre de Bruxelles — We report on the experimental realization of a uniform synthetic magnetic flux and the observation of Aharonov-Bohm cages in a rhombic photonic lattice of optical waveguides. In the regime where half a flux quantum is realized in each plaquette, all the energy bands collapse into nondispersive (flat) bands. The resulting localized eigenstates are then probed by studying the propagation of light in the bulk and at the edge of the photonic lattice. Our photonic lattice constitutes an appealing platform where the interplay between engineered gauge fields, frustration, localization, and topological properties can be finely studied. We further theoretically explore the localization properties of this system in the presence of interparticle mean-field interactions, which appear in photonic lattices as optical nonlinearities when increasing the light beam power. Surprisingly, we find that there still exist caged solutions and their nonlinear dynamics is accompanied with a breathing motion of the particle density reminiscent of a bosonic Josephson junction. Our results open an interesting route towards the characterization of nonlinear dynamics in flat band systems.

Role of long-range interactions in one-dimensional non-Hermitian topological photonic systems*  
BOXIANG WANG (Presenter), CHANGYING ZHAO, Shanghai Jiao Tong University — We study topological phonon polaritons (TPhPs) in one-dimensional dimerized silicon carbide nanoparticle chains. While the topological property of longitudinal modes is like the conventional Hermitian Su-Schrieffer-Heeger (SSH) model, for transverse modes, we find a topological phase transition at a substantially large lattice constant, due to the presence of long-range non-Hermitian interactions in an infinitely long chain. On the other hand, in the finite chain, due to these interactions, the edge and bulk modes become hybridized. In this situation, the non-Hermitian skin effect, i.e., the emergence of localized bulk modes over the edges, leads to the breakdown of bulk-boundary correspondence. By considering this effect and subsequently proposing a modified complex Zak phase for a finite chain, the topological behavior of the conventional SSH model is still recovered. Our study provides profound implications to the fields of non-Hermitian topological physics and quantum mechanical models with long-range interactions.

Optical Information Processing with Entangled Topological States*  
DAVID SIMON (Presenter), Physics and Astronomy, Stonehill College, SHUTO OSAWA, ALEXANDER SERGIENKO, Boston University — Topological quantities such as winding number or Chern number have become important tools for solid state physics, and more recently for photonic systems. These topological numbers are highly stable against external perturbations, which makes them attractive for encoding qubits in a robust manner. But they are difficult to determine by local measurements, especially in photonic systems, where the relevant information is often carried by a single photon that is destroyed in the measurement. Here, we use linear optical multiports as a means of constructing systems in which winding number and polarization are jointly entangled. This leads to a reduction in bit flip errors, due to the topological stability of the winding number, while the linkage to polarization simplifies the process of measuring the topological variable. This opens a new range of possible quantum information processing applications. We examine topologically-entangled bulk and boundary states, and outline several applications, such as the construction of topologically-protected photonic memory registers and of entangled memory registers.

3:06PM V24.00004: Near-field levitated optomechanics with a photonic crystal cavity* SUNKUN HONG, LORENZO MAGRINI (Presenter), Faculty of Physics, University of Vienna, RICHARD NORTE, Kavli Institute of Nanoscience, Delft University of Technology, RALF RIEDINGER, Faculty of Physics, University of Vienna, IGOR MARINKOVIĆ, Kavli Institute of Nanoscience, Delft University of Technology, DAVID GRASS, UROS DELIC, Faculty of Physics, University of Vienna, SIMON GROEBLACHER, Kavli Institute of Nanoscience, Delft University of Technology, MARKUS ASPELMEYER, Faculty of Physics, University of Vienna — Optically levitated dielectric particles has recently emerged as a new system in quantum optomechanics. It offers excellent mechanical coherence under high vacuum and a possibility to optically configure potential landscapes. An outstanding problem is the lack of methods to manipulate the particle at the quantum level. Here we introduce a nanophotonic interface that addresses this challenge. By optically trapping a 150 nm silica particle and placing it in the near field of a nanofabricated photonic cavity, we achieve a single-photon optomechanical coupling of up to \( g_0/2\pi = 9 \text{ kHz} \). Combined with an efficient guiding of light through the nanophotonic structure, we demonstrate a 'per-photon' displacement sensitivity increased by two orders of magnitude compared to previous experiments using far-field detection. I will discuss future outlook of the work, including several room-temperature quantum experiments that can be performed.

*This project was supported by the European Research Council (CoG QLev4G and StG Strong-Q), the Austrian Science Fund under the projects F40 (SFB FOQUS), P28172, the Foundation for Fundamental Research on Matter Projectruimte grant (15PR3210) and by the Netherlands Organisation for Scientific Research, as part of the Frontiers of Nanoscience program.

3:18PM V24.00005: Electromagnetically induced transparency in disordered and bidirectional chiral waveguide quantum electrodynamics* IMRAN MIRZA (Presenter), Physics, Miami University, OH, JOHN C SCHOTLAND, University of Michigan — Emitters coupled to nanophotonic waveguides architectures have gained a lot of attention due to the possibility of chiral (unidirectional) couplings between the emitters and the waveguide field [Nature, 541, 473-480 (2017)]. Till date most of the work on many emitter-waveguide quantum electrodynamics has focused on the scenario in which emitters are periodically placed and are symmetrically coupled with the waveguide. I will present single-photon transport problem in a one-dimensional disordered lattice of three-level emitters coupled to a waveguide [JOSA B, 35, 5 (2018)]. In particular, I'll consider Λ-type three-level emitters capable of exhibiting electromagnetically induced transparency and separately consider disorder in the atomic positions and transition frequencies. The question I'll address is how chiral emissions can impact the formation of spatially localized states. This work has possible applications to quantum networks and quantum communications.

*I. M. would like to acknowledge support from Miami University Ohio college of arts science startup funding.

3:30PM V24.00006: Light localization in disordered medium by scattering dislocation sites* FARBOD SHAFIEI (Presenter), The University of Texas at Austin, TOMMASO ORZALI, MAN HOI WONG, SEMATECH, GENNADI BERSUKER, The Aerospace Corporation, MICHAEL C DOWNER, The University of Texas at Austin — Threading dislocation defects at mismatch interfaces between III-V and Si substrate, act as light scattering sites in this disordered medium. Light get localized within the semiconductor film due to multiple scattering by these sites. We had studied the signature of such localizations in nonlinear regime (to avoid the dominating surface linear reflection). Localization signatures are observed in the series of optical measurements using a fiber scanning probe microscope that allows to analyze the light–matter interaction at these atomic irregularities in the material stacks.

*Welch Foundation
Disordered photonic bandgap materials, from functional device design to self-assembly progress.*

BOWEN YU (Presenter), BRANDON GUNN, ZHENNAN FENG, Physics and Astronomy, San Francisco State University, REMI DREYFUS, CNRS, WEINING MAN, Physics and Astronomy, San Francisco State University — Disordered photonic band gap materials are not limited to crystalline symmetries, hence offering unprecedented freedom for functional-defect designs, an inherent advantage associated with the isotropy of the structure. Beyond our previous works in disordered photonic structures, we made further progresses in both functional device designs and self-assembling attempts. We designed hyperuniform-disordered wall-networks for coupling 1.55-micron waves effectively in and out thin Silicon slabs. We systematically studied how various design parameters can be optimized for the best total efficiency, the best directional coupling and the broadest angle coupling. This can be potentially useful for integrated photonic circuits, and large-area and wide-angle light emitters and sensors. Microscopic disordered patterns with different degrees of hyperuniformity can be experimentally realized by driving colloidal suspensions out of equilibrium in a flow with different degrees of shearing. We found a clear correlation between the easiness (minimum required index-contrast) in opening photonic bandgap with the transition of displacement amplitude. This may open new routes for bottom-up self-assemblies of functional photonic materials.

Chiral transport and localization in a bosonic analogue of the Kitaev-Majorana chain

ALEXANDER MCDONALD (Presenter), University of Chicago, TAMI PEREG-BARNEA, McGill University, AASHISH CLERK, University of Chicago — We study a bosonic system whose real-space Hamiltonian has a form analogous to the celebrated Kitaev chain model of a 1D p-wave superconductor [1]. The system is a 1D chain of non-interacting bosonic cavities which are subject to nearest-neighbour parametric driving. With a suitable choice of drive phases, the system has a number remarkable properties. It exhibits phase dependent chirality: photons propagate and are amplified in a direction that is determined by the phase of the initial drive or excitation. Further, we find a extreme sensitivity to boundary conditions which could serve as a potential quantum sensor. We show that many of these properties can be connected to the dynamics and topology of effective non-Hermitian models (despite our system being fully Hermitian). Our model could be realized in several different superconducting microwave circuits setups (e.g. [2,3]) or silicon photonic platforms (e.g. [4]).

Topological bands and triply-degenerate points in non-Hermitian hyperbolic metamaterials*

JUNPENG HOU (Presenter), ZHITONG LI, XIWANG LUO, QING GU, CHUANWEI ZHANG, University of Texas at Dallas — Hyperbolic metamaterials (HMMs), an unusual class of electromagnetic metamaterials, have found important applications in various fields due to their distinctive properties. A surprising feature of HMMs found recently is that even continuous HMMs can possess topological edge modes. However, previous studies based on equal-frequency surface (analogy of Fermi surface) may not correctly capture the topology of entire bands. Here we develop a topological band description for continuous HMMs that can be described by a non-Hermitian Hamiltonian formulated from Maxwell's equations. We find two types of three dimensional photonic triply-degenerate points with topological charges ±2 and 0 induced by chiral and gyromagnetic effects that break spatial inversion and time-reversal symmetries, respectively. Because of the photonic nature, the vacuum band plays an important role for topological edge states and bulk-edge correspondence in HMMs. The topological band results are numerically confirmed by direct simulation of Maxwell's equations. Our work presents a general nonHermitian topological band treatment of continuous HMMs, paving the way for exploring interesting topological phases in photonic continua.

4:18PM V24.00010: Large Stark Tuning of InAs/InP Quantum Dots  SHAHRIAR AGHAEIMEIBODI (Presenter), CHANG-MIN LEE, MUSTAFA ATABEY BUYUKKAYA, CHRISTOPHER RICHARDSON, EDO WAKS, University of Maryland, College Park — Quantum dots are excellent sources of single-photon emission and are among the most promising candidates for scalable quantum photonic circuits. However, geometric differences in each quantum dot lead to slightly different emission wavelengths and hinders the possibility of generating multiple identical quantum emitters on the same chip. Stark tuning is an efficient technique to overcome this issue by controlling the emission energy of individual quantum dots. InAs/InP quantum dots are bright single-photon emitters in the telecommunication wavelength band. Stark tuning of these quantum dots has been previously limited to shifts below 1 nm due to the introduction of additional charges. Here, we demonstrate up to 8 nm of Stark tuning in the emission wavelength of InAs/InP quantum dots. Moreover, the single-photon nature and narrow linewidth of the quantum dot emission is preserved under the applied electric field. This result is an important step toward implementing multiple identical quantum emitters at telecom wavelengths, which is crucial for realizing complex quantum photonic circuits for quantum information processing.

4:30PM V24.00011: A nanomechanical-circuit QED analogue of the Unruh effect  HUI WANG (Presenter), MILES BLENCOWE, ALEXANDER J RIMBERG, Physics & Astronomy, Dartmouth College, CHRISTOPHER WILSON, Institute for Quantum Computing, University of Waterloo — In the Unruh Effect (UE), a uniformly accelerating detector is predicted to 'see' thermal photons in the vacuum. A longstanding challenge is to demonstrate the UE in tabletop experiments. However, impractically high accelerations are required in order to produce a measurable thermal photon signal. An alternative approach is to consider condensed matter analogues, where the governing quantum dynamics closely maps onto that of the genuine UE, but which are more easily realised in experiment. We consider a feasible UE analogue involving two coupled superconducting circuit microwave resonators, one playing the role of the photon detector, the other the vacuum cavity. The coupling is via a GHz mechanically oscillating film bulk acoustic resonator, with its fundamental dilatational frequency matching the microwave resonators' fundamental frequencies, functioning effectively as a non-degenerate parametric amplifier with mechanical pump. We show how the resulting photon pair production from vacuum can be verified through available quantum limited linear detection techniques.

4:42PM V24.00012: Experimental design and theoretical model building for higher-order topological insulators  RONNY THOMALE (Presenter), University of Wurzburg — Higher-order topological states establish a new complexity class of topological matter. The contemporary challenge is to devise experimental scenarios in which such exotic states of matter can unfold. We report on a synthetic topological matter realization of a quadrupolar topological insulator in a topolectrical circuit array [Imhof et al., Nature Physics 14, 925 (2018)]. Transcending from specific realizations of this phenomenon, we attempt to draw a line to previous observations of dimensional edge mode hierarchies [Sessi et al., Science 354, 1269 (2016)] before the field's terminology first emerged in 2017.

*The work was supported by ERC-StG-Thomale-336012 and by DFG-SFB 1170, project B04.

4:54PM V24.00013: Measurement of fractional corner charges in rotationally symmetric crystalline topological insulator metamaterials  CHRISTOPHER PETERSON (Presenter), University of Illinois at Urbana-Champaign, WLADIMIR BENALCAZAR, Pennsylvania State University, TIANHE LI, TAYLOR HUGHES, GAURAV BAHL, University of Illinois at Urbana-Champaign — Topological crystalline insulators (TCIs) with bulk dipole and higher multipole moments can host quantized fractional charges at their boundaries. Recently, it was shown that rotationally symmetric TCIs with vanishing bulk electric moments can also host quantized fractional electric charges at their corners. We used arrays of coupled microwave frequency resonators to experimentally investigate the local density of states (LDOS) in C3- and C4-symmetric crystalline topological lattices. We find that the LDOS is indeed fractionally quantized, in an analogous way as what is expected for the corner charge in their fermionic counterparts. Moreover, we show experimentally that these fractional LDOS are associated with corner-localized states that, although initially may be hidden within bulk energy bands, can be pulled out of them and be spectrally isolated. When these arrays are transitioned into their topological trivial phase, on the other hand, no fractionalization is observed, and consequently, corner-localized states cannot be isolated.

*We acknowledge support from the US National Science Foundation and the US Office of Naval Research.
Weyl exceptional rings in a lossy magnetically biased plasma

KUNAL SHASTRI (Presenter), FRANCESCO MONTICONE, Cornell University — Weyl exceptional rings are closed contours in momentum space along which both energy eigenvalues and eigenvectors of a system coalesce. These rings emerge in Weyl semimetals subject to non-Hermitian perturbations. We report the existence of Weyl exceptional rings in the electromagnetic dispersion of a lossy plasma in the presence of an external magnetic field. We describe the conditions under which topologically protected surface states can be preserved or destroyed by changing losses in the system. Increasing losses changes the size of the exceptional rings and anisotropic losses at certain angles relative to the external magnetic field can cause two rings of opposite charge to annihilate each other. This system offers a window to study the rich physics of exceptional rings in a range of plasmonic materials including the optical response of magnetically biased metals and semiconductors.

Microwave shielding of ultracold polar molecules

TIJS KARMAN (Presenter), Institute for Theoretical Atomic, Molecular and Optical Physics (ITAMP), Harvard-Smithsonian Center for Astrophysics, JEREMY M. HUTSON, Department of Chemistry, Durham University — Use microwaves to engineer repulsive long-range interactions between ultracold polar molecules [1]. The resulting shielding suppresses various loss mechanisms and provides large elastic cross sections. Hyperfine interactions limit the shielding under realistic conditions, but a magnetic field allows suppression of the losses to below $10^{-14}$ cm$^3$ s$^{-1}$. The mechanism and optimum conditions for shielding differ substantially from those proposed by Gorshkov et al. [Phys. Rev. Lett. 101, 073201 (2008)], and do not require cancelation of the long-range dipole-dipole interaction that is vital to many applications.

Session V25 DPOLY GSOFT DBIO: Polymer-Mediated Structural Transitions in Soft Materials

2:30PM V25.00001: Rouleaux formation: polymer induced Red Blood Cells aggregates [Invited] CHRISTIAN WAGNER (Presenter), Saarland University — Plasma proteins such as fibrinogen induce the aggregation of red blood cells (RBC) into rouleaux, which are responsible for the pronounced shear thinning of blood, control the erythrocyte sedimentation rate (ESR) — a common hematological test — and are involved in many situations of physiological relevance such as structuration of blood in the microcirculation or clot formation in pathological situations. Confocal microscopy is used to characterize the shape of RBCs within rouleaux at equilibrium as a function of macromolecular concentration, revealing the diversity of contact zone morphology. Three different configurations that have only been partly predicted before are identified, namely parachute, male-female and sigmoid shapes, and quantitatively recovered by numerical simulations. Stable polymer induced clusters in capillary flow are also observed in-vivo in a mouse model by use of intravitral epillumination microscopy and in-vitro in a microfluidic device, wherein the protein or the macromolecule concentration can be freely varied. The interaction energies between the cells are determined by use of single cell force spectroscopy and optical tweezers. Numerical simulations of flowing cells show again a good agreement with the experimental observations.

3:06PM V25.00002: Extracellular polymers control bacterial biofilm expansion and material properties JING YAN (Presenter), BONNIE BASSLER, NED WINGREEN, HOWARD A STONE, Princeton University — Biofilms, surface-attached communities of bacterial cells, are a concern in health and in industrial operations because of persistent infections, clogging of flows, and surface fouling. In this talk, I will explore the consequences to biofilm growth and robustness when the biofilm matrix functions as a material that is responsive to environmental perturbations such as changes in osmotic pressure. Using Vibrio cholerae as the model organism, we showed that matrix production enables biofilm-dwelling bacterial cells to establish an osmotic pressure differential between the biofilm and the external environment. The pressure difference promotes colony biofilm expansion on nutritious surfaces, controls growth of submerged biofilms, and enables matrix-producing cells in biofilms to exclude non-matrix-producing cheaters and to resist invasion by planktonic cells. Furthermore, we discovered how extracellular polysaccharides, proteins, and cells function together to define biofilm mechanical and interfacial properties.
3:18PM V25.00003: Glass transition temperature of poly(lactic-co-glycolic acid) particles YIQING YANG, QINGRUI JIANG, STEVEN HERRERA, KATHLEEN MCENNIS (Presenter), New Jersey Institute of Technology — Poly(lactic-co-glycolic acid) (PLGA), is a commonly used biodegradable biomaterial used to make many different biomedical products including drug delivery particles. The glass transition temperature ($T_g$) of a polymer particle can have a profound effect on its behavior \textit{in vivo} such as aggregation behavior and drug release profile. Bulk PLGA has a $T_g$ of approximately 40°C. Since normal body temperature is 37°C, it is assumed that PLGA particles will remain in their solid, glassy state during \textit{in vivo} experiments. However, many factors can affect the $T_g$ of a particle, such as thermal history. The method used to produce the PLGA particle will therefore affect its $T_g$. Most experiments are done with polymer samples in the bulk form that have been annealed to erase thermal history. In this work, PLGA particles are made by nanoemulsion, nanoprecipitation, and electrohydrodynamic jetting and the $T_g$ of the particles is measured using the first heating scan of a modulated differential scanning calorimetry to run the determination of the role of processing conditions on the $T_g$ of PLGA particles.

3:30PM V25.00004: Polyelectrolyte-Mediated Colloidal Interactions at the Interfaces of Liquid Crystals MICHAEL TSUEI (Presenter), YOUNG KI KIM, Chemical and Biomolecular Engineering, Cornell University, HAO SUN, Department of Chemistry, Northwestern University, XIN WANG, YU YANG, Chemical and Biomolecular Engineering, Cornell University, NATHAN C. GIANNESCHI, Department of Chemistry, Northwestern University, NICHOLAS L. ABBOTT, Chemical and Biomolecular Engineering, Cornell University — Nematic liquid crystals (LCs) are complex fluids within which molecules exhibit long-range orientational order leading to an anisotropic elasticity. When introduced into a LC host, colloidal particles (microcargo) elastically strain the LC and generate topological defects. Consequently, the microcargo experience strong repulsive forces near interfaces of LCs (e.g., LC-aqueous, LC-air interfaces). In this presentation, we will show that formation of polyelectrolyte and polyelectrolyte-surfactant complexes at a LC interface modulates the interactions of colloidal microcargo with that interface. We will describe elastic and electrical double layer interactions occurring at these interfaces and how the interplay of the two interactions is modulated by the formation of complexes of polyelectrolytes and surfactants. We will also illustrate how this competition of interactions can be used to trigger the release of microcargo from the LC.

3:42PM V25.00005: Phase behavior and structure of polyelectrolyte-nanoparticle complex assemblies E NEILSEN (Presenter), SAMANVAYA SRIVASTAVA, Chemical and Biomolecular Engineering, University of California, Los Angeles — Numerous examples of complex assemblies comprising oppositely charged polyelectrolytes and nanoparticles (or proteins) in aqueous environments exist in natural and synthetic systems. The structure and stability of these complex assemblies are dictated by numerous factors including solution conditions as well as polyelectrolyte and nanoparticle properties and are far from being fundamentally understood and controlled. In this work, we examine the effect of polyelectrolyte and nanoparticle concentrations, polyelectrolyte size, flexibility, charge density and degree of ionization, nanoparticle size and effective charge density and the pH and ionic strength of the solution on the structure and phase behavior of model nanoparticle-polyelectrolyte complex assemblies comprising negatively charged silica nanoparticles and diverse polycations. Conditions that lead to destabilization and phase separation of the complexes will be identified through turbidimetric and light scattering studies. Furthermore, X-ray and light scattering investigations on the structure and morphology of phase separated and the "soluble" stable complexes will be presented.

3:54PM V25.00006: Polymer mediated interaction between colloids and their role in the formation of colloidal aggregates* ALEXANDER CHERVANYOV (Presenter), Institute of Theoretical Physics, WWU Munster, Munster, Germany — We theoretically study the polymer mediated (PM) interactions between colloids immersed in different host polymer systems such as (i) semi-dilute polymer solutions; (ii) polymer melts; (iii) polymer blends; (iv) rubber materials. A significance of the effect of attractive polymer-colloid (P-C) and polymer-polymer (P-P) interactions on the effective forces acting between colloids immersed in a polymer melt is shown to drastically depend on the colloid-to-polymer size ratio. For the case of colloids immersed in polymer blends we predict a novel mechanism of the PM interactions caused by non-uniformities in the local composition of the polymer blend induced by these colloids. This mechanism, specific to polymer blends, is shown to play a dominant role in the PM interactions. As a practical application of the developed approach, we study the polymer mediated aggregation of colloids immersed in the above host polymer systems. In addition, we discuss several practical examples showing how the effective interactions between colloids induced by polymers are used to drive thermodynamic, mechanical, and electrical properties of the selected polymer-colloid composites.

*Financial support of Deutsche Forschungsgemeinschaft (DFG) through Grant No. CH 845/2-1, is gratefully acknowledged.
4:06PM V25.00007: Dielectric virial expansion of polarizable dipolar spheres  
HUADA LIAN (Presenter), Department of Materials Science and Engineering, Stanford University, JIAN QIN, Department of Chemical Engineering, Stanford University — Predicting the static dielectric permittivity for composites with polarizable components remains a theoretical challenge. The typical Maxwell-Garnett mixing rule or its variant approximates the composite permittivity with a linear average of inclusion’s polarizability, which neglects the inter-particle interactions. A systematic density expansion is developed to predict the composite permittivity that includes the contribution from interactions of multiple polarizable particles. The lowest order term in such expansion reduces to the Maxwell-Garnett rule. Including the second order term results in a parameter-free prediction, which matches the independently measured values for a set of seven polymer-nanoparticle composites.

4:18PM V25.00008: Co-assembly of anisotropic colloids and diblock copolymer mixtures  
JAVIER DIAZ (Presenter), Centre for Computational Physics, University of Lincoln, ROY SHENHAR, Institute of Chemistry, The Hebrew University of Jerusalem, MARCO PINNA, Centre for Computational Physics, University of Lincoln, IGNACIO PAGONABARRAGA, Departament de Fisica Fonamental, Universitat de Barcelona, ANDREI ZVELINDOVSKY, Centre for Computational Physics, University of Lincoln — Block copolymers are excellent candidates to template the localisation of colloids, in order to create ordered arrays of nanoparticles, with uses in optical and electrical applications. The co-assembly of block copolymer nanocomposite materials can lead to highly ordered systems in the mesoscale. Computer simulations have been used to address the complex assembly of anisotropic rod-like colloids. The crossover between the block copolymer intrinsic length scales and the shape and orientation of anisotropic nanoparticles leads to a rich variety of phase behaviors, both in terms of polymeric morphologies and colloidal organisation. Rod-like nanoparticles have been found to form side-to-side configuration in block copolymer ultrathin films. SEM images are compared with a hybrid Cell Dynamic/Brownian Dynamic computational method which is used to characterise the assembly of anisotropic nanoparticles in diblock copolymers.

4:30PM V25.00009: Predicting chi for polymers with different chain architectures using simulation*  
SHREYA SHETTY (Presenter), MILENA MARIE ADAMS, ENRIQUE D GOMEZ, SCOTT MILNER, Pennsylvania State University — The Flory Huggins interaction parameter chi governs phase behavior in polymer blends and block copolymers. Chain architecture affects how chains pack in the melt, which can significantly influence chi. To explore this, we investigate chi for two different architectures of flexible bead-spring chains, using molecular dynamics simulations and our recently developed “morphing” method to compute the excess free energy of mixing. In the first case, we consider an idealized bead-spring model of polyethylene and polypropylene, in which all beads have the same interactions, but polypropylene chains have a side bead on every other backbone bead. In the second case, we examine blends in which both chain species have the “polypropylene” bead-spring structure, but one species has beads with a slightly weaker interaction – either the side beads (case 1), main chain beads (case 2) or branch point beads (case 3). We use our method to find c for all three cases, for which random mixing models would give identical results. Finally, we compare our values with predictions from PRISM, with correlation functions from simulations as input, as a purely simulation-based test of PRISM.

*Financial support from the National Science Foundation under Award DMREF-1629006 is acknowledged.

4:42PM V25.00010: Novel Dynamical behaviors of charged Macromolecules in a crowded environment*  
DI JIA (Presenter), MURUGAPPAN MUTHUKUMAR, Department of Polymer Science and Engineering, University of Massachusetts Amherst — The phenomenon of “ordinary-extraordinary” dynamical transition in salt-free polyelectrolyte solutions is well known. We report the emergence of additional dynamical mode at higher molecular weights of the polyelectrolyte. We find that the key variable Cp/Cs, which is normally used in describing the onset of the ordinary-extraordinary transition (fast and slow modes), is inadequate in describing the dynamics of polyelectrolyte solutions. For concentrated solutions of sodium polystyrene sulfonate of higher molecular weights, we observe a third intermediate mode. The emergence of the new mode depends crucially on the polymer molecular weight and the concentration of the added salt. We find that Cp/C* (where C* is overlap concentration) is a key variable in addition to Cp/Cs.

*National Science Foundation (DMR-15 04265)
4:54PM V25.00011: Similarity of Crambin Lattice Protein Homologues in the Semi-flexible H0P Model*  
ZEWEN ZHANG (Presenter), ALFRED FARRIS, GUANGJIE SHI, Center for Simulational Physics, University of Georgia, THOMAS WUEST, Scientific IT Services, ETH Zürich, DAVID P LANDAU, Center for Simulational Physics, University of Georgia — The semi-flexible H0P lattice protein model is an extension of the HP model with an extra kind of “neutral” monomer and an energetic term for “bends”. Crambin (a 46 amino acids protein) has been mapped onto the H0P model and studied by replica-exchange Wang-Landau sampling. From the obtained density of states, thermal properties of the lattice protein are extracted at all temperature. With further study by multicanonical sampling, ground state degeneracy as well as the temperature-dependence of structural quantities are measured with high resolution. In this study, we examine five H0P lattice protein homologues of Crambin, i.e. proteins with similar sequences and structures in nature. Our results show that, at low temperature, thermal properties of these H0P-modeled homologues are close to those of Crambin itself, all showing two significant conformational changes. However, results also show that the previous value for the bending energy can lead to high degeneracies for some low excited states of the homologues. Therefore, a slight change has been made to this term, to keep the degeneracies of all tested homologues low and stable.

*The computing sources are provided by Georgia Advanced Computing Resource Center; and Texas Advanced Computing Center under XSEDE Grant No. PHY130014.

5:06PM V25.00012: Is there a universal equation of state for flexible polymers beyond the semi-dilute regime?*  
JAROSLAW PATUREJ (Presenter), JENS-UWE SOMMER, TORSTEN KREER, Leibniz Institute for Polymer Research Dresden — We reconsider the isothermal equation of state (EoS) for linear homopolymers in good solvents, \( p = p(c, T) \), which relates the osmotic pressure, \( p \), of polymers with the bulk concentration, \( c \), and the temperature, \( T \). The classical scaling theory predicts the EoS in dilute and semi-dilute regimes. We suggest a generalized EoS which extends the universal behavior of polymer solutions up to the highly concentrated state and confirmed it by molecular dynamics simulations and using available experimental data. Our conjecture implies that properties of polymer chains dominate the EoS in the presence of many-body interactions. Our theoretical approach is based on a viral expansion in terms of concentration blobs leading to a superposition of two power laws in the regime of concentrated solutions.

5:18PM V25.00013: Gelation of hydrogel films and coatings induced by substrate swelling.*  
DAVID MOREAU, Centre des Matériaux, Mines ParisTech, CAROLINE CHAUVET, FRANÇOIS ETIENNE, FRANÇOIS P RANNOU, INSERM UMR S1124, Université Paris Descartes, LAURENT CORTE (Presenter), Centre des Matériaux, Mines ParisTech — Hydrogel films used as membranes or coatings are essential components of devices interfaced with biological systems. Their design is greatly challenged by the need to find mild synthesis and processing conditions that preserve their biocompatibility and the integrity of encapsulated compounds. Here, we report an approach to produce hydrogel films spontaneously in aqueous polymer solutions [1]. This method uses the solvent depletion created at the surface of swelling polymer substrates to induce the gelation of a thin layer of polymer solution. Using a biocompatible polymer that self-assembles at high concentration (poly(vinyl alcohol)), hydrogel films are produced within minutes to hours with thicknesses ranging from tens to hundreds of micrometers. A simple model predicts how the solution composition, substrate geometry and swelling properties govern film growth. We also demonstrate the potential of this technique by incorporating other solutes to fabricate ceramic-hydrogel coatings for bone anchoring of osteo-articular implants and matrices for cell-encapsulation.

Session V26 DQI: Superconducting Qubits: Control Hardware and Methods  
Abdo, IBM Thomas J. Watson Research Center
**2:30PM V26.00001: Integration of classical electronics for quantum computing tasks in superconducting qubit systems**

ANTONIO CORCOLES (Presenter), MAIKA TAKITA, KEN INOUE, SCOTT LEKUCH, ABHINAV KANDALA, JAY GAMBETTA, JERRY M. CHOW, IBM Thomas J. Watson Research Center — The acts of controlling and measuring superconducting qubits for quantum information processing rely on classical electronic systems. Although metrics primarily associated to the quantum system, such as qubit coherence time and gate fidelity, are typically quoted as benchmarks for quantum processor quality, the integration of classical hardware and associated software with the quantum device plays a critical role both in these metrics and in the overall performance of a quantum computer.

In this talk we will discuss some important details of this architecture for superconducting quantum processors, touching on current limitations and future outlook.

*This work is supported by IARPA under contract W911NF-16-1-0114.

---

**2:42PM V26.00002: Evaluating the performance of classical electronics for quantum computing tasks in superconducting qubit systems**

MAIKA TAKITA (Presenter), ANTONIO CORCOLES, KEN INOUE, SCOTT LEKUCH, ABHINAV KANDALA, JAY GAMBETTA, JERRY M. CHOW, IBM Thomas J. Watson Research Center — We present and discuss quantum protocols for near-term superconducting quantum processors for which quantum feedback or feedforward plays a key role. These protocols hinge heavily on classical electronics for qubit control and signal processing, which makes them ideal candidates for evaluating the performance of NISQ devices in the present and near future. We will discuss, in addition, ways in which these quantum protocols can be used for benchmarking systems exposed to errors that reach beyond quantum noise and coherent errors in qubit control.

*This work is supported by IARPA under contract W911NF-16-1-0114.

---

**2:54PM V26.00003: Atomic flux pulses for a superconducting quantum processor, part 1: real-time corrections and repeatability of flux pulses**

FILIP MALINOWSKI (Presenter), MICHIEL ADRIAAN ROL, LIVIO S CIORCIARO, BRIAN M TARASINSKI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, YVES SALATHE, NIELS HAANDBAEK, JAN ŠEDIVÝ, Zurich Instruments AG, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — We present the calibration and characterization of atomic, repeatable flux pulses compatible with a flexible Quantum Instruction Set Architecture (QISA). The flux pulses take advantage of distortion corrections realized by real-time filtering in the arbitrary waveform generator as the sequence of pulses is executed, rather than conventional pre-distortion of the waveform shape in software. We combine the corrections with the net-zero waveform shape and quantify the repeatability of flux pulsing. The phases acquired by the qubit in each of two consecutive flux pulses match within 1 deg, independent of the delay between them.

*This research is supported by Intel Corporation and IARPA (U.S. Army Research Office grant W911NF-16-1-0071).

---

MICHIEL ADRIAAN ROL (Presenter), FILIP K MALINOWSKI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, FRANCESCO BATTISTEL, QuTech, Delft University of Technology, BRIAN M TARASINSKI, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, BARBARA TERHAL, QuTech, Delft University of Technology, LEONARDO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology — We use a novel pulse shape, named net-zero, to realize a coherence limited, codeword-triggered, and repeatable conditional-phase (CZ) gate between transmon qubits in a circuit QED processor. We characterize the performance of both conventional and net-zero CZ flux pulses and quantify specific error sources such as leakage, dephasing, relaxation, non-markovianity, and coherent errors. We compare experimental results to simulations that include realistic modeling of these effects.

*This research is supported by IARPA (U.S. Army Research Office grant W911NF-16-1-0071), Intel Corporation and ERC grant EQEC No. 682726.
3:18PM V26.00005: Superconducting qubit control electronics - Part 1/2: system overview and control hardware

AMIT VAINSENCHER (Presenter), Google Inc - Santa Barbara, BEN CHIARO, Physics, University of California, Santa Barbara, ROBERTO COLLINS, Google Inc - Santa Barbara, BROOKS FOXEN, Physics, University of California, Santa Barbara, EVAN JEFFREY, ERIK LUCERO, Google Inc - Santa Barbara, MATTHEW MCEWEN, Physics, University of California, Santa Barbara, DANIEL SANK, JOHN M MARTINIS, Google Inc - Santa Barbara — The need for numerous analog control lines presents a unique challenge in building control systems for large quantum processors. In the context of superconducting Josephson qubits, particular requirements for the control lines include phase matching across all channels, low noise, and minimal drift. In this talk, we discuss the design, implementation, and challenges encountered in building our next generation modular control system. Using this system in a configuration with 256 DACs, 84 IQ mixers, 24 ADC, and 16 microwave sources, we will show preliminary measurements on Bristlecone, our 72-qubit processor.

3:30PM V26.00006: Superconducting qubit control electronics - Part 2/2: dispersive measurement

DANIEL SANK (Presenter), ROBERTO COLLINS, EVAN JEFFREY, ERIK LUCERO, AMIT VAINSENCHER, Google Inc - Santa Barbara, BROOKS FOXEN, BEN CHIARO, Physics, UCSB, JOHN M MARTINIS, Google Inc - Santa Barbara — Dispersive measurement of transmon-type qubits requires a microwave receiver with nearly 100 dB gain and ~100 mK system noise temperature. Recent increases in qubit number have introduced a new set of requirements on our receivers. These constraints include the need for smaller parts at cryogenic and room temperature stages, higher reliability, lower cost, and uniformity across multiple systems to ensure agreement between staging and production systems. In this talk, we discuss the design and implementation of our dispersive measurement system that meets our integration needs while maintaining performance, with particular focus on the room temperature electronics. We present preliminary results on our latest chips.

3:42PM V26.00007: Superconducting Qubit Control with Single Flux Quantum Pulses in A Multichip Module: Part I – Fabrication and Pulse Driver*

CHUAN-HONG LIU (Presenter), EDWARD M LEONARD, MATTHEW A BECK, Physics, University of Wisconsin-Madison, KENNETH DODGE, ANDREW L BALLARD, CALEB HOWINGTON, VITO M IAIA, JJ NELSON, Physics, Syracuse University, ALEX KIRICHENKO, DANIEL T YOHANNES, IGOR VERNIK, JASON WALTER, OLEKANDR CHERNYASHEVSKYY, OLEG MUKHANOV, Hypres Inc, BRITTON L PLOURDE, Physics, Syracuse University, ROBERT F MCDERMOTT, Physics, University of Wisconsin-Madison — Superconducting qubits are an attractive candidate for quantum information. However, existing control techniques do not scale well to large-scale qubit arrays processing. A promising candidate for scalable control is the Single Flux Quantum (SFQ) digital logical family. In an initial implementation, the fidelity of SFQ-based qubit gates was limited by quasiparticle (QP) poisoning of the qubit induced by the dissipative SFQ pulse driver. Here we introduce a quantum-classical multichip module (MCM) where the SFQ driver and the qubit are segregated onto separate chips in order to suppress QP poisoning. We describe the design, fabrication, and thermalization of the MCM. Finally, we discuss the operation and characterization of the SFQ pulse generator and qubit.

*This work was supported by the U.S. Government under Grant W911NF-15-1-0248.

3:54PM V26.00008: Superconducting Qubit Control with Single Flux Quantum Pulses in A Multichip Module: Part II Qubit and Quasiparticle Measurement

KENNETH DODGE (Presenter), ANDREW BALLARD, CALEB HOWINGTON, VITO M IAIA, JJ NELSON, Syracuse University, CHUAN-HONG LIU, EDWARD M LEONARD, MATTHEW A BECK, Univ of Wisconsin, Madison, ALEX KIRICHENKO, DANIEL T YOHANNES, IGOR VERNIK, JASON WALTER, OLEKANDR CHERNYASHEVSKYY, OLEG MUKHANOV, Hypres Inc, ROBERT F MCDERMOTT, Univ of Wisconsin, Madison, B.L.T. PLOURDE, Syracuse University — We demonstrate coupling of a Single Flux Quantum (SFQ) driver on a classical control chip to a superconducting qubit on a quantum chip in a multi-chip module package. A DC-SFQ driver on the classical chip emits quantized pulses that are capacitively coupled to the qubit island of a transmon on the quantum chip, allowing subharmonic driving of qubit rotations. We examine the effects of on- and off-resonant SFQ pulses on the state of the qubit and the response of the read-out cavity. Quasiparticle (QP) excitations created from the operation of the SFQ circuitry can be a source of decoherence and temporal instability in the qubit. QP contribution to the qubit admittance are examined by monitoring how relaxation and dephasing times correlate with QP creation. Mitigation strategies for QP poisoning will be discussed.
4:06PM V26.00009: Reciprocal Quantum Logic Compatible SFQ-to-CMOS Amplifiers for High-Speed Data Transmission ELIAS GALAN, MARIE MCLAIN (Presenter), MICAH STOUTIMORE, ANDREW MIKLICH, KURT PLEIM, RATZ PAUL, DAVID MCGUIRE, OLIVER OBERG, ZACHARY KYLE KEANE, Northrop Grumman — We have developed an amplifier for use in transmitting high-speed reciprocal quantum logic signals to CMOS digital circuitry at room temperature. The amplifier uses an integrated digital latch to convert the normally return-to-zero (RZ) format of a single flux quantum (SFQ) signal to non-return-to-zero (NRZ) format with a simple and space-efficient design. The NRZ format provides more signal power per unit bandwidth than RZ, and is easier to interface with CMOS circuitry. The output voltage is provided by a series of inductively isolated asymmetric DC superconducting quantum interference devices (SQUIDs). The power efficiency is estimated to be 32±9%. The DC SQUIDs are designed in-line with a 50 Ohm transmission line to reduce high frequency oscillation and improve output signal integrity. Experimentally, the output amplifier demonstrated a bit error rate of better than 9.5E-8 at 1 Gb/s; extrapolations to the optimal operating point project a bit error rate of 1E-37.

4:18PM V26.00010: Engineering cryogenic setups for 100-qubit scale superconducting circuit systems* SEBASTIAN KRINNER (Presenter), SIMON STORZ, PHILIPP KURPIERS, PAUL MAGNARD, JOHANNES HEINSOO, RAPHAEL KELLER, JANIS LUETOLF, CHRISTOPHER EICHLER, ANDREAS WALLRAFF, Department of Physics, ETH Zurich — A robust cryogenic infrastructure in form of a wired, thermally optimized dilution refrigerator is essential for solid-state based quantum processors. In this talk, we present a cryogenic setup, which minimizes passive and active heat loads, while guaranteeing rapid qubit control and readout. We review design criteria for qubit drive lines, flux lines, and output lines used in typical experiments with superconducting circuits. The passive heat load of stainless steel and NbTi coaxial cables and the active load due to signal dissipation are measured, validating our robust and extensible concept for thermal anchoring of attenuators, cables, and other microwave components. Our results are important for managing the heat budget of future large-scale quantum computers based on superconducting circuits.

*This work is supported by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA), via the U.S. Army Research Office grant W911NF-16-1-0071 and by ETH Zurich.

4:30PM V26.00011: Scalable instrumentation for general purpose quantum computers GLENN JONES (Presenter), DEANNA ABRAMS, STEPHAN BROWN, LAUREN CAPELLUTO, SCHUYLER FRIED, SABRINA HONG, BLAKE JOHNSON, ROB LION, ADAM MOCARSKI, MIKE PELSTRING, CHAD RIGETTI, DAMON RUSSELL, MICHAEL RUST, COLM RYAN, DIEGO SCARABELLI, RODNEY SINCLAIR, PRASAHNT SIVARAJAH, CHLOE SONG, ALEXA N STALEY, JOHN STEVENSON, MARK SUSKA, NIMA TAIE-NOBARI, CELENA TANGUAY, NIKOLAS TEZAK, STEFAN TURKOWSKI, Rigetti Quantum Computing — As quantum computers grow to increasing numbers of qubits, it becomes advantageous to use specialized or customized hardware to generate the microwave pulses that control the qubits. We present an FPGA-based system for controlling qubits that demonstrates a number of advantages over commercially available test equipment. The system has been optimized to minimize the noise sources to which the qubits are most susceptible, enabling high fidelity quantum gates. The overall architecture is designed to support hybrid quantum-classical algorithms. Optimized processor cores control the microwave signal generation and provide arbitrary control flow, allowing gates to be applied conditioned on a measurement result. Gate parameters, such as rotation angle, can also be dynamically computed, or loaded from classical shared memory, and applied in real-time. We present results from a straightforward usage of this capability: actively resetting a qubit to its ground state.

4:42PM V26.00012: Scaling the input/output architecture of quantum processors to kQbit, and beyond, size in the NISQ era DAAN KUITENBROUWER, WOUTER BOS, KIEFER VERMEULEN, KELVIN LINDEBOG, RIEMER SORGEDRAGER, VIVIEN THINEY, JAKOB KAMMHUBER, SAL BOSMAN (Presenter), Delft Circuits — Most quantum computing hardware in the NISQ era is designed to support hybrid quantum-classical algorithms. Optimized processor cores control the microwave signal generation and provide arbitrary control flow, allowing gates to be applied conditioned on a measurement result. Gate parameters, such as rotation angle, can also be dynamically computed, or loaded from classical shared memory, and applied in real-time. We present results from a straightforward usage of this capability: actively resetting a qubit to its ground state.
4:54PM V26.00013: Optimizing readout hardware for large scale quantum computers  THEODORE WHITE (Presenter), Google Inc - Santa Barbara, BEN CHIARO, BROOKS FOXEN, U.C. Santa Barbara, JOHN M MARTINIS, Google Inc - Santa Barbara — In a superconducting quantum computer, each microwave readout line requires low noise parametric amplifiers, circulators, and filters. These are expensive resources, not only in cost but also in weight and size. In larger systems it is increasingly necessary to use frequency multiplexed readout tones such that many qubits can be measured with a single line. This in turn requires superconducting parametric amplifiers that operate with broad bandwidth and high saturation power, while maintaining near quantum limited noise performance. In this talk we will compare several different varieties of amplifier from the perspective of device performance, fabrication difficulty, yield, and wiring complexity. We will also report on performance metrics for these architectures in our superconducting qubit processors.

5:06PM V26.00014: Scalable FPGA-based qubit control hardware*  GANG HUANG (Presenter), YILUN XU, LAWRENCE DOOLITTLE, Lawrence Berkeley National Laboratory, UNPIL BAEK, IRFAN SIDDIQI, Physics, University of California, Berkeley — As quantum computing technology evolves from research laboratories to potential industrial applications, the scalability and synchronization of classical control hardware becomes a limiting factor in the development of intermediate-scale (50-100) qubit systems. We introduce a novel FPGA-based architecture comprised of multiple qubit control boards, interconnected by a fiber-based synchronization system, to implement basic operations such as qubit control and readout. Our hardware represents a cost-effective alternative to commercial test and measurement style AWGs and detectors, and can be readily scaled up for intermediate-scale quantum processors with low latency and synchronization among all channels to a common clock cycle. Having assembled a prototype system with commercial evaluation boards, we present results from bench testing of the hardware and initial tests demonstrating qubit control. Customized hardware with higher channel density is under development.

*This work was supported by the Department of Energy.

5:18PM V26.00015: An FPGA-based quantum feedback system for real-time qubit control*  UNPIL BAEK (Presenter), Physics, University of California, Berkeley, YILUN XU, GANG HUANG, LAWRENCE DOOLITTLE, Lawrence Berkeley National Laboratory, IRFAN SIDDIQI, Physics, University of California, Berkeley — Measurement-based quantum feedback is highly sought after due to its potential for quantum error correction and preserving quantum coherence. However, measurement-based quantum feedback has been difficult to achieve due to the limited lifetime of qubits as compared to the longer time required for readout and feedback signal processing. We present a new FPGA-based qubit control architecture that integrates the qubit readout, state recognition, and feedback response together to minimize latency. Using our initial hardware, we demonstrate real-time quantum feedback on superconducting qubits and apply this technology to a multi-qubit superconducting quantum processor.

*This work was supported by the Department of Energy.

Session V27 DQI: Quantum Foundations I BCEC 160C - Mordecai Waegell, Chapman University - Tag(s): Focus

2:30PM V27.00001: Wigner's friend as a rational agent*  [Invited]  CASLAV BRUKNER (Presenter), Institute for Quantum Optics and Quantum Information — In 1961 the physicist Eugene Wigner proposed the “Wigner’s friend” thought experiment in which an observer, Wigner, observes another observer, his friend, who performs a quantum measurement on a physical system. I will first derive a no-go theorem for observer-independent outcomes (directly observable “facts” such as “detector clicks”) which would be common both for Wigner and the friend. The outcomes then are to be understood as relational in the sense that their determinacy is relative to an observer. I will then discuss a situation where the rationale is to force Wigner's friend to depart from “standard rules of quantum mechanics” when updating her degrees of belief.

The opinions expressed in this publication are those of the authors and do not necessarily reflect the views of the John Templeton Foundation.
3:06PM V27.00002: Contextuality without access to a tomographically complete set* MATTHEW F. PUSEY (Presenter), Department of Computer Science, University of Oxford, LIDIA DEL RIO, BETTINA MEYER, Institute for Theoretical Physics, ETH Zürich — The operational approach to contextuality due to Spekkens requires finding operationally equivalent preparation procedures. Previously these have been obtained by demanding indistinguishably under a set of measurements taken to be tomographically complete. That is, it is taken for granted that the experimenter has access to the full dimension of the system of interest. However, there may in fact be other measurements in the true tomographically complete set, which could break the operational equivalences and hence eliminate the putative contextuality. Here we design tests of contextuality that are immune to this effect for a given number of unknown measurements in the tomographically complete set, allowing contextuality to be demonstrated with weaker assumptions.

*LdR acknowledges support from ERC AdG NLST, EPSRC grant DIQIP, Perimeter Institute for Theoretical Physics (PI), and the Institute for Quantum Computing at University of Waterloo. This work was partially supported by the COST Action MP1209.

3:18PM V27.00003: Symmetric Informationally Complete Measurements Pinpoint the Essential Difference between Classical and Quantum Probability Theories BLAKE STACEY (Presenter), University of Massachusetts Boston — I describe a general procedure for crafting a purely probabilistic representation of the Born Rule by means of a reference measurement: a minimal informationally-complete quantum measurement (MIC) and a set of linearly independent post-measurement quantum states. It follows that the Born Rule is a consistency condition between probabilities assigned to the outcomes of different, mutually exclusive experiments. The difference between quantum and classical physics is the way their physical assumptions augment bare probability theory: Classical physics corresponds to a trivial augmentation— one just applies the Law of Total Probability between the scenarios—while quantum theory makes use of the Born Rule expressed in one or another of the forms of our general procedure. To mark the essential difference between quantum and classical, one should seek the representations that minimize the disparity between the expressions. Using a symmetric informationally-complete measurement (SIC) minimizes this disparity, according to a large family of optimality criteria. This work complements recent studies in quantum computation where the deviation of the Born Rule from the LTP is measured in terms of negativity of Wigner functions.

(Joint work with J. B. DeBrota and C. A. Fuchs, arXiv:1805.08721)

3:30PM V27.00004: A Volume-Maximizing Map from Quantum States to the Probability Simplex, with Applications to QBism* JOHN DEBROTA (Presenter), University of Massachusetts Boston — In this talk, I make use of a recent formulation of quantum theory in terms of minimal informationally complete quantum measurements (MICs) to promote the idea that probability is more central to quantum theory than either state vectors or operators. One advantage of this formulation is that it permits a direct comparison of classical statistical physics with quantum theory via a standard reference measurement. Classically, the possibility of perfect knowledge of a system's phase space point means any vector in the reference probability simplex is an allowable state of knowledge. By contrast, the image of quantum state space under a MIC is necessarily a proper subset of the simplex. This suggests we could take the size of the allowable subset under a given MIC to be a measure of the representation's deviation from classicality. I report work from arxiv:1805.08721, where we prove that this deviation is minimized if and only if the MIC is chosen to be a symmetric informationally complete quantum measurement (SIC)—that is, the SIC representation minimizes the deviation from classicality. Finally, I speculate that this grants the SICs a unique foundational significance. (Joint work with C. A. Fuchs and B. C. Stacey)

*JBD and CAF were supported in part by grant FQXi-RFP-1612.
Noncontextuality inequalities are usually derived from the distinguishability properties of quantum states, i.e. their orthogonality. Here, we show that antidistinguishability can also be used to derive noncontextuality inequalities. Briefly, a set of states can be antidistinguished if there exists a measurement on the basis of which one can exclude one of the states as definitely not having been prepared. The Yu-Oh 13 ray contextuality inequality can be rederived and generalized as an instance of our antidistinguishability method. For qubit systems subjected to unitary gates and projective measurements, we prove that any strategy in our game can be mapped to a strategy in the CHSH game, which implies that Tsirelson's bound also holds in our setting. More generally, we show that the optimal success probability depends on the reversible or irreversible character of the gates, the quantum or classical nature of the system and the system dimension. We analyse the bounds obtained in light of Landauer's principle, showing the entropic costs of the erasure associated with the game. This shows a connection between the reversibility in fundamental operations embodied by Landauer's principle and Tsirelson's bound, that arises from the restricted physics of a unitarily-evolving single-qubit system.
4:30PM V27.00009: Contextuality and the Fundamental Theorems in Quantum Mechanics*  MARKUS FREMBS
(Presenter), Imperial College London — Contextuality is a key feature of quantum mechanics, as was first properly brought to
light by the Kochen-Specker theorem. Isham and Butterfield put contextuality at the heart of their topos-based formalism
and gave a reformulation of the Kochen-Specker theorem in the language of presheaves. Here, we broaden this
perspective considerably (partly drawing on existing, but scattered results) and show that apart from the KS theorem, also
Wigner's theorem, Gleason's theorem and Bell's theorem relate fundamentally to contextuality. The language of
presheaves serves as a useful tool in this and allows to give reformulations of the theorems with a topological-geometric
flavour. Moreover, we show in a mathematically exact way how much of the structure of a quantum system is encoded by
contextuality, and also what is missing.

*This work is funded through a studentship in the Centre for Doctoral Training on Controlled Quantum Dynamics at
Imperial College London funded by the EPSRC.

4:42PM V27.00010: Rank of contextuality  KAROL HORODECKI, Institute of Informatics, National Quantum Information Centre,
Department of Physics, Mathematics and Informatics, University of Gdansk, JINGFANG ZHOU (Presenter), University of Tokyo, PAWEL
HORODECKI, Faculty of Applied Physics and Mathematics, Gdansk University of Technology, ROBERT RAUSSENDORF, Department of
Physics & Astronomy, University of British Columbia, RYSZARD HORODECKI, Faculty of Applied Physics and Mathematics, National
Quantum Information Centre, Gdansk University of Technology, RAVISHANKAR RAMANATHAN, Laboratoire d’Information
Quantique, Universite Libre de Bruxelles, EMILY TYHURST, University of Toronto — We propose a new measure of statistical
Kochen-Specker contextuality, called rank of contextuality. The rank of contextuality is the minimal number of
noncontextual boxes (input-output devices admitting a non-contextual hidden variable model) that are needed to switch
between in order to simulate a contextual box. We show that the logarithm of the rank of contextuality is additive, faithful
measure of contextuality, monotonous under simple wirings. We also provide a construction of contextual boxes with
arbitrary high rank of contextuality, exhibiting thereby extremely high logical contradiction.

4:54PM V27.00011: Perturbative expansion of entanglement negativity*  JESSE CRESSWELL, ILAN TZITRIN (Presenter),
AARON GOLDBERG, Physics, University of Toronto — A common way to quantify entanglement in bipartite systems is through
entanglement negativity. Because negativity is a non-analytic function of a density matrix, existing methods used in
physics literature are insufficient to compute its derivatives. To this end we develop novel techniques in the calculus of
complex, patterned matrices and use them to conduct a perturbative analysis of negativity in terms of arbitrary variations
of the density operator. The result is an easy-to-implement expansion that can be carried out to all orders. On the way we
provide new and convenient representations of the partial transposition map appearing in the definition of negativity. Our
methods are well-suited to study the growth and decay of entanglement in a wide range of physical systems, including the
generic linear growth of entanglement in many-body systems, and have broad relevance to many functions of quantum
states and observables.

Ontario Graduate Scholarship.

5:06PM V27.00012: Near-100% two-photon-like coincidence-visibility dip with classical light and the role of
complementarity  SIMANRAJ SADANA, DEBADRITA GHOSH, KAUSHIK JOARDER, NAGA LAKSHMI A, Raman Research
Institute, BARRY SANDERS, University of Calgary, URBASI SINHA (Presenter), Raman Research Institute — The famous Hong-Ou-
Mandel two-photon coincidence-visibility dip (TPCVD), which accepts one photon into each port of a balanced beam
splitter and yields an equal superposition of a biphoton from one output port and vacuum from the other port, has
numerous applications in photon-source characterization and to quantum metrology and quantum computing.
Exceeding 50% two-photon-coincidence visibility is widely believed to signify quantumness. In this talk, we show
theoretically that classical light can yield a 100% TPCVD for controlled randomly chosen relative phase between the two
beam-splitter input beams and experimentally demonstrate a 99.635 +/- 0.002% TPCVD with classical microwave fields.
We show quantumness emerges via complementarity for the biphoton by adding a second beam splitter to complete an
interferometer thereby testing whether the biphoton interferes with itself: Our quantum case shows the proper
complementarity trade-off whereas classical microwaves fail.
Out-of-time-ordered-correlator quasi-probabilities for the quantum kicked top* JOSE RAUL GONZALEZ ALONSO (Presenter), Chapman University, NATHAN SHAMMAH, RIKEN, SHAHNAWAZ AHMED, Chalmers University of Technology, FRANCO NORI, RIKEN/University of Michigan, JUSTIN G. DRESSEL, Chapman University — The cumulative nonclassicality of the quasi-probability distribution (QPD) behind the out-of-time-ordered correlator (OTOC) exhibits different time scales that have been conjectured to be useful for distinguishing integrable and nonintegrable Hamiltonians (arXiv: 1806.09637). We further investigate the QPD for a quantum kicked top, and use the time scales of its nonclassicality to understand the relationship between entanglement and chaos for different parameter regimes.

Thursday, March 7, 2019 2:30 PM - 5:06 PM

Session V28 DQI: Quantum Measurement with Amplifiers and Photon Detectors BCEC 161 -

2:30PM V28.00001: Achieving the Heisenberg limit in quantum metrology using quantum error correction* [Invited] LIANG JIANG (Presenter), Yale Univ — Quantum metrology has many important applications in science and technology, ranging from frequency spectroscopy to gravitational wave detection. Quantum mechanics imposes a fundamental limit on measurement precision, called the Heisenberg limit, which can be achieved for noiseless quantum systems, but is not achievable in general for systems subject to noise. We study how measurement precision can be enhanced through quantum error correction, a general method for protecting a quantum system from the damaging effects of noise. We find a necessary and sufficient condition for achieving the Heisenberg limit using quantum probes subject to Markovian noise, assuming that noiseless ancilla systems are available, and that fast, accurate quantum processing can be performed. When the sufficient condition is satisfied, a quantum error-correcting code can be constructed that suppresses the noise without obscuring the signal; the optimal code, achieving the best possible precision, can be found by solving a semidefinite program.

3:06PM V28.00002: Broadband Amplification and Squeezed Light Generation with Dispersion Engineered Josephson Metamaterial* JACK YANJIE QIU (Presenter), Massachusetts Institute of Technology, KEVIN O’BRIEN, University of California, Berkeley, Massachusetts Institute of Technology, ARNE GRIMSMO, University of Sydney, BHARATH KANNAN, YOUNGYU SUNG, PHILIP KRANTZ, Massachusetts Institute of Technology, GREG CALUSINE, VLADIMIR BOLKHOVSKY, MIT Lincoln Laboratory, TERRY PHILIP ORLANDO, Massachusetts Institute of Technology, IRFAN SIDDIQI, University of California, Berkeley, SIMON GUSTAVSSON, Massachusetts Institute of Technology, WILLIAM D OLIVER, MIT Lincoln Laboratory, Department of Physics, Massachusetts Institute of Technology — The generation of highly-squeezed states using superconducting amplifiers is a valuable tool for quantum optics and quantum metrology in the microwave domain. The high saturation power of these devices makes them promising candidates for generating highly squeezed states. In this talk, we present our latest results for operating in non-degenerate four wave mixing with dual dispersion engineered Josephson traveling wave parametric amplifier (JTWPA) and discuss our investigations of the JTWPA squeezing performance.

Ideal two-mode phase sensitive quantum amplifier: theory

ANJA METELMANN (Presenter), Dahlem Center for Complex Quantum Systems and Department of Physics, Free University Berlin, OLIVIA LANES, TZU-CHIAO CHIEN, XI CAO, GANGQIANG LIU, CHENXU LIU, DAVID PEKKER, Department of Physics and Astronomy, University of Pittsburgh, JOSE AUMENTADO, Boulder, National Institute of Standards and Technology, MICHAEL HATRIDGE, Department of Physics and Astronomy, University of Pittsburgh, AASHISH CLERK, Institute for Molecular Engineering, University of Chicago — Quantum-limited amplifiers are crucial for the processing of sensitive quantum information in the microwave world. The textbook (phase-sensitive) quantum-limited amplifier is a degenerate parametric amplifier with just a single mode, which comes with the disadvantage of having a fixed gain-bandwidth product and of no separation between input and output ports. One would think that adding a second mode to get separation between these ports would always be detrimental, as one introduces an extra degree of freedom and therewith extra noise. Here, we show this is not the case: one can have a two-mode phase-sensitive amplifier that is ideal with respect to a number of metrics: it has distinct input and output ports, no reflection gain, is quantum-limited and it does not suffer from a gain-bandwidth limit. Consequently it is more robust to pump-depletion effects. In addition, the here presented phase-sensitive amplifier produces squeezed output light with an enhanced bandwidth compared to single-mode squeezing setups. The proposed setup could easily be implemented in a range of different superconducting circuit architectures.

Ideal Two-Mode Phase Sensitive Quantum Amplifier: Experiment*

OLIVIA LANES (Presenter), TZU-CHIAO CHIEN, XI CAO, GANGQIANG LIU, CHENXU LIU, DAVID PEKKER, University of Pittsburgh, ANJA METELMANN, Physics, Freie Universitaet Berlin, AASHISH CLERK, Molecular Engineering, Institute for Molecular Engineering at the University of Chicago, JOSE AUMENTADO, NIST Boulder, MICHAEL HATRIDGE, University of Pittsburgh — Josephson parametric amplifiers, although nearly quantum limited, typically operate in reflection and have a fixed gain-bandwidth product. Recently, there have been both theoretical and experimental efforts to address these shortcomings by combining multiple parametric processes within a single multimode device. In this presentation, we focus on using multiple parametric processes to couple two modes of a Josephson Parametric Converter. We will present data which uses paired, detuned gain processes as well as two separate methods of combining gain and photon conversion, all in the same physical device. All three schemes avoid the fixed gain-bandwidth product of a singly pumped JPC. We will examine their relative bandwidth, efficiency, and saturation power, as well as the prospects for adding further couplings to a third mode to generate directional amplification.

How Hamiltonian non-linearities limit the performance of Josephson parametric amplifiers*

CHENXU LIU (Presenter), TZU-CHIAO CHIEN, MICHAEL HATRIDGE, DAVID PEKKER, Department of Physics and Astronomy, University of Pittsburgh — The implementation of a Josephson Parametric Amplifier with a large saturation power is an essential ingredient in achieving efficient signal detection in superconducting quantum computing circuits. Using numerical evolution of the classical non-linear equations of motion that describe a single non-degenerate gain process in a Josephson Parametric Converter (JPC), we analyze the factors limiting its performance. We demonstrate that the 3rd order coupling between the signal, idler and pump modes effectively generates a complex cross-Kerr term coupling the signal and idler modes, which can limit device saturation. By comparing properties of the full-nonlinear description of the JPC to descriptions truncated at third, fourth, and higher orders we identify which terms limit the device performance and how to optimize them.

Lumped, Single-ended Josephson Parametric Converters for Hamiltonian Engineering*

TZU-CHIAO CHIEN (Presenter), University of Pittsburgh, KATARINA CICAK, FLORENT LECOCQ, NIST-Boulder, OLIVIA LANES, XI CAO, CHENXU LIU, GANGQIANG LIU, DAVID PEKKER, University of Pittsburgh, JOSE AUMENTADO, NIST-Boulder, MICHAEL HATRIDGE, University of Pittsburgh — Quantum-limited parametric amplifiers have become a crucial tool for quantum information processing. However, they have limited bandwidth and saturation power and operate in reflection. We present a design and implementation of a lumped single ended design for the Josephson Parametric Converter (JPC) whose inductance is dominated by the central Josephson Ring Modulator (RM). Implementation of the JPC as a lumped circuit was facilitated by fabrication in a Nb/Al-AlOx/Nb tri-layer process incorporating a low-loss amorphous silicon dielectric. This design allows us to more easily engineer the device's Hamiltonian to control the amplitude of the JRM's three wave mixing terms which provide gain, and control higher order terms to enhance the saturation power and simplify operation as a directional multi-parametric amplifier.

4:06PM V28.00007: Quantum nonlinear dynamics of non-degenerate parametric amplification beyond the stiff-pump approximation  SAEED KHAN (Presenter), Princeton University, A. METELMANN, Physics, Freie Universität, HAKAN TURECI, Princeton University — In circuit QED, non-degenerate parametric amplification is commonly realized using Josephson Parametric Converter (JPC) based nonlinear circuits. While such systems are often studied within a linear stiff-pump approximation, their nonlinear dynamics become important for strong input signals, nonlinearity strengths, and large gain operation. We present a theoretical analysis of non-degenerate parametric amplification going beyond this stiff-pump approximation, in particular accounting for the quantum dynamics of the pump mode. Within a regime of weak quantum fluctuations, strongly amplified input signals dominate the depletion of the pump, and the associated compression of amplifier gain is characterized analytically. By further allowing for fluctuations in the pump mode, we find that interactions between the idler-signal subspace and the common pump mode in the nonlinear regime can strongly modify the noise properties of the amplifier. Finally, we analyze nonlinear dynamics in the regime of strong quantum fluctuations. Employing a reduced nonlinear two-mode description enables full quantum simulations in this regime where pump depletion can be strongly influenced by amplified vacuum fluctuations, leading to additional gain compression and added noise.

4:18PM V28.00008: Microwave photo-multiplication based on inelastic Cooper-pair tunneling  ROMAIN ALBERT (Presenter), FLORIAN BLANCHET, CEA Grenoble, DIBYENDU HAZRA, University of Aalto, JUHA LEPPÄKANGAS, Karlsruher Institut für Technologie, SALHA JEBARI, University of Oxford, MAX HOFHEINZ, University of Sherbrooke — When a Josephson junction is embedded in a low impedance circuit Cooper pair transport is usually elastic and the DC voltage across the junction has to be zero to allow for tunneling through the junction. By coupling a DC voltage-biased junction to a microwave circuit, the light-charge interaction enables inelastic charge transport with photon emission or absorption. The nonlinearity of this light-charge interaction can be tuned via the characteristic impedance of the microwave circuit and makes it possible to design sources of non-classical microwave radiation [Westig17, Grimm18], parametric amplifiers [Jebari18] or in our case, a photon multiplier [Leppäkangas18].

By designing particular high impedance electromagnetic environments, processes involving 3 or more photons can become dominant. In this case, we can show that the energy of a tunneling Cooper pair can be used to convert an incoming single photon state into a n-photon Fock state in a different mode. By cascading two of these multiplication stages followed by linear amplification, this device can discriminate itinerant single photon state from vacuum without dead time.

4:30PM V28.00009: A Superconducting Single Microwave Photon Detector Enabled by Dissipation Engineering - Theory*  EMMANUEL FLURIN (Presenter), Quantronics, CEA Saclay, RAPHAEL LESCANNE, LPA, Ecole Normale Superieure, SAMUEL DELEGLINE, LKB, Sorbonne Universités, ZAKI LEGHTAS, centre automatique et systèmes, Mines ParisTech — Superconducting circuits carry microwave photons five orders of magnitude lower in energy than photons of visible light. For their detection, one must bridge the gap between these low energy excitations and signals measurable by standard microwave electronics. In this work, we develop a new class of detectors, based on dissipation engineering, that perform quantum non demolition measurements of travelling microwave wavepackets. We fabricated and measured a single microwave photon detector that imprints on a transmon qubit the passage of a single photon without destroying it. The key advantage of this scheme is its intrinsic robustness against the main decoherence mechanisms found in these circuits, leading to both low dark counts, high detection efficiency and continuous operation, paving the way towards applications in quantum sensing and computing.

A Superconducting Single Microwave Photon Detector Enabled by Dissipation Engineering -
Experiment*  RAPHAEL LESCANNE (Presenter), LPA, Ecole Normale Superieure, EMMANUEL FLURIN, Quantronics, CEA Saclay, SAMUEL DELEGLISE, LKB, Sorbonne Université, ZAKI LEGHTAS, Centre Automatique et Systèmes, Mines ParisTech —
Superconducting circuits carry microwave photons five orders of magnitude lower in energy than photons of visible light. For their detection, one must bridge the gap between these low energy excitations and signals measurable by standard microwave electronics. In this work, we develop a new class of detectors, based on dissipation engineering, that perform quantum non demolition measurements of travelling microwave wavepackets. We fabricated and measured a single microwave photon detector that imprints on a transmon qubit the passage of a single photon without destroying it. The key advantage of this scheme is its intrinsic robustness against the main decoherence mechanisms found in these circuits, leading to both low dark counts, high detection efficiency and continuous operation, paving the way towards applications in quantum sensing and computing.

Detecting single-Infrared-photon by graphene Josephson junction*  KIN CHUNG FONG (Presenter), BBN Technologies, EVAN WALSH, MIT, GIL-HO LEE, POSTECH, DMITRI K. EFETOV, ICFO, WOO-CHAN JUNG, POSTECH, KO-FAN HUANG, Harvard University, THOMAS A OHKI, BBN Technologies, PHILIP KIM, Harvard University, DIRK R. ENGLUND, MIT — Single-photon detector is a key enabling technology in quantum information processing, cryotography, and deep space communication. However, detecting low frequency photons is challenging because of their vanishingly small energy. Here we will present the concept of a graphene-based Josephson junction single-photon detector that can potentially perform in a wide electromagnetic spectrum. We will focus on our experimental results of the Josephson junction switching induced by single-infrared-photon. We will conclude by its applications in quantum information science, radio astronomy, as well as dark matter detection.

Thursday, March 7, 2019 2:30 PM - 5:30 PM
Session V29 DQI: Hybrid Systems: Coupling to Ensembles and Single Electrons in Helium

Broadband electron spin resonance spectroscopy with a superconducting resonator, Part 1: Theory*  JEROME BOURASSA (Presenter), Département des Sciences de la Nature, Cégep de Granby, GREGORY BROOKES, Institut quantique and Département de Physique, Université de Sherbrooke, DANY LACHANCE-QUIRION, Research Center for Advanced Science and Technology, The University of Tokyo, DAVID ROY-GUAY, RAPHAËL LAFOND-MERCIER, Institut quantique and Département de Physique, Université de Sherbrooke, LÉO DESORMIERS, VINCENT BONNEAU, Département des Sciences de la Nature, Cégep de Granby, MICHEL PIORO-LADRIERE, Institut quantique and Département de Physique, Université de Sherbrooke — Electron spin resonance (ESR) spectroscopy is a useful tool for characterizing spin defects relevant to quantum technologies. Typical ESR systems are based on a resonant exchange interaction between the spins and a high-Q resonant cavity or resonator. While sensitive, the small magnetic-dipole coupling strength limits the ESR detection bandwidth in the dispersive regime and alternative coupling strategies must be used. One such strategy is to rely instead on a longitudinal interaction where the spin magnetization directly influences the resonator frequency, irrespective of the spin transition frequency.

In this talk, we show how we can realize such broadband spectroscopy of spin systems using high-kinetic-inductance superconducting resonators. We demonstrate that the longitudinal interaction is dominated by spins close to the resonator surface and discuss how the coupling strength and detection sensitivity can be optimized. This analysis paves the way towards a broadband ESR spectrometer suitable for novel quantum materials, as well as numerous other applications in chemistry, biology and material sciences.

*This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund and the Institut Transdisciplinaire de Recherche en Information Quantique.
We report experimental evidence of this longitudinal spin-resonator interaction where the resonator is affected by the spins polarization for detunings between the spin and the resonator larger than 1 GHz, where the contribution of the dispersive interaction is vanishing. In the specific implementation, numerical simulations show that the main contributions come from near-surface spins. This novel coupling can lead to new characterization tools and methods of quantum defects, complex quantum materials and many other paramagnetic systems.

Superradiant emission from colour centres in diamond

Superradiance is a fundamental collective effect where radiation is amplified by the coherence of multiple emitters. Superradiance plays a prominent role in optics (where it enables the design of lasers with substantially reduced linewidths) and quantum mechanics, and is even used to explain cosmological observations such as Hawking radiation from black holes. Superradiance plays a prominent role in optics (where it enables the design of lasers with substantially reduced linewidths) and quantum mechanics, and is even used to explain cosmological observations such as Hawking radiation from black holes.5. Resonators coupled to spin ensembles are promising future building blocks of integrated quantum devices that will involve superradiance. As such, it is important to study its fundamental properties within such devices. Although experiments in the strong-coupling regime have shown oscillatory behaviour in these systems, a clear signature of Dicke superradiance has so far been missing. Here we explore superradiance in a system composed of a three-dimensional lumped element resonator in the fast cavity limit inductively coupled to an inhomogeneously broadened ensemble of nitrogen–vacancy centres. We observe a superradiant pulse being emitted a trillion times faster than the decay for an individual nitrogen–vacancy centre. This is further confirmed by the nonlinear scaling of the emitted radiation intensity with respect to the ensemble size. Our work provides the foundation for future quantum technologies including solid-state superradiant masers.
4:06PM V29.00006: Electron spin hyperpolarization via radiative cooling  BARTOLO ALBANESE (Presenter), SEBASTIAN PROBST, VISHAL RANJAN, DENIS VION, EMANUEL FLURIN, DANIEL ESTEVE, Quantronics, SPEC, CEA-Saclay, JOHN MORTON, University College London, GENGLI ZHANG, REN-BAO LIU, Chinese University of Hong Kong, PATRICE BERTET, Quantronics, SPEC, CEA-Saclay — Electron spin resonance (ESR) spectroscopy is widely employed for the detection and characterization of paramagnetic species [1]. A high degree of spin polarization is essential to maximize the signal. Here, we are interested in increasing the polarization beyond thermal equilibrium. Techniques such as optical pumping are available only for systems with special electronic structures. In the present work we give a proof of principle of a new universal hyperpolarization scheme based on the coupling of the electron spins to a colder electromagnetic bath via Purcell-enhanced radiative relaxation. A superconducting micro-resonator is used in order to reach the regime in which radiative relaxation constitutes the dominant mechanism of spin thermalization [2]. The spin system under study is an ensemble of bismuth donors implanted into a host silicon crystal. The sample is installed at the 800 mK stage of a dilution cryostat while the resonator is coupled via a switch either to a 10 mK or to a 800 mK thermal source. When the switch is connected to the colder black body, the electronic spins are cooled via radiative relaxation while the silicon crystal remains at 800 mK. [1] A. Schweiger and G. Jeschke, Oxford University Press (2001) [2] A. Bienfait et al., Nature 531, 74-77 (2016)

3:54PM V29.00006: Coherent spin-wave excitations in an optically cooled nuclear ensemble  DORIAN GANGLOFF (Presenter), GABRIEL ETHIER-MAJCHER, CONSTANTIN LANG, University of Cambridge, EMIL VOSMAR DENNING, Photonics Engineering, Technical University of Denmark, JONATHAN BODEY, DANIEL JACKSON, CLAIRE LE GALL, METE ATATURE, University of Cambridge — Collective excitations of isolated many-body systems offer the opportunity to control complex quantum dynamics. A simple quantum system, such as a central spin, can act as a probe and a control over a larger and more complex quantum system in ways otherwise intractable, and can help us perform spectroscopy and engineering over its quantum dynamics. Driving the central spin can stimulate exchange of energy with its surrounding spins, and thus modify the mean-field state of its own environment. In this work, we engineer this very interaction between an InGaAs quantum dot electron spin and its isolated ensemble of nuclear spins in a driven-dissipative regime to remove entropic heat from the ensemble, and so vastly reduce the mean-field state uncertainty tied to its thermal fluctuations. Having cooled the system, we reveal an absorption spectrum of transitions between many-body states that are collectively-enhanced by the creation of single spin-wave excitations – nuclear magnons. Resonantly driving such a transition, we stimulate coherent exchange of single magnons between the electron and the nuclear spin ensemble, which is consistent with the controlled creation of entanglement among all constituent particles.

4:06PM V29.00006: High-Q Superconducting Mm-wave Cavities for Rydberg Cavity Quantum Electrodynamics.*  AZIZA SULEYMANZADE (Presenter), ALEXANDER ANFEROV, MARK STONE, JONATHAN SIMON, DAVID SCHUSTER, University of Chicago — We will outline our progress towards a cryogenic hybrid experimental system for engineering strong interactions between single optical and mm-wave photons using Rydberg atoms as an interface. Bulk 3D cavities in the microwave regime routinely reach quality factors above 10^7 at single photon powers and even in some case as high as 10^10. At the same time there has been far less study of resonators at millimeter wave frequencies close to 100GHz. We present experimental results of superconducting fundamental mode niobium cavities at 100GHz, with quality factors exceeding 10^7. We will also present experiments showing tuning the cavity frequency in-situ, to be able to exactly match Rydberg transitions.

*MURI, MRSEC

4:18PM V29.00008: Accessing Nonlinearity in Superconducting Millimeter Wave Coplanar Resonators*  ALEXANDER ANFEROV (Presenter), AZIZA SULEYMANZADE, JONATHAN SIMON, DAVID SCHUSTER, University of Chicago — Current superconducting quantum systems rely on ultra-cold temperatures to reduce sources of noise and quantum decoherence. While many advances have been made in the purification and refinement of quantum devices in the low microwave frequency range, millimeter frequencies have been far less explored. Using higher energy photons as a building block could potentially allow quantum experiments to be run faster, at higher temperatures, and easily access other high frequency quantum systems, such as Rydberg atoms. We use superconducting thin film materials to fabricate resonators with planar geometries to ensure scalability and direct compatibility with other elements in the superconducting quantum toolbox, while gaining a natural increase of kinetic inductance based nonlinear effects with frequency. Here, we present and characterize low-loss millimeter wave resonators with planar geometries exhibiting nonlinear behavior, demonstrating a scalable core component for a new generation of high frequency quantum devices.

**4:30PM V29.00009: Coupling a single electron on helium to a superconducting resonator**

GERWIN KOOLSTRA (Presenter), GE I YANG, DAVID SCHUSTER, University of Chicago — Electrons on helium is a unique two-dimensional system on the interface of superfluid He-4 and vacuum. Both the motional state and spin state of a single electron on helium have been proposed as candidates for long-lived qubits. To trap a single electron on helium, we use a small electrostatic trap located at the voltage anti-node of a superconducting microwave resonator. By adjusting the trap potential we are able to consistently load between one and four electrons and detect their spectroscopic features through the resonator. In particular, in the single electron regime a large resonator frequency shift reveals when the electron motional frequency is resonant and allows us to extract an electron-photon coupling of ~ 10 MHz. I will highlight our latest experiments leading towards the development of an electron on helium qubit.

*Support was provided by the Chicago MRSEC, which is funded by NSF through grant DMR-1420709 and the DOE Office of Basic Energy Sciences*

**4:42PM V29.00010: Thermopower based hot electron thermometry of helium surface states at 1.6 K**

ETHAN KLEINBAUM (Presenter), STEPHEN APLIN LYON, Princeton University — Inelastic scattering processes are crucial for understanding and describing a wide variety of phenomena observed in surface state electrons (SSE) on helium including non-linear transport and microwave absorption line shapes. Further interest in inelastic scattering has been motivated by the relevance to coherence times of Rydberg state based SSE qubits. Despite their fundamental importance, relatively little experimental work have examined inelastic processes which can be attributed to challenges associated with electron thermometry of hot SSE.

We have developed a method to probe SSE temperature using the Seebeck effect. We demonstrate the use of this technique by measuring SSE temperature as a function of applied power at a bath temperature of 1.6 K in a microchannel device with 0.6 μm deep helium. We compare our measurements to the predictions for both vapor atom and 2-ripplon scattering in the single electron regime. Our measurements demonstrate a strong qualitative agreement with the predictions and we attribute small quantitative discrepancies to many body effects. We conclude that this technique provides a reliable and flexible measure of electron temperature.

*This research was supported by the NSF (Grant No. DMR-1506862).*

**4:54PM V29.00011: Phase transitions in a strongly interacting electron system under confinement**

NIYAZ BEYSENGULOV (Presenter), Michigan State Univ, DAVID G REES, Cryogenic Ltd., London, United Kingdom, MIKHAIL ZAKHAROV, Institute of Physics, Kazan Federal University, Kazan, Russia, YURIII LYSOGORSKIY, ICAMS, Ruhr-Universitat Bochum, Bochum, Germany, KIMITOSHI KONO, Department of Electrophysics, National Chiao Tung University, Hsinchu 300, Taiwan, DMITRII TAYURSKII, Institute of Physics, Kazan Federal University, Kazan, Russia — Phase transition in a two-dimensional lattice is described by a Berezinskii-Kosterlitz-Thouless (BKT) mechanism. At low temperatures the ground state of strongly interacting 2D electron system is a Wigner solid, which was experimentally observed in a many experiments with electrons on the surface of liquid helium. A well controlled system of electrons on liquid helium provide an excellent platform to investigate a many-body phenomena. Here we investigate the influence of a quasi-one-dimensional confinement on the structural order and melting of electrons on helium experimentally and by numerical simulations. In the experiments electrons are confined by electrostatic potential in a microchannel structures. By tuning voltages on gate electrodes we were able to demonstrate the control of number of electron rows (from a single chain up to 25 rows). We show that for small number of rows gamma parameter (the ratio of Coulomb energy to thermal energy) is suppressed, while for large number of rows a BKT theory prediction is recovered. We compare the results with molecular dynamics simulations. The temperature dependence of topological defects density, translational correlation function and structure factor were calculated and discussed in the context of BKT transition.
5:06PM V29.00012: Transport measurements of electrons above shallow helium-filled microchannels

ABRAHAM ASFAW (Presenter), ETHAN KLEINBAUM, STEPHEN APLIN LYON, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544, USA — The spins of electrons floating on superfluid helium constitute a promising platform for quantum computation. Quantum devices for electrons on helium, such as electrostatically defined quantum dots, require gate electrodes that are patterned beneath thin helium films. This can be particularly challenging at helium depths below 1 μm, since the electrons can be trapped by potential fluctuations on the surface of the gate electrode resulting from surface roughness and variations in the work function.

In this talk, we report transport measurements of electrons on helium in a microchannel device where the channels are 200 nm deep and 3 μm wide. The channels are fabricated above amorphous metallic TaWSi, which has surface roughness below 1 nm and minimal variations in work function across the surface due to the absence of polycrystalline grains. We are able to set the electron density in the channels using a ground plane, obtaining electron densities as high as $2.56 \times 10^9$ cm$^{-2}$. We also demonstrate control of the transport using a barrier which enables pinchoff at a central microchannel connecting two reservoirs. The mobility of electron transport through the central microchannel is at least 300 cm$^2$/Vs.

*This research was supported by the NSF (Grant Nos. DMR-1506862 and DMR-1420541).

5:18PM V29.00013: Acoustoelectric transport of electrons on helium

HEEJUN BYEON (Presenter), KOSTYANTYN NASYEDKIN, JUSTIN LANE, NIYAZ BEYSENGULOV, REZA LOLOEE, JOHANNES POLLANEN, Michigan State Univ — We report on the acoustoelectric transport of electrons on helium induced by coupling to piezoelectric surface acoustic waves (SAWs). In our device, the SAWs propagate along the surface of a lithium niobate piezoelectric crystal that is submerged beneath a thin layer of superfluid $^4$He. Electrons are deposited onto the superfluid and float ~10 nm above its surface. When SAWs propagate along the lithium niobate substrate, electrons are trapped in the moving electric potential of the SAW and transported across the device at the speed of the piezoooustic wave. Electrodes positioned beneath the lithium niobate capacitively couple to the electrons and are used to detect acoustoelectric transport. We have performed time and frequency domain measurements and analysis to characterize the electric current dragged along by the SAW. To our knowledge, these measurements constitute the first demonstration of acoustoelectric charging pumping of electrons on helium.

Session V31 DCP: Surfaces and Adsorbates (SA) BCEC 203 - Silvina Gatica, Howard University - Tag(s): Focus

2:30PM V31.00001: TBD [Invited] SVETLANA MINTOVA (Presenter), University of Caen, France — TBD

3:06PM V31.00002: Methane Adsorption on Zeolitic Imidazolate Framework -8 (ZIF-8) DINUKA HAR GALLABA (Presenter), ALDO DANTE MIGONE, Department of Physics, Southern Illinois University Carbondale — Zeolitic Imidazolate frameworks (ZIFs) are porous Metal Organic Framework materials that have zeolite-like structures. ZIF -8 has shown structural transition when adsorbing gas molecules, this leads to increment in loading. This has been previously observed with N$_2$, CO, O$_2$ and Xe adsorption. Adsorption studies of energy related gasses are great significant to the petroleum and automotive industries. Among those gasses methane is a good alternative to petroleum based fuels. We present the results of an experimental study of methane sorption in ZIF-8. We measured isotherms at five different temperatures between ~ 85 K and 107 K. We have observed three sub-steps in each of the isotherms. The intermediate sub-step had not been observed experimentally in previous studies of this system. We measured a sharp increase in the equilibration times at loadings corresponding to the intermediate sub-step in the isotherms. We have explored the isosteric heat of adsorption, and its dependence on sorbent loading, for this system.
3:18PM V31.00003: Improving the Adsorption Selectivity of CO₂/CH₄ by Strength, Shape and Kinetics*  
SILVINA GATICA (Presenter), Physics and Astronomy, Howard University — Gas separation by adsorption can be accomplished by three basic physical mechanisms: equilibria, kinetics, and steric effects. Equilibrium mechanisms rely on the strength of attraction between gas molecules and their substrate. For example, the interaction of CO₂ with a substrate is usually stronger than methane-substrate. As a result, the equilibrium mechanism presents a plausible strategy to separate carbon dioxide from mixtures. We have studied the adsorption of CO₂/CH₄ mixtures on various substrates by Monte Carlo and Molecular Dynamics simulations. Our findings show that on substrates including MOFs, carbon nanohorns and graphene, the selectivity of adsorption of CO₂/CH₄ at room temperature is low (near 1). We explore the kinetics and steric effects on the selectivity, finding that the combination of the three above-mentioned mechanisms can significantly boost the CO₂/CH₄ separation at 300K. In this talk, I will present a review of the various cases studied.

3:30PM V31.00004: Hydrogen Adsorption on Pt(111) Revisited from Random Phase Approximation  
LEI YAN (Presenter), Institute for Solid State Physics, The University of Tokyo, YANG SUN, Global Research Center for Environment and Energy Based on Nanomaterials Science, National Institute for Materials Science, YOSHIYUKI YAMAMOTO, SHUSUKE KASAMATSU, Institute for Solid State Physics, The University of Tokyo, IKUTARO HAMADA, Global Research Center for Environment and Energy Based on Nanomaterials Science, National Institute for Materials Science, OSAMU SUGINO, Institute for Solid State Physics, The University of Tokyo — It is generally believed that H is predominantly adsorbed on the fcc site of Pt(111), as supported by the calculations using density functional theory (DFT) within generalized gradient approximation (GGA). Experiments, however, observe the signal from the top site. Similar problem exists in CO/Pt(111), where GGA is known to wrongly predict the fcc site as the most stable site, for which a correct answer was given recently using a more advanced correlation functional called random phase approximation (RPA). Here we attack this H/Pt(111) problem using DFT-RPA [1]. By using DFT within the exchange-correlation functionals of different level, we evaluate the stability of fcc adsorption site relative to the top site. The most advanced one based on the RPA, is found to revise our knowledge so far derived from the conventional functionals. Two adsorption sites are hereby found to compete sensitively depending on lattice spacing of the surface, mass of the hydrogen isotope, and hydrogen coverage. The revised knowledge provides natural explanation for the controversy regarding the electrochemical and spectroscopic data, giving impact on the research on the fuel-cell reaction mechanism.

3:42PM V31.00005: ADSORPTION OF PHENOL IN ZEOLITES: MULTI-TECHNIQUE MODELING  
HICHAM JABRAQUI (Presenter), University of Lorraine, GUILLAUME MAURIN, Institut Charles Gerhardt Montpellier (ICGM), Université de Montpellier, SÉBASTIEN LEBÈGUE, University of Lorraine, IBRAHIM KHALIL, KARINE THOMAS, FRANCOISE MAUGÉ, Université de Caen Normandie, MICHAEL BADAWI, University of Lorraine — Protonated zeolites were explored as effective adsorbent materials for removing phenol from biofuels using multi-scale modeling. Here, we used a powerful combination of the multiple modeling techniques: i) Density Functional Theory (DFT) [1],[2] allows to determine binding energies of several configurations of guest molecule in zeolites ii) Grand Canonical Monte Carlo (GCMC) [3],[4] shows how much molecules can zeolite hold, i.e. the adsorption capacity as intermolecular interactions at high loading, iii) ReaxFF Molecular Dynamics (RFF-MD) [5] allows knowing both the mobility of molecules within the zeolite framework, and the structure of molecule-loaded faujasite. The obtained results are compared with those measured by different experimental tools (Infrared Spectroscopy, breakthrough curves, and desorption experiments). We will show that USY zeolites provide a good regenerability of the zeolites as a high adsorption capacity.

3:54PM V31.00006: Adsorption and Separation of CO2 and CH4 Gas Mixture in a Graphene Layer and a Graphite Surface* HIND ALJADDANI (Presenter), SILVINA GATICA, Howard University — The goal of this work is to predict the selective adsorption of CO2 from a mixture with CH4 on a graphene/graphite substrate. The substrate consists on a layer of graphene with slits suspended on top of graphite at a distance of 10 Å. Molecular dynamics was used to simulate this adsorption. In this system, methane is modeled as a single, spherical atom with one Lennard-Jones site. Carbon dioxide is modeled as a linear rigid body with three Lennard-Jones sites and three partial charges. The slits in graphene are made by deleting carbon atoms from the lattice within a region of specified width. Graphite is modeled as a 10-4-3 wall. We run the simulations at 300K and compare the selectivity of CO2/CH4 on the substrate to test the capability of the graphene/graphite to separate CO2 from CH4. The result shows that the selectivity is higher for narrow slits.

4:06PM V31.00007: Impact of nuclear vibrations on van der Waals interactions and radiative heat transfer in graphene PRASHANTH VENKATARAM (Presenter), Princeton University, JAN HERMANN, University of Luxembourg, TEERIT VONKOVIT, Princeton University, ALEXANDRE TKATCHENKO, University of Luxembourg, ALEJANDRO RODRIGUEZ, Princeton University — We apply a recent theoretical framework describing thermal and quantum electromagnetic phenomena arising from the coupling of photons and phonons in molecular systems, including van der Waals interactions and radiative heat transfer, to interactions among parallel sheets of neutral graphene and metallic substrates. In particular, we show that atom-scale features as well as contributions of phonons to the response of graphene, as captured in ab-initio density functional theory calculations, along with long-range retarded electromagnetic fields, are of utmost importance to describing its van der Waals interactions and radiative heat transfer over a broad range of length scales; interactions no longer behave as simple power laws in terms of surface separation and show noticeable temperature sensitivity at separations well below the micron-scale radiative thermal wavelength. The contributions of phonons and atom-scale effects to the response are largely neglected in continuum treatments of the electromagnetic response of neutral graphene, which typically consider only the electronic contributions to the response derived from a tight-binding model; consequently, we observe significant differences in the predictions of our microscopic framework from such macroscopic treatments.

4:18PM V31.00008: Pseudo-Palladium alloys for catalytic applications* MIKAEL RÅSANDER (Presenter), J. ANDREAS LARSSON, Department of Engineering Sciences and Mathematics, Luleå University of Technology — Palladium is a commonly used catalyst for the formation of C-C, C-O and C-N bonds in pharmaceutical manufacturing. However, Palladium is expensive which results in high production costs. In this project, we have used computational modelling based on density functional theory to search for possible combinations of elements which mimic the behavior of Palladium in order to lower the cost of production. We have investigated both bulk as well as nanoparticles of, e.g., Rh0.5Ag0.5, Pd1-xCu x and Pd1-xAgx alloyed systems and found that these systems have Palladium-like electronic properties and are therefore expected to have similar catalytic properties as pure Palladium. The Pd1-xCu x and Pd1-xAgx systems have Palladium-like electronic structures up to about 25% Cu or Ag, respectively.

4:30PM V31.00009: Influence of inter-crystalline space on diffusion in zeolites: A molecular dynamics investigation* ANGELA THOMAS (Presenter), YASHONATH SUBRAMANIAN, Indian Institute of Science — Understanding the difference in diffusivities of guest molecules in zeolites obtained from different techniques has always been a challenge. The diffusivity values, $D_{\text{P}}$, measured using methods like uptake or PFG-NMR are often smaller by several orders of magnitude than those measured using methods like QENS or MD simulations. In order to understand the underlying reason for this reduction in $D_{\text{P}}$, molecular dynamics simulations of xenon atoms have been carried out in zeolite systems where an inter-crystalline space is introduced along the x-axis. It is seen that the $D_{\text{P}}$ in these systems are significantly altered by the presence of the inter-crystalline space and the value is smaller compared to the other axes, which reduces the total effective $D_{\text{P}}$ when compared to a purely intra-crystalline diffusion. Interestingly, in the intercrystalline space, $D_{\text{P}}$ along y- and z-axes are higher and exhibit ballistic motion. Diffusion measurement techniques of shorter timescales (QENS or MD) generally obtain $D_{\text{P}}$, which are higher as the guest molecules sample intra-crystalline space during these timescales, while in longer timescale methods (e.g., PFG-NMR or uptake) guests manage to sample both the intra- and inter-crystalline space leading to lower values for diffusivities.

4:42PM V31.00010: Theoretical Studies of Activation Energies and Pre-Exponential Factors of Alcohol Dehydrogenation on Cu*  WEI CHEN (Presenter), ROBERT J. MADIX, CYNTHIA M. FRIEND, EFTHIMIOS KAXIRAS, Harvard University — We study the thermodynamic and kinetic processes involved in the anhydrous dehydrogenation of linear-chain alcohols on the Cu(110) surface using multiscale approaches. We determine the kinetic barriers for the two dehydrogenation steps, namely, the O–H and the subsequent C–H bond-breaking on Cu. The reaction of methoxy-to-formaldehyde has a rather high-energy transition state, in contrast to that of alkoxide-to-aldehyde in the longer-chain systems. This difference qualitatively explains the lower production efficiency of formaldehyde on Cu. We also use a Monte Carlo sampling to calculate the entropies of initial and transition states. The estimated pre-exponential factors, beyond the harmonic approximation, are found to have a molecular size dependence.

4:54PM V31.00011: Kinetics of ligands mediated ultra-small silver cluster formation. MOHSEN FARSHAD (Presenter), DYLAN SUVLU, JAYENDRAN C RASAIAH, University of Maine — We discuss a kinetic mechanism that predicts different average size distributions of silver clusters with peak diameters around 0.7 nm and 1.2 nm in solution depending on the initial conditions in a redox reaction. Nanoparticle growth occurs through ligand addition and elimination followed by irreversible dimerization and reversible ligand-monomer addition to the seed cluster. We have also incorporated the coalescence of clusters which can dominate the growth of silver nanoparticles in the presence of a strong reductant. Our calculations provide further insight into the mechanistic details of ultra-small silver cluster formation from an atomic perspective.

5:06PM V31.00012: Boron-doped silicene as a promising anode for Li-ion batteries* ALEX CHEN (Presenter), XUAN LUO, National Graphene Research and Development Center — Two-dimensional (2D) materials as electrodes are the trend for future Li-ion battery technology. By using first-principles calculations, we investigate the adsorption of Li-ions on boron-doped silicene as a potential electrode material. We identified the most stable adsorption sites and their corresponding adsorption energies for the adsorption of Li adatoms on the doped silicene. Then, we increase the ion concentration to examine the impact of Li-ions on the stability and structure of the material. With Bader charge analysis, we confirm the charge transfer from the Li-ion to doped silicene and use that to calculate a high specific capacity for the B-doped silicene. We then used the nudged elastic band method to analyze the energy barriers of Li-ion diffusion along the surface and through the hexagonal hollow of the monolayer. Our findings reveal the potential application of B-doped silicene as an electrode material in lithium batteries.

*This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

5:18PM V31.00013: Direct Determination of the Thermodynamic Properties of Melting for Amino Acids* YEONG ZEN CHUA (Presenter), AMIR ABDELAZIZ, DZMITRY ZAITSAU, SERGEY VEREVKIN, University of Rostock, CHRISTOPH HELD, TU Dortmund University, CHRISTOPH SCHICK, University of Rostock — The properties of melting are used for the prediction of solubility of solid compounds. Unfortunately, by using the conventional DSC or adiabatic calorimetry direct determination of the melting enthalpy and melting temperature is often not possible for biological compounds due to the decomposition during the measurement. The apparent activation energy of decomposition is at least one order of magnitude smaller than that of melting. This allows shifting of the decomposition process to higher temperature without seriously disturbing the melting by applying very high heating rates. High scanning rates up to 2×10^4 K s^{-1} are utilized with fast-scanning calorimeter Mettler Toledo Flash DSC1, which employs thin film chip sensors with sub µJ K^{-1} addenda heat capacities. With the help of this technique the melting parameters for a series of amino acids were successfully determined. The ultra-fast cooling of the melted samples allows the studied compounds to retain in the liquid state and to determine for the first time its glass transition temperatures. The results are in reasonable agreement with the simulated PC-SAFT values.

Session V34 FIAP: Innovations from Industry BCEC 205A - Steven Lambert, American Physical Society - Tag(s): Careers, Industry, Invited, Undergraduate
2:30PM V34.00001: Innovations from Texas Instruments Inc. DLP® Products Division: M7 – MEMS Mirrors Moving in Many Modes for a Multitude of Markets [Invited] PATRICK ODEN (Presenter), DLP(R) Products Division, Texas Instruments Inc. — For nearly a quarter century of commercial manufacturing, the Microelectromechanical Systems (MEMS)-based micro-mirrors produced by Texas Instruments Inc. have, by necessity, needed to innovate to stay relevant to various market demands. The highlights of which will be addressed here as well as a discussion of potential innovations to come. I will also share my thoughts on how Physicists trained in solid-state, surface-science, like myself, can contribute to the future of this technology.

3:06PM V34.00002: Next Generation Technology from Google AI Quantum [Invited] ALAN HO (Presenter), Google Inc., Santa Barbara — Alan Ho, product manager from Google AI Quantum, will provide an overview of recent hardware, algorithms, and software developments at Google. He will first provide an overview of Google's superconducting qubits, and highlight the differences between its digital and analog computing architectures. For software, Alan will give an overview of its recent progress on its open source packages - Cirq and OpenFermion, and how physicists can get started to programming a quantum computer.

Alan will also review collaboration research and funding opportunities at Google. He will provide an overview of recent academic partnerships and government partnerships, and the research that has resulted from it. He will also discuss funding opportunities at Google including Ph.D fellowships, internships, Faculty and Focus Award grants. Finally, he will then provide information on how physicists can get access to Google’s experimental hardware.

3:42PM V34.00003: The Economic Impact of Industrial Physics on the U.S. Economy: What value we physicists bring to economic activity [Invited] JOHN RUMBLE (Presenter), R&R Data Services — The American Physical Society, with support from the American Institute of Physics, recently sponsored an in-depth analysis of the impact of industrial physics on the U.S. economy. This report attempts to provide quantitative answers to the specific question: How does industrial physics impact the economy of the United States? Posing the question this way allows us to consider the four major ways that physics contributes to the economy: (1) The direct hire of college-trained physicists of all degrees; (2) Physics as an essential element in the training of scientists and engineers who work in industry; (3) The use of physical principles in the technology that creates products and services; and (4) The emergence of new physics that drives disruptive changes to the economy. The study shows that in 2016 an estimated 12.6% of the U.S. economy (2.3 trillion dollars) with direct employment of about 11,500,000 people can be ascribed directly to the practice of industrial physics. In this talk, the complete results are presented with a discussion of economic analysis methodology and the assumptions made. We provide concrete data on the creation of jobs, investments in the future, and the impact on tax receipts in the period from after World War II to the present day (2016). We present evidence of the creativity that physics brings to industry and the economy, as well as draw conclusions on why this has happened. The data confirm what we inherently know from our knowledge of modern physics – that since the end of World War II, physics discoveries of the twentieth century have been transformed by industrial physicists into incredible products and services. The flow of physics into industry is neither stopping, nor even slowing down as new disruptive products and services continue to emerge. We provide recommendations for academia, industry, government funding agencies and APS itself about how they can support industrial physics in the future.

4:18PM V34.00004: How IBM Research is Enabling the Internet of Things [Invited] HEIKE RIEL (Presenter), Thomas J. Watson Research Center, IBM — TBD
Invited] ALEXANDER JOHN MAJEWSKI (Presenter), United Technologies Research Center — A career path in industry focuses on various products and applications and requires an in-depth knowledge of physics as well as system phenomenology. One topical area of particular interest in industry is sensors. Optical sensors are a broad class of devices for detecting light amplitude, intensity and/or phase. These sensors can range from simple devices (detectors) for threshold detection or a highly complicated system for detecting single photons, measuring the phase variation (wave-front) of an optical system, or a spectrometer used in characterizing the spectral signature of a material.

Optical sensing can encode photons – either through intensity and/or phase, in a temporal and/or spatial manner; e.g. interferometers. These optical sensors and sensing techniques are used in various optical systems with widespread applications in instrumentation, signal processing, spectroscopy, and imaging. They present many design and performance challenges: knowledge of optical, material, and environmental properties that effect sensor performance.

Optical sensors range from micro-probes to large devices used for standoff monitoring and operate across a vast region of the electromagnetic spectrum, from THz to X-rays and are deployed on systems operating in environments from ground to space. An overview of optical sensors and systems with an example of THz chemical detection spectrometers will be presented.

Thursday, March 7, 2019 2:30 PM - 5:30 PM

Session V35 DQI: Materials and Fabrication for Superconducting Qubits

2:30PM V35.00001: A New Technique to Measure Microwave Dielectric Material Loss* KAICHEING LI (Presenter), CHRISTOPHER J AXLINE, LUKE BURKHART, BENJAMIN CHAPMAN, CHAN U LEI, VIJAY JAIN, LEV KRAYZMAN, PHILIP REINHOLD, LUIGI FRUNZIO, ROBERT J SCHOELKOPF, Yale Univ — Qubit coherence time is essential in quantum computation, since, in tandem with gate speed, it governs the number of coherent operations one can eventually perform on a quantum computer. In the field of circuit quantum electrodynamics, a qubit is often formed by the non-linearity of a Josephson junction fabricated on a dielectric substrate. Therefore, any dielectric loss in the substrate can be an important contribution to qubit coherence. Indeed, recent studies suggest that among different qubit loss channels dielectric loss may be a substantial one. In this talk, we describe a sensitive method to selectively measure microwave dielectric substrate loss and present preliminary measurements with the technique.

*This research is supported by US Army Research Office grant W911NF-18-1-0212 and W911NF-16-1-0349, and Air Force Office of Scientific Research grant FA9550-15-1-0015.

2:42PM V35.00002: Atomic defects in silicon compared with standard two-level defects LIUQI YU (Presenter), Laboratory for Physical Sciences, College Park, MD, Y. J. ROSEN, Lawrence Livermore National Laboratory, Livermore, CA, KEVIN DANIEL OSBORN, Laboratory for Physical Sciences, College Park, MD — Atomic two-level systems (TLSs) in materials affect the performance of superconducting quantum devices and new fundamental studies are needed to better understand them. It was found\(^1\)\(^2\) that the TLS bath, initially saturated by the microwave field excitations, can undergo adiabatic transitions when an additional sweeping fields is applied. Although more TLSs would remain in the ground state, the overall rate of TLSs absorbing the microwave field, increases as the sweep rate is increased due to the increase in TLS crossings in the standard distribution. It leads to a universal plateau in non-equilibrium loss equal to the intrinsic linear dielectric loss at the low power limit. Here, we extend the measurements by using a new dielectric which is important in light of qubit substrates and semiconductor qubit devices: amorphous silicon. Quite surprisingly, the loss tangent reveals a second increases in loss with increasing bias rate. The data will be compared to previous data which fit the standard TLS model. We plan to verify the phenomenon with further studies.

2:54PM V35.00003: Atomic Layer Deposition of Titanium Nitride for Quantum Circuits* ABIGAIL SHEARROW (Presenter), GERWIN KOOLSTRA, SAMUEL WHITELEY, NATHAN D EARNEST, PETER BARRY, University of Chicago, JOSEPH HEREMANS, Argonne National Laboratory, DAVID AWSCHALOM, ERIK SHIROKOFF, DAVID SCHUSTER, University of Chicago — High kinetic inductance thin films are of great interest for superconducting detectors, coupling to hybrid systems, and novel superconducting qubits. We demonstrate that titanium nitride thin films grown via plasma-enhanced atomic layer deposition support superconducting microwave resonators with internal quality factors up to 1.0 million at single photon powers, and find that the dominant loss mechanism in these resonators is likely due to two-level systems. Utilizing nanowire geometries, we realize characteristic impedances greater than a resistance quantum with $Z \approx 28 \, \text{k}\Omega$ while maintaining low losses and a compact device footprint ($8 \times 8 \, \mu\text{m}^2$). The corresponding increase in zero point voltage fluctuations makes this material an excellent candidate for integration into hybrid quantum systems and quantum sensing.

*This research was supported by the Army Research Office under contract W911NF-17-C-0024. Support was provided by the Chicago MRSEC, which is funded by NSF through grant DMR-1420709.

3:06PM V35.00004: Fabrication of Sn-Cu alloy superconducting films for filled superconducting through-silicon vias* GO FUJII (Presenter), MASASHI UKIBE, KAZUMASA MAKISE, MUTSUO HIDAKA, SHUICHI NAGASAWA, HIROTKE YAMAMORI, KUNIHIRO INOMATA, TAKAHIRO YAMADA, SHIRO KAWABATA, National Institute of Advanced Industrial Science and Technology — Quantum annealing (QA) is one of quantum computers to solve combinatorial optimization and sampling problems. We have developed new three-dimensional (3D) packaging structure, which obtain a scalability and a flexibility in the circuit size to realize customized circuits for solved problems by stacking qubit-chip, interposer, and package-substrate as much as necessary. In the 3D packaging, superconducting TSVs are necessary because generating heat in through-silicon vias (TSVs) used to connect the qubit and the package-substrate is a big problem. So far, we have fabricated superconducting TSVs with pure Sn, however, fabrication yield of the TSVs was low because it was difficult to fill the Sn in deep holes by electroplating process (EP). In this work, we have changed the material from the Sn to Sn-Cu alloy to solve the above problem. A Sn$_9$-Cu alloy film fabricated by the EP exhibited transition temperature ($T_c$) of 2.4 K. Although the $T_c$ of the Sn$_9$-Cu alloy is about 30 % lower than that of the pure Sn, it is sufficient for our QA machine system.

*This is based on results obtained from a project commissioned by the New Energy and Industrial Technology Development Organization (NEDO). A part of this work was conducted in Waseda University, supported by Nanotechnology Platform Program.

3:18PM V35.00005: Fabrication of superconducting qubits using free-standing mineral masks* IOANNIS TSIOUTSIOS (Presenter), KYLE SERNIAK, ZHIXIN WANG, SHYAM SHANKAR, LUIGI FRUNZIO, ROBERT SCHOELKOPF, MICHEL H. DEVORET, Applied Physics, Yale University — Over the last years there has been a significant improvement on the energy relaxation properties of superconducting qubits. State-of-the-art transmon and fluxonium qubits exhibit energy relaxation times in the order of hundreds of microseconds and few milliseconds respectively. Progress in their design has resulted in minimizing losses coming from the dielectric environment and radiation into the electromagnetic environment, in addition to gains due to better understanding and control of their inductive losses. However, advancements on reducing dielectric losses associated with organic residues produced by traditional fabrication techniques have been modest. In this talk, we will propose a new fabrication technology for planar superconducting circuits that replaces the commonly used resist-based lithography masks with free-standing mineral masks. Furthermore, we will present preliminary results on the energy relaxation properties and reproducibility of transmon qubits that are fabricated using this new method.

*ARO, ONR, NSF, AFOSR, and YINQE

3:30PM V35.00006: MBE grown AlN-TiN heterostructures for superconducting quantum circuits CHRISTOPHER RICHARDSON (Presenter), ASHISH ALEXANDER, CHRISTOPHER WEDDLE, Laboratory for Physical Sciences — Superconducting transition metal nitrides are a family of superconductors that have been used to produce high internal quality factor superconducting coplanar waveguide (CPW) resonators. Plasma assisted molecular beam epitaxy (MBE) is used to grow both superconducting nitrides and wide-bandgap nitride bilayer heterostructures. This combination of nitride materials provides sufficient degrees of freedom that synthesis of an epitaxial Josephson junction may be possible. Here early stages of this approach are evaluated through measurement of the single photon loss of aluminum nitride that is explored as both an overlayer and underlayer of TiN superconducting CPW resonators.
3:42PM V35.00007: Suspended trace air-gap resonators for superconducting circuits  MICHAEL FANG (Presenter), ANDREW J KELLER, OSKAR PAINTER, Caltech — Quantum memories and networks for distributed quantum information processing require links between the microwave, mechanical, and optical domains. Coherent integration of long-lived superconducting qubits (SCQs) with optomechanical and photonic devices (OMPDs) remains an outstanding challenge. We present a step towards coherent integration using a suspended trace air-gap resonator (STAR): a superconducting resonator on a silicon-on-insulator (SOI) substrate with the center trace suspended by silicon tethers above and between galvanically connected ground metal planes. As a result, the electric field energy is closely confined within the microwave structure, yielding lower crosstalk compared to conventional coplanar waveguides (CPW). Field participation in bulk dielectrics, a dominant source of loss in previous measurements of aluminum CPW resonators on SOI, is reduced to the point where the dominant loss factor is at the metal-air interface. The loss factor of the metal oxide can be reduced by several factors with choice of superconductor. Most importantly, STAR fabrication is compatible with Josephson junction and air-bridge evaporation for integration of SCQs and OMPDs.

3:54PM V35.00008: Microwave loss in amorphous silicon for coherent superconducting technologies  WILLIAM KOEHL (Presenter), STANLEY F STEERS, MOE KHALIL, JON COCHRAN, DANIEL ROBERT QUEEN, JUSTIN HACKLEY, KHYOUTH LIM, JIM KELLIHER, AUSTIN DOYLE, PATRICK WARNER, MONICA LILLY, MICAH STOUTIMORE, Northrop Grumman — Efforts to design superconducting quantum technologies have generated an interest in understanding the materials mechanisms responsible for microwave photon loss in coherent devices. While a desire for long coherence times has driven many groups to pursue devices fabricated on crystalline substrates, close study of loss in deposited dielectrics has also played an important role in the development of the field. Recent efforts at 3D integration suggest that a more complete understanding of the relationship between loss and defectivity in amorphous films is still needed. We discuss current microstructural models of defectivity in amorphous silicon (a-Si), a material commonly used in the semiconductor and solar industries, and relate these concepts to microwave photon loss in superconducting resonators fabricated on a-Si films deposited under growth conditions targeting low defect incorporation. Experimental data from cryogenic quality factor measurements will be presented and coupled to structural information derived via TEM and other materials spectroscopies.

4:06PM V35.00009: Optical Direct-Write Lithography of Shadow Mask Josephson Junctions*  JONATHAN MONROE (Presenter), KATER MURCH, Washington University, St. Louis — We have developed a technique to fabricate Josephson junctions with a direct-write laser lithography system, enabling fast writing of large-area patterns. Using standard Niemeyer-Dolan bridge shadow deposition techniques, we create relatively large junctions (0.5 um^2) suitable for array-based parametric amplifiers. We explore fabrication techniques to create low critical current junctions for superconducting qubits. We present results on reproducibility and performance of Josephson parametric amplifiers and transmon qubits utilizing these junctions.

*This work was supported the ONR Grant No. 12114811 and the NSF Grant No. PHY-1607156

4:18PM V35.00010: Surface Loss Characterization and Comparison in Aluminum, Niobium, and Titanium Nitride Superconducting Resonators*  ALEXANDER MELVILLE (Presenter), GREG CALUSINE, WAYNE WOODS, EVAN GOLDEN, JOVI MILOSHI, ARJAN SEVI, JONILYN L YODER, WILLIAM D OLIVER, MIT Lincoln Lab — Uniquely characterizing loss from two-level systems (TLS) at metal-substrate, metal-air, and substrate-air interfaces and in a dielectric substrate is challenging due to the nearly proportional scaling of the dielectric participations in response to changes in geometry and anisotropic trench depth. We developed a technique utilizing isotropic etching to assign a specific loss tangent to each dielectric, and use that to determine the dominant dielectric losses for a specific fabrication process, enabling targeted geometry and process changes to maximize performance. In this talk, we characterize the loss from high quality factor resonators (Q>1M) for aluminum, titanium nitride, and niobium, and demonstrate the technique's application by targeting specific defect layers to alter the dielectric losses specifically from these defect layers.

*This material is based upon work supported in part by the Intelligence Advanced Research Projects Activity (IARPA) and in part by the Department of Defense under Air Force Contract No. FA8721-05-C-0002 and/or FA8702-15-D-0001. Any opinions, findings, conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of IARPA, the Department of Defense, or the US Government.
4:30PM V35.00011: Study of atomic two-level defects within a Josephson junction proxy

CHIH-CHIAO HUNG (Presenter), NEDA FOROUZANI, KEVIN DANIEL OSBORN, LPS - ESPCI- use #1304 — In superconducting qubits, thermally grown aluminum oxide is generally used as the barrier between two superconducting electrodes to form the S-I-S Josephson junction (JJ). This oxide is amorphous and is known to contain random, atomic-sized two-level systems (TLSs) which are a source of decoherence in superconducting qubits. Here, we present a study of TLSs in parallel plate capacitors mimicking a JJ (Al/AlOx/Al), but where the dielectric layer is 20 nm and therefore block the tunneling supercurrent. In this JJ proxy, the defects near the in AlOx and near the interface of Al/AlOx can be studies using a new analysis method only demonstrated before with a different dielectric. Using a resonator device with a four-arm bridge capacitor, one can tune the frequency of TLSs by applying a DC electric field, and observe individual TLSs reach degeneracy with the resonator in a demonstration of cavity QED with TLS. The transmission versus applied electric field would give us the TLS dipole moment's z-component. We will study these resonators in an effort to better understand TLSs within typical JJs.

4:42PM V35.00012: Microwave Properties of Exfoliated Hexagonal Boron Nitride*

ABHINANDAN ANTONY (Presenter), Columbia University, MARTIN V GUSTAFSSON, GUILHEM RIBEILL, Raytheon BBN Technologies, MITALI BANERJEE, Columbia University, THOMAS A OHKI, Raytheon BBN Technologies, JAMES HONE, Columbia University, KIN CHUNG FONG, Raytheon BBN Technologies — Interfacial and bulk dielectric losses in superconducting qubits are some of the key factors limiting device coherence. We investigate the microwave properties of thin flakes of hexagonal boron nitride (h-BN), which have the potential to serve as low-loss elements in superconducting transmon qubits. The flakes, which are exfoliated from high-quality single-crystals to thicknesses of a few tens of nanometers, have atomically flat interfaces and low defect densities. Our process allows them to be coated with superconducting layers on both sides, thus forming parallel-plate capacitors. By embedding these capacitors in superconducting microwave resonators, we can determine the dielectric constant and loss tangent of h-BN under conditions relevant for qubit operation. Apart from the promise of improved coherence, the parallel-plate geometry would enable qubits to be designed with drastically reduced footprints and cross-talk compared to planar devices.

*We acknowledge funding support from ARO's quantum computing program (W911NF18C0044). AA thanks the sponsor of NSF's QISE-NET program (award number 1747426).

4:54PM V35.00013: Operating a Quantum Processor with Material Defects [Invited]

PAUL KLIMOV (Presenter), Google AI Quantum — A challenge in operating a quantum processor is mitigating computational errors from material two-level-system defects. Defects cause qubit-performance metrics to fluctuate in frequency, time, and between nominally identical qubits [1]. In frequency-tunable qubit architectures, it is possible to mitigate defect-related performance fluctuations in-situ by judiciously picking qubit operating frequencies. The defect avoidance problem thus maps to an optimization problem with a high-dimensional, non-convex, and time-dependent objective whose parameters are defined by defects' physical properties. In this talk, I will discuss recent research towards understanding defect properties, the defect avoidance problem, and related benchmarks.

Thursday, March 7, 2019 2:30 PM - 5:30 PM

Session V36 DAMOP: Experimental Realizations of Many-Body Localization and Simulation

BCEC 205C - Alex (Ruichao) Ma, University of Chicago - Tag(s): Invited

2:30PM V36.00001: Generating many-body localization in a trapped ion quantum simulator* [Invited]

PAUL HESS (Presenter), Middlebury College — Levitated crystals of trapped atomic ions are a versatile platform for realizing interacting quantum spin models and studying quantum nonequilibrium phenomena. In this talk, I will discuss how programmable laser-induced disorder can be used to generate a many-body localized (MBL) state in a long-range interacting trapped ion crystal. This technique for generating MBL was also applied in concert with a time-periodic Hamiltonian to explore how MBL can help stabilize discrete time crystalline states of matter. The experiment's single spin resolved measurements and controllable interactions allow us to characterize the MBL state's properties in ways not accessible to other atomic or condensed matter systems.

*This work was supported by the ARO Atomic and Molecular Physics Program, the AFOSR MURI on Quantum Measurement and Verification, the IARPA MQCO and LogiQ programs, and the NSF Physics Frontier Center at JQI.
3:06PM V36.00002: Exploring the many-body localization transition in two dimensions* [Invited] JAE-YOON CHOI
(Presenter), Physics, KAIST — Non-equilibrium dynamics in a closed quantum system has become a central theme in modern statistical mechanics, where experimental studies are accessible via cold atoms, trapped ion, and NV-center spin system. Many-body localization (MBL) is one example of non-trivial quantum phases of matter in non-equilibrium, where initial state information can persist for infinitely long time, violating fundamental hypothesis of classical statistical physics. In this talk, I will introduce a recent experiments of the MBL phase in two dimensions using ultra cold atoms in optical lattice. We prepare a far out-of-equilibrium state and trace its dynamical evolution under disorder potential. We observe the system does not thermalize above a non-zero disorder and verify the interaction effect. Finally, I will present a effect of finite thermal bath on the MBL phase, which can shed light on the stability of the MBL system in higher dimensions.

*We acknowledge funding by Max-Planck-Gesellschaft, Deutsche Forschungsgemeinschaft, the European Union (UQUAM and Marie curi fellowship).

3:42PM V36.00003: Engineering Trapped-Ion Systems for Large Scale Quantum Simulation* [Invited] GUIDO PAGANO
(Presenter), ANTONIS KYPRIANIDIS, HARVEY B KAPLAN, WEN LIN TAN, PATRICK M BECKER, KATE S COLLINS, ALEXEY GORSHKOV, University of Maryland, ZHEXUAN GONG, Colorado School of Mines, ANIRUDDHA BAPAT, University of Maryland, STEPHEN P JORDAN, Microsoft Research, JIEHANG ZHANG, University of Maryland, PAUL HESS, Middlebury, CHRISTOPHER ROY MONROE, University of Maryland — Laser cooled trapped ions offer unprecedented control over both internal and external degrees of freedom at the single-particle level. They are considered among the foremost candidates for realizing quantum simulation and computation platforms that can outperform classical computers at specific tasks. In this talk I will show how linear arrays of trapped $^{171}$Yb$^+$ ions can be used as a versatile platform for studying quantum dynamics of strongly correlated many-body quantum systems. In particular I will describe how to realize time-crystalline phases in a Floquet setting, where the spin system exhibits persistent time-correlations under many-body-localized dynamics. I will also present our observation of a new type of out-of-equilibrium dynamical phase transition in a spin system with over 50 spins. Moreover I will show our latest efforts towards scaling up the trapped-ion quantum simulator using a cryo-pumped vacuum chamber where we can trap more than 100 ions indefinitely. The reliable production and lifetime of large linear ion chains enabled us to investigate quasiparticle excitations showing confinement in the quench dynamics and the implementation of Quantum Approximate Optimization Algorithms (QAOA) with up to 40 spins.

4:18PM V36.00004: Signatures of the Many-Body Localized Regime in Two Dimensions* [Invited] THORSTEN WAHL
(Presenter), University of Oxford — Lessons from Anderson localization highlight the importance of dimensionality of real space for localization due to disorder. More recently, studies of many-body localization have focussed on the phenomenon in one dimension using techniques of exact diagonalization and tensor networks. On the other hand, experiments in two dimensions have provided concrete results going beyond the previously numerically accessible limits while posing several challenging questions. We present the first large-scale numerical examination of a disordered Bose-Hubbard model in two dimensions realized in cold atoms, which shows entanglement based signatures of many-body localization. By generalizing a low-depth quantum circuit to two dimensions we approximate eigenstates in the experimental parameter regimes for large systems, which is beyond the scope of exact diagonalization. A careful analysis of the eigenstate entanglement structure provides an indication of the putative phase transition marked by a peak in the fluctuations of entanglement entropy in a parameter range consistent with experiments.

**Session V37 GMAG DCMP DMP: Spin Ice: Kagome, Artificial, and Theory**

2:30PM V37.00001: Dynamic kagome ice state [Invited]  
ELSIA LHOTEL (Presenter), Institut Néel, CNRS, SYLVAIN PETIT, LLB, CEA Saclay, MONICA CIOMAGA HATNEAN, University of Warwick, JACQUES OLLIVIER, ILL, ERIC RESSOUCHE, INAC, CEA Grenoble, MARTIN LEES, GEETHA BALAKRISHNAN, University of Warwick — Coulomb phases form a novel exotic state of matter which, because of frustration, lacks long range order, yet is described by a local organizing principle. Spin ice is the emblematic example of this physics: in a lattice where magnetic ions occupy the vertices of corner sharing tetrahedra (pyrochlore lattice), the combination of strong Ising anisotropy along local <111> axes with ferromagnetic interactions leads to the so called ice rule (2 spins point in and 2 spins point out in each tetrahedron). Kagome ice is another example, in 2 dimensions, with a lattice made of corner sharing triangles. In this case, the organizing principle is the kagome ice rule, 2 spins pointing into each triangle, and 1 out, or vice versa. The pyrochlore and kagome lattices are intimately related: along the [111] direction, the pyrochlore lattice can be viewed as a stacking of kagome layers separated by the apical spins. Applying a magnetic field along [111] in spin ice freezes out the apical spins, decouples the kagome layers and operates a dimension reduction. In this context, we report here the effect of a [111] magnetic field on Nd$_2$Zr$_2$O$_7$. In this pyrochlore compound, classical spin ice physics is considerably modified by the existence of transverse terms in the Hamiltonian: spin ice signatures are transferred in the excitation spectrum, taking the form of a flat spin ice mode [1]. Correspondingly, we show that above 0.25 T, a flat dynamic kagome ice mode forms in the excitation spectrum, featuring a “dynamic kagome ice” state [2]. Mean-field calculations using the XYZ Hamiltonian [3] account qualitatively for our observations, although some discrepancies point to the existence of more complex processes. More generally, our study highlights the key role of transverse terms in the physics of pyrochlore magnets.

ZHILING DUN, XIAOJIAN BAI (Presenter), School of Physics, Georgia Institute of Technology, JOSEPH PADDISON, Churchill College, University of Cambridge, EMILY HOLLINGWORTH, School of Physics, Georgia Institute of Technology, FRANZ DEMMEL, ISIS facility, Rutherford Appleton Laboratory, NICHOLAS BUTCH, NIST Center for Neutron Research, CLARINA DELA CRUZ, MATTHEW BRANDON STONE, TAO HONG, Neutron Scattering Division, Oak Ridge National Laboratory, MARTIN MOUG, School of Physics, Georgia Institute of Technology, HAIYAN ZHOU, Department of Physics and Astronomy, University of Tennessee — A promising route to realize entangled magnetic states combines geometrical frustration with quantum tunneling effects. Spin-ice materials are canonical examples of frustration, and Ising spins in a transverse magnetic field are the simplest many-body model of quantum tunneling. Here, we show that the tripod kagome lattice material Ho3Mg2Sb3O14 unites an ice-like magnetic degeneracy with quantum-tunneling terms generated by an intrinsic splitting of the Ho3+ ground-state doublet, realizing a frustrated transverse Ising model. Using neutron scattering and thermodynamic experiments, we observe a symmetry-breaking transition at 0.32 K to a remarkable quantum spin-fragmented states with strongly reduced ordered/local moment. Using exact diagonalization and mean-field calculation, we demonstrate that whereas the transverse field tends to drive the system into a spin-liquid state with zero on-site moment, the hyperfine interaction helps to stabilize the fragmented local moments. Our results establish that Ho3Mg2Sb3O14 realizes a quantum spin-fragmented state on the kagome lattice.

*The work at Georgia Tech was sponsored by the Department of Energy under grant DE-SC-0018660.

KAI-HSIN WU (Presenter), Department of Physics, National Taiwan University, YI-PING HUANG, Max Planck Institute for the Physics of Complex Systems, YING-JER KAO, Department of Physics, National Taiwan University — We study the spin-1/2 kagome Heisenberg XYZ Hamiltonian model in the so-called quantum kagome ice regime[1]. From our recent topological entanglement entropy and thermal entropy studies, we find that the system does not show a Z2 topological order down to β=48, while the thermal entropy down to β=200 is consistent with the residual entropy of a classical kagome ice in a magnetic field [2]. Using degenerate perturbation theory (DPT) out of the classical ice manifold, we derive an effective model which shows an intricate competition between the ring-exchange and diagonal processes. Here, we perform exact diagonalization on the effective Hamiltonian. By tuning the weight of the diagonal term, we find that the competition can lead to a quasi-degenerate energy spectrum, consistent with the Quantum Monte Carlo simulation results.

JUSTIN WOODS (Presenter), BARRY W FARMER, University of Kentucky, YONGLEI WANG, Physics, Nanjing University, WAI-KWONG KWOK, Material Science Division, Argonne National Laboratory, JEFFREY T HASTINGS, LANCE DE LONG, University of Kentucky — We study the ordering of magnetic charges in honeycomb artificial spin ice (ASI) having distortions created by applying an aperiodic Fibonacci sequence of binary digits mapped onto short (d1) and long (d2) 2D lattice parameters. Patterned Permalloy (Ni,Fe) thin films were deposited on Si3N4 using standard electron beam lithography (EBL) to create samples with a range of distortion ratios d2/d1 = 1.00, 1.15, 1.30, 1.45 and 1.62.

The lengths of disconnected segments and their location around three-fold honeycomb vertices were modified by these distortions. Two pattern types were studied: 1) Varied segment length; 2) Varied segment distance to vertex. In both cases, the values of d1 and d2 uniquely determine the positions of the pattern vertices.

The magnetic charge distribution of each pattern was imaged using standard magnetic force microscopy (MFM) techniques before and after the system is annealed into a low-energy ASI state. The magnetic charge distributions are then analyzed to determine the effect of the distortions on frustration of the magnetic textures, and relation to the coercive fields measured by SQUID magnetometry.

*Research was supported by U.S. Department of Energy Grant Nos. DE-SC0016519 and DE-AC02-06CH11357 (Argonne Center for Nanoscale Materials).
Degenerate Ground States in Vertex-Frustrated Artificial Spin Ice*  

**3:42PM V37.00005:** Degenerate Ground States in Vertex-Frustrated Artificial Spin Ice*  

XIAOYU ZHANG (Presenter), Applied Physics, Yale Univ, YUYANG LAO, Physics, University of Illinois, NICHOLAS S. BINGHAM, Applied Physics, Yale Univ, JOSEPH SKLENA, Physics, University of Illinois, AYHAN DUZGUN, Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, JUSTIN WATTS, Physics, University of Minnesota, JOSEPH BATLEY, Chemical Engineering and Materials Science, University of Minnesota, RAJESH V CHOPDEKAR, Lawrence Berkeley National Laboratory, CHRIS LEIGHTON, Chemical Engineering and Materials Science, University of Minnesota, CRISTIANO NISOLI, Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, PETER E SCHIFFER, Applied Physics, Yale Univ — Artificial spin ice systems (ASI) are two-dimensional arrays of interacting single-domain ferromagnetic nano-islands, with uniaxial anisotropy. With careful consideration of the lattice geometry, some ASI systems can have degenerate ground states that include excited vertices, so called vertex-frustrated systems, and these can manifest a wealth of different emergent behavior in the collective dynamics of the magnetic moments. In one example of a vertex-frustrated system, the Santa Fe lattice, the ground state degeneracy changes with the strength of interactions and the excited vertices whose fluctuations control the low energy kinetics of the moments. To examine the ground state behavior of Santa Fe ASI, we performed Photoemission Electron Microscopy measurements as a function of lattice spacing and island moment after a thermal annealing treatment, and we observed a range of novel behavior. The results show a notable change in the possible ground state configurations across different lattice parameters, demonstrating that Santa Fe ASI is an excellent candidate for studying novel order induced by vertex frustration.

Magnetotransport of Vertex Frustrated Artificial Spin Ice Structures*  

**3:54PM V37.00006:** Magnetotransport of Vertex Frustrated Artificial Spin Ice Structures*  

ELYSIA SHARMA (Presenter), Physics, Imperial College London, DAAN M ARROO, Physics, University College London, NIRAT RAY, Indian Institute of Technology Gandhinagar, LESLEY COHEN, WILL BRANFORD, Physics, Imperial College London — Artificial spin ice (ASI) systems are 2D analogues of pyrochlore spin ice, which exhibit frustrated magnetism and magnetic monopole-like defects [1]. ASI is commonly studied in honeycomb or square lattices, but other geometries which exhibit frustration are of growing interest. Previous magnetotransport studies have observed an asymmetric Hall signal and postulated this is related to the phase transition to the chirally ordered state in the kagome lattice [2]. Due to the possible effect of exchange bias [3] and the breakdown of the macrospin approximation for cobalt ASI systems below 50K [4] this has continued to be a topic of much interest and debate. The comparison of the response of different geometries could provide insight which could clarify the origin of this effect. Here we present an investigation of the Longitudinal and Hall resistivity, in the range 2K<T<290K, for non-conventional ASI geometries. Samples consist of permalloy nanowires in 5 geometries: kagome, square, Shakti, brickwork and tetris.

*The authors thank the EPSRC for funding.

Imaging the stray field of chiral artificial spin ice with scanning nanoSQUID-on-tip  

**4:06PM V37.00007:** Imaging the stray field of chiral artificial spin ice with scanning nanoSQUID-on-tip  

MARCUS WYSS (Presenter), DENIS VASYUKOV, University of Basel, SEBASTIAN GLIGA, Physics, University of Glasgow, LORENZO CECCARELLI, GIULIO ROMAGNOLI, University of Basel, ROBERT L. STAMPS, Physics, University of Glasgow, MARTINO POGGIO, University of Basel — We use a scanning nanometer-scale superconducting quantum interference device (nanoSQUID) [1] to image the stray field of an artificial spin ice, which displays structural chirality. Experiments are carried out in a series of magnetic fields at 4.2 K. The "chiral ice" [2] is a 2D arrangement of lithographically patterned permalloy nanomagnets. Each stadium-shaped nanomagnet is much thinner than its in-plane dimensions, producing a strong shape anisotropy that favors a single-domain magnetization configuration [3]. Nevertheless, scanning nanoSQUID measurements, backed by micromagnetic simulations, show that the magnetization in the nanomagnets is not uniform, displaying a bending at the edges of the nanostructures. The results show that the number of degrees of freedom in artificial spin ice can be much larger than typically captured in dipolar models. These additional degrees of freedom contribute to the field-induced dynamics and may be used to create reprogrammable magnonic crystals [4].

4:18PM V37.00008: Simulation of electron holography of pyrochlore spin ice  ANKUR DHAR (Presenter), Okinawa Institute of Science and Technology, LUDOVIC JAUBERT, LOMA, CNRS, University of Bordeaux, NICHOLAS SHANNON, TSUMORU SHINTAKE, Okinawa Institute of Science and Technology — A major topic in frustrated magnetism is emergent magnetic monopoles in spin ice [1]. These low-energy excitations are effective classical analogues of Dirac monopoles and have only been seen indirectly thus far [2]. Electron holography could allow for direct observations due to its high sensitivity to magnetic fields. Electron holography has achieved 3D spatial imaging of spin phenomena with nanometer resolution [3]. This makes the technique uniquely suited for directly imaging spin ice monopoles. I have developed computational methods to predict how an electron wave would propagate through the spin ice’s magnetic structure. The dipole arrangement of pyrochlore spin ice thin films was generated with the help of Monte Carlo simulation [4]. From there I calculate the magnetic vector potential around the spin ice, and its resulting effect on electron phase. These simulated results enable us to show for the first time what a monopole would look like if imaged using electron holography, and what it would take to achieve in experiment.

4:30PM V37.00009: Zone center physics in magnetic diffuse neutron scattering  MIKAEL TWENSTROM (Presenter), Physics, Royal Institute of Technology, LAURA BOVO, Innovation and Enterprise, University College London, PATRIK HENELIUS, Physics, Royal Institute of Technology, STEVEN T. BRAMWELL, London Centre for Nanotechnology, Physics and Astronomy, University College London — Probing physical quantities using neutron scattering is crucial in many areas of physics. Magnetic neutron scattering measures a generalized magnetic susceptibility, but which susceptibility is actually measured as the scattering vector \( Q \rightarrow 0 \)? We consider the case of spin ice, which lends itself well to such a study as it obeys both the static approximation of neutron scattering, the classical fluctuation-dissipation theorem and it also has an extremely large paramagnetic susceptibility. By comparing a direct magnetic measurement using a SQUID magnetometer and a neutron scattering measurement near a Brillouin zone center, we show that the external susceptibility is recovered rather than the intrinsic one. Theoretically we investigate this result by Monte Carlo simulations of the spin ice Hamiltonian with different boundary conditions. Our conclusion is that when measuring the paramagnetic structure factor for a Brillouin zone center point in Fourier space, a demagnetizing transformation may be needed in order to recover the intrinsic susceptibility of a magnetic material.

4:42PM V37.00010: Spectroscopy of spinons in quantum spin ice  SIDDHARDH MORAMPUDI (Presenter), CHRISTOPHER LAUMANN, Physics, Boston University, FRANK WILCZEK, MIT — We calculate the effect of the emergent photon on spectroscopic cross-sections of spinons in quantum spin ice which realizes an emergent phase of QED at low energies. We show that the photon drastically modifies threshold cross-sections of spinons from a naive density of states analysis resulting in effects such as an analogue of the Sommerfeld enhancement. We point out signatures in neutron scattering and Raman spectroscopy and show that this explains some recent numerical and experimental results.

4:54PM V37.00011: Hopfions in lattice dimer model*  GRIGORY BEDNIK (Presenter), Physics, University of California Santa Cruz — In this talk I consider hopfions in 3D lattice dimer model, i.e. topological defects, which can be characterized by 3D topological Hopf invariant. More specifically, I consider 3D bipartite lattice dimer model, define its configurations as equivalent if they can be transformed into each other by a set of local flips, and derive, that they preserve Hopf number. In this way, Hopf invariants answer the question of ergodicity in bipartite lattice dimer model. Furthermore, I consider the case of non-bipartite lattice dimer model, and by using neural networks, demonstrate that its topological phases are characterized by \( \mathbb{Z}_2 \) topological invariant. Since the lattice dimer model is known to describe classical spin ice, my work can be viewed as a proposal to search for hopfions in spin ice materials.

*NSERC of Canada
5:06PM V37.00012: Frustrated Spin Ice Nanomagnets Probed by Superconducting Vortex Dynamics.* JOSE VICENT (Presenter), University Complutense, Spain, VICTOR ROLLANO, IMDEA-Nanociencia, Spain, ALVARO MUNOZ-NOVAL, University Complutense, Spain, ALICIA GOMEZ, CSIC-INTA, Spain, FERNANDO VALDES-BANGO, MARIA VELEZ, JOSE MARTIN, University Oviedo, Spain, MANUEL OSORIO, DANIEL GRANADOS, IMDEA-Nanociencia, Spain, ELVIRA GONZALEZ, University Complutense, Spain — We have studied the superconducting vortex dynamics on hybrid superconducting/magnetic samples. The samples are connected Co nanomagnets with honeycomb structure which are embedded in Nb superconducting film. The samples are patterned in a cross-shaped bridge for magnetotransport measurements. Superconducting vortex lattice motion detects distinct magnetic states of the honeycomb array. These states are governed by the topology of the Co honeycomb which frustrates in-plane magnetic configurations which must follow spin ice rules. Furthermore, in the honeycomb array, each vertex consists of two charged Néel walls. This hybrid system can be set easily in magnetic configuration corresponding to Ice II or Ice I states. We will show that the superconducting vortex flow is sensitive to subtle changes in the magnetic state of the spin ice and remarkably the as-grown state is not fully demagnetized; that is, this spin ice presents remanent magnetization in all the possible magnetic configurations.

Session V38 GMAG DMP: Spin Glasses and Disordered Magnetic Systems BCEC 206B - Zhenzhong Shi, Duke University - Tag(s): Focus

2:30PM V38.00001: A dynamic probe of finite-size effects near the spin-glass transition temperature* GREGORY KENNING (Presenter), Physics, Indiana University of Pennsylvania, DANIEL TENNANT, QIANG ZHAI, Physics, University of Texas, DAVID HARRISON, E. DAN DALHBERG, Physics, University of Minnesota, RAYMOND ORBACH, Physics, University of Texas — Using a high sensitivity dual DC SQUID magnetometer, we have measured the growth of the spin glass correlation length, through the aging and end of aging effects. Measurements were made on bulk CuMn5% and a CuMn12% thin film multilayer with CuMn layer thicknesses of 4.5 nm. As the glass temperature Tg is approached (0.9Tg < T<0.96Tg) in the bulk sample, we find that the waiting time effect (as measured by the time associated with the inflection point of the decay) as a function of increasing temperature, shifts to shorter timescales. For T >0.96Tg, there is no waiting time effect (end of aging) on the magnetization decay, and all decays collapse onto a single decay curve indicating an end of aging even for long waiting times (tw = 10,000s). For the thin film, all effects due to the waiting time disappear at around 0.89Tf, where Tf is the freezing temperature marking the onset of irreversibility. The end of aging results are interpreted in terms of the spin glass correlation length saturating due to finite size effects.

* This work was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering, under Award DE-SC0013599. The IUP dual dc SQUID magnetometer was built under an NSF MRI, Award No. 0852643.

2:42PM V38.00002: Seeking the spin-glass state in a field through windows DILINA PERERA (Presenter), Department of Physics and Astronomy, Texas A&M University, A. PETER YOUNG, Department of Physics, University of California, Santa Cruz, HELMUT KATZGRABER, Microsoft Quantum, Microsoft — Although the presence of a finite-temperature transition in the three-dimensional Ising spin-glass is well established in zero field, the behavior in the presence of an external magnetic field has been a matter of long-standing controversy. For the infinite-range Sherrington-Kirkpatrick spin glass, mean-field theory predicts a transition line known as Almeida-Thouless (AT) line that separates the paramagnetic and spin-glass phases in the temperature-field plane. Despite extensive numerical efforts, no consensus has been reached with regard to the presence of an AT line in short-range systems, mostly due to strong corrections to finite-size scaling. Here we investigate the transition in a three-dimensional system via a method in which we perform population annealing Monte Carlo simulations for a large system, but only consider the thermodynamic properties of the system restricted to a small window. By computing the wave-vector-dependent spin-glass susceptibility for the individual windows, as well as for the whole system, we investigate the effects of finite-size corrections to the two-point correlation function.
Evidence of transition between Heisenberg and Ising-like phases in mesoscale Ge:Mn spin glass

SAMARESH GUCHHAIT (Presenter), Department of Physics and Astronomy, Howard University, Washington, DC 20059 — The glassy dynamics of vector spin glasses in presence of a weak uniaxial anisotropy has been a subject of longstanding controversy. It has been predicted that in presence of such anisotropy Heisenberg-like spin glass system first undergoes longitudinal moment freezing, followed by a transverse moment freezing at even lower temperature. Evidence of such phase transition is seen in the temperature chaos experiments in thin film Ge:Mn spin glass. Here the sample temperature is increased from the quench temperature after the correlation length has reached its thickness. For large enough positive change of temperatures the maximum barrier height increases monotonically, which is consistent with a phase change of lower temperature Heisenberg-like phase to higher temperature Ising-like phase.

Study of longitudinal fluctuations of the Sherrington-Kirkpatrick spin glass

LEOPOLDO SARRA (Presenter), Max Planck Institute for the Science of Light, Erlangen, LORENZO TALAMANCA, SV IBI UPNAE, EPFL, G. PARISI, Dipartimento di Fisica, Sapienza Università di Roma — Spin glasses are disordered systems with a complex behavior, caused by the very high degeneracy of low energy states. They have a phase transition between a paramagnetic phase and a spin glass phase, in which the ergodicity is broken in a hierarchical organization of states. This implies many peculiar properties such as aging, remanence and memory effect. In our work, we study finite-size corrections to the mean field model, the Sherrington-Kirkpatrick spin glass, whose solution is well-known. The behavior of these corrections in the low temperature phase has been debated for several years. Because of the complicated form of the theory around the mean field solution and of the difficulty to perform a numerical estimate, no final value has been found so far. We investigate the role of longitudinal fluctuations, neglecting the transverse contribution. Since they can be calculated directly into the full-replica symmetry breaking ansatz, it is easier to obtain a prediction for their behavior.

Chaotic Behavior in CuMn_{13.5} Multilayer Thin Film Spin Glasses

QIANG ZHAI (Presenter), RAYMOND ORBACH, The University of Texas at Austin, DAVID HARRISON, University of Minnesota Twin Cities — The zero field cooled (ZFC) and field cooled (FC) magnetizations of an 11 nm CuMn_{13.5} multilayer thin film spin glass was measured using a superconducting quantum interference device (SQUID) over the time scale where the correlation length has grown to the film thickness, i.e. for time scales where the thin films crossover from 3D to 2D. Temperature chaos, the vulnerability of the quasi-equilibrium state to temperature perturbations, was studied by a series of temperature drops after the crossover time. We find the ZFC and FC magnetization responses are sensitive to temperature changes after crossover. Both reversible and chaotic behavior, the latter characterized as rejuvenation, are observed. The traditional interpretation using a characteristic length for chaos, and the concept that chaos is “driven by rare events,” are discussed in comparison with experimental results.

This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, under Award DE-SC0013599.

Experimental Observation of Room-temperature Anomalous Hall Mobility and Positive Magnetic Hysteresis in Amorphous Fe-Dy-O Thin Films

KRISHNA KOIRALA (Presenter), Department of Physics and Astronomy, University of Tennessee, Knoxville, ANIRUDDHA DEB, Department of Chemistry, University of Michigan, Ann Arbor, RITESH SACHAN, Materials Science Division, Army Research Office, DEEPAK SAPKOTA, Department of Physics and Astronomy, University of Tennessee, Knoxville, VENKATANARAYANA P SANDIREDDY, Department of Chemical and Biomolecular Engineering, University of Tennessee, Knoxville, JAMES E PENNER-HAHN, Department of Chemistry, University of Michigan, Ann Arbor, RAMKI KALYANARAMAN, Department of Material Science and Engineering, University of Tennessee, Knoxville — Fe-Dy-Tb-O thin film system was recently reported with very high transparency, conductivity and room temperature ferromagnetism driven by partially filled d- and f- subshells. Here, we have synthesized and studied the Fe-Dy-O thin films. The thin film system was prepared by e-beam evaporation and its structural, transport, magnetic and optical characterizations were performed. The as-grown films were amorphous, as evidenced by transmission electron microscopy and X-ray scattering. X-ray absorption spectra revealed a progressive oxidation of thin films on reducing the dimension. The films showed highly (\sim 10 \text{cm}^2/\text{V-s}) and anomalous (\sim 10^2 \text{cm}^2/\text{V-s}) Hall mobility with n-type semiconducting behavior. Cryogenic magnetic behaviors evinced the existence of spin-glass-like transition at 79 K. Positive hysteretic loop and transverse magneto-resistivity up to 4% in the magnetic field of 5 T were observed at room temperature. Room-temperature optical studies showed the existence of a band gap of 2.42 eV in the visible range. These unique set of properties make the system a rich toolbox for not only understanding condensed matter behavior but also realizing multifunctional devices.

*R K and K P K acknowledge support by NSF grant ECCS-1607874.
By quenched-randomly mixing local units of different spatial dimensionalities, we have studied Ising spin-glass systems on hierarchical lattices continuously in dimensionalities $1<d<3$. The global phase diagram in temperature, antiferromagnetic bond concentration, and spatial dimensionality is calculated. We find that, as dimension is lowered, the spin-glass phase disappears to zero temperature at the lower-critical dimension $d_c=2.431$. Our system being a physically realizable system, this sets an upper limit to the lower-critical dimension in general for the Ising spin-glass phase. As dimension is lowered towards $d_c$, the spin-glass critical temperature continuously goes to zero, but the spin-glass chaos fully sustains to the brink of the disappearance of the spin-glass phase. The Lyapunov exponent, measuring the strength of chaos, is thus largely unaffected by the approach to $d_c$ and shows a discontinuity to zero at $d_c$.

**Trimer Magnet Ba$_4$Ir$_3$O$_{10}$**

**Luttinger Quantum Paramagnet from Dimensional Recombination in the Frustrated Spin-1/2 System**

HENGDI ZHAO (Presenter), HAO ZHENG, YIFEI NI, YU ZHANG, Department of Physics, University of Colorado, Boulder CO 80309, FENG YE, XIAOPING WANG, CHRISTINA HOFFMANN, Neutron Scattering Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37381, USA, MINHYEA LEE, ITAMAR KIMCHI, MICHAEL A HERMELE, GANG CAO, Department of Physics, University of Colorado, Boulder CO 80309 — We report a highly frustrated spin state persisting down to 0.2 K in the monoclinic Ba$_4$Ir$_3$O$_{10}$ with Ir$^{4+}$($5d^5$) ions, which consists of Ir$_3$O$_{12}$ trimers of face-sharing IrO$_6$ octahedra and wavy two-dimensional Ir-O sheets. This iridate conspicuously avoids any long-range magnetic order down to 0.2 K despite strong antiferromagnetic interaction with Curie-Weiss temperature $-766$ K. The corresponding frustration ratio reaches an astonishing value of 3830. This frustrated spin state is further evidenced by a sizable, linear heat capacity, indicating substantial residual entropy even at milli-Kelvin temperatures. It is equally striking that a mere 2% nonmagnetic Sr substitution for Ba readily lifts frustration and precipitates a long-range antiferromagnetic order at 130 K, suggesting proximity to a quantum critical point potentially with emergent random spin nucleation.

This work was supported by the National Science Foundation via grant DMR-1712101.

**Weird scaling for 2-D avalanches: curing the faceting, and scaling in the lower critical dimension**

L. X. HAYDEN (Presenter), ARCHISHMAN RAJU, JAMES PATARASP SETHNA, Cornell University — The nonequilibrium random-field Ising model (NE-RFIM) is very well studied and yet there are outstanding questions. In two dimensions, power law scaling approaches fail and the critical disorder is difficult to pin down. Additionally, the presence of faceting on the square lattice creates avalanches that are lattice dependent at small scales. We propose two methods which we find solve these issues. First, we perform large scale simulations on a Voronoi lattice to mitigate the effects of faceting. Secondly, the form of the nonlinear functions necessary to perform scaling collapses can be directly determined using our recent normal form theory of the Renormalization Group. This method has proven useful in cleanly capturing the complex behavior which occurs in both the lower and upper critical dimensions of systems and well describes the NE-RFIM in two-dimensions. The obtained scaling collapses span over a range of a factor of ten in the disorder and a factor of 10$^4$ in avalanche size. They are consistent with a critical disorder at zero and with a lower critical dimension for the model equal to two.

This material is based upon work supported by the National Science Foundation under Grant No. DMR-1719490.

**Critical behavior of the Ising model on a lattice with fractional space dimension**

CHAO FANG (Presenter), Physics and Astronomy, Texas A&M University, MAOXIN LIU, Beijing Computational Science Research Center, HELMUT KATZGRABER, Microsoft Quantum, Microsoft — Disorder can have a drastic effect on the critical behavior of a magnetic system. The Harris criterion states that if the critical exponent of the correlation length $\nu$ fulfills the inequality $\nu \geq 2d$, with $d$ the space dimension, disorder does not affect the universality class of the magnetic systems. A recent study reported a violation of this criterion for a two-dimensional three-state Potts model on a Voronoi lattice. To better understand the effects of disorder on the critical behavior of magnetic systems on disordered lattices, we study the critical behavior of a two-dimensional Ising ferromagnet on the largest component of a percolating cluster on a two-dimensional square lattice. There are two possible scenarios: In the weak universality scenario the disordered structure of the underlying lattice slowly changes the critical exponents, whereas in the strong universality scenario the critical exponents are not affected by the fractional space dimension of the system. Our results suggest a strong universality scenario with weak (logarithmic) corrections.
4:30PM V38.00011: Maximally Random Discrete-Spin Systems with Symmetric and Asymmetric Interactions and Maximally Degenerate Ordering* A NIHAT BERKER (Presenter), Kadir Has U, MIT, BORA ATALAY, Kadir Has U, Sabanci U — Discrete-spin systems with maximally random nearest-neighbor interactions that are symmetric or asymmetric, ferromagnetic or antiferromagnetic, including off-diagonal disorder, are studied for q=3,4 states in d dimensions, using renormalization-group theory exact for hierarchical lattices and approximate (Migdal-Kadanoff) for hypercubic lattices. For all d>1 and non-infinite temperatures, the system eventually renormalizes to a random single state, signaling q×q degenerate ordering, which is maximally degenerate ordering. For high-temperature initial conditions, the system crosses over to this highly degenerate ordering after many renormalization-group iterations near the disordered infinite-temperature fixed point. Thus, a temperature range of short-range disorder in presence of long-range order occurs, as previously seen in underfrustrated Ising spin-glasses. The calculated entropy behaves similarly for ferromagnetic and antiferromagnetic interactions and shows a derivative maximum at the short-range disordering temperature. The system is disordered at all temperatures for d=1.

4:42PM V38.00012: Direct Observation of Magnetic Long-range Order in Ammann-Beenker Artificial Quasicrystals* LANCE DE LONG (Presenter), BARRY W FARMER, University of Kentucky, JOHN UNGURIS, NIST Gaithersberg, JUSTIN WOODS, University of Kentucky — Magnetic long-range order (LRO) in 3D Ammann-Beenker tilings (ABT) has been modeled in simulations1,2, but has yet to be experimentally observed3. We fabricated artificial ABT composed of a connected wire network of elongated Permalloy film segments that mimic classical Ising spins interacting via long-range dipolar and short-range exchange interactions. Our MC analysis of ABT (NN interactions) generated a magnetic ground state built upon distinct sublattices, similar to fivefold Penrose tilings4,5. High-resolution images of the in-plane magnetization of ABT were acquired with scanning electron microscopy with polarization analysis (SEMPA). An annealing protocol that yielded improved agreement with the MC ground state. We developed a novel cluster covering that introduces frustration among neighboring clusters, and suggests low-energy, long-range interactions are required for full LRO, and provides a possible explanation for the non-existence of magnetic LRO in atomic quasicrystals.

5:06PM V38.00014: Study of a generalized XY model using the correlation length*  
NUI XUAN DUONG, Faculty of Mechanics and Civil Engineering, Vietnam National University of Forestry, TUAN LE, School of Engineering Physics, Hanoi University of Science and Technology, KIEN DUC-TRUNG NGUYEN, HUY THANH PHAM, Advanced Institute for Science and Technology, Hanoi University of Science and Technology, HUNG DANG (Presenter), Thanh Tay Institute for Advanced Study, Thanh Tay University, VIET XUAN DAO, Advanced Institute for Science and Technology, Hanoi University of Science and Technology — The correlation length is examined in a generalized XY model where, together with the usual ferromagnetic interaction between spins, there is an additional nematic interaction that allows for half-vortices. The power of the correlation length is demonstrated in distinguishing different phases, thus fully reconstructing the phase diagram of the model. Moreover, it allows for further investigation of the tricritical region in the phase diagram where the paramagnetic, the nematic and the quasi-long-ranged phases meet. It shows that the Ising-type transition between the nematic and the quasi-long-range ordered phases stops at the tricritical point. Starting from this tricritical point, there is an intermediate range of different physics separates the two regions corresponding to the Ising-type and the Berzinskii-Kosterlitz-Thouless-type transitions.

5:18PM V38.00015: Dangerously Irrelevant Field at Clock Models - A study with the Monte Carlo Based RG Flows*  
HUI SHAO (Presenter), Center for Advanced Quantum Studies, Beijing Normal University, WENAN GUO, Physics Department, Beijing Normal University, ANDERS W SANDVIK, Boston University &IOP-CAS Beijing — The phase transitions between the paramagnetic phase and the \( Z_q \) symmetry-breaking phase in the three dimensional XY model with \( Z_q \)-anisotropic field is now well accepted as belonging to the 3D XY universality class for \( q > q_c \), with the \( Z_q \)-anisotropic field being irrelevant at the critical point. However, when \( T < T_c \) it is always relevant as the symmetry is broken discretely. This is “dangerous” because it leads to a larger length scale \( \xi' \) than the normal correlation length \( \xi \), which, by definition, governs the crossover behavior from \( U(1) \) to \( Z(q) \) symmetry breaking. While RG theory has provided generic pictures of the RG flow in coupling space, we here construct a quantitative Monte Carlo based RG flow using corresponding physical observables, where not only the crossover behaviors can be observed explicitly but also the critical exponents \( \nu \) and \( \nu' \) can be extracted accordingly. For this purpose, we have firstly restudied the anisotropy order parameter and confirm that its scaling dimension at the critical point is the same as that of the \( Z_q \) field. We also clarify unsettled issues in several recent studies of this quantity.

Session V39 GMAG DMP: Magnetism in Rare Earth Materials  
BCEC 207 - Brian Kirby, National Institute of Standards and Technology - Tag(s): Focus

2:30PM V39.00001: Controlling magnetism and magneto-structural phase transformation in rare earth containing materials*  
DURGA PAUDYAL (Presenter), Ames Laboratory — In rare earth element based materials the alloyed p-block elements provide chemical formation and stability, and control magnetism exhibited by rare earths. We report here two examples of how non-magnetic elements substitution pinpointed enhanced and controlled magnetism and phase transformation. First example is Eu2In, in which the Eu 5d states strongly hybridize with the In 5p states exhibiting large exchange splitting in ferromagnetic configuration. This unexpectedly high exchange splitting is the root cause of the sharp paramagnetic to ferromagnetic transition [1]. The other example is scandium substituted Gd2Ge4. Total energy calculations show that Sc favors the Gd atoms located inside the slabs and predict a stable ferromagnetic ground state with the 20 atomic % Sc substituted Gd2Ge4. The predicted phase is Pu5Rh4-type which is intermediate between the Sm2Ge4-type and Gd2Si4-type. The delocalized 3d electronic states of Sc strongly hybridize with delocalized 5d electronic states of Gd, thus promoting indirect interslab 4f-4f exchange interactions [2].

*The Ames Laboratory is operated for the USDOE by Iowa State University under contract No. DE-AC02-07CH11358. This work is supported by the DOE, Office of BES, MSED.
Spin dynamics in magnetic reorientation transitions
MASAMICHI NISHINO (Presenter), Research Center for Advanced Measurement and Characterization, National Institute for Materials Science, SEIJI MIYASHITA, Department of Physics, The University of Tokyo — The Nd-Fe-B magnet is known as a permanent magnet with strong coercive field and commercially used for motors and generators, etc. It shows a magnetic reorientation transition at around 150 K (magnetic Tc is 600–700 K) [1]. The origin of the reorientation transition is higher order magnetic anisotropy constants, which causes a tilted spin state at low temperatures. We study the temperature dependence of ferromagnetic resonance frequency of an atomistic spin model of the magnet. We estimate the power spectrum by using the stochastic Landau-Lifshitz-Gilbert equation [2]. We find non-monotonic temperature dependence of the peak position of the frequency. We analyze the cause of this phenomenon and show that this non-monotonicity is universal for this type of magnetic reorientation transitions.

Magnetic Neutron Scattering Study of Rare-Earth Titanates
SAJNA HAMEED (Presenter), School of Physics and Astronomy, University of Minnesota, SAMI EL-KHATIB, Chemical Engineering and Materials Science, University of Minnesota, JOSEPH JOE, School of Physics and Astronomy, University of Minnesota, KARL OLSON, Chemical Engineering and Materials Science, University of Minnesota, MASAAKI MATSUDA, SONGXUE CHI, TAO HONG, DANIEL PAJEROWSKI, TRAVIS J WILLIAMS, Oak Ridge National Laboratory, JOHN BARKER, NIST Center for Neutron Research, CHRIS LEIGHTON, Chemical Engineering and Materials Science, University of Minnesota, MARTIN GREVEN, School of Physics and Astronomy, University of Minnesota — The Mott-insulating rare-earth (R) titanates (RTiO3) are known to host ferromagnetic-antiferromagnetic transitions in solid-solution systems such as Y1-xLaxTiO3, as well as metal-insulator transitions in charge carrier-doped systems such as Y1-xCa_xTiO3. Neutron scattering studies have been largely restricted to the undoped YTiO3 and LaTiO3. Here, we report on our neutron scattering work on the magnetic order and excitations in the doped systems Y1-xLaxTiO3 and Y1-xCa_xTiO3, using triple-axis spectrometry and small-angle neutron scattering (SANS). We find a strong reduction in the transition temperature and ordered magnetic moment, but accompanied by very little change in the spin-wave dispersion in the Y1-xLaxTiO3 system as we approach the critical doping x~0.3. SANS results suggest a rotation of the easy axis with substitution, development of magnetic inhomogeneities on ~10 nm scales, and distinct changes in critical scattering as the magnetic crossover is approached. These results suggest significant changes in the magnetic ground state as one approaches the crossover. Initial studies on the Y1-xCa_xTiO3 system will also be reported.

Phase diagram of emergent orders of rare-earth nickelates
MINJAЕ KIM (Presenter), GABRIEL KOTLIAR, Rutgers University, New Brunswick, ANTOINE GEORGES, College de France — Phase diagram of Rare-earth nickelates, thin films and heterostructures, is a paradigmatic problem of strongly correlated material having strong coupling in between spin, orbital, lattice degrees of freedom. [1] Recently, there have been suggestions on possible new emergent orders includes antiferromagnetism. [2] In this talk, based on low energy hamiltonian of eg manifold, [3] we discussed possible emergent orders of Rare-earth nickelates includes superconductivity, charge disproportionation, and magnetism. These emergent orders would be accessible by tuning material parameters such as interaction strength and effective crystal field.

ALEXANDER HAMPEL (Presenter), CLAUDE EDERER, Materials Theory, ETH Zurich — Rare-earth nickelates exhibit a metal-insulator transition (MIT) accompanied by a structural distortion that breaks the symmetry between formerly equivalent Ni sites. The quantitative theoretical description of this coupled electronic-structural instability is extremely challenging. Here, we address this issue by simultaneously taking into account both structural and electronic degrees of freedom using a charge self-consistent combination of density functional theory and dynamical mean-field theory, together with screened interaction parameters obtained from the constrained random phase approximation. Our total energy calculations show that the coupling to an electronic instability towards a charge disproportionated insulating state is crucial to stabilize the structural distortion, leading to a clear first order character of the coupled transition. Decreasing octahedral rotations across the series suppress this electronic instability weakening the correlation effects responsible for the MIT. Our approach allows to obtain accurate values for the structural distortion and thus facilitates a comprehensive understanding of the complex interplay between structural properties and electronic correlation effects across the nickelate series.

STEPAN FOMICHEV (Presenter), MONA INESA BERCIU, University of British Columbia, GINHYAT KHALULLIN, Max-Planck-Institut FKF, Stuttgart — We study the magnetic order appearing in the rare-earth nickelates at low temperatures, the exact nature of which is still debated vigorously in the literature. While there is an established link between the metal-insulator transition and lattice distortions in the nickelates, to our knowledge there has been little work on the impact of lattice distortions on the magnetic order, e.g. whether they favor some orders over others. To address this, we consider a two-band Hubbard model for the nickelates, coupled to the lattice distortions (which are treated semiclassically), and use the Hartree-Fock approximation to find the resulting phase diagram. Aside from quantitatively demonstrating how lattice distortions drive bond disproportionation, we find that a variety of 4-site magnetic orders are self-consistent within the model, including both collinear and non-collinear orders. However, in our model a magnetic order can only couple to the lattice distortions if there is an asymmetry in average charge occupation of neighbouring sites. As a result, we find that coupling to the lattice distortions broadly favors the collinear 1-o-1-o order in large sectors of the parameter space.

XINWEI LI (Presenter), Department of Electrical and Computer Engineering, Rice University, MOTOAKI BAMBA, Department of Materials Engineering Science, Osaka University, NING YUAN, Department of Physics, Shanghai University, QI ZHANG, Argonne National Laboratory, YAGE ZHAO, Department of Physics, Rice University, MAOLIN XIONG, KAI XI, ZUANMING JIN, WEI REN, GUOHONG MA, SHIXUN CAO, Department of Physics, Shanghai University, DMITRY TURCHINOVICH, Fakultät für Physik, Universität Duisburg-Essen, JUNICHIRO KONO, Department of Electrical and Computer Engineering, Rice University — Dicke cooperativity is a many-body effect in quantum optics describing the process of N oscillators in a photonic cavity developing macroscopic coherence amongst themselves by interacting with a single light field, while exhibiting a $N^{1/2}$ enhancement of the light-matter coupling rate. Here, we have discovered that cooperatively enhanced coupling similar to this canonical light-matter interaction effect occurs in a magnetic solid in the form of matter-matter interaction. We studied an ErFeO$_3$ single crystal with terahertz magnetospectroscopy at low temperatures and high magnetic fields, and discovered that the exchange coupling of the paramagnetic Er$^{3+}$ ions with a Fe$^{3+}$ magnon field within the crystal quantitatively follows the scaling behavior expected by the Dicke cooperativity effect. This scaling behavior also enables quantitative determination of the Er$^{3+}$-Fe$^{3+}$ exchange coupling coefficients. Our finding provides a novel route for understanding, controlling, or predicting new phases of condensed matter using concepts and tools available in quantum optics.

JASON WHITE, KISHAN SINHA, XIAOSHAN XU (Presenter), University of Nebraska - Lincoln — We have studied crystal structure and magnetic properties of Sc-doped rare earth ferrites R$_1$-xScFeO$_3$ (R=Ho, Er, Yb). For R=Ho, pure structural phases, orthorhombic, garnet, and bixbyte, were observed for $x=0$, $0.5$, and $1$ respectively. Pure garnet phase was also found for $x=0.5$ and R=Er. In contrast, when $x=0.5$ and R=Yb, mixed phases dominated with hexagonal and garnet were observed. Magnetic properties of Ho$_{0.55}$Sc$_{0.5}$FeO$_3$ show incomplete magnetic compensation, with a magnetization minimum at a temperature lower than the compensation temperature of the undoped Ho-Fe-O garnet. These results indicate that Sc atoms occupy both Fe and rare earth sites due to the intermediate atomic radius.

**4:06PM V39.00009: Optimizing the intrinsic magnetic properties of REFe₁₂₋ₓMₓ phases**

HEIKE HERPER (Presenter), OLGA VEKILOVA, OLLE ERIKSSON, Uppsala University — Collecting energy from renewable resources, using e.g. wind power plants has become important and goes hand in hand with a growing demand for new permanent magnets (PM) with magnetic performance comparable to Nd-Fe-B magnets. A key task is to identify new PM with less rare earth (RE). Systems with ThMn₁₂ structure are of special interest. They have the lowest RE concentration of all known phases. However, Fe-based 1:12 systems with light RE need a phase stabilizer which goes on the Fe sites. Two types have been studied, (Nd₁₋ₓYₓ)Fe₁₂₋ₓTiₓ and SmFe₁₂₋ₓVₓ, using state of the art density functional theory methods (VASP; FP LMTO RSPt). The phase stability and the magnetic properties were calculated depending on the Ti and V concentration. Aiming to reduce the RE amount the performance depending on the Nd/Y ratio was monitored. We find that the Nd-Y (Sm) system is stable down to y = 0.5 (y=1) which leads to an increase of the magnetization by 17% compared to the commonly used concentrations of Ti (V). In view of the MAE a replacement of Nd by Y turned out to be preferable over a reduction of Ti. MAE values of 1.3 MJ/m³ ((NdY)Fe₁₁Ti) and 1.7 MJ/m³ (SmFe₁₁V) are predicted. The latter could be verified in recent experiments.

*Support by NOVAMAG (EU686056) and VR (SE), STandUP (SE).

**4:18PM V39.00010: Nanoscale characterization of magnetic microstructure in Gd₃Fe₅O₁₂**

SAMUEL MARKS (Presenter), Materials Science and Engineering, University of Wisconsin - Madison, DANNY MANNIX, MAX IV, Lund, Sweden, STEPHAN GEPRÄGS, Walther Meißner Institute, Munich, Germany, PAUL G EVANS, Materials Science and Engineering, University of Wisconsin - Madison, DINA CARBONE, MAX IV, Lund, Sweden — A key barrier to the understanding of magnetic phenomena and design of functional magnetic materials is the limited scope of nanoscale characterization of magnetic microstructure. We utilize scanning x-ray diffraction microscopy to image the magnetic domain morphology in rare-earth iron garnets as a function of temperature using an x-ray wave plate and zone plate focusing optics to generate a 100 nm beam of circularly polarized synchrotron light. Rare earth iron garnets such as Gd₃Fe₅O₁₂ are magnetic systems that can exhibit spin Seebeck effect (SSE) voltage generation with an efficiency that could depend on the morphology of the magnetic domain structures. We have obtained linear and circular x-ray magnetic dichroism maps of the micron- to submicron-scale distributions of magnetic domains recorded in a prototype SSE device composed of epitaxial layers of Gd₃Fe₅O₁₂ capped with 10 nm of Pt for temperatures ranging from 4 K to 250 K. These results bring insight into the relationship between the temperature-dependent magnetic domain morphology and the efficiency of SSE devices based on rare-earth iron garnets.

**4:30PM V39.00011: Large magneto-crystalline anisotropy in strain-tuned epitaxial BiYIG thick films**

RAVINDER KUMAR (Presenter), BISWANATH SAMANTARAY, ZAKIR HOSSAIN, Physics, Indian Institute of Technology Kanpur — Bi-doped Yttrium Iron Garnet (Bi:YIG) with large Magneto-optical (MO) activity and low optical losses still needs to get probed for its magnetization dynamics. The fact that the ablation laser fluence strongly affects the lattice constant of the films, was used to grow two sets of BiYIG/GGG(111) samples with different strain states. The set-A films with lower thicknesses (10.2, 37.0, and, 92.5 nm), grown using ∼ 1 J/cm² laser fluence, show large magnetocrystalline anisotropy (MCA) due to larger rhombohedral distortion induced strain. The set-B films with larger thicknesses (120 and 150 nm) grown using higher laser fluence of ∼ 2 J/cm² show large strain irrespective of film thicknesses and large magnitude of MCA, comparable to the value of a film as-thin-as ∼ 37 nm from Set-A. Interestingly, the substitution of strong spin orbit coupling Bi³⁺ ions enhances the magnetoelastic coupling (MEC) but weakly affects the precessional damping (∼ 9.7×10⁻⁴). Coexistence of two mutually exclusive parameters i.e., low precessional damping and strong MEC, combined with large MO activity and large MCA in BiYIG films may provide a possible material platform for light dependent magnonics and other spintronics applications.

*IIT Kanpur*
Magnetic and Magnetocaloric Properties of (Nd$_{1-x}$Ce$_x$)YFe$_{15}$ Alloys* BISHNU DAHAL, PARASHU KHAREL (Presenter), THOMAS OTT, Physics, South Dakota State University, WENYONG ZHANG, Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE, United States, SHAH VALLOPPILLY, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE, United States, YUNG MOO HUH, Physics, South Dakota State University, RALPH SKOMSKI, DAVID SELLMYER, Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE, United States — Magnetocaloric materials exhibiting a second-order phase transition (SOP) near room temperature have attracted much attention because these materials are free from magnetic and thermal hysteresis, and may show large cooling efficiency and moderate magnetic entropy change. We have investigated (Nd$_{1-x}$Ce$_x$)YFe$_{15}$ (x = 0 - 1) alloys prepared by arc melting and vacuum annealing. The x-ray diffraction patterns analyzed using the Rietveld method shows that the samples crystallized in the rhombohedral Th$_2$Zn$_{17}$-type structure with space group R-3m. The thermomagnetic curves $M(T)$ measured at $\mu_0H = 1T$ show smooth SOP with Curie temperatures near 300 K. The values of peak magnetic entropy change ($\Delta S_M,\text{max}$) and relative cooling power (RCP) measured at 3 T increase with increasing Nd concentration reaching 4.20 Jkg$^{-1}$K$^{-1}$ and 285 Jkg$^{-1}$ for (Nd$_{0.7}$Ce$_{0.3}$)YFe$_{15}$. The measured $\Delta S_M$ and RCP values are relatively high as compared to those of other Gd-free compounds showing magnetocaloric effect due to SOFT near room temperature. This suggests that the (Nd$_{1-x}$Ce$_x$)YFe$_{15}$ alloys have potential for room temperature magnetic refrigeration.

2:30PM V40.00001: Intertwined orbital and magnetic order in 5d$^1$ and 5d$^2$ Double Perovskite Mott Insulators* [Invited] MOHIT RANDERIA (Presenter), Ohio State University — In this talk I summarize our work on understanding the unusual properties of Mott-insulating double perovskites $A_2BB'O_6$ where the B' sites are 5d magnetic ions with either 1 or 2 electrons in t$_{2g}$ orbitals and the B sites are non-magnetic. Our theory is motivated by several experimental puzzles, including: (i) Why do almost all cubic 5d$^1$ materials exhibit ferromagnetic (FM) order, rare in Mott insulators, while all the 5d$^2$ materials have antiferromagnetic (AFM) ground states? (ii) Why is only partial (log 2) entropy recovered above the magnetic transition, rather than the expected log 4 for $j = 3/2$, in cubic 5d$^1$ materials? (iii) Why do the cubic 5d$^1$ materials exhibit a high temperature magnetic susceptibility that deviates from a Curie-Weiss form? We derive and analyze low-energy effective Hamiltonians for these systems that include spin-orbit coupling, superexchange, inter-site Coulomb interactions and Hund's coupling. We predict that novel orbital order sets in at a high temperature $T_0$ and strongly constrains the non-collinear magnetic order that appears at a much lower $T_c$. Our results allow us to understand all the puzzles noted above and make predictions for new experiments. This research was done in collaboration with W. Zhang, C. Svoboda, P. M. Woodward and N. Trivedi.

*Supported by the Center for Emergent Materials, an NSF MRSEC, under Award Number DMR-1420451.

3:06PM V40.00002: Entangled spin orbital order in 5d$^1$ and 5d$^2$ Double Pervoskite Mott Insulators* NANDINI TRIVEDI (Presenter), WENJUAN ZHANG, CHRISTOPHER SVOBODA, MOHIT RANDERIA, Department of Physics, The Ohio State University — We theoretically investigate the unusual properties of Mott-insulating double perovskites $A_2BB'O_6$ where the magnetic B' ions have 1 or 2 electrons in the 5d shell and the B sites are non-magnetic. We derive a low-energy effective Hamiltonian that includes spin-orbit coupling, super-exchange, inter-site Coulomb interactions and Hund's coupling, and analyze it within mean field theory. We show that orbital order sets in at a high temperature $T_0$ and strongly constrains the non-collinear magnetic order that appears at a much lower $T_c$. Our results give insight into several experimental puzzles. The prediction of orbital ordering well above $T_c$ explains the puzzle of the missing entropy above the magnetic transition. Orbital order is also responsible for the deviations of the high temperature magnetic susceptibility from a Curie-Weiss form. Finally, we show why cubic 5d$^1$ materials most often exhibit canted ferromagnetism, which is rare in Mott insulators, while the 5d$^2$ and distorted 5d$^1$ materials are all antiferromagnetically ordered.

*This research is supported by the Center for Emergent Materials, an NSF MRSEC, under Award Number DMR-1420451.
3:18PM V40.00003: Deterioration of Spin-Orbit Transitions in Mott Insulating CoO  PAUL SARTE (Presenter), Chemistry, University of Edinburgh, ROGER A COWLEY, Physics, University of Oxford, KA HOU HONG, Chemistry, University of Edinburgh, MANILA SONGVILAY, Physics, University of Edinburgh, RUSSELL A EWINGS, ISIS Facility, Rutherford Appleton Laboratory, DHARMALINGAM PRABHAKARAN, Physics, University of Oxford, ZAHRA-SADAT YAMANI, WILLIAM J L BUYERS, Chalk River Laboratories, JOHN PAUL ATTFIELD, Chemistry, University of Edinburgh, CHRIS STOCK, Physics, University of Edinburgh — Despite a myriad of measurements spanning several decades, the low energy magnetic excitations of the classical Mott insulator CoO in the Néel regime are still poorly understood. As a result of the strong molecular-field induced entanglement of various $j_{\text{eff}}$ manifolds, the establishment of a clear model for the low energy magnetic excitation spectrum of this deceptively simple monoxide has proven intractable using conventional spin wave approaches so far. Having extracted estimates for the exchange constants via the dilute monoxide Co$_{0.03}$Mg$_{0.97}$O (Sarte et al. PRB 98, 024415 (2018)), we have employed a random phase-type approximation in the method of Green's functions to model the rich low energy magnetic excitation spectrum of antiferromagnetically ordered CoO. The multi-level spin wave model successfully accounts for the temporally sharp spin-orbit transitions consistent with orbital ordering observed near the magnetic zone center. However, the model fails to account for higher energy transfers, where well-defined spin waves are replaced by energy and momentum broadened excitations, characterized by steeply dispersive columns of scattering. The failure of the model and breakdown of spin-orbit excitations are discussed in terms of coupling to a higher energy process.

3:30PM V40.00004: Hund nodal line semimetals: The case of twisted magnetic phase in the double-exchange model*  RICHARD GEILHUFÉ (Presenter), NORDITA, Nordic Institute for Theoretical Physics, Stockholm University and KTH, Stockholm, Sweden, FRANCISCO GUINEA, Imdea Nanoscience, Madrid, Spain, VLADIMIR JURICIC, NORDITA, Nordic Institute for Theoretical Physics, Stockholm University and KTH, Stockholm, Sweden — In this talk, we discuss a class of topological metals, which we dub Hund nodal line semimetals, arising from the strong Coulomb interaction encoded in the Hund’s coupling between itinerant electrons and localized spins [1]. We consider a particular twisted spin configuration, which is realized in the double exchange model describing the manganite oxides. As we show, the resulting effective tetragonal lattice of electrons with hoppings tied to the local spin features an antiunitary non-symmorphic symmetry that in turn, together with another non-symmorphic but unitary glide mirror symmetry protects crossings of a double pair of bands along a high-symmetry line on the Brillouin zone boundary. We also discuss the stability of Hund nodal line semimetal with respect to symmetry breaking from various perturbations of the twisted phase. Our results motivate further studies of other realizations of this state of matter, for instance in different spin backgrounds and properties of its drumhead surface states.

*RMG acknowledges support from the Swedish Research Council (638-2013-9243), the KAW Foundation (2013.0096), VILLUM FONDEN (11744), and the European Unions Seventh Framework Program (FP/2207-2013)/ERC Grant No. DM-321031.

3:42PM V40.00005: Structural and electronic properties of doped NiO from density functional theory and quantum Monte Carlo simulations*  OLLE HEINONEN (Presenter), HYEONDEOK SHIN, Argonne National Laboratory, JARON KROGEL, PANCHAPAKESAN GANESH, Oak Ridge National Laboratory, FRIEDERIKE WROBEL, ANAND BHATTACHARYA, Argonne National Laboratory, PAUL KENT, Oak Ridge National Laboratory — NiO is a prototypical strongly correlated oxide. According to band filling, it should be a metal, but correlations drive the ground state to an antiferromagnetic insulator. The general question of how doping affects the electronic – and chemical – structure of correlated oxides is of great fundamental interest, but also important for the realization of electronics,“Motttronics”, based on correlated materials. We are studying hole- and electron-doped NiO using density functional theory (DFT) methods and much more accurate quantum Monte Carlo simulations and compare our results directly with experimental results on high-quality thin films grown by molecular beam epitaxy. One surprising result is that DFT in all flavors we have used fails to properly account for the K-O bond distance, and underestimates it by over 0.3 A compared to analysis based on extended X-ray absorption fine structure. Preliminary results using QMC show much better agreement with experiments, indicating that correlation effects beyond DFT have a dramatic effect on the energy landscape around the dopant.

*Supported by the U.S. DOE, Office of Science, BES, Materials Sciences and Engineering Division, as part of the Comp. Materials Sciences Program and Center for Predictive Simulation of Functional Materials.
3:54PM V40.00006: First Principles Electronic Structure Study of Ca$_2$CuO$_2$Cl$_2$  MATTHEW MATZELLE (Presenter), Northeastern University, CHENG HU, Chinese Academy of Sciences (CAS), CHRISTOPHER LANE, ROBERT MARKIEWICZ, Northeastern University, JIANWEI SUN, Tulane University, XINGJIANG ZHOU, Chinese Academy of Sciences (CAS), ARUN BANSIL, Northeastern University — We discuss Density Functional Theory (DFT) based results on the oxychloride cuprate Ca$_2$CuO$_2$Cl$_2$ (CCOC), which are obtained by using the recently constructed Strongly-Constrained-and-Appropriately-Normed (SCAN) functional. Theoretical results are compared and contrasted with the corresponding angle-resolved photoemission (ARPES) measurements. Previous first-principles DFT studies have found the ground state of the half-filled CCOC to be metallic in sharp disagreement with the experimentally observed insulating state. Although the insulating behavior can be captured by introducing an empirical Hubbard U parameter in first-principles computations, that reduces the predictive power of the theory. In sharp contrast, the SCAN functional yields the antiferromagnetic insulator phase with a gap in good agreement with optical conductivity studies without the need to invoke the Hubbard U. We also discuss how the electronic structure of CCOC evolves with hole doping.

4:06PM V40.00007: Strange metallicity in the doped Hubbard model EDWIN HUANG (Presenter), RYAN SHEPPARD, BRIAN MORITZ, THOMAS DEVEREAUX, Stanford University — Strange or bad metallic transport, defined by its incompatibility with conventional quasiparticle pictures, is a theme common to strongly correlated materials and ubiquitous in many high temperature superconductors. The Hubbard model represents a minimal starting point for modeling strongly correlated systems. Here we demonstrate strange metallic transport in the doped two-dimensional Hubbard model using determinantal quantum Monte Carlo calculations. Over a wide range of doping, we observe resistivities exceeding the Mott-Ioffe-Regel limit with linear temperature dependence. The temperatures of our calculations extend to as low as 1/40 the non-interacting bandwidth, placing our findings in the degenerate regime relevant to experimental observations of strange metallicity. Our results provide a foundation for connecting theories of strange metals to models of strongly correlated materials.

4:18PM V40.00008: A two-pronged approach to the cuprate pseudogap: A comparison of mode-coupling and first-principles (SCAN) results ROBERT MARKIEWICZ (Presenter), CHRISTOPHER LANE, Northeastern, YUBO ZHANG, JAMES FURNESS, Tulane, BERNARDO BARBIELLINI, Lappeenranta/Northeastern, ARUN BANSIL, Northeastern, JIANWEI SUN, Tulane — Density functional theory using the new SCAN exchange-correlation functional has successfully described the antiferromagnetic ground states of undoped cuprate superconductors. In YBa$_2$Cu$_3$O$_7$ (YBCO$_7$), the energy landscape involves a competition between many different nearly degenerate states – a mixture of antiferromagnetic and stripe states[1]. The organizing principle of these states remains Mott-like: the lower-energy phases tend to have a larger planar copper magnetic moment. In particular, all these phases have substantially lower energy than the nonmagnetic Fermi liquid phase found in most previous DFT calculations, showing that it can play no role in the low-energy properties of YBCO$_7$. The contrasting behaviors of YBCO$_6$ and YBCO$_7$ are reminiscent of the Mott-Slater crossover found in a mode-coupling model of the cuprates[2]. I will demonstrate how these two approaches illuminate each other, leading to a picture of the pseudogap as a gapped paramagnetic metal with only short-range order (SRO) over a broad temperature range. This work provides a realistic model for the cuprate pseudogap phase with implications for superconducting pairing.

4:30PM V40.00009: Tunable band gaps from anion ordering and octahedral tilting in oxyfluorides* RICHARD J SABALLOS (Presenter), JAMES M RONDINELLI, Northwestern University — Heteroanionic materials are currently receiving increased interest because they may support superior functionality than single-anion materials [1]. In perovskite structures, anion ordering combined with octahedral tilting provides new degrees-of-freedom (DOFs) from which to manipulate the chemical, physical and electronic properties. This control has been shown to tune the band gap in oxynitrides, but oxyfluorides remain underexplored [2,3]. Here we discuss the results of first-principles calculations on the experimentally known wide-bandgap semiconductor, KNaNbOF5 [4], and show that octahedral tilting and anion ordering can be used to tune the band gap. We show how the combination of these DOFs make it possible to decrease the band gap so it resides in the visible range. Finally, these results will be used to propose a design strategy for creating novel photovoltaic materials.

Four-spin ring interaction as a source of unconventional magnetic orders in orthorhombic perovskite manganites. Natalya Fedorova (Presenter), Amadé Bortis, Christoph Findler, Nicola Spaldin, ETH Zurich — We use ab initio electronic structure calculations and Monte Carlo simulations to investigate the magnetic and ferroelectric properties of bulk orthorhombic HoMnO₃ and ErMnO₃. Our goals are to explain the inconsistencies in the measured magnetic properties of the orthorhombic perovskite manganites (o-RMnO₃) with small rare-earth (R) cations or Y, as well as the contradictions between the directions and amplitudes of the electric polarizations reported by different experimental groups. We find that several unconventional magnetic orders (so-called w-spiral, H-AFM and I-AFM) can be stabilized in these materials due to strong four-spin ring exchange interactions. We show that the presence of these orders resolves the contradictions in the measured magnetic and ferroelectric properties of o-RMnO₃.

Spin-orbital-entangled \( J_{\text{eff}} = 1/2 \) state in 3d transition metal oxide CuAl₂O₄. Choong Hyun Kim (Presenter), Hwanbeom Cho, Santu Baidya, Center for Correlated Electron Systems, Institute for Basic Science & Seoul National University, Vladimir Gapontsev, Sergey Streltsov, M.N. Miheev Institute of Metal Physics of Ural Branch of Russian Academy of Sciences, Daniel Khomskii, Universität zu Köln, Je-Guen Park, Center for Correlated Electron Systems, Institute for Basic Science & Seoul National University, Ara Go, Center for Theoretical Physics of Complex Systems, Institute for Basic Science, Hosub Jin, Ulsan National Institute of Science and Technology — We show that CuAl₂O₄ spinel can host a spin-orbital-entangled \( J_{\text{eff}} = 1/2 \) state. During the long history of the 3d transition metal study, spin-orbit coupling has never been a dominating energy scale. Here we propose on the CuAl₂O₄ as the first example of a \( J_{\text{eff}} = 1/2 \) Mott insulator in 3d transition metal compounds. From single crystal X-ray diffraction data, our CuAl₂O₄ is confirmed to have cubic structure without Jahn-Teller distortion and it is consistent with first-principles total energy calculations. Density functional theory combined with dynamical mean field theory calculations reveal that the \( J_{\text{eff}} = 1/2 \) state survives the competition with the orbital-momentum-quenched \( S=1/2 \) state with the help of strong electron correlation.

Multi-loop contributions in the pseudo-fermion functional renormalization group for quantum spin systems: implementation and consequences. Tobias Müller (Presenter), Institute for Theoretical Physics and Astrophysics, University of Wuerzburg, Yasin Iqbal, Indian Institute of Technology Madras, Johannes Reuther, Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, Ronny Thomale, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg — We extend the pseudo-fermion functional renormalization group (PFFRG) treatment of quantum spin systems by including diagrammatic higher loop contributions into the renormalization group flow. This allows us to consistently account for all contributions of parquet-type diagrams in the two-particle vertex and self-energy derivatives within the two-particle truncated PFFRG flow. We will discuss the impact of these corrections in different quantum spin models within PFFRG, especially in the light of the Mermin-Wagner theorem.

2:30PM V41.00001: Reservoir Computing with Random Skyrmion Fabrics [Invited] DANIELE PINNA (Presenter), Johannes Gutenberg University — The topologically protected magnetic spin configurations known as skyrmions offer promising applications due to their stability, mobility and localization. Thanks to their many nanoscale properties, skyrmions have been shown to be promising in many applications ranging from non-volatile memory and spintronic logic devices, to enabling the implementation of unconventional computational standards such as Stochastic computing. In this talk we will discuss how a random skyrmion \``fabric`` composed of skyrmion clusters embedded in a magnetic substrate can be effectively employed to implement a functional Reservoir Computing device for recognizing and predicting spatio-temporal events. This is achieved by leveraging the nonlinear resistive response of the individual skyrmions arising from their current dependent anisotropic magneto-resistance effect (AMR). Complex time-varying current signals injected via contacts into the magnetic substrate are shown to be modulated nonlinearly by the fabric’s AMR due to the current distribution following paths of least resistance as it traverses the geometry. By tracking resistances across multiple input and output contacts, we show how the instantaneous current distribution effectively carries temporally correlated information about the injected signal. This in turn allows us to numerically demonstrate simple pattern recognition. We argue that the fundamental ingredients for such a device to work are threefold: i) Concurrent probing of the magnetic state; ii) stable ground state when forcings are removed; iii) nonlinear response to input forcing. Whereas we demonstrate this by employing skyrmion fabrics, the basic ingredients should be general enough to spur the interest of the greater magnetism and magnetic materials community to explore novel reservoir computing systems.

3:06PM V41.00002: Rare Earth-Transition Metal Alloys as Promising Materials for Small Skyrmions and Ultrafast Chiral Spin Texture Dynamics LUCAS CARETTA (Presenter), MAXWELL MANN, FELIX BUETTNER, KOHEI UEDE, CAN AVCI, ETHAN ROSENBERG, JACKSON BAUER, Massachusetts Institute of Technology, BASTIAN PFALU, CHRISTIAN GÜNThER, PIET HESSING, Max-Born-Institut, ALEXANDRA CHURIKOVA, Massachusetts Institute of Technology, CHRISTOPHER KLOSE, MICHAEL SCHNEIDER, DIETER ENGEL, Max-Born-Institut, COLIN MARCUS, DAVID BONO, Massachusetts Institute of Technology, BASTIAN PFAU, CHRISTIAN GÜNTHER, PIET HESSING, Max-Born-Institut, ALEXANDRA CHURIKOVA, Massachusetts Institute of Technology, CHRISTOPHER KLOSE, MICHAEL SCHNEIDER, DIETER ENGEL, Max-Born-Institut, COLIN MARCUS, DAVID BONO, Massachusetts Institute of Technology — Spintronics aims to understand and control spins on the nanoscale and should enable next-generation data storage and logic devices. One technological and scientific key challenge is to stabilize small spin textures and to manipulate them efficiently with high speeds [1-3]. Inspired by hard disk materials, research has primarily focused on ferromagnetic materials, but these materials show fundamental limits for speed and size [4-6], calling for radically different ideas [4-7]. Here, we demonstrate that compensated ferrimagnets are not affected by these limits. We realize a current-driven domain wall velocity of over 1 km/s near the angular momentum compensation temperature (T_A) and room-temperature stable skyrmions with minimum observed diameters approaching ~10 nm near magnetic compensation (T_M). We present theory explaining these observations and demonstrate that high-speed, high-density spintronics devices based on current-driven spin textures can be realized using materials where T_A and T_M are close together.

Skyrmion lattice with a giant topological Hall effect in a frustrated triangular-lattice magnet Gd$_2$PdSi$_3$*  

TAKASHI KURUMAJI (Presenter), Physics, MIT, TARO NAKAJIMA, MAX HIRSCHBERGER, AKIKO KIKKAWA, RIKEN Center for Emergent Matter Science, YUICHI YAMASAKI, University of Tokyo, HAJIME SAGAYAMA, HIRONORI NAKAO, KEK, YASUJIRO TAGUCHI, RIKEN Center for Emergent Matter Science, TAKAHISA ARIMA, University of Tokyo, YOSHINORI TOKURA, RIKEN Center for Emergent Matter Science — Frustrated magnets provide abundant opportunities for discovering complex spin textures, which sometimes yield unconventional electromagnetic responses in correlated electron systems. It is theoretically predicted that magnetic frustration may also promote a topologically nontrivial spin state [1], i.e., magnetic skyrmions. Empirically, however, skyrmions are essentially concomitant with noncentrosymmetric lattice structures or interfacial symmetry-breaking heterostructures [2]. Here, we report the emergence of a Bloch-type skyrmion state in a frustrated centrosymmetric triangular-lattice magnet Gd$_2$PdSi$_3$ [3]. We identified the field-induced skyrmion phase via a giant topological Hall response, which is further corroborated by the observation of in-plane spin modulation probed by resonant x-ray scattering. Our results exemplify a new platform of magnetic frustration for producing topological spin textures endowed with emergent electrodynamics in centrosymmetric magnets.

*This research was supported in part by JSPS Grant-in-Aid No. 24224009, No. 17K14351, and No. 16H05990, and by PRESTO No. JPMJPR177A from JST.

Observation of topological Hall effect in amorphous Fe/Gd heterostructures with asymmetric Bloch-type domain wall chirality population.

SERGIO MONTOYA (Presenter), Space and Naval Warfare Systems Center Pacific, JORDAN J CHESS, BENJAMIN J MCMORRAN, Physics, University of Oregon, ERIC FULLERTON, Electrical and Computer Engineering, University of California San Diego — The non-trivial topological nature of chiral magnetic spin textures results in novel electromagnetic properties, such as the topological Hall effect (THE) which commonly appears as an anomaly in the Hall resistivity. So far, the THE has been primarily observed in magnetic crystals lacking inversion symmetry (e.g. MnSi [1], MnGe [2], SrRuO$_3$-SrIO$_3$[3]). In these systems, the magnetic spin textures possess a single Bloch- or Néel-type chirality that is set by either a bulk or an interfacial antisymmetric exchange interaction, commonly known as Dzyaloshinskii-Moriya interaction.

We report the observation of a THE in amorphous rare-earth transition-metal heterostructures with perpendicular magnetic anisotropy that possess a coexistence of left and right chiral Bloch-type domain walls with unequal population distribution. A combination of real-space observations by Lorentz TEM, magnetometry and transport measurements reveal one can engineer amorphous thin-film materials with a controllable THE, as will be discussed, based on temperature dependent studies on several heterostructures.

Single magnetic skyrmion creation, detection, and dynamics within a magnetic tunnel junction*  

NICHOLAS PENTHORN (Presenter), RAJAPAKSAYALAGE N RAJAPAKSE, Physics & Astronomy, University of California, Los Angeles, XIAOJIE HAO, ZIHUI WANG, YIMING HUAI, Avalanche Technology, HONGWEN JIANG, Physics & Astronomy, University of California, Los Angeles — We experimentally demonstrate the deterministic creation of a stable topological spin texture in the free layer of a magnetic tunnel junction at cryogenic temperatures. Through simultaneous measurements of tunnel magnetoresistance and spin-polarized current-induced magnetic resonance, we find that the spin texture is characterized by a field-dependent intermediate junction resistance and a unique magnetic resonance signature. Comparing our findings to micromagnetic simulations, we confirm that the spin texture transition is best described by the nucleation of a single Bloch-type skyrmion in the free layer, aided by a spatially nonuniform stray field from surrounding magnetic layers. We subsequently identify the skyrmion breathing mode in the resonance spectrum and obtain an estimate for the skyrmion diameter at zero field of 75 nm. This result is the first confirmation that magnetic tunnel junctions are viable candidates for skyrmion-based memory and logic architectures could lead to non-invasive, on-chip skyrmion measurement and detection.

3:54PM V41.00006: Sluggish steady flow of skyrmion lattice in a confined geometry  TAKURO SATO (Presenter), WATARU KOSHIBAE, AKIKO KIKKAWA, TOMOYUKI YOKOUCHI, RIKEN Center for Emergent Matter Science (CEMS), HIROSHI OIKE, The University of Tokyo, YASUJIRO TAGUCHI, NAOTO NAGAOSA, YOSHINORI TOKURA, FUMITAKA KAGAWA, RIKEN Center for Emergent Matter Science (CEMS) — An aggregate of magnetic skyrmions\textsuperscript{1,2}, topologically protected particlelike objects, is an emerging exotic fluid that flows under electric current\textsuperscript{3,4}. From a hydrodynamics point of view, the skyrmion fluid is peculiar in that its steady flow does not necessarily require a closed-loop skyrmion circuit. However, it remains largely unclear how this peculiarity is involved in the skyrmion steady-flow dynamics. Here, we show that the skyrmion steady flow dramatically slows down when the influence of system edges is not negligible. In the micrometre-sized MnSi, the steady-flow velocity is anomalously slow, as evidenced by the observation of resistance narrow-band noise with 10–10\textsuperscript{4} Hz, and its temperature evolution suggests that the steady flow entails thermally activated processes, which are due most likely to the skyrmion creation and annihilation at the edges. Moreover, numerical simulations reveal that the edges limit the skyrmion motion. Thus, our findings capture a vital role of the edges on the skyrmion steady flow, especially in a microstructure.

4:06PM V41.00007: Visualizing the dynamics of sub-100 nm Néel Skyrmions in Multilayer Nanowires* ANTHONY K C TAN (Presenter), Atomic, Mesoscopic and Optical Physics (AMOP) Group, Cavendish Laboratory, University of Cambridge, PIN HO, LISEN HUANG, JAMES LOUREMBAM, SARJOOSING GOOLAUP, ANJAN SOUMYANARAYANAN, Institute of Materials Research and Engineering (IMRE), Agency for Science, Technology and Research (A*STAR) — The emergence of room temperature skyrmions in technologically-relevant multilayers has intensified efforts towards realizing these topologically stable, nanoscale spin structures for next generation technologies, in particular, neuromorphic computing, Internet of Things. Of great interest is the lateral manipulation of skyrmions on a Racetrack, which builds on their deterministic response to current-induced spin torques in nanowires. Thus far, a clear understanding of the factors governing the dynamics of small (sub-100 nm) skyrmions in granular films remains to be established. Here we utilize magnetic force microscopy to investigate the collective dynamics of a dense skyrmion array with individual speeds up to 24ms\textsuperscript{-1}, in 2um-wide Pt/Co/MgO nanowires. By examining \textasciitilde 2x10\textsuperscript{4} instances of skyrmion motion, we observe several emergent behaviours including the interplay of edge confinement and skyrmion Hall effect, which is crucial to understanding edge-induced skyrmion pinning in Racetrack architectures. In this work, we also detail the effects of skyrmion size, skyrmion-skyrmion interactions and pinning on skyrmion dynamics. The rich dynamics of skyrmions uncovered in our study will potentially fast-track the realization of skyrmion-based Racetrack devices.

4:18PM V41.00008: Skyrmion Clustering and Dynamics in Strong Pinning or with Strong Magnus Force Dispersion CHARLES REICHHARDT (Presenter), CYNTHIA REICHHARDT, Los Alamos National Laboratory — We show that skyrmions can exhibit density phase separation when driven over strong pinning. This occurs due to the Magnus force interaction, which creates regions of differing effective skyrmion Hall angle, combined with a density dependence of the skyrmion velocity, which is similar to the density dependent velocity observed at clustering transitions in active matter systems. We also investigate the effect of introducing a dispersion in the Magnus force experienced by individual skyrmions, which could arise if different skyrmion species or sizes coexist in a single sample. In this case, we find that the motion of the different species is locked at low drives, but as the drive increases, a disordering transition occurs when the species begin to slide past each other. At higher drives there is a transition to a species phase separated state in which skyrmions with the same Magnus force cluster together. These transitions are associated with signatures in the skyrmion structure, transport response, and velocity fluctuation spectra.
Skyrmion Dynamics under the Influence of Defects from DFT to ASD

JONATHAN CHICO (Presenter), IMARA LIMA FERNANDES, STEFAN BLUEGEL, SAMIR LOUNIS, 1Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Julich & JARA — Any potential skyrmionic application must be able to handle the impact of defects on the skyrmion motion. Until now, most approaches focus on large skyrmions using phenomenological schemes in the micromagnetic regime. Using a combination of first-principles calculations and atomistic spin dynamics, the complex motion of technologically more relevant small skyrmions in Pd/Fe/Ir(111) with 3d and 4d single-atomic defects is studied. Recently, it was shown that such defects can either repel or pin skyrmions [1]. It can be observed that the current threshold needed to overcome the energy barriers, resulting from the impurities, depends on their chemical nature. The obtained dynamical behaviour is richer and goes beyond the expected from the Thiele equation. The complexity of the different motion regimes is revealed and compared with what is known for larger skyrmions. The present study also shines light on how one can engineer defects-based pathways for controlled skyrmion motion.

Anisotropic magnetoresistance in epitaxial FeGe thin films

ADAM AHMED (Presenter), BRENDAN MCCULLIAN, TAO LIU, ROLAND KAWAKAMI, P CHRIS HAMMEL, Ohio State University — The advent of skyrmion imaging and electrical detection is an exciting avenue of research as skyrmions hold promise for next-generation magnetic storage. Presently, in B20 materials, electrical measurements have focused on the detection of non-trivial topological spin textures via topological Hall effect. To further our understanding of transport properties in non-centrosymmetric materials that host skyrmions, we have performed angular-dependent magnetoresistance (ADMR) in the saturated magnetic phase. We have grown epitaxial B20 FeGe/Si(111) films by molecular beam epitaxy. Several features appear in the vicinity of the Curie temperature of 280 K that also persist well above this temperature. Additionally, these features are highly magnetic field dependent. At low temperatures, the signal is dominated by the anisotropic magnetoresistance (AMR) contribution. However, as we approach the magnetic ordering temperature, a strong six-fold symmetric contribution appears. This term, reflecting the crystal symmetry, possibly originates from the magneto-crystalline anisotropy. Curiously, this feature continues to grow in magnitude up to 14 T. We discuss possible origins of these effects above and below the Curie temperature.

Controlling Skyrmion Hall Angle by engineering mixed skyrmions with stray fields

HAMED VAKILITALEGHANI (Presenter), YUNKUN XIE, JIANHUA MA, AVIK GHOSH, University of Virginia — Skyrmions, topologically protected quasi particles in magnetic materials, are widely explored as candidate excitations to store and transmit information. The dynamics of an isolated skyrmion on a racetrack is limited by the Magnus force for a Neel skyrmion and damping force for a Bloch skyrmion. For identical parameters, Neel and Bloch skyrmions tend to move perpendicular to each other. This orthogonality can be understood by the fact that Neel and Bloch skyrmions can be continuously deformed into each other by a 90 degree rotation in parameter space, which can also be seen as a 90 degree rotation of a frame of reference fixed on a point on the boundary of the skyrmion. Accordingly for a mixed skyrmion it is possible to achieve a movement parallel to the drive current with zero spin Hall angle, which is ideal for controlled skyrmion motion in racetrack applications. The mixed skyrmion can be engineered by a combination of the interfacial DMI, which favors the Neel skyrmion, and the stray field which favors the Bloch skyrmion, without the use of synthetic antiferromagnetic multilayer structures.

*This work is supported by the DARPA-Texitronics program and NSF-SHF-1514219.
5:06PM V41.00012: Temperature dependent skyrmion Hall angle in ferrimagnets*  
MICHAEL VOGEL (Presenter), Materials Science Division, Argonne National Laboratory, XIAO WANG, Department of Physics, Bryn Mawr College, PAVEL N. LAPA, Department of Physics, University of California, San Diego, JOHN E. PEARSON, Materials Science Division, Argonne National Laboratory, XUEMEI CHENG, Department of Physics, Bryn Mawr College, AXEL F. HOFFMANN, SUZANNE GABRIELLE TE VELTHUIS, Materials Science Division, Argonne National Laboratory — Analogous to the Hall effect where electronic charges moving in the presence of a magnetic field acquire a transverse velocity, magnetic solitons with non-zero topological charges (i.e. skyrmions and chiral domains walls) exhibit the skyrmion Hall effect, which opens up new possibilities for manipulating the trajectories of these quasiparticles. The skyrmion Hall effect has been theoretically predicted to vanish for antiferromagnetic skyrmions because of the cancelation of opposite topological charges. We present a study of current driven domain wall dynamics in artificially ferrimagnetic multilayers: Ta(4 nm)/Pt (5 nm)/[Co (0.5 nm)/Gd (1 nm)/Pt(1 nm)]10/Al (2 nm). The magnetic texture in different layers of the multilayer films are coherent and antiferromagnetically aligned. Here we experimentally investigate the current driven magnetization dynamics from room temperature down to temperatures below the compensation point at around 100 K.

*Work at Argonne was supported by the US-DOE, Office of Science, MSED. Use of the Center for Nanoscale Materials was supported by the US-DOE, Office of Science, BES, under contract no. DE-AC02-06CH11357. The work at Bryn Mawr is supported by NSF DMR #1708790.

5:18PM V41.00013: Chiral fluctuation driven topological Hall effect in two-dimensional ferromagnets*  
WENBO WANG (Presenter), Department of Physics and Astronomy, Rutgers University, Piscataway, NJ 08854, USA, MATTHEW W DANIELS, Institute for Research in Electronics and Applied Physics, University of Maryland, College Park, MD 20742, ZHAOLIANG LIAO, National Synchrotron Radiation Laboratory, University of Science and Technology of China, Hefei, 230026 Anhui, People's Republic of China, JUN WANG, GERTJAN KOSTER, GUUS RIJNDERS, MESA+ Institute for Nanotechnology, University of Twente, 7500 AE Enschede, the Netherlands, DI XIAO, Department of Physics, Carnegie Mellon University, Pittsburgh, Pennsylvania 15213, USA, WEIDA WU, Department of Physics and Astronomy, Rutgers University, Piscataway, NJ 08854, USA — Topological Hall effect (THE) is a real space Berry phase phenomenon originated from the non-coplanar spin texture[1]. Recently THE has been associated with the formation of skyrmions in chiral magnets[2][3]. Although chiral fluctuation driven topological charges have been predicted in chiral magnets, the resultant THE has not been observed yet[4]. Herein, we report a surprising observation of THE around ferromagnetic transition temperature $T_C$ in the ferromagnetic SrRuO$_3$ thin films. The temperature, magnetic field, and thickness dependence of THE are in good agreement with our Monte-Carlo simulations, which provides compelling evidence of the emergence of net topological charges due to chiral fluctuation.

Session V43 DCMP: Pairing and Nematicity in Half-filled Landau Levels  
BCEC 210B - Raymond Ashoori, Massachusetts Institute of Technology - Tag(s): Invited
2:30PM V43.00001: The role of electron-electron interactions in the paired-to-nematic transition* [Invited] NOAM BERNSTEIN (Presenter), Naval Research Laboratory — The problem of the ground state of a two-dimensional electron gas at half-filled Landau levels has been a remarkably interesting one. Depending on the number of filled Landau levels, besides the Fermi liquid ground state there are two well-known ordered phases: paired fractional quantum Hall states in the second Landau level and the electronic nematic (or stripe) phases in high Landau levels. Nonetheless, the presence of both of these ordered phases and therefore a transition between them did not seem possible in the absence of an externally applied symmetry breaking field favoring the nematic. This state of affairs has changed recently with the observation a pressure-driven quantum phase transition between the ν=5/2 fractional quantum Hall state, a paired state, and the nematic phase. Here we provide evidence of a similar quantum phase transition at filling factor ν=7/2 and discuss the role of the hydrostatic pressure in driving the transition. Our work highlights universal aspects of the competition of pairing and nematicity present in various condensed matter systems as well as in very clean two-dimensional electron gases. Work done in collaboration with Katherine Schreiber, Nodar Samkharadze, Y. Lyanda-Geller, G. Gardner, M.J. Manfra, L.N. Pfeiffer, and K.W. West.

3:06PM V43.00002: Even-denominator fractional quantum Hall states in bilayer graphene [Invited] CORY DEAN (Presenter), Columbia University — TBD

3:42PM V43.00003: Competing correlated phases in orbitally mixed half-filled Landau levels [Invited] JOSEPH FALSON (Presenter), Max Planck Institute for Solid State Research — An astounding array of correlated phases have been experimentally realized in high quality two-dimensional electron systems (2DES). By exploiting the quantizing effects of a magnetic field, these systems form an ideal platform for studying the competition between compressible, incompressible and nematic liquids owing to a tunable Landau level index (N) which influences the nature of the ground state. Here, I will present data taken on state-of-the-art MgZnO/ZnO heterostructures that offer the ability to tune N while remaining at a constant Landau level filling. By rotating the sample within a magnetic field, it is possible to selectively decouple the Zeeman and cyclotron energy terms and induce a level crossing between opposing spin branches of the neighboring N=1 and 0 levels. In contrast to the naive expectation of a first-order spin flop transition, an unexpectedly complex cascade of phases is resolved as we incrementally shift the spin and orbital polarization of carriers between levels while remaining at v=5/2 filling. Transport signatures associated with two instances of incompressibility are observed, in addition to two compressible phases and an unanticipated anisotropic phase which breaks rotational symmetry. Our experiments indicate that the depolarization process is gradual and complex. In addition to level polarized states, the unexpected incompressible and anisotropic phases observed in the orbitally mixed regime open questions concerning the possibility of novel interlevel coherence occurring at fractional fillings in systems with strongly mixed levels.

4:18PM V43.00004: Competing charge density waves probed by non-linear transport and noise in the second and third Landau levels [Invited] GUILLAUME GERVAIS (Presenter), McGill University — Competing quantum ground states are ubiquitous in strongly-interacting many-body systems. One prime example is the competition between Wigner crystallization and fractional quantum Hall (FQH) liquids that occurs deep in the first Landau level (LL) of the two-dimensional electron gas (2DEG). In higher LLs, the situation is much more complex, where charge density waves (CDWs) in the form of stripe and bubble phases are also competing with incompressible FQH liquids. In this talk, I will present our results [1] concerning the competition of CDWs and FQH in the second and third LL of an ultra-high mobility GaAs/AlGaAs 2DEG, as probed by both non-linear electronic transport and noise measurements. These measurements were performed in a Corbino geometry to ensure that only bulk properties of the 2DEG were probed, thereby precluding any contribution coming from edge states. Sliding transport of CDWs was revealed by narrow-band noise in re-entrant quantum Hall states of the second LL identified by the Csathy group [2], as well as in pinned CDWs of the third LL. The combining of noise data with maps of conductivity versus magnetic field and bias voltage revealed a complex competition occurring between various quantum phases in the form of stripes, pinned CDWs and fractional quantum Hall liquids, and is consistent with recent results from the Manfra group for the stripe phase suggesting a transition between a smectic and nematic phase at finite temperatures [3].

4:54PM V43.00005: Energy, Momentum, and Spin-resolved tunneling spectra of quantum Hall systems* [Invited]

HEUN MO YOO (Presenter), JOONHO JANG, Massachusetts Institute of Technology, LOREN PFEIFFER, KIRK BALDWIN, KENNETH WEST, Princeton University, RAYMOND ASHOORI, Massachusetts Institute of Technology — Tunneling spectroscopy has an unique power in probing strong electronic correlations of many-body states in a solid. Here, we introduce a novel contactless pulsed tunneling technique that can visualize the energy, momentum, and spin-resolved electronic structure of a quantum Hall effect system. Unlike conventional planar tunneling that requires in-plane conductivity of the system, the pulsed tunneling method functions on strongly insulating systems at exact integer or fractional quantum Hall states. Furthermore, through use of pulses that drive tunneling in the extremely short time intervals, the technique eliminates perturbations such as heating effects or photo-excited defects that commonly occur in other methods. Using the pulsed tunneling technique, we visualize the evolution of discrete quantization of energy levels as well as the effect of electron-optic phonon interactions in energy-momentum space [1]. In addition to momentum and energy resolution, we performed spin-resolved tunneling that probes the ground-state spin polarization of the fractional quantum Hall states in a wide range of magnetic fields and filling factors. Moreover, we can detect the spin-dependent high energy states arising from the strong pair interactions. From these high energy features, we measure Haldane's pseudopotentials that enabled us to directly determine the stability of the composite Fermi sea in a half-filled Landau level. These results illustrate the potentially broad applicability of the pulsed tunneling technique for studying the correlated electronic phases in a variety of two-dimensional materials.

Session V44 DCMP: Topological Magnons BCEC 210C - Nandini Trivedi, Ohio State University - Tag(s): Invited

2:30PM V44.00001: Topological magnon bands in ultra-thin film pyrochlore iridates and iron jarosites* [Invited]

GREGORY FIETE (Presenter), Department of Physics, Northeastern University — We describe recent theoretical efforts of our group aimed at exploring two-dimensional magnetic systems described by local moment models that possess topological band structures of the low-energy spin fluctuations. We study two systems: (1) Ultra-thin film pyrochlore iridates grown along the [111] direction and (2) the iron jarosites. For the thin film pyrochlore iridates, we consider a bilayer and trilayer and find that in the trilayer case the ground state is the all-in–all-out (AIAO) state, whereas the bilayer has a deformed AIAO state. For range of parameters the lowest magnon band in the trilayer and bilayer case has a nonzero Chern number. We calculate the magnon Hall response for both geometries, finding a striking sign change as a function of temperature. For the iron jarosites, we study magnetic and topological properties of antiferromagnetic kagome spin systems in the presence of both in- and out-of-plane Dzyaloshinskii-Moriya interactions. The in-plane interactions stabilize a canted noncollinear “umbrella” magnetic configuration with finite scalar spin chirality. We derive expressions for the canting angle and use the resulting order as a starting point for a spin-wave analysis. We find topological magnon bands, characterized by nonzero Chern numbers. We calculate the magnon thermal Hall conductivity and propose the iron jarosites as a promising candidate system for observing the magnon thermal Hall effect in a noncollinear spin configuration. We also show that the thermal conductivity can be tuned by varying an applied magnetic field or the in-plane Dzialoshinskii-Moriya strength. In contrast to previous studies of topological magnon bands, the effect is found to be large even in the limit of small canting.

*Work done in collaboration with Pontus Laurell. We gratefully acknowledge funding from the NSF, ARO, and the Simons Foundation.
3:06PM V44.00002: Topological spin excitations in a three-dimensional antiferromagnet* [Invited] WEILIANG YAO, CHENYUAN LI, LICHEN WANG, SHANJIE JUE, YANG DAN, International Center for Quantum Materials, Peking University, KAZUKI IIDA, KAZUYA KAMAZAWA, Comprehensive Research Organization for Science and Society, Japan, KANGKANG LI, JIANGPING HU, CHEN FANG, Institute of Physics, Chinese Academy of Sciences, YUAN LI (Presenter), International Center for Quantum Materials, Peking University — The recent discovery of topological semimetals, which possess distinct electron-band crossing with non-trivial topological characteristics in the bulk, has stimulated intense research interest. By extending the notion of symmetry-protected band crossing into one of the simplest magnetic groups, namely by including the symmetry of time-reversal followed by space-inversion, we predict the existence of topological magnon-band crossing in three-dimensional antiferromagnets [1]. The crossing may take the forms of Dirac points and nodal lines, in the presence and absence, respectively, of the conservation of the total spin along the ordered moments. In a concrete example of a Heisenberg spin model for a “spin-web” compound, Cu3TeO6, we theoretically demonstrate the presence of Dirac magnons over a wide parameter range using linear spin-wave approximation [1]. Inelastic neutron scattering experiments have been carried out to detect the bulk magnon-band crossing in a single-crystal sample [2]. The highly interconnected nature of the spin-1/2 lattice suppresses quantum fluctuations and facilitates our experimental observation, leading to remarkably clean experimental data and very good agreement with the linear spin-wave calculations. The predicted topological magnon Dirac points are confirmed. Further studies will be discussed, including determination of non-collinear spin canting in the ground state with neutron diffraction, and search for topological magnon surface states with inelastic neutron scattering.

*This work is supported by the NSFC and the MOST of China.

3:42PM V44.00003: Topology of magnons: classification and application to honeycomb Kitaev magnets* [Invited] YUAN-MING LU (Presenter), Ohio State University — Compared to their electronic counterparts in topological band theory, much less is known about the topology of spin wave excitations in a general magnetic order. Here we provide a generic theory framework to classify and compute the topology of magnons, by mapping an arbitrary linear spin wave into a local free-fermion Hamiltonian with exactly the same spectrum, symmetry implementation and band topology. This allows us to achieve a full classification and calculation on any topological properties of magnon bands. We apply this fermionization approach to honeycomb Kitaev magnet α-RuCl3, and show the existence of topologically protected magnon band crossings, and field-induced magnon Chern bands under small magnetic fields.

*This work is supported by the Center for Emergent Materials, an NSF MRSEC, under award number DMR-1420451; by NSF under award number DMR-1653769 and in part by NSF PHY-1607611.

4:18PM V44.00004: Discovery of coexisting Dirac and triply degenerate magnons in a three-dimensional antiferromagnet* [Invited] JINSHENG WEN (Presenter), Nanjing University — Topological magnons are emergent quantum spin excitations featured by magnon bands crossing linearly at the points dubbed nodes, analogous to fermions in topological electronic systems. In this talk, we show direct spectroscopic evidence for the coexistence of symmetry-protected Dirac and triply degenerate nodes, the latter involving three-component magnons beyond the Dirac–Weyl framework, by measuring spin excitations of a three-dimensional antiferromagnet Cu3TeO6 with inelastic neutron scattering. Our theoretical calculations show that the observed topological magnon band structure can be well described by the linear-spin-wave theory based on a Hamiltonian dominated by the nearest-neighbor exchange interaction J1. As such, we showcase Cu3TeO6 as an example system where Dirac and triply degenerate magnonic nodal excitations coexist, demonstrate an exotic topological state of matter, and provide a fresh ground to explore the topological properties in quantum materials.

*Work at Nanjing University was supported by National Natural Science Foundation of China with Grant Nos. 11674157, 11774152, 11374138, 11674158 and 11525417, National Key Projects for Research & Development of the Ministry of Science and Technology of China with Grant No. 2016YFA0300401, and Fundamental Research Funds for the Central Universities with Grant No. 020414380105. The research at Oak Ridge National Laboratory’s Spallation Neutron Source was sponsored by the US Department of Energy, office of Basic Energy Sciences, Scientific User Facilities Division.
The surprising usefulness of magnons at intermediate and high energies: from frustration to topology

RODERICH MOESSNER (Presenter), MPI-PKS Dresden — Magnons are among the oldest known elementary excitations, yet very recent developments have yielded plenty of surprises. This talk will cover three aspects of magnons in frustrated magnets -- (i) their topological properties, (ii) their survival at intermediate energies, as well as (iii) their unexpected utility in an S=1 spin liquid state.

Thursday, March 7, 2019 2:30 PM - 5:30 PM

Session V46 DMP GMAG: 4d/5d Transition Metal Systems -- New Phases

Magnetic interactions and possible quantum paraelectricity in spin liquid candidate H₃LiIr₂O₆

SHUAI WANG, Peking University, LONG ZHANG, Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, FA WANG (Presenter), Peking University — H₃LiIr₂O₆ was recently synthesized and found to be potentially a quantum spin liquid. We studied the crystal structure and magnetic interactions of this material by first principles calculations, and further studied the resulting phase of the obtained pseudospin model by exact diagonalizations. We found that the dominant magnetic interaction of this material is ferromagnetic Kitaev interaction, but residue (further neighbor) Heisenberg interactions would still produce a zigzag magnetic order. We then studied the quantum effect of the hydrogen ions(protons), and found that the electric dipoles of O-H-O “hydrogen bonds” are disordered by strong quantum fluctuations. The electric dipole fluctuations can renormalize the magnetic interactions and potentially lead to a Kitaev spin liquid state in this material. We thus propose that H₃LiIr₂O₆ is a quantum spin liquid promoted by quantum paraelectricity.

RIXS studies of the low-energy magnetic excitations in double perovskite iridates La₂BIrO₆ (B=Co, Ni, Zn)

WENTAO JIN (Presenter), SAE HWAN CHUN, Department of Physics, University of Toronto, Canada, JUNGHO KIM, DIEGO M CASA, Advanced Photon Source, Argonne National Laboratory, USA, CHOONGJAE WON, KYUNGDONG LEE, NAMJUNG HUR, Department of Physics, Inha University, Korea, YOUNG-JUNE KIM, Department of Physics, University of Toronto, Canada — Ordered double perovskite (DP) materials [1-3], A₂BB'₆O₆, where B is a 3d and B’ is a 4d or 5d transition metal ion, respectively, provide a rare opportunity to study the interaction between the intriguing magnetic behaviors of 5d systems and the better understood 3d magnetism, which is important for developing potential applications of these novel magnetic systems. Using resonant inelastic x-ray scattering (RIXS) measurements at Ir L₃ edge, we have investigated the low-energy magnetic excitations in a series of La₂BIrO₆ single crystals, where B is Co, Ni and Zn, respectively. In La₂CoIrO₆ and La₂NiIrO₆, clear magnetic excitations with a large magnon gap ~ 40 meV were revealed, indicating an extremely large magnetic anisotropy in the magnetic interaction in these two compounds containing magnetic 3d ions. In contrast, the low energy magnon mode was absent in La₂ZnIrO₆ in which the 3d ions are non-magnetic, suggesting the importance of 3d-5d hybridization in the magnetic properties of DP iridates.

This work is supported by Natural Science and Engineering Research Council of Canada through Discovery Grant and CREATE program.
2:54PM V46.00003: Effect of charge doping in Os-based double perovskites with strong spin-orbit coupling  
ERICK GARCIA (Presenter), RONG CONG, Brown University, PHUONG TRAN, PATRICK WOODWARD, Department of Chemistry, The Ohio State University, VESNA F. MITROVIC, Brown University, SAMUELE SANNA, Department of Physics and Astronomy, University of Bologna — The combined effects of strong electronic correlations and spin-orbit coupling (SOC) leads to a plethora of emergent novel quantum states. However, predicting such emergent properties is complicated by the fact that spin is not a good quantum number in the presence of SOC. Therefore, experimental studies by local probes are highly sought to guide theoretical descriptions of this new physics. Double perovskite structures are particularly interesting cases of materials with such novel quantum states. Here, we investigate the effects of charge doping via the Na+/Ca++ partial substitution on the magnetic ground state of Ba$_2$NaOsO$_6$, a double perovskite with strong SOC. Ba$_2$NaOsO$_6$ is a 5d$_1$ Mott insulator that displays an exotic canted two-sublattice ferromagnetic state believed to be driven by the staggered quadrupolar order [L. Lu et al. *Nature Comm.* 2017], while Ba$_2$CaOsO$_6$ is a 5d$_2$ compound which displays an antiferromagnetic phase [C.M. Thompson et al. *J. Phys. Cond. Matter* 2014]. We present zero field μSR measurements on powder samples of the compound Ba$_2$Na$_{1-x}$Ca$_x$OsO$_6$ for 0 < x < 1 to investigate the interplay between spin, orbital, and charge degrees of freedom, which are believed to govern novel quantum states of compounds with strong SOC.

3:06PM V46.00004: EDRIXS: an open source toolkit for simulating resonant inelastic x-ray scattering spectrum based on exact diagonalization  
YILIN WANG (Presenter), Department of Condensed Matter Physics and Materials Science, Upton, New York 11973, USA, Brookhaven National Laboratory, XUERONG LIU, School of Physical Science and Technology, Shanghai 201210, China, ShanghaiTech University, MARK DEAN, GABRIEL KOTLIAR, Department of Condensed Matter Physics and Materials Science, Upton, New York 11973, USA, Brookhaven National Laboratory — In this work, we present an open source toolkit called “EDRIXS” to simulate the resonant inelastic x-ray scattering (RIXS) spectrum based on exact diagonalization (ED) of a model Hamiltonian. It can deal with single atom, cluster models with the parameters being obtained by DFT+Wannier90 calculation, and Anderson impurity models obtained from a converged DFT+DMFT calculation. A very efficient parallel ED solver based on arpack library is implemented and RIXS spectrum is calculated by Krylov subspace technique. These key components are written by Fortran90 and a Python interface is designed to prepare the inputs and setup the calculations. We apply this toolkit to study two 5d materials. First, we perfectly reproduce the dimer excitations observed in the experimental RIXS spectrum of Ba$_5$AlIr$_2$O$_{11}$ based on a two site Ir-Ir model and it directly confirms the existence of dimer orbital in this material. Second, we simulate the measured RIXS spectrum in Ba$_2$YOsO$_6$ based on an Anderson impurity model from a DFT+DMFT calculation, and based on this simulation we found that the energy scale of spin-orbit coupling (SOC) and Hund's coupling is comparable and the effective SOC effects in this 5d$_3$ compound is still significant so that it cannot be described by a pure spin-3/2 state.

3:18PM V46.00005: Interplay of novel magnetism and structural symmetry in Ba$_2$NaOsO$_6$ as a function of magnetic field and temperature revealed via resonant and non-resonant x-ray scattering  
ZAHIRUL ISLAM (Presenter), Advanced Photon Source, Argonne National Laboratory, KRISTIN WILLA, ULRICH WELP, Materials Science Division, Argonne National Laboratory, JACOB P.C. RUFF, Advanced Photon Source, Argonne National Laboratory, ZHU DIAO, Physics and Engineering, Halmstad University, ANDREAS RYDH, Physics, Stockholm University, RITESH K. DAS, Advanced Photon Source, Argonne National Laboratory, WAI-KWONG KWOK, Materials Science Division, Argonne National Laboratory, IAN R FISHER, Applied Physics, Stanford University — We studied correlation of lattice symmetry and magnetism in Ba$_2$NaOsO$_6$ (BNOO) showing that it was tetragonal (T) even at 300K, with a transition into an orthorhombic (O) phase near a "ferromagnetic" transition at $T_c$~6.9K . Fluctuations of O-phase seem to appear well above $T_c$, and calorimetric data, concurrently recorded with scattering, indicates a T-to-O transition at $T>T_c$. At $T<T_c$, a commensurate order at $q=(1,0,0)$ (a is the shortest axis of O phase) is observed. In a magnetic field normal to $q$, this staggered order saturates, indicating a coherent rotation of ordered magnetic domains to align with field direction as well as revealing some qualitative differences with bulk M(H) data. Due to structural twins, bulk measurements are susceptible to effects of field applied along all three directions simultaneously, while scattering uniquely probes magnetic order within individual twins. This field evolution of $q$-satellite along with its angular, polarization, and azimuthal properties of resonant scattering is indicative of a novel orbital-ordered phase with quantization (or principal) axis confined to the orthorhombic $bc$-plane.

*This research at the Advanced Photon Source is operated for the DOE Office of Science by Argonne National Laboratory under Contract No. DE-AC02-06CH11357.
Spin-orbit entanglement and \( j=1/2 \) state in \( \text{CuAl}_2\text{O}_4^* \)

SERGEY STRELTSOV (Presenter), Institute of Metal Physics, SERGEY NIKOLAEV, IGOR SOLOVYEV, National Institute for Materials Science, ANDREY IGNATENKO, Institute of Metal Physics, SANTU BAIDYA, Department of Physics and Astronomy, Seoul National University, VALENTIN IRKHIN, Institute of Metal Physics, DANIEL KHOMSKII, University of Cologne, JE-GUEN PARK, Department of Physics and Astronomy, Seoul National University — Spin-orbit (SO) Mott insulators are regarded as a new paradigm of magnetic materials, whose properties are largely influenced by the SO coupling and featured by highly anisotropic bond-dependent exchange interactions, as manifested in 4d and 5d systems. We show that a very similar situation can be realized in cuprates, when the \( \text{Cu}^{2+} \) ions reside in a tetrahedral environment. A special attention will be paid to \( \text{CuAl}_2\text{O}_4 \), which was experimentally found to retain cubic structure and does not show any long-range magnetic order down to \( T=0.5 \) K. These are the strong Coulomb correlations and the spin-orbit coupling, which conspire to suppress the Jahn-Teller distortions in \( \text{CuAl}_2\text{O}_4 \). The spin-orbit-entangled \( j_{\text{eff}}=1/2 \) state is then naturally realizes in the situation of \( t_{2g}^5 \) configuration and degenerate \( t_{2g} \) subshell. This in turn explains unusual magnetic properties of \( \text{CuAl}_2\text{O}_4 \). Using first-principles calculations, we construct a realistic spin model and show that the magnetic properties of this compound are largely controlled by anisotropic compass-type exchange interactions that dramatically modify the magnetic ground state by lifting the spiral spin-liquid degeneracy and stabilizing a commensurate single-q spiral.

Dirac Nodal Lines and Density-Functional Prediction of a Large Spin Hall Effect in 6H-perovskite Iridate \( \text{Ba}_3\text{TiIr}_2\text{O}_9 \)

SAYANTIKA BHOWAL (Presenter), SASHI SEKHAR SATPATHY, University of Missouri — Topological semi-metals have received considerable attention recently due to their nontrivial band structure protected by symmetry, resulting in a number of emerging quantum phenomena such as Fermi arcs, anomalous Hall effect, spin Hall effect (SHE), etc. While the Dirac and Weyl semi-metals, the typical examples of 3D topological semi-metals, are well studied in the literature, currently an interest has been emerging in the Dirac nodal line semi-metals (DNLS) because they are good candidates for SHE. Here, based on the density-functional calculations, we predict a new iridate material \( \text{Ba}_3\text{TiIr}_2\text{O}_9 \) with nodal lines present in the band structure, which with the introduction of SOC become gapped along certain high symmetry directions in the Brillouin zone, but not along the other directions, being protected by the non-symmorphic symmetry of the crystal structure. The latter type of nodal lines are characterized by the quantized Berry phase \( \pi \), while the former kind of nodal lines are responsible for a strong SHE. The magnitude of the SHE is calculated using a tight-binding fit to the DFT band structure. Our work suggests \( \text{Ba}_3\text{TiIr}_2\text{O}_9 \) as a potential SHE material for spintronics applications and motivates experimental work on the system.

Covalency-driven collapse of strong spin-orbit coupling in face-sharing iridium octahedra*

MAI YE (Presenter), HEUNG SIK KIM, JAE-WOOK KIM, Rutgers University, New Brunswick, CHOONG-JAE WON, Max Planck POSTECH/Korea Research Initiative, Pohang University of Science and Technology, KRISTJAN HAULE, DAVID VANDERBLIT, SANGWOOK CHEONG, GIRSH E BLUMBERG, Rutgers University, New Brunswick — We report ab-initio density functional theory calculation and Raman scattering results to explore the electronic structure of \( \text{Ba}_5\text{CuIr}_3\text{O}_{12} \) single crystals. This insulating iridate, consisting of face-sharing \( \text{IrO}_6 \) octahedra forming quasi-one-dimensional chains, cannot be described by the local \( j_{\text{eff}}=1/2 \) moment picture commonly adopted for discussing electronic and magnetic properties of iridate compounds with \( \text{IrO}_6 \) octahedra. The shorter Ir-Ir distance in the face-sharing geometry, compared to corner- or edge-sharing structures, leads to strong covalency between neighboring Ir. Then this strong covalency results in the formation of molecular orbitals (MO) at each Ir trimers as the low-energy electronic degree of freedom. The theoretically predicted three-peak structure in the joint density of states, a distinct indication of deviation from the local \( j_{\text{eff}}=1/2 \) picture, is verified by observing the three-peak structure in the electronic excitation spectrum by Raman scattering.

*Supported by: Crystal growth (CJW): the National Research Foundation of Korea, Ministry of Science and ICT (No. 2016K1A4A4A01922028), Ab-initio DFT study (HSK, KH, DV) and crystal characterization (JWK, SWC): NSF DMR-1629059, Spectroscopy (MY, GB): NSF DMR-1709161. MY and HSK contributed equally to this work.
Spin-orbit coupled ground state of mixed valence iridate Ba$_2$AlIr$_2$O$_9$*  VAMSHI MOHAN KATUKURI (Presenter), C3MP, IPHYS, École Polytechnique Fédérale de Lausanne, Switzerland, XINGYE LU, Center for advanced quantum studies and Department of physics, Beijing Normal University, China, THORSTEN SCHMITT, Laboratory of Synchrotron Radiation, Paul Scherrer Institute, Switzerland, OLEG YAZYEV, C3MP, IPHYS, École Polytechnique Fédérale de Lausanne, Switzerland — Interplay of electronic correlations and spin-orbit interactions in Ir$^{4+}$ and Ir$^{5+}$ oxides results in insulating $J_{\text{eff}} = 1/2$ and $J_{\text{eff}} = 0$ ground states, respectively. By now, this has been well understood theoretically and established experimentally. However, in compounds where the dimerisation of Ir$^{4+}$ and Ir$^{5+}$ ions is structurally more favourable, the microscopic understanding of the local electronic structure is lacking. For example, a direct overlap of the Ir $d$-orbitals within the dimers may lead to significant bonding-antibonding splittings, which diminishes the role of spin-orbit mixing, considerably modifying the local electronic picture. With Ba$_2$AlIr$_2$O$_{11}$ as an example, we show that the direct $d$-$d$ hybridisation effects are relatively weak, while electronic correlations (configuration mixing) and spin-orbit coupling play a dominant role. Using a combination of ab initio many-body wave function quantum chemistry calculations and resonant inelastic X-ray scattering experiments, we elucidate the electronic structure of Ba$_2$AlIr$_2$O$_{11}$. Our investigation shows that the two Ir ions (Ir$^{4+}$ and Ir$^{5+}$) in Ir$_2$O$_9$ dimer units preserve their local $J_{\text{eff}}$ ground states close to 1/2 and 0, respectively.

*We acknowledge funding from Swiss National Science Foundation Sinergia project 171003.

Magnetic field tuning of non-reciprocal and achiral spin waves in antiferromagnetic Ba$_3$NbFe$_3$Si$_2$O$_{14}$*  CHRIS STOCK (Presenter), MANILA SONGVILAY, University of Edinburgh, JOSE A RODRIGUEZ, NIST Center for Neutron Research, PAOLO G. RADAELLI, LAURENT CHAPON, Physics, University of Oxford, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University — Reciprocity, in the context of optics and scattering, is defined as invariance when a source and detector are swapped indicating that the motion of an object in one direction being the same as that in the opposite. We investigate the magnetic field tuning of non-reciprocal spin waves in antiferromagnetic langasite Ba$_3$NbFe$_3$Si$_2$O$_{14}$ using neutron spectroscopy. Applying a time reversal symmetry breaking magnetic field that also breaks a two-fold symmetry of the underlying structure, different spin wave energies are observed when the sign is reversed for either the total momentum +/- $Q$= +/-($G$ +/- $q$) or applied magnetic field +/- $\mu_0H$. We discuss the scaling of this effect with field and suggest it microscopically originates from spin-orbit coupling mediated through antisymmetric exchange.

*We are grateful for funding from the EPSRC, the Carnegie Trust for the Universities of Scotland, the STFC and through the NSF (DMR-09447720).

New insight into the low temperature phase of Ca$_3$Ru$_2$O$_7$*  DANILO PUGGIONI (Presenter), JAMES M RONDINELLI, Northwestern University — Despite the countless theoretical studies on the Ruddlesden-Popper ruthenate Ca$_3$Ru$_2$O$_7$, the structure and physics of its low temperature phase (T < 48 K) remains unclear. Here, using first principle calculations, we shed light on this phase, reconciling several disparate experimental results with a model based on band theory and static correlations. Our results suggest that an accurate description of the strong interplay among electronic correlation, magnetic ordering, spin-orbit interaction, and structural degrees of freedom are necessary to understand the properties of the low temperature phase of Ca$_3$Ru$_2$O$_7$.

*Support from Army Research Office under Grant No. W911NF-15-1-0017

Electric Field-Tuned Electronic Structure Revealed by Time- and Angle-Resolved Photoemission Spectroscopy  SHAOHUA ZHOU (Presenter), CHANGHUA BAO, YANG WU, SHUYUN ZHOU, Department of Physics, Tsinghua University — External electric field can easily modify the electronic structure of materials and create novel or useful quantum states. Such electric field tunable electronic structure is difficult to be probed by angle-resolved photoemission spectroscopy (ARPES) experiment because the electric field will deflect the photoelectrons. Here I will present our experimental results on electric field-tunable electronic structure by using a new strategy which can obtain the transient electronic structure under a tunable electric field, based on time- and angle-resolved photoemission spectroscopy (TrARPES).
4:54PM V46.00013: Low temperature thermal conductivity measurement of magnetic delafossite PdCrO$_2$  
SEITA ONISHI (Presenter), SEUNGHYUN KHIM, ANDREW MACKENZIE, ELENA HASSINGER, Max Planck Institute for Chemical Physics of Solids — Ultrapure delafossite metals are remarkably distinct from conventional metal oxides with their high electrical conductivity (some even exceeding that of noble metals) [1]. Thermal conductivity has previously been studied in PdCoO$_2$ [2] but never in the magnetic partner compound PdCrO$_2$. Here, we present such a study, down to sub-Kelvin temperatures. The high conductivities of delafossites necessitate samples with high aspect ratios to reach low temperatures with a reliable temperature gradient and minimal sample heating. I will discuss how this was achieved in our experiments.

5:06PM V46.00014: Structural Study of the Multiferroics Perovskite Sr$_{1-x}$Ba$_x$Mn$_{1-y}$Ti$_y$O$_3$  
KAMAL CHAPAGAIN (Presenter), BOGDAN DABROWSKI, OMAR CHMAISSEM, STANISLAW KOLESNIK, HAUMOD SOMALI, DENNIS BROWN, Northern Illinois University — The structural and magnetic properties of unique single-ion manganese-based multiferroic perovskites Sr$_{1-x}$Ba$_x$Mn$_{1-y}$Ti$_y$O$_3$ (SBMTO) were investigated by XRD. For compounds near $x = 0.45$–0.65 and $y = 0$–0.1, a cubic to non-centrosymmetric tetragonal transition takes place below $\sim 430$ K on heating and at $\sim 60$ K lower temperature on cooling. Ferroelectric (FE) distortions $c/a$ that are larger than the $P4mm$ distortions of nonmagnetic BaTiO$_3$ have been observed with maximum estimated polarization of $\sim 29 \, \mu C/cm^2$ at $\sim 220$ K. At lower temperatures, the polarization is suppressed by $\sim 40\%$ due to development of antiferromagnetic (AFM) phase, indicating very strong coupling between FE and AFM. The FE phase is rapidly suppressed by hydrostatic pressure.

5:18PM V46.00015: Emergent quantum criticality from spin-orbital entanglement in d$^8$ Mott insulators: the case of a diamond lattice antiferromagnet  
FEI-YE LI (Presenter), GANG CHEN, Fudan University — Motivated by the recent activities on the Ni-based diamond lattice antiferromagnet NiRh$_2$O$_4$, we theoretically explore on a general ground the unique spin and orbital physics for the Ni$^{2+}$ ions with a 3d$^8$ electron configuration in the tetrahedral crystal field environment and on a diamond lattice Mott insulator. The superexchange interaction between the local moments usually favors magnetic orders. Due to the particular electron configuration of the Ni$^{2+}$ ion with a partially filled upper $t_{2g}$ level and a fully filled lower $e_g$ level, the atomic spin-orbit coupling becomes active at the linear order and would favor a spin-orbital-entangled singlet with quenched local moments in the single-ion limit. Thus, the spin-orbital entanglement competes with the superexchange and could drive the system to a quantum critical point that separates the spin-orbital singlet and the magnetic order. We further explore the effects of magnetic field and uniaxial pressure. The non-trivial response to the magnetic field is intimately tied to the underlying spin-orbital structure of the local moments. We discuss the future experiments such as doping and pressure, and point out the general correspondence between different electron configurations under tetrahedral and octahedral crystal field environments.

2:30PM V47.00001: 2D Metal-Organic Frameworks as a New Class of Thermoelectric Material**

RYUICHI TSUCHIKAWA (Presenter), Department of Physics and Astronomy, University of Utah, NABAJIT LAHIRI, Department of Chemistry, University of Utah, NEDA LOTFIZADEH, SHUWAN LIU, MACKENZIE LACH, CELINE SLAM, Department of Physics and Astronomy, University of Utah, JANIS LOUIE, Department of Chemistry, University of Utah, VIKRAM DESHPANDE, Department of Physics and Astronomy, University of Utah — Organic materials are desired in many fields of thermoelectric applications due to material abundance, light weight, and flexibility. Electrically conductive 2D metal-organic frameworks (MOFs) are a new class of organic material, and the two dimensionality and nanopores have a potential to realize a comparable thermoelectric figure of merit in 2D MOFs. As such, we measured thermal conductivity, electrical conductivity, and Seebeck coefficient of Copper Benzenehexathiol (Cu-BHT), an electrically conductive 2D MOF, in a mesoscopic device scale. We found that phonon mean free path is of the order of the length scale associated with nanopores and interlayer distance and it is responsible for the observed low thermal conductivity of 0.25 W/mK at room temperature. This result ensures low thermal conductivity in any 2D MOFs without artificially imposing nanostructures. Electronic transport and Seebeck coefficient measurements revealed that the charge carrier is n-type and the electronic transport is governed by the degree of polycrystallinity. However, unlike conductive polymers, each domain retains a definite crystal structure, resulting in an electronic band in each domain. This leads to a possibility of enhancing Seebeck coefficient by band engineering.

**Funded by ACS PRF and USTAR

2:42PM V47.00002: High thermoelectric properties of As-based 122-Zintl compounds Ba$_{1-x}$K$_x$Cd$_2$As$_2$

HARUNO KUNIOKA (Presenter), KUNIHIRO KIHOU, HIROTAKA NISHIATE, National Institute of Advanced Industrial Science and Technology, HIDETOMO USUI, KAZUHIKO KUROKI, Osaka University, CHUL-HO LEE, ATSUSHI YAMAMOTO, National Institute of Advanced Industrial Science and Technology, TSUTOMU IIDA, HARUHIKO OBARA, Tokyo University Of Science — 122-Zintl phase is well known as a high performance thermoelectric (TE) material. For the past decade, Sb-based 122-Zintl compounds have been found that the dimensionless figure-of-merit exceeds the value of 1. In contrast, there are only few studies on As-based Zintl compounds. Lighter atomic mass of As than Sb discourages exploring As-based compounds because the lattice thermal conductivity ($k_L$) usually becomes higher with lighter atoms. Recently we have found that Ba$_{1-x}$K$_x$Zn$_2$As$_2$ exhibits low $k_L$ of 0.8 W/mK and high $ZT$ of 0.67 at 900 K [1]. This discovery demonstrates that the As-based 122-Zintl compounds also have a potential for a high performance TE material.

Being based of the first principle calculation, we decided to examine TE properties of As-based 122-Zintl compounds Ba$_{1-x}$K$_x$Cd$_2$As$_2$. Polycrystalline samples of Ba$_{1-x}$K$_x$Cd$_2$As$_2$ was synthesized by the solid reaction method. The power factor of Ba$_{1-x}$K$_x$Cd$_2$As$_2$ reached to 1.3 mW/mK$^2$ at $T = 773$ K. $k_L$ was 0.5 W/mK at $T = 773$ K. Consequently, $ZT$ reached to 0.81 at 773 K, which is the highest $ZT$ value at As-based 122-Zintl compounds [2].

2:54PM V47.00003: Cold Spray Additive Manufacturing of Thermoelectric Generators*

HARRY RADOUSKY (Presenter), ALEXANDER A. BAKER, Lawrence Livermore National Laboratory, RICHARD THUSS, TTEC LLC, ELISSAIOIS STAVROU, JOSEPH MICHAEL ZAUG, SCOTT MCCALL, Lawrence Livermore National Laboratory — Thermoelectric generators (TEGs) provide a pathway to recovering and converting thermal energy directly into electricity. Adoption of the technology has often been limited due to the difficulty of manufacturing TEGs that can be incorporated into industrial environments where waste heat is prevalent. To address this shortcoming an additive manufacturing technique has been developed for the fabrication of arbitrary shape Bi$_2$Te$_3$ based (and other semiconductors) thermoelectric generators, promising greater design flexibility to harvest low grade waste heat. We have demonstrated that cold-spraying of powdered material yields near-full density parts, without significant loss of thermoelectric properties in the operating window of ~100 C. A systematic study is presented of the structural characteristics for the deposited material, correlated with thermal and electrical transport measurements to allow further understanding of the thermoelectric efficiency in the cold-sprayed samples. In particular cold spraying allows deposition on curved geometries such as copper pipes, and produces thermoelectric materials with Seebeck coefficients comparable to the bulk starting material.

*Prepared by LLNL under Contract DE-AC52-07NA27344.
3:06PM V47.00004: Interplay between flexoelectric and thermoelectric effects in bismuth telluride thin films*  
BRUNO LORENZI (Presenter), SVETLANA BORISKINA, Mechanical Engineering, Massachusetts Institute of Technology, AKIHIRO KOBAYASHI, MASAYUKI TAKASHIRI, Department of Materials Science, Tokai University, GANG CHEN, Mechanical Engineering, Massachusetts Institute of Technology — Flexoelectricity is a phenomena for which a strain gradient induces an internal polarization in semiconductor and dielectric materials. This effect can be used to enhance thermoelectric properties, and to enable the collection of photo-generated carriers without the need of a p-n junction. In this context, flexoelectricity was claimed to be the reason behind the variation of Seebeck coefficient in bismuth telluride (Bi$_2$Te$_3$) thin films deposited on different substrates, and was shown in many materials under illumination. However, a clear explanation of the relation between the applied strain and the detected signal is still missing, along with a comprehensive theoretical and experimental analysis.

We will present the experimental demonstration of flexoelectric effect in Bi$_2$Te$_3$ thin films deposited on flexible substrates, by magnetron sputtering. We will show and discuss how the open circuit voltage in our samples can be varied as a function of applied strain, temperature, and illumination level. Our results help to shed light on the relation between applied strain, material polarization, and the thermo/photoelectric performance, revealing new possible applications of the flexoelectric effect in low-gap materials.

3:18PM V47.00005: Superionic diffusion and anharmonic lattice dynamics in AgCrSe$_2$*  
JINGXUAN DING (Presenter), Mechanical Engineering and Materials Science, Duke University, JENNIFER L NIEDZIELA, Oak Ridge National Laboratory, DIPANSHU BANSAL, Indian Institute of Technology Bombay, ANDREW MAY, GEORG EHLERS, DOUGLAS L ABERNATHY, Oak Ridge National Laboratory, YANG REN, AYMAN SAID, Argonne National Laboratory, OLIVIER DELAIRE, Mechanical Engineering and Materials Science, Physics, Duke University — Superionic conductors exhibit promising thermoelectric properties due to their ultralow thermal conductivity. The fundamental mechanisms have long been debated between the anharmonicity or the breakdown of transverse acoustic (TA) phonons, where the shearing vibrational degrees of freedom are lost, as in a liquid state. We report on neutron/x-ray scattering and first-principles studies on the lattice dynamics and ionic diffusion of AgCrSe$_2$. Our momentum-resolved measurements on single-crystals clearly establish the persistence of long-wavelength TA phonons in the superionic phase, whereas the shorter wavelength, non-dispersive portions of the TA branches severely broaden reflecting extreme anharmonicity. Further, we find a strong repulsion between Ag neighbors, affecting the diffusion mechanism. Our studies of atomic dynamics and diffusion will help rationalize the emergence of ultralow thermal conductivity for thermoelectrics and facilitate the design of high-performance solid-state electrolytes.

3:30PM V47.00006: Fabrication and Measurement of the Physical and Thermoelectric properties of Ca$_{3-x}$Dy$_x$Co$_{4-y}$Fe$_y$O$_{9+p}$ systems*  
IFEANYI IFEDUBA (Presenter), ROBERT M CATCHINGS, Howard University, DAVID MCKEOWN, Vitreous State Laboratory, WINNIE WONG-NG, NIST, XUEYAN SONG, University of West Virginia — The properties and performance of Cobalt oxide material as a p-type semiconductor for commercial use depends on its stability at high temperature region and its excellent physical and thermoelectric properties. Here in, we substitute (dope) and study the effects of magnetic ions (Dy, Fe) for (Ca, Co) in polycrystalline Ca$_3$Co$_4$O$_9$. A series of Ca$_{3-x}$Dy$_x$Co$_{4-y}$Fe$_y$O$_{9+p}$ samples was synthesized using the sol-gel combustion method. After preparations, the samples were subjected to heat treatment at different temperature. X-ray diffraction analysis indicates the partial substitution of Dy in the Ca site and Fe in the Co site. It also confirmed the formation of single phase compound, as well as changes in the structure of the materials depending on the sintering temperature. The obtained values of the electrical resistivity for all samples falls within the range of a semiconductor. The thermopower values are all positive, indicating that the majority carrier are holes.

*The Support of the Materials Measurement Division at the National Institute of Standard and Technology (NIST) is greatly appreciated.
3:42PM V47.00007: Axis Dependent Transport Properties of Single Crystal Re₄Si₇*  BIN HE (Presenter), MIKE SCUDDER, YAXIAN WANG, WOLFGANG E WINDL, JOSHUA E. GOLBERGER, JOSEPH P C HEREMANS, Ohio State University — We measured the thermoelectric transport properties of Re₄Si₇ along different axis and prove Re₄Si₇ to have axis dependent carrier polarity. In the cryostat measurement, we observe electrical conductivity and thermopower both increasing with temperature. In-plane Hall effects shows the crystals we obtained has a carrier density around 2*10¹⁹/cm³, while the Hall coefficient in-plane and cross-plane have opposite signs. Thermal conductivity measurement shows an isotropic lattice thermal and Nernst measurement shows a small Nernst coefficient and eliminates the possibility of two carrier system. High temperature thermoelectric properties measurement shows the resistivity keeps decreasing at high temperature. The thermopower of the cross-plane direction reaches 300 µV/K and turns flat at high temperature, which may come from a thermal smearing effect. With an estimate of the thermal conductivity, we propose a promising ZT over unity for future optimization.

3:54PM V47.00008: Spin Effects Making zT > 1  DARYOOSH VASHAEE (Presenter), Department of Electrical and Computer Engineering, North Carolina State University, MD MOBARAK HOSSAIN POLASH, Department of Materials Science and Engineering, North Carolina State University, VLADISLAV PERELYGIN, Department of Chemistry, North Carolina State University, MORTEZA RASOULIANBOROUJENI, Department of Developmental Science, Marquette University, YUANHUA ZHENG, Department of Mechanical and Aerospace Engineering, The Ohio State University, TIANQI LU, NING LIU, Chinese Academy of Sciences, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, MICHAEL MANLEY, RAPHAEL HERMANN, Materials Science and Technology Division, Oak Ridge National Laboratory, ALEX I SMIRNOV, Department of Chemistry, North Carolina State University, JOSEPH P C HEREMANS, Department of Mechanical and Aerospace Engineering, The Ohio State University, HUAIZHOU ZHAO, Chinese Academy of Sciences, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics — Recent studies of thermoelectric properties of the antiferromagnetic MnTe:Li have revealed the existence of a strong spin effect that extends across a broad range of temperature leading to zT>1 [1,2]. While carrier mobility and heat capacity were strongly affected by spin contributions near the Neel temperature, T_N=307K, the thermopower demonstrated robust spin effects extending up to 900K. Spin contribution to those properties below T_N has been attributed to the magnon-drag effect [3]. A recent study [2] attributed the thermopower enhancement to paramagnon-drag effect originated from the mid or short-range magnetic ordering above T_N. Neutron scattering study showed an agreement to that theory to some extent while some competing theories such as the spin-fluctuations and spin entropy can also explain thermopower enhancement in magnetic materials [1,4]. The objective of this work is to show the agreements and disagreements of different spin-based theories in describing the transport properties of MnTe:Li and to compare similar material systems to gain better insight to the underlying physics.

4:06PM V47.00009: Thermal transport and thermoelectric effects at solid-melt interfaces in semiconductors:
Underlying physical phenomena that give rise to Thomson heat in semiconductors* SADID MUNEER, Electrical and Computer Engineering, University of Connecticut, Storrs, CT 06269, USA, GOKHAN BAKAN, Electrical and Electronics Engineering, Attilim University, Ankara, Turkey, NATHAN HENRY, HELENA SILVA, ALI GOKIRMAM (Presenter), Electrical and Computer Engineering, University of Connecticut, Storrs, CT 06269, USA — Partial melting in self-heated nanocrystalline silicon microwires via fast pulses show a drastic asymmetry in melting profiles, where half of a wire may be melted and recrystallized while the other half remain in solid state. This asymmetry, in the direction of the electrical current, point to the significance of Thomson heat close to the solid-melt interfaces in semiconductors. The diffusion of the electron-hole pairs away from the melted regions cause thermal transport via (i) increased electronic convective heat flow and (ii) recombination of the excess carriers away from the melted region. In presence of an electric field a non-equilibrium non-isothermal condition is achieved. Generation (G) of electrons and holes, transport (T), and recombination (R) of the minority carriers downstream, GTR¹, lead to a strong asymmetry in thermal profiles at melt-solid interfaces in semiconductors.

KORNELIUS NIELSCH (Presenter), Institute of Metallic Materials, Leibniz IFW - Dresden — Micro-thermoelectric modules are of potential use in fields such as energy harvesting, thermal management, thermal imaging and high spatial-resolution temperature sensing. In particular, micro-thermoelectric coolers (μ-TECs) – in which the application of an electric current cools the device based on the Peltier effect – can be used to manage heat locally on a micrometer spot in microelectronic circuits, optoelectronic devices and microfluidic channels. However, a cost-effective μ-TEC device that is compatible with the modern semiconductor fabrication industry has been developed. N-type BiTeSe and p-type pure Te were electrochemically deposited at room temperature into microstructured photoresist patterns. A comprehensive study the electrochemically synthesis if thermoelectric chalcogenide materials is presented [1]. The material quality is every high, that even fundamental aspect like topological surface states can be demonstrated in these chalcogenide film by transport measurements.

The final device performance of μ-TECs in terms of transient responses, cycling reliability and cooling stability has not been adequately assessed. Here we report the fabrication of μ-TECs that offer a rapid response time of 1 ms, reliability of up to 10 million cycles and a cooling stability of more than one month at constant electric current. The high cooling reliability and stability for our μ-TEC module [2] can be attributed to a design of free-standing top contacts between the thermoelectric legs and metallic bridges, which reduces the thermomechanical stress in the devices.

**MATTHIAS AGNE (Presenter), Northwestern University, PENGFEI QIU, XUN SHI, SIC CAS, JEFF SNYDER, Northwestern University — The possibility of decomposition in superionic mixed ionic-electronic conductors (MIEC) has limited their engineering applications. Specifically, high efficiency MIEC thermoelectric materials have not been utilized due to decomposition under large electronic currents and large temperature gradients. Herein, we derive the critical condition for decomposition, which corresponds to a critical chemical potential difference defined from linear non-equilibrium thermodynamics. This analysis leads to the conclusion that voltage, not current density, is the relevant design parameter. Consequently, the decomposition condition is independent of the geometry of the device; whereby, a strategy is presented for improving stability in devices subjected to electrical and temperature gradients. By using a series of electronically conducting, but ion-blocking barriers to reset the chemical potential it is possible to keep the material below the threshold for decomposition. Experimentally, the thermodynamic theory is validated in the Cu2-dSe MIEC system.

**NASA Science Mission Directorate's Radioisotope Power Systems Thermoelectric Technology Development program

RINKLE JUNEJA, TRIBHUWAN PANDEY, ABHISHEK SINGH (Presenter), Indian Institute of Science — Silicon-based thermoelectric materials would be of great significance due to the huge dependence of electronic industry on silicon. Bulk silicon is not a good thermoelectric material due to its very high thermal conductivity, thereby limiting its thermoelectric efficiency. Nanostructuring and alloying are alternative solutions to reduce thermal conductivity, but the techniques involved are complex and costly. Recently, a silicon-based chalcogenide Si$_2$Te$_3$ has been experimentally synthesized. Si$_2$Te$_3$ exhibits layered structure, in which Te atoms form hexagonal sub-lattice and Si atoms can occupy any of the octahedral voids. Due to uncertainty in Si positions, previously unknown ground state structure of Si$_2$Te$_3$ was obtained using the Wyckoff positions of space group P-31c. The minimum energy configuration exhibits combination of desirable electronic and transport properties. In particular, n-doped Si$_2$Te$_3$ has an unprecedented figure of merit of 1.86 at 1000 K, which is comparable to some of the best state-of-the-art thermoelectric materials. Hence, n-doped Si$_2$Te$_3$ can be a long-sought silicon-based thermoelectric material which could be integrated to the existing electronic devices.

5:18PM V47.00013: Enhanced Cross-plane Thermoelectric Transport of Rotationally-disordered SnSe$_2$ via Se Vapor Annealing* JIHAN CHEN (Presenter), University of Southern California, DANIELLE HAMANN, University of Oregon, DAVID CHOI, University of Texas, Austin, NIRAKAR POUTDEL, LANG SHEN, University of Southern California, LI SHI, University of Texas, Austin, DAVID JOHNSON, University of Oregon, STEVE CRONIN, University of Southern California — In this talk I will review our recent progress in cross-plane thermoelectric measurements of SnSe and SnSe$_2$ films grown by the modulated element reactant (MER) approach. The initially grown SnSe films have relatively low cross-plane Seebeck coefficients due to significant unintentional doping originating from Se vacancies. By performing post-growth annealing at a fixed Se partial pressure, a transition from SnSe to SnSe$_2$ is induced. This results in a 16-fold increase in the cross-plane Seebeck coefficient (from -38.6 to -631μV/K) after Se annealing due to both the SnSe to SnSe$_2$ transition and the mitigation of unintentional doping by Se vacancies. The power factor $S^2σ$ increased by 44X after Se annealing. We believe that these results demonstrate a robust method for mitigating unintentional doping in a promising class of materials for thermoelectric applications.1

Session V48 DFD GSOFT GSNP: Drops III BCEC 251 - A Hirsa, Rensselaer Polytech Inst - Tag(s): Focus

2:30PM V48.00001: The Effect of Detaching Force on the Droplet Residue on a Fiber NEDA OJAGHLOU (Presenter), Department of Chemistry, Virginia Commonwealth University, HOOMAN TAFRESHI, Department of Mechanical and Nuclear Engineering, Virginia Commonwealth University, DUSAN BRATKO, ALENKA LUZAR, Department of Chemistry, Virginia Commonwealth University — The adherence to, and removal of droplets from cylindrical fibers underlie applications from fog harvesting, oil-water, and water transport in fuel cells. When the droplets are forcibly removed from hydrophilic fibers, the ease of detachment strongly depends on droplet volume and the rate of the process controlled by the applied force. In the present work, we study the mechanism of water droplet detachment and retention of residual water on smooth hydrophilic fibers using nonequilibrium molecular dynamics simulations. We extract scaling relations that allow extrapolation of our findings to larger length scales that are not directly accessible by molecular models. Our studies of the droplet breakup uncover a strongly nonmonotonic influence of external force, with the amount of residual water maximized under the intermediate force strengths whereas a complete or near-complete detachment of the droplet can be achieved in both extremes, with the applied force only slightly, or considerably exceeding the minimal force of detachment. The strength of this force decreases with the size of the drop, while the maximal residue increases with the droplet volume, V, sub-linearly, in proportion to the V$^{2/3}$.

2:42PM V48.00002: Effects of surfactant transport on the electro-deformation of viscous prolate drops HERVE NGANGUIA (Presenter), Indiana University of Pennsylvania, ON SHUN PAK, Mechanical Engineering, Santa Clara University, YUAN-NAN YOUNG, Mathematical Sciences, New Jersey Institute of Technology — We report quantification of effects of surfactant transport on a viscous prolate drop under a DC electric field, focusing on characterization through the dimensionless Peclet number. Our findings reveal distinct equilibrium deformations that depend on the type of drops (leaky dielectric versus conducting) and the transport regime (convection or diffusion).
The mode of deformation, described by the flow circulation in a leaky dielectric drop, also contributes to the non-trivial deformation. For counter-clockwise circulation, we found leaky dielectric drops consistently yield larger deformation compared to perfectly conducting drops. The deformations result from the non-linear coupling between surfactant concentration and transport: higher surfactant concentrations yield larger (smaller) deformation with strong convective (diffusive) flows. For clockwise circulation, the deformation decreases (increases) with increasing surfactant concentration when convection (diffusion) dominates. We show that in this case conducting drops can yield larger deformations compared to leaky dielectric drops at moderate to high surfactant concentration. Finally, we look at the transient evolution of the drop shape, and discuss novel findings that have yet to be disseminated.
2:54PM V48.00003: Migration of droplets on a conical fiber  CARMEN LEE (Presenter), KARI DALNOKI-VERESS, McMaster University — In arid climates, nature has developed an efficient method of harvesting water from the air. Organisms, like cacti, are covered in a multitude of needle-like conical spines. Water droplets that condense on the tip of the fiber are spontaneously driven toward the base by Laplace pressure. The changing curvature of the conical shape is the mechanism responsible for the motion. We examine the effect of geometry on the droplet movement and compare the motion of multiple droplets on a conical glass fiber to that of a single droplet.

3:06PM V48.00004: Preliminary observations of bursting of molten steel thick films in a steel plate irradiated by a high energy laser*  MARY LANZEROTTI (Presenter), Physics and Nuclear Engineering, United States Military Academy, KENNETH BRAKKE, Department of Mathematical Sciences, Susquehanna University, KENNETH ALLEN, JOHN HARTKE, Physics and Nuclear Engineering, United States Military Academy — This talk presents preliminary observations of the bursting of films of molten steel following illumination of a thin vertical steel plate by a 1075-nm continuous-wave 1000W Ytterbium fiber laser. Molten steel formed in the illuminated region persists as a molten disk for several seconds before a hole forms. Gravity is responsible for the formation of a dimple in the upper part of the molten disk and a bulge in the lower part. After several seconds, a hole appears at the dimple. Hole enlargement is quite sudden, like a soap film popping. Following this, a molten drop forms and falls under the influence of gravity below the laser beam, leaving behind a hole in the plate. Images of the initial hole captured by a high speed digital camera show that the hole forms first in the top portion of the molten disk, not in the center.

The molten steel is modeled as liquid contained within a hoop with size of the final hole. 3D images produced by Surface Evolver, an interactive program for modelling liquid surfaces, indicate the presence of a dimple within the molten region near the location of first appearance of the hole, and a bulge in the molten region near the lower portion for a liquid with density and surface tension taking on values near the melting point of iron.

3:18PM V48.00005: Mechanism of Contact between a Droplet and an Atomically Smooth Substrate  HAU YUNG LO (Presenter), YUAN LIU, LEI XU, Physics Department, Chinese University of Hong Kong — When a droplet gently lands on an atomically smooth substrate, it will most likely contact the underlying surface in about 0.1 s. However, theoretical estimation from fluid mechanics predicts a contact time of 10–100 s. What causes this large discrepancy, and how does nature speed up contact by 2 orders of magnitude? To probe this fundamental question, we prepare atomically smooth substrates by either coating a liquid film on glass or using a freshly cleaved mica surface, and visualize the droplet contact dynamics with 30-nm resolution. Interestingly, we discover two distinct speed-up approaches: (1) droplet skidding due to even minute perturbations breaks rotational symmetry and produces early contact at the thinnest gap location, and (2) for the unperturbed situation with rotational symmetry, a previously unnoticed boundary flow around only 0.1 mm/s expedites air drainage by over 1 order of magnitude. Together, these two mechanisms universally explain general contact phenomena on smooth substrates. The fundamental discoveries shed new light on contact and drainage research.

3:30PM V48.00006: Manipulating drop shapes in a microchannel  ROCIO NAVARRO (Presenter), ALEXANDER ZINCHENKO, ROBERT DAVIS, Chemical and Biological Engineering, University of Colorado Boulder — We use a boundary-integral algorithm that simulates the motion of a freely suspended, three-dimensional deformable drop in a plane-parallel microchannel at small Reynolds number, large Peclet number, and moderate capillary number. The drop size is comparable to the channel height, which is much smaller than the channel depth. In this problem, the final shape of the drop is extremely dependent on the channel shape, flow ratios and time, so we have studied a variety of conditions. By changing the number of inlet and outlet channels, as well as the physical geometry of the channel and the drop properties, we are able to create a diverse set of droplet shapes, including shapes with interesting geometric properties such as deltoids, dumbbells and oblate spheroids. In principle, desired shapes could subsequently be “frozen” by a temperature-induced or flow-induced phase change, to yield particles with desired geometries and properties for drug delivery, tissue scaffolds, etc. This presentation will describe the simulation method and present example results of how different shapes may be achieved.
FRANK RILEY (Presenter), SHREYASH GULATI, Rensselaer Polytechnic Institute, JUAN MANUEL LOPEZ, Arizona State University, A HIRSA, Rensselaer Polytechnic Institute — In the ring-sheared drop, a liquid drop is constrained by two contact rings, where the rings differentially rotate. This differential rotation generates a flow in the bulk primarily through surface shear viscosity. Numerical predictions of bulk flow and mixing within ring-sheared drops were recently reported. The previous work assumed that the surface shear viscosity, non-dimensionalized by the size of the drop, is large. However, in many cases, especially for large drops, which can be studied in microgravity, the dimensionless surface shear viscosity can be arbitrarily small but still able to affect the bulk flow. Computations reveal that an increasing Reynolds number correlates to an increase in sensitivity to the effects of changing surface shear viscosity. Furthermore, upon decreasing surface viscosity, the coupling between the surface and the bulk flows strengthens. The system is then driven towards solid-body rotation.

3:54PM V48.00008: Droplet Motion on Superhydrophobic Surfaces  
ALEXANDER SMITH (Presenter), REBECCA SUTTON, KEONI MAHELONA, SHAUN C HENDY, University of Auckland — In this talk, molecular dynamics simulations are used to investigate the roles of droplet size and surface geometry on the equilibrium velocity of droplets moving down superhydrophobic surfaces. An extension of prior theoretical descriptions, accounting for interfacial slip, is used to interpret these results. This approach yields three limiting cases for the drop's steady-state velocity, where energy losses are dominated by viscous dissipation, surface friction or contact line friction respectively. We find that for droplets on ideal textured high-slip surfaces, contact line dissipation dominates droplet motion, with droplet velocity increasing with radius. At droplet radii larger than the capillary length, we retrieve the usual viscosity-dominated motion.

4:06PM V48.00009: Numerical Investigation of Hypoxic Effects on the Biodegradation of Oil Microdroplets  
GEORGE KAPELLOS (Presenter), Chemical Engineering, Massachusetts Institute of Technology, NICOLAS KALOGERAKIS, Environmental Engineering, Technical University of Crete, PATRICK DOYLE, Chemical Engineering, Massachusetts Institute of Technology — We present an extended compound particle model for the biodegradation of solitary oil microdroplets moving through a seawater column. The compound particle is of the core-shell type and consists of an oily core that is successively surrounded by an ultrathin bioreactive skin of oleophilic microbes and another bioreactive biofilm shell. The extended model accounts for the counter transport of dissolved oxygen and multiple oil components of varying bioavailability and toxicity within the biofilm that covers and degrades the oily droplet. The governing advection-diffusion-bioreaction PDEs are solved numerically to calculate the droplet shrinking rate as a function of the drifting speed, the non-linear microbial kinetics, the biofilm thickness, and other key parameters. A system of coupled ODEs is also formulated for the evolution of the compound particle dimensions. The impact of hypoxic and inhibitory conditions on the droplet biodegradation rate is quantified and critically discussed in connection with the potential for the - very slow, but feasible-anaerobic hydrocarbon degradation in oxygen-depleted marine waters and sediments.

Session V49 GSOFT GSNP: Mechanics of Materials Processing  
BCEC 252A - Frederick Gosselin, Ecole Polytechnique de Montreal - Tag(s): Focus
Plastic instabilities, mechanochemistry, and a bag of (metal) chips*  [Invited]  KOUSHIK VISWANATHAN (Presenter), Indian Institute of Science — Soft and highly strain hardening metals like Ni, Al, Ta and stainless steels, are notoriously difficult to cut, earning them the moniker “gummy”. This difficulty is well-known for its commercial implications, yet its origins have remained largely mysterious. This talk presents high-speed in situ investigations of this problem in two parts. In the first, we unveil the occurrence of a highly unsteady plastic flow mode, termed sinuous flow, as the cause of this difficulty. Sinuous flow arises due to a surface plastic buckling instability and is characterized by repeated material folding, large local strains (>10) and energy dissipation. The physics of this flow, its dependence on material properties, and manifestation across metals are directly observed. In the second part, we demonstrate how sinuous flow can be perturbed using mechanochemistry. A suitable chemical medium applied to the metal surface causes a local ductile-to-brittle transition by coupling plastic instabilities with interface energetics. Consequently, surface buckling and sinuous flow are replaced by a periodic fracture instability in the presence of the medium, with near absence of defects on the cut surface and significantly lower energy dissipation (~80%). The transition in flow is also reflected in the morphologies of the resulting metal chips. This mechanochemical effect is controllable and largely material agnostic, with many chemical media working equally well across different metal systems. Additionally, the benign nature of the media presents exciting opportunities for fundamentally enhancing deformation processing of metals in industrial settings.

Mechanics of bilayers: What soft matter physics can teach us about shot peen forming of aircraft wing skins*  FREDERICK GOSSELIN (Presenter), PIERRE FAUCHEUX, MARTIN LEVESQUE, Laboratory for Multiscale Mechanics, Ecole Polytechnique de Montreal — Peening treatments (e.g., shot, laser, and cavitation peening) are ubiquitous when designing metallic parts against fatigue failure: by introducing compressive surface residual stresses that oppose crack initiation and growth, they can significantly increase the fatigue strength of treated parts. Peening induced stresses also cause distortions. Although usually seen as an unwanted side effect, these distortions can be controlled to form thin-walled structures into complex contours—a process referred to as peen forming. In this talk, we focus on modeling shot peen forming (a variant that consists in bombarding the parts with small hard shot). By analogy with thin bilayer actuated systems usually encountered in the fields of smart structures, soft robotics, and composite manufacturing, we investigate the shape and stability of peen formed parts. We also present a procedure to generate peening patterns required to form initially flat plates into a desired shape, alongside experimental validation.

*The authors gratefully acknowledge financial support from Airbus, the Rio Tinto group through a graduate scholarship, and the Canada Research Chairs program.

Cutting as a Tool for Investigating Crack-Blunting-Involved Soft Fracture*  BINGYANG ZHANG (Presenter), CHENG-SHEN SHIANG, SHELBY HUTCHENS, University of Illinois at Urbana-Champaign — During tearing of soft elastomers, large deformation occurs due to crack-blunting. The incorporated material nonlinearity alters the fracture response, resulting in a measured fracture energy value higher than the prediction from network binding energy [Lake and Thomas, 1967]. To understand the dependence of fracture energy on the nonlinear constitutive response, we control the crack tip geometry via cutting. A Y-shaped cutting geometry, inspired by Lake and Yeoh (1978), uses two separate “legs” to form a cutting notch that minimizes contact friction. A blade aligned with the notch imposes its radius during cutting. We find that cutting fracture energy increases nonlinearly with large blade radii. The radius sensitivity reflects the strain-stiffening constitutive response governing crack-blunting during tearing. However, as the blade radius decreases, the effect of nonlinearity is minimized and the cutting energy plateaus to a constant that appears to scale with elastic modulus. We evaluate the potential of cutting as a method for characterizing “intrinsic” fracture energy and provide insight into the microstructural origin of the plateauing transition using cutting tests from idealized, end-linked polydimethylsiloxane (PDMS) networks.

*National Science Foundation (no.1562766)
3:30 PM V49.00004: Stable and collision-free manipulation of an elastic rod using multiple grippers* ANDY BORUM (Presenter), Department of Mathematics, Cornell University — Despite the widespread adoption of robots in manufacturing, many tasks that involve handling and assembly of deformable objects are still completed manually. Automating these tasks requires reasoning about deformations, instabilities, and self-contact experienced by the deformable objects. As a canonical example of such a task, I will discuss the problem of deforming a slender elastic rod into a desired configuration using two or more robotic grippers that grasp the rod at multiple points. In the case when the grippers are required to grasp the rod at fixed arc lengths, I will show that the set of all equilibrium configurations of the rod that are stable is path-connected. If the grippers are allowed to slide along the rod, I will show that the set of all equilibrium configurations that are both stable and non-self-intersecting is path-connected. The proofs of these two results are constructive and provide analytical solutions that can be exploited when designing algorithms for automated handling of slender structures.

3:42 PM V49.00005: Pleat formation and the geometry of pure bending TIAN YU (Presenter), JAMES HANNA, Virginia Tech — We will discuss our recent attempts towards understanding the mechanics of pleat forming in soft textile sheets. This is an elastic-plastic bending process that we formulate as a variable-arc-length multi-point boundary value problem for an inextensible rod, with a moment-curvature constitutive relation as input. To determine this moment-curvature relation, we have developed a linkage mechanism that can impose an exact pure bending (constant curvature) state up to high curvatures. A simpler approximate mechanism that nearly matches the exact boundary conditions is nonetheless shown to result in significant curvature variations. Our approach is relevant to recent studies of crease formation in polymers that can inform models of folded deployable structures.

3:54 PM V49.00006: Mechanistic Insights into Mixed Surfactant-Biosurfactant Self-Assembly, Rheology and Surface Properties SAMIUL AMIN (Presenter), LIANGCHEN XU, YAO ZHOU, Department of Chemical Engineering, Manhattan College — The global surfactant market is expected to reach $44.9 billion by 2022, of which 67% of the demand is from the personal care and detergents market. Due to consumers’ increasing awareness on product sustainability, the microbially produced biosurfactants are increasingly gaining the interest of the personal care industry as potential alternatives for traditional petroleum derived and chemically synthesized surfactants. However, prior to that, an understanding of how performance criteria such as rheology and interfacial properties are affected by substitution of traditional surfactants with biosurfactants is required. In this study, the effect of rhamnolipid and sophorolipid biosurfactants on the rheological response and interfacial properties of traditional surfactants such as sodium laureth sulfate and cocamidopropyl betaine is explored utilizing a range of advanced characterization techniques. Diffusing Wave Spectroscopy based Optical Microrheology is specifically carried out to gain insights into the short time dynamics in these systems and is also utilized for extracting wormlike micelle structural parameters such as contour lengths and persistence lengths. These insights are utilized to develop unique formulation design rules for biosurfactant based products.

4:06 PM V49.00007: Scratching viscoelastic liquids* ASHEESH SHUKLA (Presenter), NICOLAS CHANUT, Civil and Environmental Engineering, Massachusetts Institute of Technology, ROLAND JM PELLENQ, Civil and Environmental Engineering, MIT / CNRS, FRANZ-JOSEF ULM, Civil and Environmental Engineering, Massachusetts Institute of Technology, THIBAUT DIVOUX, Civil and Environmental Engineering, MIT / CNRS — Viscoelastic materials are ubiquitous in our everyday life: from skin tissue to butter or bitumen, we are surrounded by materials that display both a viscous and an elastic response under external deformation. Beyond the linear deformation regime, such materials often exhibit complex flow profiles, from spatially heterogeneous ductile flow to crack and fractures. In this presentation, we focus on the latter category of materials and show that a scratch technique, which has been extensively applied for determining the resistance to fracture of solids, can be successfully applied to viscoelastic materials. Using a Rockwell diamond probe of conical shape mounted on a micro scratch tester (Anton Paar), we perform direct measurements of the fracture toughness of various type of bitumen samples at ambient temperature. We show that the fracture toughness of bitumen increases as a power-law of the horizontal scratch speed, independently of the vertical loading rate. The power-law exponent is characteristic of the sample and increases for decreasing penetration grade. Finally, we use the scratch test to quantify the impact of various additives (polymer, glass beads, etc.) on the fracture toughness of bitumen samples.

*Ditecsesa/Ferrovial
We use classical microfluidics flow-focusing technique to synthesize concentrated emulsions, based on a difunctional acrylic monomer, as constitutive “atoms” of size ~50μm. Then, using in situ photopolymerization, the emulsions turn into soft colloidal particles that interact with each other to form soft colloidal-based gels. We vary the rheological properties of these emulsions by regulating conditions for photopolymerization. Using conventional optical microscopy, we also use a microfluidics-based test cell to hydraulically fracture these soft gels at controlled flow rates and examine both micro-cracking and plastic events, i.e. the local irreversible displacements around the crack tip.

**3D printing by tailored extrusion of carbon nanotube inks**

CRYSTAL OWENS (Presenter), GARETH MCKINLEY, JOHN HART, Massachusetts Institute of Technology — 3D printing through direct-ink writing builds objects by layerwise deposition of material; and the properties of the final object are governed both by the ink and by the hierarchical organization within and across layers. In extrusion 3D printing of thermoplastics, strength and thermal stability can be improved by addition of rod-like fillers such as carbon nanotubes (CNTs) or carbon/glass microfibers. However, the mechanical properties of 3D printed objects are far from those achieved by spinning of continuous fibers out of the same material. We study the flow-mediated structure evolution of rigid rod-like particle-based inks using single-walled carbon nanotubes (SWCNTs) at high concentrations from 0.7-1%wt. We report the influence of processing parameters such as the flow rate, rate of elongation, and rate of reaction or diffusion on the strength, conductivity, and dimensions of the extruded filament, and of printed test artifacts. Our results suggest that 3D printing processes for architected materials can be improved by incorporating key principles of fiber spinning.

**Electrospinning Polyelectrolytes from Complex Coacervates**

XIANGXI MENG, SARAH PERRY, JESSICA SCHIFFMAN (Presenter), Chemical Engineering, University of Massachusetts Amherst — Electrospun fibers are canvases that can be tailored towards a wide variety of applications. However, traditional electrospinning often involves organic solvents that can cause cytotoxicity concerns. Here, I will highlight our revolutionary fibers that form using only water and salt. Polyelectrolyte complexes (PECs) form due to the electrostatic complexation between oppositely-charged polymers. We have recently demonstrated that by exploiting the salt-driven plasticization of PECs, we can enable the electrospinning of ultra-stable solid fibers from an aqueous solution containing a pair of strong polyelectrolytes and salt. Electrospun PEC fiber mats are stable over a wide range of pH values, ionic strength conditions, and many organic solvents. To address the challenge of delivery, we encapsulated a library of dyes into the coacervate phase and subsequently, achieved highly-loaded electrospun fibers. Finally, I will propose a mechanistic understanding of the design rules for electrospinnable coacervates by correlating polymer chain length, with coacervate phase behavior, and as-spun fiber morphology. The overall goal of the talk is to illustrate our recent findings and how these results can guide the green engineering of multifunctional fiber mats.

4:54PM V49.00011: Modeling of shot peen forming using non-Euclidean plate theory* VLADISLAV SUSHITSKII (Presenter), Mechanical Engineering, Ecole Polytechnique de Montreal, GUY LEVASSEUR, Aerosphere Inc., WILLEM MARINUS VAN REES, Mechanical Engineering, Massachusetts Institute of Technology, MARTIN LEVESQUE, FREDERICK GOSSELIN, Mechanical Engineering, Ecole Polytechnique de Montreal — Shot peen forming is a versatile technique for shaping large thin panels by impacting them with thousands of high-velocity millimeter-sized shots. The process is widely used in aerospace, notably to form wing skins. Two main factors hinder the process' efficiency: the lack of accurate and simple modeling tools and the lack of automation. Without modeling, the process' setup relies on a lengthy trial and error procedure. Our project is intended to fill this gap and to provide the industry with a reliable and efficient modeling software. The software is based on innovative theoretical framework of non-Euclidean plate theory relying on Riemannian geometry. This theory was initially developed to describe growth-induced reconfiguration of thin organic tissues, and in terms of mechanics these processes share many similarities with peen forming. It is the incompatibility between local stretching and curvature induced by different mechanical processes that is viewed as the reason of reconfiguration. The accuracy and performance of our software were examined in laboratory conditions by comparing simulations with experimental results for the case of large 1x1m aluminum plates submitted to peen forming.

*The authors acknowledge the financial support from Aerosphere Inc., FRQNT and REGAL.

5:06PM V49.00012: A deep learning approach to solving the peen forming inverse problem WASSIME SIGUERDIDJANE (Presenter), FARBOD KHAMENEIFAR, FREDERICK GOSSELIN, Mechanical Engineering, Ecole Polytechnique Montreal, GUY LEVASSEUR, AeroSphere Inc. — Peen forming is a cold forming process where surface plastic deformations are created by high-velocity projectile impacts. The resulting local expansions of the treated surface lead to local curvature variations. The effect of the peening treatment can be represented as a thermal expansion on a bi-layered plate, making this problem identical to bilayers in soft material physics. The motivation for this work is the development of automated robotic peen forming, which will increase the repeatability, accuracy, and efficiency of the process. With our goal being full process automation, we are interested in solving the inverse problem of calculating the required peening trajectories to form a part into the desired shape. To achieve this, we present an efficient method using deep learning to recognize patterns linking deformed plates to the required peening trajectories. The proposed model is trained on a large dataset to infer the required peening trajectories. Our results show that the predicted patterns create deformed shape deviations in the order of 100 microns. We consider that this approach can be used as part of a feedback loop to achieve full process automation.

5:18PM V49.00013: The effect of cryogenic thermal cycling on potential energy states and mechanical properties of metallic glasses NIKOLAI PRIEZJEV (Presenter), Mechanical & Materials Engineering, Wright State University — The structural relaxation, potential energy states, and mechanical properties of a model glass subjected to thermal cycling are investigated using atomistic simulations. We study a non-additive binary mixture which is annealed with different cooling rates from the liquid phase to a low temperature well below the glass transition. The thermal treatment is applied by repeatedly heating and cooling the system at constant pressure. We find that poorly annealed glasses are relocated to progressively lower levels of potential energy over consecutive cycles, whereas well annealed glasses can be rejuvenated at sufficiently large amplitudes of thermal cycling. The structural transition to different energy states is accompanied by collective nonaffine displacements of atoms that are organized into clusters, whose typical size becomes larger with increasing cooling rate or temperature amplitude. We show that the elastic modulus and the peak value of the stress overshoot exhibit distinct maxima at the cycling amplitude, which corresponds to the minimum of the potential energy. The simulation results indicate that the yielding peak as a function of the cycling amplitude for quickly annealed glasses represents a lower bound for the maximum stress in glasses prepared with lower cooling rates.

Session V50 DPOLY: Ion Transport Mechanisms in Ionic Liquid/Polymer Hybrids BCEC 252B -

Lisa Hall, Ohio State University - Tag(s): Focus
Influence of Side-chain Chemistry on Structure and Ionic Conduction Characteristics of Polythiophene Derivatives: A Computational and Experimental Study

BAN DONG (Presenter), Institute for Molecular Engineering, University of Chicago, CHRISTIAN NOWAK, School of Chemical and Biomolecular Engineering, Cornell University, JONATHAN ONORATO, Department of Materials Science and Engineering, University of Washington, FERNANDO A ESCOBEDO, School of Chemical and Biomolecular Engineering, Cornell University, CHRISTINE LUSCOMBE, Department of Materials Science and Engineering, University of Washington, PAUL F NEALEY, SHRAYESH PATEL, Institute for Molecular Engineering, University of Chicago

While extensive efforts have been devoted to understand electronic transport in conjugated polymers, little is known about their ionic conduction characteristics in relation to polymer chemistry and morphology. This work presents a combined computational and experimental study on morphology and ion transport in thin film blends of polythiophene derivatives and lithium bis(trifluoromethanesulfonyl)imide (LiTFSI). Using molecular dynamics (MD) simulation, we show that in the amorphous phase, a polythiophene derivative P3EGT bearing oligoethylene glycol side-chains with an oxygen directly attached to the thiophene rings possesses lower Li⁺ ion conductivity compared to its analog P3MEGT that has a methyl spacer between the oxygen and the thiophene rings. Structural characterization of P3EGT- and P3MEGT-LiTFSI thin films indicates that LiTFSI preferably resides in the amorphous domain especially at high LiTFSI concentrations. Ionic transport measured by impedance spectroscopy is found to occur in amorphous domain, and ionic conductivity in P3MEGT is always higher than in P3EGT, consistent with prediction from simulation. Our work provides a platform to predict and study the influence of polymer chemistry on ionic conductivity of conjugated polymers.

Ion-Transport Properties of Nanothin Film Dry Polymer Electrolytes

BAN DONG, PAUL F NEALEY, SHRAYESH PATEL (Presenter), Institute for Molecular Engineering, University of Chicago

Polymer electrolytes have demonstrated promise as dry electrolyte materials to enable lithium-metal batteries. However, majority of studies have focused only on thick samples (100's of microns). However, interfaces play a critical role on the performance of batteries, thus investigating polymer electrolyte in the context of nanothin films (5-100 nm) will lead to better understanding of the role of interfaces on charge transport properties. Here, we report on ion transport characteristics of nanothin films of PEO and LiTFSI blends as a function of salt concentration, temperature and film thickness. Ion transport measurements were successfully performed using impedance spectroscopy on films fabricated on custom-designed nanofabricated interdigitated electrode (IDE) devices. Importantly, thickness dependence study of ion transport shows a monotonic decrease in ionic conductivity upon decreasing film thickness from 250 nm to ca. 10 nm, and the effect is stronger at low salt concentrations. The decrease of ionic conductivity at thinner films originate from the increasing fraction of the immobilized layer near the polymer/substrate interface. Our results suggest that using nanothin film configuration is a promising strategy to probe interfacial effects on ion conducting properties.

Proton transport through acid aggregates in a hydrated precise sulfophenylated polyethylene

BENJAMIN PAREN (Presenter), University of Pennsylvania, LIONEL PICARD, LITEN-DEHT-SCGE-LM, CEAtch, PATRICE RANNOU, MANUEL MARECHAL, Univ. Grenoble Alpes, CNRS, CEA, INAC-SYMMES, WILLIAM NEARY, AARON KENDRICK, JUSTIN G KENNEMUR, Florida State University, AMALIE FRISCHKNECHT, Sandia National Labs, KAREN WINEY, University of Pennsylvania

Hydrated acid aggregates in a precise sulfophenylated polyethylene exhibit high proton conductivity. This study focuses on a new precise polymer, synthesized by ring-opening polymerization, that has a polyethylene backbone with a sulfonated phenyl group pendant on every 5th carbon, p5PhSA. The structure of p5PhSA is characterized with X-ray scattering and the proton conductivity is characterized with electrical impedance spectroscopy. Both experiments are performed as a function of relative humidity and temperature. Sorption measurements determined the water uptake in p5PhSA as a function of humidity as well. Atomistic molecular dynamics simulations are used to elucidate the structure of the acid aggregates in the amorphous polymer matrix and are directly compared to absolute X-ray scattering data. At 40°C and 90% relative humidity, the proton conductivity of p5PhSA is 0.17 S/cm, exceeding that of Nafion. At room temperature, interaggregate distance nearly doubles from 1.8 nm at 0% relative humidity, to 3.4 nm at 100% relative humidity. The swelling of these ordered acid aggregates with water is reversible, and facilitates the proton transport through p5PhSA.

3:06PM V50.00004: Mesoscale Organization and Dynamics in Ionic Liquids* [invited] JOSHUA SANGORO (Presenter), Chemical and Biomolecular Engineering, University of Tennessee — The impact of mesoscale organization on transport and dynamics in ionic liquids is investigated by broadband dielectric spectroscopy and dynamic mechanical spectroscopy as well as x-ray and neutron scattering techniques, complemented by computational approaches. Signatures of slow, sub-α dynamics are identified in the dynamic-mechanical and dielectric spectra and employed to probe lifetimes and dynamics of mesoscale aggregates in ionic liquids. It is found that the dynamics of mesoscale aggregates dominate many physicochemical properties such as the static dielectric permittivity and viscosity. By using mixtures of ionic liquids to tune composition-dependent evolution of the morphology, it becomes possible to realize ionic liquids with enhanced physicochemical properties that are otherwise inaccessible in neat systems. This talk will discuss the role of mesoscale organization and dynamics on macroscopic physical properties of ionic liquids.

3:42PM V50.00005: Diffusion of Ions in Diblock Copolymers: Understanding the Molecular Weight Effect Through Coarse-Grained Modeling* YOUNGMI SEO, LISA HALL (Presenter), Ohio State University — Diblock copolymers in which one microphase is mechanically robust while the other solvates and allows conduction of ions are of interest as solid battery electrolytes. The transport of ions through the conducting microphase is generally slower than through the analogous homopolymer, and is thought to depend on the distribution of ions within the conducting phase, among other factors. To understand these effects, we use coarse-grained molecular dynamics simulations and consider a wide range of systems with various ion-polymer and ion-ion interaction strengths. Our model reproduces the experimental trend of increasing ion transport with copolymer molecular weight, and this trend is more dramatic as ions are solvated in one polymer block more strongly or as the ion-ion interactions get stronger. The degree to which ions are locally concentrated, quantified by their average number of nearest ion neighbors out to a distance of approximately three diameters, is a good predictor of the ion diffusion constant. Specifically, systems whose ions are more locally aggregated (have more ion neighbors) have a reduced diffusion constant.

3:54PM V50.00006: Study of Segmental Dynamics in Polymer-Ceramic Composite Electrolytes using Quasi-elastic Neutron Scattering* CHELSEA CHEN (Presenter), NARESH OSTI, ROBERT L SACCI, NANCY J DUDNEY, Oak Ridge National Laboratory — Composite solid electrolytes consisting of a polymer electrolyte and an ion-conducting ceramic electrolyte have potential in achieving high ionic conductivity, high mechanical modulus and good processability to enable higher energy density technologies. In this work we fabricated composite electrolyte consisting of poly(ethylene oxide) (PEO), lithium trifluoromethanesulfonate (LiTf), and a lithium-conducting glass ceramic (LICGC) from Ohara corporation. We discovered that thermal history has a profound impact on the PEO segmental dynamics, resulting in drastically different conductivities below the melting point of PEO in the first heating and cooling cycles. The average relaxation time of PEO chains decreased with the presence of LICGC. However, the enhanced segmental motion contradicts the decrease in the ionic conductivity of the composite electrolyte. The relationship between ionic conductivity, segmental motion, crystallinity and tortuosity in the composite electrolyte will be discussed.

*This work was sponsored by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Science and Engineering. Neutron scattering experiments were performed at Spallation Neutron Source.

4:06PM V50.00007: Analyzing Ion Conductivity in Block Copolymer Electrolytes from Molecular Dynamics Simulations with an Applied Electric Field KUAN-HSUAN SHEN (Presenter), LISA HALL, William G. Lowrie Department of Chemical and Biomolecular Engineering, The Ohio State University — Salt-doped block copolymers can be created with one microphase that is mechanically robust and another that solvates and conducts ions. A variety of polymer and ion types can be chosen, and molecular simulations can show how these choices impact ion motion to guide design of new materials. One strategy to increase conduction is to tune dielectric constant to reduce the degree of correlation of cation and anion motion, which can be significant in salt-doped copolymers. However, it is difficult to assess such a strategy in simulations, which often calculate self-diffusion constants of ions and estimate conductivity using the Nernst-Einstein equation (neglecting ion correlations). Conductivity can be directly calculated, including effects of correlated ion motion, from equilibrium simulations. However, this approach introduces a large statistical uncertainty. We aim to calculate conductivity from ion mobilities under an applied electric field. We ensure the field is low enough that the systems are in the linear response regime while still allowing for mobility high enough to measure accurately in the timescale of the simulation. We then compare conductivity of various systems as a function of Coulombic and polymer-ion interactions.
In this study, the diffusion coefficient of lithium salt through a polystyrene-poly(ethylene oxide) block copolymer (SEO) was investigated using time-resolved Fourier Transform infrared - attenuated total reflectance (FTIR-ATR) spectroscopy. FTIR-ATR directly measures change of concentration in response to a concentration gradient, which is relevant for battery operation. FTIR-ATR is simpler and faster than electrochemical measurements, such as restricted diffusion, that require calibration and assumption about how cell potential relates to concentration gradient. Since the measurements are made in the absence of other driving forces, such as applied potential, the diffusion coefficient is independent of ionic conductivity and transference number. We studied the effect of salt concentration on the diffusion coefficient above the melting temperature of the electrolyte. Our results indicate that the diffusion coefficient is concentration-dependent, but not monotonic.

*This work was supported by funding from LG Chem.

We investigate the influence of doping on the conductivity of high molecular weight, crystalline PEO₆ based solid polymer electrolytes (SPEs). Polyethylene oxide (PEO) based SPEs are an attractive alternative to the flammable liquid/gel electrolytes currently used in rechargeable lithium ion batteries. But, SPEs suffer from low ionic conductivity. The conductivity is linked to PEO segmental motion; in order to increase the segmental motion, we must reduce the glass transition temperature $T_g$. Unfortunately increase in polymer dynamics reduces mechanical strength of SPE. PEO₆-LiClO₄ complex is a tunnel like PEO/salt co-crystal which conducts Li⁺ based on a mechanism that decouples conductivity and segmental motion of the polymer. Inspired from ceramics, we dope small amounts of anions or cations to disrupt the PEO₆-LiClO₄ lattice. We vary the size of the anion, and cation to create defects in the crystal lattice. We observe up to 900% increase in the conductivity of doped samples even with small amount dopant (1%). Interestingly, the increase in conductivity is not correlated with the decrease in $T_g$ of the SPEs. With wide angle X-ray scattering, we observe transition from single crystalline phase to mixed phase morphology with increase of the dopant concentration.

In recent work [ACS Macro Lett. 2018, 7, 1149-1154], we explored the role of polymer host polarity on ionic conductivity using the Stockmayer model of polar fluids applied to a coarse-grained Kremer-Grest polymer. In this model, a freely rotating electric dipole moment is embedded in each monomer bead. We found that the ionic conductivity maximized at some intermediate host polarity, as measured by the monomeric point dipole moment strength. We demonstrated that this maximization arises from a tradeoff between reduced ionic aggregation and slowed segmental dynamics as the host polarity increased. In this work, we investigate the influence of salt concentration, temperature, and host molecular weight on ionic conductivity and the nonmonotonic variations with the polarity of the host polymer medium.

*The authors acknowledge the Welch Foundation and the National Science Foundation for funding this work.

We developed a coarse-grained molecular dynamics simulation model incorporating a dynamic bonding scheme to study the transport properties of associated particles in polymeric melts. In order to mimic the hopping of lithium ions in polymer electrolytes, a probability of breaking a dynamic bond between an associated particle and an active bead along polymer chains, $P_{\text{break}}$, was introduced to tune the activation energy between bound and unbound states. Both static (Kuhn length of solvated polymer chains, radial distribution functions, and connectivity of associated particles) and dynamic (mean squared displacement, and diffusion coefficient) properties of two classes of macromolecules were studied: a linear chain system with various bending rigidity and a brush system with various architectures. Simulation results show that the diffusion coefficient of associated particles is linearly proportional to $P_{\text{break}}$ and scales with the diffusion coefficient of polymer chains as $D_{\text{assoc}} \sim D_{\text{poly}}^{3/2}$. These results provide insight in understanding the design rules of polymeric materials for solid-state lithium-ion batteries.
5:06PM V50.00012: Dissolution of Lithium Metal in Poly(ethylene oxide)*  
MICHAEL GALLUZZO (Presenter), WHITNEY LOO, NITASH BALSARA, University of California, Berkeley — Salt doped poly(ethylene oxide) (PEO) has been studied extensively as a model polymer electrolyte system for lithium metal battery applications. In this study, we examine the widely accepted assumption that a stable interface forms between lithium and PEO above the PEO melting temperature by studying lithium symmetric cells. Using Li7 NMR, we show that a lithium species dissolves from the lithium electrode and diffuses into the bulk of initially neat PEO. Impedance spectroscopy is used to demonstrate that the lithium species contributes to ionic conductivity, and small angle X-ray scattering demonstrates that the dissolution also occurs in a PEO containing block copolymer, resulting in a significant increase (>20°C) of the order-to-disorder transition temperature. The results indicate that the lithium/PEO interface is not stable at elevated temperatures and there are clear implications for lithium metal batteries using PEO-based electrolytes.

*Primary funding for the work was provided by the Electron Microscopy of Soft Matter Program from the Office of Science, Office of Basic Energy Sciences, Materials Sciences and Engineering Division of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231 (KC11BN).

5:18PM V50.00013: Designing efficient polymer electrolytes via end-group controls  
HA YOUNG JUNG (Presenter), GYEONG-CHAN KANG, MOON JEONG PARK, Pohang University of Science and Technology — There has been an increasing demand for the development of high-conductivity solid-state polymer electrolytes (SPEs) to be used in lithium batteries by replacing liquid electrolytes. The most widely studied SPEs are based on poly(ethylene oxide) (PEO) and its derivatives owing to PEO's high solvating capability for lithium salt and low glass transition temperature. Given that lithium ion conduction occurs through the segmental motion of PEO chains, high mobility of lithium ion was feasible in amorphous phases. This prompted extensive research efforts to suppress PEO crystallinity by various physical and chemical approaches. In the present study, we investigate PEO-based polymers incorporated with various terminal functional groups as an effective means of controlling crystallinity of PEO phases. Further, by attaching various di-functional groups to the end of PEO chains, it has been revealed that morphology, ionic conductivity, and lithium transference number of PEO electrolytes are fine-tunable, attributed to the alteration of inter- and intramolecular interactions within.

Session V51 DBIO DPOLY: Protein Liquid-Liquid Phase Separation  
BCEC 253A - Xiaoqin Zou, University of Missouri - Tag(s): Invited

2:30PM V51.00001: Physical Basis of Protein Liquid-Liquid Phase Separation* [Invited]  
HUAN-XIANG ZHOU (Presenter), Department of Physics and Department of Chemistry, University of Illinois at Chicago — Intracellular membraneless organelles, corresponding to the droplet phase upon liquid-liquid phase separation (LLPS) of mixtures of proteins and possibly RNA, mediate myriad cellular functions [Qin & Zhou 2017 Curr Opin Struct Biol]. Cells use a variety of biochemical signals such as expression level and posttranslational modification to regulate droplet formation and dissolution. Our study focuses on elucidating the physical basis of phase behaviors associated with cellular functions of membraneless organelles, using three complementary approaches. First, we use colloids and polymers, respectively, as models for structured and disordered proteins, to investigate both the common basis for protein phase separation and the unique characteristics of structured and disordered proteins in LLPS [Zhou et al 2018 Trends Biochem Sci]. Disordered proteins are characterized by both extensive attraction throughout the sequence and low energetic cost from steric repulsion, contributing to easy observation of phase separation. Second, we use multi-component patchy particles to investigate the wide range of effects of regulatory components on the droplet formation of driver proteins [Nguemaha & Zhou 2018 Sci Rep]. Third, we have developed a powerful computational method called FMAP for determining liquid-liquid phase equilibria [Qin & Zhou 2014 J Chem Theory Comput; 2016 J Phys Chem B]. By using fast Fourier transform to efficiently evaluate protein-protein interactions, FMAP enables an atomistic representation of the protein molecules. Application to g-crystalins reveals how minor variations in amino-acid sequence, similar to those from posttranslational modifications and disease-associated mutations, lead to drastic differences in critical temperature. These studies contribute to both qualitative and quantitative understanding on the phase behaviors of membraneless organelles and their regulation and dysregulation.

3:06PM V51.00002: Identifying sequence-determinants of protein liquid-liquid phase separation using molecular simulations
[Invited] JEEATN MITTAL (Presenter), Chemical and Biomolecular Engineering, Lehigh University — In this talk, I will describe ongoing efforts in my group aimed at developing an accurate simulation model to study the liquid-like assemblies of disordered proteins. We use a "top-down" approach for constructing a Cα-based (one interaction site per amino acid) protein model, which involves comparisons with experimental data available from the recent literature as well as comparisons with atomistic single-chain simulations. The resulting model is found to be of enormous help in decoding the role of specific features of the protein sequence that control their liquid-liquid phase separation. We will demonstrate this with a combination of simulation and experiment data for several protein systems such as Laf-1, FUS, TDP-43.

3:42PM V51.00003: Atomic details of protein/RNA liquid-liquid phase separation by experiment and simulation
[Invited] NICK FAWZI (Presenter), Brown University — Phase separation of RNA-binding proteins via multivalent interactions between aromatic/polar-rich disordered domains contributes to the formation of functional cytoplasmic granules and nuclear puncta, which have been shown to behave as liquids -- flowing, fusing, and returning to spherical shape -- within live cells. These domains have also been identified as the nucleators of cytoplasmic inclusions associated with amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). We use atomic resolution nuclear magnetic resonance spectroscopy approaches to visualize low complexity domain structure and interactions along the pathway from monomer, to liquid-liquid phase separated state, to static aggregates and hydrogels. We show that the low complexity domains of RNA-binding protein Fused in Sarcoma (FUS LC, associated with ALS and FTD) and hnRNP A2 (associated with ALS and IBM) remain disordered even within liquid phase separated puncta (Burke et al. Molecular Cell, 2015). FUS LC also recruits unphosphorylated RNA-polymerase II C-terminal domain into the liquid phase separated state, adding a potential explanation for FUS LC transcriptional activation in cancer. Importantly, phase separation is reversible and is modulated by interaction with RNA, distinguishing these assemblies from static inclusions that can arise from missense mutations in the LC regions. In contrast, we show that liquid-liquid phase separation of TDP-43 is mediated in part by structured α-helical assembly and extension (Conicella et al. Structure, 2016). Some ALS-associated mutations disrupt helix-helix interaction inhibiting liquid-liquid phase separation while leading to enhanced aggregation. Our current work aims to evaluate the potential of post translational modification to alter assembly and hence disrupt pathological interactions of these disordered domains (Monahan and Ryan et al. EMBO J 2017).

4:18PM V51.00004: Features and consequences for transcriptional activity of transcription factor condensation*
[Invited] XAVIER SALVATELLA (Presenter), Chemistry and Molecular Pharmacology, ICREA and Institute for Research in Biomedicine (IRB Barcelona), The Barcelona Institute of Science and Technology — Transcription activation relies on weak, transient interactions between the activation domains of transcription factors, general transcription factors, transcriptional co-regulators and RNA Pol II. Characterizing these interactions is important to understand the physical principles that govern this important process and, also, to identify opportunities for therapeutic intervention, especially in oncology. We are interested in characterizing how this type of interactions regulate the transcriptional activity of a specific transcription factor, the androgen receptor (AR) - the main therapeutic target for prostate cancer - and in perturbing them with small molecules. In this communication we will provide a characterization of the interactions established by the activation domain of AR [1–3] as well as evidence that the activation domain forms condensates [4] stabilized by hydrophobic interactions between partially structured motifs that are important for transcriptional activity. Finally we will put forward the hypothesis that the multivalent nature of these interactions is in part responsible for AR condensation at the initiation of transcription.

*AGAUR (2017 SGR 324), Marató TV3 (102030), MINECO (BIO2012-31043 and BIO2015-70092-R) and the European Research Council (CONCERT, contract number 648201). IRB Barcelona is the recipient of a Severo Ochoa Award of Excellence from MINECO (Government of Spain).
YING WANG (Presenter), Chemistry and Biochemistry, University of North Carolina Wilmington — Liquid-liquid phase separation (LLPS) is a well-known phenomenon in the field of colloid physics. In the past few decades, LLPS has been reported for various protein solutions. Remarkably, LLPS of protein solutions was observed in living organisms, from “cold cataract” in the eye lenses of fish to the recently reported intracellular segregation of signal protein complexes.

One interesting question is whether LLPS is a ubiquitous phenomenon for proteins or just a serendipitous observation in isolated cases? Theoretically, metastable LLPS can be expected for the particles with short-range interactions. However, LLPS of protein solutions is rarely observed, largely due to freezing of solutions and competition from crystallization and aggregation. In this talk, I will show that LLPS can be induced for many proteins and peptides using a simple experimental method. With the ability to experimentally control LLPS, we were able to explore the phase behavior of various protein systems from large monoclonal antibodies to small lipopeptides. In our studies on the non-spherical proteins, we noticed that the shape of protein molecules has some interesting effects on the phase diagram. Our studies suggest that LLPS in protein solutions is a common phenomenon, and thereby may play important roles in living organisms as well as in practical applications of proteins.

Session V52 DPOLY: Block Copolymer Thin Films II: Experiment and Application

2:30PM V52.00001: Sequential Infiltration Synthesis – Mechanism and Applications of Metal Oxide Growth within Block Copolymers [Invited] TAMAR SEGAL-PERETZ (Presenter), Technion - Israel Institute of Technology — Sequential infiltration synthesis (SIS) is an emerging technique which harnesses atomic layer deposition (ALD) chemistry for growth of inorganic materials within polymers. The highly selective growth within the polar domains of block copolymers (BCP) makes it an attractive method for fabricating hybrid BCP-metal oxide composite with synergic properties as well as for BCP-templated inorganic nanostructure fabrication. However, complete understanding of SIS mechanism is still missing and exploring its application space has only just began.

Here we investigate the principles that govern SIS growth in homopolymers and block copolymers thin films using a combination of in-situ and ex-situ methods. We characterize the diffusion-limited growth profile within the polymers and show its relationship to the polymer chemistry, precursor chemistry, and SIS process parameters. Judicious selection of the BCP enabled SIS growth of even bulky metalorganic precursor and templating SnO2 porous nanostructure. SIS was also utilized to construct multi-layer BCP-templated Al2O3 membranes with tuned 3D pore structure. Finally, fundamental understanding of diffusion and growth in SIS enabled us to template 3D metal oxide heterostructures, opening a pathway of direct 3D nanofabrication from BCP.

3:06PM V52.00002: Self-Assembly Kinetics Enhancement in Ternary “Wet Brush” Block Copolymer/Homopolymer Blend Thin Films* GREGORY DOERK (Presenter), RUIPAENG LI, MASAFUMI FUKUTO, Brookhaven National Laboratory, ALFREDO RODRIGUEZ, Mechanical Engineering, City College of City University of New York, KEVIN G. YAGER, Brookhaven National Laboratory — In this talk we discuss our recent work investigating the enhanced ordering kinetics in thin film ternary blends of polystyrene-block-poly(methyl methacrylate) (PS-b-PMMA) block copolymers with low molecular weight “wet brush” PS and PMMA homopolymers that distribute more uniformly throughout the domains. In lamellar thin films, blending dramatically increases the power law exponent governing the development of long-range order during thermal annealing. For cylinders the impact of blending is more dramatic in films thicker than one monolayer due to rapid early stage ordering and faster domain reorientation with respect to the substrate. This blending strategy is also compatible with solvent vapor annealing, where it is applied to promote rapid self-assembly of ultrahigh molecular weight PS-b-PMMA (> 1000 kg/mol). The robust enhancement in ordering kinetics afforded through wet brush homopolymer blending is attributed to changes in the effective segregation strength.

*Research performed at the Center for Functional Nanomaterials, a U.S. DOE Office of Science Facility, at Brookhaven National Laboratory under Contract No. DE-SC0012704.
Directed self-assembly of block copolymers facilitates the creation of films with highly oriented domains over large areas. However, further enhancing our control over surface design requires the ability to create regions of a desired pattern which could be arbitrarily spaced. We have recently discovered that the utilization of substrates with topographically-defined stripes leads to the formation of different morphologies in the trenches and on the plateaus in ultra-confined block copolymer films. This is explained by the fact that capillary action drives more material to deposit in the trenches than on the plateaus during spin coating. The high sensitivity of the patterns displayed by ultra-confined films to minute differences in film thickness and substrate selectivity gives rise to different patterns in the trenches and on the plateaus. Specifically, we were able to demonstrate the formation of hexagonally packed dots on the plateaus concomitant with featureless appearance of the slightly thicker films in the trenches, owing to the ability of the latter to accommodate lying lamellae. As the widths of the trenches are controlled by the lithographic design, this situation facilitates the creation of patterned domains that are spaced by featureless regions as needed.

Block Copolymer Derived Uniform Mesopores For Supercapacitors

High mass loading and fast charge transport are two crucial but often mutually exclusive characteristics of pseudocapacitors. On conventional carbon supports, high mass loadings inevitably lead to sluggish electron conduction and ion diffusion due to the thick pseudocapacitive layer and clogged pores. Herein from the macromolecular perspective, we revolutionize the design of carbon supports. Utilizing block copolymers that microphase-separate, we synthesize porous carbon fibers (PCFs) with uniform mesopores, which are partially filled with MnO₂. The uniform mesopores and ultrathin MnO₂ enable fast electron/ion transport comparable to carbons in electrical double layer capacitors. The gravimetric and areal capacitances of MnO₂ reach 1148 F/g and 3141 mF/cm², respectively.

Multi-scale Block Copolymer Coating That Induces Hydrophobic Properties on Inorganic Surfaces

Superhydrophobic surfaces hold promise of a technology with various applications spanning different environments, service conditions and length scales. We demonstrated a cost-effective and robust method for imparting superhydrophobicity to target surfaces through self-assembly of block copolymers (BCPs), while the optical properties of underlying materials are preserved. Our approach involves iterative steps of spin-coating, annealing, and etching of different molecular weight (MW) PS-b-PDMS BCPs into multi-layer hierarchical structure. The resulting periodic pattern introduces necessary nanoscale roughness to trap air and increases hydrophobicity of surfaces, and can be controlled by altering tuning parameters such as MW and composition of BCPs. To understand how superhydrophobicity emerged from multi-layer hierarchical BCP structures, multilayer BCP models were constructed by matching experimental observed dimensions, sweeping through wetting configurations, and calculating externally observed contact angles. The results verified the observed experimental trend, demonstrating superhydrophobicity behavior through modulation of roughness at different layers and formation of air pockets. This technology fulfills a pressing need for superhydrophobicity in optically sensitive settings.

Generalized method for perpendicular orientation of block copolymer microdomains in thin films with surface crosslinking process

By effectively cross-linking the surface of a randomly existing BCPs, the cross-linked BCP layer can be worked as natural-born fraction-tailored neutral brush. The cross-linking method can be directly applied to the poly(styrene-block-methyl methacrylate), poly(styrene-block-dimethylsiloxane) and poly(styrene-block-2-vinylpyridine) films to realize perpendicular orientation from the top surface after thermal/solvent annealing on pristine Si or pre-patterned substrate for chemo-epitaxy directed self-assembly. Also, perpendicular orientation from the bottom interface can be also realized by introducing the new BCP film onto the cross-linked BCP layer.
4:06PM V52.00007: Modification Toward Fluorine-Containing High-$\chi$ Block Copolymers and Orientation Control on Thin Films  SEONJUN JO (Presenter), SEUNGBAE JEON, TAESUK JUN, DU YEOL RYU, Yonsei University — To approach miniaturized patterns such as sub-10 nm, block copolymer (BCP) has emerged as an attractive material to overcome the size limit of the conventional lithography, where Flory-Huggins interaction parameter ($\chi$) plays the key role to control the size. In this study, fluorine-containing high-$\chi$ BCP is newly designed which was synthesized using transesterification method. High-yield conversion was achieved using a polymeric catalyst, where the polymer dispersity remain unchanged during the transesterification. Evaluated $\chi$ was above 0.2 over the entire temperature range which is 8 fold higher than polystyrene-$b$-poly(methyl methacrylate) and the smallest half-pitch feature size was approximately 5 nm from 6.3 kg/mol BCP. Film experiments were demonstrated on a neutralized homopolymer mat substrate where a sub-10 nm perpendicular lamellar morphology was observed in as spun state.

4:18PM V52.00008: Self-organization of Triblock Copolymer Melt Chains Physisorbed on Non-neutral Surfaces* DANIEL SALATTO (Presenter), NAISHENG JIANG, XIAOYU DI, Stony Brook University, CHANG-YONG NAM, MASAFUMI FUKUTO, Brookhaven National Laboratory, MAYA ENDOH, TADANORI KOGA, Stony Brook University — Polymer physisorption is an unavoidable event even when weakly attractive surfaces contact a polymer melt. We report the self-organization process of poly(styrene-$b$-ethylene/butadiene-$b$-styrene) (SEBS) triblock copolymer chains physically adsorbed on a non-neutral surface. The results revealed that the SEBS chains form the two different chain structures on the substrate simultaneously: (i) “flattened chains” with an average height of 2.5 nm, but without forming microdomain structures; (ii) “loosely adsorbed chains” with an average height of 11.0 nm forming perpendicular oriented cylindrical microdomains to the substrate surface. In addition, it was found that the lateral microdomain structures were distorted and the characteristic length of the microdomains varied from the bulk after reaching the quasi-equilibrium state. Furthermore, we highlight the role of the adsorbed chains in the self-assembling process of the entire SEBS thin film: A long-range perturbation propagates into the film interior, overwhelming the free surface effect associated with surface segregation of the lower surface tension of polystyrene blocks.

4:30PM V52.00009: Fabrication of Dual Nanopatterns at desired area using Block Copolymer Containing Photocleavable Linker* CHUNGRYONG CHOI (Presenter), SOYEONG PARK, YESEONG SEO, JAEYONG LEE, SEONGHYEON AHN, EUNSEOL KIM, JIN KIM, Pohang University of Science and Technology — Block copolymers (BCPs) with various nanodomains, such as spheres, cylinders, and lamellae, have received attention for their nanolithography application. However, those microdomains are determined by the volume fraction of one block. Meanwhile, nanopatterns with multiple shapes are required for the next-generation nanolithography. Although various methods have been reported to achieve dual nanopatterns, all the methods need sophisticated processes using E-beam. Here, we synthesized two kinds of BCP, linear and miktoarm typed BCP, containing o-nitrobenzyl alcohol(ONB) as photo-cleavable linker. In the case of linear BCP, dual nanopatterns consisting of nano-dots and nano-hole were easily fabricated by changing the wavelength of ultraviolet (UV) light. We also fabricated dual nanopatterns consisting of dots and lines at desired regions on a single substrate using miktoarm typed BCP.

4:42PM V52.00010: Development of Shape-Tuned, Monodisperse Block Copolymer Particles through Solvent-Mediated Particle Restructuring  JAE MAN SHIN (Presenter), YOUNG JUN LEE, MINGOO KIM, KANG HEE KU, JUNHYUK LEE, YONGJOO KIM, HONGSEOK YUN, BUMJOON KIM, KAIST — Controllability of the shape, size, and internal structure of block copolymer (BCP) particles as well as their uniformity is crucial to determine their functionality in the practical applications. Here, we demonstrate the particle restructuring by solvent engineering (PRSE) strategy to produce monodisperse particles using functional BCPs with well-defined structure. Importantly, the advantage of PRSE is the general applicability to various types of functional BCPs including polystyrene-$block$-poly(1,4-butadiene) (PS-b-PB), polystyrene-$block$-polydimethylsiloxane (PS-b-PDMS), and polystyrene-$block$-poly(4-vinylpyridine) (PS-b-P4VP). PRSE starts with producing monodisperse BCP spheres in a wide range of particle size using membrane emulsification, followed by transformation to shape-anisotropic BCP particles by solvent annealing. Monodispersity of particle size was maintained during the PRSE, and the shape transformations to prolate and oblate ellipsoids were successfully achieved. PRSE was also effective in controlling the aspect ratio (AR) of the particles, which was supported by theoretical calculation for describing the particle elongation. Further investigation on the kinetics during the PRSE revealed that the morphology transformation was driven by reorientation of BCP domains.
4:54PM V52.00011: Order-to-disorder transition of block copolymer thin films and its dependence on thickness and preferential interaction  JAEUP KIM (Presenter), DÆSEONG YONG, Ulsan National Institute of Science and Technology, YEONGSIK KIM, DU YEOL RU, Yonsei University — Unlike the phase transitions in the bulk block copolymers (BCPs), the order-to-disorder transition (ODT) in film geometry is influenced by interfacial interactions. An intuitive prediction is that a preferentially selective interaction toward one block promotes microphase separation. Such a prediction is supported by a few theoretical and experimental reports, but a few studies including thermally generated defects or field fluctuation effects suggested an increase in $\chi_N$ value with decreasing film thickness. In this study, we focus on the phase transition behavior of cylinder- and lamella-forming block copolymer films subject to an asymmetric wetting condition. Our self-consistent field theory calculation using a discrete bead-spring model with finite-range interactions exhibits a decrease in $\chi_N$ with decreasing film thickness for both lamella- and cylinder-forming BCP films. This result is consistent with our experiments using PS-$b$-P2VP BCP films with an asymmetric wetting condition that confines the films with selective interactions of the PS/air and P2VP/substrate. For both theory and experiment, the onset of the ODT shift was much thicker for the lamellar case (~20 layers) than for the cylinder case (~10 layers).

5:06PM V52.00012: Directional Alignment of Quasi-Single-Crystalline 2D Dot Array in Diblock Copolymer Thin Films via Epitaxial Cylinder-to-Sphere Transition  YE CHAN KIM (Presenter), SO YOUN KIM, Ulsan National Institute of Science and Technology — Despite the great applicability of block copolymer (BCP) thin films capable of producing dense periodic nanostructures, the difficulty to control the pattern orientation acts as an obstacle to the successful bottom-up lithography of BCPs. The production of guiding pattern on the substrate such as grapho- or chemo- epitaxy has been suggested to create highly ordered nanostructures. However, these methods can be experimentally complicated and expensive, particularly in a large-area.

In this work, we suggest a facile method to fabricate highly aligned quasi-single-crystalline 2D dot array of BCP thin films over large-area (cm²). We utilized the epitaxial morphology transition from BCP cylinders to spheres. First, sphere forming polystyrene-$b$-poly(2-vinyl pyridine) thin films were transformed to cylinders by shear; shear results in the nicely aligned parallel cylinders along the shear direction. Then, the subsequent solvent vapor annealing (SVA) induces a cylinder-to-sphere transition where the dot pattern of BCP spheres is epitaxially grown on the aligned stripe pattern of the cylinders. We found that the increase of d-spacing with SVA is a key factor for the successful generation of highly ordered 2D array, which could compensate the lattice mismatch between dot and stripe pattern.

5:18PM V52.00013: Pore Size Control using Cooperative Assembly with Block Copolymers and Low Volatility Solvents*  MEETA TRIVEDI (Presenter), BRYAN VOGT, Department of Polymer Engineering, University of Akron — Block copolymers (BCPs) provide a facile avenue to the generation of nanoporous materials with well-defined pore geometries. Cooperative assembly of BCPs with functional precursors enables families of materials to be fabricated from a single BCP template. However, the pore size is generally controlled by the BCP, which can be limiting for applications. Here, we demonstrate the ability to effectively tune the pore size (both up and down) through the addition of low volatility solvents during triconstituent co-assembly of carbonizable and silica precursors with a commercial block copolymer (Pluronic F127) that are fabricated by film casting on roll-to-roll equipment. Four different low volatility solvents with varying selectivity were examined. The pore size obtained depends on the hydrophobicity, volatility, and relative amount of solvent added. This enables mesoporous carbon-silica materials with pore sizes ranging from 5 nm to 12.8 nm. The morphology of these materials was elucidated with transmission electron microscopy (TEM) and small angle x-ray scattering (SAXS) to understand how these solvent additives impact the ordered structure.

Session V53 GSOFT: Extraordinary Mechanical Properties of Bio-inspired Soft Materials

BCEC 253C - Wouter Ellenbroek, Eindhoven University of Technology - Tag(s): Invited
2:30PM V53.00001: Do bio-inspired metal-coordination crosslink dynamics offer anything new for engineers of hydrogel mechanics? [Invited] NIELS HOLTEN-ANDERSEN (Presenter), Massachusetts Institute of Technology — Efforts to engineer synthetic polymer hydrogel mechanics is increasingly coupled to the design of transient crosslink dynamics. Based on the growing evidence supporting a critical role in desirable material applications in nature, bio-inspired metal-coordinate transient crosslinking might provide unique opportunities in these efforts. Using simple metal-coordinating polymers, we have sought to gain a deeper understanding of whether polymer hydrogel mechanical properties can be controlled over multiple hierarchical time-scales via design of metal-coordinate crosslink structure on multiple length-scales. Specifically, by utilizing metal ion-coordination complexes and metal nanoparticle-coordination junctions as supramolecular crosslink structures, we have obtained easy access to control over network dynamics on the microscopic scale, and thereby unique opportunities to broadly shape the distribution of network stress relaxation on the macroscopic scale. Our findings suggest that bio-inspired metal-coordination crosslink dynamics can indeed be utilized to engineer complex gel mechanics directly via simple design of supramolecular crosslink structure, and could help improve our understanding of and control over spatio-temporal molecular hierarchy in loadbearing biological and bio-inspired materials.

3:06PM V53.00002: Flex your mussels: Harnessing nature's designs to build next-generation materials* [Invited] MEGAN T. VALENTINE (Presenter), University of California, Santa Barbara — Marine mussels create an array of adhesive contacts (the byssus) to secure themselves to rocks, wood, metals and other mussels in the harsh conditions of the intertidal zone. Their superb mechanical and adhesive performance has served as inspiration to create mussel-inspired materials for a wide range of applications ranging from surgical glues to primers and coatings. Historically, much of this success has relied on mimicry of the molecular properties of the mussel's adhesive interfacial proteins. By contrast, the translation of the meso- to macro-scale properties of the natural materials has been comparatively unexplored, providing rich opportunities for further property enhancement to create tough, durable, load-bearing materials. Here, I will present my laboratory's recent work characterizing the properties of natural mussel byssal plaques, and translating these discoveries to enable the design and manufacture of new materials. Experimentally, we observe the dynamics of mussel plaques as they debond from glass using a custom built load frame with integrated dual view imaging capabilities, under monotonic and cyclic loading. We pair these mechanical tests with ultrastructural analysis to understand the molecular origins of strength and toughness. Using insights from the natural materials, we then create high-performance synthetic materials that are extremely strong without compromising extensibility, as well as mussel-inspired 3D structures with tunable stiffness and strength. These innovations open new possibilities for applications of mussel-inspired materials in packaging, soft robotics, and connective tissue repair, and demonstrate the importance of understanding the multiscale, multiphase properties of biological materials.

3:42PM V53.00003: Mechanical stresses control the size, shape, and location of phase-separated liquid droplets in polymer networks [Invited] ERIC DUFRESNE (Presenter), Materials, ETH Zurich — Spontaneous phase separation has recently emerged as an essential driver of cytoplasmic organization. With experiments in synthetic materials and living cells, we demonstrate that elastic stresses in polymer networks can regulate phase separation. We apply these insights to the design of photonic materials.

4:18PM V53.00004: DNA-directed hydrogel deformation* [Invited] REBECCA SCHULMAN (Presenter), Johns Hopkins University — DNA polymerization reactions within DNA-crosslinked hydrogels can direct the dramatic shape change of DNA-crosslinked hydrogels, leading of up to 100-fold changes in gel volume. The well-understood kinetics and thermodynamics of these reactions and of DNA transport make it possible to design a myriad of molecular scale reactions and to study the emergent shape-change behavior of these reactions at the millimeter scale. And because DNA molecules can be coupled to molecular sensors, amplifiers, and logic circuits, understanding DNA-directed hydrogel shape change introduces the possibility of building soft devices that respond to diverse biochemical inputs and autonomously implement chemical control programs.

*DOE Early Career 221874
NSF EFRI 1830893
How to toughen polymer gels with entropy-mediated reversible crosslinking* [Invited] NICHOLAS TITO (Presenter), Department of Applied Physics, Eindhoven University of Technology, COSTANTINO CRETON, Laboratory of Soft Matter Science and Engineering, ESPCI ParisTech, CORNELIS STORM, WOUTER ELLENBROEK, Department of Applied Physics, Eindhoven University of Technology — Materials composed of polymers that are permanently crosslinked into a network, such as gels and rubbers, eventually break if strained enough. This is because the network irreversibly ruptures once the local forces acting on the polymers and crosslinks become too large for the bonds to withstand. Recent experiments have revealed that adding *reversible* crosslinks to a gel allows it to be strained to a much larger extent, yet without altering its small-strain elasticity [1]. We are using theory, molecular simulation, and polymer self-consistent field theory for networks, to explore reversible crosslinking as a design paradigm for creating polymer materials that are tough but elastic [2]. Emphasis will be placed on how entropy itself drives reversible crosslinks to toughen the material, while preserving its intrinsic elasticity. Practical guidelines will be outlined to optimise this design in experiment, along with a discussion of key kinetic and timescale considerations.

Session V54 DPOLY DBIO: Sequence and Charge Driven Bio- and Bio-inspired Macromolecular Assembly BCEC 254A - Charles Sing - Tag(s): Focus

Theoretical Perspectives on Cellular Compartmentalization by Phase Separation* [Invited] YI-HSUAN LIN, Department of Biochemistry, University of Toronto; and Molecular Medicine, The Hospital for Sick Children, SUMAN DAS, ALAN AMIN, Department of Biochemistry, University of Toronto, ADAM EISEN, Department of Mathematics & Statistics, Queen's University, JULIE D. FORMAN-KAY, Molecular Medicine, The Hospital for Sick Children; and Department of Biochemistry, University of Toronto, HUE SUN CHAN (Presenter), Departments of Biochemistry and Molecular Genetics, University of Toronto — Compartmentalization is essential for many cellular functions. Besides organelles encapsulated by lipid membranes—mitochondria and the nucleus, e.g., dynamic non-membrane-bound compartments also exist in the eukaryotic cell. These include stress granules, germ granules, the nucleolus, and many others. Recent investigations indicate that these bodies behave like mesoscopic liquid droplets. Referred to as “membraneless organelles”, or “biomolecular condensates”, they are underpinned to a significant extent by liquid-liquid phase separation (LLPS) of intrinsically disordered proteins (IDPs) and nucleic acids. Their formation/dissolution is governed largely by the information encoded in the sequences of nucleic acids and proteins. To gain physical insights into this novel phenomenon, we developed analytical theories and simulation models for sequence-specific IDP LLPS. Our effort rationalizes experiments on the DEAD-box RNA helicase Ddx4, elucidates the effect of sequence charge patterns on LLPS, and points to a “fuzzy” mode of molecular recognition by charge pattern matching that likely bears on whether different IDP species remain miscible or demix upon LLPS to serve their biological functions. IDP LLPS depends on temperature and hydrostatic pressure. As a first step toward understanding these behaviors, we show that the trend of such dependence can be qualitatively rationalized by empirical and atomic modeling of elementary hydrophobic interactions.

3:06PM V54.00002: Transfer Matrix Theory Model of Sequence-Dependent Polyampholyte Phase Separation  JASON MADINIA (Presenter), CHARLES E. SING, University of Illinois at Urbana-Champaign — Intrinsically disordered proteins (IDPs) participate in many critical biological functions within the cell. These proteins lack a well-defined structure and can take on many conformations depending on its sequence and local environment. IDPs can be modeled as polyampholytes and can undergo a liquid-liquid phase separation that is primarily driven by electrostatic interactions. The charge sequence along the polymer is critical to the solution behavior. In this work, we present a Transfer Matrix (TM) model to describe this liquid-liquid phase separation as a function of charge sequence. We show how the TM theory is created for a polyampholyte, and how it can be used to determine the free energy of interaction between the polyampholyte and its local environment. In conjunction with the TM theory, we perform MD simulations of charge-patterned polyampholytes in solution to compare with the model. We find that increasing charge blockiness increases the tendency to undergo phase separation, limiting to the behavior typically seen in polymeric complex coacervates, while alternating positive and negative charges do not exhibit charge-induced phase separation.

3:18PM V54.00003: Impact of complex coacervation on tau amyloid aggregation*  YANXIAN LIN (Presenter), KATE ZENG, YANN FICHOU, YUGE HU, SONGI HAN, University of California, Santa Barbara — Amyloid aggregation of tau protein is implicated in human neurodegenerative diseases. While complex coacervation (CC) of tau and polyanion has shown both biological and pathological significance, its impacts on tau amyloid aggregation is not well understood. We report here recent findings and characterizations of tau-polyanion CC and its relationship with tau aggregation. We first demonstrate that tau can form complex coacervates with almost any polyanion. We found whether tau CC remains fluidic or solidifies towards fibrils is determined by the aggregation propensity of the CC forming constituents, not the CC forming process. Further, we closely examined changes of aggregation kinetics of tau resulting from the CC environment, and found the collision dependence of tau aggregation to be reduced by CC. Finally, we investigated the effect of CC on the fibrillization kinetics and seeding activity by tau fibrils.

3:30PM V54.00004: Effect of pH on polymer adsorption and bridging in a two oppositely charged nanoparticle/protein system  RITUPARNA SAMANTA (Presenter), VENKATRAGHAVAN GANESAN, University of Texas at Austin — We discuss the results of molecular simulations of charged particles in presence of oppositely charged, dissociable polymers. The effect of pH on adsorption and bridging characteristics of the polyelectrolyte for both homogeneous and heterogeneously charged particles is studied. We have studied the effect of charge distribution on the particles, charge and size of polyelectrolytes and concentration of polymers on adsorption, bridging and effective interactions between the particles.

3:42PM V54.00005: Tuning interactions between hybrid physical-covalent rigid rods made of computationally designed coiled coils by peptide sequence manipulation  NAIRITI SINHA (Presenter), RAJKUMAR MISRA, Materials Science & Engineering, University of Delaware, DE, RUI GUO, Chemistry, University of Pennsylvania, PA, CHRISTOPHER KLOXIN, Materials Science & Engineering, University of Delaware, DE, JEFFERY G SAVEN, Chemistry, University of Pennsylvania, PA, DARRIN POCHAN, Materials Science & Engineering, University of Delaware, DE — Application of computational design to biomolecular sequence, structure and function prediction provides vast opportunity in artificial biomaterial construction and assembly. Non-natural coiled coils, oligomers of α-helical peptides, can be designed to assemble in solution by computational sequence discovery and manipulation via strategic placement of amino-acids exposed to the solvent. Utilizing a hybrid assembly pathway, computationally designed homotetramer coiled coil bundles are linked in an end-to-end fashion resulting in rigid rods of bundles or “bundlemers”. Transmission Electron Microscopy (TEM) and Small-Angle Neutron Scattering (SANS) confirm that the rods have a 2 nm cross-section commensurate with that of a single bundle. SANS is also used to study inter-rod interactions for peptides that carry increasing net negative charge. Differences in local repulsive interactions between rods is observed due to changes in rod charge density, which is responsive to pH and ionic strength of the solution. Larger percolated clusters of rods which form due to local patchiness of interaction sites is also confirmed. This control of solution structure with fine control of the charged state, length, dispersity and concentration of bundliemer rods will be discussed.
3:54PM V54.00006: Influence of Charge Sequence on the Adsorption of Polyelectrolyte Solution on to Polyelectrolyte Brush*  
VAIDYANATHAN SETHURAMAN (Presenter), MICHAEL P MCGOVERN, DAVID CLARK MORSE, KEVIN DORFMAN, University of Minnesota — We use coarse-grained MD to elucidate the role of charge sequence on the adsorption efficacy of oppositely charged free polyelectrolytes on to a polyelectrolyte brush. We consider four different model systems wherein the free and the brush polyelectrolytes can have either brush or alternating charge sequence. Our model treats the polyelectrolytes in a bath of implicit solvent, excess salt and explicit counterions. Adsorption efficiency is highest when both free and brush polyelectrolytes possess a block charge sequence, and it is lowest when both free and brush polyelectrolytes possess an alternating charge sequence. By computing the free energy, internal energy and entropy of adsorption using umbrella sampling methods, we find that the origin of the differences in adsorption efficiency for different charge sequences is enthalpic. Additionally, equilibrium conformations for different charge sequences reinforce the results obtained from energetic calculations. When the number of brush polymers is more than that of the free polymers, a spatial heterogeneity is observed in the charge distribution within the brush region which is strongly dependent on the charge sequence of free and brush polyelectrolytes.

4:06PM V54.00007: Biomolecules for non-biological things: 1-D and 2-D polymer formation through peptide design and solution assembly*  
DARRIN POCHAN (Presenter), University of Delaware — A new solution assembled system comprised of theoretically designed coiled coil bundle motifs will be introduced. The molecules and nanostructures are not natural sequences and provide opportunity for arbitrary nanostructure creation with peptides. With control of the display of all amino acid side chains (both natural and non-natural) throughout the peptide bundles, desired physical and covalent (through appropriate “click” chemistry) interactions have been designed to produce one and two-dimensional nanostructures. One-dimensional nanostructures span exotically rigid rod molecules that produce a wide variety of liquid crystal phases to semi-flexible chains, the flexibility of which are controlled by the interbundle linking chemistry. The two dimensional nanostructure is formed by physical interactions and are nanostructures not observed in nature. All of the assemblies are responsive to temperature since the individual bundle building blocks are physically stabilized coiled coil bundles that can be melted and reformed with temperature. Additional, novel nanostructures to be discussed include uniform nanotubes as well as the templated growth of metallic nanoparticle on and in peptide nanostructures.

NSF DMREF award # 1235084

4:18PM V54.00008: Engineering protein and polyelectrolyte complexation for cellular applications [Invited] ALLIE OBERMEYER (Presenter), RACHEL KAPELNER, VIVIAN YEONG, NICHOLAS ZERVOUDIS, Columbia University — Oppositely charged polyelectrolytes are known to undergo a liquid-liquid phase separation, termed complex coacervation, under the appropriate solution conditions. Protein polyelectrolytes have also been shown to phase separate with polyelectrolytes. However, protein polymers differ significantly from synthetic polyelectrolytes. Proteins are polyampholytes, have low charge density, and frequently adopt a globular folded structure. These differences impact the complexation and phase separation of proteins with polyelectrolytes. These differences also make protein polymers interesting to study in this context; the charge, charge density, and charge orientation on proteins can be precisely controlled through genetic engineering. Additionally, it has recently been demonstrated that the phase separation of proteins is a fundamental mechanism for eukaryotic cellular compartmentalization. These phase separated membraneless organelles create distinct environments that are essential to cellular processes ranging from cell signaling to gene expression. Many membraneless organelles appear to have the same physical properties as complex coacervates – liquid-liquid phase separated mixtures of oppositely charged polynions. We are motivated to understand protein complex coacervation in order to enable new biological applications of these materials. Toward this end, we have investigated the complex coacervation of engineered proteins with synthetic and biological polynions to determine predictive design rules for protein phase separation. We have also used these design rules to promote phase separation of engineered proteins in vivo.
4:54PM V54.00009: Conditions for complex coacervation of the microtubule-associated tau protein predicted from field theoretic simulations*  JAMES MCCARTY (Presenter), YANXIAN LIN, KRIS T DELANEY, GLENN FREDRICKSON, SONGI HAN, JOAN-EMMA SHEA, University of California, Santa Barbara — The microtubule associated tau protein is a highly charged intrinsically disordered protein (IDP) that has been linked to neurodegenerative diseases including Alzheimer’s disease. Recently, tau has been shown to undergo a liquid-liquid phase transition, leading to speculation about how this process may mediate pathological tau fibrillation. To understand the thermodynamic driving forces of this process, we apply a discrete Gaussian-chain polyelectrolyte model and compute thermodynamic observables using a numerical technique known as field theoretic simulation (FTS). Results from FTS for this coarse-grained tau model reveal how the combination of charge distribution, salt concentration, and temperature-dependent excluded volume determine the observed phase diagram. Our results suggest new avenues for simulation to inform experimental design. Finally, we will comment on extensions of the model and applications to other IDPs.

5:06PM V54.00010: Sequence Effects on Block Copolymer Self-Assembly through Tuning Chain Conformation and Segregation Strength Utilizing Sequence-Defined Polypeptoids*  ANASTASIA PATTERSON (Presenter), SCOTT DANIESEN, BEIHANG YU, EMILY C DAVIDSON, GLENN FREDRICKSON, RACHEL SEGALMAN, University of California, Santa Barbara — Polymers with precise sequence control offer the possibility of tuning segregation strength with comonomer sequence instead of chemical identity. We have synthesized polystyrene-b-polypeptoid block copolymers with different sequences of comonomers in the polypeptoid block, where nonpolar phenyl side chains are incorporated to tune compatibility with polystyrene. Using small-angle X-ray scattering, we see that these materials self-assemble into lamellae with domain spacings and order–disorder transition (ODT) temperatures varying with sequence, despite identical composition. The variation in the ODT suggests that sequence control at the monomer level alters segregation strength, and by comparing domain spacings and SCFT simulations, we find that the main driving force is likely chain conformational effects that localize comonomers at the block–block interface. However, trends seen in the ODT are not captured by SCFT simulations or effective χ parameters (measured in the disordered phase by approximating the copolypeptoid as a uniform block). The disagreement between measured thermodynamic properties and coarse-grained approaches like SCFT and effective χ points to the importance of molecular-scale effects in sequence-defined materials.

5:18PM V54.00011: Kinetics of conformational changes in polyelectrolyte systems*  SWATI SEN, SOUMIK MITRA, ARINDAM KUNDAGRAMI (Presenter), Department of Physical Sciences & Centre for Advanced Functional Materials, Indian Institute of Science Education and Research Kolkata — Equilibrium phase behavior of polyelectrolytes is well-studied in literature. The kinetics of conformational changes in such systems, however, has received sporadic attention, which has increased recently given its relevance to biological problems like protein-folding or biomedical processes like drug-delivery. Our group has been working on studying the time-dependent, inhomogeneous profiles of physical variables, such as mass and charge densities and osmotic stress, related to the swelling kinetics of polyelectrolyte gels. We will present our recent results obtained from the nonlinear theory that uses the expression of osmotic stress as a function of mass and charge densities, and hence is capable of addressing arbitrarily large deformations that are beyond the scope of traditional theories with linear stress-strain relationship. Considering issues like charge-regularization and role of elasticity and electrostatics, the major results we have obtained include estimation of effective elastic modulus, time-dependency of the size, and the relaxation times of charged gels as functions of its charge content, temperature, density of cross-links, and chemical affinity of the polymer and the solvent.

Session V55 DPOLY: Polymer Crystallization III: Copolymer Crystallization, Intercrystalline Topology and Mechanical Properties  BCEC 254B - Wenbing Hu, Nanjing University Rufina Alamo, Florida A&M and Florida State University - Tag(s): Focus
2:30PM V55.00001: Statistics of Ties and Loops in Amorphous Regions of Polymer Crystals  SABIN ADHIKARI (Presenter), MURUGAPPAN MUTHUKUMAR, University of Massachusetts Amherst — Polymer crystals grown from melt consist of alternating lamellar crystalline regions and amorphous regions. We study the statistics of ties and loops in the amorphous region. Mechanical properties of crystalline polymers are highly dependent on the relative populations of ties and loops in the amorphous regions. We develop a statistical mechanical formulation to calculate the conformational entropy of ties and loops with consideration of finite chain length and possible association of a chain with multiple lamellae. Results of our numerical calculations show that, the fraction of the tie population relative to loops increases with increasing chain length, and it decreases with increasing the interlamellar separation and the lamellar thickness. The average number of lamellae connected by a chain is also calculated. It is also found to increase with increasing the chain length and to decrease with increasing the amorphous thickness.

2:42PM V55.00002: Tie Molecule Formation in High Density Polyethylene*  SEONG HYUK CHO (Presenter), RICHARD ALAN REGISTER, Princeton University — The mechanical toughness of a semicrystalline polymer, such as polyethylene (PE), originates from tie molecules: polymer chains that span two or more crystalline lamellae. During rapid crystallization, polymers cannot disentangle, so tie molecules form when the size of the polymer coil in the melt, controlled by its molecular weight (M), exceeds the intercrystalline spacing (L) in the solid state, governed by the specimen's crystallization history. Prior studies have yielded some insight into the brittle-to-ductile transition in PE as M is increased, but often for broadly-distributed PE with no measure of L. Here we synthesize a series of narrowly-distributed (dispersity < 1.2), perfectly linear (high density) PEs with targeted M using ring-opening metathesis polymerization of cyclopentene followed by hydrogenation. PEs were either quenched or slow-cooled to vary crystallinity (0.65 - 0.85) and L, measured by differential scanning calorimetry and small-angle x-ray scattering. We investigate the brittle-to-ductile transition of PE by uniaxial tensile testing in relation to its M, end-to-end distance in the melt, and L, and find a relatively abrupt transition in these narrow-distribution PEs.

2:54PM V55.00003: Does crystal thickness dictate yield kinetics in polyethylene?  JEVAN FURMANSKI (Presenter), Corporate Strategic Research, ExxonMobil, JONATHAN SCHAEFER, ExxonMobil Chemical Company, LEON GOVAERT, HANS VAN DOMMELEN, Eindhoven Technical University — There has been a longstanding effort to predict the resistance to plastic deformation of polyethylene via crystal plasticity-based micromechanical modeling, deriving the plasticity kinetics from the assumption that the strain carrier is a screw dislocation. This leads to the notion that the yield kinetics are dominated by crystal thickness, or more precisely the chain stem length within the crystal. There is in general a high degree of correlation between the crystallinity and crystal thickness, making it difficult to distinguish between these two microstructural attributes as the driving variable for plasticity. A wide range of crystallinity and stem lengths was obtained by varying crystallization via both cooling rate and various concentrations of short-chain branching, permitting the disentangling of stem length from crystallinity. The rate- and temperature-dependence of yield strengths were fit to a two-term stress-activated Ree-Eyring model. Chain stem length was measured via the Longitudinal Acoustic Mode in low wavenumber Raman spectroscopy. With this material series it was shown that crystallinity drives yield kinetics, rather than stem length. These insights will be placed in the context of a micromechanical model employing stress-activated crystal slip kinetics.

3:06PM V55.00004: Structure and morphology of poly(ethylene)-block-isotactic poly(propylene) di-block copolymers  CLAUDIO DE ROSA (Presenter), ROCCO DI GIROLAMO, ANNA MALAFRONTE, FINIZIA AUEREMMA, MIRIAM SCOTI, Chemical Sciences, University of Napoli Federico II — A study on the structure and morphology of crystalline di-block copolymers (BCP), composed of stereoregular crystallizable polyolefins is presented. In particular, we report a structural characterization of di-block copolymers formed by crystalline PE block linked to crystalline isotactic polypropylene (IPP) block of different block lengths. The dependence of the thin film BCP morphology on the sequential crystallization from the phase separated melt of the crystallizable blocks has been investigated. The BCPs have been epitaxially crystallized onto crystals of a substrate to achieve a better control over the crystallization. Ordered nanostructures where the two blocks are organized in separated alternating lamellar domains guided by the orientation of the crystalline lamellae are obtained. We demonstrate that, tuning the block length and using a specific substrate, it is possible to control the crystallization process and obtain large-sized, well-oriented lamellar microstructures with long range order achieved over the area in contact with the crystalline substrate. Possible applications of these nanostructures are discussed.
Quiescent and flow-induced crystallization of polyolefins studied by a novel low-field RheoNMR combination

KARL-FRIEDRICH RATZSCH, VOLKER RÄNTZSCH, BEGÜM M. ÖZEN, MANFRED WILHELM (Presenter), Karlsruhe Institute of Technology — Combining NMR and rheology has received great attention in the past, as it allows studying the interdependence of macroscopic and molecular properties of soft matter, e.g. polymers, liquid crystals or colloids. Flow profiles (e.g. steady or oscillatory shear) both in the linear and non-linear regime can be applied to monitor and also to modify the (time) evolution of sample properties. Most RheoNMR designs have been realized for high-field NMR spectrometers using only simple shear cells. Here we present a low-field RheoNMR set-up based on a portable 30 MHz NMR unit that was integrated into a commercial strain-controlled rheometer. This unique combination can be employed to simultaneously conduct a full rheological characterization while monitoring molecular dynamics in-situ via $^1$H TD-NMR. Possible applications include the measurement of quantitative composition in crystallizing soft matter (fats, polymers, etc.) and multiphase systems during the application of shear protocols. To display the possibilities of this new technique, studies on the quiescent and flow-induced crystallization of polyolefins are presented. A short time steady-shear protocol was applied to study flow-induced crystallization as a function of different temperatures and flow conditions.

Distribution of Chain Ends in a Crystal-Fixed Polymer Elucidated by Solid-State NMR

SHICHEN YUAN (Presenter), KLAUS SCHMIDT-ROHR, Chemistry Department, Brandeis University — The location of chain ends in the morphology of semicrystalline polymers has recently received renewed attention. In particular, chain ends at the crystal surface can help avoid density anomalies in the noncrystalline surface layers. Here we present a detailed analysis of the distribution of chain ends across the ~ 15 nm repeat unit of semicrystalline poly(ε-caprolactone) (PCL), a crystal fixed polymer of moderate crystallinity. An excellent signal-to-noise ratio and spectral resolution is achieved by isotopic labeling of chain ends via conversion of OH end groups with $^{13}$COO-acetyl groups. Through distinct (an)isotropic chemical shifts and relaxation times, one can distinguish chain ends in the crystalline, interfacial, and amorphous layers. 56% of the chain ends are found in the core amorphous layers, which exceeds the amorphous core fraction. About 20% are immobilized in the crystal lattice; many of these segments are found near the interface, according to fast $^1$H spin diffusion from the amorphous core layer.

The effect of multi-block structure on the crystallization and properties of ethylene/1-octene copolymers from chain shuttling technology.

FINIZIA AURIEMMA (Presenter), CLAUDIO DE ROSA, University of Naples Federico II — The crystallization properties, the morphology at nanometric length scale and the tensile properties of ethylene/1-octene multi-block copolymers (EOBCs) obtained from chain shuttling technology are analyzed. The samples are characterized by a statistical multi-block architecture, where soft and amorphous blocks with high octene concentration (~18.9mol%) alternate with hard and crystalline blocks with low octene concentration (~0.5mol%). A set of samples with similar octene concentration in the hard and soft blocks, fraction of hard blocks and melting temperature of ~120°C, but different average length of the blocks and average number of blocks/chain are selected. We show that the crystallization properties of EOBCs and the structural organization of the chains which develops by effect of crystallization are strongly influenced by the multiblock architecture, the tendency of the hard blocks to crystallize in separated domains, the short and polydisperse length of the hard blocks and the steric constrains imposed by the covalent bonding between the hard and soft blocks. This results in a hierarchical structural organization which is articulated over different length scales, involving the stacking of the chain folded lamellae in separated domains at lamellar length scale, and the relative arrangement of the hard domains in the compliant matrix populated by the soft blocks, at the scale of domain spacing. The block architecture also influences the mechanical properties. The samples, in spite of similar octene concentration, molecular mass and fractional content of hard blocks, show remarkable differences of mechanical properties, which reflect differences in the average block length ad number of block/chain. The achieved properties encompass those of strong elastomers, in the case of samples with low block length and high number of blocks/chain, up to reach those of soft elastomers in the case of samples with high block length and low number of blocks/chain.
4:18PM V55.00008: Contrasting melt memory of homopolymers and random ethylene copolymers using halogen substitution with precision placement or random distribution  STEPHANIE MARXSEN (Presenter), RUFINA ALAMO, Chemical and Biomedical Engineering, FAMU-FSU College of Engineering, Tallahassee, FL — Polyethylenes with Cl or Br atoms placed at an equal distance of 21 or 15 backbone carbons are known to crystallize as homopolymers, accommodating the halogen in layered crystallites. In contrast, analogs with a random distribution display a crystallization path dominated by sequence-length selection. A consequence of the sequence selection of random copolymers is a constrained interlamellar region and broader melting peaks displaced at higher temperatures than systems with the precise placement. Precision and random ethylene-vinyl halides are excellent models to contrast the strong melt-memory behavior observed in random ethylene 1-alkene copolymers with lack of melt-memory seen in linear polyethylene. While precision polyethylenes with Cl or Br placed on each 21st or 15th backbone carbon show negligible deviation in crystallization rate above the observed melting, the increase in crystallization rate of analogs with the random distribution is observed even from melts 60 degrees above the observed melting point. These data give further evidence of the sharp difference of melt-memory behavior between homopolymers and random copolymers.

4:30PM V55.00009: Study on the Thermodynamics of Polymer Crystallization Based on Twin-Lattice Model  NUOFEI JIANG (Presenter), Department of Macromolecular Science, Fudan University — Polymer crystallization is the most important part in determining the performance of polymeric materials. The twin-lattice model originally provided by Lennard-Jones and Devonshire, developed by Pople and Karasz and other researchers, is extended for describing the thermodynamics of polymer crystallization. The positional order of segments and the orientational order of bonds are considered in this model. The free energy of polymers is obtained by further introducing the conformational energy and entropy. We studied two kinds of processes in polymer crystallization, including the process with plastic crystal phase and without any mesophases. The choice of crystallizing process is determined by the magnitude of lattice energy and conformational energy. Considering data reliability, n-paraffins are chosen as the representation of polymers to compare the predictions of the model with experimental observations. We predict the number of carbons beyond which the rotator phase disappears, which is quite in agreement with the experiments. These calculations and results show this model can provide a new understanding to the crystallization of polymers.

4:42PM V55.00010: Crystallization Process with Aggregation of Small Crystallites for Polytrimethylene Terephthalate*  TAKASHI KONISHI (Presenter), DAISUKE OKAMOTO, DAISUKE TADOKORO, YOSHITAKA KAWAHARA, YOSHIHISA MIYAMOTO, Graduate School of Human and Environmental Studies, Kyoto University, KOJI FUKAO, Department of Physics, Ritsumeikan University, — Polymer crystallization mechanism has explained the crystal nucleation and growth mechanism, while the existence of density fluctuations during the initial stage of crystallization has been discussed. In order to clarify the density fluctuations, the isothermal crystallization from the melt state of poly(trimethylene terephthalate) (PTT) has been studied by wide-angle X-ray diffraction (WAXD) and small-angle X-ray scattering (SAXS). Large scattering intensity in the low-q region $I_L(q)$ has been observed by SAXS during the early stage of crystallizations. $I_L(q)$ increases with time, reaches a maximum, and decreases. The results revealed the crystallization mechanism in which the small crystallites cover the entire sample with the aggregation regions[1]. The conclusion quantitatively showed that $I_L(q)$ is due to the correlations among the heterogeneous aggregation regions of the crystallites.

4:54PM V55.00011: Effects of diffusion barriers on the temperature dependence of polymer crystallization rates*
CAI JUN (Presenter), JIPING WANG, WENBING HU, Nanjing University — Jun Cai, Jiping Wang, Chenghuan Xu, Wenbing Hu*

Department of Polymer Science and Engineering, State Key Laboratory of Coordination Chemistry, Collaborative Innovation Center of Chemistry for Life Sciences, School of Chemistry and Chemical Engineering, Nanjing University, 210023 Nanjing, China.
*E-mail: wbhu@nju.edu.cn

We employed kinetic Monte Carlo simulations of bulk lattice polymers to investigate the kinetics of polymer isothermal crystallization in a broad temperature range. Four diffusion barrier parameters were taken into consideration, i.e. the frictional barrier $E_f$ induced by the leaving neighbors of monomers, the diffusion barrier $E_r$ for sliding diffusion of polymers in the crystalline phase, the barriers of the transition from trans to gauche conformation and the reverse transition $E_t$ and $E_g$, respectively. $E_f$ affects the crystallization kinetic greatly at low temperatures. $E_r$ affects less but appears more important at high temperatures than low temperatures. A larger $E_t$ and $E_g$ reduces significantly the crystallization rate at low temperatures. The results shed light onto the comprehension understanding of polymer crystallization kinetics at low temperatures.

5:06PM V55.00012: Low-Temperature Crystal Nucleation of Enantiomeric Poly (lactic acids)†
HE YUCHENG (Presenter), Nanjing University, PENGJU PAN, College of Biological and Chemical Engineering, Zhejiang University, WENBING HU, Nanjing University — We employed the commercial chip-calorimeter Flash DSC 1 to investigate the crystal nucleation behaviors of diblock copolymers and blends of half-half enantiomeric poly (lactic acids) at 35°C. The results show that crystal nucleation below the glass transition temperature can accelerates the crystallization rates at higher temperatures. For instance, the crystallization rate of 140°C increases by two orders of magnitude for the diblock copolymer. Such an accelerate can be attributed to the special interactions of stereo-complex crystals, because homo-crystal does not show such effect.

*This work is supported by National Natural Science Foundation of China (Grant No. 21474050 and 21734005)

5:18PM V55.00013: Crystallization Behavior and Kinetics of Blends of PVDF with a Fluorinated Copolymer†
NELAKA DILSHAN GOVINNA (Presenter), Department of Physics and Astronomy, Tufts University, ILIN SADEGHI, AYSE ASATEKIN, Department of Chemical and Biological Engineering, Tufts University, CHRISTOPH SCHICK, Institute of Physics, University of Rostock, PEGGY CEBE, Department of Physics and Astronomy, Tufts University — We present a study on crystallization of poly(vinylidene fluoride), PVDF, blended with a random fluorinated copolymer (FCP) of poly(methyl methacrylate) and 1H,1H,2H,2H-perfluorodecyl methacrylate. These blends are of interest as candidates for use as oil-water separation membranes. The glass transition and crystallization behavior were studied by fast scanning calorimetry using heating and cooling rates from 20 K/s to 4000 K/s. Crystal fraction and crystal formation rate decreased as the fraction of FCP increased in the blends. PVDF, which exhibits crystal polymorphism, crystallizes into β-phase when cooled from the melt at rates faster than 3000 K/s. Cooling rates between 2000 and 3000 K/s resulted in mixed α- and β-phase, while only α-phase occurred at rates slower than 2000 K/s. A series of isothermal melt crystallization experiments was carried out at temperatures in the range 80-120 °C for holding times of 0.1–100 s. It was found that β-phase crystal formation can be completely suppressed even at high cooling rates by generating a sufficient amount of α-phase crystals isothermally. The variation of these isothermal times and temperatures were also studied for the blends to study the effect of FCP in suppressing β-phase.

Session V56 GSNP: Interactions of Elastic Structures with Fluids and Granular Matter II
BCEC 255 - Douglas Holmes, Virginia Tech
2:30PM V56.00001: Bioinspired soft fluidic channels  MARTIN BRANDENBOURGER, CORENTIN COULAIS (Presenter), University of Amsterdam — Taking inspiration from the lymphatic system, we devise millimetre scale fluidic channels made of soft asymmetric valves. We investigate their non-linear flow response combining experiments, numerics and lubrication theory. We demonstrate that softness, structural asymmetry and geometric nonlinearities govern the fluid-structure interaction, and give rise to a tunable nonlinear flow response. Our work provides a fundamental understanding of how lymphatic system operate and lays the foundation for a novel generation fluidic metamaterials.

2:42PM V56.00002: Hydro-elasto-capillary interactions for programmable microfluidics* HERVE ELETTRO (Presenter), FRANCOIS GALLAIRE, Ecole polytechnique federale de Lausanne — Soft microfibers can be strongly bent by capillary forces and can even be reversibly coiled inside fluid cavities. If present, hydrodynamic forces may compete with capillary forces, uncoil the microfiber and induce its deployment from its original coiled state. Here we fabricate a microfiber coiled within a droplet that is attached on the wall of a microfluidic channel. This is done by photocuring a liquid microjet of hydrogel (PEG-DA) and transporting the resulting soft microfibre to the carefully prepared droplet for adequate coiling. The mechanical response of the hybrid system is then investigated under increasing flow rates. The present results open opportunities to form the building blocks of microfluidic elements with high on-off ratio that may be useful for the design of on-chip tunable circuits for bioengineering applications.

*We acknowledge funding from the Marie Sklodowska-Curie Actions Fellowship, project "El_CapiTun" n°750802.

2:54PM V56.00003: Kirigami fog nets* PIERRE BINTEIN, AXEL CORNU, Physique, trio S lab, ULB, NICOLAS VANDEWALLE, Physique, GRASP, University of Liege, DENIS TERVAGNE (Presenter), Physique, trio S lab, ULB — Fog is harvested in numerous arid coastal regions by nets placed in dominant winds to catch water droplets. We study experimentally how flexible meshes can adapt their shapes to wind and avoid clogging by capillary effects, in order to maintain a good efficiency of fog collection. By considering aerodynamic, capture and drainage requirements together with mechanical constraints, we propose an optimal geometry for kirigami nets of a given material.

*This work was supported by the Fonds de la Recherche Scientifique – FNRS under Grant(s) n° PDR-WISD- 12

3:06PM V56.00004: Capillary stresses in disordered unsaturated porous materials SIAVASH MONFARED (Presenter), TINGTAO ZHOU, Massachusetts Institute of Technology, FARHANG RADJAI, CNRS-Universite de Montpellier, ROLAND JM PELLENQ, FRANZ-JOSEF ULM, Massachusetts Institute of Technology — Capillary condensation in disordered porous materials - specifically, the interplay of spatial distribution of grains/pores, temperature and distribution of capillary stresses - is explored. This is achieved through lattice gas density functional theory and a recently proposed method for computing capillary stresses based on equivalency of lattice and phase field fluid models in the continuum limit. Gaining insights into the distribution of capillary stresses at a given relative humidity and temperature in disordered porous materials pave the way for fluid mixture coupling with solid deformation while enriching current methods for inferring pore size distribution and pore connectivity from adsorption/ desorption experiments.

3:18PM V56.00005: Deformations in the hook and flagellum during bacterial flick motility HENRY FU (Presenter), MEHDI JABBARZADEH, University of Utah — Dynamical bending, buckling, and polymorphic transformations of the thin flagellar filament are known to affect bacterial motility in fluids. The run-reverse-flick motility of monotrichous bacteria also involves the even more flexible hook which connects the flagellum to its rotary motor. First, I will discuss the role of dynamic bending of both the hook and flagellum during the initiation of flicks. We obtain accurate estimates of forces and torques on the hook that suggest that flicks occur for stresses below the (static) Euler buckling criterion, then provide a mechanistic model for flick initiation that requires combined bending of the hook and flagellum. We calculate the triggering torque-stiffness ratio and find that our predicted onset of dynamic instability corresponds well with experimental observations. Second, I will discuss a more efficient numerical treatment of the dynamics of an inextensible filament that will allow modeling of the complete dynamics of the flick as well as recently discovered unconventional bacterial flagellar motility modes.
3:30PM V56.00006: On the unusual swimming gaits of sea-slugs.  
SHANKAR VENKATARAMANI (Presenter), KENNETH YAMAMOTO, University of Arizona — Nudibranchs (sea-slugs) are a family of soft-bodied marine invertebrates. They typically crawl on the sea-floor, but some species (eg. Hexabranchus sanguineus ‘Spanish dancer’) are capable of free swimming. They possess a peculiar swimming gait, which we will argue comes from constraints on their geometry. I will present an analysis of free swimming sea-slugs that touches upon interesting questions in the mechanics of non-Euclidean thin sheets as well as on the interaction of such sheets with a fluid environment. I will also discuss potential applications our analysis to soft robots.

*This work was supported by the Simons Foundation.

3:42PM V56.00007: Buckling Instability to Control the Swimming Direction in Bacterial Flagella
MOHAMMAD KHALID JAWED (Presenter), WEICHENG HUANG, Department of Mechanical and Aerospace Engineering, University of California, Los Angeles, MOJTABA FORGHANI, Department of Mechanical Engineering, Massachusetts Institute of Technology — We analyze the control of a uniflagellar soft robot in low Reynolds fluid. Inspired by the locomotion of bacteria, we consider a robot comprised of a flagellum - a flexible helical filament - attached to a spherical head. The flagellum rotates about the head at a controlled angular velocity and generates a propulsive force that moves the robot forward. When the angular velocity exceeds a threshold value, the hydrodynamic force by the fluid can cause the flagellum to buckle, characterized by a dramatic change in shape. A fluid-structure interaction model that combines Discrete Elastic Rods algorithm with Lighthill's Slender Body Theory is employed to simulate the system. We demonstrate that the robot can follow a prescribed path in three dimensional space by exploiting buckling of the flagellum. The control scheme involves only a single scalar input - the angular velocity of the flagellum. We also show that the complexity of the dynamics can be captured using a deep neural network, from which we identify the input-output functional relationship between the control inputs and the trajectory of the robot. Our study underscores the potential role of buckling in the locomotion of natural bacteria.

*We acknowledge support from HSSEAS, University of California, Los Angeles.

3:54PM V56.00008: Modelling the Transition from Fracture to Granular Flow
JOEL CLEMMER (Presenter), MARK OWEN ROBBINS, Johns Hopkins University — As a brittle solid is loaded, crack growth leads to fracture and fragmentation. The system then transitions to granular flow where these fragments continue to break down into smaller grains in a process known as comminution. To explore this transition, we created a discrete element model of an isotropic, brittle material. The solid is modelled as a disordered packing of locally interacting spheres. Interactions include an attractive and a repulsive pairwise force as well as a three-body angular stiffness. If stretched a critical distance, the attractive and angular interactions will break. The relative strength of interactions can be tuned to control the material's elastic response (Poisson's ratio) as well as the ratio of mode 1 to mode 2 fracture toughness. We use this model to explore how material properties, initial defect density, and strain rate affect both the transition to granular flow and the resulting rheology and comminution. We track the stress response of the system, the spatial and temporal locations of crack growth, and the evolution of the grain size distribution. The grain size distribution shows power-law behavior and with increasing strain rates one can identify a decreasing maximum grain size.

4:06PM V56.00009: Hydraulically Driven Jamming of Rods
JORDAN KENNEDY (Presenter), LAKSHMINARAYAN MAHADEVAN, John A. Paulson School of Engineering and Applied Sciences, Harvard University — Hydraulically driven flow of filament-like objects has a broad range of natural and industrial applications such as log jams in rivers, or the clogging of an open channel irrigation ditch in agriculture. To investigate the phase space of the jamming of rods in a fluid driven flow, we have performed experiments on buoyant particles over a range of aspect ratios in an open channel flume with a gated restriction, and quantify the results as a function of channel geometry, Froude number and density of logs in the channel.

4:18PM V56.00010: Hydraulic fracturing dynamics in natural and artificial low-permeability porous media
THOMAS COCHARD (Presenter), SEAS, Harvard — Despite the impact that hydraulic fracturing has on the energy sector, the physical mechanisms that control its efficiency and environmental impacts remain poorly understood in part because of the complex heterogeneous structures of the natural low permeability formations. We developed an experimental approach to study the hydraulic fracture propagation in both natural and model low-permeability media. Natural shale sample, thin sections of Mancos Shale, and engineered gels have been hydro-fractured under controlled conditions. The combination of high-speed imaging during the process and X-ray tomography before and after allows us to monitor the fracture propagation and gives insight on how heterogeneities drive hydraulic fracturing dynamics.
Scaling and spatial correlations in the quasibrittle process zone

JARON KENT-DOBIAS (Presenter), JAMES PATARASP SETHNA, Cornell University — We describe a scaling theory for the spatial distributions of damage and stress in the process zone of cracks propagating through quasibrittle materials. Brittle but disordered, these materials are ubiquitous in everyday life, including concrete, shell, and bone. Like in ductile materials, propagating cracks in quasibrittle materials have an extended process zone surrounding the crack surface, but unlike ductile materials this zone is comprised of a large complicated region of microfracture with correlated damage across many length scales. As a result, fracture in these materials exhibits strong sample size and shape dependence whose underlying nature evades standard analysis. Motivated by simulations of disordered fuse networks, our results work towards explaining the way damage and stress are correlated in and around the process zone and use renormalization group ideas first developed by Shekhawat et al. (PRL 110(18), 185505) to grapple with their system size dependence.

Session V57 GSNP: Mechanical Metamaterials I

2:30PM V57.00001: Sequential Metamaterials [Invited] MARTIN VAN HECKE (Presenter), Leiden University & AMOLF — Ordered sequences of motion govern the morphological transitions of a wide variety of natural and man-made systems, while the ability to interpret time-ordered signals underlies future smart materials that can be (re)programmed and process information. Here we introduce two types of mechanical metamaterials, that either exhibit sequential output or are sensitive to sequential input.

First, we obtain metamaterials that translate a global uniform compression into a precise multistep pathway of reconfigurations.

Second, we introduce the notion of non-commuting metamaterials that are sensitive to a sequence of mechanical inputs. Our work establishes generic principles for infusing metamaterials with sequential input and output.

3:06PM V57.00002: Inverse Kirigami Design* GARY CHOI (Presenter), LEVI DUDTE, L MAHADEVAN, Harvard University — The basic building block of any kirigami pattern is a periodic planar motif with cuts that allow the unit cell to open or close via planar rotations. The tessellations of the plane can take many forms - quads, kagome lattices, and even Islamic tilings. Recent work has explored these geometries in the context of mechanical metamaterials, and focused primarily on the forward problem - given a topology and geometry of the kirigami pattern, how does it deploy and what are the mechanical properties of the structure. In this work, we pose and solve the inverse problem of designing the number, size, and orientation of cuts that allows us to convert a closed, compact regular kirigami tessellation of the plane into a deployment that conforms approximately to any prescribed target shape in two and three dimensions.

*This work was supported in part by the Croucher Foundation (to Gary Choi), National Science Foundation Grant DMR 14-20570 and DMREF 15-33985 (to Levi Dudte and L. Mahadevan).

3:18PM V57.00003: Inverse design of mechanical metamaterials that harness instabilities GIORGIO OLIVERI (Presenter), JOHANNES OVERVELDE, AMOLF — Metamaterials derive their properties from their structure rather than their chemical composition. Their microstructure is specifically designed to create new functionalities not found in nature. Harnessing instabilities is a prominent practice of turning continuous deformations into a discrete response, allowing for sequential transformations, multistability and hysteretic behavior. Despite the complex behavior that these mechanical metamaterials show, their architecture is often surprisingly simple. An iconic example of auxetic material is an elastomeric material patterned with circular pores. While several studies focused on the effects of pore shape and pore distribution, the mechanical properties can only be tuned within limits set by a few geometrical parameters. Our aim is to reverse this paradigm. We introduce a stochastic topology optimization strategy, to inversely design mechanical metamaterials with targeted buckling behavior. Our study, while first focusing on optimizing structure with assigned buckling force, extends at designing structures with predefined post-buckling behavior. This opens up exciting opportunities for the design of soft robots where functionalities can be encoded in the material itself. We complement our results with experimental verification.
3:30PM V57.00004: Bayesian Optimization of Equilibrium States in Architected Elastomers  DAVID YOO (Presenter), CARSON WILLEY, ANDREW GILLMAN, VINCENT CHEN, UES, Inc, ABIGAIL JUHL, PHILIP BUSKOHL, Air Force Research Laboratory — Hyperelastic lattice-based architectures have demonstrated potential for energy absorption and vibration control due to their inherent buckling instabilities, which reconfigure the energy and stiffness distribution of the structure. Multi-resonant vibration isolation can possibly be achieved by tuning the local stiffness properties between the stable equilibrium states. In this study, we develop a design optimization framework to tune the local configuration of the stable equilibrium points and characterize the transition in stiffness through the bistability. We utilize Bayesian optimization to navigate the design space through a balanced approach of exploitation and exploration. The design architecture is parameterized with a Fourier series expansion of the beam geometry, which controls the periodicity and phase of the beam thickness as a function of length. The force-displacement relationship of each design candidate is calculated by the finite element method and segmentation of mono- and bi-stable designs is employed to retain the desired behavior of the response surface. The preliminary results suggest the periodicity of the beam thickness, parameterized by the 1st term in Fourier series, most critically affects the bistability mode.

3:42PM V57.00005: Understanding the Effect of Torsion on Auxetic Behaviors of Three-Dimensional Networks  MENG SHEN (Presenter), The Institute for Molecular Engineering, The University of Chicago, NIDHI PASHINE, SIDNEY ROBERT NAGEL, Department of Physics, The University of Chicago, JUAN DE PABLO, The Institute for Molecular Engineering, The University of Chicago — Bond pruning has recently proved to be an effective method for designing auxetic networks. Previous theoretical work on architected networks includes bond compression terms only, which is a reasonable analog for tenuous systems and frictionless granular packings. For networks made in the laboratory, however, our recent work has shown that the auxetic behavior depends not only on geometry, but also on the interaction parameters, in particular the angle bending term. In three-dimensional networks, the torsion of local connected bonds provides an additional degree of freedom. Here we investigate the effect of torsion on the auxetic behavior of ordered and disordered 3D networks. The research provides insights for the design of 3D networks for the auxetic behavior.

3:54PM V57.00006: Elastic multipole method for describing deformation of 2D solid structures with circular holes and inclusions*  SIDDHARTHA SARKAR (Presenter), Electrical Engineering, Princeton University, MATJAZ CEBRON, MIHA BROJAN, Faculty of Mechanical Engineering, University of Ljubljana, ANDREJ KOSMRLJ, Mechanical and Aerospace Engineering, Princeton University — The analogies between electrostatics and elasticity help us to solve complicated boundary value problems in linear elasticity of 2D solid structures. For example, a hole inside an elastic body is analogous to a perfect conductor in electrostatics in the sense that at the circumference of them the fields, namely the traction force and the parallel component of the electric field respectively, have to be zero. Similarly, an inclusion in an elastic material is equivalent to a dielectric since in both cases the fields have to be continuous at the edge of the inhomogeneity. Furthermore, just like external electric field induces polarization (dipoles, quadrupoles, etc.) of conductive objects, external stress induces elastic multipoles inside holes. Based on this idea, we present a method for obtaining deformations of 2D solid structures with circular holes and inclusions under applied load. We validated the method by comparing the results with table-top experiments. We also utilized the method of image charges from electrostatics to capture the effect of boundaries on the deformed shapes of the holes/inclusions. The excellent agreement with the experimental results shows the power of this intuitive method.

4:06PM V57.00007: Homogenisation bounds for micro-architected polymer materials with extreme mechanical properties*  FILIPPO MATTEO AGNELLI (Presenter), ANDREI CONSTANTINESCU, GRIGOR NIKA, Ecole Polytechnique — The aim of this work is the optimal design, additive manufacturing, and testing of micro-architected polymer materials with desired effective mechanical properties. The design process is discussed in terms of homogenisation bounds for composite materials. These bounds define the limits of the space of printable micro-architected materials. The optimal shape design process, uses topology optimisation via a level set method to identify material distribution and track boundary changes within the context of the smoothed interface, allowing us to capture the topological changes that take place within the unit cell. The designed microstructures were printed using stereolithography and mechanically tested. The results are analysed in terms of the overall effective elastic moduli and compared with a series of classical homogenisation bounds for composite materials, e.g. Hashin-Shtrikman, Milton-Kohn, etc. This discussion permits to better define the set reachable elastic coefficients by printing materials with controlled micro-architecture.

Mechanical failure of disordered networks derived from frictional packings.*

To characterize these networks, we focus on their mechanical stability. We study the uniaxial response of networks with geometry derived from the force chains observed in granular experiments. We perform experiments on samples created by laser-cutting these networks from acrylic sheets. We find that the mean degree of the network is a control parameter of the failure behavior, which ranges from ductile to brittle.

We explain this ductile-brittle transition with rigidity analysis using a frictional (3,3)-pebble game algorithm. We find that the brittle behavior corresponds to the emergence of a percolating rigid cluster occurring at a mean degree close to the isostatic value of a high friction coefficient packing. Finally, we find that for networks close to the transition point, failure events predominantly occur within the floppy regions between the rigid clusters.

2:30PM V58.00001: Hyperuniformity and optimal tessellations: structure, formation and properties [Invited] JASNA BRUJIC (Presenter), New York University — After recent breakthroughs in the search for ordered optimal tessellations (for example, including Frank-Kasper phases in copolymer melts), now findings of the optimal properties of amorphous tessellations are emerging, e.g., in biological tissues.

At the same time, there have been intensive studies of amorphous systems with an anomalous suppression of density fluctuations on large length scales, known as hyperuniformity. This geometric concept qualitatively and quantitatively characterizes a hidden-order in amorphous states that allows for unique physical properties--combining those of crystalline and disordered phases. Thus it offers candidates for optimal amorphous tessellations of space.

This session will foster a discourse between these subfields and about the role of hyperuniformity in the search for tessellations that are optimal with respect to geometrical and physical properties. The session will discuss both a theoretical understanding, computational exploration and experimental verification of the temporal evolution of growing or compressed soft cellular entities and the formation of surprising ordered and amorphous phases and their unexpected structures and physical properties. The applications range from functional designer materials to the cell biology of membrane organelles.

3:06PM V58.00002: Disordered Hyperuniform Many-Particle Systems via Tessellations* [Invited] SALVATORE TORQUATO (Presenter), Princeton University — Disordered hyperuniform many-particle systems are exotic amorphous materials characterized by an anomalous suppression of long-wavelength density fluctuations that endows them with novel transport, mechanical and optical properties. I will describe two different tessellation-based procedures that lead to disordered systems that are hyperuniform. Both methodologies convert initially disordered nonhyperuniform systems into disordered hyperuniform ones.

3:42PM V58.00003: Quantifying The Mechanical Energy Landscape of Two-Dimensional Cellular Matter* SASCHA HILGENFELDT (Presenter), University of Illinois at Urbana-Champaign, XAVIER CAUVIN, Mechanical and Aerospace Engineering, Princeton University, SANGWOO KIM, Mechanical Engineering, University of California, Santa Barbara — The local mechanical equilibrium states of cellular materials - consisting of space-filling domains with dominant interfacial energy - are characterized by a spectrum of metastable-state energies on a generally complex landscape. Recent theoretical work quantifies these energies in dramatically simpler ways exploiting geometric and topological statistical information from the structure of the system only, independent of the specific energy functional [1]. We elaborate on and test these theories by analyzing cellular matter samples, particularly in foam monolayer systems, where energies can be directly and independently determined. Two approaches to inferring energies are tested using (i) measured lengths of select boundaries between domains; (ii) the probability distribution of domain sizes and topologies. The experimental results support both theories and elucidate advantages and disadvantages of either approach. It is thus practically demonstrated that the mechanical state of cellular matter is quantifiable by its morphology only, suggesting simple and general diagnostic tools in the study of systems as diverse as biological tissues, foams, or superlattice materials.

*work supported by NSF grant #1504301
Disordered hyperuniform two-phase systems are characterized by anomalous suppression of volume-fraction fluctuations at infinite long wavelengths. They provide fertile ground for fundamental research and have attracted considerable practical interest because they often are endowed with exotic physical properties, including possessing optimal or nearly optimal physical properties. The Hashin-Shtrikman (HS) two-phase multiscale dispersions are derived from special tessellations of space that endow these two-phase systems with the optimal effective transport and elastic properties for given phase properties and phase volume fractions. Using a new tiling formulation that ensures perfect hyperuniformity, we rigorously establish the hyperuniformity of the optimal HS structures. We analytically show that these structures are strongly hyperuniform by deriving the small-wavenumber scaling behavior of their spectral density. We verify these theoretical results numerically in two dimensions by constructing extremely dense polydisperse disk packings. Our work provides insights about the relationship between hyperuniformity in two-phase systems and property optimization.

General Mechanical Energy Landscape in Two-Dimensional Interacting Systems

Domain systems composed of individual entities, cells, or particles commonly exhibit complex mechanical energy landscape with a plethora of metastable states. Recent studies on a class of domain systems governed by dominant interfacial energy show that an equivalent foam energy (the sum of interfacial lengths), is a strong predictor of metastable state energies, regardless of the exact interfacial energy functionals. The landscape of equivalent foam energies is in turn described accurately by theoretical predictions based either on geometric measures or on statistical measures. Here, we show that this theoretical framework can be extended to systems with particle-based interactions. While the energy of particle-based systems depends on constituent particle positions rather than interfacial structure, the equivalent foam energy of a 2D tessellation generated from particle positions not only yields a strong correlation with the actual energy level but also generates an identical energy landscape. Geometric measures and statistical measures can be obtained from visual information only so this framework can serve as a diagnostic tool for identifying mechanical energy states in a variety of domain systems, including foams, emulsions, granular systems, and confluent tissues.

Nano-Real Space Analysis Takes Dynamics of Colloids Three Decades Closer to the Glass Transition

Glasses are among the most widely used of everyday materials, yet the process by which a liquid's viscosity increases by 14 decades to become a glass remains unclear, as often contradictory theories provide equally good descriptions of the available data. Knowledge of emergent lengthscales and higher-order structure could help resolve this, but this requires time-resolved measurements of dense particle coordinates—previously only obtained over a limited time interval, and a some means of determining local free energy in model glassformers such as hard spheres [1]. Here we present an experimental study of a model colloidal system over a dynamic window significantly larger than previous measurements, revealing structural ordering more strongly linked to dynamics than previously found. Furthermore we find that immobile regions and domains of local structure grow concurrently with density, and that these regions have low configurational entropy [2].

This work was partially supported by the National Science Foundation under Grant No. CBET-1701843 and DMR-1714722.

Experiments on periodically sheared colloidal suspensions with diffusion

Periodically sheared dilute, non-Brownian suspensions explore new configurations through collisions in an otherwise reversible flow. Below a critical strain, the particles remain active until they find a configuration with no collisions and reach an absorbing state. However, in a colloidal system at finite temperature, Brownian motion ensures that no state is ever truly absorbed and simulations by Hexner et. al. have shown that a small amount of diffusion enhances the order of the structures near the critical strain. We built a compact rotational shear cell to drive Brownian colloidal suspensions to explore the effect of diffusion on structures $S(q)$ and dynamics (mean squared displacement) simultaneously using a confocal microscope. From dynamical measurements, we see that the effective diffusion constant is equal to the self-diffusion of the particles below the transition and increases linearly with strain amplitude above. For a 20% volume fraction suspension, we see $S(q)$ at small q in the strain direction drop by a factor of 3 from thermal equilibrium in the strain direction with hyperuniform scaling $S(q) \sim q^{0.5}$ while in the vorticity direction, there is no hyperuniform scaling and $S(q)$ at small q only decreases by 50%.
We show that externally forced particles in a suspension self-organize hyperuniformly in certain directions relative to the force. For this phenomenon to occur, the force-induced coupling between the concentration of particles and their velocity field should satisfy three conditions: (i) it should be long-ranged, decaying with distance $r$ as $1/r^\beta$, with $\beta$ smaller than the dimensionality $d$; (ii) it should have a finite divergence, i.e., the flow of particles should not conserve volume; (iii) it should not be inversion-symmetric. These conditions are fulfilled, for example, for particles which tend to align with the force, or in the presence of a steady concentration gradient. The directions of hyperuniformity depend on the specific coupling. The structure factor for wavevectors $q$ along these directions tends to zero for small $q$ as $q^\alpha$, $\alpha = d – \beta$. We check these analytical results in a simple two-dimensional simulation, showing that they are robust against particle collisions and diffusion.

**Complex Spherical Micelle Packings in Aqueous Dispersions of Diblock Polymers**

ASHISH JAYARAMAN (Presenter), Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, DIANA Y ZHANG, McKetta Department of Chemical Engineering, University of Texas at Austin, BETH L DEWING, Department of Chemistry, University of Minnesota, Minneapolis, MAHESH MAHANTHAPPA, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis — Aqueous self-assembly of diblock polymers enables access to a plethora of concentration- and temperature- dependent morphologies including lamellae, hexagonally-packed cylindrical micelles (H), and high-symmetry packings of spherical micelles. Herein, we describe the aqueous lyotropic phase behaviour of poly(ethylene–block–ethylene oxide) using small angle X-ray scattering. The temperature versus amphiphile concentration phase diagram exhibits multiple micellar packings, including well-known body- and face-centered cubic structures as well as the lower symmetry Frank-Kasper (FK) A15 phase. On heating, the A15 phase undergoes a transition into the H-phase. Rapidly quenching this sample from high temperature to 25 °C results in the nucleation and growth of a FK $\sigma$ phase, which contains 30 quasispherical micelles situated at five different symmetry equivalent positions in a tetragonal lattice. We find that the $\sigma$ phase is metastable with respect to A15, and that the metastability strongly depends on the rate of cooling from the H phase and the quench depth. We rationalize our findings based on a subtle energy balance which maximizes interchain cohesion while minimizing both variations in coronal chain stretching and the interfacial penalty for the hydrophobic/hydrophilic contacts.

**Hyperuniformity of generalized random organization models**

ZHENG MA (Presenter), SALVATORE TORQUATO, Princeton University — Studies of random organization models of monodisperse spherical particles have shown that a hyperuniform state is achievable when the system goes through an absorbing phase transition. Here we investigate to what extent hyperuniformity is preserved when the model is generalized to particles with a size distribution and/or nonspherical shapes. We examine binary disks, disks with a size distribution and hard rectangles of various aspect ratios. We show that the systems are hyperuniform as two-phase media at their respective critical points. This analysis reveals that the redistribution of `mass" of the particles rather than the particle centroids is central to this dynamical process. Our results suggest that general particle systems subject to random organization can be a robust way to fabricate a wide class of hyperuniform states of matter by tuning the structures via different particle-size and -shape distributions. This in turn enables the creation of multifunctional hyperuniform materials with desirable optical, transport and mechanical properties.

Mechanics and inverse-design of thin shape-shifting structures

WILLEM VAN REES (Presenter), Massachusetts Institute of Technology, LAKSHMINARAYANAN MAHADEVAN, Harvard University — Recent progress in additive manufacturing and materials engineering has led to a surge of interest in shape-changing plate and shell-like structures. Such structures are typically printed in a planar configuration and, when exposed to an ambient stimulus such as heat or humidity, swell into a desired three-dimensional geometry. Viewed through the lens of differential geometry and elasticity, the application of the physical stimulus can be understood as a local change in the metric of a two dimensional surface embedded in three dimensions. In this talk we present our numerical approach for simulating the elastic response to such a metric change for thin structures. We also show our theoretical contributions on the inverse-design of shape-shifting bilayers, and discuss how these developments have led to the design and experimental realization of a 4D printed lattice that can undergo complex shape changes.

*We thank the Swiss National Science Foundation for support through a postdoctoral grant (WMvR), the American Bureau of Shipping for support through a Career Development Chair at MIT (WMvR), and the National Science Foundation for support from DMR 14-20570 and DMR 15-33985 (LM)

The shape of a rose petal

LAUREN NIU (Presenter), LAKSHMINARAYANAN MAHADEVAN, Department of Physics, Harvard University — The rose petal has a distinctive set of sharp bends along the edges of its outer petals. To understand the origin of this growth pattern, we dissect rose petals to show that the their Gaussian curvature changes from positive to negative toward the outer edges. Using scaling and stability analysis, we show that a curved “sonic” line controls the shape and location of edge buckling, which is itself driven by in-plane growth. We verify our results by numerically solving the nonlinear elastic equations associated with the growing surface. Our analysis suggests a method of designing buckled edge structures with controlled in-plane growth.

Topography Driven Surface Renewal

LUKA POCIVAVSEK (Presenter), University of Chicago, JOSEPH PUGAR, SACHIN VELANKAR, University of Pittsburgh, ENRIQUE CERDA, Universidad de Santiago de Chile — Natural surfaces excel in self-renewal and preventing bio-fouling, while synthetic materials placed in contact with complex fluids quickly foul. We present a novel biophysics inspired mechanism for surface renewal using actuating surface topography, generated by wrinkling. We calculate a critical surface curvature, given by an intrinsic characteristic length scale of the fouling layer that accounts for its effective flexural or bending stiffness and adhesion energy, beyond which surface renewal occurs. The effective bending stiffness includes the elasticity and thickness of the fouling patch, but also the boundary layer depth of the imposed wrinkled topography. The analytical scaling laws are validated using finite element simulations and physical experiments. Our data span over five orders of magnitude in critical curvatures and are well normalized by the analytically calculated scaling. Moreover, our numerics suggests an energy release mechanism whereby stored elastic energy in the fouling layer drives surface renewal. The strategy is broadly applicable to any surface with tunable topography and fouling layers with elastic response.

Differential swelling of boundary-prescribed patterns

CARLOS DUQUE (Presenter), CHRISTIAN SANTANGELO, University of Massachusetts Amherst — Non-Euclidean plates, thin elastic sheets that grow or shrink inhomogeneously, can be thought as geometrically frustrated surfaces that are unable to completely eliminate in-plane stress and are forced to adopt interesting 3D rest configurations as means of reducing their elastic energy cost. We use conformal flattening methods as a natural framework to prescribe isotropic, nonuniform growth patterns on elastic sheets as a way of making them buckle into a given target shape. We tune the ratio of maximal to minimal area distortion required by modifying the planar domain shape and produce 3D patterns that range from ellipsoids and Gaussian bumps to undulating spheres and corroborate the results using finite thickness simulations of growing sheets. Though surfaces with both positive and negative Gaussian curvature behave differently from those with only one sign of Gaussian curvature, we discuss what seems to be a more general composition property of optimal swelling patterns.

Twist-induced snapping in a bent elastic ribbon*  TOMOHIKO SANO (Presenter), HIROFUMI WADA, Ritsumeikan University — Snapping a slender structure is utilized in a wide range of natural and man-made systems, to achieve rapid movement without relying on muscle-like elements. Although several mechanisms for elastic energy storage and rapid release have been studied in detail, a general understanding to design such a kinetic system is a key challenge in mechanics. Here we study a twist-driven buckling and flip dynamics of a geometrically constrained ribbon by combining experiments, simulations, and analytical theory. We identify two distinct types of shape transitions; a narrow ribbon snaps, whereas a wide ribbon forms a pair of localized helices. We construct a phase diagram and explain the origin of the boundary determined by geometry. We quantify effects of gravity and timescale dictating the flipping. Our study reveals the unique role of twist-bend coupling on the fast dynamics of a thin constrained structure, which has implications for a wide range of biophysical and applied physical problems.

Self-folded pleated structures in twisted elastic sheets*  ARSHAD KUDROLLI (Presenter), ANDREEA PANAITESCU, Clark University, JULIEN CHOPIN, Physics, Universidade Federal da Bahia — We examine with experiments the post-wrinkling growth of curvature condensation and self-folded structures in thin sheets which are twisted about their axis while held under tension. Using x-ray imaging, we show that the initial sinusoidal wrinkles are found to increasing focus curvature resulting in spontaneous development of pleated structures. Unlike purely tensional wrinkles which decrease in amplitude after an application of a critical strain, the wrinkles are observed to persist and approach a finite value given by the mode number of the primary instability. The number of pleats can be controlled by varying the applied tension and the aspect ratio of the sheet with greater width to length ratios giving rise to more wrinkles and pleats.

Instability of an active-elastic chain  TINGYUAN ZHENG (Presenter), MARTIN BRANDENBOURGER, CORENTIN COULAIS, University of Amsterdam — While active materials have drawn an explosion of interest recently, the researches are almost exclusively focused on active fluids. Hereby, we created a simplest form of an active solid: a one-dimensional elastic chain comprising polar self-propelled centimeter scale particles. Combining rapid prototyping and precision desktop experiments, numerical simulations and theory, we report the emergence of the self-oscillating instability in such active chain. We further establish that the bifurcation towards the self-oscillatory dynamics is controlled by the competition between activity and elasticity.

The results provide some key insights into the potential of active solids in mimicking living matter and forming novel materials with far from equilibrium responses.

Dynamics of optical and anisotropic mechanical responses in hydrogels*  C. NADIR KAPLAN (Presenter), Harvard University, PETER A. KOREVAAR, Radboud University, ALISON GRINTHAL, JOANNA AIZENBERG, Harvard University — Materials that perform complex chemical sensing are ubiquitous in living systems, and would transform developments in biomedicine, environmental monitoring, and many other areas. We introduce a continuum mechanical framework that predicts the minimal set of components needed to integrate dynamical signal processing capabilities into simple hydrogels without structural modifications. For a common polyacrylic acid hydrogel, with copper cations and acid as representative chemical stimuli, the theory explains the experimentally observed (i) two-dimensional traveling waves of copper induced blue color selectively indicating a slowly progressing acid stimulus, (ii) anisotropic mechanical responses depending on the direction of acid progression, associated with tilting of an array of embedded passive microplates that report local hydrogel deformations. These results suggest simple hydrogels have a much larger sensing space than is currently made use of.

Active structuring of a particle film on a droplet's surface and examples of its applications

KHOBAB KHOBAB (Presenter), ALEXANDER MIKKELSEN, Faculty of Physics, Adam Mickiewicz University, Poland, ZBIGNIEW ROZYNEK, Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University, USA and, Faculty of Physics, Adam Mickiewicz University, Poland — Particle films have a broad range of applications, for instance in smart materials as constituent of strain sensors, actuators, or smart windows. Such films can be assembled and actively controlled by acoustic, magnetic, or electric fields. In this work, we used electric fields to actively compress and stretch particle film monolayers on a droplet interface. Particle manipulation was achieved through the synergetic action of electric field-induced droplet deformation and electrohydrodynamic flows. We studied in detail how droplet deformation and particle structuring are influenced by parameters such as electric field strength, ionic conductivity, and viscosity. We found that the time for particles to compress at the droplet interface was strongly influenced by the electric field, and that it scaled as $E^{-4}$. Moreover, hysteresis effects were observed both in the magnitude of droplet deformation and particle expansion and contraction. Looking towards practical applications, we also demonstrated how particles at droplet interfaces manipulated by electric fields could be used as an active optical lens, a tool for detecting of material encapsulated in particle-covered droplets, or for fabrication of porous materials used in biological applications.

Development of hydrogel-based cell stretching devices as in vitro model of atherosclerotic vessel walls*

QI LU (Presenter), WEIGUO HUANG, Department of Polymer Science and Engineering, University of Massachusetts, Amherst, ARITRA NATH KUNDU, MARIA FERNANDA GENCOGLU, SHELLY PEYTON, Department of Chemical Engineering, University of Massachusetts, Amherst, RYAN HAYWARD, Department of Polymer Science and Engineering, University of Massachusetts, Amherst — Atherosclerosis, the hardening of arteries, is the leading cause of heart attacks and strokes. The disease is worsened by smooth muscle cell (SMC) dedifferentiation, but the cause is difficult to study in vitro because it involves coupling between multiple physical and chemical factors. We sought to improve SMC culture models by creating a device with independent control over substrate stiffness, mechanical stretch and cell attachment. This device was fabricated by embedding micro-heaters under temperature-responsive hydrogel with patterned creases on the surface, and one SMC was seeded between two neighboring creases by photo-lithographically patterned attachment of peptides in desired location. The actuation is achieved by driving the heaters at 1 Hz, which mimics the resting pulse rate, causing the cell to be cyclically stretched and released by the repeatable deepening and relaxation of the creases. The cell is stretched by a strain of 5-10%, which is comparable to the stretch ratio that it experiences in physiological environment. This device can be systematically engineered, avoids macroscopic deformation and can potentially be scaled to high-throughput arrays.

Actuated Fibre Networks to Study Physical Principles of Multicellular Organization*

FAZIL USLU (Presenter), Institute of Mechanical Engineering, Ecole polytechnique federale de Lausanne, CHRISTOPHER D. DAVIDSON, Department of Biomedical Engineering, University of Michigan, Ann Arbor, NIKOLAOUS BOUKLAS, Department of Mechanical and Aerospace Engineering, Cornell University, Ithaca, BRENDON BAKER, Department of Biomedical Engineering, University of Michigan, Ann Arbor, MAHMUT SELMAN SAKAR, Institute of Mechanical Engineering, Ecole polytechnique federale de Lausanne — Cells continuously sense and respond to passive mechanical and topographical properties of the surrounding matrix as well as active forces transmitted through the same matrix. Cell-generated forces in deformable fibrous matrices enable long-range intercellular communication and drive collective cell behavior. Our aim is to quantitatively describe how matrix architecture and mechanics influence transmission of forces, and elucidate principles of physical organization instantiated by remodeling of a fibrillar substrate. We developed a microrobotic manipulation platform along with an experimentally validated finite element modeling framework to systematically manipulate and monitor stress on engineered fibre networks with tunable properties. Our approach allows application of spatiotemporally defined deformations using magnetically controlled microactuators and mapping of stress using simulations of materials, for which we performed measurements using confocal imaging, atomic force microscopy and MEMS force sensors. Preliminary results show that cells do respond to the signals generated by the synthetic actuators and a two-way communication can be established through the fibres using real-time feedback provided by time-lapse microscopy.

*European Research Council ROBOCHIP (714609)
LEYOU ZHANG (Presenter), Department of Physics, University of Michigan, D. ZEB ROCKLIN, School of Physics, Georgia Institute of Technology, LEONARD M SANDER, XIAOMING MAO, Department of Physics, University of Michigan — We present simulation results on fracture mechanics of two lattice models on the verge of mechanical instability. For both models, we show that the fracture and failure mechanism is distinctive from traditional brittle solids: stress does not concentrate on crack tips. In the first model which is a randomly diluted triangular lattice under isostaticity, we observed that nonlinear alignments of fiber chains lead to a steady state in which new load-bearing fiber chains emerge to replace those lost to fracture. We show that the stress concentration is dissipated and eventually prevented when the rigidity of the model decreases to zero. In the second model which is a kagome lattice with topologically protected states of self stress on devised domain walls, we show that stress concentrates on domain walls instead of cracks, leading to delayed catastrophic failure. Suitable boundary conditions for experiments will also be discussed.

OCTAVIO ALBARRAN (Presenter), PETER WEIST, EUGENIA BUTKEVICH, RENATA GARCES, Third Institute of Physics, University of Goettingen, CHRISTOPH SCHMIDT, Department of Physics, Duke University — To perform undulatory locomotion, C. elegans nematodes generate forces with their body-wall muscles acting on the surrounding environment and against their own body bending resistance. The knowledge of the passive elastic body response is crucial to understand the dynamic functions of the worm. It has been hypothesized that the worm kinematics can be understood in terms of linear viscoleastic beam theory. However, to date, mechanical studies in the large deformation regime, typical of native undulatory locomotion, are lacking. We here present a micro-needle-based experiment imposing large strains. Living worms were kept straight by clamping their extremities onto agar plates. We laterally displaced the centers of worms with a glass cantilever of known spring constant and directly probed the linear beam model. To separate passive responses from muscle activity, we varied the contraction-relaxation state of the muscles using pharmacological interference. We provide a synthesis of the typical range of magnitudes of the worm's material parameters for different muscles states.

JOSEPH MONTI (Presenter), MARK OWEN ROBBINS, Johns Hopkins University — Disorder at the interface of an amorphous slider on a crystalline substrate leads to vanishing friction for large rigid contacts. The inclusion of elasticity introduces an energetic contribution that competes with the random interfacial potential and allows frictional pinning over a domain with characteristic radius $a_c$. The interfacial force scales linearly with $a_c$, while the elastic restoring force from deformation on the scale of $a_c$ depends upon the dimension of the substrate. For a 2D substrate, the restoring force is independent of $a_c$, while it grows linearly with $a_c$ in 3D. Comparison of the interfacial and elastic contributions shows that the pinning force is proportional to $a_c$ in 2D. The 3D case is marginal because the forces scale with the same power of $a_c$. Extensive simulations are used to test the scaling of friction with disorder strength and system size. In 3D, we find an exponential decrease of the pinning force and increase in $a_c$ with increasing substrate stiffness. In 2D, the expected power law scaling is observed. Substrates of finite thickness show a crossover in scaling with contact size that may be important in understanding solid lubricants with a plate structure.

5:18PM V59.00015: Global and Local Mechanical Properties of Responsive Microgels Adsorbed to Solid-Liquid Interfaces  
MARIE FRIEDERIKE SCHULTE (Presenter), ANDREA SCOTTI, MONIA BRUGNONI, STEFFEN BOCHENIKE, RWTH Aachen University, AHMED MOURRAN, DWI - Leibniz Institute for Interactive Materials, WALTER RICHTERING, RWTH Aachen University — Microgels are highly interfacial active, although not being amphiphilic. They readily adsorb to liquid/liquid, liquid/air or solid interfaces and deform [1]. We studied microgels with unique internal structures, (i) one with a rigid silica core and a PNIPAM shell, (ii) hollow microgels obtained by dissolving the silica core, and (iii) ultra-low cross-linked microgels. These responsive microgels were investigated at the solid-liquid interface by scanning force microscopy. An important parameter is the size of the probe compared to the dimensions of the microgel [2]. Colloidal probe experiments lead to a compression of the whole microgel and provide information on their global mechanical properties. Changing the probe dimensions, we will demonstrate that indentation experiments using sharp tips lead to a local penetration of the porous swollen microgel network. Therefore, force-distance curve measurements enable to probe the segment density distribution orthogonal to the substrate of adsorbed single microgels.

Session V60 FPS: The Future of U.S. Nuclear Forces: What Do We Need? BCEC 258A - Frank von Hippel, Princeton University - Tag(s): Invited, Undergraduate

2:30PM V60.00001: Nuclear Modernization, ICBMs, and Launch On Warning [invited] STEVE FETTER (Presenter), University of Maryland, College Park — The US is replacing all three legs of the triad, ballistic missile submarines (SSBNs), bombers, and intercontinental ballistic missiles (ICBMs), at a cost of over $1.2 trillion. The SSBN force is the core of the deterrent because it can survive a Russian attack and deliver a devastating retaliatory strike. The strategic bomber can support conventional missions and the cost of adding a nuclear capability is modest. But silo-based ICBMs are not survivable; they can be destroyed in a first-strike. For this reason, ICBMs are kept ready to be launched on warning of a Russian attack. This forces decisions to be made in minutes and creates the possibility of launch on false warning.

Two arguments are made in favor of retaining a ICBMs. First, ICBMs are a hedge against failures in other legs of the triad. But ICBMs cannot serve as a hedge unless the US commits to launch under attack. Second, without the 400-plus aimspoints provided by ICBMs, Russia might be tempted to strike the small number of remaining targets. Why Russia would take this risk knowing that SSBNs armed with over 700 warheads would remain capable of delivering a devastating retaliatory strike is unclear. The key is the survivability of command, control, and communication capabilities.

3:06PM V60.00002: US Plans for New Nuclear Weapons [invited] LISBETH GRONLUND (Presenter), Union of Concerned Scientists — For decades, the United States produced a stream of nuclear warheads, with new types replacing previous types on an ongoing basis. It did not seriously consider the behavior of aging warheads until it declared a moratorium on nuclear explosive testing in 1992. At that time the United States believed it could not validate new warhead designs without nuclear testing, and that it would therefore have to extend the life of existing warheads. Two warhead types have undergone life extension programs that were straightforward refurbishments. However, the latest plan is to replace—not refurbish—one of the warheads deployed on silo-based missiles. The weapons designers now believe their computer models allow them to validate new designs without explosive testing. I will discuss the rationale for this new warhead and the downsides of deploying it.
3:42PM V60.00003: Current Nuclear Weapons Issues, and Sid Drell’s Contributions to Arms Control and Strategic Stability [Invited] RICHARD L. GARWIN (Presenter), IBM Thomas J. Watson Research Center — 1. The history of the M-X missile, of various bomber programs, and naval ship procurement confirms that one of the great threats to U.S. national security is the aggressive overselling and underpricing of weapon systems. Beware envy of weapons we don't need, in contrast with countering adversary weapon systems by defense, deception, or a combination of electronic warfare and cyber attack, or by the use of alternative (asymmetric) systems. 2. At Sid’s retirement from SLAC 20 years ago, I recounted some of his work in creating and perfecting satellite imagery that greatly improved our knowledge of denied territories. His work, both technical and programmatic, resulted in his being named one of the ten Founders of National Reconnaissance. A separate portion of his efforts was devoted to work on and to the leadership of the strategic military panel of the President’s Science Advisory Committee --PSAC-- with its annual assessment of proposals for U.S. national missile defense. He undertook public analysis of various proposals for land-basing of the 10-warhead M-X missile in Nevada or Utah, and lectured there, and worked within the JASON group for the US Department of Defense to propose a novel and highly unwelcome system for basing four encapsulated M-X missiles alongside each of a fleet of small non-nuclear submarine. In the 1990s, Sid was key to readying the Defense Department and the nuclear weapons elements of the Department of Energy to support a total ban of nuclear explosion testing-- the CTBT-- and to put substance on the Science-based Stockpile Stewardship Program for maintaining U.S. nuclear weapons safe and reliable under the CTBT. In recent decades Sid worked with George P. Shultz, Sam Nunn, Henry A. Kissinger, and William J. Perry toward massive reductions of nuclear weaponry, and with the goal of eliminating nuclear weapons. Sid's energy and warm personality enhanced his effectiveness, making it a pleasure to work with him.

4:54PM V60.00004: Engaging the Physics Community in Nuclear Threat Reduction [Invited] STEWART PRAGER (Presenter), Princeton University — The threat posed by nuclear weapons has been well-known, well-articulated, and well-studied for 70 years. Most importantly, a network of international agreements has slowed proliferation and led to dramatic reduction in the number of warheads in the US and Russia. Despite these advances, the grave threat persists and is arguably getting worse – a result of weapons spread to nine nations, the appearance of non-state actors, the threat of cyber attacks against weapon systems, weapons modernization over the coming decades, withdrawal from treaties, potential new tactical weapons, and government discussions of reducing the threshold for the use of nuclear weapons. Yet, this issue is largely ignored by the public. Physicists have a special relation to nuclear arms and, if organized, can add an influential voice to the effort to reduce the threat. There are many threat reduction steps that the physics community can encourage, such as de-alerting, adoption of policies of no-first-use and no launch-on-warning, reduction of global weapons-usable materials and much more. An initiative is being formulated to engage and activate the US physics community to this end.

Thursday, March 7, 2019 2:30 PM - 5:30 PM

Session V61 GSOFT: Physics and Hydrodynamics of Micro-swimmers' Suspensions BCEC 258B -

Arnold Mathijssen, Stanford University - Tag(s): Focus

2:30PM V61.00001: Swimming bacteria in a Poiseuille flow : the quest for active Bethoven-Jeffery trajectories*

GASPARD JUNOT (Presenter), THIERRY DARNIGE, ESPCI ParisTech, NURIS FIGUEROA MORALES, 508 Wartik Lab, PA 16802, USA, The Pennsylvania State University, ANKE LINDNER, ESPCI ParisTech, HAROLD AURADOU, F-91405, Orsay, France, FAST, Univ. Paris Sud, ERIC CLEMENT, ESPCI ParisTech — Using a 3D Lagrangian tracking technique, we determine the swimming trajectories of E.coli in a Poiseuille flow. We identify many trajectories displaying the qualitative features of an “active Bretherton-Jeffery” model featuring an axi-symmetric self-propelled ellipsoid swimming in a flow. By deriving closed-forms for two phase-portraits involving one spatial and two angular coordinates as well as, the mean angular shift displayed by the families of cycloid trajectories, we show that for a smooth swimmer mutant, a quantitative mapping with the actual experimental trajectories can be made. Furthermore we show that from cycloid trajectories, the effective aspect ratio of the swimmer can be extracted. This analysis also allows to highlight the crucial influence of Brownian rotation noise, on the swimmer trajectories.

2:42PM V61.00002: Characteristics of collective and individual motions of swimming Phytophthora zoospores
QUANG TRAN (Presenter), PHILIPPE THOMEN, CÉLINE COHEN, Institut de Physique de Nice (INPHYNI), Université Côte d’Azur, CNRS UMR 7010, Nice, France, ERIC GALIANA, Institut Sophia Agriobiotech (ISA), Université Côte d’Azur, INRA UMR 1355, CNRS 7254, France, XAVIER NOBLIN, Institut de Physique de Nice (INPHYNI), Université Côte d’Azur, CNRS UMR 7010, Nice, France — Phytophthora diseases cause big threats to agriculture and eco-systems. Spreading is based on rapid dispersion of biflagellate swimming zoospores that once having reached a host initiate plant infection. Understanding their swimming mechanism and their interactions against gradients and surrounding environments becomes important. In this study, we develop a microfluidic system to investigate collective and individual motions of Phytophthora parasitica zoospores, a species that infects a broad range of host plants. Our system has the ability to generate a chemical gradient diffusing to a group of swimming zoospores and observe their swimming motions as well as the changes of the gradient at the same time. Our results show that a group of P. parasitica react differently against different doses of potassium chloride gradients: Low concentration of potassium reduces their speed and lures them away or initiates auto-aggregation, while high concentration (>3mM) causes them to change their swimming pattern to circulating around or stop moving. Moreover, observing a single zoospore swimming in water, we achieved the characteristics of its beating flagella. The correlation between zoospore velocity and its flagella motions helps us explain their reactions against the potassium gradients.

2:54PM V61.00003: Dancing to the swimmers’ beat: Loopy Lévy flights enhance tracer diffusion in active suspensions*
KIYOSHI KANAZAWA, Institute of Innovative Research, Tokyo Institute of Technology, TOMOHIKO SANO, Department of Physical Sciences, Ritsumeikan University, ANDREA CAIROLI (Presenter), Department of Bioengineering, Imperial College London, ADRIAN BAULE, School of Mathematical Sciences, Queen Mary University of London — The diffusion process followed by a tracer in a medium out of equilibrium typically exhibits anomalous diffusion that cannot be modelled by Brownian motion. Prototypical active media are suspensions of swimming microorganisms like algae and bacteria, where the tracer is dragged by the hydrodynamic flow generated by the swimmers. Several experiments have characterised the tracer diffusion in dilute conditions by a greatly enhanced diffusion coefficient, non-Gaussian tails of the displacement statistics, and crossover scaling phenomena. Despite the abundant experimental results, there is so far no comprehensive theory that can describe all these features. Here we present a theoretical framework of the enhanced tracer diffusion from first-principles, by coarse-graining the microscopic tracer-swimmer interactions as a coloured Lévy Poisson process. This theory not only provides the toolkit necessary to characterise theoretically the tracer diffusion but also paves the way to the study of its stochastic thermodynamics.

3:06PM V61.00004: Active colloidal particles in emulsion droplets: A model system for the cytoplasm
VIVA HOROWITZ (Presenter), Physics Department, Hamilton College, ZACHARY C. CHAMBERS, Department of Physics, Harvard University, IREP GÖZEN, Department of Medicine, University of Oslo, Norway, THOMAS G. DIMIDUK, VINOTHAN N MANOHARAN, Department of Physics, Harvard University — In living cells, molecular motors create activity that enhances the diffusion of particles throughout the cytoplasm, and not just ones attached to the motors. We demonstrate initial steps toward creating artificial cells that mimic this phenomenon. Our system consists of active, Pt-coated Janus particles and passive tracers confined to emulsion droplets. We track the motion of both the active particles and passive tracers in a hydrogen peroxide solution, which serves as the fuel to drive the motion. We first show that correcting for bulk translational and rotational motion of the droplets induced by bubble formation is necessary to accurately track the particles. After drift correction, we find that the active particles show enhanced diffusion in the interior of the droplets and are not captured by the droplet interface. At the particle and hydrogen peroxide concentrations we use, we observe little coupling between the active and passive particles. We discuss the possible reasons for lack of coupling and describe ways to improve the system to more effectively mimic cytoplasmic activity.
Microswimmers can self-organize to a variety of collective geometries and can exhibit spontaneously broken mirror symmetry. This allows for the realization of chiral Beltrami vector fields, which can support inverse energy transport from smaller to larger scales, in contrast to classical 3D turbulence.

3:18PM V61.00005: Spontaneous chiral symmetry breaking in active fluids* [Invited] JORN DUNKEL (Presenter), Physics, University of Warwick, JORGE ARRIETA, RAMON SALETA-PIERSANTI, IDAN TUVAL, Instituto Mediterraneo de Estudios Avanzados, IMEDEA, Universitat de les Illes Balears-CSIC — Microorganismal motility is often characterised by complex responses to environmental physico-chemical stimuli. Although the biological basis of these responses is often not well understood, their exploitation already promises novel avenues to directly control the motion of living active matter at both the individual and collective level. Here we leverage the phototactic ability of the model microalg Chlamydomonas reinhardtii to precisely control the timing and position of localised cell photo-accumulation, leading to the controlled development of isolated bioconvective plumes. This novel form of photo-bio-convection allows a precise, fast and reconfigurable control of the spatio-temporal dynamics of the instability and the ensuing global recirculation, which can be activated and stopped in real time. A simple continuum model accounts for the phototactic response of the suspension and demonstrates how the spatio-temporal dynamics of the illumination field can be used as a simple external switch to produce efficient bio-mixing.

*We acknowledge the support of the Spanish Ministry of Economy and Competitiveness Grants No. FIS2016-77692- C2-1-P, and CTM-2017-83774-D, and the subprogram Juan de la Cierva No. IJCI-2015-26955.

3:54PM V61.00006: Dial-a-plume: Active Control of Localised Photo-Bio-Convection* MARCO POLIN (Presenter), Physics, University of Warwick, JORGE ARRIETA, RAMON SALETA-PIERSANTI, IDAN TUVAL, Instituto Mediterraneo de Estudios Avanzados, IMEDEA, Universitat de les Illes Balears-CSIC — Microorganismal motility is often characterised by complex responses to environmental physico-chemical stimuli. Although the biological basis of these responses is often not well understood, their exploitation already promises novel avenues to directly control the motion of living active matter at both the individual and collective level. Here we leverage the phototactic ability of the model microalg Chlamydomonas reinhardtii to precisely control the timing and position of localised cell photo-accumulation, leading to the controlled development of isolated bioconvective plumes. This novel form of photo-bio-convection allows a precise, fast and reconfigurable control of the spatio-temporal dynamics of the instability and the ensuing global recirculation, which can be activated and stopped in real time. A simple continuum model accounts for the phototactic response of the suspension and demonstrates how the spatio-temporal dynamics of the illumination field can be used as a simple external switch to produce efficient bio-mixing.

4:06PM V61.00007: Percolation theory of intercellular communication through hydrodynamic trigger waves* ARNOLD MATHIJSSEN (Presenter), Department of Bioengineering, Stanford University, JOSH CULVER, SAAD BHAMLA, School of Chemical & Biomolecular Engineering, Georgia Institute of Technology, MANU PRAKASH, Department of Bioengineering, Stanford University — Here, akin to a chain reaction, we present the discovery of hydrodynamic trigger waves in cellular communities of the protist Spirostomum ambiguum, propagating hundreds of times faster than their swimming speed. These cells can contract their body by 50% within milliseconds, equivalent to 14g-forces. A single contraction (transmitter) generates long-ranged vortex flows that trigger neighbouring cells, in turn. We further present a microfluidic device to measure the sensitivity to hydrodynamic signals (receiver). Using percolation theory, a phase transition is revealed that requires a critical cell density to sustain communication. Our results suggest that this signalling could help organise cohabiting communities over large distances, comparable to quorum sensing. Moreover, as contractions release toxins, synchronised discharges could also facilitate the repulsion of large predators, or conversely immobilise large prey. We postulate that beyond protists numerous other freshwater and marine organisms could coordinate with variations of hydrodynamic trigger waves.

*We acknowledge funding from the Human Frontier Science Program (Fellowship LT001670/2017).

4:18PM V61.00008: Gravity induced structures of microswimmers on a surface* ZAIYI SHEN (Presenter), ALOIS WÜRGER, JUHO LINTUVUORI, LOMA, Université de Bordeaux — Microswimmers can self-organize to a variety of collective states. The underlying forces, however, are not well characterized. Besides the electric, magnetic or chemical surface forces, hydrodynamic interactions are believed to play important role on the collective motion of active colloids. In typical experiments of artificial self-propelled colloids, the particles are observed to sediment. We study microswimmer suspensions by lattice Boltzmann simulations, using a squirmer model. We show that hydrodynamic interactions, together with a gravity-like field, lead to tunable collective behaviors of self-propelled spheres near a surface. For example chiral spinners, swarming clusters and living crystals are observed. We rationalize the formation of these structures, in detail, based on hydrodynamic interactions between a pair of swimmers. These interactions depend crucially of the swimming mechanism, pusher or puller, and can be tuned such that they are either directional, leading to the formation of small chiral spinners or mutually attractive, creating large hydrodynamically bound motile aggregates.

*We acknowledge support from IdEx (Initiative d'Excellence) Bordeaux and French National Research Agency through Contract No. ANR-13-IS04-0003.
4:30PM V61.00009: Emergence of phytoplankton patchiness at small scales in mild turbulence  
REBEKKA BREIER, CRISTIAN C LALESCU, MICHAEL WILCZEK, Max Planck Institute for Dynamics and Self-Organization, MARCO G. MAZZA (Presenter), Loughborough University — Phytoplankton often encounter turbulence in their habitat. The spatial distribution of motile phytoplankton cells exhibits patchiness at distances of decimeter to millimeter scale for numerous species with different motility strategies. The explanation of this general phenomenon remains challenging. We combine particle simulations and continuum theory to study the emergence of patchiness in motile microorganisms in three dimensions, by including hydrodynamic cell-cell interactions, which grow more relevant as the density in the patches increases. By addressing the combined effects of motility, cell-cell interaction and turbulent flow conditions, we uncover a general mechanism: the coupling of cell-cell interactions to the turbulent dynamics favors the formation of dense patches.

4:42PM V61.00010: Non-Gaussian limit fluctuations in active swimmer suspensions [Invited]  
DAISUKE MIZUNO (Presenter), TAKASHI KURIHARA, Kyushu University, ZAID IRWIN, Oxford University — Hydrodynamic fluctuations in suspensions of swimming microorganisms (Chlamydomonas and E-coli) exhibit heavily-tailed distribution which is not Gaussian nor Levy, for which both the classical and extended central limiting theories do not apply. In this study, the physical limit distribution, instead of mathematical ones, was derived in an analytical form by summing the general power-law interactions from field sources (here, swimming microorganisms) randomly distributed in general spatial dimensions. The origin of the non-Gaussianity is not just the power-law decay of hydrodynamic fields, but the summing procedure of the fields, which we refer to as the physical limit operation [1].

The non-Gaussian shape of the hydrodynamic fluctuations in active swimmer suspensions obeys the analytic theory concomitantly with independently determined parameters such as the strength of force generations and the concentration of swimmers. Time evolution of the distributions collapsed to a single master curve, except for their extreme tails, for which our theory presents a qualitative explanation. Investigations thereof and the complete agreement with theoretical predictions revealed broad applicability of the formula to fluctuations in active systems [2].

Fluctuations show up differently in different spatial dimensions since dimensionality affects the spatial correlations of fields and the population of field sources as a function of system size. Swimmers that resist to sedimentation or ordinary force-dipolar swimmers confined in 2D generate $1/r$-decaying fields that are long-ranged in the sense that there is no thermodynamic limit. If time permitted, I will discuss the implication of our study for the dimensionality dependence of active fluctuations.

5:18PM V61.00011: Bacterial diodes: Rectified transport of swimming cells in porous media flow  
NICOLAS WAISBORD, JEFFREY GUASTO (Presenter), Tufts University — Directed motility enables swimming microbes to navigate their porous habitats for resources, where self-propulsion competes with fluid flow to affect processes ranging from disease transmission and bioremediation. Despite this broad importance, how directed motility affects the self-transport and dispersion of microswimmers in flow through constricted pores remains unknown. Focusing on magnetotactic bacteria in a microfluidic porous medium, we show that upstream oriented cells, directed by a magnetic field, are localized and trapped in vortical orbits at a constriction. Vortical cell localization results in three distinct regimes of rectified bacterial conductivity through a throat, akin to a ‘bacterial diode’, whereby cells swim upstream, become trapped within a pore, or are advected downstream with increasing flow speed. Langevin simulations reveal that the trapping regime results in near-complete transport suppression, while ephemeral trapping in the downstream regime enhances dispersion. We also show that vortical cell localization persists in three-dimensional flow through a packed microfluidic bed, emphasizing the relevance of this phenomenon in realistic hydraulic networks.

Thursday, March 7, 2019 2:30 PM - 5:30 PM

Session V63 GSOFT: Membranes, Micelles and Vesicles  
BCEC 259A - Anna Wang, Massachusetts General Hospital
2:30PM V63.00001: Electrostatic shape control of a charged molecular membrane from ribbon to scroll* SUMIT KEWALRAMANI (Presenter), CHANGRUI GAO, HONGHAO LI, MONICA OLVERA DE LA CRUZ, MICHAEL J BEDZYK, Northwestern University — Bilayers of amphiphiles can organize into a number of distinct mesoscopic shapes, which interconvert under suitable conditions. The pathway for such transformations is often elusive. We use a charged amphiphile (palmitoyl-lysine, C16-K1) to elucidate the planar nanoribbon to cochleate transition induced by salt (NaCl) concentration (c). In-situ small- and wide-angle X-ray scattering (SAXS/WAXS), atomic force and cryogenic transmission electron microscopies (AFM and cryo-TEM) tracked transformations over Å to µm length scales. AFM reveals that the large length (L) to width (W) ratio nanoribbons (L/W > 10) convert to sheets (L/W ~ 1) before rolling into cochleates. A theoretical model based on electrostatic and surface energies shows that the ribbon to sheet conversion is a first order transition, occurring at a critical Debye length. SAXS shows that the interbilayer spacing (D) in the cochleates scales linearly with Debye length (or c^-1/2). Theoretical arguments that include electrostatic, bending and van der Waals energies explain the membrane rolling and the linearity between D and Debye length. These models suggest that the salt-induced ribbon to cochleate transition should be common to all charged bilayers possessing an intrinsic curvature.

2:42PM V63.00002: A gel based on vesicle-vesicle adhesion induced by polyelectrolyte: from morphology to rheology* RUI CAO (Presenter), DEEPAK KUMAR, IAN TORRES, NARAYANAN MENON, ANTHONY DINSMORE, Physics, University of Massachusetts Amherst — Phospholipid membranes are of great interest for encapsulation due to its outstanding barrier properties. Here we show that one can build an elastic solid with giant vesicles (1-30 mm diameter) that adhere to one another. A slight negative potential on the lipid membrane enables electrostatic attraction with polycations, which induces vesicle-vesicle adhesion. The vesicle adhesion leads to a macroscopic vesicle based gel that is >99% water but has a closed-cell structure. Shear rheology measurements show a low-frequency modulus of a few Pa and linear response extending to very large strains of approximately 0.7. We find that the vesicle adhesion strength and shear modulus can be tuned with polyelectrolyte concentration. We also find that the shear modulus does not scale with vesicle size as long as the adhesion strength is held constant. The vesicle gel system shows great potential as a soft-solid platform for a stimulus-responsive material that can deliver reagents on demand.

*This work was supported by a MURI grant from the U.S. Army Research Office (W911NF-15-1-0568).

2:54PM V63.00003: Controlling the elasticity of lipid membranes with pluronic block copolymers PETER BELTRAMO (Presenter), Chemical Engineering, University of Massachusetts Amherst, SANDRO STUCKI, JAN VERMANT, ETH Zurich — Pluronic triblock copolymers consisting of a hydrophobic poly(propylene-oxide) (PPO) block, flanked by two hydrophilic poly(ethylene-oxide) (PEO) blocks have been widely investigated in drug delivery applications as membrane sealants and plasticizers. However, despite a single pluronic (F68) being FDA approved, there is minimal insight into how block copolymer architecture can be engineered to dictate membrane response. Here, we investigate the influence of the structure of the pluronic on the interaction with artificial biological membranes using the large-area model biomembrane (LAMB) technique. We systematically measured the change in membrane tension and elasticity of a planar, freestanding DOPC membrane upon interaction with several pluronics with with varying PEO and PPO chain lengths and HLB values. Based on the membrane tension - area relationship, the apparent elasticity modulus was calculated. Interestingly, the main factor determining the membrane elasticity is the length of the hydrophilic PEO chain, rather than the hydrophobic PPO block. We also discuss the effect of concentration above and below the cmc on the membrane elasticity. These findings may prove beneficial for future medical applications of pluronics as treatment for membrane-tension mediated maladies.
3:06PM V63.00004: Spontaneous division of model protocell membranes* ANNA WANG (Presenter), Molecular Biology and Center for Computational and Integrative Biology, Massachusetts General Hospital, STEPHANIE ZHANG, Department of Chemistry and Chemical Biology, Harvard University, JACK W. SZOSTAK, Molecular Biology and Center for Computational and Integrative Biology, Massachusetts General Hospital — Prior to the existence of phospholipid membranes, the ancestors of modern day cells likely had membranes consisting of much simpler molecules. On early Earth, these membranes would have provided the function that modern cell rely on proteins for - nutrient transport, growth and division - prompting the question of whether such functions can arise from a lipid-only system.

We show that fatty acids can self-assemble into giant unilamellar vesicles (GUVs) without the need for scaffolding droplets, substrates, or microfluidics. Remarkably, such GUVs are capable of spontaneously dividing upon an increase in surface area to volume ratio, instead of simply forming tubular vesicles. When nucleic acids are encapsulated, the protocells - membranous compartments containing nucleic acids - are able to divide into daughter protocells without apparent loss of content.

We find that the bilayer properties of fatty acid membranes depend on the pH and ionic strength of the surrounding solution, and explore how the differences between fatty acid membranes and the better-studied phospholipid systems enable the unusual self-assembly and morphology changes we see.

*A.W. would like to thank the NASA Postdoctoral Program for support

3:18PM V63.00005: Direct imaging of micelle dynamics with an electron microscope* HIMANAGAMANASA KANDULA (Presenter), YE-JIN KIM, OH-HOON KWON, STEVE GRANICK, Center for soft and living matter, Institute for Basic Sciences — Direct imaging of single micelle dynamics and the kinetics of their assembly is not possible with conventionally used imaging techniques such as transmission electron microscopy (TEM) or cryo-TEM. In this talk, I will discuss our efforts to image the dynamics of simple block copolymer micelles using liquid-phase TEM. By directly visualizing small micellar assemblies in solution, we demonstrate the structure-dependent dynamics of these assemblies, with intriguing surprises.

*Institute for Basic Sciences, South Korea.

3:30PM V63.00006: The role of particle shape in the deformation and disruption of lipid membranes: Experiments with tunable particle shape and adhesion* SARAH ZURAW (Presenter), ANTHONY DINSMORE, University of Massachusetts Amherst, MAHSA SIAVASHPOURI, physics, Brandeis University, ZVONIMIR DOGIC, Physics, University of California Santa Barbara — We seek to understand the effects of DNA origami nano-rods on membrane structure and morphology. We combine giant unilamellar lipid vesicles (GUVs) with a sufficiently high concentration of oppositely charged nano-rods and observe the interactions. The adhesion of the nano-rods to the membrane is a tunable parameter controlled by the lipid composition, and results in three primary behaviors. At weak adhesion strengths, vesicles adhere to one another and form a stable gel, with the nano-rods acting as a glue that holds the gel together. At intermediate adhesion strengths, gel forms but is subsequently destroyed by avid binding of the nano-rods. At higher adhesion strengths, the vesicles are ruptured by the nano-rods without ever forming a gel. These behaviors can be explained respectively by shallow, deep, or complete wrapping of the nano-rods onto the lipid membrane. These results are a robust example of tuning response in a synthetic membrane system and provide a physical understanding of the design principles toward controlled membrane morphologies. These results will lead to a bio-inspired membrane material that is stimuli-responsive, has high surface area and is reconfigurable.

*This work is funded by the NSF Materials Research Science and Engineering Center grant DMR-1420382
Controlling Cargo Trafficking in Multicomponent Membranes

TINE CURK (Presenter), Institute of Physics, Chinese Academy of Sciences, PETER WIRNSBERGER, Department of Chemistry, University of Cambridge, JURE DOBNIKAR, Institute of Physics, Chinese Academy of Sciences, DAAN FRENKEL, Department of Chemistry, University of Cambridge, ANDELA SARIC, Physics, UCL — Biological membranes typically contain a large number of different components dispersed in small concentrations in the main membrane phase, including proteins, sugars, and lipids of varying geometrical properties. Most of these components do not bind the cargo. Here, we show that such “inert” components can be crucial for the precise control of cross-membrane trafficking. Using a statistical mechanics model and molecular dynamics simulations, we demonstrate that the presence of inert membrane components of small isotropic curvatures dramatically influences cargo endocytosis, even if the total spontaneous curvature of such a membrane remains unchanged. Our results suggest a robust and general method of controlling cargo trafficking by adjusting the membrane composition without needing to alter the concentration of receptors or the average membrane curvature. This study indicates that cells can prepare for any trafficking event by incorporating curved inert components in either of the membrane leaflets.

Refs:

Precision measurements of lipid membrane hydrodynamic drag

PHILIP JAHL (Presenter), RAGHUVEER PARTHASARATHY, Physics, University of Oregon — The hydrodynamic drag at a lipid bilayer determines, among other things, the flow properties of suspensions of cells and liposomes. For spherical liposomes or lipid vesicles, the Stokes equation relates the drag coefficient ζ to the radius r and the fluid viscosity η by ζ = Cπηr, where the dimensionless C depends on the hydrodynamic boundary between the sphere and the fluid. For solid spheres C=6 and for liquid spheres C=4. This constant has been assumed to be 6 for lipid membranes, but we have found no direct measurements of it, and given the fluidity of lipid membranes it is not obvious that the solid-sphere value applies. The Stokes-Einstein relationship D = kBT/(Cπηr), where D is the diffusion coefficient, kB is Boltzmann's constant, and T is the temperature allows determination of C provided D can be determined precisely. We use light sheet fluorescence microscopy to image lipid vesicles far from surfaces that complicate application of the Stokes-Einstein relationship. Combined with high-accuracy image localization, this allows us to measure C, finding that it closely matches the C=6 value of a solid sphere. We comment on deviations from C=6 for non-spherical vesicles with thermally driven undulations.

Shape Control of Deformable Nanocontainers by Modulating Surface Tension and Charge Patterning

VIKRAM JADHAO (Presenter), NICHOLAS BRUNK, Intelligent Systems Engineering, Indiana University Bloomington — Shape-reconfigurable polymeric vesicles, micelles and other soft-matter-based nanomembranes have important applications as adaptive drug-delivery carriers that change shape in response to external cues, and as dynamic building blocks for designing reconfigurable materials. The shape of these nanocontainers can be controlled by modulating their surface composition and environment. Molecular dynamics simulations are used to explore the role of surface tension and surface charge patterning in changing the shape of charged, elastic, volume-preserving nanocontainers. For homogeneously charged nanocontainers, sphere-to-rod-to-disk shape transitions are shown to be facilitated by decreasing surface tension; this could be realized by functionalizing the nanocontainer surface with surfactants. For inhomogeneous, hemispherically-charged Janus nanocontainers, transitions to hemispherical shapes are observed. Shape control of nanocontainers with inhomogeneous surface charge patterns characteristic of pH values near the pKa of the charged surface moieties is discussed. Robustness of shape transitions is investigated by including the effects of ions via mean-field models and explicit-ion simulations.

Morphology of toroidal vesicles

YIHAO LIANG (Presenter), Northwestern University, XIANGJUN XING, Shanghai Jiao Tong University, MONICA OLVERA DE LA CRUZ, Northwestern University — The equilibrium shapes of toroidal fluid vesicles have been studied for many years. Recently, a new class of stable nonaxisymmetric circular shapes has been observed both from experiment and simulation. This shape contains a necklace-like main ring, usually accompanied by buds. Using Monte Carlo simulation and theoretical analysis, we investigate the morphology of toroidal vesicle. Based on Delaunay unduloids we give a perturbative estimation of the properties of the main ring.

4:30PM V63.00011: A  ORRIN SHINDELL (Presenter), Department of Physics & Astronomy, Trinity University, NATALIE MICA, School of Physics and Astronomy, University of St. Andrews, K KELVIN CHENG, Department of Physics & Astronomy, Trinity University, EXING WANG, Department of Cell Systems & Anatomy, University of Texas Health Science Center San Antonio, VERNITA GORDON, Department of Physics, University of Texas at Austin — We report on a complex fingering pattern that forms in an approximately 25μm-diameter circular lipid membrane adhered by biotin-avidin bonds to a solid supported membrane. The experiment involves applying tension to form a tear in the bound circular membrane. The pattern in the torn membrane then evolves as 1μm-scale pores form intermittently on the scale of tens of seconds at the boundary of the tear. As the pores form, the biotin-avidin bonds are laterally compressed. As the density of bonds increases, the width of the pores decreases linearly and the rate of new pore formation decreases exponentially. Finally, when the biotin-avidin bonds are compressed into a solid-like state, the process arrests leaving a complex finger pattern in the membrane. We show that these findings are consistent with a thermodynamic description of tension induced pore formation.

4:42PM V63.00012: Arbitrary Lagrangian–Eulerian finite element method for biological lipid membranes*
AMARESH SAHU (Presenter), YANNICK OMAR, University of California, Berkeley, ROGER SAUER, Aachen Institute for Advanced Study in Computational Engineering Sciences, RWTH Aachen University, KRANTHI K MANDADAPU, University of California, Berkeley — We present an arbitrary Lagrangian–Eulerian (ALE) finite element method for arbitrarily curved and deforming lipid membranes. We provide a formalism to determine the equations of motion governing lipid membrane behavior using an irreversible thermodynamic analysis of curved surfaces. We develop an ALE theory by endowing the surface with a mesh whose in-plane velocity is independent of the in-plane material velocity, and which can be specified arbitrarily. The general isoparametric finite element implementation of the theory, based on an arbitrary surface parametrization with curvilinear coordinates, is used to model lipid membranes in several biologically relevant situations. A new physical insight is obtained by applying the ALE developments to cylindrical lipid membrane tubes: though lipid membrane tubes are stable, in the limit of vanishing bending rigidity (the limiting case of a fluid film) we numerically and analytically find tubes to be unstable with respect to long-wavelength perturbations when their length exceeds their circumference.

4:54PM V63.00013: Stretching induced disk-to-ribbon transition of chiral colloidal membranes*
LEROY JIA (Presenter), Brown University, ANDREW J BALCHUNAS, MARK J ZAKHARY, Brandeis University, ZVONIMIR DOGIC, UC Santa Barbara, ROBERT ALAN PELOCVITS, THOMAS POWERS, Brown University — Colloidal membranes are fluid monolayers consisting of rod-like virus particles held together by the depletion interaction. When optical tweezers are used to apply a diametric stretching force, these disks transform into twisted ribbons. We measure the force and pitch as functions of membrane extension and identify three distinct regimes of twisting. Assuming that the bending stiffness of the membrane is large, we also calculate the shape of the membrane as it deforms using a purely geometric theory that effectively incorporates liquid crystal degrees of freedom.

5:06PM V63.00014: Localization of flexural waves in randomly curved membranes  JONATHAN KERNES (Presenter), ALEXANDER JACOB LEVINE, Physics, Univ of California - Los Angeles — We consider the propagation of flexural waves across a thin membrane whose unstressed state has a quenched random geometry. Since the local curvature of the unstressed surface couples the mechanics of in-plane and out-of-plane displacements, flexural waves are scattered by these changes in the local geometry of the unstressed surface. Due to this effect we expect that flexural waves are localized by the random geometry of the surface. We investigate this localization phenomenon using the Donnell-Mushtari-Vlasov theory of membrane elasticity. We show that the energy density associated with flexural waves obeys a diffusion equation at long length and time scales. We observe that local curvature scatters flexural waves anisotropically, leading to a decrease in both the phase coherence length of the waves and the diffusion of their energy. Time-reversed interference corrections, i.e., coherent backscattering, is shown to reduce the diffusion coefficient logarithmically with system size, in agreement with general results for 2D localization. Finally, we consider a self-consistent calculation of the energy diffusion coefficient at high frequencies and use it to estimate the localization length.
FATEMEH AHMADPOOR (Presenter), GUIJIN ZOU, HUAJIAN GAO, School of Engineering, Brown University — Understanding the interaction of 2D materials including graphene-based nano-sheets, boron nitride and MoS2 with biological systems is a growing topic of interest to many applications such as biosensors, drug delivery, gene therapy and nanotoxicity. In this paper, we show that the interaction of 2D materials with cellular membranes at its early stage of approaching is dominantly controlled by entropic factors. Recent experiments indicate that graphene sheets, depending on their size, can either undergo a near-orthogonal cutting or a parallel attachment mode of interaction with cell membranes. Here we perform a theoretical statistical mechanics analysis as well as coarse-grained molecular dynamics simulations to characterize the entropic energy barrier for these modes of interactions. Our results indicate that micro-sized graphene sheets strongly prefer to approach cellular membranes through their sharp corners. In contrast, nano-sized sheets are likely to adhere to the membranesurface, instead of piercing through their sharp corners.

Session V64 DBIO GSOFT: Robophysics: Robotics Meets Physics II

2:30PM V64.00001: Microrobots as robophysical models for the study of biomechanics and control of small animals

[Invited] ROB J WOOD (Presenter), Harvard University — This talk will highlight our recent work on the development of physical models for the exploration of structure-function relationships in small animals (primarily arthropods), and for the development of robots that exhibit similar capabilities. Examples include centimeter-scale legged robots that help uncover gait strategies for high speed and robust locomotion on planar surfaces and for vertical and inverted climbing; ultra-fast power amplification mechanisms that produce rapid strikes and jumps; and insect-like flapping-wing robots used as a testbed for studies of fluid mechanics and under-actuated flight control. These models are enabled by the use of a multi-scale, multi-material fabrication paradigm, high bandwidth micro actuators, and detailed analytical, numerical, and experimental investigations. Robot complexity (e.g., measured by actuated degrees of freedom) typically decreases with reduced size. Our methods, however, buck this trend and allow us to create fully-actuated physical models that mimic key features of the biomechanics of the organisms in question. Furthermore, these robots serve as platforms for experimentation with novel sensors, computation architectures, and power solutions that all must reconcile strict size, weight, and power limits of these bioinspired devices with the desire to achieve similar capabilities as the organisms they are inspired by.

3:06PM V64.00002: Physics of animal and robot locomotor transitions in complex terrain

RATAN SADANAND OTHAYOTH MULLANKANDY, GEORGE S THOMS, CHEN LI (Presenter), Johns Hopkins University — Robots are still poor at traversing complex terrain like earthquake rubble and construction sites for applications like search and rescue and structural examination. By contrast, animals move through nature by transitioning between different forms of movement. This is largely due to a lack of understanding of the physics of locomotor transitions in complex terrain. Here, we propose locomotion energy landscape as a framework for understanding how macroscopic, self-propelled, legged locomotors physically interact with terrain to probabilistically transition between locomotor modes. By integrating animal and robophysical experiments and physics modeling, we discovered that: (1) Different locomotor modes have different “terradynamic favorability”, measured by the potential energy barrier that must be overcome to traverse using each mode; and (2) Kinetic energy fluctuation from body vibration, induced by seemingly wasteful, oscillatory leg movement, helps animals and robots overcome mode-separating potential energy barriers and transition from less favorable to more favorable modes. Our study is a step in establishing terradynamics of locomotion in complex 3-D terrain. Such physics-based terrain traversal complements geometry-based obstacle avoidance and expands the reaches of robots.
Giving Fish Robots a Pulse: Implementing Bio-inspired Control Algorithms in Fish Robots

STEPHEN HOWE (Presenter), HENRY ASTLEY, Biology, University of Akron — Most fish use undulatory locomotion to control forward swimming and direction change relying heavily on their body and caudal fin to produce the motions. This style of locomotion allows for robust locomotion across aquatic environments. As such they have been models for designing autonomous under water vehicles (AUVs). To date, fish robots have been designed to maneuver using two basic modes of turning. The first is a waveform offset in which the frequency and amplitude of the oscillation remain unchanged, but the entire wave is biased to the right or the left, causing the fish to favor bending in one direction. The second is akin to the C-start maneuver in fish, in which a maximum amplitude deflection is simultaneously applied to all joints of the body to one side, interrupting the typical locomotor body oscillations. We developed a new turning model based on observations from high speed videos of live Giant Danio (*Devario aequipinnatus*). These videos show that maneuvers consist of propagating pulses of curvature. These pulses are independent events and can be modeled as a transient wave with a speed, amplitude, and width. Using a 3D printed robot, we will be evaluating the performance of the pulse model alongside the offset wave and C-start methods.

Classroom Robophysics: Methods for teaching bioinspired design

MARIANNE ALLEYNE (Presenter), AIMO A WISSA, University of Illinois at Urbana-Champaign — In our Bioinspired Design course, students work in interdisciplinary teams to design engineering solutions based on biological analogies. Teams study core physics principles that enable biological functions and build prototypes to mimic these principles for applications in wearable technologies and robotics. Lectures cover current research in the area of bioinspiration, and the different design concepts and tools that can be used for bioinspired design. In this paper, we detail the approach the students undertake to distil the core physics principles and how to use them to create mechanical prototypes. The ultimate goal of the prototypes is to either solve an engineering challenge using lessons from nature, or to use engineering tools to study a biological phenomenon. In the course we present pedagogical tools to help students compare multiple organisms with similar functions but different underlying physics. Students are then asked to brainstorm different embodiments based on learned physics principles. They then apply design evaluation tools to choose the most suitable embodiment to solve the problem they identified at the start of the course. Students use their prototypes to verify that they captured the enabling physics rather than simply copying the superficial function.

Fabricating Autonomous Machines for the Cellular Scale

MARC MISKIN (Presenter), ALEJANDRO CORTESE, ITAI COHEN, PAUL L MCEUEN, Laboratory of Atomic and Solid State Physics, Cornell University — This talk presents a new approach for fabricating cell-sized robots that can explore their environment, be manufactured en masse, and carry the full power of silicon-based information technology. We fabricate 10 to 100 um walking robots that are powered and controlled wirelessly using embedded silicon photovoltaics. Our robots walk using a new class of voltage controllable, electrochemical actuators made from nanometer thick membranes of platinum. These actuators impose low power requirements yet can carry loads ten thousand times their own weight. Moreover, actuation only requires 200 mV signals, facilitating straightforward integration with silicon microelectronics. Combine, these results present a broad platform that can unite mechanical systems, information processing and control into autonomous robots that operate at the cellular scale.

4:06PM V64.00007: How to force an army of self-propelled mindless robots to act collectively? ANTOINE DEBLAIS (Presenter), Institute of Physics, University of Amsterdam, THOMAS BAROIS, THOMAS GUERIN, PIERRE-HENRI DELVILLE, REMI VAUDAIN, JUHO LINTUVUORI, JEAN-FRANÇOIS BOUDET, JEAN-CHRISTOPHE BARET, HAMID KELLAY, University of Bordeaux — We study assemblies of rodlike robots made motile through self-vibration. When confined in circular arenas, dilute assemblies of these rods act as a 2D gas of molecules. But above a critical surface fraction, some fraction of the bots line up in one or more tight clusters along the corral boundary while, in the bulk, gaslike behavior is retained. We find that the unified pushing of the cluster bots can drive collective motion: by selecting corrals that are deformable but free to move, we take advantage of surface cluster formation to force the robot army to work together.

KIRSTY WAN (Presenter), Living Systems Institute, University of Exeter, KELIMAR DIAZ CRUZ, YASEMIN OZKAN AYDIN, DANIEL GOLDMAN, Georgia Institute of Technology — Multi-legged animals exhibit several distinctive patterns of limb movements, or gaits. In most cases, rhythmic patterns of limb actuation are generated by neural circuits called central pattern generators (CPGs), which operate in the absence of external timing cues or higher-level input. However, the capacity to coordinate locomotion gaits is by no means a feature exclusive to vertebrates. Indeed, species of micron-sized, pond-dwelling algae were recently discovered to be capable of orchestrating the beating of their four whip-like flagella to produce swimming gaits reminiscent of the motor patterns of quadrupeds (Wan & Goldstein 2016). Here it is thought that coordination is driven by contractile elements within the algal flagellar apparatus, which fulfill the role of the vertebrate CPG. In order to understand this unique intracellular control of motility, we developed robots which modeled quadriflagellate swimming at low-Reynolds number, and systematically evaluated the hydrodynamic performance of distinct gaits, including the trot, pront, and gallop. Our results suggest a novel role of the algal cytoskeleton in providing mechanical stability during active flagellar beating.

4:30PM V64.00009: Body compliance helps snake robots traverse large steps QIYUAN FU (Presenter), CHEN LI, Johns Hopkins University — Snake robots still struggle to traverse complex 3-D terrain such as earthquake rubble and construction sites. By contrast, snakes traverse similar terrain like mountains and forests at ease. In both cases, how well the body engages the terrain is critical to successful traversal. Here, we use robophysical experiments to test the hypothesis that body compliance helps better engage and traverse complex 3-D terrain. We developed a snake robot with one-way wheels capable of traversing a large step using a partitioned gait that we recently discovered in snakes. An adjustable suspension was added to the wheels to vary compliance between the body and terrain. When traversing steps as high as 35 ± 3 % body length (BL), higher compliance allowed the suspension to compress more (from 1.0 ± 0.3 mm to 2.1 ± 0.6 mm) to better maintain contact with ground below and above the step (from 81 ± 8 % to 87 ± 5 % of the body), which increased traversal probability (from 63 ± 19 % to 90 ± 0 %) at the cost of 12 ± 6 % more power consumption (P < 0.05, ANCOVA). For larger step height (40% BL), however, the larger compression increased the chance of the rigid body edges being caught by the step corner. This is a limitation of the discrete robot body and highlights the need for a continuum compliant body.
It is well known in thermodynamics that viscosity-like dissipation external and internal disturbances. We explore the extent to which a learning-based approach can generate strategies that are robust to dynamics of the environment, we posit that the agents can learn transition probabilities to achieve an optimal digging probabilities based on their sensed environmental information. By varying the learning rules that rely on the local tunnel density via contact sensing, the robots can excavate more effectively by adjusting their behavior transition duration and timing of robot-robot contacts correlates with tunnel density. We hypothesize that with the ability to deduce sensing capabilities so that each robot can distinguish different kinds of contact; preliminary results suggest that the tunnels, in which maximal robot activity enables high performance. We have now augmented the robots with contact distribution strategy in mitigating clogs and jams in congested environments. This contrasts with a strategy for spacious swarm experiments and numerical/theoretical models demonstrated the importance of this unequal workload approximately 30% of the workers performed 70% of the digging [Aguilar et al, PNAS 2015]. With data from sidewinders interacting with pegs embedded in sand and a robophysical model, we investigate a peg-snake interaction where the animal forms a static contact with the substrate at an anatomical point anterior to the peg. This interaction mode facilitates "squeezing" the posterior body sections past the peg. Using a copper foil wrapped peg and 7 capacitive sensors along the 14-joint robot, we tested passive and active obstacle-clearing control templates. Early data shows the robot actively clears a peg using an increase in lateral wave amplitude or a reversal turn. When setting the multiphase undulations to produce two wavelengths along the robot's body, the robot passively clears the peg if the peg interacts with a region of the robot's body closest the head. These results will generate hypotheses for control strategies based on muscle activation patterns involved in sidewinding (Jayne, J. exp. Biol. 1988).

Flying insects may achieve energy efficient flight by storing and releasing elastic energy in their thorax and muscle. Similarly, flapping wing micro-aerial vehicles (FWMAVs) may benefit from inclusion of elastic components in their actuation system. Despite significant investigation into the aerodynamics of flapping wings, the actuation of these movements through elastic structures in insects and robots is relatively unexplored. We have developed a dynamically-scaled robophysical experiment to study the dynamics of series-elastic flapping wings, with specific emphasis on discovering the role of linear and nonlinear elastic components in energy efficiency, perturbation resistance, and control. We vary system (elasticity) and actuation (amplitude and frequency) parameters and find that energy storage and recovery by an elastic element is dependent upon the stiffness of the element and upon the driving amplitude, frequency, and stroke profile. System response experiments suggest that the inclusion of series-elastic elements may have a negative overall effect on control capabilities. The results of the project will inform the design of future FWMAVs, providing insight into elastic element selection, power requirements, and control design.

Flying insects may achieve energy efficient flight by storing and releasing elastic energy in their thorax and muscle. Viscous friction-like relationship arises from a simple Columb friction locomotion model

Learning Multi-agent Workload Distributions in Confined Excavation

5:18PM V64.00013: Learning Multi-agent Workload Distributions in Confined Excavation* KEHINDE AINA (Presenter), Georgia Institute of Technology, LEWIS CAMPBELL, Morehouse College, HUI-SHUN KUAN, Max Planck, M. BETTERTON, UC Boulder, DANIEL GOLDMAN, Georgia Institute of Technology — Our recent work with collective fire ant tunnel excavation revealed that approximately 30% of the workers performed 70% of the digging [Aguilar et al, Science 2018]. Complementary robot swarm experiments and numerical/theoretical models demonstrated the importance of this unequal workload distribution strategy in mitigating clogs and jams in congested environments. This contrasts with a strategy for spacious tunnels, in which maximal robot activity enables high performance. We have now augmented the robots with contact sensing capabilities so that each robot can distinguish different kinds of contact; preliminary results suggest that the duration and timing of robot-robot contacts correlates with tunnel density. We hypothesize that with the ability to deduce local tunnel density via contact sensing, the robots can excavate more effectively by adjusting their behavior transition probabilities based on their sensed environmental information. By varying the learning rules that rely on the local dynamics of the environment, we posit that the agents can learn transition probabilities to achieve an optimal digging performance. We explore the extent to which a learning-based approach can generate strategies that are robust to external and internal disturbances.

2:30PM V65.00001: Amphiphilic nanoparticles can modify lipid membrane permeability*  
MUKARRAM TAHIR (Presenter), ALFREDO ALEXANDER-KATZ, Massachusetts Institute of Technology — Lipid bilayers are the structural foundation of biological membranes and contain a characteristic hydrophobic interior that prevents passive permeation of water and other polar molecules. Proteins embedded in these membranes controllably modify these barrier properties by allowing selecting transport in response to environmental stimuli. Previous work from our group has demonstrated that a certain class of nanoparticles can assume a transmembrane configuration similar to these protein channels, and that charged ligands grafted to these nanoparticles can cross the hydrophobic interior of the membrane at an anomalous rate. In this work, we use molecular dynamics simulations to demonstrate that this ligand flipping behavior is associated with transient water transport across the membrane and can be exploited for altering the permeability of lipid membranes to water and charged solutes. Through a combination of free energy analysis and unbiased simulations, we reveal that this gating ability is sensitive to membrane tension, allowing these nanoparticles to function as synthetic mimics of mechanosensitive membrane channels, and have potential applications ranging from single-cell therapeutics to novel methods of water desalination.

2:42PM V65.00002: Direct observation of topological turbulence in the oocyte membrane  
JINGHUI LIU (Presenter), TZER HAN TAN, PEARSON WHITEHEAD MILLER, MELIS TEKANT, Physics, Massachusetts Institute of Technology, JOERN DUNKEL, Mathematics, Massachusetts Institute of Technology, NIKTA FAKHRI, Physics, Massachusetts Institute of Technology — Living systems self-organize local interactions into global structures and dynamics. Despite prevalence of such features across biological entities, the underlying self-organization principles have not been fully understood. Here we report on direct observation of a class of biochemical patterns formed during early development in starfish oocytes. The observed patterns maintain long-live structures despite short molecular turn-over times, and each pattern has distinguishing wavelength and orientation in spite of sharing the same local interaction rules. Through field analysis, we find that phase singularity dynamics in the chemical field dominates evolution of observed patterns. The pair interactions between the point singularities drive topological turbulence in phase velocity field. Such topological turbulence shares the same characteristic vortex size across observed patterns, reminiscent of quantum turbulence feature. An Onsager vortex model with pairwise interaction potential captures the essential features of the experimentally observed phase singularity dynamics. We propose topological turbulence in phase velocity field underlies dynamics of the observed self-organized biochemical patterns, propagating order from local molecular to global cellular scales.

2:54PM V65.00003: Physical Models of Proton-Pumping Complexes of Mitochondria Membranes*  
LEV MOUROKH (Presenter), Physics, Queens College of CUNY, MICHELE VITTADELLO, Chemistry, Medgar Evers College of CUNY — The models are proposed for all three proton-pumping complexes. The model for Complex IV includes the electron source, electron drain, and three electron sites in between, as well as proton source, proton drain and three proton sites in between. Electon transport occurs along the inner mitochondria membrane and the protons are transferred across the membrane. The chemical potential of the electron source is larger than that of the electron drain, while the protons are pumped to the higher potential. The middle electron and proton sites are in the close proximity, so their electrostatic interaction facilitates the energy transfer. We suggest that in Complex I the energy exchange is mediated by the conformational changes. In both cases, we use the methods of condensed matter and statistical physics to derive quantum equations of motion for the electron and proton operators in the presence of protein environment and to calculate the electron and proton currents. In the model of the Complex III, we couple the equations of motion to phenomenological Langevin equation describing electron and proton transport by quinons.

**3:06PM V65.00004: Nanovesicles versus Nanoparticle-Supported Lipid Bilayers: Differences in Equilibrium Structures and Properties Unraveled by Molecular Dynamics Simulations**

HAOYUAN JING (Presenter), YANBIN WANG, PARTH RAKESH DESAI, University of Maryland, College Park, KUMARAN RAMAMURTHI, National Cancer Institute, National Institute of Health, SIDHARTH DAS, University of Maryland, College Park — Molecular Dynamics (MD) simulations are conducted to unravel the equilibrium properties of the nanoparticle-supported lipid bilayers (NPSLBs) in atomistic details and the findings are compared with that of the similar-sized nanovesicles (NVs). Three key differences emerge. First, the NV is found to contain significantly larger number of lipid molecules in the outer layer/leaflet, while the NPSBL has equal number of lipid molecules in inner and outer layers. Second, for the NV the lipid molecules in the outer and inner layers showed identical diffusivities, while for the NPSBL the diffusivity of the lipid molecules in the outer layer was more than double than that of in the inner layer. Finally, the nanoconfined water (located in the cavity for the NV, while being present as a few layers between the inner leaflet and the NP core for the NPSBL) showed much lesser diffusivity for the NPSBL as compared to that for the NV. The findings will be key to better understand the structure of this important nanomaterial (namely NPSBL) with applications in a plethora of disciplines ranging from targeted drug and gene delivery to characterization of curvature-sensitive biomolecules.

**3:18PM V65.00005: Microfluidic Generation of Giant Lipid Vesicles with Membrane Protein Reconstitution**

ANQI CHEN (Presenter), YUTING HUANG, DAVID A WEITZ, Harvard University — Giant unilamellar lipid vesicles (GUV) are clean experimental models to study the biophysical mechanisms of biomembranes and transmembrane proteins from a quantitative point of view. Traditional generation methods of GUVs like rehydration or electroswelling produce vesicles with a wide size and composition distribution. These drawbacks limit experiment accuracy, and thus hinder the capacity of experiments to validate theoretical models in lipid membrane biophysics. Here we present a microfluidic emulsion template method to generate monodispersed lipid vesicles with transmembrane protein reconstitution. Compared to other emulsion-templated methods, our protocol allows a wider range of lipid choices, eliminates the influence of residual solvents, requires a shorter incubation time for solvent evaporation, and supports fabrication of lipid vesicles with more complicated structures. Our method opens up opportunities for more quantitative lipid membrane-related experiments and are also potential candidates in synthetic biology constructions.

*We acknowledge NSF Collaborative Research Grant DMR-1705775 for supporting this project.*

**3:30PM V65.00006: Thermodynamic equilibrium of lipid mixtures on curved substrates**

PIERMARCO FONDA (Presenter), LUCA GIOMI, DANIELA JUTTA KRAFT, MELISSA RINALDIN, Leiden University — It has been known since long that thermodynamic stability of two-dimensional lipid mixtures is influenced by curvature. Inspired by recent experimental results on lipid membranes coated on colloidal scaffolds, we propose a simple and general framework for interpreting the phase diagram of inhomogeneous closed systems. When the critical behaviour of a system is affected by its shape, we further show how new thermodynamic states can arise in the phase diagram, where lipids are in a mixed phase yet exhibit strong lateral segregation. We prove how different types of inhomogeneous couplings must induce qualitatively different phenomena - such as a curvature dependent line tension - and thus provide a way to distinguish different types of curvature interactions.

**3:42PM V65.00007: Numerical simulations of intracellular membranes of high genus**

DAVID YLLANES (Presenter), Chan Zuckerberg Biohub, GEORGE LYKOTRAFITIS, Department of Mechanical Engineering, University of Connecticut, GREG HUBER, Chan Zuckerberg Biohub — Bilayer membranes within eukaryotic cells adopt dynamic geometries of extraordinary complexity and interdependency. Examples include the continuous vesicular traffic of the endocytic and secretory pathways, the layers of the Golgi apparatus, the inner membranes of mitochondria, and the sheets, tubes, and, indeed, the nuclear envelope itself, comprising the endoplasmic reticulum. Some of these have topological genus zero (or near zero) while others have very high genus.

We use a coarse-grained molecular dynamics (CGMD) model to study the mechanics of intracellular membranes with complicated geometries. In particular, we investigate the behavior of pores in sheets, and how junctions of sheets organize and interact.

*Simulations carried out on the Cierzo supercomputer (BIFI-ZCAM, Spain). We acknowledge funding by FIS2015-65078-C2-1-P (MINECO, Spain and FEDER, EU).
3:54PM V65.00008: Simulation of the passive permeation of potassium ion through phospholipid membranes: Thermodynamics and kinetics*  
ARMAN FATHIZADEH (Presenter), RON ELBER, University of Texas at Austin — Here we revisit the problem of passive ion permeation through a phospholipid membrane and find new rich mechanisms that were not captured in earlier investigations by introducing new coarse variables. Numerous experimental and simulation studies have been performed on passive permeation through membranes. Most of simulation studies only consider one reaction coordinate that is the vertical position of the center of mass of the permeant with respect to the center of mass of the membrane. However, when the permeant is positively charged, it interacts strongly with the phosphate groups and permeation is accompanied by significant distortions of the membrane. To model their distortion of the membrane, we introduce two new coarse variables: the minimal distances of the positively charged group from the phosphate groups of each leaflet. We illustrate the efficiency of this new set of coarse variables on permeation of a single potassium ion. Using Milestoning, we were able to calculate free energy landscape, mean first passage time, and the permeability of the ion in the space of the two new coarse variables. The results compared favorably to the available experimental data.

4:06PM V65.00009: Assembly of mechanosensitive channels can regulate whole cell volume*  
SMITHA HEGDE (Presenter), Centre for Synthetic and Systems Biology, School of Biological Sciences, University of Edinburgh, ALEXANDRU PARASCHIV, ANDELA SARIC, Department of Physics and Astronomy, Institute for the Physics of Living Systems, University College London, TEUTA PILIZOTA, Centre for Synthetic and Systems Biology, School of Biological Sciences, University of Edinburgh — E.coli's membrane embedded mechanosensitive channels (MSC) protect them from bursting when the intracellular osmotic pressure increases due to hyposmotic shock. MSC sense an increased membrane tension and respond by opening a large pore to passively let out cytoplasmic solutes. Using epifluorescence microscopy to look at single E.coli cells, we previously demonstrated that upon a hyposmotic shock cells rapidly swell due to water diffusion into the cytoplasm. Subsequently, MSC open to recover cell volume and osmotic pressure by solute efflux which lasted up to few minutes. Our phenomenological model explained the observed dynamics, however, could not capture large cell-to-cell variability. So, we propose a coarse-grained model which considers MSC dynamic aggregation and incorporate into the phenomenological model. Results suggests that MSC cluster at lower membrane tensions and disaggregate at higher membrane tensions, altering MSC's opening probability, which also depends on tension. Additionally, we constructed a hepta-mutant (all 7 MSC genes deleted) and show that upon hyposmotic shock, the mutant swells but fails to recover cell volume; we illustrate the cells' survivability and dynamics of death when they fail to restore internal pressure.

*Darwin Trust of Edinburgh and IBioIC

4:18PM V65.00010: Membranes and Machine Learning: Designing a Model of Antibiotic Activity to Bypass Gram Negative Membranes and Efflux Pumps  
RACHAEL MANSBACH (Presenter), CESAR LÓPEZ, NICOLAS HENGARTNER, Theoretical Biology and Biophysics, Los Alamos National Lab, HELEN ZGURSKAYA, Chemistry and Biochemistry, University of Oklahoma, S GNANAKARAN, Theoretical Biology and Biophysics, Los Alamos National Lab — Due to the growing prevalence of antibiotic-resistant bacteria, there is a pressing need for rapid design of new antibiotics with unique modes of action. Gram negative bacteria in particular pose a thorny problem for antibiotic design due to the combined effects of their impermeable outer membranes and their antibiotic-removing efflux pumps. We employ a combined theoretical and experimental approach to understand the limiting factors on antibiotic efficacy in *P. aeruginosa* and rationally design experiments to rapidly zero in on promising antibiotic candidates. By using machine learning to identify a relevant subset of descriptors produced by simulation and experiment for predicting experimentally-measured minimum inhibitory concentrations of different antibiotic candidates, we are able to learn a self-consistent model of antibiotic retention based on a simple kinetic approximation. We separately employ a Gaussian process regressor to direct a search for antibiotic candidates with optimal experimental and simulated properties. This work leads to heightened understanding of the qualities important to antibiotic retention in Gram negative bacteria and offers a simple way to narrow the experimental design space of antibiotic candidates, allowing for rapid, high-throughput screening.
4:30PM V65.00011: Diffusion Rate of Cholesterol through a Single Lipid Bilayer* YANGMINGYUE LIU, MICHAEL STANFIELD (Presenter), NETI BHATT, ARTHUR RALKO, WONWHA CHO, JUSTIN LORIEAU, URSULA PEREZ-SALAS, University of Illinois at Chicago — Our lab has measured the rate and energetics of the intramembrane diffusion (flip-flop) of the steroid-lipid cholesterol using small angle neutron scattering (SANS) and found that the diffusion rate was much slower (hundreds of minutes) than the accepted value (under a second). Our work showed that the discrepancy was due to artifacts produced by differences between cholesterol and its analogues or by the use of compounds, like cyclodextrin, that, our group argued, disrupts the membrane. Our results were based on measurements in which cholesterol flip-flop within the membrane occurred while cholesterol was also diffusing between different membranes (exchange). So, our team has been taking steps to eliminate exchange from the measurement, thus measuring the flip-flop diffusion rate directly. We used a new method to craft an asymmetric distribution of cholesterol in the lipid bilayers of unilamellar vesicles to measure the rate at which cholesterol diffuses through the bilayer. We used orthogonal cholesterol sensors, nuclear magnetic resonance spectroscopy (NMR), and SANS in order to follow the change of cholesterol’s distribution within the bilayers as a function of time and temperature.

*We thank CAREER award DMR-1753238 and UIC’s LASURI award for funding.

4:42PM V65.00012: Real-time measurements of lipid domain rearrangements, membrane thickness, and intermembrane forces during membrane hemifusion* KAI KRISTIANSEN (Presenter), DONG WOOG LEE, University of California, Santa Barbara, STEPHEN DONALDSON, Physics, Ecole Normale Superieure, NICHOLAS CADIROV, University of California, Santa Barbara, XAVIER BANQUY, Pharmacy, Universite de Montreal, JACOB ISRAELACHVILI, University of California, Santa Barbara — We have developed a Fluorescence Surface Forces Apparatus (FL-SFA), which can fluorescently image the surfaces while measuring interaction forces and distance between surfaces in real-time. Using the FL-SFA, hemifusion of two supported model lipid bilayers was monitored. At the membrane-membrane contact, the localization of liquid disordered phases and depletion of liquid ordered domains are observed during lipid membrane hemifusion. Interaction forces and lipid membrane thicknesses are simultaneously measured together with the fluorescence images of model membranes. The results show that the domain rearrangements decrease the energy barrier to fusion illustrating the significance of dynamic domain transformations in membrane fusion processes. Importantly, the FL-SFA can unambiguously correlate interaction forces and in situ imaging in many dynamic interfacial systems.

*This study was research-supported by the US Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02-87ER-45331.

4:54PM V65.00013: Influence of Pressure-Induced Fluid Flow on DNA Translocation Dynamics in Solid-State Nanopores* KUN LI (Presenter), DEREK STEIN, Brown University — We studied the translocation dynamics of DNA through solid-state nanopores under the influence of an electrokinetic driving force and a pressure-driven fluid flow. Through the use of long, λ-DNA molecules, we sought to probe conformation-dependent translocation modes that were not observable in the pioneering experiments of Lu et al. (Nano Lett. 2013 Jul 10; 13(7): 3048–3052) on short molecules. We fabricated nanopores in 10-nm thick SiN membrane using the controlled dielectric breakdown (CBD) technique, which gave useable nanopores about 90% of the time. Then a pressure difference was applied across the nanopore to provide a drag force to counter the electrokinetic driving force. We monitored the disruptions of the ionic current through the nanopore and studied the influence of the applied pressure on the distribution of translocation times and the integrated charge deficits (ECDs) of λ-DNA translocations. We present the results of measurements with applied pressures ranging from 0 to 300 kPa and a theoretical analysis that models the initial polymer configurations and the fluid and electrokinetic force profiles.

**5:06PM V65.00014: Improving membrane protein expression by optimizing simulated integration efficiency**

MICHIEL NIESEN (Presenter), Chemistry, MIT, THOMAS MILLER, Caltech — Integral membrane proteins (IMPs) are critical for the transport of information and matter across the cell membrane. However, their study is often hindered by difficulties in obtaining sufficient purified IMP using heterologous overexpression.

Co-translational insertion into the cell membrane via the Sec translocon is a key step in the production of IMPs. However, both experimental and computational studies of this process are difficult due to the role of long-timescale non-equilibrium dynamics during ribosomal translation. We have developed a coarse-grained molecular dynamics (CGMD) approach that is capable of reaching experimentally relevant (i.e. minute) timescales, while retaining the level of detail required to capture the effect of individual amino-acid substitutions.

Using a combination of simulations of IMP integration and experimental quantification of IMP expression levels; we demonstrate a link between the efficiency of IMP integration into the cell membrane and IMP expression, yielding a powerful tool for the rational prediction of sequence modifications that improve expression.

---

**5:18PM V65.00015: A Biophysical Model of Intermediate Phases in Developing Cell Plates.**

MUHAMMAD ZAKI JAWAID (Presenter), GEORGIA DRAKAKAKI, DANIEL LEE COX, University of California, Davis — Plant cell cytokinesis is a fascinating process that involves the formation of a cell plate via a homotypic fusion of vesicles. Cell plate formation depends on organized vesicle delivery, accumulation, fusion, and membrane maturation, along with the timely deposition of polysaccharides such as callose, cellulose, and cross-linking glycans. One unanswered question is the role of callose in cell plate formation.

We hypothesize that callose deposition produces an anisotropic driving force that acts along the periphery of the cell plate. A biophysical model based on the Helfrich general shape equation is presented to explain flat regions within the developing cell plate. The increase in callose deposits is reflected in the increase of membrane area and the anisotropic driving force. By postulating a force per callose polymer of 0.25-0.3pN, as well as an osmotic pressure difference of 0.01MPa and a finite surface tension of 0.0014N/m, we can achieve stable disks of radius 80-100nm, in agreement with observed sizes corresponding to intermediate stages of plate development.

**2:30PM V66.00001: RNA virus evolution and the predictability of next year's flu**

[Invited] RICHARD NEHER (Presenter), Biozentrum, University of Basel — RNA viruses like HIV of influenza virus evolve rapidly and thereby evade human immunity. We have performed whole genome deep sequencing of longitudinal samples spanning 5-10 years from acute to chronic HIV infection. From these data, we estimate the landscape of fitness costs at every nucleotide in the genome and characterize the the complex dynamics of immune escape and reversion. Similarly, influenza viruses change their antigenic properties rapidly and the seasonal influenza vaccine needs to be updated whenever the viruses change antigenically. We show how sequence data can be used predict which influenza virus variants are most likely to succeed and circulate in future seasons. These predictions use theoretical insights into the structure of genealogies of rapidly adapting populations and are provided in near real-time at nextflu.org.
3:06PM V66.00002: Single nucleotide mapping of locally accessible trait space in evolving yeast [Invited]  
YUPING LI, Genetics and Biology, Stanford University, GAVIN SHERLOCK, Genetics, Stanford University, DMITRI PETROV (Presenter), Biology, Stanford University — Tradeoffs constrain the improvement of performance of all traits simultaneously. Such tradeoffs define a Pareto optimality front that represents a set of optimal individuals that cannot be improved in any one trait without reducing performance in another trait. While widely assumed, direct experimental evolutionary approaches often fail to detect tradeoffs with many experiments generating individuals that improve performance in all measured traits. Moreover, even when an improvement in one trait is found to be associated with the loss of performance in another, it is hard to establish that such a negative correlation is not induced by the specific features of sampled mutations and that other possible adaptive mutations cannot escape such apparent tradeoffs. Here we detect tradeoffs and define the Pareto optimality front in the context of short-term evolution of *S. cerevisiae* in glucose-limited media. We have evolved barcoded yeast populations under several conditions, with each condition selecting for improved performance in different parts of the yeast growth cycle. By isolating hundreds of adaptive clones and quantifying their performances in each growth part of the cycle, we defined tradeoffs between performances in fermentation and respiration and respiration and stationary phase. Importantly, due to the large numbers of the studied clones we were able to claim that no single point mutation in the yeast genome can improve the performance beyond either of the defined optimality fronts. We found that in both cases the shape of the optimality front is convex suggesting the possibility of short term evolution to select for generalists. Finally, by sequencing hundreds of adaptive clones, we identified the molecular basis underlying identified trade-offs and revealed novel targets of adaptation.

3:42PM V66.00003: Tracking pathogenetic bacteria at the plasmid, genome, and pan-genomic level.*  
NICHOLAS NOLL (Presenter), RICHARD NEHER, Biozentrum, University Basel — The rapid global increase of multidrug-resistant organisms presents a major global health threat that will dramatically reduce the efficacy of antibiotics and thus constrain the number of effective treatments available to patients. As opposed to analogous efforts in viral epidemiology, accurate reconstruction of the pandemic spread of antibiotic resistance remains intractable for reasonable sample sizes due, in large part, to the high rate of homologous recombination and horizontal gene transfer that prevents the application of traditional phylogenetic approaches. Lastly, complete assemblies are a prerequisite to such quantitative study.

In this talk, I will present a novel computational framework for bacterial evolution that generalizes the traditional linear reference genome to a pan-genomic non-planar graph. Using this framework, I will analyze 120 antibiotic resistant genomes collected in Basel, Switzerland over the course of a decade, sequenced with both ONT and Illumina data. We show that the evolution of antibiotic resistance exhibits a nested doll structure in which genetic transposition, homologous recombination, and clonal expansion occur at similar time-scales.

*University of Basel

3:54PM V66.00004: Investigating the role of hemagglutinin protein stability in influenza A evolutionary dynamics*  
CHADI SAAD-ROY (Presenter), Lewis-Sigler Institute for Integrative Genomics, Princeton University, YIGAL MEIR, Department of Physics, Ben-Gurion University of the Negev, BRYAN T GRENFELL, SIMON LEVIN, Department of Ecology and Evolutionary Biology, Princeton University, NED WINGGREEN, Lewis-Sigler Institute for Integrative Genomics, Princeton University — Influenza A viruses (IAVs) cause a significant burden to human populations. They are notable for their rapid evolution arising from error-prone RNA polymerases in conjunction with selective pressures from hosts. Most host immune responses target the surface protein hemagglutinin (HA) and typically generate lifelong antibodies to seen strains. Thus to survive, IAVs must undergo mutations in HA that allow immune escape, while the HA protein must also satisfy functional constraints. We formulate a mathematical model of IAV evolution and transmission that spans scales from molecular to population processes. We couple models for HA protein thermal stability, mutation, and cross-immunity with a population-level model for the spread of infection, and characterize the effects of stability. Certain residues buried in the core of the HA protein may affect stability but not immunogenicity. We adapt our model to include these "buried" residues, and evaluate their influence on viral diversity, transmission, and evolutionary dynamics.

4:06PM V66.00005: Dynamics of lineage diversity during adaptation to weak antibiotic pressure

MICHAEL MANHART (Presenter), Harvard University and ETH Zurich, JESSE LERNER, WERONIKA JASINSKA, Ben-Gurion University of the Negev, ADRIAN SEROHJOS, University of Montreal, SHIMON BERShteIN, Ben-Gurion University of the Negev —

Tracking low-frequency lineages in large microbial populations is key to fully elucidating their evolutionary dynamics, especially under weak selection pressures and short time scales. However, resolution is often limited by methods for labeling lineages or whole-genome sequencing. To overcome this challenge, we introduce a large library of random DNA barcodes into *E. coli*, allowing us to track lineages down to tens or hundreds of cells. We observe two distinct phases of lineage dynamics during adaptation to low levels of antibiotics. During the first phase, the diversity of lineages undergoes a rapid and predictable drop which is characteristic of the drug and concentration. In particular, we find that low amounts of trimethoprim actually slow down the loss of diversity compared to the absence of drug. This initial loss of diversity appears to be driven by selection on standing genetic variation, leading to groups of lineages rising or falling together both within and between populations. During the second phase of dynamics, new mutations arise on these lineages, leading to clonal interference. Lineage diversity then stabilizes at a low but nonzero level, which appears to be universal across conditions despite the variation in initial dynamics.

4:18PM V66.00006: Testing the Retroelement Invasion Hypothesis for the Emergence of the Ancestral Eukaryotic Cell

GLORIA LEE, NICHOLAS SHERER, NEIL KIM, DAVNEET KAUR, K MICHAEL MARTINI, CHI XUE, NIGEL GOLDENFELD, Physics, University of Illinois at Urbana-Champaign, THOMAS KUHLMAN (Presenter), Physics and Astronomy, University of California Riverside —

Phylogenetic evidence suggests that the ancestral eukaryotic cell emerged as a result of invasion and proliferation of retroelements, selfish mobile genetic elements that copy and paste themselves within a host genome. Here we test this hypothesis by determining the pressures retroelements exert on simple genomes. We transferred two retroelements, human LINE-1 and the bacterial group II intron LL1.LtrB, into bacteria, and find that both are functional and detrimental to growth. We find, surprisingly, that retroelement lethality and proliferation is enhanced by the ability to perform eukaryotic-like nonhomologous end-joining (NHEJ) DNA repair. We show that the only stable evolutionary consequence in simple cells is maintenance of retroelements in low numbers, and that retrotransposition in eukaryotes must be finely tuned to allow proliferation.

4:30PM V66.00007: Physical Constraints on Epistatic Interactions

KABIR HUSAIN (Presenter), ARVIND MURUGAN, James Franck Institute —

Epistasis, or the context-dependence of mutations, makes evolutionary trajectories difficult to predict. Here, we argue that knowledge of the physics of a system can tame its apparent evolutionary complexity. We focus on proteins, inspired by recent work on low-energy mechanical modes of bio-inspired, functional mechanical networks. Mutations in the sequence of a protein affect its shape, thereby modulating the effect of subsequent mutations; we find epistatic interactions at all probed orders. However, the structure of deformations limits the number of independent epistatic parameters. We find that such constrained epistasis is reflected in the topology of the fitness landscape. In addition to providing a mechanistic basis for experimentally observed epistatic couplings in proteins, we demonstrate how similar considerations may constrain epistasis in other complex systems.

4:42PM V66.00008: Effects of clonal interference on adaptation in a fixed fitness landscape

YIPEI GUO (Presenter), ARIEL AMIR, Harvard University —

Adaptation in a fixed environment, where as a population evolves its fitness increases, is typically thought of as a hill climbing process on a fitness landscape. On a fitness-parameterized landscape, the fitness trajectory depends on the statistics of mutation effects and how they vary with current fitness ('macroscopic epistasis'). Results on fitness-parameterized landscapes are typically obtained in the strong selection, weak mutation regime, where mutations fix or go extinct sequentially. In a large population, while the phenomenon of clonal interference is known to slow down the rate of evolution, it is unclear how the shape of the fitness trajectory is affected. Here, we investigate the effects of clonal interference on fitness evolution on various fitness landscapes, including ones that explicitly takes into account microscopic epistasis between mutation sites.
Disentangling effects of genetic linkage on estimates of selection in intrahost HIV evolution
MUHAMMAD S SOHAIL, Department of Electronic and Computer Engineering, Hong Kong University of Science and Technology, RAYMOND H Y LOUIE, University of New South Wales, Kirby Institute, MATTHEW R MCKAY, Department of Electronic and Computer Engineering, Hong Kong University of Science and Technology, JOHN BARTON (Presenter), Department of Physics and Astronomy, University of California, Riverside — The evolutionary history of a population contains information about the underlying forces driving population diversity and adaptation. However, it is difficult for current methods to disentangle the effects of individual mutations from complex evolutionary dynamics. Here we describe a method to infer selection from genetic time-series data while also accounting for the confounding effects of genetic linkage, using a path integral approach based in statistical physics. We apply this method to investigate within-host HIV-1 evolution at the half-genome scale. Our approach reveals selective pressures for escape from human immune responses. Due to clonal interference between escape mutants, we find that accounting for genetic linkage is crucial to infer realistic estimates of selection. Our ability to account for genetic linkage is also critical for insight into complex evolutionary scenarios, highlighted by a struggle for dominance between co-infecting strains of the virus in an individual who ultimately develops broadly neutralizing antibodies.

Dynamics of within-host evolution and strain replacement in the human gut microbiome
BENJAMIN GOOD (Presenter), Physics and Bioengineering, University of California, Berkeley, NANDITA R GARUD, Gladstone Institutes, OSKAR HALLATSCHEK, Physics and Integrative Biology, University of California, Berkeley, KATHERINE S POLLARD, Gladstone Institutes — The human gut contains trillions of rapidly reproducing bacteria, making it a potential hotbed of within-host evolution. While the species-level dynamics in the gut have been extensively studied, we currently know very little about the evolutionary dynamics that take place within individual species. In this talk, I will discuss our recent efforts to measure the statistical properties of within-host evolution from a large panel of human gut metagenomes. Our analysis shows that on short timescales, genetic differences are only rarely caused by the invasion of distantly related strains. Resident strains more commonly acquire putative evolutionary changes, in which small numbers of nucleotide variants or gene content differences rapidly sweep to high frequency within a host. However, comparisons of adult twins suggest that strain replacement eventually overwhelms evolution over multi-decade timescales, hinting at fundamental limits to the extent of local adaptation. Together, our results show that gut bacteria can evolve on human-relevant timescales, and they provide key empirical constraints necessary for future modeling efforts.

Tuning Evolution Towards Generalists Through Resonant Environmental Cycling
VEDANT SACHDEVA (Presenter), Graduate Program in Biophysical Sciences, University of Chicago, KABIR HUSAIN, James Franck Institute, University of Chicago, SHENSHEN WANG, Department of Physics and Astronomy, University of California, Los Angeles, ARVIND MURUGAN, James Franck Institute, University of Chicago — Natural environments can present diverse fitness pressures, but some genotypes remain fit across a wide range of challenges. Such 'generalist' genotypes can be hard to evolve because there may be entropic or absolute fitness costs relative to specialist genotypes. Here, we study the conditions under which time-dependent evolutionary protocols stabilize generalists even when static protocols fail. We find that cycling environments on timescales tuned to match fixation times can reliably evolve generalists when the landscape is too rugged, or deleterious selection too adverse, for static protocols to succeed. We discuss 'chirp' protocols that circumvent the need for protocol fine-tuning. Our work reveals regimes in which time-dependent 'seascapes' can find and stabilize populations around genotypes that are fundamentally unstable in any static protocol.

5:45PM W70.00001: From Nonlinear Optics to High-Intensity Laser Physics [Invited]  DONNA STRICKLAND (Presenter), University of Waterloo — With the invention of lasers, the intensity of a light wave was increased by orders of magnitude leading to new phenomena being observed like violet light coming out when red light went into the material. The laser intensity increased dramatically again with the development of Chirped Pulse Amplification, which created short, intense pulses of light that kicked electrons off their atoms. This new high-intensity laser matter interaction lead to new laser machining techniques that are now commonly used in eye surgery.

6:21PM W70.00002: Passion Extreme Light [Invited]  GERARD MOURO (Presenter), Ecole Polytechnique — Extreme-light laser is a universal source providing a vast range of high energy radiations and particles along with the highest field, highest pressure, temperature and acceleration. It offers the possibility to shed light on some of the remaining unanswered questions in fundamental physics like the genesis of cosmic rays with energies in excess of $10^{20}$ eV or the loss of information in black-holes. Using wake-field acceleration some of these fundamental questions could be studied in the laboratory. In addition, extreme-light makes possible the study of the structure of vacuum and particle production in "empty" space which is one of the field's ultimate goal, reaching into the fundamental QED and possibly QCD regimes. Looking beyond today's intensity horizon, we will introduce a new concept that could make possible the generation of attosecond-zeptosecond high energy coherent pulse, de facto in x-ray domain, opening at the Schwinger level, the zettawatt, and PeV regime; the next chapter of laser-matter interaction.

Session X01 DCMP: Integer Quantum Hall Effect BCEC 106

8:00AM X01.00001: Landau Velocity for Collective Quantum Hall Breakdown in Bilayer Graphene*  HOLGER GRAEF (Presenter), WEI YANG, Laboratoire Pierre Aigrain, Paris, France, XIAOBO LU, GUANGYU ZHANG, Beijing National Laboratory for Condensed Matter Physics, Beijing, China, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Tsukuba, Japan, ADRIAN BACHTOLD, ICFO, Barcelona, Spain, EDWIN HANG TONG TEO, Nanyang Technological University, Singapore, EMMANUEL BAUDIN, ERWANN BOCQUILLON, GWENDAL FÈVE, JEAN-MARC BERROIR, Laboratoire Pierre Aigrain, Paris, France, DAVID CARPENTIER, ENS Lyon, Lyon, France, MARK OLIVER GOERBIG, Université Paris Saclay, Orsay, France, BERNARD PLAÇAIS, Laboratoire Pierre Aigrain, Paris, France — Breakdown of the integer quantum Hall effect (QHE) is associated with an electric field approaching the inter-Landau-level (LL) Zener field, ratio of the Landau gap and the cyclotron radius. The intrinsic Zener limit, corresponding to critical drift velocity, is reported here [1] using high-mobility bilayer graphene and high-frequency shot noise [2] over a large number of LLs. The steep onset of shot noise at breakdown, exhibiting super-Poissonian Fano factors, shows that collective excitations arising from electron-electron interactions are essential. The breakdown mechanism can be described by a Landau critical velocity limited by the excitation of large momentum magneto-excitons, in analogy with the roton mechanism of superfluids [3]. The fractional QHE counterpart would involve magneto-rotons [4].

8:12AM X01.00002: Stabilizing a SQUID-based amplifier in high magnetic fields*  VIDHI SHINGLA (Presenter), Purdue University, ETHAN KLEINBAUM, LOREN PFEIFFER, KENNETH WEST, Electrical Engineering, Princeton University, GABOR CSATHY, Purdue University — dc SQUID-based circuits, when connected to sources exposed to strong magnetic fields, are often unstable in their fluxed-locked mode. We present a low noise SQUID-based current amplifier, which is unconditionally stable with a source exposed to magnetic fields up to 10 T.

Stability is achieved by inserting a four-pole low-pass filter between the source and the current amplifier. With this circuit, we demonstrate Johnson noise measurements below 1 K for source impedances in the kΩ range subjected to strong magnetic fields. We also discuss preliminary high-resolution thermal transport data in a two-dimensional electron gas confined in GaAs/AlGaAs.

8:24AM X01.00003: Andreev reflection at the interface with an oxide in the quantum Hall regime*  YUSUKE KOZUKA (Presenter), National Institute for Materials Science, ATSUSHI SAKAGUCHI, The University of Tokyo, JOSEPH FALSON, Max-Planck Institute, ATSUSHI TSUKAZAKI, Tohoku University, MASASHI KAWASAKI, The University of Tokyo — Quantum Hall/superconductor junctions have been an attractive topic as the two macroscopically quantum states join at the interface. Despite longstanding efforts, most semiconductors hosting high-mobility two-dimensional electron systems (2DES) usually form Schottky barriers at the metal contacts, preventing efficient proximity between the quantum Hall edge states and Cooper pairs. In this study, we propose another material system for investigating 2DES/superconductor junctions, that is ZnO-based heterostructure. Due to the ionic nature of ZnO, a Schottky barrier is not effectively formed at the contact with a superconductor MoGe, as evidenced by the appearance of Andreev reflection at low temperatures. With applying magnetic field, while clear quantum Hall effect is observed for ZnO 2DES, conductance across the junction oscillates with the filling factor of the quantum Hall states. We find that Andreev reflection is suppressed in the well-developed quantum Hall regimes, which we interpret as a result of equal probabilities of normal and Andreev reflections as a result of multiple Andreev reflection at the 2DES/superconductor interface.

8:36AM X01.00004: Graphene in a Uniform Magnetic Field*  ANKUR DAS (Presenter), RIBHU KAUL, GANPATHY N MURTHY, University of Kentucky — We study monolayer graphene in a uniform magnetic field in the absence and presence of interactions. In the non-interacting limit for 1/q flux quanta per unit cell, the central two bands have 2q Dirac points in the Brillouin zone for nearest neighbor hopping. The Dirac points can be gapped out with a 2nd nearest neighbor hopping ($t_2$) and the central two bands pick up large Chern numbers. If we break the inversion symmetry by introducing a staggered potential ($m$) Chern number of the central bands becomes 1. Competition between $t_2$ and $m$ leads to a topological phase transition.

In the case of interacting graphene, there are at least three different competing phases when we consider Hubbard interaction and nearest neighbor spin-spin interaction. In the continuum limit, the theory has been studied before. It has been found that there exist four competing phases namely, ferromagnetic, antiferromagnetic, charge density wave, and Kekule distortion phase[1]. In our study, we attempt to understand all the phases in the lattice model. We investigate if there are phases in the lattice model not found in the continuum limit.

*We thank NSF DMR-1611161 & DMR-1306897
8:48AM X01.00005: Edge excitations in the 2D electron gas at \( v=2 \)

AMARTYA SAHA (Presenter), GANPATHY N MURTHY, University of Kentucky — Edge reconstruction for the 2D electron gas in a magnetic field at \( v=2 \) has been studied by Dempsey, Gelfand, and Halperin[1], who found that when the confining potential is softened the two spin polarized channels spatially separate. In this project we study the collective excitations both in the bulk and the edge at \( v=2 \) using the time dependent hartree fock (TDHF) method. We find that beyond a certain slope of the edge potential both the spin-wave and the charged excitations have instabilities. This analysis is similar to what Franco and Brey[2] did for the \( v=1 \) edge, where they showed that there are other phases (spin textured and charge density wave) with lower energy than the earlier proposed stripe phase by Chamon and Wen[3]. Finally, we will look for translation-symmetry-breaking ground states with lower energy than the one proposed in ref. 1 using Hartree-Fock methods.

9:00AM X01.00006: Boundary critical behavior of the integer quantum Hall transition

MARTIN PUSCHMANN (Presenter), Department of Physics, Missouri University of Science and Technology, PHILIPP CAIN, MICHAEL SCHREIBER, Institute of Physics, Chemnitz University of Technology, THOMAS VOJTA, Department of Physics, Missouri University of Science and Technology — We recently performed a high-accuracy study of the integer quantum Hall transition for a microscopic model of non-interacting disordered electrons: Based on a recursive Green function approach, we investigated the electronic wave functions in the lowest Landau band of a tight-binding model on a simple square lattice. To determine the bulk critical behavior, we employed lattices with the topology of an infinite cylinder [1].
Here, we consider quasi-one-dimensional lattices with the topology of an infinite strip, i.e., open boundary conditions. Edge states can expand along the entire rim of the system. They can undergo a boundary localization-delocalization transition. We investigate its critical behavior in the lowest Landau band and compare it with previous works. Additionally, we study the localization-delocalization transitions in the lowest Landau band of two-dimensional topologically disordered random Voronoi-Delaunay lattices [2].

9:12AM X01.00007: Black Hole Phenomena in Quantum Hall Systems 1: Quasinormal Modes

VARSHA SUBRAMANYAN (Presenter), SURAJ HEGDE, SMITHA VISHVESHWARA, BARRY BRADLYN, University of Illinois at Urbana-Champaign — Point contact geometries in quantum Hall systems have formed excellent probes of quasiparticle scattering. Here, we demonstrate how they can access quasinormal modes – temporally decaying excitations – which are hitherto unexplored in QH settings. On the astronomical scale, quasinormal modes are one of the characteristic signatures of black holes and have played a key role in the recent LIGO detection of black hole mergers. We show how lowest Landau level physics in the presence of a saddle potential, such as at a point contact, can directly simulate the scattering of scalar particles by a black hole spacetime. The S matrix obtained from this scattering problem has poles in the complex plane corresponding to the quasinormal modes. We present the results of Gaussian wavepacket scattering to discern these states in the reflected wavepacket. We also discuss the possible signatures of the quasinormal modes in time-resolved measurements on quantum Hall systems in point contact geometries.

9:24AM X01.00008: Black Hole phenomena in Quantum Hall Systems 2: The Hawking-Unruh effect

SURAJ HEGDE (Presenter), VARSHA SUBRAMANYAN, BARRY BRADLYN, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign — In this talk, we present a parallel between dynamics in quantum Hall systems and the Hawking-Unruh effect associated with black holes. Hawking-Unruh radiation can be looked upon as a thermal distribution that arises from a Bogoliubov transformation generated by the Rindler Hamiltonian, corresponding to accelerated observers. We show that the Rindler Hamiltonian is functionally identical to that of Hamiltonian governing electrons in the lowest Landau level in the presence of a saddle potential. We show that this arises from a deeper connection between the symmetries of the two disparate systems – the isomorphism between the lie algebras of the 2+1D Lorentz group and that of SL(2,R) group of area-preserving transformations. This connection further allows us to see quantum Hall phenomena in the light of Lorentz kinematics.
Quantum tomography of electrical currents

REMI BISOGNIN (Presenter), Laboratoire Pierre Aigrain, Ecole Normale Supérieure - CNRS, BENJAMIN ROUSSEL, Laboratoire de Physique, ENS de Lyon - CNRS, CAMILLE CHAPDELAINE, Laboratoire des signaux et systèmes, Centrale-Supélec CNRS, ARTHUR MARGUERITE, MANOHAR KUMAR, Laboratoire Pierre Aigrain, Ecole Normale Supérieure - CNRS, CLÉMENT CABART, Laboratoire de Physique, ENS de Lyon - CNRS, ALI MOHAMMED-DJAFARI, Laboratoire des signaux et systèmes, Centrale-Supélec CNRS, JEAN-MARC BERROIR, ERWANN BOCQUILLON, BERNARD PLAÇAIS, Laboratoire Pierre Aigrain, Ecole Normale Supérieure - CNRS, ANTONELLA CAVANNA, ULF GENNSER, YOUNG JIN, Centre de Nanosciences et Nanotechnologies, C2N-Marcoussis CNRS, PASCAL DEGIOVANNI, Laboratoire de Physique, ENS de Lyon - CNRS, GWENDAL FÈVE, Laboratoire Pierre Aigrain, Ecole Normale Supérieure - CNRS — Recent developments in quantum nanoelectronics have enabled the realization of electron sources emitting a quantized number of excitations. However, reconstructing all wavefunctions of the elementary excitations embedded in electrical currents was still out of reach. Combining two-electron Hong-Ou-Mandel interferometry [1] with signal processing techniques, we demonstrate a quantum tomography protocol [2, 3, 4] able of extracting from any electrical current the generated electron and hole wavefunctions as well as their emission probabilities. The interferometer is implemented in a 2D electron gas in the integer quantum Hall effect where charges propagate along 1D ballistic edge channels. First we demonstrate the protocol with sinusoidal currents which allow for simple comparison with theoretical predictions. Then we turn to periodic single electron Lorentzian pulses and show that thermal effects lead to the generation of a statistical mixture between two single-electron wavefunctions.

QED-Bloch Theory with Homogeneous Magnetic Fields: Modifications of the Landau Levels and the Hofstadter Butterfly

VASIL ROKAJ (Presenter), MARKUS PENZ, MICHAEL SENTEF, MICHAEL RUGGENTHALER, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter — Probing electronic properties of periodic systems by arbitrary homogeneous magnetic fields has unravelled fundamental new phenomena in condensed matter physics. Much theoretical work has been devoted to describe those systems in different regimes, still a general first principles modeling of such fundamental effects is lacking. Here we propose a solution to the problem of Bloch electrons in a homogeneous magnetic field by including the quantum fluctuations of the photon field. A generalized quantum electrodynamical (QED) Bloch theory from first principles is presented. As an application we show how the well known Landau physics shows up in this framework and we derive quantum corrections to the Landau levels. These quantum corrections have direct implications for the integer quantum Hall effect. Moreover, in the case of a 2D solid in a perpendicular magnetic field, in the limit where the field fluctuations go to zero, we recover the fractal pattern of the Hofstadter butterfly. Further generalizations and modifications of the Hofstadter butterfly will be presented.

A Topological Sum-Rule Causes the Total Suppression of the Hall Response

MICHELE FILIPPONE (Presenter), CHARLES-EDOUARD BARDYN, SEBASTIAN GRESCHNER, THIERRY GIAMARCHI, University of Geneva — We present a topological sum-rule for the transverse polarization valid for out-of-equilibrium quantum states in two-dimensional lattices. Whenever the state equally spreads over all bands at a fixed energy, the topological sum-rule implies the identical suppression of the polarization, regardless of the magnetic field strength. As a remarkable consequence, the Hall response robustly vanishes even in absence of particle-hole symmetry and with arbitrary strong magnetic fields. We show that these out-of-equilibrium states are commonly realized in standard (Landauer) quantum transport settings and we rely on DMRG to show that our results equally apply to strongly interacting regimes.
**10:12AM X01.00012: Andreev edge state in the quantum Hall regime**

LINGFEI ZHAO (Presenter), ETHAN ARNAULT, ANDREW SEREDINSKI, ANNE M DRAELOS, Department of Physics, Duke University, HENGMING LI, TATE FLEMING, BRANDON BELL, Department of Physics and Astronomy, Appalachian State University, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, NIMS, FRANCOIS AMET, Department of Physics and Astronomy, Appalachian State University, GLEB FINKELSTEIN, Department of Physics, Duke University — We investigate Andreev reflections in the quantum Hall regime. We study an encapsulated graphene sample contacted by both superconducting and normal electrodes. In the well-quantized regime, we find evidence for Andreev reflections of the QH edge states traveling along the superconducting contacts. The observed spectroscopic features decay to zero with increasing temperature and magnetic field. We attribute them to beating between electron-hole modes hybridized by Andreev reflections. These chiral modes under certain conditions are predicted to be Majorana-Weyl fermions.

**10:24AM X01.00013: Interacting quantum Hall states at integer filling with a non-Abelian twist: a coupled wire description**

PEDRO LOPES, Physics, University of British Columbia, VICTOR QUITO, Physics, Iowa State University, BO HAN, Physics, University of Illinois, Urbana-Champaign, JEFFREY TEO (Presenter), Physics, University of Virginia — We construct a theoretical coupled wire model that describes new many-body interacting quantum Hall states at integer filling. The strongly-correlated states support exotic electric and thermal Hall transport that violate the Wiedemann-Franz law $\nu/c=(\alpha_{xy}/\kappa_{xy})[\pi^2 k_B^2/(3e^2)]T>1$. We focus on strongly-paired states where combinations of pairs of electrons form the fundamental interacting constituents. These bosonic combinations associate to a Kac-Moody current algebra, which is removed from low-energy by the interaction in the 2+1D bulk but is left behind along the 1+1D boundary. We propose a new quantum Hall state at filling $\nu=16$ that supports a bosonic chiral $E_8$ edge current algebra at level 1 and is intimately related to the topological paramagnets in 3+1D. This topological state can be partitioned into two quantum Hall states at filling $\nu=8$, each carries a bosonic chiral $G_2$ or $F_4$ edge current algebra at level 1 and hosts non-Abelian Fibonacci anyonic excitations in the bulk. Moreover, we discover a new notion of particle-hole conjugation, based on the $E_8$ bosons, that switches between the $G_2$ and $F_4$ states.

*National Science Foundation under Grant No. DMR-1653535

**10:36AM X01.00014: Filling-enforced quantum oscillation phase shift anomaly in few-layer graphene**

BISWAJIT DATTA (Presenter), PRATAP CHANDRA ADAK, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research, LI-KUN SHI, Institute of High Performance Computing, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, JUSTIN SONG, Division of Physics and Applied Physics, Nanyang Technological University, MANDAR DESHMUKH, Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research — Quantum oscillations provide a striking visualization of the Fermi surface of metals: Fermi surface size, shape, and Berry phase naturally manifest in quantum oscillation frequency, field-direction dependence, and phase shift respectively. We report on unconventional magneto-transport of ABA-trilayer graphene, a multiband system comprising a (non-trivial) gapped monolayer graphene (MLG)-like band, nested within a large (trivial) bilayer graphene (BLG)-like band. Detailed field and density maps reveal BLG-like Shubnikov-de Hass (SdH) oscillations shifted by an anomalous non-trivial phase that sharply departs from that expected from the constant and trivial (2n) Berry phase of the BLG-like Fermi surface. The anomalous phase shift switches sharply from $\pi$ to $-\pi$ as density is tuned from below the MLG-like gap to above it. This originates from a strong filling-enforced constraint between the BLG-like and MLG-like Fermi surfaces, enabling the quantum oscillations of one Fermi surface to inherit the phase shifts of the other co-existing Fermi surface. We expect filling-enforced phases in quantum oscillations to arise generically in multi-Fermi-surface metals, and provide a detailed window to map the rich pattern of carrier filling in multi-band topological materials.
10:48AM X01.00015: Taming electronic decoherence in 1D chiral ballistic conductor*  
CLEMENT CABART, Ecole Normale Superieure de Lyon, BENJAMIN ROUSSEL, Advanced Concept Team, European Space Agency, GWENDAL FÈVE, Laboratoire Pierre Aigrain, Ecole Normale Superieure (Paris), PASCAL DEGIOVANNI (Presenter), Ecole Normale Superieure de Lyon —  
Decoherence and relaxation of single-electron excitations induced by strong effective screened Coulomb interactions in Quantum Hall edge channels are an important challenge for the applications of electron quantum optics in quantum information and quantum sensing. We present a complete study of intrinsic single-electron decoherence within an ideal single-electron channel with long-range effective Coulomb interactions to determine the influence of the material and sample properties [Phys. Rev. B 98, 155302 (2018)]. We find that weak-coupling materials characterized by a high velocity of hot-electron excitations such as graphene may offer interesting perspectives for limiting intrinsic decoherence due to electron/electron interactions compared to lower velocity materials such as AlGaAs/AsGa. We discuss quantitatively how extrinsic decoherence due to the coupling with the channel's electromagnetic environment can be efficiently inhibited in specifically designed samples at filling fraction two with one closed edge channel and we propose a realistic geometry for testing decoherence control in a Hong Ou Mandel experiment.

BCEC 107A - Lu Li, University of Michigan - Tag(s):

Focus

8:00AM X02.00001: Observation of topological nodal-loop fermionic state in CaAs3 family*  
MD MOFAZZEL HOSEN (Presenter), GYANENDRA DHAKAL, University of Central Florida, BAOKAI WANG, Northeastern University, KLAUSS DIMITRI, FIROZA KABIR, CHRISTOPHER SIMS, SABIN REGMI, YANGYANG LIU, University of Central Florida, TOMASZ DURAKIEWICZ, National Science Foundation, DARIUSZ KACZOROWSKI, Polish Academy of Sciences, ARUN BANSIL, Northeastern University, MADHAB NEUPANE, University of Central Florida — Nontrivial states in topological semimetals are attracting intense interest driven by their numerous novel properties such as high bulk carrier mobility, Fermi arcs, chiral anomaly, large negative magnetoresistance, and high density of states. Here, using high-resolution angle-resolved photoemission spectroscopy (ARPES) along with first-principles calculations, we report the discovery of a topological nodal-loop (TNL) state in CaAs3 family. Our analysis reveals that surface projections of the bulk nodal-points are connected by surface states. Notably, the observed topological state in CaAs3 family are well separated from other bands in the vicinity of the Fermi level. CaAs3 family thus offers a unique materials realization of a prototype nodal-loop semimetal, and a platform for gaining a deeper understanding of the interplay between TNL and topological insulator physics in semimetals.

8:12AM X02.00002: Prediction of a large-gap and switchable Kane-Mele quantum spin Hall insulator from first-principles simulations*  
ANTIMO MARRAZZO (Presenter), Ecole polytechnique federale de Lausanne, MARCO GIBERTINI, Department of Quantum Matter Physics, University of Geneva, DAVIDE CAMPI, NICOLAS MOUNET, NICOLA MARZARI, Ecole polytechnique federale de Lausanne — Fundamental research and technological applications of topological insulators are hindered by the rarity of materials exhibiting a robust topologically non-trivial phase, especially in two dimensions. Here, by means of extensive first-principles calculations, we propose a novel quantum spin Hall insulator (QSHI) with a sizeable band gap of ~0.5 eV that is a monolayer of jacutingaite [1, 2], a naturally occurring layered mineral first discovered in 2008 in Brazil [3] and recently synthesised [4]. This system realises the paradigmatic Kane-Mele model for QSHIs in a potentially exfoliable two-dimensional monolayer, with helical edge states that are robust and that can be manipulated exploiting a unique strong interplay between spin-orbit coupling, crystal-symmetry breaking and dielectric response [1]. Finally, we give an update on ongoing experimental efforts in the synthesis and characterisation of bulk and monolayer jacutingaite.

Clarification of charge-density wave gap symmetry and topology in bulk 1T-TiSe$_2$*  

SHIN-MING HUANG (Presenter), Physics, National Sun Yat-sen University, SUYANG XU, Department of Physics, Massachusetts Institute of Technology, BAHADUR SINGH, SZU-NUS Collaborative Center and International Collaborative Laboratory of 2D Materials for Optoelectronic Science & Technology, Engineering Technology Research Center for 2D, MING-CHIEN HSU, Physics, National Sun Yat-sen University, CHUANG-HAN HSU, Centre for Advanced 2D Materials and Graphene Research Centre, National University of Singapore, CHENLIANG SU, SZU-NUS Collaborative Center and International Collaborative Laboratory of 2D Materials for Optoelectronic Science & Technology, Engineering Technology Research Center for 2D, ARUN BANSIL, Department of Physics, Northeastern University, HSIN LIN, Institute of Physics, Academia Sinica —

We examine the symmetry of the charge density wave (CDW) phase of 1T-TiSe$_2$ and answer the connection of electronic structures between the normal and the CDW states. Especially, we unravel the consequential irreducible representations (IRs) of electronic states and, more ahead, those of gap functions among bands when the CDW occurs. Normally symmetry-related topology will be achieved directly, so we assert that the theory is valuable and practical for the search of topological CDW insulators.

Exotic Topological properties in compensated half-metallic inverse-Heusler systems*  

HYOSUN JIN (Presenter), YOUNG-JOON SONG, Department of Applied Physics, Graduated School, Korea University, WARREN E PICKETT, Department of Physics, University of California, Davis, KWAN-WOO LEE, Division of Display and Semiconductor Physics, Korea University — Recently three-dimensional (3D) topological features mixing with zero-dimensional (0D) band-crossings (Dirac, Weyl, multi-Weyl, and triple-nodal points [TNPs]) have stimulated further interest. An exotic phase, so called nexus fermion, has been expected when a 0D TNP coincides with a 1D nodal line. The nexus fermions are a yet more intricate excitation that have been proposed, but no realistic system has been proposed for such an exotic phase.

In this presentation, we will address a unique topological metallic system displaying simultaneous pure spin WPs, TNPs, nodal loops, and nexus fermions in the absence of (minor) spin-orbit coupling (SOC), in Cr-based inverse-Heusler compensated half-metals with neither inversion nor time-reversal symmetry, using density functional theory-based calculations. This combination gives rise to fully spin polarized nexus fermions, in a system with broken time-reversal symmetry but negligible macroscopic magnetic field. The observed high Curie temperature of 750 K and calculated SOC hybridization mixing of several meV should make these nexus fermions readily measurable.

*This research was supported by NRF Grants No. NRF-2016R1A2B4009579.
Topological materials host various novel quantum phases of electrons which are characterized by band topology and topologically protected surface/edge states. [1] Despite recent progress, intense world-wide research activity in search of new classes of topological materials is continuing unabated. This interest is driven by the need for materials with greater structural flexibility and tunability to enable viable applications in spintronics and quantum computing. We have used first-principles band theory computations to successfully predict many new classes of 3D topologically interesting materials, including Bi2Se3 series, [2] ternary half-Heuslers, [3] TlBiSe2 family, [4] Li2AgSb-class, and GeBi2Te4 family as well as topological crystalline insulator (TCI) SnTe family [5] and Weyl semimetals TaAs, [6,7] SrSi2, [8] (Mo,W)Te2,[9] Ta3S2, and LaAlGe family. [10] I will also highlight our recent work on unconventional chiral fermions in RhSi, [11] cubic Dirac points in LiOsO3, [12], rotaional symmetry protected TCIs [13], and Kramer-Weyl fermions in non-magnetic chiral cyrstals. [14]

Quantum Oscillations in Trigonal PtBi1.6 Single Crystals*

LINGYI XING (Presenter), RAMAKANTA CHAPAI, ROSHAN NEPAL, RONGYING JIN, Louisiana State University — Transition-metal dichalcogenide PtBi2 is known to form multiple structures with extreme large magnetoresistance (XMR). We have successfully grown high-quality PtBi1.6 single crystals with the trigonal structure. In addition to the XMR effect, the magnetization exhibits de Haas–van Alphen (dHvA) oscillations at low temperatures. Through Fourier transformation, we identify two oscillation frequencies $F_\delta = 4$ T and $F_\alpha = 39$ T with the sign of Zeeman splitting. Using Lifshitz–Kosevich (LK) formula to fit experimental data, we obtain the effective masses ($m^*_\delta = 0.092m_0$ and $m^*_\alpha = 0.189m_0$) and Berry phases ($\Phi_{B\delta} = (0.82 + 2\delta)\pi$ and $\Phi_{B\alpha} = (0.86 + 2\delta)\pi$) for both $\delta$ and $\alpha$ bands. The results indicate the trigonal PtBi1.6 has non-trivial topological properties.

Crystal Structure determination of Ge2Sb2Te5 and Se-doped Ge2Sb2Te5 material

ZHENYANG XU (Presenter), JOHN SCHNEELOCH, KEESONG PARK, DESPINA LOUCA, Physics, University of Virginia — The [GeTe]n[Sb2Te3]m layered materials have been widely used as component of data storage devices and electronic memories. Ge2Sb2Te5 is a well-known phase change material that exhibits three phases: an amorphous phase, a rock-salt NaCl-type metastable phase and a hexagonal stable phase. To obtain the amorphous phase in bulk samples, we synthesized Ge2Sb2Te5-xSex where we replaced Te with Se. At about 90 % of Se, the system becomes amorphous by quenching. The Se atom function as a stabilizer of the amorphous phase and helps to trigger the local displacements of the Sb and Ge atoms within the unit cell, thus breaking the long-range order and render the system into an amorphous one. The rich physics within this transition will be discussed. Moreover, Ge2Sb2Te5 is associated with naturally occurring stacking faults and a topological phase transition depends sensitively on the distribution of these faults. It has been proposed theoretically that depending on the stacking sequence, GST can undergo a topological phase transition from the low temperature topological insulating phase with the so-called Kooi structure to the high temperature Weyl semi-metal phase with the Ferro structure. We synthesized the Kooi structure and the results from the DFT calculations will be discussed.
Topological properties are not protected in unstable crystal structures

(ALEX ZUNGER (Presenter), GUSTAVO DALPIAN, XINGANG ZHAO, University of Colorado Boulder, OLEKSANDR MALYI, University of Oslo, Norway, HANNES RAEBIGER, University of Yokohama, Japan, QIHANG LIU, Southern University of Science and Technology, China — The ability of DFT to reveal the consequences of assumed crystal symmetries on band inversion, band crossing and degeneracy in solids has led to a plethora of predicted compounds that should be topological insulators(TI's), Dirac Semimetals(DSM) and unconventional quasiparticles. Before offering predicted compounds for experimental evaluation, it may be wise to use not only the band structures as design filters, but also the DFT total energy (E_{tot}) of the given crystal. Inspecting E_{tot} one finds: i) the predicted 3D non-symmorphic DSM band crossing of BiO_2 in assumed SiO_2 structure is dynamically unstable and disappears if its structure is allowed to relax to another polymorph; ii) the predicted 8-fold band degeneracy of CuBi_2O_4 in assumed nonmagnetic configuration disappears once energy-lowering spin polarization is allowed; iii) the predicted oxide TI BaBiO_3 with upshifted Fermi level disappears once allowed to lower its energy in response to n-type doping; iv) the predicted unconventional quasiparticle in Ba_4Bi_3 with downshifted Fermi energy is destabilized by the required p-type doping. Thus, although proven bulk topological characteristics lead to protected surface/edge states, nothing protects bulk states from thermodynamic instability.

Giant negative magnetoresistance in a topological hourglass candidate

(PRISCILA ROSA (Presenter), Los Alamos National Laboratory, SATYA K KUSHWAHA, Pulsed Field Facility, NHMFL, MAREIN RAHN, MARC JANOSCHEK, ERIC BAUER, Los Alamos National Laboratory, MUN KEAT CHAN, NEIL HARRISON, Pulsed Field Facility, NHMFL, JOE D THOMPSON, FILIP RONNING, Los Alamos National Laboratory — Non-symmorphic materials have been recently predicted to host protected surface fermions displaying hourglass dispersion [1]. Here we report the physical properties of Eu_5In_2Sb_6 single crystals crystallizing in the non-symmporphic space group Pbam (55) [2]. Our results show that Eu_5In_2Sb_6 is a narrow-gap antiferromagnetic insulator that exhibits giant negative magnetoresistance driven by magnetic polarons. We discuss the potential surface states in Eu_5In_2Sb_6, and the role of magnetic correlations on hourglass fermions.

Properties of Bi_2Se_3 and Bi_xSb_2-xTe_3 grown by MBE

(YANG BAI (Presenter), DAVID FLÖTOTTO, BRIAN MULCAHY, JOSEPH HLEVYACK, XUN ZHAN, TAI-CHANG CHIANG, JIAN-MIN ZUO, JAMES ECKSTEIN, XIANGYU SONG, University of Illinois at Urbana-Champaign — We have studied molecular beam epitaxy growth of Bi_2Se_3 and Bi_xSb_2-xTe_3. We have demonstrated that by using a two-step growth recipe, very flat films of both materials can be obtained. The film quality was confirmed using RHEED oscillations during growth and, post-growth XRD, AFM, and STEM. Under other growth and processing conditions, we have observed a more complicated film morphology in the growth of Bi_xSb_2-xTe_3, which we attribute to compositional phase segregation. Using different substrates strongly impacts the film morphology. By tuning the ratio of Bi to Sb, the carrier type can be tuned from p-type to n-type measured via the Hall effect. The films were also studied by ARPES using a flip-chip cleaving approach in which the film plane at the interface to the substrate is measured after cleaving. The Hall and ARPES results agreed with regard to carrier type.

*This work is supported by the National Science Foundation.
**10:24AM X02.00011: Epitaxial growth of ultrathin Bi$_2$Se$_3$ films as characterized by *in situ* angle-resolved photoemission spectroscopy**

DONGSUNG CHOI (Presenter), NIKE SH KOIRALA, EDOARDO BALDINI, CHANGMIN LEE, NUH GEDIK, Massachusetts Institute of Technology — Combining molecular beam epitaxy with time- and angle-resolved photoemission spectroscopy (MBE-trARPES) provides a powerful way to investigate electronic structures of quantum materials. By using our *in situ* MBE-trARPES system, we measured ultrathin epitaxial films of Bi$_2$Se$_3$ grown on sapphire substrate. In its ultrathin limit, i.e. below 6 quintuple layers (QL), topological surface states are gapped due to hybridization and theory predicts the film to become a two-dimensional topological insulator (2D TI) until 3QL. From 3QL to 2QL, topological phase transition to trivial insulator is expected to occur. Previous ARPES experiments explored this phase transition in ultrathin Bi$_2$Se$_3$ films grown on bilayer graphene on SiC and Si substrate. In this experiment, we investigated various growth methods for ultrathin (2-6 QL) Bi$_2$Se$_3$ film on sapphire substrate: one-step growth, two-step growth, and growth on (Bi$_{0.5}$In$_{0.5}$)$_2$Se$_3$ buffer layer. By measuring ARPES spectra at several positions on the film, we evaluated band structure and uniformity of film. This work provides a guideline for growth of ultrathin Bi$_2$Se$_3$ on sapphire substrate for future experiments exploring topological phase transition in ultrathin Bi$_2$Se$_3$.

**10:36AM X02.00012: Crystal phase control in an YBiO$_3$ thin film by using a BaBiO$_3$ buffer layer**

ROSA LUCA BOUWMEESTER (Presenter), KIT DE HOND, University of Twente, NICOLAS GAUQUELIN, EMAT, University of Antwerp, GERTJAN KOSTER, ALEXANDER BRINKMAN, University of Twente, JO VERBEECK, EMAT, University of Antwerp — Topological insulating materials are very promising for applications in spintronics and quantum computing. The presently confirmed topological insulators are not suitable for room temperature applications. Perovskite oxides are interesting in this respect, since topological insulating phases have theoretically been predicted with large band gaps. YBiO$_3$ has been predicted to be a topological insulator for the perovskite phase with yttrium and bismuth located at the A-site and B-site, respectively. However, the fluorite phase turns out to be thermodynamically more stable than the perovskite phase. In this work we show that we were able to engineer the perovskite crystal phase of thin film YBiO$_3$ by using a BaBiO$_3$ buffer layer and interval deposition. When the YBiO$_3$ is deposited on top of the BaBiO$_3$, a single oriented perovskite phase is observed with the expected lattice constants. These findings pave a way towards the fabrication of quantum devices for testing the hypothesized topological insulating phase in YBiO$_3$.

*This work is financially supported through a NWO Vici grant. For the work in Antwerp, we acknowledge the financial support of the GOA project “Solarpaint” and the Hercules Fund of the Flemish Government.

**10:48AM X02.00013: Structure-Property relationships and superconductivity in Single Crystals of Nb$_x$Bi$_2$Ch$_3$, (Ch ≡ S, Se, Te)**

CHRISTIAN PARSONS (Presenter), YANAN LI, PRASENJIT GUPTASARMA, Department of Physics, University of Wisconsin Milwaukee, Wisconsin 53211 — Studies of Topological Insulators, possibly a new quantum phase of matter believed to possess a 2-dimensional Fermi surface, have led to a search for other insulators or semi-metals in which topologically non-trivial properties can be tuned using a chemical, structural, or external thermodynamic parameter. Topological insulators such as Bi$_2$Se$_3$ and Bi$_2$Te$_3$ have attracted much interest due to not just their non-trivial topology, but also due to the appearance of superconductivity upon intercalation or substitution with elements such as Cu, Sr and Nb. Many potentially interesting transition-metal intercalated/doped Bismuth-Chalcogenides have not yet been explored. Here, we discuss our growth and study of Nb$_{0.2}$Bi$_2$Ch$_3$ crystals (Ch = S, Se, Te). We report resistivity measurements and confirm a superconducting transition near 3K for Nb$_{0.2}$Bi$_2$Se$_3$. We also report a possible charge density wave (CDW) transition in Nb$_{0.2}$Bi$_2$Te$_3$. In contrast, Nb$_{0.2}$Bi$_2$S$_3$ was found to be a good conductor with no phase transitions. Detailed fitting of x-ray diffraction shows that all three families of single crystals have a primary phase of Bi$_2$Ch$_3$ and a minor secondary phase of BiNbCh$_3$. We discuss our results together with Raman Spectroscopy, X-ray Diffraction and Electron Diffraction studies of our crystals.

**Session X03 DCMP: Topological Superconductors and Superfluids**

BCEC 107B - Tag(s): Focus
8:00AM X03.00001: Symmetry-protected line nodes and Majorana flat bands in nodal crystalline superconductors
SHINGO KOBAYASHI (Presenter), Nagoya University, SHUNTARO SUMITA, YOUICHI YANASE, Kyoto University, MASATOSHI SATO, YITP, Kyoto University — Over the last few years, the study on node structures in SCs has received renewed interest due to the fact that they are a kind of topological objects. In this context, a line node in time-reversal (TR) invariant SCs is protected by a one-dimensional (1D) topological number and induces a Majorana flat band (MFB) in a surface. The MFBs exhibit a zero-bias conductance peak through the tunneling measurement for TR invariant SCs such as high-$T_c$ SCs and non-centrosymmetric SCs, which gives a conclusive evidence for the bulk topological line nodes.

In this talk, we discuss topology of crystal symmetry protected line nodes in unconventional SCs. We introduced the 1D and 0D topological numbers associated with line nodes, each of which ensures the existence of MFBs and stability of line nodes, respectively. Establishing a relationship between them, we clarified that MFBs are classified into three classes of SCs [1]: (i) odd-parity SCs, (ii) even-parity SCs with pure TR symmetry, and (ii) even-parity SCs with a magnetic translation. These classes are distinguishable through surface sensitive experiments.

8:12AM X03.00002: Full proximity approach to induced gap in topological superconductor junctions
FNU SETIAWAN (Presenter), James Franck Institute, University of Chicago, CHIEN-TE WU, Electrophysics, National Chiao Tung University, KATHRYN LEVIN, James Franck Institute, University of Chicago — Recently, a Josephson junction formed from a two-dimensional electron gas (2DEG) proximitized by two superconductors subjected to an in-plane magnetic field has emerged as a viable platform to realize topological superconductivity [1-3]. In this talk, we address the proximity-induced superconductivity in this setup by studying the full proximity model of a superconductor-insulator-superconductor junction in contact with a spin-orbit-coupled substrate. To this end, we numerically solve the Bogoliubov-de Gennes Hamiltonian of this model and study the effect of spin-orbit coupling and thickness of the substrate on the induced pairing amplitude and energy dispersion. Finally, we will discuss the topological phase diagram of multiband topological Josephson junctions for a thick substrate.

8:24AM X03.00003: Hot electron magnetotransport in the high mobility GaAs/AlGaAs two dimensional electron system below 1K
C.RASADI MUNASINGHE (Presenter), BINUKA GUNAWARDANA, RASANGA SAMARAWEERA, THARANGA NANAYAKKARA, U. KUSHAN WIJEWARDENA, SAJITH WITHANAGE, ANNIKA KRIISA, Physics and Astronomy, Georgia State University, CHRISTIAN REICHL, WERNER WEGSCHEIDER, Laboratorium für Festkörperphysik, ETH Zürich, RAMESH MANI, Physics and Astronomy, Georgia State University — Non-equilibrium hot electron phenomena play a major role in semiconductor transport when, for example, the heat applied directly to the electronic system becomes substantial. The carrier temperature can differ from the lattice temperature, and the carrier temperature results, in the steady state, from a balance between energy gain from the heating source, and energy loss to the lattice from electron-phonon scattering. In this experimental study, we examine heating induced by the small ac-bias current utilized in the low-frequency lock-in based four terminal transport measurements. Since at small bias current, the carrier heating is expected to be small, we have utilized an effect that is associated with a small energy scale to follow the heating effect, namely the spin splitting in the Shubnikov-de Haas effect. The development of fields such as spintronics and spin-based quantum computing have encouraged further studies, such as this one, of the parameters affecting the behavior of electron spin in low dimensional electron systems. Thus, magneto-transport measurements have been carried out below 1K to observe the ac current effect on the characteristic features of the GaAs/AlGaAs system. In this report, we show evidence for a carrier heating effect due to the small ac bias.
8:36AM X03.00004: Topological Phases in Nodeless Tetragonal Superconductors*  
SANTIAGO VARONA (Presenter), LAURA ORTIZ, Departamento de Física Teórica, Complutense University, OSCAR VIVUELA, Department of Physics, Harvard University, MIGUEL ANGEL MARTIN-DELGADO, Departamento de Física Teórica, Complutense University — We compute the topological phase diagram of 2D tetragonal superconductors for the only possible nodeless pairing channels compatible with that crystal symmetry. Subject to a Zeeman field and spin-orbit coupling, we demonstrate that these superconductors show surprising topological features: non-trivial high Chern numbers, massive edge states, and zero-energy modes out of high symmetry points, even though the edge states remain topologically protected. Interestingly, one of these pairing symmetries, $d+i\sigma$, has been proposed to describe materials such as water-intercalated sodium cobaltates, bilayer silicene or highly doped monolayer graphene.

8:48AM X03.00005: Fractional Josephson Vortices and Braiding of Majorana Zero Modes in Planar Superconductor-Semiconductor-Superconductor Josephson junctions*  
ADY STERN (Presenter), EREZ BERG, Weizmann Institute of Science — We consider the one-dimensional (1D) topological superconductor that may form in a planar superconductor-metal-superconductor Josephson junction in which the metal is subjected to spin orbit coupling and to an in-plane magnetic field. This 1D topological superconductor has been the subject of recent theoretical and experimental attention. We examine the effect of perpendicular magnetic field and a supercurrent driven across the junction on the position and structure of the Majorana zero modes that are associated with the topological superconductor. In particular, we show that under certain conditions the Josephson vortices fractionalize to half-vortices, each carrying half of the superconducting flux quantum and a single Majorana zero mode. Furthermore, we show that the system allows for a current-controlled braiding of Majorana zero modes.

9:00AM X03.00006: An Exactly Solvable Interacting Edge Theory for a Weak 2D Topological Superconductor.  
JOSEPH SULLIVAN (Presenter), MENG CHENG, Yale Univ — We study interacting edge states of a 2D weak topological superconductor protected by time-reversal symmetry. Such a system can be viewed as a stack of Majorana/Kitaev chains (class BDI), possessing translation symmetry in the transverse direction. Interestingly, in this model, time-reversal symmetry forbids terms quadratic in fermionic degrees of freedom on the edge, so any edge dynamics must be inherently interacting. We proposed an exactly solvable model for the edge and worked out its phase diagram. It is shown that the edge is either symmetry breaking or gapless as expected from the bulk-boundary correspondence of a topological phase. We then construct a low energy field theory for the model in the gapless phase. We propose that the same field theory describes the edge of an intrinsically interacting fermionic symmetry-protected phase with $Z_4 \times Z_2^T$ symmetry.

9:12AM X03.00007: Majorana corner states in D class*  
XIN LIU (Presenter), XIAO-HONG PAN, KAI-JIE YANG, Huazhong University of Science and Technology — Majorana corner states (MCSS) in D class can naturally form a topological qubit. In this talk, we show that how to realize MCSS in two-dimensional topological insulators in the presence of both superconductivity and magnet. It is noted that there is only one MCS at each corner which is allowed due to the time-reversal symmetry broken. An edge theory is performed to clearly demonstrate the physics behind these results. At last, we study the spin property of MCSS and propose to use spin-resolved scanning tunneling microscope to detect their existence.

9:24AM X03.00008: Generalized Aubry-André-Harper model with p-wave superconducting pairing  
Qi-Bo Zeng (Presenter), Tsinghua University, Shu Chen, Chinese Academy of Sciences, Institute of Physics, Rong Lu, Tsinghua University —  
We investigate a generalized Aubry-André-Harper (AAH) model with p-wave superconducting pairing. Both the hopping amplitudes between the nearest-neighbor lattice sites and the on-site potentials in this system are modulated by a cosine function with a periodicity of $1/\alpha$. In the incommensurate case ($\alpha = (\sqrt{5} - 1)/2$), due to the modulations on the hopping amplitudes, the critical region of this quasiperiodic system is significantly reduced and the system becomes easier to be turned from extended states to localized states. In the commensurate case ($\alpha = 1/2$), we find that this model shows three different phases when we tune the system parameters: Su-Schrieffer-Heeger (SSH)-like trivial, SSH-like topological, and Kitaev-like topological phases. The phase diagrams and the topological quantum numbers for these phases are presented in this work. This generalized AAH model combined with superconducting pairing provides us with a useful test field for studying the phase transitions from extended states to Anderson localized states and the transitions between different topological phases.

9:36AM X03.00009: Conformal phase transition in topological superconductors  
Flavio Nogueira (Presenter), Jeroen van den Brink, IFW Dresden, Asle Sudbo, Dept. of Physics, Norwegian University of Science and Technology —  
A conformal phase transition (CPT) is a phase transition defining a critical point with a non-power law diverging correlation length, but which nevertheless exhibits a universal jump in some generalized stiffness of the system. A well-known example is the Berezinskii-Kosterlitz-Thouless (BKT) phase transition taking place in two-dimensional superfluids and superconductors when they transition from the low-temperature phase to the normal state, and in the melting transition of two-dimensional crystals. In this talk we will introduce a more subtle type of CPT, one that is driven by a topological term in the effective action in 2+1 dimensions. The main motivation comes from the modification of Maxwell electrodynamics in topological insulators and superconductors. Quite generally, the surface of a topological insulator features an electromagnetic response characterized by a Chern-Simons term in the Lagrangian. We will show in this context that a topological Abelian Higgs model exhibits quantum criticality with BKT scaling when the Hall conductivity lies in a well defined interval where conformality is lost. We explore the physical consequences of this novel quantum critical phenomenon in topological materials.

9:48AM X03.00010: Superconformal Cardy states and entanglement structure of 1D quantum critical points with emergent supersymmetry  
Chun Chen (Presenter), Joseph Maciejko, Physics Department, University of Alberta —  
Condensed matter systems with quantum critical points exhibiting emergent spacetime supersymmetry in the long-wavelength, low-energy limit have attracted much attention recently. In particular, several elements of the N=1 series of superconformal minimal models originally discovered by Friedan, Qiu, and Shenker in 1985 have been realized recently in a variety of 1D quantum lattice models ranging from anyonic spin chains to interacting Majorana chains and boson-fermion mixtures. To better understand the entanglement structure of these exotic quantum critical points, we revisit the problem of the construction of boundary states for the superconformal minimal models and find a new set of Cardy states not previously discussed. As an application of this formalism we present and discuss numerical DMRG results for the entanglement spectrum of the Grover-–Sheng–Vishwanath model as a lattice realization of the tricritical Ising universality class.

10:00AM X03.00011: Majorana Corner Modes in a High-Temperature Platform  
Zhongbo Yan (Presenter), School of Physics, Sun Yat-sen University, Fei Song, Zhong Wang, Institute for Advanced Study, Tsinghua University —  
We introduce two-dimensional topological insulators in proximity to high-temperature cuprate or iron based superconductors as high-temperature platforms of Majorana Kramers pairs of zero modes. The proximity-induced pairing at the helical edge state of the topological insulator serves as a Dirac mass, whose sign changes at the sample corner because of the pairing symmetry of high-Tc superconductors. This sign changing naturally creates at each corner a pair of Majorana zero modes protected by time-reversal symmetry. Conceptually, this is a topologically trivial superconductor-based approach for Majorana zero modes. We provide quantitative criteria and suggest candidate materials for this proposal. [Reference: Phys. Rev. Lett. 121, 096803 (2018)]

10:12AM X03.00012: Zero-energy Andreev bound states from quantum dots in proximitized Rashba nanowires  
CHRISTOPHER REEG (Presenter), OLESIADMYTRUK, DENIS CHEVALLIER, DANIEL LOSS, JELENA KLINOVKAJA, University of Basel
— We study an analytical model of a Rashba nanowire that is partially covered by and coupled to a thin superconducting layer, where the uncovered region of the nanowire forms a quantum dot. We find that, even if there is no topological phase possible, there is a trivial Andreev bound state that becomes pinned exponentially close to zero energy as a function of magnetic field strength when the length of the dot is tuned with respect to its spin-orbit length such that a resonance condition of Fabry-Perot type is satisfied. In this case, we find that the Andreev bound state remains pinned near zero energy for Zeeman energies that exceed the characteristic spacing between Andreev levels but that are smaller than the spin-orbit energy of the dot. Importantly, as the pinning of the Andreev bound state depends only on properties of the dot, we conclude that this behavior is unrelated to topological superconductivity. To support our analytical model, we also perform a numerical simulation of a hybrid system that explicitly incorporates a thin superconducting layer, showing that all qualitative features of our analytical model are present in the numerical results.

10:24AM X03.00013: The survival of topological signatures in the presence of average symmetries*  
YINGYI HUANG (Presenter), Physics, Sun Yat-Sen University, CHING-KAI CHIU, Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences — The robust properties in topological states of matter under the effect of disorders is of great theoretical as well as experimental interests. One focus is on the disorders breaking either spatial symmetry or non-spatial symmetry (e.g., time-reversal, particle-hole and chiral symmetry) but restoring it on average. In this work, we consider a quasi-one-dimensional topological superconductor in the presence of disorders preserving average time-reversal symmetry or mirror symmetry. By calculating the transport signatures of multi-chain Kitaev and Majorana models, we show that the survival of the edge modes depends on the form of the disorders.

Electronic structure of twin wall/surface intersections in CaTiO$_3$ (001)*

NICHOLAS BARRETT (Presenter), QIANG WU, EKHARD SALJE, Department of Earth Sciences, University of Cambridge, ZIYUAN ZHAO, Department of Materials Science and Engineering, Xi’an University of Technology, CLAIRE MATHIEU, CHRISTOPHE LUBIN, DOMINIQUE MARTINOTTI, CEA-Saclay — Domain wall engineering of functional oxides provides a new paradigm for post-CMOS electronics [1]. Domain walls are potentially the perfect structural discontinuity, maintaining the crystalline phase but defining a change in the functional order parameter.

In CaTiO$_3$ the strain order is defined by the octahedral tilt. At the twin walls the octahedral tilt goes to zero allowing Ti off-centering and the twin wall acquires a ferroelectric polarization [2, 3].

We have studied the intersections between different twin walls and the (001) surface using low energy electron microscopy (LEEM) and molecular dynamics simulations including Landau springs and Coulomb interactions. The domain surfaces develop polarity close to the twin walls. The elastically induced dipoles cause contrast in LEEM, unexpected for nominally non-polar surfaces. The outward and inward twin wall polarity is in good agreement with simulations.

Nature of the Atomic Structure Underlying the Vortex Polarization Domains in Hexagonal RMnO$_3^*$

HAN ZHANG, SIZHAN LIU, New Jersey Inst of Tech, SUYIN GRASS WANG, YU-SHENG CHEN, Argonne National Laboratory, SANG-WOOK CHEONG, Rutgers University, TREVOR TYSON (Presenter), New Jersey Inst of Tech — Hexagonal phase RMnO$_3$ systems exhibit polarization domains with complex vortex pattern with density depending on the cooling rate from the high temperature paraelectric phase. Structural measurements are used to probe the structure on length scales commensurate with the variations in polarization. Structural measurements reveal variations on the lengthscale of the changes in polarization.

Towards adaptable nano-circuitry - functional domain walls and disorder engineering in improper ferroelectrics [Invited]

DENNIS MEIER, DONALD M. EVANS (Presenter), Materials Science and Engineering, Norwegian University of Science and Technology - NTNU — Oxide materials exhibit a broad range of tunable phenomena, including magnetism, multiferroicity, and superconductivity. Oxide interfaces are particularly intriguing. The low local symmetry combined with the sensitivity to electrostatics and strain leads to unusual physical properties. Recently, ferroelectric domain walls have attracted attention as conducting and spatially mobile interfaces. In order to ultimately design domain-wall-based devices and circuitry, however, additional functionality beyond just conduction is required.

In my talk, I will discuss how improper ferroelectric domain walls can be used to emulate key electronic components. In the first part, I will address domain walls in ErMnO$_3$. The system naturally develops all fundamental types of ferroelectric domain walls, including neutral as well as negatively and positively charged wall configurations. I will show how the electronic domain-wall properties can be controlled and discuss the possibility to use such walls for designing, e.g., 2D digital switches and half-wave rectifiers [1]. In the second part, I will consider domain walls in spin-spiral multiferroics with strong magnetoelastic couplings and additional functionality that arises from the interplay of charge and spin degrees of freedom. Because of the coupling, it is possible to reversibly control the configuration at ferroelectric domain walls by magnetic fields, switching between nominally charged and neutral domain wall states [2,3]. Furthermore, I will present an innovative approach for controlling conductivity and wiring up domain-wall-based devices with nanoscale spatial resolution, bringing us an important step closer to adaptable all-domain-wall circuitry for next-generation nanotechnology.

9:12AM X04.00005: Probing Microwave Dynamics of Ferroelectric Domain Walls* [Invited] KEJI LAI (Presenter), University of Texas at Austin — The past decade has witnessed the emergence and rapid development of domain wall (DW) nanoelectronics, which take advantage of the enhanced electronic conductivity at ferroelectric DWs due to the accumulation of free carriers. For practical high-speed electronics, however, the dielectric dispersion of ferroelectric materials at microwave frequencies has to be taken into account. Using a cohort of imaging techniques such as piezo-force microscopy, conductive atomic-force microscopy, and microwave impedance microscopy, we are able to determine the contribution of both mobile carriers and bound dipoles to the GHz response at ferroelectric domain walls. In LiNbO₃, BiFeO₃, and YMnO₃, the effective microwave conductivity of certain DWs is higher than that at DC by several orders of magnitude, while other walls behave the same at both DC and AC. First-principles and model calculations indicate that the AC-conductive DWs exhibit a localized vibrational mode, which can be excited by the alternating electric fields from the tip. In addition to the DW dynamics, the local electromechanical energy transduction in ferroelectric domains can also be visualized by the microwave probe. Our work opens up a new avenue to explore various phenomena in complex materials and novel devices by near-field electromagnetic imaging.

9:48AM X04.00006: Microwave Conductivity of Ferroelectric Domain Walls in BiFeO₃ Bulk Crystals LU ZHENG (Presenter), University of Texas at Austin, XIAOCHE FANG, XIANGHAN XU, SANG-WOOK CHEONG, Rutgers University, KEJI LAI, University of Texas at Austin — Domain walls (DWs) in multiferroic materials exhibit novel functionalities that may be utilized for nanoelectronic applications. In recent years, the enhanced DW dc conductivity due to the accumulation of free carriers and ac conductivity due to the excitation of wall vibration have both been reported in various ferroelectrics. Combining piezo-force microscopy and microwave impedance microscopy, we directly probe the nanoscale dielectric response of various DWs in BiFeO₃ bulk crystals at microwave frequencies. Interestingly, regardless of the type of the walls (71-, 109-, or 180-degree), the neutral DWs always display high ac conductivity around 1 GHz, whereas the charged walls do not. In addition, interference of surface acoustic waves can be observed near the 180-degree walls. Our results provide a unified picture to understand the DW dynamics in BiFeO₃, which is crucial for its application in high-speed nano-devices.

10:00AM X04.00007: Thermal effect on domain wall roughness in epitaxial PbZr₀.₂Ti₀.₈O₃ thin films with different as-grow polarization orientations* KUN WANG (Presenter), JINGFENG SONG, LE ZHANG, XUEGANG CHEN, XIA HONG, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln — In epitaxial ferroelectric films, the asymmetric boundary condition can lead to strong polarization asymmetry that affects the thermal stability of different polar states. We have carried out piezo-response force microscopy (PFM) studies on the thermal evolution of domain walls (DW) in epitaxial 50 nm PbZr₀.₂Ti₀.₈O₃ (PZT) films grown on (La,Sr)MnO₃ and LaNiO₃ buffered SrTiO₃, which show different as-grown polarization. The correlation function of the DW roughness depends on the distance $L$ along the DW as $L^{2\zeta}$. At room temperature, the roughness exponent $\zeta$ is 0.2-0.3, consistent with 2D DWs in weak random bond disorder. The films were then heated at progressively higher temperatures till approaching $T_C$. The subsequent PFM images show that $\zeta$ gradually increases to ~0.6, evolving to dominant thermal roughening. Both the bottom electrode type and the as-grown polarization orientation affect the $T$-dependence of $\zeta$. We also compare the results obtained from in situ high temperature measurements and rapid thermal quench. Our study provides critical information about the thermal stability and size scaling limit of epitaxial thin films-based ferroelectric devices.

Giant electroresistance effect in single-crystalline lithium niobate thin films enabled by domain wall control

JAMES MCCONVILLE (Presenter), Centre for Nanostructured Media, Queen's University Belfast, HAILDONG LU, Department of Physics and Astronomy, University of Nebraska-Lincoln, MICHELE CONROY, KALANI MOORE, Department of Physics, University of Limerick, ALEXEY LIPATOV, ALEXANDER SINITSKII, Department of Chemistry, University of Nebraska-Lincoln, ALEXEI GRUVERMAN, Department of Physics and Astronomy, University of Nebraska-Lincoln, URSEL BANGERT, Department of Physics, University of Limerick, MARTY GREGG, Centre for Nanostructured Media, Queen's University Belfast — One of the most prominent features of ferroelectric domain walls (DWs) is their electrical conductivity, which was observed in a number of materials, such as BiFeO₃, Pb(Zr,Ti)O₃, ErMnO₃. We combine scanning transmission electron microscopy (STEM) and local probe techniques to investigate the conduction through charged DWs in the ion-sliced single-crystalline LiNbO₃ thin films with sub-µm thickness. STEM shows large inclination of the electrically-generated 180° DWs away from the polar z-axis (with angles reaching 16°) suggesting the DWs are strongly charged. Using piezoresponse force microscopy (PFM) in combination with conductive atomic force microscopy (CAFM) it was shown that head-to-head DWs have higher conductivity than the tail-to-tail DWs, suggesting an electronic type of conductance. One of the most important findings is a modulation of conductivity by an external voltage. It is demonstrated that the resistance of the LiNbO₃ thin film capacitors can be changed continuously by 5 to 9 orders of magnitude by controlling the DW perimeter allowing development of multi-level resistive switching devices. Resistance states can be altered by exposure to cumulative voltage pulses, suggesting that these domain wall memristors might be useful in the context of artificial synapses.

Dipole-dipole interaction and domain relaxation of ferroelectric triangular lattice

HYE-JIN JIN (Presenter), Ewha Womans University, CHANG JAE ROH, Gwangju Institute of Science and Technology, JANGHYUN JO, JUNSIK MUN, Seoul National University, JONGSEOK LEE, Gwangju Institute of Science and Technology, MIYOUNG KIM, Seoul National University, YOUNG-HAN SHIN, University of Ulsan, WILLIAM JO, Ewha Womans University — In ferroelectric lattices, dipole arrangements are controlled by manipulating structural formation and orientations of ferroelectric thin films are determining factor to control dipole arrangements. Herein, tetragonal PbTiO₃ (PTO) thin films were obtained and triangular lattice is observed in (111)-PTO thin films. We used pulsed laser deposition and compared (001)- and (111)-PTO thin films. To confirm structural characteristics, X-ray diffraction patterns and second harmonic generations were used. In addition, dipole arrangements are investigated by using transmission electron microscopy. In particular, directions of dipoles are gradually changed and vortex-like domain structure is obtained in the (111)-PTO thin films. It is induced by tilting characteristics of polarization axes of the (111)-PTO thin films. To study domain relaxation, temporal change of domain is obtained by using piezoresponse force microscopy and a stretched exponential decay mechanism is applied. In the (111)-PTO thin films, dipole frustration is induced because of poling and redistribution of dipoles occurred to release dipole frustration. During relaxation, dipole-dipole interaction should be addressed and it gives a deep insight to understand fundamental relaxation mechanism of ferroelectric thin films.

Designing ferroic domain states and coupling through low-energy He-irradiation*

ANDREAS HERKLOTZ (Presenter), ROBERT ROTH, KATHRIN DORR, Institute for Physics, Martin-Luther-University Halle-Wittenberg, YOGESH SHARMA, THOMAS WARD, Oak Ridge National Laboratory — The physical properties of ferroic thin films are typically dominated by their domain configurations and the response of domain walls to external fields. Domain engineering has thus developed as a powerful tool to tailor functionalities of oxide thin films. A particularly successful approach has been the use of strain fields through heteroepitaxy.

As an alternative approach we deploy low-energy He implantation to induce out-of-plane strain in epitaxial ferroelectric thin films, while the in-plane strain due to coherent growth on single-crystal substrates remains fixed. We show that this kind of uniaxial strain engineering effectively alters the ratio of ferroelectric and ferroelastic domains in BaTiO₃ and BiFeO₃ films. We also demonstrate that controlling domains by strain doping can provide a direct handle on ferromagnetic metal films magnetoelastically coupled to the interfaced ferroelectric films.

8:00AM X05.00001: Quasi 1D topological nodal superconducting vortex line state in doped 3D Dirac Semimetals
SHENGSHAN QIN (Presenter), Kavli Institute of Theoretical Sciences, LUN HU, Department of Physics, University of California, San Diego, California 92093, USA, CONGCONG LE, Kavli Institute of Theoretical Sciences, JINFENG ZENG, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, FU-CHUN ZHANG, Kavli Institute of Theoretical Sciences, CHEN FANG, JIANGPING HU, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We study the vortex bound states in three dimensional (3D) Dirac semimetals with both time reversal symmetry and inversion symmetry. Assuming two Dirac points on the kz-axis and bulk s-wave superconductivity, the results turn out to be strongly anisotropic: if the vortex line is perpendicular to the kz-direction, the bulk superconductor plus a single quantum vortex line is always topologically trivial; if the vortex line is parallel to the kz-direction, the system has a robust quasi 1D topological nodal superconductor phase, for certain range of doping level. The emergence of the nodal superconductor phase is a reflection of the topological property of the Dirac point. Finally, we discuss the possible material realization of such nodal superconducting vortex line state.

8:12AM X05.00002: Finite temperature topological states in a chain of magnetic adatoms on a superconductor*
MACIEJ MASKA (Presenter), ANNA GORCZYCA-GORAJ, University of Silesia in Katowice, TADEUSZ DOMANSKI, Maria Curie-Skłodowska University in Lublin — It is known that magnetic moments of a one-dimensional chain of adatoms on a superconductor self-organize into a spiral magnetic structure, which leads to topologically nontrivial superconductivity. Such a system can host the Majorana quasiparticles near its edges. The interaction between the localized moments is mediated by itinerant electrons. Upon tracing out the fermionic degrees of freedom, one obtains long range temperature-dependent effective interaction between the moments. Using Monte Carlo techniques we calculate the thermodynamic properties of the system. In particular, we demonstrate that with increasing temperature the correlation length of the magnetic order decreases, eventually driving the system to a topologically trivial phase. Using the simulated annealing method we also show, that at low temperature a phase separation can take place in the chain, where only part of the system is in the topologically nontrivial state and the rest of it is in the trivial state.

8:24AM X05.00003: Quantum Transport in Nanowires Grown via Template Assisted Selective Epitaxy and Contacted by an s-wave Superconductor*
M A MUEED (Presenter), BENJAMIN MADON, IBM Almaden Research Center, FABRIZIO NICHELE, MARKUS RITTER, IBM Zurich Research Center, NOEL ARELLANO, IBM Almaden Research Center, HEINZ SCHMID, IBM Zurich Research Center, FENNER HARPER, RAHUL ROY, Physics, University of California at Los Angeles, HEIKE RIEL, IBM Zurich Research Center, AAKASH PUSHP, IBM Almaden Research Center — The hybrid system of an s-wave superconductor and a semiconducting nanowire with strong spin-orbit coupling (e.g. InAs, InSb) is a robust platform for realizing Majorana Fermion, a quasi-particle which is considered to be the building block for fault tolerant quantum computation. In our study, we prepare InAs nanowire networks using Template Assisted Selective Epitaxy (TASE) method and contact them using an s-wave superconducting material. The TASE method offers a reproducible way to grow high-quality nanowire in non-trivial device geometries, such as cross and Y-junctions, proposed for braiding operations of Majorana Fermions. Here, we present the quantum transport data measured on TASE-grown InAs nanowires with different device geometries.

8:36AM X05.00004: Enhanced Triplet Pairing in Magnetic Junctions with s-wave Superconductors  
CHENGHAO SHEN (Presenter), University at Buffalo, The State University of New York, THOMAS VEZIN, École Polytechnique, JONG E HAN, IGOR ZUTIC, University at Buffalo, The State University of New York — A common path to Majorana fermions and topologically-protected quantum computing relies on spin-triplet superconductivity[1]. While spin-triplet pairing is elusive in nature and even common spin-triplet candidates, such as Sr2RuO4, could support alternative explanations[2], proximity effects in heterostructures can overcome these limitations. Specifically, a common expectation is that robust spin-triplet superconductivity in magnetic junctions should rely on highly spin-polarized magnets or complex magnetic multilayers[3]. Instead, we predict that the interplay of interfacial spin-orbit coupling and the barrier strength in simple magnetic junctions with s-wave superconductors can lead to nearly complete spin-triplet superconducting proximity effects when magnets have only a small spin polarization. We show that this enhanced spin-triplet regime is characterized by a huge increase in conductance magnetoanisotropy[4], orders of magnitude larger than in the normal state.

We thank P. Högl for valuable discussions.

8:48AM X05.00005: Magnetic coupling between dopant atoms in superconducting doped topological insulators*  
CODY YOUMANS (Presenter), City College of New York, AREG GHAZARYAN, Physics, Institute of Science and Technology, Austria, POUYAN GAHEMI, City College of New York — Doped topological insulators have been shown to exhibit unconventional superconducting phases where novel bound states can occur at defects such as vortices. Recent experimental studies on Niobium-doped Bismuth Selenide have shown that the magnetic properties of dopant atoms can strongly affect the resulting superconducting phase. This effect is mainly due to the development of Yu-Shiba-Rusinov bound-states at the magnetic atoms and the coupling of such states through the superconducting environment. In this talk, we show that the doping level can critically affect the type of magnetic coupling between dopant atoms in superconducting doped topological insulators and thereby influence their magnetic and superconducting properties.

9:00AM X05.00006: Superconductor Quasiparticles with Random Curvature, Robust Criticality, and T-Linear Resistivity  
SAYED ALI AKBAR GHORASHI, Physics, College of William & Mary, MATTHEW FOSTER (Presenter), Physics & Astronomy, Rice University — We study quenched random curvature disorder for 2D massless relativistic carriers. This describes a topological superconductor Majorana surface fluid with generic time-reversal invariant dirt. It should also apply to any non-topological Dirac or Majorana system in which the disorder is sufficiently smooth, as could be the case for d-wave quasiparticles in the cuprates with remote dopants.

Random curvature is strongly irrelevant at zero energy, but we show that it profoundly affects the finite-energy states. These are found to exhibit robust, universal criticality (see also Ghorashi, Liao, and Foster, PRL 2018). Our results imply that the local density of states imaged via STM would exhibit minimal spatial structure near zero bias, but robust, static and universal fluctuations over a large finite bias range.

We also consider a speculative connection to the pseudogap regime. Assuming that the superfluid component is quenched by phase fluctuations, we calculate the electrical conductivity. Preliminary results indicate linear-in-T resistivity, attributed to the crossover between ballistic and critical states at zero and finite-energy, respectively.

9:12AM X05.00007: Majorana bound states in magnetic skyrmions imposed onto a superconductor  
STEFAN REX (Presenter), IGOR V. GORNYI, ALEXANDER D. MIRLIN, Karlsruhe Institute of Technology — We consider a two-dimensional superconductor exchange-coupled to the magnetic texture of a close-by chiral magnetic layer. In particular, we study how magnetic skyrmions can induce the formation of Majorana bound states (MBS) in the superconductor, where we focus on realistic skyrmions with winding number one. We show that MBS are supported if a vortex is pinned to the skyrmion core. In addition, we consider a chain of skyrmions, which may host MBS at its ends. In light of recent experimental progress on the manipulation of skyrmions, such systems are promising candidates to achieve direct spacial control of MBS.
9:24AM X05.00008: Development of the Scanning Majorana Microscope*  ERIC GOODWIN (Presenter), MICHAEL GOTTSCHALK, Michigan State University, ALEX LEVCHENKO, University of Wisconsin-Madison, STUART HOLDEN TESSMER, Michigan State University — The Scanning Majorana Microscope (SMM) is being developed to provide novel ways for verification of the existence of Majorana zero modes. Inspired by a variety of scanning probe methods, the SMM consists of an aluminum quantum dot fabricated on the end of a sharp glass tip. By connecting the probe to an ultrasensitive charge-sensing circuit, the counting statistics of electrons entering the quantum dot can be characterized. It has been predicted theoretically that cases with and without Majorana coupling should exhibit qualitatively different full counting statistics of charge tunneling events despite the fact that differential linear conductance might have zero-bias features in both cases. Thus this microscope represents an important tool for detecting Majoranas going beyond existing experimental probes. Fabrication and preliminary measurements of the SMM will be presented.

9:36AM X05.00009: Local Andreev reflection induced by Chiral Majorana Fermions  ZHESHEN GAO (Presenter), KAM TUEN LAW, CHUI-ZHEN CHEN, Department of Physics, Hong Kong University of Science and Technology — When superconductivity is proximity induced into a quantum anomalous system, it is predicted to host Chiral Majorana Edge Modes(CMEMs), which would induce a unique half quantized plateau as its transport signature. This was recently found in the experiments[Science 357, 294 (2017)]. However, it was argued that without superconductivity, disorder alone could also induce such signature. Thus more experimental evidence is called to determine whether superconductivity was the actual factor. Here we proposed to use local tunneling spectroscopy to directly probe the edge state of the hybrid system. We used Non-Equilibrium Green's Function to show that for topological phase with chern number N=±1/2 which hosts 1/2 actual factor. Here we proposed to use local tunneling spectroscopy to directly probe the edge state of the hybrid system.

9:48AM X05.00010: Erasing odd-parity states in a semiconductor quantum dot coupled to a superconductor  PO ZHANG (Presenter), HAO WU, ZHAOEN SU, Department of Physics and Astronomy, University of Pittsburgh, ROK ZITKO, Department of Theoretical Physics, Jozef Stefan Institute, EDUARDO LEE, Department of Condensed Matter Physics, Universidad Autonoma de Madrid, DIANA CAR, Applied Physics, Eindhoven University of Technology, SÉBASTIEN PLISSARD, LAAS CNRS, MOIRA HOCEVAR, Institut NEEL CNRS, SASA GAZIBEgovIC, ROY OP HET VELD, GHADA BADAWY, ERIK P. A. M. BAKKERS, Applied Physics, Eindhoven University of Technology, SERGEY M FROLOV, Department of Physics and Astronomy, University of Pittsburgh — Andreev bound states (ABS) exhibit many similarities to Majorana bound states (MBS). It would be of interest to study ABS in the system where MBS may emerge. The knowledge of ABS in a single dot is also crucial to understand more complicated systems, such as an artificial NbTiN /InSb dot chain that emulates a 1D Kitaev model. Here we study the erasing of odd-parity ABS in a quantum dot with gate-tunable superconducting coupling. The dot is defined in an InSb nanowire/NbTiN superconductor hybrid system. Fine gates are used to tune the coupling, the barrier and the chemical potential. In weak coupling regime, a parity-changing pattern of ABS is observed inside the Coulomb diamonds. In strong coupling regime, the ABS pattern opens a gap and the odd-parity regime is ‘erased’ from the pattern. We study this transition with different source-drain bias, map the phase boundary between even/odd states in magnetic fields and compare it to a finite-size Majorana nanowire.

10:00AM X05.00011: Observing pairs of zero-bias states in three-terminal Superconductor-Semiconductor devices: Part I*  DENISE PUGLIA (Presenter), GIAN-LUCA ANSELMETTI, GERBOLD MENARD, FILIP MALINOWSKI, ESTEBAN A MARTINEZ, University of Copenhagen, JOON SUE LEE, SUKGEUN CHOI, MIHIR PENDHARKAR, University of California Santa Barbara, GEOFFREY C. GARDNER, SERGEI GRONIN, RAY KALLAHER, MICHAEL MANFRA, Microsoft, CHRIS PALMSTROM, University of California Santa Barbara, CHARLES M MARCUS, LUCAS CASPARIS, ANDREW P HIGGINBOTHAM, Microsoft — Majorana zero-energy modes located at the ends of topological superconductors are an appealing platform for topological quantum computing. Zero-bias peaks (ZBPs) are ubiquitously observed in tunneling spectroscopy of hybrid superconductor-semiconductor nanowires, consistent with expectations for Majorana modes. However, the emergence of those zero-energy modes in pairs at the ends of 1D topological superconductors is a central -- and so far untested -- prediction. Enabled by recent materials breakthroughs in selective area growth (SAG), we demonstrate a platform for testing this prediction by probing the conductance matrix of a three-terminal InAs wire proximitized by Al. We introduce the measurement technique and study correlations of sub-gap states at zero field, finding evidence of localized states at the wire ends and delocalized bulk states. Correlated, zero-bias features emerging in finite field at both ends of the device will be presented in Part II.

*This work was supported by Microsoft Project Q, the Danish National Research Foundation and the Villum Foundation.
Observing pairs of zero-bias end states in three-terminal superconductor-semiconductor nanowires, consistent with expectations for Majorana modes. However, the emergence of those zero-energy modes in pairs at the ends of 1D topological superconductors is a central -- and so far untested -- prediction. Enabled by recent materials breakthroughs in selective area growth (SAG), we demonstrate a platform for testing this prediction by probing the conductance matrix of a three-terminal InAs wire proximitized by Al. We perform tunneling spectroscopy independently on both ends of the wire as a function of longitudinal magnetic field and voltage. ZBPs emerge which are correlated and robust for these parameters.

Session X06 DCMP: Quantum Phase Stability and Criticality: Theory BCEC 109A

8:00AM X06.00001: Superconductivity from quantum fluctuations of itinerant quantum critical points* YUNCHAO HAO (Presenter), YANG QI, Physics, Fudan University, KAI SUN, Physics, University of Michigan — In the vicinity of a quantum critical point, critical fluctuations can often act as glue for the formation of BCS pairs, which is one important path way towards unconventional superconductivity. Recently, thanks to the development in quantum numerical techniques, such as sign-problem quantum Monte Carlo simulations, new insights and unbiased numerical understanding about this phenomenon become accessible. In particular, the numerical results suggest superconductivity emerged from these quantum critical points are highly diversified and are highly sensitive microscopic details. In this study, we investigate these systems utilizing analytic approach. By exploring different model systems and compare with numerical results, we aim at understanding universal properties behind these diversified behaviors.

8:12AM X06.00002: Characterizing the quantum critical point between a Dirac spin liquid and an antiferromagnet* ERIC DUPUIS (Presenter), WILLIAM WITCZAK-KREMPA, Universite de Montreal — The spin-1/2 kagome Heisenberg antiferromagnet hosts a putative quantum spin liquid phase for which a candidate ground state is the Dirac spin liquid. At low energies, this state is described by quantum electrodynamics in 2+1 dimensions with 2 Nf = 4 flavors of two-component gapless spinons. We describe a transition to a coplanar antiferromagnetic (AFM) phase by coupling the spinons to a vectorial bosonic order parameter. We find a non-trivial quantum critical point and compute critical exponents using a one-loop d=4-ε expansion. The compactness of the U(1) gauge field allows topological configurations named monopoles which must condense to induce the AFM phase. We classify the monopole operators by their isospin and compute their contributions to the AFM critical behavior. The agreement between our results and other model systems will be discussed.

*This work is supported by Minstry of Science and Technology of China under grant numbers 2015CB921700, and by National Science Foundation of China under grant number 11874115.

8:24AM X06.00003: Quantum Criticality in the Two-Dimensional Periodic Anderson Model* THOMAS SCHAEFER (Presenter), CPHT, Ècole Polytechnique, ANDREY A. KATANIN, Institute of Metal Physics, Ekaterinburg, MOTOHARU KITATANI, ALESSANDRO TOSCHI, KARSTEN HELD, Institute of Solid State Physics, TU Wien — Despite the fascinating phenomena accompanying a quantum critical point, e.g. non-Fermi liquid behavior, a general theory for quantum phase transitions is lacking. In this talk, I will present a step forward by analyzing results from the dynamical vertex approximation, a cutting-edge quantum field theoretical method including temporal as well as spatial correlations. Within this framework, I will analyze the fundamental model of strongly correlated heavy fermion compounds, the periodic Anderson model. By varying the hybridization strength of localized f-electrons and itinerant d-electrons, and a careful analysis of response functions, one can trace the change in the ground state from an antiferromagnet to a paramagnetic Kondo insulating phase, resembling the famous Doniach phase diagram. Eventually, I will show the evolution of the critical exponents of the magnetic susceptibility, which are changing from the one of free spins γ=1 to γ=2 in the quantum critical regime. T. Schäfer, A. Katanin, K. Held, and A. Toschi, PRL 119, 046402 (2017), T. Schäfer, A. Katanin, M. Kitatani, A. Toschi, and K. Held, in preparation.

8:36AM X06.00004: Quantum critical scaling beyond Ginzburg-Laudau-Wilson paradigm in heavy-fermion metals YUNG-YEH CHANG (Presenter), National Chiao Tung University, STEFAN KIRCHNER, Department of Physics, Zhejiang Institute of Modern Physics, CHUNG-HOU CHUNG, National Chiao Tung University — Within the standard bosonic Ginzburg-Landau-Wilson (G-L-W) theory of phase transitions, the hyperscaling ansatz exists only below the upper critical dimension (d+z < 4) with d being spacial dimension and z being the dynamical exponent. Surprisingly, however, we show that the hyperscaling ansatz can survive above the upper critical dimension (d+z > 4) in an effective field theory of a large-N approach to the Kondo-Heisenberg lattice model, relevant for describing a wide range of heavy-fermion materials. A novel Bose-Fermi effective field theory is constructed beyond our large-N saddle-point solution. Via perturbative renormalization group approach, a nontrivial interacting Gaussian fixed point is discovered due to the presence of a boson-fermion (Yukawa) coupling in our field theory, giving rise to novel hyperscaling relations beyond the G-L-W paradigm. The outstanding open issues on the singular-in-temperature behaviors for the specific heat coefficient and the Gruneisen ratio in the strange metal regime observed in heavy-fermion metal Ge-substituted YbRh2Si2 are well accounted for within our theory. The implications of our results to heavy-fermion quantum criticality, in general, are discussed.

8:48AM X06.00005: Exact non-linear I-V curve near two-channel Kondo-Luttinger quantum critical point  CHAO-YUN LIN (Presenter), YUNG-YEH CHANG, Department of Electrophysics, National Chiao-Tung University, Hsinchu, Taiwan, R.O.C., COLIN RYLANDS, NATAH ANDREI, Department of Physics, Rutgers University, Piscataway, New Jersey, U.S.A., CHUNG-HOU CHUNG, Department of Electrophysics, National Chiao-Tung University, Hsinchu, Taiwan, R.O.C. — It has been known since 1990’s that a Kondo impurity coupled to Luttinger liquid wire undergoes an exotic quantum phase transition with decreasing Luttinger parameter $K$ (or increasing electron interactions) from the 1-channel to 2-channel Kondo ground states at $K=1/2$. However, the quantum critical properties near this transition is still not known to date due to lack of controlled theoretical tools to examine the physics near the strong coupling 2-channel Kondo fixed point. In this paper, we address this long-standing issue via bosonization-refermionization approach near 2-channel Kondo state. We overcome the problem by mapping the system at the Toulouse point onto an effective two-lead free fermion model subject to a local tunneling. Remarkably, the non-equilibrium transport of the system is exactly solvable in this limit. An analytic form for the non-linear differential conductance is obtained. Our results offer an unique example of exactly and analytically accessible non-equilibrium transport near a quantum critical point; they are relevant for the recent experiment in a dissipative Kondo dot.

9:00AM X06.00006: Thermodynamic properties of 3D plaquette antiferromagnet  GUANG YU SUN (Presenter), NUSEN MA, Chinese Academy of Science, ANDERS W SANDVIK, Boston University & Chinese Academy of Science, ZI YANG MENG, Chinese Academy of Science — We design a 3D checker-board J-Q model to capture phase transitions between a plaquette-singlet solid with lattice translational symmetry breaking to a 3D Neel phase with spin rotational symmetry breaking. The system is investigated via unbiased large-scale quantum Monte Carlo simulation. We use Binder cumulant to determine the finite temperature phase boundary and measure the specific heat and magnetic susceptibility to reveal the nature of the different phases and their transitions. Our results are closely related with the on-going experimental effort in pressure-induced magnetic phase transitions in Shastry- Sutherland (SS) compound SrCu$_2$(BO$_3$)$_2$.

9:12AM X06.00007: Emergence of non-Fermi liquid dynamics through nonlocal correlations in an interacting disordered system*  SUDESHNA SEN (Presenter), School of Physics, University College Dublin, Ireland, N S VIDHYADHIRAJA, Theoretical Sciences Unit, Jawaharlal Nehru Centre for Advanced Scientific Research, MARK JARRELL, School of Physics and Astronomy, Louisiana State University — We provide strong evidence for a quantum critical point (QCP) associated with the destruction of Kondo screening in the Anderson-Hubbard model for interacting electrons with quenched disorder. The evidence comprises three elements: (a) the identification of an energy scale, that delineates infrared Landau damping from higher frequency non-Fermi liquid (nFL) dynamics; (b) the finding that this crossover scale appears to vanish with increasing disorder; and (c) the concomitant appearance of a finite intercept in a broad distribution of Kondo scales. Our findings indicate a Kondo destruction scenario, albeit distinct from the local QCP picture. The nFL behavior is shown to stem from an interplay of strong electron-electron interactions and the systematic inclusion of short-range dynamical fluctuations induced by the underlying random potential. The results have been obtained through a computational framework based on the typical medium dynamical cluster approximation.

9:24AM X06.00008: U(N)/U(m)U(N-m) nonlinear sigma model: critical behavior and a physical realization*  DA WANG (Presenter), Nanjing University — The nonlinear sigma model defined on the Grassmann manifold U(N)/U(m)U(N-m) is a direct generalization of the widely studied $\mathbb{C}P^{N-1}$ model. In space dimension $2<d<4$, we use 1/N expansion technique to obtain its critical exponents including two-particle ones, which are found to be only functions of $m/N$ up to the first order. As a result, larger $m$ effectively reduces $N$ and thus brings stronger fluctuations. Next, we show such a model is a low energy description of the SU(N) Hubbard model which has been realized in cold atom experiments. With determinant quantum Monte Carlo simulations of the half-filled SU(6) Hubbard model on the square lattice, we have found strong evidences of a continuous quantum phase transition from the antiferromagnetic to valence bond solid states as $U$ increases. Such a phase transition is described by the U(6)/U(3)U(3) nonlinear sigma model.

*NSFC (Nos. 11504164, 11574134)
9:36AM X06.00009: Phase transitions in the "easy plane" JQ model*  NISHEETA DESAI (Presenter), RIBHU KAUL, University of Kentucky — We study the JQ model on the square lattice after adding to it "easy plane" terms that explicitly break the SU(2) symmetry of the original model. The Néel to VBS transition is believed to be continuous for the full SU(2) symmetric model. In the easy-plane limit, this model was shown to have a first order transition between the superfluid and the VBS phases. We use Stochastic Series Expansion Quantum Monte Carlo to investigate the nature of this transition for various strengths of this easy-plane anisotropy. We find that the first order nature of the transition weakens as we weaken the strength of the easy-plane interaction. However, we find no evidence that this transition becomes continuous before the SU(2) symmetric point.

9:48AM X06.00010: Phase diagram of effective model for twisted bilayer graphene at particle-hole symmetric point

YUAN DA LIAO (Presenter), Institute of physics, Chinese Academy of Sciences, XIAO YAN XU, Department of Physics, Hong Kong University of Science and Technology, ZI YANG MENG, Institute of physics, Chinese Academy of Sciences — We study an effective extended Hubbard model on the honeycomb lattice with two orbitals per site at the particle-hole symmetry filling. The tight-binding part of the model is believed to describe the low-energy electronic properties of the twisted bilayer graphene. Using large-scale projection quantum Monte Carlo method, we map out the ground state phase diagram of the model, the novel properties of electrons in the presence of non-local (plaquette) interaction, are revealed with high accuracy.

10:00AM X06.00011: Renormalization group analysis of phase transitions in the two dimensional Majorana-Hubbard model*

KYLE WAMER (Presenter), IAN AFFLECK, Stewart Blusson Quantum Matter Institute and the Department of Physics and Astronomy, University of British Columbia — A lattice of interacting Majorana modes can occur in a superconducting film on a topological insulator in a magnetic field. The phase diagram as a function of interaction strength for the square lattice was analyzed recently using a combination of mean field theory and renormalization group methods, and was found to include second order phase transitions. One of these corresponds to spontaneous breaking of an emergent U(1) symmetry, for attractive interactions. Despite the fact that the U(1) symmetry is not exact, this transition was claimed to be in a supersymmetric universality class when time reversal symmetry is present and in the conventional XY universality class otherwise. Another second order transition was predicted for repulsive interactions with time reversal symmetry to be in the same universality class as the transition occurring in the Gross-Neveu model, despite the fact that the U(1) symmetry is not exact in the Majorana model. We analyze these phase transitions using a modified ε-expansion, confirming the previous conclusions.

10:12AM X06.00012: Imaginary-spin-bond order induced by a magnetic field

MENGXING YE (Presenter), ANDREY CHUBUKOV, University of Minnesota — We show that a 2D fermion system with well separated electron and hole pockets may develop a time-reversal symmetric directional imaginary-spin-bond order. It emerges when some interactions are repulsive and some are attractive. Moreover, we demonstrate that this order is necessarily triggered by a magnetic field, even if the order at zero field is a conventional spin-density-wave state. We show that a finite field linearly couples the bond order to the spin-density-wave order. We also discuss the ways to probe such an order in experiments.

10:24AM X06.00013: Nonthermal states in nonintegrable magnetic models*

NEIL ROBINSON (Presenter), Institute for Theoretical Physics, University of Amsterdam, ANDREW J JAMES, Physics, University College London, GIUSEPPE BRANDINO, exact-lab, ROBERT KONIK, Condensed Matter Physics & Material Science, Brookhaven National Lab — There is a new paradigm emerging for quantum systems: those which are nonintegrable but nevertheless possess nonthermal states embedded throughout their many-body spectrum (whose number is polynomial in the system size). The presence of such states violates a strong version of the eigenstate thermalization hypothesis, and the behaviour expected for generic nonintegrable systems, such as thermalization, can be broken. Why such nonthermal states appear in certain models is currently not understood, although recent works have drawn analogies with the physics of "quantum scars". We show that nonthermal states, extending far into the many-body spectrum, can arise in simple magnetic (continuum and lattice) models that exhibit confinement and the associated formation of "meson-like" excitations. As a result, certain quenches in these models do not lead to thermalization and the nonequilibrium dynamics of local observables can show persistent, long-lived oscillations.

10:36AM X06.00014: Spin echoes in disordered Hubbard models  
TASNEEM BIADSY (Presenter), YOAV SAGI, NETANEL LINDNER, Physics Department, Technion - Israel Institute of Technology — We study spin-echo signals in disordered Hubbard models. We numerically show that the spin echo signal is characterized by a timescale which depends non-monotonically on disorder strength through the many-body localization transition. Our results yield a tool for detecting the transition which is based on short time evolution, making it efficient numerically and an attractive tool for experimental implementation.

Friday, March 8, 2019 8:00 AM - 11:00 AM

Session X07 DCMP: Novel Approaches to Studying Quantum Matter  
BCEC 109B - Laurel Winter, Los Alamos National Laboratory

8:00AM X07.00001: Boson-Fermion Duality in Four Dimensions*  
TAKUYA FURUSAWA (Presenter), YUSUKE NISHIDA, Tokyo Institute of Technology — In this talk, we propose a novel boson-fermion duality in four space-time dimensions by generalizing the lattice construction approach [1], which was applied to derive 3D boson-fermion duality [2]. Our analysis suggests that the Abelian Higgs model of $\theta=\pi$ is equivalent to a free Dirac fermion. The phase transition between topological and trivial insulators on the fermion side is dual to that between Higgs and confined phases on the boson side. Moreover, the Dirac fermion corresponds to a three-body bound state of one Higgs boson and two dyons in the bosonic theory.

8:12AM X07.00002: Monte Carlo Study of Compact Quantum Electrodynamics at larger Fermion Flavors  
WEI WANG (Presenter), BEIJING NATIONAL LABORATORY FOR CONDENSED MATTER PHYSICS AND INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCE, CHONG WANG, PERIMETER INSTITUTE FOR THEORETICAL PHYSICS, ZI YANG MENG, BEIJING NATIONAL LABORATORY FOR CONDENSED MATTER PHYSICS AND INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCE — Based on our development in quantum Monte Carlo (QMC) technique (arXiv:1807.07574), the compact U(1) lattice gauge theory coupled to fermionic matter at (2+1)D is now accessible with large-scale numerical simulations, and the phase diagram as a function of fermion flavor and the strength of gauge fluctuations is mapped out. Here we focus on the large fermion flavor case ($N_f \geq 8$), where the deconfine-confine phase transition is investigated in detail. In the deconfine phase, fermions coupled to the fluctuating gauge field to form U(1) spin liquid and in the confined phase, fermions are gapped out into valence bond solid. The different behaviors in terms of gauge flux, spectral of gauge-invariant observables as well as the deconfine-confine phase transition (QED3-Gross-Neveu-type) are presented.

8:24AM X07.00003: Exact Results on Itinerant Ferromagnetism and the 15-puzzle Problem*  
ERIC BOBROW (Presenter), KEATON STUBIS, YI LI, Johns Hopkins University — We apply a result from graph theory to prove exact results about itinerant ferromagnetism. Nagaoka's theorem of ferromagnetism is extended to all non-separable graphs except single polygons with more than four vertices by applying the solution to the generalized 15-puzzle problem, which studies whether the hole's motion can connect all possible tile configurations. This proves that the ground state of a $U \to \infty$ Hubbard model with one hole away from the half filling on a 2D honeycomb lattice or a 3D diamond lattice is fully spin-polarized. Furthermore, the condition of connectivity for $N$-component fermions is presented, and Nagaoka's theorem is also generalized to $SU(N)$-symmetric fermion systems on non-separable graphs.

**8:36AM X07.00004: The Fermion Bag Approach to Hamiltonian Theories**  
EMILIE HUFFMAN (Presenter), Physics, Perimeter Institute, SHAILESH CHANDRASEKHARAN, Duke University — Quantum Monte Carlo (QMC) methods, when applicable, offer dependable ways to extract the nonperturbative physics of strongly-correlated many-body systems. However, there are some formidable bottlenecks to the applicability of these methods such as the sign problem and algorithmic update inefficiencies. Using the t-V model Hamiltonian, we demonstrate how the fermion bag approach--originally developed in the context of Lagrangian lattice field theories--led to the first sign problem solution for this model. We then show how using fermion bag ideas to develop a new efficient QMC algorithm to study the t-V model allowed us to compute critical exponents for the chiral Ising universality class (involving one flavor of four-component Dirac fermions) that seem to be more reliable than those from previous QMC calculations. Finally, we discuss how the fermion bag approach offers certain advantages to the study of other models involving Dirac fermions and also extends to fermion-spin interactions and $Z_2$ gauge theories.

**8:48AM X07.00005: Fracton and Holography**  
HAN YAN (Presenter), Okinawa Institute of Science and Technology — We propose that the fracton topological order is a class of toy models for holography. The discovery of AdS/CFT correspondence as a concrete construction of holography, and the subsequent developments including the Ryu-Takayanagi formula of entanglement entropy have revolutionized our understanding of quantum gravity, and provided a powerful tool set for solving various strongly-coupled quantum field theory problems. In this work we discuss a classical toy model based on fracton topological order, a class of exotic many-body systems with boundary area law of ground state degeneracy and (partially) immobile excitations. We show that such a model defined on the hyperbolic lattice satisfies some key properties of holographic correspondence. These properties include: the AdS-Rindler reconstruction is realized; the mutual information obeys the Ryu-Takayanagi formula, and a naively defined black hole's entropy scales as its horizon area.

*HY is supported by the Theory of Quantum Matter Unit at Okinawa Institute of Science and Technology, and the Japan Society for the Promotion of Science (JSPS) Research Fellowships for Young Scientists.

**9:00AM X07.00006: Monte Carlo Study of Compact Quantum Electrodynamics with Fermionic Matter: the Parent State of Quantum Phases**  
YANG QI (Presenter), Department of Physics, Fudan University, XIAO YAN XU, Department of Physics, Hong Kong University of Science and Technology, LONG ZHANG, Kavli Institute for Theoretical Sciences, University of Chinese Academy of Sciences, FAKHER ASSAAD, Institut für Theoretische Physik und Astrophysik, Universität Würzburg, CENKE XU, Department of Physics, University of California, Santa Barbara, ZI YANG MENG, Institute of Physics, Chinese Academy of Sciences — The interplay between lattice gauge theories and fermionic matter accounts for fundamental physical phenomena ranging from the deconfinement of quarks in particle physics to quantum spin liquid with fractionalized anyons and emergent gauge structures in condensed matter physics. Here we show that the problem of compact U(1) lattice gauge theory coupled to fermionic matter in (2+1)D is possible to access via sign-problem-free quantum Monte Carlo simulations. One can hence map out the phase diagram as a function of fermion flavor and the strength of gauge fluctuations. By increasing the coupling constant of the gauge field, gauge confinement in the form of various spontaneous symmetry breaking phases such as valence bond solid (VBS) and Néel antiferromagnet emerge. Deconfined phases with algebraic spin and VBS correlation functions are also observed. Such deconfined phases are an incarnation of exotic states of matter, i.e. the algebraic spin liquid, which is generally viewed as the parent state of various quantum phases. The phase transitions between deconfined and confined phases, as well as that between the different confined phases provide various manifestations of deconfined quantum criticality.

**9:12AM X07.00007: Hidden SU(2) Symmetries, Symmetry Hierarchy and Emergent Eight-Fold-Way in Spin-1 Quantum Magnets**  
HUI-KE JIN (Presenter), YI ZHOU, JIAN-JIAN MIAO, Physics Department, Zhejiang University — The allowed largest symmetry in quantum spin-1 systems is SU(3) rather than spin rotational SO(3). In this work, we study some SU(2) symmetries as subgroups of the SU(3), which was not bewared in literature to the best of our knowledge. We construct two-body Hamiltonians where these SU(2) symmetries are respected, and explore the ground phase diagram according to the symmetry hierarchy SU(3)/SU(2)×U(1). It is natural to treat the eight generators of the SU(3) symmetry on an equal footing, called eight-fold-way. And possible experimental consequences are discussed as well.

9:24AM X07.00008: Numerically study the conformality of Q-state 1+1D quantum Potts model at Q>4  HAN MA  
(Presenter), University of Colorado, Boulder, YIN-CHEN HE, Perimeter Institute — The existence of complex conformal field theory (CFT) is proposed to be a mechanism of weak first order phase transition featuring extremely slow renormalization group flow with approximate scale invariance. We numerically study the simplest platform of this physics — the Q-state 2D Potts model when Q>4. We find that the properties of the phase transition are well captured by the complex CFTs. The central charge and conformal tower are extracted and studied. We also analyze how these data rely on length scale using conformal perturbation theory away from the nearby complex CFT.

9:36AM X07.00009: Slow scrambling in a quantum rotor model with random exchange interactions  DAN MAO  
(Presenter), DEBANJAN CHOWDHURY, SENTHIL TODADRI, Physics, MIT — In recent years, out-of-time-order correlation functions (OTOC) have been used to diagnose the onset of information scrambling in a wide class of problems, ranging from black holes to interacting field theories and lattice models. We study the OTOC for a solvable model of a large number (N) of M-component quantum rotors coupled by Gaussian-distributed random, infinite-range exchange interactions [1]. At a finite temperature above the quantum critical point separating a spin-glass and a paramagnetic phase, there is no exponential growth of the OTOC of the rotor fields. We show that in this large N, M limit, the random rotor model is integrable, and can be described by random matrix theory. The apparent lack of quasiparticle excitations in this limit arises as a result of disorder averaging and not strong interactions. We also compute the leading 1/M contribution to the OTOC of the rotor fields and find a slow exponential growth.

9:48AM X07.00010: Superfluidity without Condensation  ANTHONY HEGG (Presenter), Shanghai Jiao Tong University, WEI KU, Tsung-Dao Lee Institute — The connection between superfluidity and Bose-Einstein condensation (BEC) is well studied in 3D, but it is untenable in 2D due to the lack of condensation in such systems. We develop a new microscopic theory that exhibits low temperature superfluidity on a 2D lattice despite the lack of condensation and show that it has surprising properties. Fluctuations play a key role in the stability of this superfluid, and it is more robust than superfluidity in the presence of a BEC. Finally, we discuss the application of this mechanism to produce superfluidity in a 3D system.

10:00AM X07.00011: Numerically efficient parquet-equations solver for correlated electron systems*  CHRISTIAN ECKHARDT (Presenter), ANNA KAUCH, Institut für Festkörper Physik, TU Wien, GIULIO A.H. SCHOBER, CARSTEN HONERKAMP, Theoretical Solid State Physics, RWTH - Aachen, KARSTEN HELD, Institut für Festkörper Physik, TU Wien — The parquet equations are a set of self-consistent equations for the effective interaction vertex of an interacting many-fermion system [1]. Their numerical solution has, however, been plagued by the extreme memory consumption of the vertex functions, even for small systems. We use the truncated-unity method, previously developed in the context of the functional renormalization group (fRG), to approximate the complex emergent momentum structure of the vertex [2]. There, the full momentum dependence of the vertex is projected onto few formfactors. By these means, we can reduce the memory needed to solve the parquet equations by several orders of magnitude. This makes the parquet-approach a useful tool to calculate two particle properties in the parquet approximation and as nonlocal corrections to Dynamical Mean Field Theory (DMFT) calculations (parquet Dynamical Vertex Approximation)[3]. We will show results for the two-dimensional Hubbard model and comparisons with the ladder-Dynamical Vertex Approximation and fRG methods.

10:12AM X07.00012: ABSTRACT WITHDRAWN —
10:24AM X07.00013: Fibonacci Topological Superconductor  YICHEN HU (Presenter), CHARLES KANE, University of Pennsylvania — In this talk we will present a model of interacting Majorana fermions that describes a superconducting phase with a topological order characterized by the Fibonacci topological field theory. Our theory, which is based on a SO(7)\textsubscript{1}/(G\textsubscript{2})\textsubscript{1} coset factorization, leads to a solvable one dimensional model without parafermions that is extended to two dimensions using a network construction. In addition, we predict a closely related "anti-Fibonacci" phase, whose topological order is characterized by the tricritical Ising model. We will show that Majorana fermions can split into a pair of Fibonacci anyons, and propose an interferometer that generalizes the Z\textsubscript{2} Majorana interferometer and directly probes the Fibonacci non-Abelian statistics.

10:36AM X07.00014: Nonlocal probes for strongly-correlated quantum phases  BARBARA CAPOGROSSO-SANSONE (Presenter), FABIO LINGUA, Clark University, WEI WANG, Max Planck Institute for the Physics of Complex Systems, LIANA SHPANI, Clark University — In this talk, we propose non-local probes to study correlations in lattice bosons. We argue that these probes can be used as an alternative to characteristic quantum phases. We use Path-Integral Monte-Carlo and define the proposed probes in terms of the geometric braiding in world-line configurations. We show that these probes can be used as alternatives to local order-parameters in certain known phase transitions. Further, we describe a framework which links these probes (based on braiding properties of in world-line configurations) to entanglement in hardcore lattice bosons.

10:48AM X07.00015: Effective spin-orbit models using correlated first-principles wave functions*  YUEQING CHANG (Presenter), LUCAS WAGNER, Department of Physics, University of Illinois at Urbana-Champaign — In recent years, spin-orbit effects have been used to design and predict new emergent phases in condensed matter systems. Most of the theory has been done at the level of band structure. It is of high current interest how to extend these ideas to correlated electron systems. We present a new computational technique that uses first-principles quantum Monte Carlo calculations to address spin-orbit effects efficiently while also treating electron correlation accurately. To test this technique, we perform benchmark calculations in atomic systems and monolayer tungsten disulfide. The calculated results of the spin-orbit splittings in these systems agree with the experimentally determined values. This new tool allows us to investigate electron-electron interaction, spin-orbit effects and one-body terms on the same footing in realistic materials, with a cost similar to the standard fixed-node diffusion Monte Carlo.

Session X08 DCMP: Superconductivity: Odd-Frequency, Non-Centrosymmetric and Other Exotic States  BCEC 150 - Stuart Brown, Univ of California - Los Angeles

8:00AM X08.00001: The Effect of Antisymmetric Spin-Orbit Coupling on the Superconducting Order Parameter in Noncentrosymmetrical Superconducting PbTaSe\textsubscript{2} Single Crystal*  CONG REN (Presenter), Physics, Yunnan University — In superconducting material without an inversion center of symmetry the spin degeneracy of the conducting band is lifted by an antisymmetric spin orbit coupling (ASOC). As a consequence, spin and parity cannot be seperately used to classify the Cooper pairing states. The superconducting order parameter is generally a mixture of spin singlet and triplet pairing states. However, such spin mixture state has rarely been revealed in weakly correlated noncentrosymmetrical superconductors. In this talk, we report a pressure-dependent point contact Andreev reflection measurement on high quality single crystals of the noncentrosymmetrical superconductor PbTaSe\textsubscript{2}. The experimental result reveals the effects of ASOC on the superconducting order parameter of PbTaSe\textsubscript{2}.

In the normal state, spin current generated by RSOI was studied analytically and found to be proportional to $J^2$. For the electrical spin generation, the Edelstein-effect with Rashba spin-orbit interaction (RSOI) is a representative one. Spin current play an important role and there are several methods to make spin current, for example, spin Hall effect and spin pumping. As for the electrical spin generation, the Edelstein-effect with Rashba spin-orbit interaction (RSOI) is a representative one. In the normal state, spin current generated by RSOI was studied analytically and found to be proportional to $J^2$. And as for non-centrosymmetric superconductors with RSOI, there is a previous theoretical work about Edelstein-effect [2], which is focusing on the temperature region slightly below the superconducting critical temperature and chemical potential well above the band crossing point. Here we study the magnetization and spin current produced by the super current in 2D non-centrosymmetric superconductors with RSOI for the whole region of temperature and chemical potential. We have found the highly efficient spin supercurrent generation when the electron density is small.

8:24AM X08.00003: Occurrence of Non-Centrosymmetric Superconductivity by Tuning the Antisymmetric Spin-orbital Coupling in La(Pt$_x$Si$_{1-x}$)$_2$ Thin Films

YUNBO OU (Presenter), Plasma Science and Fusion Center and Francis Bitter Magnet Laboratory, Massachusetts Institute of Technology, JIAN LIAO, Department of Physics, University of Texas at Dallas, CIGDEM OZSOY-KESKINBORA, School of Engineering and Applied Sciences, Harvard University, STEPHAN KRAEMER, Center for Nanoscale Systems, Harvard University, DAVID BELL, School of Engineering and Applied Sciences, Harvard University, XIAOYAN SHI, Department of Physics, University of Texas at Dallas, JAGADEESH MOODERA, Department of Physics, Massachusetts Institute of Technology — The physical properties of solid compounds are governed by the symmetry of their crystal structure. In superconductors, an unconventional mixed-parity pairing which is neither spin singlet nor triplet state can emerge due to Fermi surface splitting caused by the absence of inversion symmetry. The complicated spin structure originating from mixed-parity pairing can cause topologically nontrivial surface or edge states in non-centrosymmetric superconductors. In this work, La(Pt$_x$Si$_{1-x}$)$_2$ thin films have been grown by systematically varying $x$ from 0 to 0.68 by MBE technique. The superconductivity has been observed up to 2.60 K by transport measurement. The increasing concentration of Pt tends to suppress the transition temperature. Furthermore, incorporating Pt without changing the crystal structure can continuously tune the strength of the asymmetric spin-orbital coupling (ASOC) in La(Pt$_x$Si$_{1-x}$)$_2$ thin films, which thereby results in a non-centrosymmetric superconductor with multiple unconventional phases. Our work could facilitate the search for topologically nontrivial surface or edge states in non-centrosymmetric superconductors.

8:36AM X08.00004: Fermi surface instabilities of spin-orbit-coupled metals

TILMAN SCHWEMMER (Presenter), DOMENICO DI SANTE, MARIO FINK, XIANXIN WU, WERNER R HANKE, RONNY THOMALE, Institute for Theoretical Physics and Astrophysics, University of Wuerzburg — The pursuit of novel phases in correlated electron systems, such as possibly topological instances of unconventional superconductivity, must consider multiple energy scales including interaction strength, electronic band width, and, in particular, spin-orbit coupling (SOC). While density functional theory and related ab initio techniques can provide a detailed description of a materials electronic structure that can carefully account for the effects of SOC, it is necessary to additionally refine quantum many body techniques to study Fermi surface instabilities in the presence of SOC. Starting from a picture of itinerant electrons, we study the effect of electronic correlations on the Fermi surface via renormalization group techniques. Combining ab initio electronic structures with perturbative and functional renormalization group calculations, we develop the toolbox to analyse a plethora of symmetry breaking phases arising from the interplay of SOC, fermi surface topology, and electronic correlations.

8:48AM X08.00005: Superconducting pairing transition tuned by structural distortions in strong spin-orbit coupled systems

AUSTIN LINDQUIST (Presenter), HAE-YOUNG KEE, Physics, University of Toronto — Strong spin-orbit coupled systems have been gaining increased attention, as they may host exotic phases such as spin liquids and topological superconductors. In particular, Sr$_2$IrO$_4$ has been suggested as a potential candidate for a high temperature d-wave superconductor. However, these materials have strong spin-orbit couplings, and the electronic band structures are sensitive to the structural distortions such as the rotation and tilting of the octahedral cages. Here, we study the effects of these structural distortions on pairing instabilities, and present the transitions between spin-singlet and spin-triplet pairings tuned by structural distortions. Testing our proposals using a series of superlattices is also discussed.
9:00AM X08.00006: Singlet-Quintet Mixing in Superconductors with $j=3/2$ Fermions*  JIABIN YU (Presenter), CHAO-XING LIU, Pennsylvania State University — Recently, a new pairing state with the mixing between s-wave singlet channel and isotropic d-wave quintet channel induced by centrosymmetric spin-orbit coupling has been theoretically proposed in the superconducting materials with $j = 3/2$ electrons. It is the first realistic proposal of the mixing between different spin channels that preserves the inversion symmetry in solid state systems. As physical consequences, the singlet-quintet pairing mixing can give rise to topological nodal-line superconductivity and surface Majorana flat bands. In this talk, the singlet-quintet-mixed state will be reviewed. Moreover, its experimental signatures, including spin susceptibility, upper critical field, disorder effect and surface local density of states, will be discussed.

9:12AM X08.00007: Odd-frequency pairing in a superconductor coupled to two parallel nanowires  CHRISTOPHER TRIOLA (Presenter), ANNICA M BLACK-SCHAFFER, Department of Physics and Astronomy, Uppsala University — We study the behavior of Cooper pair amplitudes that emerge when a two-dimensional superconductor is coupled to two parallel nanowires, focusing on the conditions for realizing odd-frequency pair amplitudes in the absence of spin-orbit coupling or magnetism. In general, any finite tunneling between the superconductor and the two nanowires induces odd-frequency spin-singlet pair amplitudes in the substrate as well as a substantial odd-frequency interwire pairing. Since these amplitudes are odd in spatial parity, they do not directly impact the local observables. However, in the regime of strong superconductor-nanowire tunneling, we find that the presence of two nanowires allows for the conversion of non-local odd-frequency pairing to local even-frequency pairing. By studying this higher-order symmetry conversion process, we are able to characterize the effect of the odd-frequency pairing in the superconductor on local quantities accessible by experiments. Specifically, we find that odd-frequency pairing has a direct impact on the local density of states of the superconductor and on the maximum Josephson current, measurable using Josephson scanning tunneling microscopy.

9:24AM X08.00008: Odd-frequency spin-triplet superconductivity in two dimensional disordered electron liquid.*  VLADIMIR ZYUZIN (Presenter), ALEXANDER FINKELSTEIN, Texas A&M University — In this work we theoretically study the odd-frequency spin-triplet superconductivity in disordered two dimensional electron liquid. We propose a pairing mechanism based on the interplay of screened Coulomb interaction and the interference of electrons due to the impurity scattering. The mechanism suppresses possible attraction in the singlet part of the Cooper channel, and depending on the ratio of repulsive interaction in the charge and spin channels, it results in attraction between electrons in the odd-frequency spin triplet part of the Cooper channel. Being derived for the metallic phase of the system, it can be relevant for the metal to insulator transition point.

9:36AM X08.00009: Odd frequency Berezinski pairing and cross junction coherence in Josephson effect.*  ALEXANDER BALATSKY (Presenter), Nordita, SERGEY PERSHOGUBA, Physics, Yale University, CHRISTOPHER TRIOLA, Physics, Uppsala University — Odd frequency or Berezinski pairing state is now claimed to be present in multiple heterjunctions. We now demonstrate the emergence of odd-frequency pair amplitudes as a cross junction Berezinski coherence in conventional Josephson junctions. We considerate both in the absence of a voltage (DC effect) and in the presence of a finite voltage (AC effect). In both cases, we find that Berezinski interlead pairing emerges whenever a Josephson current is expected to flow. Additionally, we show that the interlead spin-susceptibility is directly influenced by the presence of the odd-frequency pair amplitudes. Specifically, we find that the spin-susceptibility is suppressed when the odd-frequency component is the largest. By establishing a novel link between the physics of Josephson junctions and Berezinski pairing, we extend the notion of Berezinski pairing to cross junction coherences and to conventional Josephson effect.

Study of chiral d-wave superconductor candidate URu$_2$Si$_2$ by using scanning SQUID microscopy

YUSUKE IGUCHI (Presenter), IRENE ZHANG, Department of Applied Physics, Stanford University, Stanford, California 94305, USA, ERIC BAUER, FILIP RONNING, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, KATHRYN ANN MOLER, Department of Applied Physics, Stanford University, Stanford, California 94305, USA — The heavy electron superconductor URu$_2$Si$_2$ has been extensively studied since the transitions of its hidden order and superconducting state were reported by the specific heat measurement in 1985[1]. Recent studies of thermal conductivity[2] and optical Kerr measurement[3] on URu$_2$Si$_2$ have shown evidence of chiral d-wave superconductivity. The chiral d-wave order superconductivity has also been suggested by a theoretical calculation of the magnetic excitation spectrum[4]. A chiral superconductor is expected to show chiral edge current modes analogous to a topological insulator. In order to search for evidence of chiral superconductivity in URu$_2$Si$_2$, we will report a study of the local superconducting and local charge current states of URu$_2$Si$_2$ single crystals using a scanning SQUID microscope.

Ir d-band derived superconductivity in the lanthanum-iridium system LaIr$_3$ system*

NEEL HALDOLAARACHCHIGE (Presenter), Physical Sciences, Bergen Community College, LESLIE SCHOOP, Princeton University, MOJAMMEL ALAM KHAN, Physics, Louisiana State University, WENXUAN HUANG, Department of Mat. Sci. and Eng., Massachusetts Institute of Technology., HUIWEN JI, Princeton University, KALANI HETTIARACHCHILAGE, Physics, The Collage of New Jersey, DAVID P YOUNG, Physics, Louisiana State University — Here, we have reported the synthesis and characterization of LaIr$_3$, which displays superconductivity below $T_c = 3.3$ K.

LaIr$_3$ is a superconductor where the bands near the Fermi surface are dominated by Ir 5 d states that are strongly affected by SOC. Thus, it is one of the few examples of a lanthanide-based superconductor where 5 d electrons play the dominant role in the superconductivity. The superconducting parameters obtained from physical properties measurements of LaIr$_3$ suggest that it is a weakly-coupled BCS-type superconductor. These results motivate future work focused on exploring intermetallic Ir-based superconductors that form in noncentrosymmetric structure types. Strong SOC in these systems would then be antisymmetric, which often leads to exotic and unconventional superconductivity.

Low-Energy Quasiparticle Excitations in Half-Heusler Superconductors with $j = 3/2$ Fermions

KOTA ISHIHARA (Presenter), TAKAAKI TAKENAKA, YIJIE MIAO, YUTA MIZUKAMI, University of Tokyo, OREST PAVLOSIUK, PIOTR WISNIEWSKI, DARIUSZ KACZOROWSKI, Polish Academy of Sciences, TAKASADA SHIBAUCHI, University of Tokyo — In noncentrosymmetric half-Heusler compounds where the strong spin-orbit coupling causes a band inversion, fermions with total angular momentum $j = 3/2$ contribute mainly to the transport phenomena, including the superconductivity. Interestingly, Cooper pairs formed by the $j = 3/2$ fermions can form not only usual singlet and triplet states but also even-parity quintet and odd-parity septet states. Recently, it has been reported that the temperature dependence of magnetic penetration depth shows a power-law behavior in YPtBi, which suggests an unconventional nodal gap structure. Several theories with the quintet or septet pairings have been proposed to explain this result, whereas it is still experimentally unclear whether the reported nodal structure is universal or not in the non-magnetic half-Heusler superconductors with $j = 3/2$ fermions. To study the gap structure in several half-Heusler superconductors, we have measured the magnetic penetration depth on YPtBi, LuPtBi, and LuPdBi with different spin-orbit coupling strength. Our data suggest the existence of gap minima rather than nodes in all the materials, which strongly indicates that the nodal structure is not protected by symmetries. Based on these results, we discuss the pairing symmetry of these half-Heusler compounds.
10:24AM X08.00013: Nonlinear susceptibility of unconventional superconductors* DAMJAN PELC (Presenter), ZACHARY ANDERSON, BIQIONG YU, SAJNA HAMEED, MARTIN GREVEN, University of Minnesota — Nonlinear magnetic response can be used to investigate several important features of superconductors: the pre-pairing regime above $T_c$, the superconducting gap features through the low-temperature nonlinear Meissner effect, and time-reversal symmetry. Based on our work on the superconducting precursor in oxides [1,2], we present complementary experiments on a wide range of conventional and unconventional superconductors. Several characteristic types of behavior are observed, including mean-field Ginzburg-Landau nonlinear response, an inhomogeneity-dominated precursor, and strong fluctuations not described by mean-field theory.

*This work was funded by the DOE through the University of Minnesota Center for Quantum Materials under DE-SC-0016371.

10:36AM X08.00014: Suppression of odd-frequency superconducting pairing by phase-disorder in a nanowire coupled to Majorana zero modes DUSHKO KUZMANOVSKI, ANNICA M BLACK-SCHAFFER, JORGE CAYAO (Presenter), Uppsala University — Majorana zero modes (MZMs) exhibit pure odd-frequency superconducting pairing correlations. Recently, it was reported that a robust odd-frequency superconducting pairing can be induced in a spin-polarized wire due to an array of MZMs, where their coupling to the wire was considered real.

Considering the physically more realistic case of complex coupling strengths that generically appear for varying system parameters, we demonstrate that all superconducting correlations, including odd-frequency, suffer a considerable suppression due to phase-disorder averaging. In the first part we, evaluate the $T$-matrix within the second Born approximation, and demonstrate exponential suppression of the electron-hole pairing with phase-disorder strength. In the second part, we perform numerical calculations on a tight-binding lattice model and study the effects of phase-disorder averaging on the local density of states and superconducting correlations.

We attribute the suppression of superconducting correlations in the wire to the filling of the energy gap by in-gap Andreev Bound States appearing due to phase-matching conditions between spatially-separated MZMs. Our work helps clarify the conditions favorable for practical realization of the proposed odd-frequency superconducting system.

Session X09 DCMP: Topological Materials -- Thin Films BCEC 151A - Hang Chi, Massachusetts Institute of Technology - Tag(s): Focus

8:00AM X09.00001: Quantum transport in ultra-thin topological crystalline insulator films STEPHEN D ALBRIGHT (Presenter), Department of Physics, Yale University, FREDERICK J WALKER, CHARLES H AHN, Department of Applied Physics, Yale University — Recent developments have demonstrated the unique properties of conventional topological insulators, such as from dissipation-free transport and the creation of Majorana fermions by interfacing with superconductors, and offered a method for controlling them spatially with magnetic fields. Topological crystalline insulators (TCIs), such as SnTe, offer the same unique properties but an alternate mode of control: crystal symmetry breaking through strain or electric fields. Growth of TCIs thin and uniform enough to access these unique properties is challenging to achieve. This work presents structural and electronic characterization of ultra-thin SnTe films, down to 5nm, grown by molecular beam epitaxy on SrTiO$_3$ substrates. X-ray diffraction and atomic force microscopy reveal that SnTe films are single-domain and uniform, which is critical to realizing controllable topological properties. Quantum transport effects observed in magnetotransport measurements are consistent with the existence of topological states. To better understand their behavior and inform next steps towards their control, we extract details of the topological states by fitting the magnetotransport over a range of film thicknesses.
In topological crystalline insulators the topological conducting surface states are protected by crystal symmetry. Here, we show using scanning tunneling microscopy/spectroscopy that defects that break local mirror symmetry of SnTe suppress electron tunneling over an energy range as large as the bulk band gap, an order of magnitude larger than that produced globally via magnetic fields or uniform structural perturbations [1]. The results reveal the influence of various defects on the electronic properties, including screw dislocations, point defects, and tilt boundaries that lead to dislocation arrays that serve as periodic nucleation sites for pits grown on SrTiO3 [2,3].

Complementary ab initio calculations show how local symmetry breaking obstructs topological surface states as shown by a threefold reduction of the spectral weight of the topological surface states. The findings highlight the potential benefits of manipulating the surface morphology to create devices that take advantage of the unique properties of surface states and can operate at practical temperatures.

GdBi is an antiferromagnetic semimetal which has been proposed to have non-trivial band topology [1,2]. Despite attempts to experimentally observe its topological nature, it is challenging due to the large band overlap between the conduction and valence bands. Here we show via electrical transport measurements that quantum confinement can suppress the band overlap in GdBi thin films. The semimetallicity is lifted below a film thickness of approximately 8 crystallographic unit cells while the antiferromagnetic order is preserved down to our minimum thickness of 5 crystallographic unit cells. This is a step toward realizing a bulk insulating antiferromagnetic topological insulator, which can potentially realize a Chern insulating state in the monolayer limit.

Recent studies have shown that Rare-earth Bismuth (RBi) hosts topologically protected Dirac surface states [1,2]. However, spectroscopic measurements on bulk single crystals thus far have limited to (001) natural cleavage surface of RBi. Here we report the first successful realization and characterization of GdBi (111) films grown on BaF2 substrates with Molecular Beam Epitaxy. GdBi, in a bulk form, is a semimetal with type-II antiferromagnetic (AFM) order below $T_{N,bulk} = 28$ K. With torque magnetometry, we confirm that type-II AFM order is preserved in our films with a Neel temperature $T_{N,film} = 30$ K. From electrical transport measurements, we observe a non-linear Hall effect and non-saturating magnetoresistance, the characteristics of a compensated semimetallic electronic structure. Stabilization of GdBi (111) films enables previously unexplored studies of the interplay of symmetry-breaking and Dirac crossings on the (111) surface of RBi. We further anticipate a possible Chern insulator phase in the ultrathin limit, when quantum confinement lifts semimetallicity while retaining non-trivial band topology. Reference: [1] M. Zeng and C. Fang et al., arXiv:1504.03492 (2015), [2] J. Nayak et al., Nat. Comm. 8, 13942 (2017).
8:48AM X09.00005: Nanoscale Synthesis and Characterization of Topological Materials* [Invited] ILIJA ZELJKOVIC (Presenter), Boston College — Interest in the superconducting proximity effect (SPE) has recently been reignited by theoretical predictions that it could be used to achieve topological superconductivity. However, small proximity-induced gaps ($\Delta_{\text{ind}}$) of ~1 meV have predominantly been obtained so far using select few low-Tc superconductors. In this talk, I will discuss how we use a combination of molecular beam epitaxy and scanning tunneling microscopy/spectroscopy to study topological insulators grown on high-Tc superconductors Fe(Te,Se) and Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$. On the surface of Bi$_2$Te$_3$ grown on Fe(Te,Se), we detect $\Delta_{\text{ind}}$ as high as ~3.5 meV, which is the largest reported gap induced by proximity to an s-wave superconductor to-date. We find that $\Delta_{\text{ind}}$ exponentially decays with Bi$_2$Te$_3$ thickness, but remains finite even after the topological surface states had been formed. By imaging the scattering and interference of surface state electrons, we provide a microscopic visualization of the fully gapped Bi$_2$Te$_3$ surface state due to Cooper pairing. We contrast this observation with the lack of observed superconducting gap in Bi$_2$Te$_3$/Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$ heterostructures. We conclude by discussing the roles of various parameters in driving the SPE effect across complex interfaces.

9:24AM X09.00006: In-situ analysis of MBE-grown ZrTe$_5$ thin films* TIMOTHY PILLSBURY (Presenter), ANTHONY RICHARDELLA, YANAN LI, NITIN SAMARTH, Department of Physics and Materials Research Institute, Pennsylvania State University — Originally of interest for its resistivity anomaly, ZrTe$_5$ has been predicted by recent theoretical work to be a quantum spin Hall insulator (QSHI) with band-gap of ~100meV [PRX 4, 011002 (2014)]. Additionally, bulk measurements of ZrTe$_5$ have shown a variety of states from a strong topological insulator (TI) to a weak TI and even a Dirac Semimetal depending on the experimental methods [Scientific Reports 7, 45667 (2017)]. This makes ZrTe$_5$ also interesting for studying the transition from a weak to strong TI. Since experiments so far have used films exfoliated from bulk crystals, they are complicated by the difficulty of exfoliating large area crystals. Moreover, rapid oxidization of ZrTe$_5$ films prevents thorough analysis of exfoliated thin films. To help elucidate the nature of the topological properties of ZrTe$_5$ and achieve a large band-gap QSHI, we have grown epitaxial thin films under ultra-high vacuum using molecular beam epitaxy (MBE) and performed in-vacuo analysis using ARPES and STM to confirm the growth quality and analyze the band structure, laying the groundwork for future MBE studies that utilize strain engineering to study the strong to weak TI transition and the observation of a large gap QSHI.

*Funded by 2DCC-MIP under NSF Grant No. DMR-1539916.

9:36AM X09.00007: Remote Doping of Sb Quantum Wells with Te RYAN P O’TOOLE, KAUSHINI WICKRAMASINGHE, TETSUYA D MISHIMA, MICHAEL SANTOS (Presenter), University of Oklahoma — Antimony (Sb) has topological surface states, but its bulk band structure is semimetallic. Our goal is to study the transport properties of the topological states by suppressing the bulk conductivity through quantum confinement and enhancing the surface conductivity through remote n-type doping. A series of Sb quantum-well structures was grown by molecular beam epitaxy with Al$_x$Ga$_{1-x}$Sb barrier layers and GaAs (111) substrates. The Sb layer thickness of 4 nm was chosen to be thin enough to open a bandgap in the bulk band structure. To populate the topological electron states in the Sb quantum well, a section of one Al$_x$Ga$_{1-x}$Sb barrier was doped with Te atoms, which act as donor impurities. We report on Hall effect measurements that characterize the effectiveness of our approach in increasing the contribution of topological surface states to the conductivity of the structure.
9:48AM X09.00008: Nanoscale strain induced effects on the optoelectronic properties of monolayer transition metal dichalcogenides. MARKUS TEAGUE (Presenter), JIAQING WANG, WEI-HSIANG LIN, DUXING HAO, CHEN-CHIH HSU, NAI-CHANG YEH, Physics, California Institute of Technology — We perform simulations and scanning tunneling spectroscopic (STS) studies of the strain effects on the optoelectronic properties of monolayer TMDC materials MS₂, where M = Mo and W. We use molecular dynamics to simulate the strain effect on MS₂ by relaxing a (60x60) nm² monolayer MS₂ sheet on top of a 2.5 nm radius semi-sphere gold nanoparticle. We find that the strain tensor component \( \varepsilon_{xy} \) changes between the top S-layer (positive) and bottom S-layer (negative), indicating the top S-layer experiences an effective stretching force whereas the bottom S-layer is compressed. For STS studies, high quality monolayer MoS₂ single crystals with areas to 200x200 nm² are synthesized by CVD and transferred to Si substrates with triangular arrays of nanostructures. Nanostructures are ~20 nm in size with a lattice constant of ~400 nm. Spatially resolved STS studies on the LDOS in MS₂ are carried out to investigate spatial variations resulting from strain and temperature evolution of the local electronic bandgap. Using a variable-wavelength light source, circularly polarized light is also applied to the sample under STS studies, and the spatially resolved LDOS in strained MS₂ are investigated as a function of temperature, optical wavelength and polarization. This work is supported by NSF and ARO.

10:00AM X09.00009: Electrical Transport Study in Wafer Scale Epitaxial WTe₂ Film Grown by Molecular Beam Epitaxy. JASON TRAN (Presenter), JUNXUE LI, JUSTIN HOROWITZ, JING SHI, PENG WEI, University of California, Riverside — WTe₂, a member of the layered transition metal dichalcogenides (TMDs), has recently garnered attention due to its topological properties. Current studies of WTe₂ have mainly focused on samples produced by mechanical exfoliation. Recent success has shown that WTe₂ is able to grow on graphene using molecular beam epitaxy (MBE). As a conducting layer, graphene may weaken or smear any signatures of topological transport in WTe₂. In this talk, we present our electrical transport studies in wafer scale WTe₂ grown on insulating sapphire substrate. The 1T' structural phase of the MBE grown samples is confirmed by in situ reflection high energy electron diffraction (RHEED). Electrical transport studies show a sharply enhanced magnetoresistance (MR) at low temperature. The MR has a clear linear magnetic field dependence over a range of magnetic fields up to 12 Tesla. In the low field regime, we observe signatures of weak antilocalization which suggest the presence of strong spin-orbit coupling. We will also present the effect of varying thickness of WTe₂ on magnetotransport, and discuss potential signatures related to topological order. *This work is supported by the Startup fund from University of California, Riverside.

10:12AM X09.00010: Epitaxial growth and electronic properties of 2D topological insulator 1T WSe₂. CHENHUI YAN (Presenter), HUIMING ZHANG, LIAN LI, Department of Physics and Astronomy, West Virginia University — Monolayer 1T WSe₂ has recently been predicted to be a two-dimensional topological insulator (2D TI) with a larger bulk bandgap than 1T WTe₂, more preferable for practical applications. However, the energetically stable structure of WSe₂ is the 2H phase, and hence the 1T WSe₂ doesn't exist in the bulk. Here, we report the molecular beam epitaxial growth of monolayer 1T WSe₂ on epitaxial graphene/SiC(0001). We find the growth of homogeneous monolayer WSe₂ is strongly dependent on the substrate temperature: while the 1T phase can be grown below 300, a mixed 1T and 1H is obtained with increasing substrate temperature, with a complete 1H phase formation above 400°C. Using scanning tunneling microscopy/spectroscopy and angle resolved photoemission spectroscopy, we determine a bulk bandgap of 130 meV in monolayer 1T WSe₂, almost twice that of 1T WTe₂ (70 meV). We further observe one-dimensional edge states within the bulk bandgap in tunneling spectroscopy, confirming that monolayer 1T WSe₂ is indeed a 2D TI. This research is supported by NSF (DMR-1734017). *This research is supported by NSF (DMR-1734017).
Effect of epitaxial strain on topological properties of LaSb

SHOAIB KHALID (Presenter), Department of Physics and Astronomy, University of Delaware — RARE-EARTH MONO-PNICTIDES DISPLAY INTERESTING PROPERTIES THAT INCLUDE EXTREME MAGNETORESISTANCE AND NON-TRIVIAL TOPOLOGICAL BAND STRUCTURES, YET HAVE SIMPLE CRYSTAL STRUCTURE. FOR INSTANCE, LaSb IS ON THE VERGE OF A TRANSITION FROM TRIVIAL TO NON-TRIVIAL TOPOLOGICAL SEMIMETAL, LABI BEING A NON-TRIVIAL SEMIMETAL, AND LAAS A TRIVIAL SEMIMETAL. SINCE THESE MATERIALS CAN BE EPITAXIALLY GROWN ON III-V SUBSTRATES AND, THEREFORE, EASILY INTEGRATED TO WELL-KNOWN ELECTRONIC MATERIALS, IT IS IMPERATIVE TO UNDERSTAND THE EFFECTS OF EPITAXIAL STRAIN ON THEIR BAND STRUCTURES AND TOPOLOGICAL PROPERTIES. USING DFT WITH THE HSE06 HYBRID FUNCTIONAL, WE STUDY THE EFFECTS OF EPITAXIAL STRAIN ON THE ELECTRONIC PROPERTIES OF THESE RARE-EARTH MONO-PNICTIDES. FOR EXAMPLE, WE FIND THAT AT AROUND 1.5% COMRESSIVE EPITAXIAL STRAIN THERE IS A BAND CROSSING BETWEEN La d band AND Sb p band NEAR THE Z POINT OF THE BCT BRILLOUIN ZONE OF STRAINED LaSb. THIS BAND CROSSING INDICATES A TOPOLOGICALLY NON-TRIVIAL BEHAVIOR OF LaSb UNDER APPLIED EPITAXIAL STRAIN. THESE RESULTS HELP UNDERSTANDING THE NOVEL TRANSPORT AND TOPOLOGICAL PROPERTIES OF EPITAXIALLY GROWN STRAINED THIN FILMS OF THESE RARE EARTH MONO-PNICTIDES.

Electric Field Tuned Quantum Phase Transition from Topological to Conventional Insulator in Few-Layer Na3Bi

JAMES COLLINS (Presenter), Department of Physics and Astronomy and Centre for Future Low Energy Electronics Technologies, Monash University, ANTON TADICH, Australian Synchrotron, LIDIA GOMES, JOÃO RODRIGUES, Department of Physics and Centre for Advanced 2D Materials, National University of Singapore, JOHN HELLERSTEDT, CHANG LIU, Department of Physics and Astronomy and Centre for Future Low Energy Electronics Technologies, Monash University, HYEJIN RYU, SHUJIE TANG, Lawrence Berkeley National Laboratory, WEIKANG WU, SHENGYUAN YANG, Singapore University of Technology and Design, SHAFFIQUE ADAM, Department of Physics and Centre for Advanced 2D Materials, National University of Singapore, SUNG-KWAN MO, Lawrence Berkeley National Laboratory, MARK T EDMONDS, Department of Physics and Astronomy and Centre for Future Low Energy Electronics Technologies, Monash University — Na3Bi in bulk is a zero-bandgap topological Dirac semimetal (TDS), but when confined to a few layers it is predicted to be a large-gap (~300 meV) topological insulator. Application of an electric field to few-layer Na3Bi has been predicted to drive a band inversion due to Stark effect and induce a topological phase transition, which could be the basis of a topological transistor. Here we demonstrate the growth of epitaxial few-layer Na3Bi via MBE, and probe its electronic structure and response to an electric field using scanning probe microscopy/spectroscopy (STM/STS) and angle-resolved photoelectron spectroscopy, and compare with results from DFT. Both monolayer and bilayer Na3Bi show bandgaps >300 meV in STS, and the observation of an edge state with exponential decay into the bulk confirms their topological nature, consistent with DFT. With application of an electric field via potassium doping or approach of the STM tip the bandgap can be tuned to semi-metallic and then re-opened to greater than 100 meV. The electric fields required to induce this transition are below the breakdown field of many conventional dielectrics, making the creation of a topological transistor based on a few-layer TDS within reach.

molecules binding to metallo-porphyrins can be probed with STM combined with DFT methods. The experimental STM images in the simulated images. Thus, our study shows that geometric structures of small molecules, binding to metallo-porphyrin on Au(111). We observed square ring, rectangular ring, and center-bright (STM) images at the single molecule level. Here, we present STM images of further systems, di, tri, and quadra-atomic systems such as oxygen delivery, muscle contraction, and synaptic transmission. Their geometrical structures such as reaction between small gas molecules and metallo-porphyrins play crucial roles in functional processes of biological systems such as oxygen delivery, muscle contraction, and synaptic transmission. Their geometrical structures such as tilted binding of NO to metallo-porphyrin have been recently confirmed by high-resolution scanning tunneling microscopy (STM) of metal-free naphthalocyanine (NPC) molecules adsorbed on Ag(111) surfaces. As guided by the theoretical predictions, at elaborately adjusted scanning temperature and bias, STM experiments achieve a direct visualization of the cis-intermediate. This work demonstrates a practical way to directly visualize elusive intermediates, which enhances understanding of the quantum dynamics of hydrogen atoms.

Imaging Binding Structures of Small Molecules to Metallo-porphyrin Using Scanning Tunneling Microscopy

Minhui Chang (Presenter), Korea University, Yun Hee Chang, Na Young Kim, Kaist, Un Seung Jeon, Howon Kim, Kyung Min Kim, Korea University, Yong-Hyum Kim, Kaist, Se-Jong Kahng, Korea University — Binding reaction between small gas molecules and metallo-porphyrins play crucial roles in functional processes of biological systems such as oxygen delivery, muscle contraction, and synaptic transmission. Their geometrical structures such as tilted binding of NO to metallo-porphyrin have been recently confirmed by high-resolution scanning tunneling microscopy (STM) images at the single molecule level. Here, we present STM images of further systems, di, tri, and quadra-atomic small molecules, binding to metallo-porphyrin on Au(111). We observed square ring, rectangular ring, and center-bright structures for three different small molecules. With the help of density functional theory (DFT) calculations, we reproduce the experimental STM images in the simulated images. Thus, our study shows that geometric structures of small molecules binding to metallo-porphyrins can be probed with STM combined with DFT methods.

Sub-Monolayer Annealed CuPc on Cu(111): Defect Hinderred Dynamic Clusters

William Huxter (Presenter), Jun Nogami, Chandra Veer Singh, Materials Science and Engineering, University of Toronto — Annealed sub-monolayer copper phthalocyanine on Cu(111) was studied with room temperature scanning tunneling microscopy (STM) and density functional theory (DFT). At coverages of 0.25 ML we observed that annealing produces a disordered cluster network of CuPc that attach together by forming C-C bonds across isoindole lobes. At lower coverages we find that smaller CuPc clusters (less than ~20 CuPc in size) are mobile on the Cu(111) surface. This dynamic motion was tracked by repeated STM image scans. Subsequent deposition of CuPc (without annealing) produced a Cu(111) surface covered with highly mobile single CuPc molecules and less mobile CuPc clusters. This enabled resolution of surface defects that were found to immobilize the CuPc clusters through a defect pinning mechanism.

9:24AM X10.00006: Structure and electronic properties of end states of self-assembled 1D covalent molecular chains on Au(111)  
ALEX CAHLIK (Presenter), JOHN HELLERSTEDT, MARTIN SVEC, V M SANTHINI, Institute of Physics, ASCR, v.v.i., SIMON PASCAL, Aix Marseille Université, CNRS, CIaNAM UMR, SIGUIOUR INGÉ ERLINGSSON, School of Science and Engineering, Reykjavík University, KAREL VYBORNÝ, Institute of Physics, ASCR, v.v.i., OLIVIER SIRI, Aix Marseille Université, CNRS, CIaNAM UMR, PAVEL JELÍNEK, Institute of Physics, ASCR, v.v.i. — One-dimensional structures offer a rich ecosystem for realizing quantum states with potential application for advanced information technologies. Surface confined molecular self-assembly is one avenue for creating 1d systems, where the extent structure is controlled by the precursor shape, and functional group interlinking chemistry. Here we study self-assembled 1d chains of zwitterionic molecule bis-bidentate ditopic (DABQDI) on Au(111) in ultrahigh vacuum, measured at 5K using combined scanning tunneling and non-contact atomic force microscopies (STM/ nc-AFM). Submolecular resolution achieved with a CO-functionalized tip offers detailed structural information, specifically regarding the unusual hydrogen bonds linking the precursor units. In-gap electronic states near the Fermi energy are observed via scanning tunneling spectroscopy (STS), strongly localized to the chain ends. We present our latest efforts to understand and simulate the observed structures via density functional theory (DFT) and nc-AFM simulations, and rationalize the observed electronic properties via modelling inspired by the Su, Schrieffer, Heeger (SSH) one-dimensional tight binding model.

9:36AM X10.00007: Long-Range Energy Level Shifts Induced by Single Impurity Molecules in C60 Thin Films  
ERIK MÅRSELL (Presenter), BINGKAI YUAN, KATHERINE COCHRANE, MIRIAM D. DEJONG, DAVID J. JONES, University of British Columbia, MORITZ RIEDE, University of Oxford, SARAH BURKE, University of British Columbia — Organic photovoltaics (OPV) is a promising technology for low-cost, flexible solar cells with low embodied energy. However, the efficiency remains low due to high exciton binding energies. The main driving force behind exciton dissociation is the energy landscape around the donor-acceptor interface. To optimize device efficiency, we therefore need to better understand the pathways of exciton dissociation at interfaces in OPV materials and how they correlate with the energy landscape. We use scanning tunneling microscopy and spectroscopy to study model systems consisting of thin films of C60 with single molecules of pure and fluorinated zinc phthalocyanine (ZnPc, F4ZnPc, and F8ZnPc) added. We measure how a molecule affects the energy levels in the surrounding C60 matrix; they shift by up to 150 meV depending on the degree of fluorination of the impurity molecule. This shift prevails over at least several C60 molecules from the impurity. This large and long-range shift induced by the phthalocyanine, and heavily influenced by the fluorine atoms, opens up new possibilities for controlled design of the energy landscape in the OPV heterojunction to optimize charge transfer efficiency.

NATHANIEL RAIMBAULT (Presenter), MARIANA ROSSI, Fritz-Haber Institute — Anharmonic contributions to vibrational Raman spectra of molecular crystals can be decisive to identify the structure of different polymorphs. In this work we characterise the low-frequency Raman spectral region of different polymorphs of the flexible aspirin and paracetamol crystals. We include anharmonicities through the time-correlation formalism, combining ab initio molecular dynamics and density-functional perturbation theory (DFPT) implemented in a full-potential, all-electron framework [1]. Lattice expansion and anharmonic thermal nuclear motion strongly affect the collective vibrations of the low-frequency region. This effect is much less pronounced at higher frequencies. We obtain excellent agreement with experimental lineshapes, highlighting the necessity of going beyond the harmonic approximation. In order to bypass the cost of DFPT evaluations of the polarizability tensor, we employ different forms of Kernel Ridge Regression (KRR) and discuss their efficiency. Training our models on several hundreds of points, we reproduce Raman spectra that would otherwise require the calculation of tens of thousands of points. This technique is extended to surface-sensitive vibrational sum-frequency generation.

10:00AM X10.00009: Evaluation of Pulay forces due to change in overlap of subspace-projection orbitals in constrained DFT: Application in calculation of reorganization energy of adsorbed molecule*  SUBHAYAN ROYCHOUDHURY (Presenter), DAVID D. O’REGAN, STEFANO SANVITO, Trinity College Dublin — Total energy of a constrained DFT calculation depends on population of subspace(s). When such subspace is defined in terms of orbitals localized on host atoms, ionic translations change the overlap of corresponding projection orbitals generating unconventional Pulay terms. We derive an exact expression for such Pulay terms maintaining non-orthogonality of projection orbitals. The corrected forces are implemented in the linear scaling DFT code ONETEP and, in conjunction with constrained DFT, are used to calculate the reorganization energy of a pentacene molecule adsorbed on a graphene flake. We show that subspace population depends on the choice of projection orbitals centred on a given set of host atoms and that non-orthogonal Wannier functions offer more precise results compared to pseudo-atomic orbitals. Our calculations of reorganization energy, performed by including ensemble DFT, correction for periodic boundary conditions and dispersion corrections show that, in general, reorganization energy of an adsorbed pentacene is lower than that of one in gas phase. This is consistent with effect of steric hindrance.

10:12AM X10.00010: Impacts of Electrostatic Screening and Interfacial Charge Transfer on Molecular Donor-Acceptor Heterojunctions Studied by Scanning Probe Microscopy/Spectroscopy*  ANDREW TAN (Presenter), PENGPENG ZHANG, Department of Physics and Astronomy, Michigan State University — A common need in organic electronics is the thorough understanding and control of the electronic structures and interfacial properties of molecular thin films on inorganic substrates. However, when donor (D) and acceptor (A) molecular heterojunctions are concerned, the interfacial charge transfer effects can compete with intermolecular charge transfer, which, along with the electrostatic effects from the substrate, exerts a significant substrate perturbation on the heterojunction. Employing archetypal D and A organic molecules and a variety of different supporting substrates, we show that the presence of the substrate, even a weakly interacting one, can still significantly perturb the intrinsic properties of the D-A heterojunction via interfacial charge transfer. Furthermore, substrate electrostatic screening can be modulated by interfacial charge transfer. This study highlights the impacts of the substrate electrostatic environment and the interfacial coupling on molecular electronic structures, an essential aspect in the applications of organic and molecular electronic devices.

10:24AM X10.00011: Spectroscopic evidence of two-impurity Kondo effect in potassium doped p-sexiphenyl films on Au (111)  YAJUN YAN (Presenter), WEI CHEN, MINGQIANG REN, YILIN ZHANG, TONG ZHANG, DONGLAI FENG, Fudan University — Molecular magnetism is usually observed in organic coordination compounds consisting of transition metals or rare-earth metals, while it is rare in transition metal free or full-shell molecules. In this work, we grow high-quality p-sexiphenyl (PSP) monolayer film on Au (111) substrate, and then doped it with potassium (K) atoms. Various ordered phases are observed, with different structural and electronic properties. For a particular ordered phase, we observe obvious Kondo resonance peaks in isolated/misarranged PSP molecules, but clear splitting of such peaks is observed in PSP dimers. These phenomena share strong similarities to the two-impurity Kondo effect. Combined with theoretical calculation, we find that local spin is induced in PSP molecules by charge transfer from K atoms, leading to the appearance of Kondo resonance and the magnetic interaction of two Kondo impurities. Such two-impurity Kondo effect has only been reported in quantum dot system or dilute adatoms system, but the splitting of the Kondo resonance peak is much smaller than in our PSP system, which is as large as 5 meV. Our study not only provides a new and simple platform for investigating the two-impurity Kondo effect, but also provides a new route to construct a Kondo lattice on metal substrate.

Session X11 DMP DCMP: Transport in Nanostructures -- Nanoscale Transport II  BCEC 152 - Xuan Gao, Case Western Reserve University - Tag(s): Focus
8:00AM X11.00001: Super-geometric transverse electron focusing on the hexagonal Fermi surface of PdCoO$_2$

PHILIP MOLL (Presenter), Ecole polytechnique federale de Lausanne, MAJA D BACHMANN, Max-Planck-Institute for Chemical Physics of Solids, AARON SHARPE, ARTHUR BARNARD, Stanford University, MARKUS KOENIG, Max-Planck-Institute for Chemical Physics of Solids, CARSTEN PUTZKE, Ecole polytechnique federale de Lausanne, SEUNGHYUN KHIM, ANDREW MACKENZIE, Max-Planck-Institute for Chemical Physics of Solids, DAVID GOLDHABER-GORDON, Stanford University — Single crystals of PdCoO$_2$ can be easily synthesized at remarkably high quality. At low temperatures, the mean-free-path of this most conductive oxide exceeds 20μm, reflected by its ultra-low residual resistivity of 8 nΩcm. This high conductivity gives rise to different transport regimes, spanning from ballistic transport to hydrodynamic transport regimes. Its ballistic transport is highly unusual, owing to its peculiar Fermi surface resembling an almost perfect hexagon. We fabricate ballistic structures for transverse electron focusing from as-grown single crystals via focused ion beam machining, and demonstrate magnetic focusing up to 20μm. Compared to typically studied materials with circular Fermi surfaces, the transverse focusing amplitude is strongly enhanced owing to its large parallel sections. We demonstrate this focusing enhancement experimentally, and corroborate it by transport simulations.

8:12AM X11.00002: Direct Growth of Vertically Aligned Carbon Nanotube Arrays on Stainless Steel and Their Field Emission Properties*

ARUN THAPA (Presenter), WENZHI LI, Physics, Florida International University — We report the growth of VACNT arrays on stainless steel (SS) via dc plasma enhanced chemical vapor deposition without the use of a metal catalyst layer. TEM and AFM examinations revealed the occurrence of nano-hills formed on the SS surface during the heating process in an NH$_3$ environment, which is a critical step for the uniform growth of VACNTs. The particles on the tips of most of the VACNTs were found to be single crystalline Fe metal, although a few other VACNTs were found to have alloy of Fe, Ni, Mn, and Cr at their tips. Field emission (FE) performance of a dense array of VACNTs was enhanced by changing the array morphology through a simple water treatment process. The FE performance was further enhanced by coating the exterior of CNTs with a layer of crystalline SnO$_2$ nanoparticles of 4.18 nm in diameter. The enhancement of FE performance was ascribed to the morphological change and mechanical strength reinforcement of VACNTs by the SnO$_2$ coating process. The characteristic features of the sample as the conductive substrate, ohmic contact between the VACNTs and the substrate, and bundled morphology resulted in a lower turn-on and threshold electric field, higher field enhancement, and excellent emission stability.

8:24AM X11.00003: The connection between enhanced phonon-exciton interaction next to localization centers and photoluminescence of few-body complexes in tungsten-based transition metal dichalcogenide monolayers.*

DINH VAN TUAN (Presenter), HANAN DERY, University of Rochester — Photoluminescence (PL) experiments in WSe$_2$ show that the neutral-exciton peak X0 in the charge-neutral regime is often accompanied by additional lower-energy peak. The spectral position of the peak is below X0 by one phonon energy. Recently, several groups reported on trion-exciton complexes in encapsulated WSe$_2$ [1,2,3,4,5], where once again, their PL spectra reveal that the peak attributed to the five-particle complex is one phonon energy below that of the biexciton. We show that these PL peaks stem from phonon-assisted recombination of excitons or biexcitons next to localized electrons (i.e., these are not real trions or trion-exciton complexes that can diffuse in the monolayer). We explain why the proposed PL mechanism is prevalent in these monolayers while being absent in absorption-type experiments [6], showing that it supports the observed PL dependences on temperature and background charge density.

*This work is supported by the Department of Energy, Basic Energy Sciences (DE-SC0014349).
8:36AM X11.00004: Synthesis, structure, and physical properties of carbon nanotubes filled with nickel sulfide nanowires*  
YUBA POUDEL (Presenter), WENZHI LI, Physics, Florida International University — We report a novel synthesis of carbon nanotubes (CNTs) filled with continuous nanowires of nickel sulfide via a chemical vapor deposition method. Pyrolysis of thiophene (C₄H₄S) on the nanoparticles of Ni catalyst can induce the simultaneous growth and filling of CNTs which can be well explained by a large volume expansion experienced by the Ni nanoparticles during the sulfidation reaction. Electron microscopy measurements reveal that most of the CNTs are completely filled with single crystalline nickel sulfide nanowires of several micrometers in length. We also validate that there exists a direct relationship between the concentration of catalyst precursor and the dimensions of nickel sulfide filled CNTs within a certain cut-off region. Besides, a simple sonication process can be a quick and reliable method to extract the filled CNTs from the substrate whereas the regrowth of nickel sulfide filled CNTs on the same layer of the catalyst particles ensure the recyclability of the synthesis technique. Fundamental physical properties of the nickel sulfide nanowire filled CNTs will also be presented.

*This work is supported by the National Science Foundation under grant DMR-1506640.

8:48AM X11.00005: Title: Refrigeration and thermometry for millikelvin and sub-millikelvin nanoelectronics.*  
JOSHUA CHAWNER (Presenter), IAN BRADLEY, ANTONY GUÉNAULT, Department of Physics, Lancaster University, DAVID GUNNARSSON, VTT Technical Research Centre of Finland Ltd, RICHARD HALEY, ALEXANDER JONES, YURI PASHKIN, Department of Physics, Lancaster University, JARI PENTTILA, Aivon Oy, JONATHAN PRANCE, Department of Physics, Lancaster University, MIKA PRUNNILA, VTT Technical Research Centre of Finland Ltd, LEIF ROSCHIER, Aivon Oy — Cooling electrons in a nanoelectronic device to a few milikelvin, and further into the microkelvin regime, is a longstanding challenge. Weak electron-phonon coupling at low temperatures creates a bottleneck in traditional cooling techniques [1]. Here we will present our approach to solving the problem: nuclear demagnetization refrigeration of on-chip copper to directly cool the electrons without intervening phonons [2]. Our method has achieved a base electron temperature below 1.3 mK, held for several 1000s. On-chip refrigeration could potentially provide improvements in the operation of quantum simulators, computers and metrology standards, and open a new regime for the study of electron transport in nanostructures and 2D materials. However, it will be necessary to couple the copper refrigerator to the system of interest and to employ non-invasive thermometry techniques. We will discuss our progress towards these goals, including the development of a single-electron thermometer that is measured by RF reflectometry and does not require galvanic connection between the cooled electron gas and the outside world.

*This research is supported by the U.K. EPSRC (EP/N019199/1)

9:00AM X11.00006: Modeling transport in phosphorus δ-doped silicon tunnel junctions*  
LEON MAURER (Presenter), MICHAEL MARSHALL, DEANNA CAMPBELL, LISA A TRACY, TZU-MING LU, DANIEL WARD, SHASHANK MISRA, Sandia National Laboratories — Electrical devices based on Si:P δ layers can be fabricated with atomic precision, which could allow for the fabrication of high-efficiency tunneling field effect transistors (TFETs). While great strides have been made in fabricating nanoelectronics from Si:P δ layers, there is little agreement about the electronic structure of the Si:P δ layers. Furthermore, the transport properties of only a few devices have been modeled. We use a scalable model to study transport in nanoscale tunnel junctions made from Si:P δ layers, and we show that the transport properties of tunnel junctions can provide insight into the electronic structure of Si:P δ layers. We also compare our model to experimental results and find good agreement.

*This work was supported by the Laboratory Directed Research and Development Program and was performed in part at the Center for Integrated Nanotechnologies, a US DOE Office of Basic Energy Sciences user facility. Sandia National Laboratories is managed and operated by National Technology and Engineering Solutions of Sandia LLC, a subsidiary of Honeywell International Inc., for the U.S. Dept. of Energy's National Nuclear Security Administration under contract DE-NA0003525. The views expressed do not necessarily represent the views of the DOE or the U.S. Government.
9:12AM X11.00007: Effect of electron-phonon interaction on the opto-electronic properties of semiconducting nanoparticles*  
HAN YANG (Presenter), University of Chicago, MARCO GOVONI, Materials Science Division, Argonne National Laboratory, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago — We report on the impact of electron-phonon coupling on the opto-electronic properties of semiconducting nanoparticles. We used a newly developed first-principle method [1] based on many-body-perturbation-theory, which efficiently combines electron-electron and electron-phonon interaction without explicitly evaluating virtual electronic orbitals. The method is implemented in the WEST code [2]. In particular we discuss carbon-based nanoparticles and chalcogenide nanostructures.

*This work was supported by MICCoM, as part of the Computational Materials Sciences Program funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division under contract number DE-AC02-06CH11357.

9:24AM X11.00008: Electronic noise due to temperature differences in atomic-scale junctions: beyond standard thermal and shot noises  
OFIR SHEIN-LUMBROSO, Department of Chemical and Biological Physics, Weizmann Institute of Science, LENA SIMINE, Department of Chemistry, University of Toronto, ABRAHAM NITZAN, Department of Chemistry, University of Pennsylvania, DVIRA SEGAL, Department of Chemistry, University of Toronto, OREN TAL (Presenter), Department of Chemical and Biological Physics, Weizmann Institute of Science — Since the discovery of electronic thermal and shot noise almost a century ago, these two forms of fundamental electronic noise have had an enormous impact on science and technology. Here, we report on a new version of electronic noise that is generated by temperature differences across nanoscale conductors, which we term ‘delta-T noise’. We experimentally demonstrate this noise in atomic and molecular junctions, and analyze it theoretically using the Landauer formalism. The delta-T noise reveals a peculiar combination of characteristics that makes it different from the known thermal noise and voltage-activated shot noise. This noise can be used to detect temperature differences across nanoscale conductors without the need for fabricating sophisticated local probes. Furthermore, delta-T noise should be considered when designing modern nanoscale electronics, since temperature gradients are often generated unintentionally across electronic components.

9:36AM X11.00009: Surface Plasmon Polaritons in Chalcogenides*  
CIGDEM OZSOY KESKINBORA (Presenter), KUNDAN CHAUDHARY, MICHELE TAMAGNONE, Harvard University, YUNBO OU, ARAVIND DEVARAKONDA, TAKEHITO SUZUKI, JOSEPH CHECKELSKY, JAGADEESH MOODERA, MIT, FEDERICO CAPASSO, DAVID BELL, Harvard University — The surface plasmon polaritons is a highly investigated field of research due to their high potential applications for sensors, information technologies, high resolution imaging, to name a few. These collective electron oscillations are common at metal dielectric interfaces. However, they also exist in highly doped semiconductors, conducting oxide systems, and in many other systems with high carrier mobility. This poses the question of whether such resonances can be observed at the insulator interfaces with these novel materials. Chalcogenides, the general name of sulfides, selenides, tellurides can show highly anisotropic crystal structures, that gives them exotic properties such as topological surface state, superconductivity or negative dielectric permittivity. It was shown that Bi₂Se₃ supports Dirac plasmons, but the Dirac state is not the only reason for the existence of plasmon resonance in Bi₂Se₃. This material also has highly anisotropic dielectric properties allowing surface plasmon excitations. It is not the only chalcogenide system that can support them. Here we show the electron energy loss spectroscopy and a finite difference frequency domain study for investigating Bi₂Se₃, and BaNbS.

*Supported by the Center for Integrated Quantum Materials, NSF Grant No DMR 1231319.
9:48AM X11.00010: Room Temperature Phonon Focusing As a Tool for Tuning Thermal Conductivity in Nanostructured Materials  GIUSEPPE ROMANO (Presenter), Department of Mechanical Engineering, Massachusetts Institute of Technology —

Phonon focusing arises from the anisotropy in the phonon dispersions in crystalline materials. This effect has been extensively studied at low temperatures in bulk materials, where relatively low phonon scattering rates lead long mean-free-paths (MFP) with respect to the material’s specimen [1]. Here we investigate this phenomenon at room temperature in Si nanostructured materials. These systems can have a feature size as small as a few nanometers thus are comparable with a large fraction of phonon MFPs. By using the MFP-Boltzmann transport equation [2], we compute heat transport of nanoporous materials with different crystal orientations with respect to the pore lattice, finding a significant variation in the thermal conductivity. These results illustrate a route for tuning thermal transport in nanostructured materials beyond shape optimization.

10:00AM X11.00011: Vertical p-n junction of a thermoelectric material investigated using photoemission technique  JIEUN LEE (Presenter), JINWOONG HWANG, MINHEE KANG, Pusan National University, KYOO KIM, Physics, POSTECH, HYEJIN RYU, KIST, SHUJE TANG, ALS, SUNGLAE CHO, Uwins, SUNG-KWAN MO, ALS, HO-SOON YANG, CHONGYU HWANG, Pusan National University — The thermoelectric materials can generate electricity out of heat when they form a p-n junction, connected to an electric circuit. Typically, such a junction is made of two pieces of a thermoelectric material that are doped by electrons and holes, respectively, and then put together. Here we report one of the plausible ways to prepare the p-n junction via the experimental investigation of the electron band structure of a thermoelectric material using photoemission technique.

10:12AM X11.00012: One-Dimensional Atomic Tellurium Chains in Boron Nitride Nanotubes: Synthesis and Devices  PAI-YING LIAO (Presenter), JINGKAI QIN, MENGWEI SI, Purdue University, SIQI ZHANG, YOKE KHIN YAP, Michigan Technology University, PEIDE (PETER) YE, Purdue University — Tellurium has a unique one-dimensional (1D) helical chain crystal structure. The adjacent tellurium atoms in a single chain are covalently bonded, and different chains interact with each other by van der Waals force to form planar and bulk crystal. As a narrow-bandgap p-type semiconductor, bulk tellurium has a direct bandgap of ~0.35 eV. Here, 1D atomic tellurium chains were grown inside the boron nitride nanotubes (BNNTs) whose inner diameter was only a few nanometers. 1D tellurium crystal was synthesized and grew along the direction of BNNTs due to the natural confinement of the BNNT physical structure. Raman spectroscopy and energy-dispersive X-ray spectroscopy (EDX) were utilized to characterize the tellurium crystal structure and guaranteed the high quality of the Te-BNNT samples. The electrical properties of Te-BNNT devices were studied by current-voltage measurement. The devices were fabricated by transferring Te-BNNTs onto SiO2/p++ Si substrate, Ar-SF6 dry etching, and deposition of metal electrodes on top of the nanotubes. The realization of BNNTs-capsulated tellurium chains enhanced the current capacity of tellurium crystal several times compared to bare tellurium nanowires.

10:24AM X11.00013: Single-molecule rectifiers based on voltage-dependent deformation of molecular orbitals in carbazole oligomers  TATSUHIKO OHTO (Presenter), Graduate School of Engineering Science, Osaka University, KEN ALBRECHT, Laboratory for Chemistry and Life Science Institute of Innovative Research, Tokyo Institute of Technology, RYO YAMADA, KEIGO MINODE, Graduate School of Engineering Science, Osaka University, KIMIHISA YAMAMOTO, Laboratory for Chemistry and Life Science Institute of Innovative Research, Tokyo Institute of Technology, HIROKAZU TADA, Graduate School of Engineering Science, Osaka University — Current-voltage characteristics of single molecule junctions are governed both by the energy level alignment of molecular orbitals with respect to the Fermi level of the electrodes and by the hybridization of electronic structures at the interface between the molecule and the electrodes. While there have been many studies on tuning the former, only a few works intended to control the latter. In the present study, we demonstrate that molecular junctions based on carbazole oligomers showed a current rectification behavior due to asymmetric-symmetric control of electronic hybridization between the molecule and electrodes at both terminals. The carbazole oligomers originally showed an asymmetric molecular orbital and, hence, electronic hybridization with the electrodes because of the electric dipole moment. Symmetric electronic hybridization was achieved when the applied electric field between electrodes deformed molecular orbital to be symmetric. This is a novel way to control charge transport in single-molecule junctions (R. Yamada et al., Nanoscale, in press).

Friday, March 8, 2019 8:00 AM - 10:48 AM

Session X12 DMP: Devices from 2D Materials -- Advanced Fabrication  BCEC 153A - Cui-Zu Chang, Pennsylvania State University - Tag(s): Focus
8:00AM X12.00001: Interlayer Excitons in Transition Metal Dichalcogenides Heterostructures* [Invited]  XIAOQIN (ELAINE) LI (Presenter), University of Texas-Austin — In van der Waals heterostructures formed by stacking two monolayers of transition metal dichalcogenides, interlayer excitons with long recombination lifetime represent the lowest energy optical resonances. In heterostructures created by using different material recombinations and different fabrication methods, interlayer exciton properties are drastically different. I will discuss the observation of multiple interlayer exciton resonances with either positive or negative circularly polarized emission in a MoSe$_2$/WSe$_2$ heterobilayer with a small twist angle created using the mechanical exfoliation and stacking method. We attribute these resonances to the ground state and excited states confined within the moiré potential. I will compare these experiments to those observed in a MoSe$_2$/WSe$_2$ heterobilayer created using the chemical vapor deposition method.

8:36AM X12.00002: Top-down nanopatterning of layered transition metal dichalcogenide heterostructures*  
PUFAN LIU (Presenter), TEODOR STANEV, Northwestern University, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS, Japan, NATHANIEL STERN, Northwestern University — Nanostructured materials give rise to useful features such as size-dependent properties, interfacial phenomena, and edge effects, allowing optimization for opto-electronics. Although electron beam lithography has been widely used for top-down fabrication of nanostructures, translating this approach to the emerging class of 2D materials has challenges. Direct electron beam exposure on 2D materials can lead to non-reversible damage and degradation of optical and electronic properties. We show that e-beam damage can be significantly reduced on monolayer transition metal dichalcogenides by covering it with a thin hexagonal boron nitride layer. The reduced damage allows direct negative resist lithographic writing of sub-10nm nanostructure fabrication without impairing the monolayer optical and electrical properties.

*Work supported by the Office of Naval Research (N00014-16-1-3055).

8:48AM X12.00003: Optical Annealing of Graphene Oxide Thin Films*  
SHASHANK RAM NANDYALA (Presenter), JOSEPH MURPHY, MICHAEL A SEAS, VIVEK SANTOSH JAIN, SUBASH KATTEL, JON M PIKAL, PATRICK A JOHNSON, JOHN ACKERMAN, WILLIAM RICE, University of Wyoming — Graphene oxide (GO) can be converted to highly conductive reduced GO (rGO) via photochemical methods, solution chemistry, and high-temperature treatments. Specifically, highly localized, controllable laser-based annealing has been shown to create conductive patterns of rGO. This optically induced thermal transition is characterized by the ratio of $sp^2$-to-$sp^3$-hybridized carbon (using Raman spectroscopy) and electrical conductivity. Here, we show that circuit-like patterns of rGO can be created using a 532 nm laser at intensities of ~6 MW/cm$^2$. Using the integrated ratio of the GO $sp^2$ G-band (~1594 cm$^{-1}$) to $sp^3$ D-band (~1363 cm$^{-1}$), we show that the optically generated GO-to-rGO conversion is slower and more uniform in an argon environment than in vacuum, an observation we attribute to the greater thermal exchange created by the high heat capacity argon gas. We determine the GO-to-rGO transition temperature of our optical process using the ratio of the integrated Stokes to anti-Stokes peaks and find that this temperature is consistent with standard induction furnace rGO annealing. Our findings suggest that optically created circuits of conductive rGO can be reproducibly created from GO films.

*We acknowledge support of the UW School of Energy Resources.
9:00AM X12.00004: One-Dimensional Potential in Graphene  APOORV JINDAL (Presenter), AVISHAI BENYAMINI, Department of Physics, Columbia University in the City of New York, SAI SUNKU, Department of Applied Physics and Mathematics, Columbia University in the City of New York, YIHANG ZENG, Department of Physics, Columbia University in the City of New York, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, JAMES HONE, Department of Mechanical Engineering, Columbia University in the City of New York, CORY R DEAN, DIMITRI BASOV, ABHAY PASUPATHY, Department of Physics, Columbia University in the City of New York — With improvements in fabrication techniques, low-disorder graphene devices have been realized to study a variety of correlated physics including fractional quantum Hall effect, and Mott insulating behavior. One possibility for inducing new electronic phenomena is by the use of nanometer-scale one-dimensional potentials to define narrow channels in graphene sheets. Previous efforts to study such effects in graphene have relied on lithographic fabrication of narrow metal gates. Lithographic methods suffer from edge disorder and a resolution limited to tens of nanometers. In this talk, we describe the engineering of a 1D potential in graphene using a carbon nanotube (CNT) that is a few nanometers from the graphene surface. We will describe cryogenic magnetotransport measurements that indicate the presence of a one-dimensional mode in graphene under appropriate gating conditions from the CNT. Electronic 1D bound states are also predicted to cause plasmonic reflections. These have been observed with cracks, stacking faults, and wrinkles in graphene. Our system provides an ideal platform to probe these reflections with the CNT gate inducing a tunable 1D barrier in graphene. In this talk, we also report near-field optical microscopy measurements probing such plasmonic reflections.

9:12AM X12.00005: Two dimensional SrTiO3 membranes*  WEI GUO (Presenter), AGHAM POSADAS, ALEXANDER DEMKOV, ANUPAM ROY, AMRITESH RAI, OMAR MOHAMMED, SANJAY BANERJEE, KEVIN OLSSON, XIAOQIN (ELAINE) LI, University of Texas at Austin — Perovskite SrTiO3 (STO) exhibits a wide range of exciting phenomena in addition to being a common substrate in epitaxial growth of various oxides like LaAlO3, BaTiO3, etc. There is a growing interest in studying new physical phenomena happens in the oxide materials in the two dimensional limit. We developed an etching method to fabricate free-standing STO membranes. The membranes are typically 5-8 um wide and 10-20 um long with thickness ranging from two to several tens of nanometers. We use Micro-Raman spectroscopy to investigate the STO membranes’ vibrational spectra and compare with that of the bulk STO. To exploit the high dielectric constant of STO, we design and fabricate electronic devices combining STO membranes with other two dimensional materials such as graphene and h-BN.

*This research was partially supported by the National Science Foundation through the Center for Dynamics and Control of Materials: an NSF MRSEC under Cooperative Agreement No. DMR-1720595 and by the Air Force Office of Scientific Research under Grant FA9550-18-1-0053.

9:24AM X12.00006: Lithographically-defined strain control in atomically-thin semiconductors  LEO YU (Presenter), JINGYUAN LINDA ZHANG, Stanford University, SVEN BORGHARDT, Stanford University & Forschungszentrum Jülich, MINDA DENG, GEUN HO AHN, JELENA VUCKOVIC, Stanford University, TONY F HEINZ, Stanford University & SLAC National Accelerator Laboratory — Frontier quantum science calls for a large-scale deployment of solid-state artificial atoms, or quantum dots (QDs). But the progress has been limited due to the lack of simultaneous control of a material's bandgap spatially and in energy. Here, we present a new approach based on lithographically-defined strain to achieve control of both the spatial position and bandgap energy in atomically-thin semiconductors. In our method, we first suspend a monolayer over a nanoscale cavity in the substrate; we then deform the layer using high-pressure gas, atomic force microscopy or thermal molding. With an optimized new process, we have produced localized biaxial strain down to 40-nm widths at defined positions in a WSe2 monolayer and in other atomically-thin semiconductors. Tensile strains up to 3.5% have been achieved appropriate design of the cavity depth and can be maintained without any external pressure or voltage. Because of the strain-induced reduction in the bandgap, these QDs exhibit emission peaks spectrally separated from the intrinsic peaks by more than 100 meV. We discuss potential applications of such localized QD structures in 2D semiconductors.

9:36AM X12.00007: Design of Nanocarbon Electronic Devices for Single-Molecule Measurements  AMIRA BENCHERIF (Presenter), Biomedical Engineering, Universite de Montreal, RICHARD MARTEL, Department of Chemistry, Universite de Montreal, DELPHINE BOULLY, Physics, Universite de Montreal — With the miniaturization of electronics, it is now possible to assemble field-effect transistors (FET) with single-molecule components as channel or gate. Single-molecule FETs have been recently used to study different fundamental mechanisms at the individual molecule scale, such as charge transport, folding and chemical reactions, both for small molecules and complex biological macromolecules. Here, our goal is to use nanocarbon materials (graphene or carbon nanotubes) to design and fabricate FET architectures suitable for single-molecule measurements. First, we report the fabrication of large arrays of FET devices with similar electrical characteristics, built from long carbon nanotubes or large-area graphene synthesized by chemical vapor deposition (CVD). Second, we used electron-beam lithography to pattern high-resolution features (20nm), in order to design nanoconstrictions in the graphene channel, as well as nanofluidic cavities allowing for single-point reaction chemistry. We will present the electrical characteristics of these devices, as well as high-resolution imaging using scanning electron and atomic force microscopy (SEM/AFM). Finally, we will discuss future work in terms of single-molecule functionalization with biological molecules.
In this presentation, the mechanical resonance behaviors of porous graphene resonator used for were studied. The goal of this research is to find an optimal geometric structure of drum-like graphene for with obtaining its mechanical resonance with high frequencies and high Q-factors. Resonance behavior of graphene drums with various periodic hole-patterns has been studied by using finite element modeling simulation. The geometry and number of hole structures on graphene were designed and fabricated according to the simulation modeling. Our simulation results suggest that the resonance frequency of the graphene drum gradually increases and then drops as the number of pores of the graphene increases from 0 to 100. In addition, the porous graphene resonator devices are experimentally realized by transferring a porous graphene membrane on substrate with a trench structure. Experimentally measured resonance frequencies and estimated quality factors of graphene resonator with various pore structures were compared to and analyzed by simulation results.

We have investigated switching characteristics in graphene/semiconducting single-walled carbon nanotube (SWCNT) junction device, so-called graphene/SWCNT barristor. We modulated Schottky barrier between the graphene and the carbon nanotube by using top and bottom gate electrodes, and achieved on-off ratio of $10^8$ and the subthreshold swing of 74 meV/dec with high current density. This all-carbon device can be useful to graphene logic circuit, flexible electronics circuit and memory device.

We present high throughput thermal conductance data at alloy/graphene interfaces as a function of alloy composition and adhesion layer thickness, with a maxima observed at 10 at. % Pd in Ni without an adhesion layer. Graphene contact research has been exclusively limited to pure metals, where the metal/graphene interface inhibits the flow phonons, quantified by the thermal interface conductance. For future electronics to fully capitalize on the revolutionary transport properties of graphene, sufficient heat dissipation at the contact interface is critical to performance. [1]

To make high throughput measurements, metal films with a continuous alloy composition gradient spanning two pure metals were deposited on monolayer graphene on SiO$_2$/Si substrates. Frequency domain thermoreflectance was used to measure thermal interface conductance as a function of metal composition. Future measurements of electrical contact resistance will be done through transmission line measurement structures, in order to determine the optimal alloy concentration for both electrical and thermal transport across the interface.

Quantum point contact in bilayer graphene

HAILONG FU (Presenter), JING LI, YA-WEN CHUANG, Pennsylvania State University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, 1-1 Namiki, Tsukuba 305-0044, JUN ZHU, Pennsylvania State University — Edge state interferometry has been an important tool in probing the charge and statistics of elementary excitations of the quantum Hall and fractional quantum Hall effect of a two-dimensional electron gas. The recent observations of a plethora of fractional quantum Hall states in bilayer graphene, especially a series at even denominators, made this technique all the more appealing. A quantum point contact (QPC) is a key component of an interferometer, the realization of which is difficult in graphene owing to its gapless nature. In bilayer graphene, a pair of aligned top and bottom gates[1, 2] can be used to open a band gap and therefore construct a QPC. Here we report on our effort in fabricating QPC devices using high-quality h-BN encapsulated bilayer graphene. Because of the thin gating profile, the confining potential of the QPC in bilayer graphene is much sharper than what can be achieved in GaAs 2D systems. We observed well-developed quantum Hall states across QPCs with large openings and gate-controlled backscattering of edge states in QPCs with smaller openings. We discuss our fabrication processes, challenges and progress towards a Fabry-Perot interferometer in bilayer graphene.

Friday, March 8, 2019 8:00 AM - 11:00 AM

Session X13 DMP: 2D Materials (General) -- Mechanical Properties and Phases BCEC 153B - Niyaz

Atomistic Origin of Phase Stability in Oxygen-Functionalized MXene

AVANISH MISHRA (Presenter), POOJA SRIVASTAVA, Materials Research Centre, Indian Institute of Science, ABEL CARRERAS, ISAO TANAKA, Department of Materials Science and Engineering, Kyoto University, HIROSHI MIZUSEKI, KIWANG-RYEOL LEE, Computational Science Research Center, Korea Institute of Science and Technology, ABHISHEK KUMAR SINGH, Materials Research Centre, Indian Institute of Science — Oxygen-functionalized MXene, M2CO2 (M = group III-V metals), are two-dimensional (2D) materials with the immense possibility for device applications. Using first-principles calculations, we perform a study on the stability of M2CO2 MXenes. Depending on the position of O atoms, the M2CO2 can exist in two different phases. CB phase, where O at the top of carbon and metal atom. On the other side, O atom can occupy either the site on the top of the metal atom (BB' phase). We found that for M = Sc and Y the CB phase is stable, whereas for M = Ti, Zr, Hf, V, Nb, and Ta the stable phase is BB'. The electron localization function and atom-projected density of states, provide a rational explanation for the relative stability. Instability of BB'- M2CO2 (M = Sc and Y) originates from the weakening of M−C interactions due to the motion of C atom in the−b plane. The insight into the stability of these competing structural phases of M2CO2 is an important step in the direction of identifying the stable phases of these 2D materials and their applications.

DFT study of Ni-doped MoS2 as a solid lubricant for space applications

ENRIQUE GUERRERO (Presenter), RIJAN KARKEE, DAVID STRUBBE, University of California, Merced — MoS2 is a layered material with interesting mechanical properties not unlike graphite. The weak Van der Waals forces between MoS2 sheets allow the material to be used as a solid lubricant with application in the low temperature and pressure environment in space, where liquid lubricants fail. Some preliminary studies suggest that doping with transition metals can improve tribology performance by reducing friction and wear. We use density functional theory (DFT) calculations to determine the structure and properties of bulk Ni-doped MoS2, considering formation energy of Ni in different sites as a function of growth conditions, and study the potential energy for sliding to connect to frictional forces measured in atomic-force microscopy (AFM). We calculate vibrations with density-functional perturbation theory (DFPT) for comparison to infrared and Raman spectra in experimental characterization. Our resulting DFT data will be used to parametrize classical force fields for larger-scale reactive molecular dynamics (MD) simulations that can directly address friction and wear.

*Funding from Merced nAnomaterials Center for Energy and Sensing, a NASA-funded research and education center, under award NNX15AQ01
**Effect of net charge on the relative stability of different 2D boron allotropes**

DAN LIU (Presenter), DAVID TOMANEK, Michigan State Univ — We study the effect of electron doping on the bonding character and stability of 2D structures of elemental boron, called borophene, which is known to form many stable allotropes. Our *ab initio* calculations reveal a previously unknown stable 2D \( \varepsilon \)-B structure for the neutral system. We find that the chemical bonding characteristic in this and other boron structures is strongly affected by extra charge. Beyond a critical degree of electron doping, the most stable allotrope changes from \( \varepsilon \)-B to a buckled honeycomb structure. Additional electron doping, mimicking a transformation of boron to carbon, causes a gradual decrease in the degree of buckling of the honeycomb lattice that can be interpreted as piezoelectric response. Net electron doping can easily be achieved by placing borophene in direct contact with the layered \( \text{Ca}_2\text{N} \) electride. In particular, electron doping can be doubled by changing from a bilayer to a sandwich geometry.

**VIBRATIONAL PROPERTIES OF PHOSPHORENE UNDER HIGH PRESSURE**

MANTHILA RAJAPAKSE (Presenter), MEYSAM AKHTAR, CONGYAN ZHANG, MD RAJIB KHAN MUSA, MING YU, Physics and Astronomy, University of Louisville, JACEK JASINSKI, University of Louisville, GAMINI SUMANASEKERA, Physics and Astronomy, University of Louisville — In this study, few layer phosphorene was subjected to high pressure using a Diamond Anvil Cell (DAC) and its vibrational properties were studied via in-situ Raman spectroscopy. Systematic shifting in the Raman frequency of \( A^1_g \), \( B^2_g \), and \( A^2_g \) modes were observed and theoretical calculations were performed to understand the relationship between the strain and the electronic/phononic band structure. The results from computational calculations carried out by employing the density functional theory (DFT) framework, as implemented in the Vienna Ab-initio Simulation Package (VASP) agree well with the experimental data. The results can enable rational engineering of strain towards additional functionalities and device applications of phosphorene and few-layer black phosphorous.

*DOE funded this work.*

**Capillary Origami with Atomically Thin Sheets**

MICHAEL REYNOLDS (Presenter), KATHRYN L MCGILL, Department of Physics, LASSP, Cornell University, MARITHA WANG, Department of Chemistry, Institute for Molecular Engineering, and James Franck Institute, University of Chicago, MARC MISKIN, Department of Physics, LASSP, Cornell University, HUI GAO, Department of Chemistry and Chemical Biology, Cornell University, FAUZIA MUJID, Department of Chemistry, Institute for Molecular Engineering, and James Franck Institute, University of Chicago, KIBUM KANG, Department of Chemistry and Chemical Biology, Cornell University, JIWOONG PARK, Department of Chemistry, Institute for Molecular Engineering, and James Franck Institute, University of Chicago, ITAI COHEN, PAUL L MCEUEN, Department of Physics, LASSP, Cornell University — The paper art of origami has inspired several works in which two-dimensional materials are cut and folded into desired geometries at the micron scale. At this scale, surface energies can easily dominate over bending energies, allowing sheets to be folded with droplets, a technique known as capillary origami. In this talk, we show capillary origami of monolayer molybdenum disulfide (MoS\(_2\)) using droplets in water. By adding rigid panels to the MoS\(_2\), we demonstrate controllable folding of polyhedra. Finally, we show that these shapes can be self-folded by using partially miscible droplets in water. These results provide a new approach for creating pre-patterned three-dimensional devices using two-dimensional materials.

9:00AM X13.00006: Modeling the dynamics of a single graphene ripple with LAMMPS  JAMES MANGUM (Presenter), PAUL THIBADO, University of Arkansas — In recent years, graphene has shown great promise for a variety of reasons, but most notably for its potential for energy harvesting. Graphene requires ripples to maintain stability. It has been speculated that kinetic energy of the spontaneous flipping of ripples may be converted into electrical energy using vibration energy harvesting technology. The dynamics of larger graphene sheets may be understood by running molecular dynamic simulations with nanoscale sheets that contain a single ripple. Creating single ripples in graphene requires introducing an optimal level of compressive strain, and freezing the molecules on the edge of the sheet. In this talk, we discuss single-ripple graphene dynamics, modeled on LAMMPS. This includes the effect that compressive strain has on flipping time, and equilibrium position. Additionally, videos of the output will be included to elucidate the mechanics of graphene ripple flipping. Our results will be compared to previous results.

9:12AM X13.00007: Organized Brownian Motion in Freestanding Graphene: A New Type of Thermal Motion  PAUL THIBADO (Presenter), PRADEEP KUMAR, SURENDRALAL SINGH, University of Arkansas, MIGUEL RUIZ GARCIA, University of Pennsylvania, ANTONIO LASANTA, LUIS BONILLA, Universidad Carlos III de Madrid — Conversion of omnipresent thermal motion into stored electrical charge has been achieved using vibration energy harvesting technology. Our studies demonstrate that the thermal movement of freestanding graphene produces an alternating electrical current when near a biased metal electrode. The magnitude of this induced electrical current is consistent with a constant-voltage, variable-capacitance power generator. The key mechanism behind this discovery is the spontaneous curvature inversion of ripples, during which thousands of atoms move coherently [PRL 117, 126801 (2016)]. The collective motion of the atoms is a many-body effect and represents a new type of thermal motion with long time correlations enabling energy extraction [PRL 71, 1477 (1993)]. Our results lay the groundwork for a new source of thermal power originating from organized Brownian motion. Circuit details and quantities of energy harvested from this new many-body thermal force will be highlighted in the presentation.

9:24AM X13.00008: Exploring out-of-plane Mechanics of Graphene Membrane by 3D Force Field Spectroscopy on various Nanotubes  MAKOTO ASHINO (Presenter), Department of Electrical and Electronic Engineering, Kanazawa Institute of Technology, ROLAND MARTIN WIESENDANGER, Department of Physics, University of Hamburg — Bending rigidity and Gaussian modulus are key parameters to understand flexibilities of two-dimensional (2D) crystalline membrane embedded in three-dimensional (3D) space. These two parameters of graphene membranes are still unclear because of their difficulties to distinguish purely intrinsic characteristics from others due to thermal fluctuations, consequent local strains and so on. Here we present experimental determinations of those properties by analyzing noncontact interaction between the opposing two atoms of probe-tip apex and convexly-curved graphene folding into various nanotubes. We have quantitatively evaluated the relationship between out-of-plane displacement and elasticity of monolayer graphene by 3D force field spectroscopy at low temperature not only on folded nanotubes with well-defined curvatures but also on unfolded one (i.e. graphene nanoribbon) with unknown curvatures. The quantitative evaluations allow us to determine the smaller and locally different curvatures of unfolded monolayer. Our findings to separate the in-plane and out-of-plane contributions allow us to derive the substantially small bending modulus enough to expect the intrinsic characteristics of negligibly small (zero) modulus for the ultimate 2D membrane without any curvature.

9:36AM X13.00009: Probing the Domain Architecture in 2D α-Mo2C via Polarized Raman*  TIANSHU LI (Presenter), Materials Science and Engineering, Boston University, WEIJUN LUO, HIKARI KITADAI, XINGZHI WANG, XI LING, Chemistry, Boston University — MXenes are a group of two-dimensional (2D) materials with excellent stability and intriguing properties. Here, we conduct a systematic study on the Raman spectra of α-Mo2C and use it to study the unique domain structure of 2D α-Mo2C crystals grown by chemical vapor deposition (CVD). Six experimentally observed Raman modes are assigned with the assistance of phonon dispersion calculated from density functional theory (DFT). Angle-resolved polarized Raman spectroscopy indicates the anisotropy of α-Mo2C in the b-c plane, which is further applied to study the domains of the CVD grown 2D α-Mo2C crystals with different morphologies. Most of the α-Mo2C flakes contain multiple domains and the c-axes of neighboring domains within the same flake tend to form a 60° or 120° angle, indicating the carbon chains in α-Mo2C align along three equivalent directions. This is attributed to weak Mo-C bonds in this interstitial carbide and the low formation energy of the carbon chains along certain directions. Our study demonstrates that polarized Raman spectroscopy is a powerful and effective way to characterize the domain structures in α-Mo2C, which will facilitate the further exploration of properties and applications of α-Mo2C, as well as other MXenes.

*This work is supported by Boston University.
9:48AM X13.0001: On the mechanism for the 2D phase transition in freestanding group-IV monochalcogenide monolayers*  
JOHN VILLANOVA (Presenter), SALVADOR BARRAZA-LOPEZ, University of Arkansas — Group-IV monochalcogenides monolayers MX (M=Ge,Sn ; X=S,Se) are low-dimensional semiconductors which exhibit significant piezoelectric and ferroelectric responses. Monochalcogenide monolayers undergo a structural phase transition from a rectangular unit cell to a square unit cell at a critical temperature. There exist two intriguing descriptions of this behavior: (1) a Landau-Ginzburg effective model and (2) a description of the order-disorder transition based on ab initio molecular dynamics. We explore the phase transition by examining the softening of the phonon modes of SnSe as a function of temperature, in order to shed light on the possible physical mechanism underpinning the transition.

*This work is supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Early Career Award DE-SC0016139. Calculations were performed at Trestles, funded by the National Science Foundation, the Arkansas Economic Development Commission, and the U of A Office of the Vice Provost for Research and Innovation.

10:00AM X13.00011: Delocalization of Impact Energy in Multilayer Graphene Subjected to Supersonic Impact in Vacuum*  
WANTING XIE (Presenter), JAE-HWANG LEE, University of Massachusetts Amherst — We employed vacuum micro-ballistic characterization for the first time to explore the ballistic perforation dynamics of multilayer graphene (MLG). The vacuum level is approximately 1/3,000 of the atmospheric pressure to avoid undesired effects from air, including aerodynamic friction of a projectile or a membrane specimen. 3.7 um diameter silica spheres were accelerated to 300 – 900 m/s as projectiles and a suspended graphene membrane was subjected to projectile's impact. With an ultrafast microscopic imaging system (40 million frames per second), accurate velocities of the projectile before and after penetration were obtained. We studied the residual speed as a function of impact speed. The specific penetration energy of MLG was quantified with respect to projectile's impact speeds and specimen's thicknesses. As a result, MLG demonstrated twice better performance in vacuum compared to that in air, opposite to conventional predictions. The penetration features near the impact region were examined by scanning electron microscopy to uncover the correlations with the energy dissipation.

10:12AM X13.00012: The governing role of interlayer chemical bonding in polar properties of the van-der-Waals ferroelectric CuInP$_2$S$_6$*  
JOHN BREHM (Presenter), Vanderbilt University, MARIUS CHYASNAVICHUS, SABINE NEUMAYER, NINA BALKE, Oak Ridge National Lab, MICHAEL SUSNER, Air Force Research Laboratory, MICHAEL A MCGUIRE, PANCHAPAKESAN GANESH, PETRO MAKSYMOVYCH, Oak Ridge National Lab, SOKRATES T PANTELIDES, Vanderbilt University — Copper indium thiophosphate (CuInP$_2$S$_6$) is a van-der-Waals (vdW) layered crystal that is ferrielectric below room temperature. It has unusual properties, including a negative longitudinal piezoelectric coefficient whose atomistic origin remains unknown. In this talk, we present the results of density functional theory calculations which show that the potential energy for Cu displacement away from the centrosymmetric position has two distinct minima in each longitudinal direction instead of the usual one, with stable positions within the layer as well as in the vdW gap. The two minima correspond to two structural phases with distinct polarizations, which is corroborated by piezoresponse force microscopy experimental data. The anharmonicity of the potential governing Cu displacements yields a negative piezoresponse in one of the phases. At the same time, the potential is strongly influenced by strain and the corresponding width of the vdW gap, rendering CuInP$_2$S$_6$ a rare example of a uniaxial non-zero-polarization multi-well ferroelectric, with new potential for both fundamental studies and prospective applications.

10:00AM X13.00013: Mechanical and Electrical Studies of Two-dimensional Covalent Organic Frameworks* 
RUOFAN LI (Presenter), Cornell University, MICHIO MATSUMOTO, AMANDA CORCOS, Northwestern University, HALLEH BALCH, University of California - Berkeley, RAGHUNATH DASARI, Georgia Institute of Technology, AUSTIN EVANS, Northwestern University, GREGORY STIEHL, Cornell University, SETH R. MARDER, Georgia Institute of Technology, FENG WANG, University of California - Berkeley, WILLIAM DICTEL, Northwestern University, DANIEL RALPH, Cornell University — Two-dimensional (2D) covalent organic frameworks (COFs) are a promising new class of 2D materials with the potential for highly-tunable chemical, mechanical, electrical, and optical properties. As porous polymers, 2D COFs are predicted to have a combination of low mass density and high mechanical strength. Here we discuss mechanical and electrical measurements on COF thin films. For the mechanical measurements, we have developed a protocol for synthesizing COF films as thin as 1.5 nm at a liquid-liquid interface, lifting and drying them on a PDMS stamp, and then performing a dry transfer onto a prepatterned substrate to make suspended COF films. The transferred films exhibit excellent uniformity, smoothness, and cleanliness. We report results for the 2D Young's modulus and mechanical strength using nanoindentation measurements performed using an atomic force microscope. We will also discuss initial electrical measurements on COF films designed to have small energy gaps.

*This work was supported by the Army Research Office (W911NF-15-1-0447).

10:30AM X13.00014: Buckling of thermalized sheets* 
ALI MORSHEDIFARD (Presenter), Civil and Environmental Engineering, University of California, Irvine, MIGUEL RUIZ GARCIA, Physics, University of Pennsylvania, MOHAMMAD JAVAD ABDOLHOSSEINI QOMI, Civil and Environmental Engineering, University of California, Irvine, ANDREJ KOSMRLJ, Mechanical and Aerospace Engineering, Princeton University — Two dimensional atomically thin membranes (ATMs), such as graphene and transition metal dichalcogenides, display exceptional properties that have been exploited in advanced electronic applications. In this talk, we utilize tools from statistical physics and molecular dynamics simulations to investigate how thermal fluctuation affect buckling of ATMs. Of special interest are ATMs that are larger than the characteristic thermal length scale $l_{th}$, which is a function of temperature and material constants. Both simulations and theory predict that for small sheets of size $L< l_{th}$ the critical buckling load coincides with the classical continuum theory $\sigma \sim L^{-2}$. However, for large sheets of size $L>> l_{th}$ thermal fluctuations effectively stiffen the bending rigidity, which increases the critical buckling load that scales as $\sigma \sim L^{-2+\eta}$. Here $\eta\sim 0.8$ is the universal exponent that is related to the increased bending rigidity. We demonstrate that the critical buckling load scales the same way for both periodic and clamped boundary conditions. These results shed light on fundamental mechanisms that underlie buckling of ATMs and make possible accurate predictions that can be used for design purposes in applications.

10:45AM X13.00015: Friction Anisotropy of MoS2 Investigated via Atomic Force Microscopy 
OGULCAN ACIKGOZ (Presenter), MEHMET BAYKARA, University of California, Merced — Two-dimensional (2D) materials are of particular interest as solid lubricants for nano- and micro-scale devices as traditional fluid-based lubrication schemes fail at such small length scales due to problems including but not limited to surface tension. Among various 2D materials investigated as solid lubricants, MoS2 is of special importance for space applications since its lubricative properties do not degrade but rather improve under vacuum conditions. A particular aspect that has so far not been addressed in detail within this context is the direction dependence, i.e. anisotropy, of the frictional properties of MoS2, which could be an important design parameter for various applications. Here, we perform atomic force microscopy (AFM) measurements on CVD-grown and mechanically-exfoliated MoS2 to investigate the potential occurrence of friction anisotropy. Results indicate that (i) both CVD-grown and mechanically-exfoliated MoS2 exhibit strong friction anisotropy and remarkably, (ii) the periodicity associated with the anisotropy is not exclusively determined by the atomic structure of MoS2, but is a function of the AFM probe employed in the experiments.

Session X14 DMP DCMP: Devices from 2D Materials -- Twisted bilayers BCEC 153C - Matthew Yankowitz, Columbia University - Tag(s): Focus
8:00AM X14.00001: Bilayer graphene Josephson junctions with induced spin orbit coupling  AVRADEEP PAL
(Presenter), QuTech and Kavli Institute of NanoScience, Delft University of Technology, 2600 GA, Delft, The Netherlands, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan, SRJIT GOŚWAMI, QuTech and Kavli Institute of NanoScience, Delft University of Technology, 2600 GA, Delft, The Netherlands — Interfacial coupling of graphene with transition metal dichalcogenides (TMDs) have emerged as a way to induce enhanced spin orbit coupling in few layer graphene. In our experiment, bilayer Graphene is sandwiched between exfoliated WSe2 (bottom) and h-BN (top) and edge contacted by means of superconducting NbTiN. We report the first study of induced superconductivity in such systems by demonstrating the Josephson effect in a series of samples of varying junction lengths (300nm to 1300nm). All measured devices are found to be in the long junction limit. By means of bottom gating, we access a wide range of densities far away from the charge neutrality point, and trace the product as a function of Thouless Energy (Em). By testing the validity of standard SNS long junction diffusive limit superconducting proximity effect scaling behavior (IcRn = aEm) in spin orbit coupled graphene systems. As expected from theory, a universal scaling of these parameters is observed for all devices, however with a severely reduced a than expected.

8:12AM X14.00002: Electron scattering and thermopower in twisted bilayer graphene  TING FUNG CHUNG
(Presenter), YANG XU, LISHA AN, EVAN WITKOSKE, NA (LUNA) LU, YONG CHEN, Purdue University — Twisted bilayer graphene (TBLG) with a small twist-angle is of particular interest because of its distinct energy band, where recent electrical transport experiments revealed van Hove singularities (VHSs), hybridization gaps, and correlation-induced behaviors. To better understand the effect of VHSs in TBLG, we perform transport experiments in this study. We observe that the temperature-dependent resistivity follows a power-law for carrier density between the main charge neutrality and hybridization gap. The evolution of the temperature exponent with carrier density shows a W-shaped dependence, with minima near the VHSs and maxima toward the hybridization gap. This W-shaped behavior could be attributed to different electron scattering mechanisms. We also study thermopower in TBLG, where we observe multiple sign changes in thermopower near VHSs at low temperatures. Our work may provide more information about the electronic structure and physical process in the TBLG system.

8:24AM X14.00003: Towards a gate-controlled valley-analyzer in bilayer graphene  HAO CHEN (Presenter), JENS MARTIN, Physics, National University of Singapore — The inequivalent valleys K and K' in k-space of 2D-hexagonal materials offer a new valley-degree of freedom similar to spin and controllable via electrostatic gating. In bilayer graphene, the sign of Berry curvature in each valley is determined by the direction of the external electric field whereas the sign of Berry curvature in each valley has opposite sign. Theorists have predicted that at 1D-boundaries at which the sign of Berry curvature changes, counter-propagating valley-polarized 1D-channels emerge. Including spin and sublattice degeneracy, there are 4 quantized conduction channels in each direction. This approach provides a gate-controlled platform for valley-polarizers and analyzers, yet it is technically challenging to build such a nanoscale system. Here, we fabricate such system with four pairs of dual-split gates with optimized geometry and stacking methods. Low temperature measurements show large conductance contrast with a factor of 100 between different gate configurations. In our devices, we achieve conductivity of nearly 4 conduction channels in each valley polarized state, much closer to the ballistic limit than previous work. Ultimately, one pair can be valley polarizer and the subsequent pair could detect the valley polarization and serve as valley analyzer.

8:36AM X14.00004: Magnetotransport of twisted bilayer transition metal dichalcogenides  EN-MIN SHIH (Presenter), Physics, Columbia University, LEI WANG, Physics, Cornell University, AUGUSTO GHIOTTO, DANIEL A RHODES, CHENG TAN, ABHAY PASUPATHY, Physics, Columbia University, JAMES HONE, Mechanics, Columbia University — Two-dimensional van der Waals material has become an exciting field. One of the reason is that this system provides multiple degrees of freedom, including stacking order, interlayer spacing and interlayer twisted angle, to engineer the material band structure. Manipulate these degrees of freedom has led to observation of several emergent phenomena, including the fractal quantum Hall effect, tunable Mott insulators, and unconventional superconductivity. In particular, interlayer interaction in van der Waals heterostructures at a different twisted angle could induce many exotic phenomena. How the interlayer interaction affect the electronic structure of a material is a fundamental question. In this study, we report magnetotransport of twisted bilayer transition-metal dichalcogenides (TMDs) and demonstrate how its band structure vary with twisted angle. These results broaden the application range of van der Waals heterostructure for future electronic devices.
Charge-transfer insulation in twisted bilayer graphene. PAULA MELLADO (Presenter), Universidad Adolfo Ibáñez, LOUK RADEMAKER, Department of Theoretical Physics, University of Geneva — We studied the real space structure of states in twisted bilayer graphene at the "magic angle" θ = 1.08°. The flat bands close to charge neutrality are composed of a mix of "ring" and "center" orbitals around the AA stacking region. An effective model with localized orbitals is constructed, which necessarily includes more than just the four flat bands. Long-range Coulomb interaction causes a charge-transfer at half-filling of the flat bands from the "center" to the "ring" orbitals. Consequently, the Mott phase is a featureless spin-singlet paramagnet. We estimate the effective Heisenberg coupling that favors the singlet coupling to be J = 3.3 K, consistent with experimental values. The superconducting state depends on the nature of the dopants: hole-doping yields p+ip-wave whereas electron-doping yields d+id-wave pairing symmetry.

Phases of a phenomenological model of twisted bilayer graphene. JOHN DODARO, STEVEN KIVELSON, YONI SCHATTNER, XIAO-QI SUN, CHAO WANG (Presenter), Physics Department, Stanford University — We propose a lattice scale two-band generalized Hubbard model as a caricature of the electronic structure of twisted bilayer graphene. Various possible broken symmetry phases can arise, including a nematic phase (which is a form of orbital ferromagnet) and an orbital-triplet spin-singlet superconducting phase. Concerning the mechanism of superconductivity -- we propose an analogy with superconductivity in alkali-doped C_{60} in which a violation of Hund's first rule plays a central role.

Characterization of atomic scale lattice reconstruction in twisted van der Waals interfaces of layered material [Invited]. PHILIP KIM (Presenter), Harvard University — Control of the interlayer twist of van der Waals (vdW) interfaces has been widely used to engineer an artificial 2-dimensional (2D) electronic systems by the formation of a moiré superlattice. Many exotic physical phenomena occur associated with the incommensurability of the moiré superstructures where the wealth of the nontrivial topology of electronic band structures plays a key role to create exotic physical phenomena. In this presentation, we will discuss the engineered atomic scale reconstruction at twisted vdW interfaces using electron microscopy, optical spectroscopy, and electrical transport. We then will discuss emerging electronic and optoelectronic physics in the vdW interface between homojunctions.

Transport measurements of correlated insulating states in twisted bilayer graphene. AARON SHARPE (Presenter), ELIJ FOX, ARTHUR BARNARD, JOE FINNEY, Stanford University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, MARC KASTNER, DAVID GOLDHABER-GORDON, Stanford University — Twisted bilayer graphene (TBG) has emerged as a prominent platform for strongly correlated electrons. When two sheets of monolayer graphene are stacked at an angle near 1.1°, interactions are expected to break the four-fold spin and valley degeneracy resulting in correlated insulating states and superconductivity near densities corresponding to an integer number of electrons per superlattice unit cell [Cao et al., Nature 556, 43-50 (2018), Cao et al., Nature 556, 80-84 (2018)]. Here we present transport measurements studying these correlated states.

10:00AM X14.00009: Dynamic band structure in twisted bilayer graphene near the magic angle* JINHAI MAO (Presenter), YUHANG JIANG, XINYUAN LAI, Department of Physics and Astronomy, Rutgers University, 136 Frelinghuysen Road, Piscataway, NJ 08855 USA, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University, 136 Frelinghuysen Road, Piscataway, NJ 08855 USA — A twist between the orientations of superposed 2D crystal structures leads to a moiré superstructure which can significantly alter their electronic properties. In the case of superposed graphene layers with small twist angle, the energy band flattens resulting in a slow-down of the charge carriers until, at certain “magic angles”, they come to a complete halt. In this regime, electron-electron interactions become strong leading to the emergence of new correlated phases and topologically protected ballistic channels. Using STM on gated twisted bilayer graphene samples, we study the band structure and the emergence of correlated states as a function of doping and twist-angle near the first magic angle. Far from the magic angle, we observe two van hove singularity (VHS) peaks whose separation allows us to extract the interlayer coupling. Contrary to expectation we find that the interlayer hopping is a function of the twist angle and doping. Upon approaching the magic angle the VHS merge into a single flat band which straddles the charge neutrality point. We observe a dynamic reconstruction of the band structure with gap-like features at certain fillings and a corresponding unique spatial reconstruction of the electronic wave-function.

10:12AM X14.00010: Effect of vacancies on the electronic and optical properties on twisted bilayer graphene* FRANCISCO CULCHAC (Presenter), RODRIGO CAPAZ, Universidade Federal do Rio de Janeiro — We systematically study the effects of a random distribution of vacancies on the electronic and optical properties of twisted bilayer graphene (TBLG), using a tight-binding method. We study the density of states and optical absorption for different concentrations of vacancies and different rotation angle between the layers. The density of states and the optical absorption spectra are calculated by averaging over several vacancy configurations. The increase in the concentration of vacancies increases the number of midgap states near the Dirac point. For large twist angles, it is possible to observe that the intensity of the absorption peaks, typical of TBLG without vacancies, decrease and slightly shift when the vacancy concentration increases. In addition, peaks of lower intensity can be observed at low energies, coming from optical transitions between midgap states. For small rotation angles and for a certain range of vacancy concentrations, the optical absorption peak is eliminated. This occurs when the energy range of the midgap states located at the Fermi level is comparable to the energy of Van Hove singularities where the optical transitions occur in the case of TBLG without vacancies.

10:24AM X14.00011: Scanning tunneling microscopy of van Hove singularities in small angle twisted bilayer graphene* JEANNETTE KEMMER (Presenter), Watson Laboratory of Applied Physics, California Institute of Technology, 1200 East California Boulevard, Pasadena, California 91125, USA, YOUNGJOON CHOI, Department of Physics, California Institute of Technology, 1200 East California Boulevard, Pasadena, California 91125, USA, HARPREET SINGH ARORA, ROBERT POLSKI, Watson Laboratory of Applied Physics, California Institute of Technology, 1200 East California Boulevard, Pasadena, California 91125, USA, YIRAN ZHANG, Department of Physics, California Institute of Technology, 1200 East California Boulevard, Pasadena, California 91125, USA, HECHEN REN, Watson Laboratory of Applied Physics, California Institute of Technology, 1200 East California Boulevard, Pasadena, California 91125, USA, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, 1-1 Namiki, Tsukuba, Ibaraki 305 0044, Japan, STEVAN NADJ-PERGE, Watson Laboratory of Applied Physics, California Institute of Technology, 1200 East California Boulevard, Pasadena, California 91125, USA — Electronic properties of stacked van der Waals bilayers critically depend on the twist angle between the monolayers. A famous example of this effect is the observation of superconductivity and strongly correlated insulating phases in twisted bilayer graphene (TBG) where the two graphene monolayers are twisted by the so-called magic angle (~1.1°). This system supports electronic bands that are almost completely non-dispersive (flat), which gives rise to strong electronic correlation effects. We use scanning tunneling microscopy and spectroscopy to track the positions of van Hove singularities originating from the flat bands in gated TBG for the range of twist angles from 1° to 3°. We find that close to magic angle values the van Hove singularities are strongly modified when the flat bands cross the Fermi level.

10:36AM X14.00012: Pressure Induced Compression of Flatbands in Twisted Bilayer Graphene* BHEEMA LINGAM CHITTARI, NICOLAS LECONTE, SRIVANI JAVVAJI, JEIL JUNG (Presenter), University of Seoul — We investigate the bandwidth compression due to out of plane pressure of the moiré flatbands near charge neutrality in twisted bilayer graphene for a continuous range of small rotation angles of up to $\sim 2.5^\circ$. The flatband bandwidth minima angles are found to grow linearly with interlayer coupling $u$ and decrease with Fermi velocity. Application of moderate pressure values of up to 2.5 GPa achievable through a hydraulic press should allow accessing a flatband for angles as large as $\sim 1.5^\circ$ instead of $\sim 1^\circ$ at zero pressure. This reduction of the moiré pattern length for larger twist angle implies an increase of the effective Coulomb interaction scale per moire cell by about 50% and enhance roughly by a factor of $\sim 2$ the elastic energy that resists the commensuration strains due to the moire pattern. Application of pressure will hence notably facilitate the device preparation efforts required for exploring the ordered phases near magic angle flatbands. We also discuss the phase diagram of flatbands in other hybrid Dirac materials.

Session X15 DMP: 2D Materials (Semiconductors) -- Synthesis, Defects, and Strain BCEC 154 -

8:00AM X15.00001: Spinodal Dewetting Instabilities on Graphene and two-dimensional atomic crystals VALERI KOTOV (Presenter), DAVID PETERSON, JUAN VANEGAS, University of Vermont — We demonstrate theoretically, for the first time, the possibility of spinodal dewetting in heterostructures made of light-atom liquids (hydrogen, helium, and nitrogen) deposited on graphene and other 2D substrates. Extending our theory of film growth on 2D materials [S. Sengupta et al., Phys. Rev. Lett. 120, 236802 (2018)] to include analysis of surface instabilities via the hydrodynamic Cahn-Hilliard – type equation, we characterize in detail the resulting periodic patterns. Both linear stability analysis and advanced computational treatment of the surface hydrodynamics show unconventional, micron-sized (generally material dependent) patterns of “dry” regions. The physical reason for the development of such instabilities on graphene can be traced back to the inherently weak van der Waals interactions between atomically-thin materials and atoms in the liquid, causing the arrest of film growth under normal equilibrium conditions and triggering the associated surface instabilities. These phenomena are robust to some mechanical deformations and are also universally present in doped graphene and other 2D materials, such as monolayer dichalcogenides. Thus, two-dimensional materials represent a universal theoretical and technological platform for studies of spinodal dewetting.
Surface functionalization of two-dimensional monolayers can produce materials with different structural and electronic properties as compared to their pure counterparts. The lowest energy phase for molybdenum (Mo) based transition metal dichalcogenides is the semiconducting hexagonal H phase. However, the alternative T phase with Mo atoms in octahedral coordination and the distorted version of the T phase (T’) can be stabilized by intercalation, chemical doping, and charge mediation. In this work, we use density functional theory calculations to demonstrate that H to T phase transition can be achieved in MoX2 monolayer with hydrogenation. We find that the phase stability of the T phase increases as a function of hydrogenation coverage. This phase transition results in the semiconductor to metallic transition in these monolayers. Our results suggest that these MoX2 monolayers with controllable structural and electronic properties can find applications in catalysts and nanodevices.

The ability to control nanoscale electronic properties by introducing macroscopic strain is of critical importance for the implementation of 2D materials into flexible electronics and next generation strain engineering devices. In this work we use scanning tunneling microscopy and spectroscopy (STM/STS) to correlate the atomic-scale lattice deformation and local electronic properties with a systematic macroscopic bending of monolayer molybdenum disulfide (MoS2) films, using a custom-built sample holder. Using this technique, we find a reduction of the quasiparticle band gap with increasing strain. In addition, nanoscale strain relaxation of van der Waals monolayer sheets has been investigated and resulted in 1D ripples and 2D wrinkles which alter the local strain fields as well as the local electronic density of states.

In a recent report [1], the present authors demonstrated the existence of quantum-confined states arising from spatially varying band edge energies in a MoS2/WSe2 vertical heterostructure. Here, this system is studied in more detail, combining results from low-temperature scanning tunneling microscopy/spectroscopy (STM/STS) measurements and density functional theory (DFT) calculations. It is experimentally observed that in addition to the band edge shifts, the moiré pattern, which forms due to a 3.7% lattice mismatch, results in spatially varying biaxial strain in the MoS2 of ~2% tension (compression) at the corrugation minima (maxima). Including band edge shifts due to strain and corrugation of the underlying WSe2 leads to a consistent explanation for the observed spatial locations of the quantum-confined states.

Spin effects at mirror twin grain boundaries in monolayered dichalcogenides

MIGUEL PRUNEDA (Presenter), Theory & Simulation Group, Institut Catala de Nanociencia i Nanotecnologia — First-principles calculations are used to study the origin of the charge density wave observed in 1D inversion domain grain boundaries in monolayered MoSe$_2$. A small structural (Peierls) distortion with the same periodicity observed in the STM experiments can be reproduced. However, an opening of the gap does not require this distortion, which can be obtained with a suitable spin configuration for the edge electronic states. Spin-orbit effects on these peculiar interfacial states are also discussed. Remarkably, similar spin configurations can also be obtained for edge states in zigzag-edged domains.

Point defects, impurities, and single-photon emitters in hexagonal boron nitride

LEIGH WESTON, Lawrence Berkeley National Laboratory, DARSHANA WICKRAMARATNE, Naval Research Laboratory, MARK E. TURIANSKY, University of California, Santa Barbara, MAZENA MACKOIT, AUDRIUS ALKAUSKAS, Center for Physical Sciences and Technology, Vilnius, Lithuania, CHRIS VAN DE WALLE (Presenter), University of California, Santa Barbara — Hexagonal BN (h-BN) is attracting a lot of attention for two-dimensional electronics and as a host for single-photon emitters. We have studied the properties of native defects and impurities in h-BN using density functional theory with a hybrid functional. Native vacancy and antisite defects have high formation energies. Self-interstitials can have low formation energies, but their low migration barriers render them highly mobile, and they are unlikely to be present as isolated defects. We find that the defect chemistry of h-BN is likely dominated by unintentional impurities rather than native point defects. Substitutional carbon and oxygen, as well as interstitial hydrogen and boron vacancy–hydrogen complexes, are low-energy defects in h-BN. Our results allow us to comment on frequently observed emission lines and on the microscopic origins of single-photon emitters.

Localized strain tuning of exciton emissions on suspended two-dimensional materials

HYOWON MOON (Presenter), CHITRALEEMA CHAKRABORTY, GABRIELE GROSSO, DIRK R. ENGLUND, Massachusetts Institute of Technology — Two-dimensional materials can endure extraordinarily large strain which strongly influences its electronic and optical properties. Strain tuning has been reported for free excitons in transition metal dichalcogenides (TMDs) as well as for single photon emissions in TMDs or in hexagonal boron nitrides (hBN). However, strain applied on the entire substrate or over few micrometers has a limited ability to produce or control individual strain-induced quantum emissions in TMDs. Here we demonstrate extremely localized strain tuning of exciton emissions in suspended 2D materials induced by sub-10nm radius tip mechanical probe, which can be potentially used to create and tune nonclassical light sources in atomically thin materials.

Strain-tunable single-photon emission from an atomically thin semiconductor

Chitraleema Chakraborty (Presenter), Electrical Engineering and Computer Science, MIT, Kumarasiri Konthasinghe, The Institute of Optics, University of Rochester, Hyowon Moon, Dirk R. Englund, Electrical Engineering and Computer Science, MIT, Nick Vamivakas, The Institute of Optics, University of Rochester — One of the most unique mechanical properties of two-dimensional (2D) materials over conventional semiconductors is their high stretchability of more than 20% before fracture. Recently strain induced single photon emitters have been observed in 2D transition metal dichalcogenides. Tuning their emission energy is highly desired for efficient coupling to photonic devices. We demonstrate such tunability by engineering van der Waals heterostructure consisting of graphene/h-BN/WSe2 on a piezoelectric actuator. Application of an electric field across the piezoelectric substrate induces a biaxial strain on the emitters hosted by the monolayer WSe2 in the heterostructure. We have demonstrated a strain tunable energy shift of tens of meV using this approach.

Electrical Control of Defect Assisted Trapped Excitons and trions States in Monolayer MoS2

Pradeepa H L (Presenter), Praloy Mondal, Aveek Bid, Jaydeep K Basu, Physics, IISc Bangalore — Unique optical properties of monolayer MoS2 such as strong binding energy of excitons and trions at room temperature make it a suitable material to study the dynamics of these quasi particles. We report a transition between quasiparticle states using Time resolved Photoluminescence (TRPL) and Photoluminescence (PL) spectroscopy by tuning the carrier concentration of MoS2 monolayer in FET configuration. Since the defect assisted trapping potential is electrically sensitive, we are able to control the trapping states of quasiparticle by applying gate voltage in FET. This control of defect assisted states could influence the exciton exciton annihilation mechanism which is one of the dominant nonradiative decay channel of excitons in two dimensional materials. Our study helps in understanding the exciton dynamics in 2D materials.

Synthesis of large-scale transition metal dichalcogenide films and their applications in hydrogen production

Judy Cha (Presenter), Yale University — Transition metal dichalcogenides (TMDCs) have been studied extensively for their attractive mechanical, electrical, optical, and electrochemical properties. A large scale synthesis of these materials in thin films down to monolayers with thickness control and high crystalline quality remains a major hurdle to utilize them in applications. In this talk, I will discuss our efforts to synthesize centimeter-scale thin films and heterostructures of TMDCs including tellurides such as WTe2 and MoTe2. I will discuss how the morphology and grain size of the thin films is intimately linked to the strain that builds during synthesis and ways to mitigate such strain. With our synthesized films, we explore thermal conductivity of WTe2 thin films and aspects of hydrogen evolution reaction that is often overlooked, such as the Schottky barrier at the interface between the chalcogenide catalyst (for example MoS2) and the electrode and the dielectric substrate effect. Finally, I will discuss the detrimental surface oxidation effect on the transport properties of the TMDCs, which must be overcome for large-scale applications.

10:36AM X15.00012: Strained bilayer WSe2 with reduced exciton-phonon coupling  OZGUR BURAK ASLAN (Presenter), MINDA DENG, MARK BRONGERSMA, TONY F HEINZ, Stanford University — We investigate excitonic absorption and emission in bilayer (2L) WSe2 under tensile strain. We observe a redshift of 110 meV in the energy of the A exciton absorption peak (direct gap) under 2.1% strain. The photoluminescence (PL) spectrum exhibits multiple peaks under 0% strain, corresponding to the indirect and direct gaps. Surprisingly, the spectral linewidth of the A exciton decreases by almost a factor of two under strain, from 70 to 36 meV at room temperature. We explain this effect as the result of suppression of phonon-mediated exciton scattering channels. That suppression is associated with the relative shift under strain of the Q valley in the conduction band (involved in the indirect PL), which is nearly degenerate with the K valley (involved in the A exciton). We analyze the strain-dependent absorption and PL spectra to determine the relative positions of those valleys and to calculate the intervalley scattering rates. Our model describes well the strain-induced linewidth decrease of both monolayer (1L) and 2L WSe2 and help us understand what contributes to the linewidths. The results show that strain tuning can be employed to probe the band structures and the excitonic properties of 1L and 2L TMDCs.

10:48AM X15.00013: Mechanical control of valley magnetization and Berry curvature dipole in monolayer MoS2  JOOLEE SON (Presenter), Department of Physics and Department of Energy Systems Research, Ajou University, KYUNG-HAN KIM, Department of Physics, Pohang University of Science and Technology, YOUNGHWAN AHN, Department of Physics and Department of Energy Systems Research, Ajou University, HYUN-WOO LEE, Department of Physics, Pohang University of Science and Technology, JIEUN LEE, Department of Physics and Department of Energy Systems Research, Ajou University — Monolayer transition metal dichalcogenides (TMDs) are known to have the valley degree of freedom of electrons in momentum space, called K and K'. The control of valley degree of freedom utilizes the valley-dependent Berry curvatures which have the opposite signs at the K and K' valleys. Here we report a new type of valley control using the Berry curvature dipole. By applying strain to monolayer MoS2, we show that Berry curvature distributions about K and K' valleys become asymmetric, leading to the emergence of the Berry curvature dipole. The Berry curvature dipole is manifested by the valley magnetization arising as functions of the Berry curvature dipole and an in-plane electric field. We fabricated several flexible monolayer MoS2 devices and measured the valley magnetization by scanning Kerr rotation microscopy. We will discuss the dependence of the valley magnetization on the direction and magnitude of strain and in-plane electric fields. Our results obtained at room-temperature pave a way for practical valley-based electronic devices and information processing.

Session X17 DCOMP: Matter in Extreme Environments: Dynamic Compression BCEC 156A - Jon Eggert, Lawrence Livermore Natl Lab - Tags: Focus

8:00AM X17.00001: Watching extreme materials through the ultrafast shock compression microscope* [Invited]  DANA DLOTT (Presenter), University of Illinois at Urbana-Champaign — We have developed a microscope that looks into solids and liquids as they are subjected to controlled high velocity impacts. These impacts generate shock waves that propagate a few kilometers per second, creating intense mechanical and thermal effects that can trigger new kinds of chemistry. One of these impacts can create pressures of 200,000 atm and temperatures of 4000K while compressing matter to half its density. I will describe the shock compression microscope and the peripheral high-speed optical diagnostics that measure pressure, temperature, density, composition and structure in real time. A few applications will be discussed: shock initiation and detonation of high explosives, shock attenuation by molecular frameworks, and chemistry in extreme states of water.

8:36AM X17.00002: Results of Rayleigh-Taylor material strength experiments at high pressure and high strain rates on NIF and Omega* 

HYE-SOOK PARK (Presenter), A ARSENLIS, NATHAN R BARTON, CHANNING M HUNTINGTON, JAMES M MCNANEY, BRUCE ALLEN REMINGTON, PHILIP D POWELL, SHON T. PRISBREY, ROBERT RUDD, DAMIAN C SWIFT, CHRISTOPHER WEHRENBERG, Lawrence Livermore Nat’l Lab — We are studying material strength at high pressures (upto 8 Mbar), high strain rates (~10⁷ s⁻¹) and high strains (> 30%) under ramped compression condition using Rayleigh-Taylor instability properties. Understanding plastic deformation dynamics of materials under these extreme conditions is an area of research of high interest to a number of fields, including meteor impact dynamics and advanced inertial confinement fusion designs. We have studied various metals such as tantalum, lead and copper using laser driven high pressure platform. Our studies show that the work hardening dominates in this regime. We will describe the experimental results of the high pressure, high rate plastic deformation dynamics of various metals from Omega and NIF in comparison with the various strength models including Livermore Multiscale Model [2].

8:48AM X17.00003: In-Situ X-Ray Probes of Water-Saturated Granular Media under Dynamic Compaction* 

RYAN CRUM (Presenter), ERIC B HERBOLD, DOROTHY MILLER, JONATHAN LIND, Lawrence Livermore Natl Lab, RYAN C HURLEY, Johns Hopkins University, MICHAEL ANDREW HOME, Lawrence Livermore Natl Lab, BRIAN JENSEN, Los Alamos Natl Lab, DANIEL E EAKINS, DAVID J CHAPMAN, University of Oxford, MINTA C AFIN, Lawrence Livermore Natl Lab — Granular systems are ubiquitous in our everyday world and influence many scientific problems including mine blasts, projectile penetration, and astrophysical collisions. Despite its significance, a fundamental understanding of granular media's behavior falls short of its solid counterpart, limiting predictive capabilities. Granular response is complex in part to the intricate interplay between numerous degrees of freedom not present in its solid equivalent. To address the role of geophysically relevant water-saturation in granular media, previous studies use VISAR or PDV, diagnostics that focus on the aggregate effect leaving the principal interactions of these multiple degrees of freedom too entangled to elucidate. This study uses a gas gun platform coupled to in-situ X-ray probe diagnostics to probe the role of water-saturation in dynamic compaction. Analyses include evaluating displacement fields, grain fracture, and diffraction profiles. Results herein are directly compared to previous studies that were unable to include in-situ X-ray diagnostics.

*Work was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344 and supported by LLNL's LDRD program under grant 16-ERD-010. Experiments at DCS are supported by DOE / NNSA Award Number DE-NA0002442.

9:00AM X17.00004: Laser-induced Microparticle Impact Experiments on Viscoelastic Gels* 

DAVID VEYSSET (Presenter), YUCHEN SUN, STEVEN E KOOI, Massachusetts Institute of Technology, ALEX J HSIEH, U.S. Army Research Laboratory, ALEXEI MAZNEV, Massachusetts Institute of Technology, SHAWN T. COLE, RANDY A. MROZEK, JOSEPH L. LENHART, U.S. Army Research Laboratory, KEITH ADAM NELSON, Massachusetts Institute of Technology — High-velocity impact testing is used to study fundamental aspects of materials behavior under high strain rates as well as in applications ranging from micrometeorite detection to the development of novel drug delivery platforms. In this work, we study the high-velocity micro-particle impact response of viscoelastic gels, including hydrogels and synthetic polymer gels with non-aqueous solvents. In an all-optical laser-induced projectile impact test, micro-particles are accelerated through a laser ablation process. Depending on the laser energy, particles reach speeds up to 1 km/s in free space. Steel and silica particles are monitored during impact with an ultrahigh-speed multi-frame camera that can record up to 16 images with time resolution of each frame as short as 5 ns. We present images and movies capturing individual particle impact and penetration in gels and discuss the observed dynamics under a typical strain rate of 10⁸ s⁻¹. The results can provide direct input for modeling of high-velocity impact responses and high strain rate deformation in gels and other soft materials.

agreement between the calculations and the experimental densities obtained. In general, there is a good understanding of the shock states in double shocked experiments compared with the as obtained material densities. The Laboratory has given us the opportunity to probe the α-ε phase transition states in cerium metal. A couple of experiments were fielded measuring the in-situ material density of the shocked material. A two-phase model which was developed to apply to experiments to infer the density. Proton radiography allows the direct measurement of density. The under extreme conditions the standard Rankine-Hugoniot jump conditions are applied to experiments to infer the density. Proton radiography allows the direct measurement of density. The non-trivial refractive index distorts interferometry measurements of target-window interface velocity. An accurate optical correction to this distortion is crucial in the determination of isentropes in other experiments. We present a measurement of LiF refractive index for stress up to 825 GPa from a shock-ramp experiment at the National Ignition Facility. We argue that a relationship between true and apparent velocity of the target-window interface is more valuable than refractive index to the EOS community. Finally, we present simulated data of dynamically compressed tin and LiF to demonstrate the propagation of the optical uncertainty from this work to EOS measurements. Simulations in which the tin-LiF interface reaches a peak stress of 825 GPa show that the tin isentrope can be determined up to a peak stress of 1.5 TPa with a 0.2% uncertainty in density due to the optical response of LiF.

9:24AM X17.00006: Damage mechanics from high-velocity micro-particle impacts on polyethylene tape.* Michael Daniti (Presenter), Yuchen Sun, David Veysset, Mostafa Hassani-Gangaraj, Massachusetts Institute of Technology, Alex J Hsieh, US Army Research Laboratory, Steven E Kooi, Keith Adam Nelson, Massachusetts Institute of Technology — Understanding damage mechanics is important when designing materials that will be exposed to high velocity particle impacts, such as polymer-based erosion coatings for helicopter rotor blades or impact shields for satellites. Here, we investigate the high-velocity impact deformation response of ultra-high molecular weight polyethylene (UHMWPE) tape to determine the fundamental impact dynamics and to evaluate how material processing can modify the tape’s mechanical behaviors. Using a laser-induced projectile impact test, we conduct impact experiments using steel particles (~15-30 μm diameter) against UHMWPE tape with linearly structured fibrals at velocities up to 500 m/s. The particles are monitored pre- and post-impact with an ultra-high-speed 16-frame camera with nanosecond time resolution. Post-mortem damage morphologies are assessed as a function of particle impact speed. Based on real-time and post-mortem observations, we discuss the damage mechanisms of the UHMWPE tape under supersonic micro-particle impacts.

*This material is based upon work supported in part by the U. S. Army Research Office through the Institute for Soldier Nanotechnologies, under Cooperative Agreement Number W911NF-18-2-0048.

9:36AM X17.00007: Dynamic experiments to examine the high-pressure, solid phases of cerium Brian Jensen (Presenter), Frank Cherne, Los Alamos National Laboratory — The ability to understand and predict the response of matter at extremes requires knowledge of a materials equation-of-state including the location of phase boundaries, transition kinetics, and the evolution of material strength. Cerium metal exhibits a rich phase diagram at moderate pressures that continues to attract scientific interest as an ideal material for studies focused on the dynamic multiphase properties of materials. Recent dynamic experiments have provided information on the shock-melt transition, and the Hugoniot that spans two solid phases and the liquid. Despite these efforts, the high-pressure, solid region of the phase diagram remains largely unexplored dynamically. Static data have identified the ε phase which exists up to Mbar pressures along a room temperature isotherm. At higher temperatures (greater than 600 K), a direct α-ε transition has been reported although there are disagreements in both slope and location of the boundary. In this work, double-shock loading was used to access the α-ε region of the phase diagram to obtain equation-of-state (EOS) information, and to determine the location of the epsilon phase boundary for shock loading (LA-UR-18-30153).

9:48AM X17.00008: Proton radiography experiment probing the double shock nature around the α-ε phase boundary of cerium Frank Cherne (Presenter), Brian Jensen, Los Alamos National Laboratory — Traditionally, to understand the density variations in matter at extreme conditions the standard Rankine-Hugoniot jump conditions are applied to experiments to infer the density. Proton radiography allows the direct measurement of density. The reintroduction of the 40-mm powder driven gas gun into the proton radiography facility at Los Alamos National Laboratory has given us the opportunity to probe the α-ε phase transition states in cerium metal. A couple of experiments were fielded measuring the in-situ material density of the shocked material. A two-phase model which was developed to understand the shock states in double shocked experiments was compared with the as obtained material densities. The density comparison with the model and the interpretation of the data will be discussed. In general, there is a good agreement between the calculations and the experimental densities obtained.
10:00 AM X17.00009: Shock compression of additive manufactured metals* DAVID ROBERT JONES (Presenter), SARYU FENSIN, KENDALL JON HOLLIS, BENJAMIN M MORROW, GEORGE T GRAY, Los Alamos National Laboratory — Additive manufacturing allows production of novel structures, not possible with conventional methods. These can take the form of complex geometries, unusual microstructures, or even functionally graded materials. The benefits that these could bring to industries such as aerospace and defense have resulted in a large push to develop AM techniques for structural metals. However, the mechanical response of such parts is often far removed from that of their conventional counterparts. Here, we present results on the shock compression of a range of AM metals, including Ti6Al4V, stainless steel, and tantalum, investigating how they respond to dynamic loading. Comparisons of their equation-of-state and damage tolerance to that of wrought samples will highlight the importance of thorough testing and qualification of AM parts, and reveal some of the challenges that need to be addressed before they can replace traditional methods.

*U.S. Department of Energy: Science Campaigns, LDRD program

10:12 AM X17.00010: Backward and Forward Analyses of Shocked and Ramp-Compressed Metals to 5 Mbars* JEFFREY NGUYEN (Presenter), MINTA C AKIN, Lawrence Livermore Natl Lab, PAUL D ASIMOW, California Institute of Technology — In this report, we present a series of shocked and ramp compressed data on various metals including tantalum and tin. These samples were shocked and ramp-compressed to pressures as high as 5 Mbars with graded density impactors (GDI). To analyze these data, we utilize both backward (characteristics) and forward analyses. The former method does not require a priori knowledge of a pressure drive, and often fails in the presence of strength or phase transition. By using both of these analysis techniques, we can explore the possibility of looking at phase transition and strength during ramp compression. This study also gives us insights into the in-situ properties of GDI during ramp compression. The results are compared to non-destructive ultrasonic scans of GDIs.

*This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344

10:24 AM X17.00011: Update on multi-megabar shockless compression at the Z machine* JEAN-PAUL DAVIES (Presenter), JUSTIN BROWN, Sandia National Laboratories — Quasi-isentropic, shockless ramp-wave experiments promise accurate equation-of-state (EOS) data of materials in the solid phase at relatively low temperatures and multi-megabar (100's GPa) pressures. In this range of pressure, isothermal diamond-anvil techniques have limited pressure accuracy due to reliance on theoretical EOS of calibration standards, thus accurate quasi-isentropic compression data would help immensely in constraining EOS models. Multi-megabar shockless compression experiments using the Z Machine at Sandia as a magnetic drive with stripe targets have been performed on many solid materials over the past decade. An update is given on recent results and developments, including experimental techniques, analysis methods, and uncertainty quantification.

*Sandia National Laboratories is a multimission laboratory managed and operated by National Technology and Engineering Solutions of Sandia LLC, a wholly owned subsidiary of Honeywell International Inc. for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

Friday, March 8, 2019 8:00 AM - 11:00 AM

Session X19 DMP: Computational Materials Design and Discovery -- Potential Models and Molecular Dynamics BCEC 156C - Alexander Urban

8:00 AM X19.00001: Deep neural networks to accelerate and reproduce DFT LINDA HUNG (Presenter), Toyota Research Institute, BRIAN ROHR, KRISTOPHER S BROWN, MICHAEL STATT, Chemical Engineering, Stanford University, PATRICK HERRING, ARJUN BHARGAVA, HA-KYUNG KWON, SANTOSH SURAM, MURATAHAN AYKOL, JENS HUMMELSHØJ, Toyota Research Institute — Databases such as the Open Quantum Materials Database and the Materials Project contain the results of density functional theory (DFT) calculations for hundreds of thousands of materials structures. Data at this scale allows us to leverage machine learning models to accelerate DFT computations, or to completely replace them. In this talk we present our recent progress in deep neural network models that can accelerate or reproduce DFT predictions, including energies, band gaps, and electron densities. When training for multiple targets, these networks also generate reduced-dimensional latent space representations that may act as materials fingerprints.
8:12AM X19.00002: MAISE package: Materials prediction accelerated with neural network potentials

ALEKSEY KOLMOGOROV (Presenter), SAMAD HAJINAZAR, ERNESTO D. SANDOVAL, Binghamton University — Our recently released Module for Ab Initio Structure Evolution (MAISE) features an evolutionary algorithm for structure prediction and a neural network formalism for modeling interatomic interactions [1]. The open-source code has a simple interface for parallelized local optimization of crystalline or nanosized structures using a library of neural network or traditional classical potentials. Unique capabilities include a symbiotic evolutionary optimization of nanoparticles and a stratified construction of neural network models for multicomponent systems [2]. This presentation will review confirmed MAISE predictions and illustrate the acceleration of global structure searches with neural network models.

*NSF DMR-1410514

8:24AM X19.00003: Accelerating superalloy discovery using moment tensor potentials

HAYDEN OLIVER (Presenter), BRAYDEN BEKKER, CHANDRAMOULI NYSHADHAM, CARLOS ALBERTO LEON CHINCHAY, GUS HART, Brigham Young University — Superalloys are used in applications where high-temperature strength is necessary. Their extraordinary mechanical properties rely on the formation of the $\gamma'$ – $L1_2$ phase. The discovery of a new superior superalloy will revolutionize the energy and transit industries. Computational methods such as density functional theory (DFT) are used to predict the $\gamma'$ phase, but DFT is expensive and it limits how fast we can discover new superalloys. Moment Tensor Potentials (MTP) create an interatomic potential via machine learning that approximates the quantum mechanical energies of a crystal structure many orders of magnitude faster than DFT. We explore the ternary alloy system Al-Co-W, who's $\gamma'$ phase was discovered experimentally in 2006, and show that MTP correctly predicts this phase. We also explore the ternary alloy system Hf-Ni-Si, which is a superalloy candidate that was found to have a lower formation enthalpy and smaller decomposition energy than Al-Co-W, and report the results of the investigation.

8:36AM X19.00004: Using machine learning interatomic potentials for finding CoNiTi ternaries

CARLOS ALBERTO LEON CHINCHAY (Presenter), WILEY S MORGAN, GUS HART, Brigham Young University — Superalloys are materials with excellent mechanical properties at extreme temperatures. Superalloys including Co or Ni atoms [1] prompt for a thorough search to improve industry-demanding properties, which requires new computational methods to sweep the huge amounts of possibilities. We search through 200,000 CoNiTi crystal structures to find superalloy phases using machine learning based on interatomic moment tensor potentials (MTP) [2, 3]. We have not only reproduced results reported in the AFLOW database but also predicted stable binary and ternary phases that are not present in the literature. The MTP approach shortens the computational analysis of CoNiTi systems by a factor of 100 compared to a pure DFT methodology. Further analysis will include searching for stable structures at higher temperatures for possible industrial applications.

8:48AM X19.00005: Exploring Materials Space with Machine Learning*  BRAYDEN BEKKER (Presenter), HAYDEN OLIVER, CHANDRAMOULI NYSHADHAM, Brigham Young University, ALEXANDER SHAPEEV, Skolkovo Institute of Science and Technology, GUS HART, Brigham Young University — Electronic structure calculations are too computationally expensive to thoroughly explore the composition space of any system. We use a surrogate model approach that constructs an interatomic potential from a small training set of electronic structure calculations. The surrogate model, called the Moment Tensor Potential (MTP)[1], automates and optimizes the creation of the training set for the interatomic potentials. The potential is then used to explore materials space and predict stable structures including those with new geometries not contained in the training set[2]. We use MTP to study the six promising candidates from a recent high-throughput search for ternary superalloys [3], namely MnNiSb, NiSbTi, NiSbSi, HfNiSi, CoTaV, and CoNbV. We analyze the phase diagram of each ternary system using a pool of 1.2 million structures to show the accuracy of these machine learned surfaces and predict new stable phases at a fraction of the computational time.

9:00AM X19.00006: Combined cluster and atomic displacement expansion for solid solutions and magnetism  KEVIN GARRITY (Presenter), National Institute of Standards and Technology — Finite temperature disordered solid solutions and magnetic materials are difficult to study directly using first principles calculations, due to the large unit cells and many independent samples that are required. In this work, we develop a combined cluster expansion and atomic displacement expansion, which we fit to first principles energies, forces, and stresses. We then use the expansion to calculate thermodynamic quantities at nearly first principles levels of accuracy. We demonstrate that by treating all the relevant degrees of freedom (DOF) explicitly, we can in some cases achieve better convergence than a simple cluster expansion, and we can naturally treat coupling between structural DOF and chemical or magnetic DOF. As examples, we use our expansion to calculate properties of Si1-xGex, magnetic MnO, Al with vacancies, and KxBi1-xTiO3.

9:12AM X19.00007: High-order rotational invariants for structural representations: Application to linearized machine learning interatomic potential*  ATSUTO SEKO (Presenter), ATSUSHI TOGO, ISAO TANAKA, Kyoto University — Machine-learning interatomic potential (MLIP) has been of growing interest as a useful method to describe the energetics of systems of interest. Firstly, we examine the accuracy of linearized pairwise MLIPs and angular-dependent MLIPs for 31 elemental metals [1]. They correspond to generalizations of the embedded atom method (EAM) and modified EAM potentials, respectively. Building the optimal MLIPs for the 31 elemental metals, we show the robustness of the linearized frameworks, the general trend of the predictive power of MLIPs and the limitation of pairwise MLIPs. We also introduce higher-order rotational invariants for improving the accuracy of linearized MLIPs.In this study, a set of rotational invariants up to six-order is derived by the general process of reducing Kronecker products of irreducible representations for SO(3) group. The use of high-order invariants significantly improves the prediction error for a wide range of structures generated from many structure types.

*This study was supported by PRESTO from JST.
9:24AM X19.00008: The second-principles MULTIBINIT software project*  FABIO RICCI (Presenter), ALEXANDRE MARTIN, MARCUS SCHMITT, JORDAN BIEDER, XU HE, ERIC BOUSQUET, MATTHIEU J. VERSTRAETE, PHILIPPE GHOSEZ, Theoretical Materials Physics, Q-MAT, CESAM, Université de Liège, Belgium — Density Functional Theory calculations are limited to relatively small spatial- and time-scales. The purpose of the MULTIBINIT project is to extend the capabilities of first-principles codes to predict properties at the meso-scale, accounting for external constraints (temperature, pressure and fields), while retaining most of the first-principles predictive power and accuracy. MULTIBINIT is distributed within the ABINIT package [1] exploiting first-principles data by a “second-principles” approach. In its initial form, it relies on effective atomic potentials [2] for lattice dynamics, including also explicit coupling with homogeneous strains. Moreover, current developments involve the construction of a spin model and its coupling with the lattice. MULTIBINIT integrates efficient tools for the (i) automatic generation of the models, (ii) automatic fit of the coefficients from first-principles data, (iii) finite temperature simulations and (iv) efficient analysis of results. The power of the method will be illustrated on the full-Heusler Fe2VAl compound to predict finite temperature lattice dynamics and the influence on the thermoelectric properties.

*Work supported by the FEDER project LoCoTED.

9:36AM X19.00009: Structural Deformations in Graphene under Laser Ablation  MOHAMMAD ALAGHemandi (Presenter), MICHELLE Y. SANDER, SAHAR SHARIFZADEH, Boston University — Graphene, with its extraordinary properties, is an excellent compound for a wide range of applications. Moreover, the ability of designing, controlling, and fabricating 3D structures based on graphene would be a breakthrough for manufacturing the new advanced nano-structures. Laser ablation is currently the only technique that allows patterning of free-standing substrates. In this study, we investigate the ablation of a single layer graphene under high energy pulses by using first-principles density functional theory and reactive molecular dynamics (RMD) simulations. To mimic the laser pulse irradiation, we locally heat the selected area of the graphene layer using a Nosé-Hoover thermostat and considered a range of thermally-heated areas with a radius from 2 to 100 Å, and temperature from 1000 to 10000 K. RMD studies indicate that the shape of the ablated area is not only a function of the pulse energy, but also the radius of the pulse beam. When the radius of pulse beam is smaller than 10 Å, no deformation in graphene is observed for pulses with temperature lower than 8000 Å. Additionally, our predicted trends in the size and shape of the ablated areas coincide well with the experimental results carried out using femtosecond laser beams on a micrometer scale.

9:48AM X19.00010: Atomistic investigation of a carbonization process for C/H/O/N-based polymers with use of the reactive potentials: ReaxFF*  MALGORZATA KOWALIK (Presenter), CHOWDHURY M. ASHRAF, ADRI C. T. VAN DUIN, Mechanical Engineering, PSU — During a carbonization process of the raw polymer precursors, the graphitic structures evolve and are responsible for improved mechanical properties of the carbonized carbon fibers. To gain a deeper understanding of a chemistry behind an evolution of these graphitic structures, we perform atomistic simulations using a reactive force field: ReaxFF. We considered three different polymers as a precursor: idealized ladder PAN, proposed oxidized PAN and PBO to understand how underlying molecular details of polymers direct final carbon fibers structure. Since these are C/H/O/N-based polymers, firstly we proposed an improved force field for C/N/H chemistry based on new DFT data. Then, with use of this improved force field, we perform atomistic simulations of the carbonization process for the considered polymers. Based on these simulations we were able to determine small molecules, as well, all carbon rings productions, and analyzed the graphic structures evolutions. We also performed the stress-strain simulations on the initially carbonized samples and were able to assess how a presence of the graphitic structure affects the mechanical responds.

*Work supported by US DoE EERE VTO DE-EE0008195.
10:00AM X19.00011: Molecular Dynamics Investigations of the Mechanical Properties of Heterogeneous Structures Composed of Graphene Sheets, Graphene Ribbons, and Boron Nitride Sheets  CUIYING JIAN (Presenter), NICOLA FERRALIS, JEFFREY C GROSSMAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology — It is well known that monolayer/multilayer graphene possesses ultra-high elastic modulus and critical stress with intrinsic low toughness. In order to explore ways to reduce its brittleness, in this work we employ atomistic modeling to examine the mechanical properties of mono- and multilayers of graphene, nanoribbons, boron nitride and a range of combinations. Regardless of size, edge type exhibits a significant effect on the critical stress/strain, evidenced by the higher mechanical strength of zigzag compared to armchair ribbons, as well as the armchair direction in graphene sheets. Furthermore, our calculations show that with increasing number of layers the mechanical strength of graphene deviates from that of the monolayer sheet, while in contrast multilayer boron nitride sheets preserve the fracture point of the single layer. Based on these results, we explored a range of heterogeneous structures composed of graphene sheets, graphene nanoribbons, and boron nitride sheets. Under tensile stretch, components in these heterogeneous structures show asynchronous cracking behavior helping to improve the overall toughness. By analyzing interfacial binding/sliding between heterogeneous components, the underlying mechanisms are explored and improved compositions can be proposed.

10:12AM X19.00012: Toward Sustainable Asphaltic Materials: A Molecular Dynamics (MD) Investigation of Bio-oil Modified Asphalt*  ISKINDER ARSANO (Presenter), KSHITIJ C JHA, MESFIN TSIGE, The University of Akron — We have investigated the behavior of a novel asphaltic material obtained by adulterating a model asphalt system1 with a rationally selected foreign species of bio-oil. A wide range of systems is modeled by MD simulations featuring a systematic combination of modifier type, modifier concentration, and temperature. The mobility and structural integrity of the proposed materials were investigated in addition to mechanical response prediction by use of moduli calculations. The need to resolve issues of processability such as phase separation of commonly used modifiers, for example scrap tire2, represents an important impetus for the current project. A case is made whereby the molecular observations made in the proposed modified asphalt systems indicate a maintenance of or improvement over essential macro functionalities of pristine asphalt. The replacement of a significant proportion of traditional asphalt by bio-oils constitutes a move toward green construction materials by allowing for less use of bitumen, a byproduct in heavy oil refineries implicated in pollution.

10:24AM X19.00013: Computational design of organic molecules for reducing friction at the nanoscale  JING YANG (Presenter), JON PAUL JANET, FANG LIU, HEATHER J KULIK, Chemical Engineering, Massachusetts Institute of Technology — Computational modeling has the promise to enable atom-by-atom design of nanoscale properties that give rise to essential changes in macroscale properties. In the quest for increasing energy efficiency and resource utilization, energy losses remain an outstanding challenge that can be solved in part through computational materials design. Friction reducers (FRs) are molecular additives that can minimize friction loss in these engines by reducing friction between moving parts at the nanoscale. Traditional FRs contain metals, sulfur, and phosphorus, which can poison exhaust system catalysts and diesel particulate filters. Thus, if suitably designed, organic friction reducers (OFRs) present a promising alternative solution. Here, we apply non-equilibrium molecular dynamics simulations together with density functional theory methods to enable the atom-by-atom design of OFRs. We directly compute the coefficients of friction of OFRs on model engine iron oxide surfaces with varying coverage and temperature, and explore a number of conditions not easily probed during experiments. These studies allow us to build a quantitative structural property relationship for predicting good OFR characteristics, enabling an iteratively improving materials design workflow.
10:36AM X19.00014: Machine-Learning Provides New Insights into the Coil-to-Globule Transitions of Thermosensitive Polymers*  
KARTEEK KUMAR BEJAGAM, YAXIN AN, Chemical Engineering, Virginia Tech, SAMRENDRA SINGH, CNH Industrial, SANKET DESHMUKH (Presenter), Chemical Engineering, Virginia Tech — First of its kind, a temperature-independent coarse-grained (CG) model of poly(N-isopropylacrylamide) (PNIPAM) that can accurately predict its experimental lower critical solution temperature (LCST) in the presence of explicit water model is developed. This extensively validated CG model by conducting MD simulations by changing the radius of gyration of initial structure, the chain length, and the angle between the adjacent monomers of the initial configuration of PNIPAM. The model could retain PNIPAM's tacticity and thereby predict its LCST, which is consistent with experiments and all-atom simulations. A data-driven machine-learning (ML) approach, non-metric multidimensional scaling (NMDS) method, was used to analyze these CG MD simulation trajectories. This analysis suggest that PNIPAM chain undergoes a coil-to-globule transition above the LCST via multiple metastable states.

10:48AM X19.00015: Bayesian inference of grain growth prediction via multi-phase-field models*  
HIROMICHI NAGAO (Presenter), SHIN-ICHI ITO, TAKASHI KUROKAWA, TADASHI KASUYA, JUNYA INOUE, University of Tokyo — We propose a Bayesian inference methodology to evaluate unobservable parameters involved in multi-phase-field models with the aim of accurately predicting the observed grain growth, such as in metals and alloys. This approach integrates models and a set of observational image data of grain structures. Since the set of image data is not a time series, directly applying conventional inference techniques that require time series as the input data is difficult. Our key idea is to construct a time series with an appropriate statistic that characterizes static image data of grain structures. The empirical Bayes method estimates not only a probability density function of the parameters but also an initial phase-field, which is generally unobservable in real experiments. The proposed method is confirmed to estimate, from real experimental images of grain structures in a steel alloy, unobservable parameters together with their uncertainties, and successfully selects the initial phase-field that best explains the experimental data from among candidate initial phase-fields.

*This work was supported by the Council for Science, Technology and Innovation (CSTI), the Cross-ministerial Strategic Innovation Promotion Program (SIP) "Structural Materials for Innovation" (Funding agency: JST).
SOC strength is much larger due to the larger charge confinement effect in these materials. The results were confirmed and magneto-electroluminescence (MEL) in the 3D perovskite devices in which MC and MEL with 0.07% magnitude and distortions of the lattice, necessary for high performance solar cells. Nevertheless, fundamental studies on SOC strength of these materials have still been very limited. Here, we present the magnetic field effect (MFE) in light emitting diodes (LEDs) made of the 3D hybrid perovskite CH$_3$NH$_3$PbI$_3$ (MAPbI$_3$) and 2D Ruddlesden-Popper hybrid perovskite (CH$_3$(CH$_2$)$_3$NH$_3$)$_2$(CH$_3$NH$_3$)Pb$_2$I$_7$, where the width and the magnitude of the magnetic response in conductivity and electroluminescence are measures of the SOC strength in the materials. We observed the magneto-conductance (MC) and magneto-electroluminescence (MEL) in the 3D perovskite devices in which MC and MEL with 0.07% magnitude and 250 G half width indicate the strong SOC strength. The absence of the MFE in the 2D perovskite devices indicates that the SOC strength is much larger due to the larger charge confinement effect in these materials. The results were confirmed by our MFE studies on the photocurrent of the devices.

8:36AM X20.00004: Freestanding Crystalline Monolayers of Oxide Perovskites* DIANXIANG JI, SONGHUA CAI, National Laboratory of Solid State Microstructures, and College of Engineering and Applied Sciences, Nanjing University, TULA PAUDEL, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, HAOYING SUN, CHUNCHEANG ZHANG, LU HAN, YIFAN WEI, YIPENG ZANG, MIN GU, National Laboratory of Solid State Microstructures, and College of Engineering and Applied Sciences, Nanjing University, YI ZHANG, WENPEI GAO, HUAIXUN HUYAN, Department of Chemical Engineering and Materials Science and Department of Physics and Astronomy, University of California, Irvine, WEI GUO, DI WU, ZHENGBIN GU, National Laboratory of Solid State Microstructures, and College of Engineering and Applied Sciences, Nanjing University, EVGÉNY Y TSYMBAL, Department of Physics and Astronomy & Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, PENG WANG, YUEFENG NIE (Presenter), National Laboratory of Solid State Microstructures, and College of Engineering and Applied Sciences, Nanjing University, XIAOQING PAN, Department of Chemical Engineering and Materials Science and Department of Physics and Astronomy, University of California, Irvine — Two-dimensional (2D) materials like graphene have demonstrated new electronic phases that can emerge when a bulk crystal is thinned down to a mono-layer. As transition metal oxide perovskites host a variety of correlated phases, realizing the analogs with oxide perovskite materials would open the door to a rich spectrum of exotic 2D correlated phases that have not yet been explored. Here we report on the fabrication of freestanding perovskite films with high crystalline quality down to a single unit cell. Using the recently developed method based on water-soluble Sr$_3$Al$_2$O$_6$ as the sacrificial buffer layer we synthesize freestanding SrTiO$_3$ and BiFeO$_3$ ultrathin films by reactive molecular beam epitaxy and transfer them to different substrates such as crystalline silicon wafers and holey carbon films. We find that freestanding BiFeO$_3$ films exhibit an unexpected giant tetragonality and polarization when approaching the ultimate 2D limit. The ability to synthesize crystalline freestanding perovskite films without thickness limitation opens a new field for the 2D correlated electronic phases and interfacial phenomena.

Optoelectronic properties of layered and 3D hybrid perovskites: recent results

Invited

JACKY EVEN (Presenter), Institut foton, insa

In the past five years, solution-processed organometallic perovskite based solar cells have emerged as a promising thin-film photovoltaic technology with record conversion efficiencies as high as 23.3%. The presentation will review recent optical spectroscopy and diffraction results on 3D halide perovskites, as well as colloidal nanocrystals that also exhibit attractive light emission properties. Presently, the intended optoelectronic applications of this class of 3D materials are in the realm of semiconductors. But they can be described as unconventional semiconductors, because the spin-orbit coupling is giant and shows up in the conduction band. More, the band gap is direct with a critical wavevector located at one of the edges of the reference Brillouin zone, and among others, excitonic and Rashba-Dresselhaus effects, as well as electron-phonon coupling and lattice anharmonicity may play a crucial role. Related 2D multilayered phases, composed of perovskites multilayers sandwiched between two layers of large organic cations, have recently demonstrated improved solar cells photostability under standard illumination as well as humidity resistance, leading to conversion efficiencies in the 10-15% range. In this case, intrinsic quantum and dielectric carrier conﬁnements are afforded by the organic inner barriers and a tunable perovskite layer thickness, which lead to stable Wannier excitons at room temperature. These excitations share some similarities with the ones observed in Van der Waals heterostructures. Solar cell and LED device operations are related to internal exciton dissociation through low energy states in multilayered perovskites, as shown from the investigations of both thin films and small exfoliated single crystals. Multilayered halide perovskites shall lead to extensive chemical engineering in the future.

First-Principles Studies of the Electronic and Optical Properties of Halide Perovskites: From Three to Two Dimensions*

MARINA R FILIP (Presenter), Molecular Foundry, Lawrence Berkeley National Lab, JONAH HABER, Physics, University of California Berkeley, JEFFREY B NEATON, Molecular Foundry, Lawrence Berkeley National Lab

Metal-halide perovskites have emerged in the past six years as a disruptive new class of optoelectronic materials. Solar cells based on 3D lead-halide perovskites have recently reached a record power conversion efficiency of 23.3%. In addition, the 2D variants are gaining momentum as a promising new class of versatile materials for applications in light emission and solar energy conversion [1,2,3]. Despite these developments, fundamental optoelectronic properties of this novel family of layered materials are not yet fully understood. Here, we will explore the role of structural effects on the optoelectronic properties of 2D lead-halide perovskites with DFT and ab-initio many-body perturbation theory. We will examine the effects of various mean field starting points and self-consistency in the GW approximation, while explicitly incorporating spin-orbit interactions. Lastly, we will analyze the importance of electron-hole interactions upon optical excitation, within the Bethe-Salpeter equation, and discuss the optical spectra and photophysics of these complex class of compounds.

Making and breaking the exciton in layered halide hybrid perovskites

MIKAEL KEPENEKIAN (Presenter), BOUBACAR TRAORE, Institut des Sciences Chimiques de Rennes (ISCR), CNRS, JEAN-CHRISTOPHE BLANCON, Department of Chemical and Biomolecular Engineering, Rice University, LAURENT PEDESSEAU, Institut FOTON, INSA Rennes, WANYI NIE, LANL, CONSTANTINOS STOUMPOS, Department of Materials Science and Technology, University of Crete, MERCOURI KANATZIDIS, Department of Chemistry, Northwestern University, JACKY EVEN, Institut FOTON, INSA Rennes, ADITYA D. MOHITE, Department of Materials Science and Nanoengineering, Rice University, SERGEI TRETIAK, LANL, CLAUDINE KATAN, Institut des Sciences Chimiques de Rennes (ISCR), CNRS — Layered halide hybrid organic–inorganic perovskites (LHP) [1] have been the subject of intense investigation before the rise of three-dimensional (3D) halide perovskites and their impressive performance in solar cells. Recently, LHP have also been proposed as attractive alternatives for photostable solar cells [2] and revisited for light-emitting devices. LHP present inherent quantum and dielectric confinements imposed by the organic layers sandwiching the inorganic core, and computational approaches have successfully helped rationalize their properties [4-6].

Here combine theoretical and spectroscopic studies inspect the various ingredients of LHP strong exciton binding energy and the ways to break the electron-hole pair [3,4]. In particular, we propose an elastic model providing design principles for future layered perovskites with optimized properties for photovoltaics or light emission [7].

Rashba Splitting in Hybrid Lead Halide Perovskites probed by Photogalvanic Spectroscopy

XIAOMEI JIANG (Presenter), Physics, University of South Florida, — Hybrid Lead Halide Perovskites (HLHPs) such as MAPbX3 (where MA is methyl-ammonium and X is halogen) have shown unprecedented performance in optoelectronic device applications such as solar cells, photodetectors and light emitting diodes. The recent discoveries of giant Rashba splitting in both bulk (3D) and two-dimensional (2D) HLHPs have raised promise that these compounds may be excellent candidates for spintronic device applications. Using both photogalvanic (PGA) and photoluminescence spectroscopies we evaluate the Rashba splitting value in both polycrystalline and single crystal HLHPs. We have uncovered the morphological influence on the Rashba splitting in these compounds by measuring angular, temperature and excitation dependencies of the PGA. We also report on the influence of defects and grain boundaries on the Rashba splitting in various HLHP crystallographic phases.

Control over ultrafast Rashba splitting dynamics in quasi-2D arrays of 3D hybrid perovskite nanocrystals by the interfacial electric field

YURI GLINKA (Presenter), RUI CAI, Department of Electrical and Electronic Engineering, Guangdong University Key Lab for Advanced Quantum Dot Displays and Lighting, Shenzhen Key Laboratory for Advanced Quantum, JUNZI LI, XIAODONG LIN, TINGCHAO HE, College of Physics and Energy, Shenzhen University, Shenzhen 518060, China, RUI CHEN, Department of Electrical and Electronic Engineering, Guangdong University Key Lab for Advanced Quantum Dot Displays and Lighting, Shenzhen Key Laboratory for Advanced Quantum, XIAO WEI SUN, Department of Electrical & Electronic Engineering, Guangdong University Key Lab for Advanced Quantum Dot Displays and Lighting, Shenzhen Key Laboratory for Advanced Quantum D — Snapshot spectral imaging has been performed with 100 fs steps in delay-times for fully encapsulated quasi-2D arrays of 3D hybrid perovskite MAPbBr3 nanocrystals (~20 nm in size) spin-coated to either the clean sapphire plate or to that initially ALD-coated by a ~30 or ~100 nm thick ZnO layer. The absorption bleaching band for the bare MAPbBr3 nanocrystal arrays reveals a ~200 meV splitting appearing within ~1 ns, which has been assigned to the Rashba splitting effect. However, the splitting unexpectedly disappears for the MAPbBr3/ZnO samples at delay-times longer than ~500-600 fs when the interfacial electric field at the MAPbBr3/ZnO heterointerface develops due to charge separation. The effect has been treated theoretically in the frame of the model taking into account the interfacial-field-induced structural phase transition in MAPbBr3 nanocrystals.
10:12AM X20.00010: Revealing nanocrystal growth within CsPbI$_{2-x}$Br$_{3-x}$ perovskite thin films  LINDSEY GRAY (Presenter), JUNWEI XU, XIAOHENG SEAN YAN, DAVID CARROLL, Wake Forest University, WAYNI NIE, Los Alamos National Laboratory —

Inorganic lead halide perovskites have greatly impacted the optoelectronics field due to their band-tunability and solution-processability in high performance light emitting diodes (LEDs). However, the bulk material is unstable under room temperature which tends to phase segregate under ambient or device operational conditions. Recent breakthrough has successfully demonstrated a stabilized CsPbX$_3$ phase at room temperature by fabricating into nanostructured crystals (NC). Further, photo-physical property enhancement is attributed to the nano-scale structure control which are thus the most promising candidate for the lighting applications. It is therefore critical to systematically understand the structure of the CsPbX$_3$ NC synthesized via controlled approach and connect that with device operation efficiency and stability. In this study, we systematically investigated the synthetic approach to obtain room temperature stabilized mixed halide nanocrystals, focusing on the effect of the molar ratio between Cs source and Pb source on the optical performance in the mixed CsPbI$_2$Br perovskite thin films. The findings revealed the nanocrystal growth mechanism of the in situ processed perovskite layer which enabled us to fabricate bright and efficient red perovskite LEDs.

10:24AM X20.00011: Above-bandgap emission properties of CsPbBr$_3$ as probed by fine-scale photoluminescence excitation spectroscopy* HONG SEON RYU, Physics, Sogang University, CONSTANTINOS STOUMPOS, Materials Science and Technology, University of Crete, KYLE MCCALL, MERCOURI KANATZIDIS, Chemistry, Northwestern University, JOON JANG (Presenter), Physics, Sogang University — Halide perovskites are next-generation materials for solar cells and light emitting diodes. Despite rapid progress in applied perovskite technology, understanding of their basic properties is not complete yet. Especially, it is necessary to clarify the bandgap and the nature of the photoluminescence (PL) process (whether excitonic or electron-hole recombination) for the high performance of the devices. As a case study, we investigated unusual bandgap and recombination behaviors of CsPbBr$_3$ using PL excitation spectroscopy. Significant variation of both shape and intensity of the PL was observed when the excitation wavelength was tuned across the bandgap. Intriguingly, PL emission occurs above the bandgap, which arises presumably from radiative recombination at halide vacancies. Excitation power dependence of the PL shows that the power exponent continuously varies from 2 to 1 and to sublinear with increasing the laser intensity. The rate equation for pulsed excitation was modeled to account for this anomalous effect. Our model implies that the PL arises from electron-hole recombination at room temperature.

10:36AM X20.00012: Optical and transport properties of mixed halide all-inorganic quantum dot inkjet-printed films* DYLAN RICHMOND (Presenter), Department of Physics, State University of New York-Oswego, Oswego, NY 13126-3599, THILINI K EKANAYAKA, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE 68588-0299, MASON MCCORMICK, Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE 68588-0304, NICOLE BENKER, SYED QAMAR ABBAS, CORBYN MELLINGER, GUANHUA HAO, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE 68588-0299, ALEXANDER SINITSKII, Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE 68588-0304, PETER A DOWBEN, ANDREW J YOST, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, NE 68588-0299, CAROLINA C. ILIE, Department of Physics, State University of New York-Oswego, Oswego, NY 13126-3599 — Inorganic halide perovskite quantum dot inks may have great potential in applications related to the field of inkjet-printed photovoltaics. The photoactive inks are synthesized by a wet chemical reaction and are printed into thin films using a commercial inkjet printer. The inkjet-printed films were then characterized using optical absorption spectroscopy, photoluminescent spectroscopy, X-ray diffraction, X-ray photoemission spectroscopy, and electronic transport measurements. Characterization indicates that interlayer printing, alternating printed layers of CsPbBr$_3$ and CsPbI$_3$, results in a halide exchange producing a high quality (220) CsPbBr$_{2.10,9}$ quantum dot thin film. The repeatable properties of the inkjet-printed thin films suggest high quality, customizable, photovoltaic films are realizable with an inkjet printing method.
